6	RW	0x0	URI: USB Reset Received. When the device controller detects a USB Reset and enters the default state, this bit is set to a 1. Software can write a 1 to this bit to clear the USB Reset Received status bit. Only used by the device controller. 0 = NO_USB_RESET 1 = USB_RESET
5	RW	0x0	AAI: Interrupt and Asynchronous Advance. System software can force the host controller to issue an interrupt the next time the host controller advances the asynchronous schedule by writing a one to the Interrupt on Async Advance Doorbell bit in the USBCMD register. This status bit indicates the assertion of that interrupt source. Only used by the host controller 0 = NOT_ADVANCED 1 = ADVANCED
4	RO	X	SEI: System Error. This bit is not used in this implementation and will always be set to "0". 0 = NO_ERROR 1 = ERROR
3	RW	0x0	FRI: Frame List Rollover. The Host Controller sets this bit to a 1 when the Frame List Index rolls over from its maximum value to 0. The exact value at which the rollover occurs depends on the frame list size. For example. If the frame list size (as programmed in the Frame List Size field of the USBCMD register) is 1024, the Frame Index Register rolls over every time FRINDEX [1 3] toggles. Similarly, if the size is 512, the Host Controller sets this bit to a 1 every time FHINDEX [12] toggles. Only used by the host controller. 0 = NO_ROLLOVER 1 = ROLLOVER
2	RW	0x0	PCI: Port Change Detect. The Host Controller sets this bit to a 1 when on any port a Connect Status occurs, a Port Enable/Disable Change occurs, or the Force Port Resume bit is set as the result of a J-K transition on the suspended port. The Device Controller sets this bit to a one when the port controller enters the full or high-speed operational state. When the port controller exits the full or high-speed operational states due to Reset or Suspend events, the notification mechanisms are the USB Reset Received bit and the DCSuspend bits respectively. This bit is not EHCI compatible. 0 = NO_PORT_CHANGE 1 = PORT_CHANGE
1	RW	0x0	UEI: USB Error Interrupt. This bit gets set by the Host/Device controller when completion of a

Bit	R/W	Reset	Description
			USB transaction results in an error condition. This bit is set along with the USBINT bit, if the TD on which the error interrupt occurred also ad its interrupt on complete (IOC) bit set. 0 = NO_ERROR 1 = ERROR
0	RW	0x0	UI: USB Interrupt. This bit is set by the Host/Device Controller when the cause of an interrupt is a completion of a USB transaction where the Transfer Descriptor (TD) as an interrupt on complete (IOC) bit set. This bit is also set by the Host/Device Controller when a short packet is detected. A short packet is when the actual number of bytes received was less than the expected number of bytes. 0 = NO_INT 1 = INT

21.5.1.16 USB2_CONTROLLER_USB2D_USBINTR_0

USB2D USB Interrupt Enable Register

Offset: 138h | Read/Write: R/W | Reset: 0b0000000000000000xxxxx0x000000000

Bit	Reset	Description
31:16	0x0	PPCE: Port-n Change Detect Enable - RW. Default = 0000h. The definition for each bit in this field is identical to bit 2 of this register (Port Change Interrupt Enable) except these bits are specific to a given port, where bit 16 = Port 1, 17 = Port 2, etc. For example, if bit 17 is set (1b) then a port change event was detected on Port 2. When a bit in this field is a one, and the corresponding Port-n Change Detect bit in the USBSTS register is a one, the host controller will issue an interrupt. The interrupt is acknowledged by software clearing the Port-n Change Detect bit.
10	0x0	ULPIE: ULPI Interrupt Enable. 1 = USB controller issues an interrupt if ULPI_INT bit in USBSTS register transitions. The interrupt is acknowledged by SW by writing a 1 to the ULPI_INT bit. 0 = DISABLE 1 = ENABLE
8	0x0	SLE: Sleep Enable. 1 = Device controller issues an interrupt if DCSuspend bit in USBSTS register transitions. The interrupt is acknowledged by SW by writing a 1 to the DCSuspend bit. Only used by the device controller. 0 = DISABLE 1 = ENABLE
7	0x0	SRE: SOF Received Enable. 1 = Device controller issues an interrupt if SOF Received bit in USBSTS register = 1. The interrupt is acknowledged by software clearing the SOF Received bit. 0 = DISABLE 1 = ENABLE
6	0x0	URE: USB Reset Enable.1 = Device controller issues an interrupt if USB Reset Received bit in USBSTS register = 1 The interrupt is acknowledged by software clearing the USB Reset Received bit. Only used by the device controller. 0 = DISABLE 1 = ENABLE
5	0x0	AAE: Interrupt on Asynchronous Advance Enable. 1 = the host controller issues an interrupt at the next interrupt threshold if Interrupt on Async Advance bit in USBSTS register = 1. The interrupt is acknowledged by software clearing the Interrupt on Async Advance bit. Only used by the host controller. 0 = DISABLE 1 = ENABLE
4	0x0	SEE: System Error Enable. 1 = Host/device controller issues an interrupt if the System Error bit in USBSTS register = 1. The interrupt is acknowledged by software clearing the System Error bit. 0 = DISABLE 1 = ENABLE
3	0x0	FRE: Frame List Rollover Enable. 1 = Host controller issues an interrupt if Frame List Rollover bit in the USBSTS register = 1. The interrupt is acknowledged by software clearing the Frame List Rollover bit. Only used by the host controller. 0 = DISABLE 1 = ENABLE

Bit	Reset	Description
2	0x0	PCE: Port Change Detect Enable. 1 = Host/device controller issues an interrupt if Port Change Detect bit in USBSTS register = 1. The interrupt is acknowledged by software clearing the Port Change Detect bit. 0 = DISABLE 1 = ENABLE
1	0x0	UEE: USB Error Interrupt Enable. 1 = Host controller issues an interrupt at the next interrupt threshold if the USBERRINT bit in USBSTS = 1. The interrupt is acknowledged by software clearing the USBERRINT bit in the USBSTS register. 0 = DISABLE 1 = ENABLE
0	0x0	UE: USB Interrupt Enable. 1 = Host/device issues an interrupt at the next interrupt threshold if the USBINT bit in USBSTS = 1. The interrupt is acknowledged by software clearing the USBINT bit. 0 = DISABLE 1 = ENABLE

21.5.1.17 USB2_CONTROLLER_USB2D_FRINDEX_0

USB2D USB Frame Index Register

Offset: 13ch | Read/Write: RO | Reset: 0bxxxxxxxxxxxxxx

Bit	Reset	Description
13:0	X	FRINDEX: Frame Index. The value in this register increments at the end of each time frame (micro-frame). Bits [N: 3] are used for the Frame List current index. Each location of the frame list is accessed 8 times (frames or micro-frames) before moving to the next index. The following illustrates values of N based on the value of the Frame List Size field in the USBCMD register, when used in host mode. USBCMD [Frame List Size] Number Elements N 000b (1024) 12 001b (512) 11 010b (256) 10 011b (128) 9 100b (64) 8 101b (32) 7 110b (16) 6 111b (8) 5 In device mode the value is the current frame number of the last frame transmitted. It is not used as an index. In either mode bits 2:0 indicate the current micro-frame.

21.5.1.18 USB2_CONTROLLER_USB2D_PERIODICLISTBASE_0

USB2D Host Controller Frame List Base Address Register

Offset: 144h | Read/Write: R/W | Reset: 0b00000000000000000000

Bit	Reset	Description
31:25	0x0	USBADR: Device mode. The upper seven bits of this register represent the device address. After any controller reset or a USB reset, the device address is set to the default address (0). The default address will match all incoming addresses. Software shall reprogram the address after receiving a SET_ADDRESS request.
24	0x0	USBADRA: Device Address Advance. Default=0. When this bit is 0, any writes to USBADR are instantaneous. When this bit is written to a 1 at the same time or before USBADR is written, the write to the USBADR field is staged and held in a hidden register. After an IN occurs on endpoint 0 and is ACKed, USBADR will be loaded from the holding register. Hardware will automatically clear this bit on the following conditions: 1) IN is ACKed to endpoint 0. (USBADR is updated from staging register). 2) OUT/SETUP occur to endpoint 0. (USBADR is not updated). 3) Device Reset occurs (USBADR is reset to 0). Note: After the status phase of the SET_ADDRESS descriptor, the DCD has 2 ms to program the USBADR field. This mechanism will ensure this specification is met when the DCD can not write of the device address within 2ms from the SET_ADDRESS status phase. If the DCD writes the USBADR with USBADRA=1 after the SET_ADDRESS data phase (before the prime of the status phase), the USBADR will be programmed instantly at the correct time and meet the 2ms USB requirement.
31:12	0x0	BASEADR: Host mode: This 32-bit register contains the beginning address of the Periodic Frame List in the system memory. HCD loads this register prior to starting the schedule execution by the Host Controller. The memory structure referenced by this physical memory pointer is assumed to be 4-Kbyte aligned. The contents of this register are combined with the Frame Index Register (FRINDEX) to enable the Host Controller to step through the Periodic Frame List in sequence. Base Address (Low). These

Bit	Reset	Description
		bits correspond to memory address signals [31:12], respectively. Only used by the host controller.

21.5.1.19 USB2_CONTROLLER_USB2D_ASYNCLISTADDR_0

USB2D Next Asynchronous List Address Register

Offset: 148h | Read/Write: R/W | Reset: 0b00000000000000000000000000000000

Bit	Reset	Description
31:11	0x0	EPBASE: Device mode. This register contains the address of the top of the endpoint list in system memory. These bits correspond to memory address signals [31:11], respectively. This field will reference a list of up to 32 Queue Heads (QH). Only used by the device controller.
31:5	0x0	ASYBASE: Host mode. This 32-bit register contains the address of the next asynchronous queue head to be executed by the host. Link Pointer Low (LPL). These bits correspond to memory address signals [31:5], respectively. This field may only reference a Queue Head (OH). Only used by the host controller.

21.5.1.20 USB2_CONTROLLER_USB2D_ASYNCTTSTS_0

USB2D Asynchronous Buffer Status for Embedded TT Register

Offset: 14ch | Read/Write: R/W | Reset: 0b0x

Bit	R/W	Reset	Description
1	RW	0x0	TTAC: Embedded TT Async Buffers Clear. (Read/Write to set) This field will clear all pending transactions in the embedded TT Async Buffer(s). The clear will take as much time as necessary to clear buffer without interfering with a transaction in progress. TTAC will return to zero after being set by software only after the actual clear occurs.
0	RO	X	TTAS: Embedded TT Async Buffers Status. (Read Only) This read only bit will be 1 if one or more transactions are being held in the embedded TT Async. Buffers. When this bit is a zero, then all outstanding transactions in the embedded TT have been flushed.

21.5.1.21 USB2_CONTROLLER_USB2D_BURSTSIZE_0

USB2D Burst Size register

Offset: 150h | Read/Write: R/W | Reset: 0b0000100000001000

Bit	Reset	Description
15:8	0x8	TXPBURST: Programmable TX Burst Length. (Read/Write) This register represents the maximum length of a burst in 32-bit words while moving data from system memory to the USB bus.
7:0	0x8	RXPBURST: Programmable RX Burst Length. (Read/Write) This register represents the maximum length of a burst in 32-bit words while moving data from the USB bus to system memory.

21.5.1.22 USB2_CONTROLLER_USB2D_TXFILLTUNING_0

USB2D Transmit fill tuning register

Offset: 154h | Read/Write: R/W | Reset: 0b000010xxx0000000000000

Bit	Reset	Description
21:16	0x2	TXFIFOTHRES: FIFO Burst Threshold. (Read/Write) This register controls the number of data bursts that are posted to the TX latency FIFO in host mode before the packet begins on to the bus. The

Bit	Reset	Description
		minimum value is 2 and this value should be a low as possible to maximize USB performance. A higher value can be used in systems with unpredictable latency and/or insufficient bandwidth where the FIFO may underrun because the data transferred from the latency FIFO to USB occurs before it can be replenished from system memory. This value is ignored if the Stream Disable bit in USBMODE register is set.
12:8	0x0	TXSCHHEALTH: Scheduler Health Counter. (Read/Write To Clear) [Default = 0] This register increments when the host controller fails to fill the TX latency FIFO to the level programmed by TXFIFOTHRES before running out of time to send the packet before the next Start-Of-Frame. This health counter measures the number of times this occurs to provide feedback to selecting a proper TXSCHOH. Writing to this register will clear the counter and this counter will max. at 31.
7:0	0x0	TXSCHOH: Scheduler Overhead. (Read/Write) [Default = 0] This register adds an additional fixed offset to the schedule time estimator described above as Tff. As an approximation, the value chosen for this register should limit the number of back-off events captured in the TXSCHHEALTH to less than 10 per second in a highly utilized bus. Choosing a value that is too high for this register is not desired as it can needlessly reduce USB utilization. The time unit represented in this register is 1.267us when a device is connected in High-Speed Mode. The time unit represented in this register is 6.333us when a device is connected in Low/Full Speed Mode

21.5.1.23 USB2_CONTROLLER_USB2D_ICUSB_CTRL_0

This register enables and controls the ICUSB FS/LS transceiver.

USB2D ICUSB control register

Offset: 15ch | Read/Write: R/W | Reset: 0b0000

Bit	Reset	Description
3	0x0	IC_ENB1: ICUSB transceiver enable. This bit enables the ICUSB transceiver . To enable the interface, the bits PTS must be set to 11 in the PORTSCx. Writing a '1' to this bit selects the IC_USB interface. 0 = DISABLE 1 = ENABLE
2:0	0x0	IC_VDD1: ICUSB voltage select. It selects which voltage is being supplied to the ICUSB peripheral. 000 -> No voltage 001 -> 1.0V - reserved 010 -> 1.2V - reserved 011 -> 1.5V - reserved 100 -> 1.8V 101 -> 3.0V 110 -> reserved 111 -> reserved The Voltage negotiation should happen between enabling port power (PP) and asserting the run/stop bit in register.

21.5.1.24 USB2_CONTROLLER_USB2D_ULPI_VIEWPORT_0

This register provides indirect access to the ULPI PHY register set. Although the USB controller performs access to the ULPI PHY register set, there may be extraordinary circumstances where software may need direct access.

Note: WRITES TO THE ULPI THROUGH THE VIEWPORT CAN SUBSTANTIALLY HARM STANDARD USB OPERATIONS. CURRENTLY NO USAGE MODEL HAS BEEN DEFINED WHERE SOFTWARE SHOULD NEED TO EXECUTE WRITES DIRECTLY TO THE ULPI PHY. SEE EXCEPTION REGARDING OPTIONAL FEATURES BELOW.

Note: Executing read operations through the ULPI Viewport should have NO harmful side effects to standard USB operations.

There are two operations that can be performed with the ULPI Viewport, wakeup and read /write operations.

The wakeup operation is used to put the ULPI interface into normal operation mode and reenable the clock if necessary. A wakeup operation is required before accessing the registers when the ULPI interface is operating in low power mode, serial mode, or carkit mode.

The ULPI state can be determined by reading the sync. state bit (ULPI_SYNC_STATE). If this bit is a one, then ULPI interface is running in normal operation mode and can accept read/write operations. If the ULPI_SYNC_STATE indicates a 0 then then

read/write operations will not be able to execute. Undefined behavior will result if ULPI_SYNC_STATE = 0 and a read or write operation is performed.

To execute a wakeup operation, write all 32-bits of the ULPI Viewport where ULPI_PORT is constructed appropriately and the ULPI_WAKEUP bit is a 1 and ULPI_RUN bit is a 0. Poll the ULPI Viewport until ULPI_WAKEUP is zero for the operation to complete.

To execute a read or write operation, write all 32-bits of the ULPI Viewport where ULPI_DATA_WR, ULPI_REG_ADDR, ULPI_PORT, ULPI_RD_WR are constructed appropriately and the ULPI_RUN bit is a 1. Poll the ULPI Viewport until ULPI_RUN is zero for the operation to complete. Once ULPI_RUN is zero, the ULPI_DATA_RD will be valid if the operation was a read.

The polling method above can be changed to interrupt driven using the ULPI interrupt defined in the USBSTS and USBINTR registers. When a wakeup or read/write operation is complete, the ULPI_INT interrupt will be set.

There are several optional features that may need to be enabled or disabled by system software as part of system configuration. These bits are contained in the Interface and OTG Control registers of the ULPI PHY register set. These registers also contain bits which are controlled by the link dynamically and therefore should be only modified by system software using the Set/Clear access method. Direct writes to these registers could have harmful side effects to the standard USB operations. The optional bits are as follows: Bits 3 through 7 in the Interface Control register and Bits 6 and 7 in the OTG Control register.

Please refer to the ULPI Specification Revision 1.1 for further information on the use of the optional features.

USB2D ULPI viewport register

Offset: 160h | Read/Write: R/W | Reset: 0b000xx00000000000xxxxxxxx00000000

Bit	R/W	Reset	Description
31	RW	0x0	ULPI_WAKEUP: ULPI Wakeup. Writing the 1 to this bit will begin the wakeup operation. The bit will automatically transition to 0 after the wakeup is complete. Once this bit is set, the driver cannot set it back to 0. Note: The driver must never execute a wakeup and a read/write operation at the same time. 0 = CLEAR 1 = SET
30	RW	0x0	ULPI_RUN: ULPI read/write Run. Writing the 1 to this bit will begin the read/write operation. The bit will automatically transition to 0 after the read/write is complete. Once this bit is set, the driver cannot set it back to 0. Note: The driver must never execute a wakeup and a read/write operation at the same time. 0 = CLEAR 1 = SET
29	RW	0x0	ULPI_RD_WR: ULPI read/write control. (0) Read; (1) Write. This bit selects between running a read or write operation. 0 = READ 1 = WRITE
27	RO	X	ULPI_SYNC_STATE: ULPI sync state. (1) Normal Sync. State. (0) In another state (i.e. carkit, serial, low power) This bit represents the state of the ULPI interface. 0 = NOT_NORMAL 1 = NORMAL
26:24	RW	0x0	ULPI_PORT: ULPI PHY port no. This field should be always written as 0.
23:16	RW	0x0	ULPI_REG_ADDR: ULPI PHY register address. When doing a read or write operation to the ULPI PHY, the address of the ULPI PHY register being accessed is written to this field.
15:8	RO	X	ULPI_DATA_RD: ULPI PHY data read. The data from the ULPI PHY register can be read from here after the read operation completes.
7:0	RW	0x0	ULPI_DATA_WR: ULPI PHY data write. The data to write to the ULPI PHY register is written here.

21.5.1.25 USB2_CONTROLLER_USB2D_PORTSC1_0

USB2D Port Status/Control 1 Register

Offset: 174h | Read/Write: R/W | Reset: 0b0000000xx0000000xxx1xx00x0xx010x

Bit	R/W	Reset	Description
31:25	RW	0x0	DA: Device Address - RW. Default = 0000000b. The 7-bit USB device address for the device attached to an immediately downstream of the associated root port. A value of zero indicates no device is present or software support for this feature is not present. This is used by the Controller when sending the LPM token. This field is only valid when the core is operating in host mode. If in device mode it will be read only and always equal to 0000000b.
24:23	RO	X	SSTS: Suspend Status - RO. Default = 00b. These two bits are used by software to determine whether an L1-based suspend request was successful, specifically: 00b - L1 state entered with success. ACK received from peripheral. 01b - NYET received from peripheral. It was not able to enter L1 state this time. 10b - L1 state not supported by peripheral. STALL received. 11b - Peripheral didn't respond or an error occurred. The value of this field is only valid when the port resides in the L0 state - that is, the meaning of these bits are invalid whenever bit 7 of this register (SUSP) is one. Ideally, the Controller driver should read this register if it receives an interrupt after issuing a suspend using L1 support. In case of a non-success a port change interrupt will be fired and this field should be checked for a possible L1 failure. This field is only valid when the core is operating in host mode. If in device mode it will be always equal to 00b. 0 = L1STATE_ENTERED 1 = NYET_PERIPH 2 = L1STATE_NOT_SUPPORTED 3 = PERIPH_NORESP_ERR
22	RW	0x0	WKOC: Default = 0b. Wake on Over-current Enable: Writing this bit to a one enables the port to be sensitive to over-current conditions as wake-up events. This field is zero if Port Power(PP) is zero. This bit should only be used when operating in Host mode. Writing this bit to 1 while the controller is working in device mode can result in undefined behavior. 0 = DISBLE 1 = ENABLE
21	RW	0x0	WKDS: Wake on Disconnect Enable: Writing this bit to a one enables the port to be sensitive to device disconnects as wake-up events. This field is zero if Port Power(PP) is zero or in device mode. This bit should only be used when operating in Host mode. Writing this bit to 1 while the controller is working in device mode can result in undefined behaviour. This bit should not be written to 1 if there is no device connected. After the device disconnect is detected, this bit should be cleared to 0. 0 = DISBLE 1 = ENABLE
20	RW	0x0	WKCN: Wake on Connect Enable: Writing this bit to a one enables the port to be sensitive to device connects as wake-up events. This field is zero if Port Power(PP) is zero or in device mode. This bit should only be used when operating in Host mode. Writing this bit to 1 while the controller is working in device mode can result in undefined behaviour. This bit should not be written to 1 while the device is connected. After the device connection is detected, this bit should be cleared to 0. 0 = DISBLE 1 = ENABLE
19:16	RW	0x0	PTC: Port Test Control: Any other value than zero indicates that the port is operating in test mode. Value Specific Test 0000b Not enabled 0001b J_ STATE 0010b K_STATE 0011b SEQ_NAK 0100b Packet 0101b FORCE_ENABLE 0110b to 1111b Reserved Refer to Chapter 7 of the USB Specification Revision 2.0 for details on each test mode. 0 = NORMAL_OP 1 = TEST_J 2 = TEST_K 3 = TEST_SE0_NAK 4 = TEST_PKT 5 = TEST_FORCE_ENABLE
15:14	RO	X	PIC: Port Indicator Control: This field is not supported in the current implementation. Please use a GPIO if you wish to use Port Indicators.
13	RO	X	PO: Port Owner. Port owner handoff is not implemented in this design, therefore this bit will

Bit	R/W	Reset	Description
			always be 0.
12	RW	0x1	PP: Port Power: The function of this bit depends on the value of the Port Power Switching (PPC) field in the HCSPARAMS register. The behavior is as follows: PPC PP Operation 0b 0b Read Only. A device controller with no OTG capability does not have port power control switches. 1b 1b/0b RW. Host/OTG controller requires port power control switches. This bit represents the current setting of the switch (0=off, 1=on). When power is not available on a port (i.e. PP equals a 0), the port is non-functional and will not report attaches, detaches, etc. When an over-current condition is detected on a powered port and PPC is a one, the PP bit in each affected port may be transitioned by the host controller driver from a one to a zero (removing power from the port). 0 = NOT_POWERED 1 = POWERED
11:10	RO	X	LS: Line state. These bits reflect the current logical levels of the D+ (bit 10) and D- (bit 11) signal lines. The encoding of the bits are: 00b = SE0 01b = J-state 10b = K-state 11b = Undefined The value of this field is undefined if Port Power(PP) is zero in host mode. In host mode, the use of line-state by the host controller driver is not necessary (unlike EHCI), because the port controller state machine and the port routing manage the connection of LS and FS. In device mode, the use of line-state by the device controller driver is not necessary. 0 = SE0 1 = J_STATE 2 = K_STATE 3 = UNDEFINED
9	RW	0x0	SLP: Suspend using L1 - RW. Default = 0b. When this bit is set to '1' and a non-zero Device Address (DA) is specified Controller will instigate L1 entry during suspend (bit 7) and L1 exit during resume (bit 6). When set to zero the Controller will use the legacy (L2) mechanism. Software should only set this bit when the device attached immediately downstream supports L1 transitions. When acting as device, this bit is read-only and set to '1' by the hardware when the Controller enters is L1 state (LPM token received and accepted). Note: HSP is redundant with PSPD(27:26). This bit is not defined in the EHCI specification.
8	RW	0x0	PR: This field is zero if Port Power(PP) is zero. In Host Mode: Read/Write. 1=Port is in Reset. 0=Port is not in Reset. When software writes a one to this bit the bus-reset sequence as defined in the USB Specification Revision 2.0 is started. This bit will automatically change to zero after the reset sequence is complete. This behavior is different from EHCI where the host controller driver is required to set this bit to a zero after the reset duration is timed in the driver. In Device Mode: This bit is a read only status bit. Device reset from the USB bus is also indicated in the USBSTS register. 0 = NOT_USB_RESET 1 = USB_RESET
7	RO	X	SUSP: Port suspend. 1=Port in suspend state. 0=Port not in suspend state. In Host Mode: Read/Write. Port Enabled Bit and Suspend bit of this register define the port states as follows: Bits [Port Enabled, Suspend] Port State 0x Disable 10 Enable 11 Suspend When in suspend state, downstream propagation of data is blocked on this port, except for port reset. The blocking occurs at the end of the current transaction if a transaction was in progress when this bit was written to 1. In the suspend state, the port is sensitive to resume detection. Note that the bit status does not change until the port is suspended and that there may be a delay in suspending a port if there is a transaction currently in progress on the USB. The host controller will unconditionally set this bit to zero when software sets the Force Port Resume bit to zero. A write of zero to this bit is ignored by the host controller. If host software sets this bit to a one when the port is not enabled (i.e. Port enabled bit is a zero) the results are undefined. This field is zero if Port Power(PP) is zero in host mode. In Device Mode: Read Only. This bit is a read only status bit. 0 = NOT_SUSPEND 1 = SUSPEND
6	RW	0x0	FPR: Force Port Resume. 1= Resume detected/driven on port. 0=No resume (K state) detected/driven on port. In Host Mode: Software sets this bit to one to drive resume signaling. The Host Controller sets this bit to one if a J-to-K transition is detected while the port is in the Suspend state. When this bit transitions to a one because a J-to-K transition is detected, the Port Change Detect bit in the USBSTS register is also set to one. This bit will automatically change to zero after the resume sequence is complete. This behavior is different from EHCI where the host controller driver is required to set this bit to a zero after the resume duration is timed in the driver. Note that when the Host controller owns the port, the resume sequence follows the defined sequence documented in the USB Specification Revision 2.0. The resume signaling (Full-speed 'K') is driven on the port as long as this bit remains a one. This bit remains a one until the port has switched to the high-speed idle. Writing a zero has no effect because the port controller will time

Bit	R/W	Reset	Description
			the resume operation to clear the bit when the port control state switches to HS or FS idle. This field is zero if Port Power(PP) is zero in host mode. This bit is not-EHCI compatible. In Device mode: After the device has been in Suspend State for 5ms or more, software must set this bit to one to drive resume signaling before clearing. The Device Controller will set this bit to one if a J-to-K transition is detected while the port is in the Suspend state. The bit will be cleared when the device returns to normal operation. Also, when this bit transitions to a one because a J-to-K transition is detected, the Port Change Detect bit in the USBSTS register is also set to one. Software should ensure that the PHY clock is operational before writing a 1 to this bit to start the resume sequence. This is true for both Device and Host modes. 0 = NO_RESUME 1 = RESUME
5	RO	X	OCC: Over-current Change: Not supported 0 = NO_CHANGE 1 = CHANGE
4	RO	X	OCA: Over-current Active: Not supported 0 = NO_OVER_CURRENT 1 = OVER_CURRENT
3	RW	0x0	PEC: Port Enable/Disable Change: 1=Port enabled/disabled status has changed. 0=No change. In Host Mode: For the root hub, this bit gets set to a one only when a port is disabled due to disconnect on the port or due to the appropriate conditions existing at the EOF2 point (See Chapter 11 of the USB Specification). Software clears this by writing a one to it. This field is zero if Port Power(PP) is zero. In Device mode: The device port is always enabled. (This bit will be zero) 0 = NO_CHANGE 1 = CHANGE
2	RW	0x1	PE: Port Enabled/Disabled: 1=Enable. 0=Disable (default) In Host Mode: Ports can only be enabled by the host controller as a part of the reset and enable. Software cannot enable a port by writing a one to this field. Ports can be disabled by either a fault condition (disconnect event or other fault condition) or by the host software. Note that the bit status does not change until the port state actually changes. There may be a delay in disabling or enabling a port due to other host controller and bus events. When the port is disabled, (0b) downstream propagation of data is blocked except for reset. This field is zero if Port Power(PP) is zero in host mode. In Device Mode: The device port is always enabled. (This bit will be one) 0 = PORT_DISABLED 1 = PORT_ENABLED
1	RW	0x0	CSC: Connect Status Change: 1 =Change in Current Connect Status. 0=No change (default) In Host Mode: Indicates a change has occurred in the port's Current Connect Status. The host/device controller sets this bit for all changes to the port device connect status, even if system software has not cleared an existing connect status change. For example, the insertion status changes twice before system software has cleared the changed condition, hub hardware will be 'setting' an already-set bit (i.e., the bit will remain set). Software clears this bit by writing a one to it. This field is zero if Port Power(PP) is zero in host mode. This bit is undefined in device controller mode. 0 = NO_CHANGE 1 = CHANGE
0	RO	X	CCS: Current Connect Status: In Host Mode: 1=Device is present on port. 0=No device is present (default) This value reflects the current state of the port, and may not correspond directly to the event that caused the Connect Status Change bit (Bit 1) to be set. This field is zero if Port Power(PP) is zero in host mode. In Device Mode: 1=Attached 0=Not Attached (default) A one indicates that the device successfully attached and is operating in either high speed or full speed as indicated by the High Speed Port bit in this register. A zero indicates that the device did not attach successfully or was forcibly disconnected by the software writing a zero to the Run bit in the USBCMD register. It does not state the device being disconnected or suspended. 0 = NOT_CONNECTED 1 = CONNECTED

21.5.1.26 USB2_CONTROLLER_USB2D_HOSTPC1_DEVLC_0

USB2D Device Mode LPM Behav and Control Register

This register controls the LPM behavior and controls the behavior of each USB port. Only available in device mode. This register shares the same address with the HOSTPC1 register (which is used only in host mode).

USB2D Host Mode LPM Behav and Control Register

This register controls the LPM behavior and controls the behavior of each USB port. Only available in host mode. This register shares the same address with the DEVLC register (which is used only in device mode).

Offset: 1b4h | Read/Write: R/W | Reset: 0b0000xxxx000000000000xxxxxxxxxxx0

Bit	R/W	Reset	Description
31:29	RW	0x0	PTS: Parallel transceiver select. This bit is not defined in the EHCI specification. 0 = UTMI 1 = RESERVED 2 = ULPI 3 = ICUSB_SER 4 = HSIC
28	RW	0x0	STS: Serial transceiver not selected. This is the only value supported. This bit is not defined in the EHCI specification. 0 = PARALLEL_IF 1 = SERIAL_IF
27	RO	X	PTW: Parallel Transceiver Width. Fixed to 0. This bit is not defined in the EHCI specification. 0 = EIGHT_BIT 1 = RESERVED
26:25	RO	X	PSPD: This register field indicates the speed at which the port is operating. 00 = Full Speed 01 = Low Speed 10 = High Speed. This bit is not defined in the EHCI specification. 0 = FULL_SPEED 1 = LOW_SPEED 2 = HIGH_SPEED 3 = RESERVED
23	RW	0x0	PFSC: Port Force Full Speed Connect - RW. Default = 0b. Writing this bit to a '1b' will force the port to only connect at Full Speed. It disables the chirp sequence that allows the port to identify itself as High Speed. This is useful for testing FS configurations with a HS host, hub or device. This bit is not defined in the EHCI specification. 0 = DONT_FORCE_FULL_SPEED 1 = FORCE_FULL_SPEED
22	RW	0x0	PHCD: PHY Low Power Suspend - Clock disable: Writing this bit to a 1 will disable the PHY clock. Write a 0 enables it. Reading this bit will indicate the status of the PHY clock. NOTE: The PHY clock cannot be disabled if it is being used as the system clock. In device mode, the PHY can be put into Low Power Clock Disable when the device is not running (USBCMD RS=0b) or the host has signaled suspend (PORTSCx SUSP=1b). Low Power Clock Disable will be cleared automatically when the host has signaled resume. Before forcing a resume from the device, the Controller driver must clear this bit. In host mode, the PHY can be put into Low Power Suspend Clock Disable when the downstream device has been put into suspend mode or when no downstream device is connected. Low Power Clock Disable is completely under the control of software. 0 = DISABLE 1 = ENABLE
21:20	RW	0x0	LPMX: Auto LPM set - RW. Default = 00b. This bit field is **valid during Host Mode Only**. For Device Mode this is reserved. Value Meaning 00b Disables auto LPM. 01b If there is no activity for a certain number of SOFs the controller will send a LPM token, enter in suspend and issue a port change interrupt. 10b Same as above but without issuing an interrupt. 11b Reserved for futures LPM enhancements. The detection of no activity is based on the absence of response from the downstream device. Because of this limitation this feature should not be used if ISO OUT endpoints are being used (as no handshake is expected).

Bit	R/W	Reset	Description
17	RW	0x0	ASUS: Auto Low Power - RW. Default = 0b. This bit field is **valid during Device Mode Only**. In Host Mode it is part of ELPM field. This bit is used to control the auto low power feature. If set, the auto low power feature will be enabled and every time the port enters in suspend state it will also enter in low power state, disabling the transceiver clock. The behavior will be the same as if the PHCD bit was enabled (in fact this bit will be set to '1' as soon as low power mode is enabled). 0 = DISABLE 1 = ENABLE
19:16	RW	0x0	EPLPM: Endpoint for LPM token - RW. Default = 0000b. This bit field is **valid during Host Mode Only**. For Device Mode [19:18] is reserved and 17 is ASUS, while 16 is STL. This sets the endpoint number to which the LPM token will be sent. It will be directly mapped to the ENDP field in the LPM token with the EXT PID.
16	RW	0x0	STL: STALL reply to LPM token - RW. Default = 0b. This bit field is **valid during Device Mode Only**. In Host Mode it is a part of ELPM field. When this bit is set to '1', the Controller will reply always with STALL to all incoming LPM tokens. This bit overrides the LPM NYET bit (NYT). 0 = DISABLE 1 = ENABLE
15:12	RW	0x0	LPMFRM: Auto LPM SOF Threshold - RW. Default = 0000b. This bit field is **valid during Host Mode Only**. For Device Mode this is reserved. This holds the SOF counter threshold. When the number of SOF with no activity in between reaches this threshold and the auto LPM is enabled, a LPM token will be sent and the port will enter in suspend state. The SOF counter for this threshold is incremented each 125us, even if the port is not in HS operation.
11:1	RO	X	BA: BmAttributtes - RO. Default = 00000000000b. This holds the bmAttributes field of the LPM sub-token received, after the EXT PID token.
0	RW	0x0	NYT_ASUS: NYET reply to LPM token - RW. Default = 0b. This bit is NYT during Device Mode. Details follows: When this bit is to '1', the device controller will NYET all the LPM tokens. When this bit is set to '0', the Controller will ACK all the LPM tokens if the STALL bit (STL) is also set to '0'. This bit is ASUS in Host Mode. Details follows: This bit is used to control the auto low power feature. If set, the auto low power feature will be enabled and every time the port enters in suspend state it will also enter in low power state, disabling the transceiver clock. The behavior will be the same as if the PHCD bit was enabled (in fact this bit will be set to '1' as soon as low power mode is enabled). 0 = DISABLE 1 = ENABLE

21.5.1.27 USB2_CONTROLLER_USB2D_OTGSC_0

USB2D On-The-Go (OTG) Status and Control Register

Offset: 1f4h | Read/Write: R/W | Reset: 0b0000000x0000000xxxxxxxxxx000x00

Bit	R/W	Reset	Description
30	RW	0x0	DPIE: Data Pulse Interrupt Enable. Setting this bit enables the Data pulse interrupt. 0 = DISABLE 1 = ENABLE
29	RW	0x0	ONEMSE: 1 millisecond timer Interrupt enable. Setting this bit enables the 1 millisecond timer interrupt. 0 = DISABLE 1 = ENABLE
28	RW	0x0	BSEIE: B Session End Interrupt Enable. Setting this bit enables the B session end interrupt 0 = DISABLE 1 = ENABLE
27	RW	0x0	BSVIE: B Session Valid Interrupt Enable. Setting this bit enables the B session valid interrupt 0 = DISABLE 1 = ENABLE

Bit	R/W	Reset	Description
26	RW	0x0	ASVIE: A Session Valid Interrupt Enable. Setting this bit enables the A session valid interrupt 0 = DISABLE 1 = ENABLE
25	RW	0x0	AVVIE: A VBus Valid Interrupt Enable. Setting this bit enables the A VBus valid interrupt 0 = DISABLE 1 = ENABLE
24	RW	0x0	IDIE: USB ID Interrupt Enable. Setting this bit enables the USB ID interrupt 0 = DISABLE 1 = ENABLE
22	RW	0x0	DPIS: Data Pulse Interrupt Status. This bit is set when data bus pulsing occurs on DP or DM. Data bus pulsing is only detected when USBMODE.CM = Host (11) and PORTSC(0).PortPower = Off (0). Software writes a 1 to clear this bit. 0 = INT_CLEAR 1 = INT_SET
21	RW	0x0	ONEMSS: 1 millisecond timer Interrupt Status: This bit is set once every millisecond. Software writes a 1 to clear it. 0 = INT_CLEAR 1 = INT_SET
20	RW	0x0	BSEIS: B Session End Interrupt Status. This bit is set when VBus has fallen below the B session end threshold. Software writes a 1 to clear this bit . 0 = INT_CLEAR 1 = INT_SET
19	RW	0x0	BSVIS: B Session Valid Interrupt Status. This bit is set when VBus has either risen above or fallen below the B session valid threshold (0.8 VDC). Software writes a 1 to clear this bit. 0 = INT_CLEAR 1 = INT_SET
18	RW	0x0	ASVIS: A Session Valid Interrupt Status. This bit is set when VBus has either risen above or fallen below the A session valid threshold (0.8 VDC). Software writes a one to clear this bit. 0 = INT_CLEAR 1 = INT_SET
17	RW	0x0	AVVIS: A VBus Valid Interrupt Status. This bit is set when VBus has either risen above or fallen below the VBus valid threshold (4.4 VDC) on an A device. Software writes a 1 to clear this bit. 0 = INT_CLEAR 1 = INT_SET
16	RW	0x0	IDIS: USB ID Interrupt Status. This bit is set when a change on the ID input has been detected. Software writes a 1 to clear this bit. 0 = INT_CLEAR 1 = INT_SET
14	RO	X	DPS: Data Bus Pulsing Status. A 1 indicates data bus pulsing is being detected on the port. 0 = STS_CLEAR 1 = STS_SET
13	RO	X	ONEMST: 1 millisecond timer toggle. This bit toggles once per millisecond 0 = STS_CLEAR 1 = STS_SET
12	RO	X	BSE: B session End. Indicates VBus is below the B session end threshold 0 = STS_CLEAR 1 = STS_SET
11	RO	X	BSV: B Session Valid. Indicates VBus is above the B session valid threshold 0 = STS_CLEAR 1 = STS_SET
10	RO	X	ASV: A Session Valid. Indicates VBus is above the A session valid threshold 0 = STS_CLEAR 1 = STS_SET

Bit	R/W	Reset	Description
9	RO	X	AVV: A VBus Valid. Indicates VBus is above the A VBus valid threshold 0 = STS_CLEAR 1 = STS_SET
8	RO	X	ID: USB ID: 0 = A-device 1 = B-device 0 = A_DEV 1 = B_DEV
5	RW	0x0	IDPU: USB ID Pullup 0 = CLEAR 1 = SET
4	RW	0x0	DP: Data Pulsing. Setting this bit causes the pull-up on DP to be asserted for data pulsing during SRP. 0 = NO_DATA_PULSE 1 = DATA_PULSE
3	RW	0x0	OT: OTG Termination. This bit must be set when the OTG device is in device mode, this controls the pulldown on DM. 0 = NO_OTG_TERM 1 = OTG_TERM
1	RW	0x0	VC: VBUS Charge. Setting this bit causes the VBus line to be charged. This is used for VBus pulsing during SRP. 0 = NO_VBUS_CHRG 1 = VBUS_CHRG
0	RW	0x0	VD: VBUS_Discharge. Read/write. Setting this bit causes Vbus to discharge through a resistor. 0 = NO_VBUS_DISCHRG 1 = VBUS_DISCHRG

21.5.1.28 USB2_CONTROLLER_USB2D_USBMODE_0

USB2D USB Device Mode Register

Offset: 1f8h | Read/Write: R/W | Reset: 0b0xxxxxxxxx0xxxxx

Bit	R/W	Reset	Description
15	RW	0x0	SRT: Shorten USB Reset Time. Software should never set this to 1.
5	RW	0x0	VBPS: VBUS Power Select This can be used by logic that selects between an on-chip Vbus power source (charge pump) and an off-chip source in systems when both are available. Only to be used in Host Mode No functionality implemented for this, so SW should not use this.
4	RO	X	SDIS: Stream disbable: 1 Streaming is disabled - helpful to avoid overrun/underruns when system load is too high. 0 = STREAM_ENABLE 1 = STREAM_DISABLE
3	RO	X	SLOM: Setup Lockout Mode: In device mode, this bit controls the behavior of the setup lockout mechanism. 0 - Setup lockout is ON (default) 1 Setup lockout is OFF. Firmware requires the use of setup tripwire semaphore in USB2D_USBCMD register. 0 = LOCKOUT_ON 1 = LOCKOUT_OFF
2	RO	X	ES: Endian Select: Note: For this implementation, this should be always set to 0 (little endian). 0 = LITTLE_ENDIAN 1 = RESERVED
1:0	RO	X	CM: Controller Mode: The controller mode will default to an idle state and will need to be initialized to the desired operating mode after reset. This register can only be written once after reset. If it is necessary to switch modes, software must reset the controller by writing to the RESET bit in the USBCMD register before reprogramming this register. 00 = Idle [Default] 01 = Reserved 10 = Device Controller 11 = Host Controller 0 = IDLE

Bit	R/W	Reset	Description
			1 = RESERVED 2 = DEVICE_MODE 3 = HOST_MODE

21.5.1.29 USB2_CONTROLLER_USB2D_ENDPTNAK_0

USB2D Endpoint NAK register

Offset: 200h | Read/Write: R/W | Reset: 0b00000000000000000000000000000000

Bit	Reset	Description
31:16	0x0	EPTN: TX Endpoint NAK R/WC. Each TX endpoint has 1 bit in this field. The bit is set when the device sends a NAK handshake on a received IN token for the corresponding endpoint. 0 = CLEAR 1 = SET
15:0	0x0	EPRN: RX Endpoint NAK R/WC. Each RX endpoint has 1 bit in this field. The bit is set when the device sends a NAK handshake on a received OUT or PING token for the corresponding endpoint. 0 = CLEAR 1 = SET

21.5.1.30 USB2_CONTROLLER_USB2D_ENDPTNAK_ENABLE_0

USB2D Endpoint NAK Enable register

Offset: 204h | Read/Write: R/W | Reset: 0b00000000000000000000000000000000

Bit	Reset	Description
31:16	0x0	EPTNE: TX Endpoint NAK Enable R/W. Each bit is an enable bit for the corresponding TX Endpoint NAK bit. If this bit is set and the corresponding TX Endpoint NAK bit is set, the NAK Interrupt bit is set. 0 = DISABLE 1 = ENABLE
15:0	0x0	EPRNE: RX Endpoint NAK Enable R/W. Each bit is an enable bit for the corresponding RX Endpoint NAK bit. If this bit is set and the corresponding RX Endpoint NAK bit is set, the NAK Interrupt bit is set. 0 = DISABLE 1 = ENABLE

21.5.1.31 USB2_CONTROLLER_USB2D_ENDPTSETUPSTAT_0

USB2D Endpoint Setup Status Register

Offset: 208h | Read/Write: R/W | Reset: 0b0000000000000000

Bit	Reset	Description
15	0x0	ENDPTSETUPSTAT15: Endpoint 15 Setup Status: For every setup transaction that is received, this bit is set to 1. Software must clear or acknowledge the setup transfer by writing a 1 to it after it has read the setup data from Queue head. The response to a setup packet (as in the order of operations and total response time) is crucial to limit bus time-outs while the setup lock-out mechanism is engaged. This register is only used in device mode. 0 = NOT_RCVD 1 = SETUP_RCVD
14	0x0	ENDPTSETUPSTAT14: Endpoint 14 Setup Status: For every setup transaction that is received, this bit is set to 1. Software must clear or acknowledge the setup transfer by writing a 1 to it after it has read the setup data from Queue head. The response to a setup packet (as in the order of operations and total response time) is crucial to limit bus time-outs while the setup lock-out mechanism is engaged. This register is only used in device mode. 0 = NOT_RCVD

Bit	Reset	Description
		1 = SETUP_RCVD
13	0x0	ENDPTSETUPSTAT13: Endpoint 13 Setup Status: For every setup transaction that is received, this bit is set to 1. Software must clear or acknowledge the setup transfer by writing a 1 to it after it has read the setup data from Queue head. The response to a setup packet (as in the order of operations and total response time) is crucial to limit bus time-outs while the setup lock-out mechanism is engaged. This register is only used in device mode. 0 = NOT_RCVD 1 = SETUP_RCVD
12	0x0	ENDPTSETUPSTAT12: Endpoint 12 Setup Status: For every setup transaction that is received, this bit is set to 1. Software must clear or acknowledge the setup transfer by writing a 1 to it after it has read the setup data from Queue head. The response to a setup packet (as in the order of operations and total response time) is crucial to limit bus time-outs while the setup lock-out mechanism is engaged. This register is only used in device mode. 0 = NOT_RCVD 1 = SETUP_RCVD
11	0x0	ENDPTSETUPSTAT11: Endpoint 11 Setup Status: For every setup transaction that is received, this bit is set to 1. Software must clear or acknowledge the setup transfer by writing a 1 to it after it has read the setup data from Queue head. 21.5.1.34 USB2_CONTROLLER_USB2D_ENDPTSTATUS_0

USB2D Endpoint Status Register

Offset: 214h | Read/Write: RO | Reset: 0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx

Bit	Reset	Description
31	X	ETBR15: Endpoint Transmit Buffer Ready: One bit for each endpoint indicates status of the respective endpoint buffer. This bit is set to a one by the hardware as a response to receiving a command from a corresponding bit in the ENDPTPRIME register. There will always be a delay between setting a bit in the ENDPTPRIME register and endpoint indicating ready. This delay time varies based upon the current USB traffic and the number of bits set in the ENDPTPRIME register. Buffer ready is cleared by USB reset, by the USB DMA system, or through the ENDPTFLUSH register. This is only used in device mode. 0 = NOT_READY 1 = READY
30	X	ETBR14: Endpoint Transmit Buffer Ready: One bit for each endpoint indicates status of the respective endpoint buffer. This bit is set to a one by the hardware as a response to receiving a command from a corresponding bit in the ENDPTPRIME register. There will always be a delay between setting a bit in the ENDPTPRIME register and endpoint indicating ready. This delay time varies based upon the current USB traffic and the number of bits set in the ENDPTPRIME register. Buffer ready is cleared by USB reset, by the USB DMA system, or through the ENDPTFLUSH register. This is only used in device mode. 0 = NOT_READY 1 = READY
29	X	ETBR13: Endpoint Transmit Buffer Ready: One bit for each endpoint indicates status of the respective endpoint buffer. This bit is set to a one by the hardware as a response to receiving a command from a corresponding bit in the ENDPTPRIME register. There will always be a delay between setting a bit in the ENDPTPRIME register and endpoint indicating ready. This delay time varies based upon the current USB traffic and the number of bits set in the ENDPTPRIME register. Buffer ready is cleared by USB reset, by the USB DMA system, or through the ENDPTFLUSH register. This is only used in device mode. 0 = NOT_READY 1 = READY
28	X	ETBR12: Endpoint Transmit Buffer Ready: One bit for each endpoint indicates status of the respective endpoint buffer. This bit is set to a one by the hardware as a response to receiving a command from a corresponding bit in the ENDPTPRIME register. There will always be a delay between setting a bit in the ENDPTPRIME register and endpoint indicating ready. This delay time varies based upon the current USB traffic and the number of bits set in the ENDPTPRIME register. Buffer ready is cleared by USB reset, by the USB DMA system, or through the ENDPTFLUSH register. This is only used in device mode. 0 = NOT_READY 1 = READY
27	X	ETBR11: Endpoint Transmit Buffer Ready: One bit for each endpoint indicates status of the respective endpoint buffer. This bit is set to a one by the hardware as a response to receiving a command from a corresponding bit in the ENDPTPRIME register. There will always be a delay between setting a bit in the ENDPTPRIME register and endpoint indicating ready. This delay time varies based upon the current USB traffic and the number of bits set in the ENDPTPRIME register. Buffer ready is cleared by USB reset, by the USB DMA system, or through the ENDPTFLUSH register. This is only used in device mode. 0 = NOT_READY 1 = READY
26	X	ETBR10: Endpoint Transmit Buffer Ready: One bit for each endpoint indicates status of the respective endpoint buffer. This bit is set to a one by the hardware as a response to receiving a command from a corresponding bit in the ENDPTPRIME register. There will always be a delay between setting a bit in the ENDPTPRIME register and endpoint indicating ready. This delay time varies based upon the current USB traffic and the number of bits set in the ENDPTPRIME register. Buffer ready is cleared by USB reset, by the USB DMA system, or through the ENDPTFLUSH register. This is only used in device mode. 0 = NOT_READY 1 = READY

USB2D Endpoint Control 3 Register

Offset: 228h | Read/Write: R/W | Reset: 0b000x00x0xxxxxxxx000x00x0

Bit	R/W	Reset	Description
23	RW	0x0	TXE: TX Endpoint Enable. An Endpoint should be enabled only after it has been configured. 0 = DISABLE 1 = ENABLE
22	RW	0x0	TXR: TX Data Toggle Reset: Whenever a configuration event is received for this Endpoint software must write a one to this bit in order to synchronize the data PIDs between the Host and device. 0 = KEEP_GOING 1 = RESET_PID_SEQ
21	RW	0x0	TXI: TX Data Toggle Inhibit: This bit is only used for test and should always be written as zero. Writing a one to this bit will cause this endpoint to ignore the data toggle sequence and always transmit DATA0 for a data packet. 0 = DIS_PID_SEQ 1 = ENB_PID_SEQ
19:18	RW	0x0	TXT: TX Endpoint Type: 00 = Control 01 = Isochronous 10 = Bulk 11 = Interrupt 0 = CTRL 1 = ISO 2 = BULK 3 = INTR

Bit	R/W	Reset	Description
17	RO	X	TXD: This is fixed to 0.
16	RW	0x0	TXS: TX Endpoint Stall: This bit will be set automatically upon receipt of a SETUP request if this Endpoint is not configured as a Control Endpoint. It will be cleared automatically upon receipt of a SETUP request if this Endpoint is configured as a Control Endpoint. Software can write a one to this bit to force the endpoint to return a STALL handshake to the Host. It will continue to returning STALL until this bit is either cleared by software or automatically cleared as above. 0 = EP_OK 1 = EP_STALL
7	RW	0x0	RXE: RX Endpoint Enable. An Endpoint should be enabled only after it has been configured. 0 = DISABLE 1 = ENABLE
6	RW	0x0	RXR: RX Data Toggle Reset: Whenever a configuration event is received for this Endpoint, software must write a one to this bit in order to synchronize the data PIDs between the host and device. 0 = KEEP_GOING 1 = RESET_PID_SEQ
5	RW	0x0	RXI: RX Data Toggle Inhibit: This bit is only used for test and should always be written as zero. Writing a one to this bit will cause this endpoint to ignore the data toggle sequence and always accept data packet regardless of their data PID. 0 = DIS_PID_SEQ 1 = ENB_PID_SEQ
3:2	RW	0x0	RXT: RX Endpoint Type: 00 = Control 01 = Isochronous 10 = Bulk 11 = Interrupt 0 = CTRL 1 = ISO 2 = BULK 3 = INTR
1	RO	X	RXD: This is fixed to 0.
0	RW	0x0	RXS: RX Endpoint Stall: This bit will be set automatically upon receipt of a SETUP request if this Endpoint is not configured as a Control Endpoint. It will be cleared automatically upon receipt a SETUP request if this Endpoint is configured as a Control Endpoint, Software can write a one to this bit to force the endpoint to return a STALL handshake to the Host. It will continue to returning STALL until this bit is either cleared by software or automatically cleared as above. 0 = EP_OK 1 = EP_STALL

21.5.2 USB1 Controller Interface Registers

These are used to generate the actual RTL registers for USB1 controller interface.

21.5.2.1 USB1_IF_USB_SUSP_CTRL_0

This register controls the suspend and resume behavior of USB controller/PHY.

USB suspend control register

Offset: 400h | Read/Write: R/W | Reset: 0b00xxxxxx000xxx01000xx000000

Bit	R/W	Reset	Description
26	RW	0x0	FAST_WAKEUP_RESP: Enable Fast Response from UTMIP PHY for a Remote Wakeup request from device. This is used only for cases where wakeup response needs to be within 1ms of spec. Used for Host mode ONLY. 0 = DISABLE 1 = ENABLE
25	RW	0x0	UTMIP_SUSPL1_SET: Enable SuspendL1 for UTMIP PHY Enabling this will only cutoff clocks to

Bit	R/W	Reset	Description
			the utmip logic. The USB plls, PllU and UTMIP PLL will still be running. 0 = DISABLE 1 = ENABLE
18:16	RW	0x0	USB_WAKEUP_DEBOUNCE_COUNT: USB PHY wakeup debounce counter USB will debounce any wakeup event by the number of clocks programmed in this counter. A value of 0 results in no debounce.
12	RW	0x0	UTMIP_PHY_ENB: Enable UTMIP PHY mode Set this to 1 if using UTMIP PHY. Otherwise set this to 0. 0 = DISABLE 1 = ENABLE
11	RW	0x1	UTMIP_RESET: Reset going to UTMIP PHY (active high). This should be set to 1 whenever programming the UTMIP config registers. It should be cleared to 0 after the programming of UTMIP config registers is done. UTMIP config registers should be programmed only once before doing any transactions on USB. The UTMIP PHY registers should be programmed while UTMIP is in reset. 0 = DISABLE 1 = ENABLE
10	RW	0x0	USB_SUSP_POL: Polarity of the suspend signal going to USB PHY. 0 = Active low (default) 1 = Active high This should not be changed by software. 0 = ACTIVE_LOW 1 = ACTIVE_HIGH
9	RW	0x0	USB_PHY_CLK_VALID_INT_ENB: USB PHY clock valid interrupt enable. If this bit is enabled, interrupt is generated whenever USB clocks are resumed from a suspend. 0 = DISABLE 1 = ENABLE
8	RO	0x0	USB_PHY_CLK_VALID_INT_STS: USB PHY clock valid interrupt status. This bit is set whenever USB PHY clock is waked up from suspend. Software must write a 1 to clear this bit. 0 = UNSET 1 = SET
7	RO	X	USB_PHY_CLK_VALID: USB PHY clock valid status. This bit indicates whether the USB PHY is generating a valid clock to the USB controller. If USB PHY clock is running, this bit is set to 1, else it is set to 0. 0 = UNSET 1 = SET
6	RO	X	USB_CLKEN: USB AHB clock enable status. Indicates whether the AHB clock to the USB controller is enabled or not. If AHB clock to USB controller is enabled, this bit is set to 1, else it is set to 0. NOTE: even when this is set to 0, all essential blocks that are required to resume USB clocks from suspend will be active and their AHB clock will not be suspended. 0 = UNSET 1 = SET
5	RW	0x0	USB_SUSP_CLR: Suspend Clear Software must write a 1 to this bit to bring the PHY out of suspend mode. This is used when the software stops the PHY clock during suspend and then wants to initiate a resume. Software should also write 0 to clear it. NOTE: It is required that software generate a positive pulse on this bit to guarantee proper operation. 0 = UNSET 1 = SET
4	RW	0x0	USB_WAKE_ON_DISCON_EN_DEV: Wake on Disconnect Enable (device mode) When enabled (1), USB device will wakeup from suspend on a disconnect event. This is only valid when USB controller is in device mode, it is not applicable when USB controller is in host mode. 0 = DISABLE 1 = ENABLE
3	RW	0x0	USB_WAKE_ON_CNNT_EN_DEV: Wake on Connect Enable (device mode) When enabled (1), USB device will wakeup from suspend on a connect event. This is only valid when USB controller is in device mode, it is not applicable when USB controller is in host mode. 0 = DISABLE 1 = ENABLE

Bit	R/W	Reset	Description
2	RW	0x0	USB_WAKE_ON_RESUME_EN: Wake on resume enable. If this bit is enabled, USB will wakeup from suspend whenever a resume event is detected on USB. This is valid for both USB device and USB host modes. 0 = DISABLE 1 = ENABLE
1	RW	0x0	USB_WAKEUP_INT_ENB: USB wakeup interrupt enable. If this bit is enabled, interrupt is generated whenever USB wakeup event is generated. 0 = DISABLE 1 = ENABLE
0	RO	0x0	USB_WAKEUP_INT_STS: USB wakeup interrupt status. This bit is set whenever USB wakes up from suspend (a wakeup event is generated). Software must write a 1 to clear this bit. Note that during the wakeup sequence, PHY clocks will be resumed from suspend. Software can check when the PHY clocks are resumed by reading the bit USB_PHY_CLK_VALID. There is also a separate interrupt generated when PHY clock is resumed if USB_PHY_CLK_VALID_INT_EN is set. During the wakeup sequence, first USB_WAKEUP_INT_STS will be set, and it will take some time for the PHY clock to resume, which can be detected by checking USB_PHY_CLK_VALID. 0 = UNSET 1 = SET

21.5.2.2 USB1_IF_USB_PHY_VBUS_SENSORS_0

This register controls the OTG VBUS sensors in the USB PHY. We have the following 4 VBUS sensors:

- A_VBUS_VLD
- A_SESS_VLD
- B_SESS_VLD
- B_SESS_END

The debounced status of each sensor can be read from _STS. The field _CHG_DET is set to 1 whenever a change is detected in the value of . If _INT_EN is set, then an interrupt is generated to the processor. This interrupt can be routed to CPU/COP by appropriately writing the USBD bits in the interrupt controller registers.

In case Software wants to override the value for a , it can set _SW_EN to 1, and set _SW_VALUE to 1 or 0 as per the requirement.

We have two debouncers for each sensor - DEBOUNCE_A and DEBOUNCE_B. The debounce values for them are controlled by the register UTMIP_DEBOUNCE_CFG0, fields UTMIP_BIAS_DEBOUNCE_A and UTMIP_BIAS_DEBOUNCE_B. For each sensor, we can select whether to use DEBOUNCE_A or DEBOUNCE_B by setting the field _DEB_SEL_B to approrpriate value (SEL_A or SEL_B).

Note: Do not set either UTMIP_BIAS_DEBOUNCE_A or UTMIP_BIAS_DEBOUNCE_B to 0x0. If not using one of the debouncers, keep it at the default value of 0xFFFF.

Note: The source for A_SESS_VLD sensor can be programmed according to the setting of

USB1_VBUS_SENSE_CTL in register USB1_LEGACY_CTRL.

USB PHY VBUS SENSORS control register

Offset: 404h | Read/Write: R/W | Reset: 0b0000x00x0000x00x0000x00x0000x00

Bit	R/W	Reset	Description
30	RW	0x0	A_VBUS_VLD_WAKEUP_EN: A_VBUS_VLD wakeup enable. If this bit is enabled, USB will wakeup from suspend whenever a change is detected on A_VBUS_VLD. 0 = DISABLE 1 = ENABLE

Bit	R/W	Reset	Description
29	RW	0x0	A_VBUS_VLD_DEB_SEL_B: A_VBUS_VLD debounce A/B select. Selects between the two debounce values UTMIP_BIAS_DEBOUNCE_A or UTMIP_BIAS_DEBOUNCE_B from the register UTMIP_DEBOUNCE_CFG0. 0 = SEL_A 1 = SEL_B
28	RW	0x0	A_VBUS_VLD_SW_VALUE: A_VBUS_VLD software value. Software should write the appropriate value (1/0) to set/unset the A_VBUS_VLD status. This is only valid when A_VBUS_VLD_SW_EN is set. 0 = UNSET 1 = SET
27	RW	0x0	A_VBUS_VLD_SW_EN: A_VBUS_VLD software enable. Enable Software Controlled A_VBUS_VLD. Software sets this bit to drive the value in A_VBUS_VLD_SW_VALUE to the USB controller. 0 = DISABLE 1 = ENABLE
26	RO	X	A_VBUS_VLD_STS: A_VBUS_VLD status. This is set to 1 whenever A_VBUS_VLD sensor output is 1. 0 = UNSET 1 = SET
25	RO	0x0	A_VBUS_VLD_CHG_DET: A_VBUS_VLD change detect. This field is set by hardware whenever a change is detected in the value of A_VBUS_VLD. software writes a 1 to clear it 0 = UNSET 1 = SET
24	RW	0x0	A_VBUS_VLD_INT_EN: A_VBUS_VLD interrupt enable. If this field is set to 1, an interrupt is generated whenever A_VBUS_VLD_CHG_DET is set to 1. 0 = DISABLE 1 = ENABLE
22	RW	0x0	A_SESS_VLD_WAKEUP_EN: A_SESS_VLD wakeup enable. If this bit is enabled, USB will wakeup from suspend whenever a change is detected on A_SESS_VLD. 0 = DISABLE 1 = ENABLE
21	RW	0x0	A_SESS_VLD_DEB_SEL_B: A_SESS_VLD debounce A/B select. Selects between the two debounce values UTMIP_BIAS_DEBOUNCE_A or UTMIP_BIAS_DEBOUNCE_B from the register UTMIP_DEBOUNCE_CFG0. 0 = SEL_A 1 = SEL_B
20	RW	0x0	A_SESS_VLD_SW_VALUE: A_SESS_VLD software value. Software should write the appropriate value (1/0) to set/unset the A_SESS_VLD status. This is only valid when A_SESS_VLD_SW_EN is set. 0 = UNSET 1 = SET
19	RW	0x0	A_SESS_VLD_SW_EN: A_SESS_VLD software enable. Enable Software Controlled A_SESS_VLD. Software sets this bit to drive the value in A_SESS_VLD_SW_VALUE to the USB controller. 0 = DISABLE 1 = ENABLE
18	RO	X	A_SESS_VLD_STS: A_SESS_VLD status. This is set to 1 whenever A_SESS_VLD sensor output is 1. 0 = UNSET 1 = SET
17	RO	0x0	A_SESS_VLD_CHG_DET: A_SESS_VLD change detect. This field is set by hardware whenever a change is detected in the value of A_SESS_VLD. software writes a 1 to clear it 0 = UNSET 1 = SET
16	RW	0x0	A_SESS_VLD_INT_EN: A_SESS_VLD interrupt enable. If this field is set to 1, an interrupt is generated whenever A_SESS_VLD_CHG_DET is set to 1.

Bit	R/W	Reset	Description
			0 = DISABLE 1 = ENABLE
14	RW	0x0	B_SESS_VLD_WAKEUP_EN: B_SESS_VLD wakeup enable. If this bit is enabled, USB will wakeup from suspend whenever a change is detected on B_SESS_VLD. 0 = DISABLE 1 = ENABLE
13	RW	0x0	B_SESS_VLD_DEB_SEL_B: B_SESS_VLD debounce A/B select. Selects between the two debounce values UTMIP_BIAS_DEBOUNCE_A or UTMIP_BIAS_DEBOUNCE_B from the register UTMIP_DEBOUNCE_CFG0. 0 = SEL_A 1 = SEL_B
12	RW	0x0	B_SESS_VLD_SW_VALUE: B_SESS_VLD software value. Software should write the appropriate value (1/0) to set/unset the B_SESS_VLD status. This is only valid when B_SESS_VLD_SW_EN is set. 0 = UNSET 1 = SET
11	RW	0x0	B_SESS_VLD_SW_EN: B_SESS_VLD software enable. Enable Software Controlled B_SESS_VLD. Software sets this bit to drive the value in B_SESS_VLD_SW_VALUE to the USB controller. 0 = DISABLE 1 = ENABLE

9	RO	0x0	B_SESS_VLD_CHG_DET: B_SESS_VLD change detect. This field is set by hardware whenever a change is detected in the value of B_SESS_VLD. software writes a 1 to clear it 0 = UNSET 1 = SET
8	RW	0x0	B_SESS_VLD_INT_EN: B_SESS_VLD interrupt enable. If this field is set to 1, an interrupt is generated whenever B_SESS_VLD_CHG_DET is set to 1. 0 = DISABLE 1 = ENABLE
6	RW	0x0	B_SESS_END_WAKEUP_EN: B_SESS_END wakeup enable. If this bit is enabled, USB will wakeup from suspend whenever a change is detected on B_SESS_END. 0 = DISABLE 1 = ENABLE
5	RW	0x0	B_SESS_END_DEB_SEL_B: B_SESS_END debounce A/B select. Selects between the two debounce values UTMIP_BIAS_DEBOUNCE_A or UTMIP_BIAS_DEBOUNCE_B from the register UTMIP_DEBOUNCE_CFG0. 0 = SEL_A 1 = SEL_B
4	RW	0x0	B_SESS_END_SW_VALUE: B_SESS_END software value. Software should write the appropriate value (1/0) to set/unset the B_SESS_END status. This is only valid when B_SESS_END_SW_EN is set. 0 = UNSET 1 = SET
3	RW	0x0	B_SESS_END_SW_EN: B_SESS_END software enable. Enable Software Controlled B_SESS_END Software sets this bit to drive the value in B_SESS_END_SW_VALUE to the USB controller. 0 = DISABLE 1 = ENABLE
2	RO	X	B_SESS_END_STS: B_SESS_END status. This is set to 1 whenever B_SESS_END sensor output is 1. 0 = UNSET 1 = SET

Bit	R/W	Reset	Description
1	RO	0x0	B_SESS_END_CHG_DET: B_SESS_END change detect. This field is set by hardware whenever a change is detected in the value of B_SESS_END. software writes a 1 to clear it 0 = UNSET 1 = SET
0	RW	0x0	B_SESS_END_INT_EN: B_SESS_END interrupt enable. If this field is set to 1, an interrupt is generated whenever B_SESS_END_CHG_DET is set to 1. 0 = DISABLE 1 = ENABLE

21.5.2.3 USB1_IF_USB_PHY_VBUS_WAKEUP_ID_0

This register controls the battery charger (VDCD_DET, VDAT_DET), VBUS_WAKEUP and ID sensors. We have the following sensors in this register:

- VBUS_WAKEUP
- ID
- VDAT_DET
- VDCD_DET

The debounced status of each sensor can be read from _STS. The field _CHG_DET is set to 1 whenever a change is detected in the value of. If _INT_EN is set, then an interrupt is generated to the processor. This interrupt can be routed to CPU/COP by appropriately writing the USBD bits in the interrupt controller registers.

In case Software wants to override the value for a , it can set _SW_EN to 1, and set _SW_VALUE to 1 or 0 as per the requirement.

We have two debouncers for each sensor - DEBOUNCE_A and DEBOUNCE_B. The debounce values for them are controlled by the register UTMIP_DEBOUNCE_CFG0, fields UTMIP_BIAS_DEBOUNCE_A and UTMIP_BIAS_DEBOUNCE_B. For each sensor, we can select whether to use DEBOUNCE_A or DEBOUNCE_B by setting the field _DEB_SEL_B to approrpriate value (SEL_A or SEL_B).

Note: Do not set either UTMIP_BIAS_DEBOUNCE_A or UTMIP_BIAS_DEBOUNCE_B to 0x0. If not using one of the debouncers, keep it at the default value of 0xFFFF.

There are debouncers for VDAT_DET and VDCD_DET. These use separate debouncers -CHRG_DEBOUNCE_PERIOD_A and CHRG_DEBOUNCE_PERIOD_B. The debounce values for them are controlled by the register UTMIP_CHRG_DEB_CFG0, fields UTMIP_CHRG_DEBOUNCE_PERIOD_A and UTMIP_CHRG_DEBOUNCE_PERIOD_B. For each sensor, we can select whether to use CHRG_DEBOUNCE_PERIOD_A or CHRG_DEBOUNCE_PERIOD_B by setting the field _DEB_SEL_B to appropriate value (SEL_A or SEL_B).

Note: Do not set either UTMIP_CHRG_DEBOUNCE_PERIOD_A or UTMIP_CHRG_DEBOUNCE_PERIOD_B to 0x0. If not using one of the debouncers, keep it at the default value of 0xFFFF.

Bit	R/W	Reset	Description
			register UTMIP_CHRG_DEB_CFG0. 0 = SEL_A 1 = SEL_B
28	RW	0x0	VDCD_DET_SW_VALUE: VDCD_DET software value. Software should write the appropriate value (1/0) to set/unset the VDCD_DET status. This is only valid when VDCD_DET_SW_EN is set. 0 = UNSET 1 = SET
27	RW	0x0	VDCD_DET_SW_EN: VDCD_DET software enable. Enable Software Controlled VDCD_DET. Software sets this bit to drive the value in VDCD_DET_SW_VALUE to the USB controller 0 = DISABLE 1 = ENABLE
26	RO	X	VDCD_DET_STS: VDCD_DET status. This is set to 1 whenever VDCD_DET sensor output is 1. 0 = UNSET 1 = SET
25	RO	0x0	VDCD_DET_CHG_DET: VDCD_DET change detect. This field is set by hardware whenever a change is detected in the value of VDCD_DET. software writes a 1 to clear it 0 = UNSET 1 = SET
24	RW	0x0	VDCD_DET_INT_EN: VDCD_DET interrupt enable. If this field is set to 1, an interrupt is generated whenever VDCD_DET_CHG_DET is set to 1. 0 = DISABLE 1 = ENABLE
21	RW	0x0	VDAT_DET_DEB_SEL_B: VDAT_DET debounce A/B select. Selects between the two debounce values UTMIP_CHRG_DEBOUNCE_PERIOD_A or UTMIP_CHRG_DEBOUNCE_PERIOD_B from the register UTMIP_DEBOUNCE_CFG0. 0 = SEL_A 1 = SEL_B
20	RW	0x0	VDAT_DET_SW_VALUE: VDAT_DET software value. Software should write the appropriate value (1/0) to set/unset the VDAT_DET status. This is only valid when VDAT_DET_SW_EN is set. 0 = UNSET 1 = SET
19	RW	0x0	VDAT_DET_SW_EN: VDAT_DET software enable. Enable Software Controlled VDAT_DET. Software sets this bit to drive the value in VDAT_DET_SW_VALUE to the USB controller 0 = DISABLE 1 = ENABLE
18	RO	X	VDAT_DET_STS: VDAT_DET status. This is set to 1 whenever VDAT_DET sensor output is 1. 0 = UNSET 1 = SET
17	RO	0x0	VDAT_DET_CHG_DET: VDAT_DET change detect. This field is set by hardware whenever a change is detected in the value of VDAT_DET. software writes a 1 to clear it 0 = UNSET 1 = SET
16	RW	0x0	VDAT_DET_INT_EN: VDAT_DET interrupt enable. If this field is set to 1, an interrupt is generated whenever VDAT_DET_CHG_DET is set to 1. 0 = DISABLE 1 = ENABLE
13	RW	0x0	VBUS_WAKEUP_DEB_SEL_B: VBUS_WAKEUP debounce A/B select. Selects between the two debounce values UTMIP_BIAS_DEBOUNCE_A or UTMIP_BIAS_DEBOUNCE_B from the register UTMIP_DEBOUNCE_CFG0. 0 = SEL_A 1 = SEL_B
12	RW	0x0	VBUS_WAKEUP_SW_VALUE: VBUS wakeup software value. Software should write the appropriate value (1/0) to set/unset the VBUS_WAKEUP status. This is only valid when VBUS_WAKEUP_SW_EN is set. 0 = UNSET

Bit	R/W	Reset	Description
			1 = SET
11	RW	0x0	VBUS_WAKEUP_SW_EN: VBUS wakeup software enable. Enable Software Controlled VBUS_WAKEUP. Software sets this bit to drive the value in VBUS_WAKEUP_SW_VALUE to the USB controller. 0 = DISABLE 1 = ENABLE
10	RO	X	VBUS_WAKEUP_STS: VBUS wakeup status. This is set to 1 whenever VBUS_WAKEUP sensor output is 1. 0 = UNSET 1 = SET
9	RO	0x0	VBUS_WAKEUP_CHG_DET: VBUS wakeup change detect. This field is set by hardware whenever a change is detected in the value of VBUS_WAKEUP. software writes a 1 to clear it 0 = UNSET 1 = SET
8	RW	0x0	VBUS_WAKEUP_INT_EN: VBUS wakeup interrupt enable. If this field is set to 1, an interrupt is generated whenever VBUS_WAKEUP_CHG_DET is set to 1. 0 = DISABLE 1 = ENABLE
7	RO	X	STATIC_GPI: Static GPI status 0 = UNSET 1 = SET
6	RW	0x1	ID_PU: ID pullup enable. Set to 1. 0 = DISABLE 1 = ENABLE
5	RW	0x0	ID_DEB_SEL_B: ID debounce A/B select. Selects between the two debounce values UTMIP_BIAS_DEBOUNCE_A or UTMIP_BIAS_DEBOUNCE_B from the register UTMIP_DEBOUNCE_CFG0. 0 = SEL_A 1 = SEL_B
4	RW	0x0	ID_SW_VALUE: ID software value. Software should write the appropriate value (1/0) to set/unset the ID status. This is only valid when ID_SW_EN is set. 0 = UNSET 1 = SET
3	RW	0x0	ID_SW_EN: ID software enable. Enable Software Controlled ID. Software sets this bit to drive the value in ID_SW_VALUE to the USB controller 0 = DISABLE 1 = ENABLE
2	RO	X	ID_STS: ID status. This is set to 1 whenever ID sensor output is 1. 0 = UNSET 1 = SET
1	RO	0x0	ID_CHG_DET: ID change detect. This field is set by hardware whenever a change is detected in the value of ID. software writes a 1 to clear it 0 = UNSET 1 = SET
0	RW	0x0	ID_INT_EN: ID interrupt enable. If this field is set to 1, an interrupt is generated whenever ID_CHG_DET is set to 1. 0 = DISABLE 1 = ENABLE

21.5.2.4 USB1_IF_USB_PHY_ALT_VBUS_STS_0

USB PHY Alternate VBUS status register

Offset: 40ch | Read/Write: RO | Reset: 0bxxxxxxxxx

Bit	Reset	Description
8	X	VDCD_DET_ALT: VDCD_DET alternate status 0 = UNSET 1 = SET
7	X	VDAT_DET_ALT: VDAT_DET alternate status 0 = UNSET 1 = SET
6	X	A_SESS_VLD_ALT: A_SESS_VLD alternate status 0 = UNSET 1 = SET
5	X	B_SESS_VLD_ALT: B_SESS_VLD alternate status 0 = UNSET 1 = SET
4	X	ID_DIG_ALT: ID alternate status 0 = UNSET 1 = SET
3	X	B_SESS_END_ALT: B_SESS_END alternate status 0 = UNSET 1 = SET
2	X	STATIC_GPI_ALT: Static GPI alternate status 0 = UNSET 1 = SET
1	X	A_VBUS_VLD_ALT: A_VBUS_VLD alternate status 0 = UNSET 1 = SET
0	X	VBUS_WAKEUP_ALT: Vbus wakeup alternate status 0 = UNSET 1 = SET

21.5.2.5 USB1_IF_USB1_LEGACY_CTRL_0

This register controls legacy mode access for USB controller.

USB1 Legacy control register

Offset: 410h | Read/Write: R/W | Reset: 0b00x

Bit	R/W	Reset	Description
2:1	RW	0x0	USB1_VBUS_SENSE_CTL: Vbus_sense control. Controls which VBUS sensor input is driven to the controller. 00: Use VBUS_WAKEUP. 01: Use (A_SESS_VLD || B_SESS_VLD) output from the PHY if the PHY clock is available. Otherwise, use VBUS_WAKEUP. 10: Use (A_SESS_VLD || B_SESS_VLD) output from the PHY 11: Use A_SESS_VLD output from the PHY 0 = VBUS_WAKEUP 1 = AB_SESS_VLD_OR_VBUS_WAKEUP 2 = AB_SESS_VLD 3 = A_SESS_VLD
0	RO	X	USB1_NO_LEGACY_MODE: Legacy registers select. The default is to select legacy mode registers in APB_MISC for USB1. Selects new registers if this is set to 1. 0 = LEGACY 1 = NEW

21.5.2.6 USB1_IF_USB_INTER_PKT_DELAY_CTRL_0

This controls the interpacket delay between two consecutive transmit packets in HS mode. This only applies to host mode as device never transmits two packets in a row.

Inter packet delay control

Offset: 420h | Read/Write: R/W | Reset: 0b010010

Bit	Reset	Description
5:0	0x12	IP_DELAY_TX2TX_HS: HS Tx to Tx inter-packet delay. Software should not change this.

21.5.2.7 USB1_IF_USB_RSM_DLY_0

USB Controller Resume Signalling Delay

Offset: 490h | Read/Write: R/W | Reset: 0b0110100101111000

Bit	Reset	Description
15:0	0x6978	TIME_TO_RESUME: Send the resume back in no. of 60 MHz cycles. Default gives 900 usec delay. Only applicable in host mode.

21.5.2.8 USB1_IF_SPARE_0

For ICUSB PADCTLS. Spare Register

Offset: 498h | Read/Write: R/W | Reset: 0b11111111111111110000000000000000

Bit	Reset	Description
31:16	0xffff	SPARE_HI: Spare register bits, defaulted to 1
15:0	0x0	SPARE_LO: Spare register bits, defaulted to 0. 0 SPARE_LO[4] - usb_hs_rsm_eop_fix_en, Enable HS_RESUME EOP fix.

21.5.2.9 USB1_UTMIP_PLL_CFG0_0

USB_PHY PLL Configuration Register 0

The data sampling frequency relies on a 960MHz clock, so the goal of the PLL is to have: In_Frequency*(PLL_VCOMULTBY2+1)*(PLL_NDIV/PLL_MDIV) = 960MHz With a 12MHz input from PLL_U, the default setting of PLL_VCOMULTBY2=1, PLL_NDIV=40 and PLL_MDIV=1 results in a correct output.

21.5.3 USB1 UTMIP Configuration Registers

Note: Current UTMIP configuration registers use settings that support NV software drivers and should NOT be modified. If designing custom drivers, consult your NV representative prior to modifying these registers

21.5.3.1 UTMIP REGISTER: PLL_CFG0

This register was used to configure PLL inside UTMIP block prior to Tegra 3. This has been de-featured from UTMIP space and moved to CAR space. This register is used to configure the PHY PLL contained in the UTMIP module.

Note: This register has been moved to the Clock and Reset section of this document. PROGRAMMING THIS REGISTER HERE WILL HAVE NO EFFECT WHATSOEVER !

Offset: 800h | Read/Write: R/W | Reset: 0b00000000010100000000000110000000

Bit	Reset	Description
30:28	0x0	UTMIP_PLL_SELECT: Selects which of the eight 60MHz clock phases to produce at the output of the USB PHY PLL. This is for a test mode. See cell specification.

Bit	Reset	Description
27	0x0	UTMIP_PLL_PDIVRST: PDIVRST of the UTMIP PHY PLL. Reserved. Keep at 0x0. Currently there is no post divider on this PLL. See cell specification.
26:24	0x0	UTMIP_PLL_PDIV: PDIV[2:0] input of the USB_PHY PLL. Reserved. Keep at 0x0. Currently there is no post divider on this PLL. See cell specification.
23:16	0x28	UTMIP_PLL_NDIV: NDIV[7:0] input of USB_PHY PLL. This is the feedback divider on the VCO feedback. 0x0 is not allowed. See cell specification.
15:8	0x1	UTMIP_PLL_MDIV: MDIV[7:0] input of the USB_PHY PLL. This is the predivide on the PLL. 0x0 is not allowed. See cell specification.
7	0x1	UTMIP_PLL_VCOMULTBY2: VCOMULTBY2 control of the UTMIP PHY PLL. Recommended setting is on. Additional divide by 2 on the VCO feedback. Which is setting the bit to 1. See cell spec.
6:1	0x0	UTMIP_PLL_LOCKSEL: LOCKSEL[5:0] input of USB_PHY PLL. Used in test modes only. See cell specification.
0	0x0	UTMIP_PLL_LOCKENABLE: LOCK_ENABLE input of USB_PHY PLL. Normally only used during test. See cell specification.

21.5.3.2 USB1_UTMIP_PLL_CFG1_0

UTMIP PLL and PLLU configuration register 1

Note: This register has been moved to the Clock and Reset section of this document. PROGRAMMING THIS REGISTER HERE WILL HAVE NO EFFECT WHATSOEVER !

This register was used to configure PLL inside UTMIP block prior to Tegra 3. This has been de-featured from UTMIP space and moved to CAR space.

PLL CONFIGURATION & PARAMETERS

In normal operation, the following clock generators are in play for USB:

- Xtal clock -> enters PLL_U to generate 12MHz clock -> enters USB_PHY PLL to generate 480/60 MHz clock

The following parameters control the bringup of the plls:

Coming out of reset or suspend

- -> PllUOnState: start pllu_enable_count and pll_lock_count
- -> Wait ~1us to actually enable the PLL_U (pllu_enable_count == ClkXtal * PLLU_ENABLE_DLY_COUNT * 8)
- -> Wait ~1ms until PLL_U is actually stable (pll_lock_count == ClkXtal * PLLU_STABLE_COUNT * 256) => USB_PHY PLL_ENABLE pll_active_count = 0
- -> Wait 5us to enable pll_active: pll_active_count == ClkXtal * PLL_ACTIVE_DLY_COUNT * 16 => USB_PHY PLL_ACTIVE
- -> Wait ~2.5ms until USB_PHY is actually stable (pll_lock_count == ClkXtal * XTAL_FREQ_COUNT * 256) => USB_PHY

Numbers for a 19.2MHz Xtal clock

- PLLU_ENABLE_DLY_COUNT[4:0] = 1 * 19.2 / 8 = 2.4 = 3 = 0x03
- PLLU_STABLE_COUNT[11:0] = 1000 * 19.2 / 256 = 75 = 0x4b
- PLL_ACTIVE_DLY_COUNT[4:0] = 5 * 19.2 / 16 = 6 = 0x06

- XTAL_FREQ_COUNT[11:0] = 2500 * 19.2 / 256 = 187 = 0xbb

Offset: 804h | Read/Write: R/W | Reset: 0b00011000001000000000000011000000

Bit	Reset	Description
31:27	0x3	UTMIP_PLLU_ENABLE_DLY_COUNT: Controls the wait time to enable PLL_U when coming out of suspend or reset.
26:18	0x8	UTMIP_PLL_SETUP: SETUP[8:0] input of USB_PHY PLL.
17	0x0	UTMIP_FORCE_PLLU_POWERUP: Force PLL_U into power up.
16	0x0	UTMIP_FORCE_PLLU_POWERDOWN: Force PLL_U into power down. (Overrides FORCE_PLLU_POWERUP.)
15	0x0	UTMIP_FORCE_PLL_ENABLE_POWERUP: Force USB_PHY PLL pll_enable input on.
14	0x0	UTMIP_FORCE_PLL_ENABLE_POWERDOWN: Force USB_PHY PLL pll_enable input off. (Overrides FORCE_PLL_ENABLE_POWERUP.)
13	0x0	UTMIP_FORCE_PLL_ACTIVE_POWERUP: Force USB_PHY PLL pll_active input on.
12	0x0	UTMIP_FORCE_PLL_ACTIVE_POWERDOWN: Force USB_PHY PLL pll_active input off. (Overrides FORCE_PLL_ACTIVE_POWERUP.)
11:0	0xc0	UTMIP_XTAL_FREQ_COUNT: Determines the time to wait until the output of USB_PHY PLL is considered stable.

21.5.3.3 USB1_UTMIP_XCVR_CFG0_0

UTMIP transceiver cell configuration register 0

Offset: 808h | Read/Write: R/W | Reset: 0b00100000001001010110010100000000

Bit	Reset	Description
31:25	0x10	UTMIP_XCVR_HSSLEW_MSB: Most significant bits of HS_SLEW.
24:22	0x0	UTMIP_XCVR_SETUP_MSB: Most significant bits of SETUP.
21	0x1	UTMIP_XCVR_LSBIAS_SEL: Low speed bias selection method for USB transceiver pad
20	0x0	UTMIP_XCVR_DISCON_METHOD: Disconnect method on the USB transceiver pad
19	0x0	UTMIP_FORCE_PDZI_POWERUP: Force PDZI input into power up.
18	0x1	UTMIP_FORCE_PDZI_POWERDOWN: Force PDZI input into power down. (Overrides FORCE_PDZI_POWERUP.)
17	0x0	UTMIP_FORCE_PD2_POWERUP: Force PD2 input into power up.
16	0x1	UTMIP_FORCE_PD2_POWERDOWN: Force PD2 input into power down. (Overrides FORCE_PD2_POWERUP.)
15	0x0	UTMIP_FORCE_PD_POWERUP: Force PD input into power up.
14	0x1	UTMIP_FORCE_PD_POWERDOWN: Force PD input into power down. (Overrides FORCE_PD_POWERUP.)
13	0x1	UTMIP_XCVR_TERMEN: Enable HS termination.
12	0x0	UTMIP_XCVR_HSLOOPBACK: Internal loopback inside XCVR cell. Used for IOBIST.
11:10	0x1	UTMIP_XCVR_LSFSLEW: LS falling slew rate control.
9:8	0x1	UTMIP_XCVR_LSRSLEW: LS rising slew rate control.

Bit	Reset	Description
7:6	0x0	UTMIP_XCVR_FSSLEW: FS slew rate control.
5:4	0x0	UTMIP_XCVR_HSSLEW: HS slew rate control. The two LSBs.
3:0	0x0	UTMIP_XCVR_SETUP: SETUP[3:0] input of XCVR cell. HS driver output control. 4 LSBs.

21.5.3.4 USB1_UTMIP_BIAS_CFG0_0

UTMIP Bias cell configuration register 0

Offset: 80ch | Read/Write: R/W | Reset: 0b01100000000000110000000000

Bit	Reset	Description
24	0x0	UTMIP_HSDISCON_LEVEL_MSB: Most significant bit of UTMIP_HSDISCON_LEVEL, bit 2
23	0x1	UTMIP_IDPD_VAL: See IDPD_SEL.
22	0x1	UTMIP_IDPD_SEL: 0: Reserved. Refer to the PMC registers for this feature.
21	0x0	UTMIP_IDDIG_VAL: See IDDIG_SEL.
20	0x0	UTMIP_IDDIG_SEL: 0: IdDig = IdDig. 1: IdDig = IDDIG_VAL.
19	0x0	UTMIP_GPI_VAL: See GPI_SEL.
18	0x0	UTMIP_GPI_SEL: 0: StaticGpi = IdDig. 1: StaticGpi = GPI_VAL.
17:15	0x0	UTMIP_ACTIVE_TERM_OFFSET: Active termination control offset.
14:12	0x0	UTMIP_ACTIVE_PULLUP_OFFSET: Active 1.5K pullup control offset.
11	0x1	UTMIP_OTGPD: Power down OTG circuit.
10	0x1	UTMIP_BIASPD: Power down bias circuit.
9:8	0x0	UTMIP_VBUS_LEVEL_LEVEL: Vbus detector level.
7:6	0x0	UTMIP_SESS_LEVEL_LEVEL: SessionEnd detector level.
5:4	0x0	UTMIP_HSCHIRP_LEVEL: HS chirp detector level.
3:2	0x0	UTMIP_HSDISCON_LEVEL: HS disconnect detector level.
1:0	0x0	UTMIP_HSSQUELCH_LEVEL: HS squelch detector level.

21.5.3.5 USB1_UTMIP_HSRX_CFG0_0

UTMIP High speed receive config 0

Offset: 810h | Read/Write: R/W | Reset: 0b10010001011001010011010000000000

Bit	Reset	Description
31:30	0x2	UTMIP_KEEP_PATT_ON_ACTIVE: Keep the stay alive pattern on active
29	0x0	UTMIP_ALLOW_CONSEC_UPDN: Allow consecutive ups and downs on the bits, debug only, set to 0.
28	0x1	UTMIP_REALIGN_ON_NEW_PKT: Realign the inertia counters on a new packet
27:24	0x1	UTMIP_PCOUNT_UPDN_DIV: The number of (edges-1) needed to move the sampling point

Bit	Reset	Description
23:21	0x3	UTMIP_SQUELCH_EOP_DLY: Limit the delay of the squelch at EOP time
20	0x0	UTMIP_NO_STRIPPING: Do not strip incoming data
19:15	0xa	UTMIP_IDLE_WAIT: Number of cycles of idle to declare IDLE.
14:10	0xd	UTMIP_ELASTIC_LIMIT: Depth of elastic input store
9	0x0	UTMIP_ELASTIC_OVERRUN_DISABLE: Do not declare overrun errors until overflow of FIFO
8	0x0	UTMIP_ELASTIC_UNDERRUN_DISABLE: Do not declare underrun errors
7	0x0	UTMIP_PASS_CHIRP: When in Chirp Mode, allow chirp rx data through
6	0x0	UTMIP_PASS_FEEDBACK: Pass through the feedback, do not block it.
5:4	0x0	UTMIP_PCOUNT_INERTIA: Retime the path.
3:2	0x0	UTMIP_PHASE_ADJUST: Based on incoming edges and current sampling position, adjust phase
1	0x0	UTMIP_THREE_SYNCBITS: Sync pattern detection needs 3 consecutive samples instead of 4
0	0x0	UTMIP_USE4SYNC_TRAN: Require 4 sync pattern transitions (01) instead of 3

21.5.3.6 USB1_UTMIP_HSRX_CFG1_0

UTMIP High speed receive config 1

Offset: 814h | Read/Write: R/W | Reset: 0b010011

Bit	Reset	Description
5:1	0x9	UTMIP_HS_SYNC_START_DLY: How long to wait before start of sync launches RxActive
0	0x1	UTMIP_HS_ALLOW_KEEP_ALIVE: Allow Keep Alive packets

21.5.3.7 USB1_UTMIP_FSLSRX_CFG0_0

UTMIP full and Low speed receive config 0

Offset: 818h | Read/Write: R/W | Reset: 0b11111101010101001000010000101001

Bit	Reset	Description
31	0x1	UTMIP_FSLS_SE1_DRIBBLE_FILTER: One SE1, don't allow dribble
30	0x1	UTMIP_FSLS_SE1_FILTER: Filter SE1
29	0x1	UTMIP_FSLS_SERIAL_SE0_RCV
28:26	0x7	UTMIP_FSLS_UPR_DRIBBLE_SIZE: Do not allow <= dribble bits
25:23	0x2	UTMIP_FSLS_LWR_DRIBBLE_SIZE: Do not allow >= dribble bits
22	0x1	UTMIP_FSLS_EOP_ENDS_AT_SE0: Only look for transitioning out of EOP
21:16	0x14	UTMIP_FSLS_KCOUNT_MAX: Number of K bits in question
15	0x1	UTMIP_FSLS_KCOUNT_LIMIT: Limit the number of bit times a K can last
14	0x0	UTMIP_FSLS_ACTIVE_ON_FULL_SYNC: Require a full sync pattern to declare the data received

Bit	Reset	Description
13:8	0x4	UTMIP_FSLS_IDLE_WAIT_MAX: 4 bits of of SEO should exceed the time limit
7	0x0	UTMIP_FSLS_IDLE_WAIT_LIMIT: Enable the reset of the state machine on extended SE0
6:1	0x14	UTMIP_FSLS_IDLE_COUNT_MAX: 20 bits of idle should end the packet if FsLsIdleCountLimitCfg=1.
0	0x1	UTMIP_FSLS_IDLE_COUNT_LIMIT: Give up on packet if a long sequence of J

21.5.3.8 USB1_UTMIP_FSLSRX_CFG1_0

UTMIP full and Low speed receive config 1

Offset: 81ch | Read/Write: R/W | Reset: 0b01000100110011101010000000000

Bit	Reset	Description
26	0x0	UTMIP_EARLY_LINE_STATE_FILTER: Assumes line state filtering table is inclusive, not exclusive
25:23	0x4	UTMIP_LS_BOUNCE_LENGTH: Number of clock cycle of LS stable
22:17	0x13	UTMIP_LS_EXTRACTION_COUNT: Phase count on which LS bits are extracted
16:11	0xe	UTMIP_LS_EOP_START_COUNT: Number of SEO clock cycles to block bit extraction
10:5	0x20	UTMIP_LS_SE0_COUNT: Only for this number of 60MHz of SEO and Idle to end packet
4	0x0	UTMIP_LS_LENIENT_DRIBBLE: Allow for large dribble in low speed mode
3	0x0	UTMIP_FS_LENIENT_DRIBBLE: Allow for large dribble in full speed mode
2	0x0	UTMIP_FS_WEAK_SYNC: Only look for a KK pattern, instead of KJKK
1	0x0	UTMIP_FS_DEBOUNCE: Whether full speed uses debouncing
0	0x0	UTMIP_FS_EOP_LENGTH: Whether full speed EOP is determined within 3(0) or 4(1) 60MHz cycles

21.5.3.9 USB1_UTMIP_TX_CFG0_0

UTMIP transmit config signals

Offset: 820h | Read/Write: R/W | Reset: 0b00010000001000000000

Bit	Reset	Description
19	0x0	UTMIP_FS_PREAMBLE_J: output enable sends an initial J before sync pattern
18	0x0	UTMIP_FS_POSTAMBLE_OUTPUT_ENABLE: output enable turns off 1/2 cycle after
17	0x0	UTMIP_FS_PREAMBLE_OUTPUT_ENABLE: output enable turns on 1/2 cycle before
16	0x1	UTMIP_FSLS_ALLOW_SOP_TX_STUFF_ERR: Allow SOP to be source of transmit error stuffing
15	0x0	UTMIP_HS_READY_WAIT_FOR_VALID
14:10	0x0	UTMIP_HS_TX_IPG_DLY
9	0x1	UTMIP_HS_DISCON_EOP_ONLY: Only check during EOP
8	0x0	UTMIP_HS_DISCON_DISABLE: Disable high speed disconnect
7	0x0	UTMIP_HS_POSTAMBLE_OUTPUT_ENABLE: output enable turns off 1 cycle after

Bit	Reset	Description
6	0x0	UTMIP_HS_PREAMBLE_OUTPUT_ENABLE: output enable turns on 1 cycle before
5	0x0	UTMIP_SIE_RESUME_ON_LINESTATE: SIE, not macrocell, detects LineState change to resume
4	0x0	UTMIP_SOF_ON_NO_STUFF: Sof when OpMode 3 -- perhaps, when sending controller made packets
3	0x0	UTMIP_SOF_ON_NO_ENCODE: Sof when OpMode 2 -- not likely, for Chirp
2	0x0	UTMIP_NO_STUFFING: No bit stuffing, static programming
1	0x0	UTMIP_NO_ENCODING: No encoding, static programming
0	0x0	UTMIP_NO_SYNC_NO_EOP: Do not sent SYNC or EOP

21.5.3.10 USB1_UTMIP_MISC_CFG0_0

UTMIP miscellaneous configurations

Offset: 824h | Read/Write: R/W | Reset: 0b00000111110000000000000001111000

Bit	Reset	Description
30:27	0x0	UTMIP_DPDM_OBSERVE_SEL: Select DP/DM obs signals
26	0x0	UTMIP_DPDM_OBSERVE: Use DP/DM as obs bus
25	0x1	UTMIP_KEEP_XCVR_PD_ON_SOFT_DISCON
24	0x1	UTMIP_ALLOW_LS_ON_SOFT_DISCON

21.5.3.12 USB1_UTMIP_DEBOUNCE_CFG0_0

UTMIP Avalid and Bvalid debounce

Debounce values IdDig, Avalid, Bvalid, VbusValid, VbusWakeUp, and SessEnd. Each of these signals have their own debouncer and for each of those one out of 2 debouncing times can be chosen (BIAS_DEBOUNCE_A or BIAS_DEBOUNCE_B.)

The values of DEBOUNCE_A and DEBOUNCE_B are calculated as follows:

- 0xffff -> No debouncing at all
- ms = *1000 / (1/19.2MHz) / 4

So to program a 1 ms debounce for BIAS_DEBOUNCE_A, we have:

- BIAS_DEBOUNCE_A[15:0] = 1000 * 19.2 / 4 = 4800 = 0x12c0

Offset: 82ch | Read/Write: R/W | Reset: 0b11111111111111111111111111111111

Bit	Reset	Description
31:16	0xffff	UTMIP_BIAS_DEBOUNCE_B: simulation value -- Used for interrupts
15:0	0xffff	UTMIP_BIAS_DEBOUNCE_A: simulation value -- Used for interrupts

UTMIP spare configuration bits

Offset: 834h | Read/Write: R/W | Reset: 0b11111111111111110000000000000000

Bit	Reset	Description
31:0	-65536	UTMIP_SPARE: Spare register bits 0: HS_RX_IPG_ERROR_ENABLE 1: HS_RX_FLUSH_ALAP. Flush as late as possible 2: HS_RX_LATE_SQUELCH. Delay Squelch by 1 CLK480 cycle. 3: FUSE_SETUP_SEL. Select between regular CFG value and JTAG values for UX_SETUP 4: FUSE_TERM_RANGE_ADJ_SEL. Select between regular CFG value and JTAG values for UX_TERM_RANGE_ADJ 31 to 5: Reserved Note: 4:3 stand for using fused termination and setup value.

21.5.3.15 USB1_UTMIP_XCVR_CFG1_0

UTMIP transceiver cell configuration register 1

Offset: 838h | Read/Write: R/W | Reset: 0b00011000100000010000010101

Bit	Reset	Description
23:22	0x0	UTMIP_XCVR_SPARE: Spare bits for USB transceiver pad.
21:18	0x6	UTMIP_XCVR_TERM_RANGE_ADJ: Range adjustment on terminations.
17	0x0	UTMIP_RCTRL_SW_SET: Use a software override on RCTRL instead of automatic bias control
16:12	0x8	UTMIP_RCTRL_SW_VAL: Encoded value to use on RCTRL when software override is enabled, 0 to 16 only
11	0x0	UTMIP_TCTRL_SW_SET: Use a software override on TCTRL instead of automatic bias control
10:6	0x8	UTMIP_TCTRL_SW_VAL: Encoded value to use on TCTRL when software override is enabled, 0 to 16 only
5	0x0	UTMIP_FORCE_PDDR_POWERUP: Force PDDR input into power up.
4	0x1	UTMIP_FORCE_PDDR_POWERDOWN: Force PDDR input into power down. (Overrides FORCE_PDDR_POWERUP.)
3	0x0	UTMIP_FORCE_PDCHRP_POWERUP: Force PDCHRP input into power up.
2	0x1	UTMIP_FORCE_PDCHRP_POWERDOWN: Force PDCHRP input input into power down. (Overrides FORCE_PDCHRP_POWERUP.)
1	0x0	UTMIP_FORCE_PDDISC_POWERUP: Force PDDISC input into power up.
0	0x1	UTMIP_FORCE_PDDISC_POWERDOWN: Force PDDISC input into power down. (Overrides FORCE_PDDISC_POWERUP.)

21.5.3.16 USB1_UTMIP_BIAS_CFG1_0

UTMIP Bias cell configuration register 1

Offset: 83ch | Read/Write: R/W | Reset: 0b00000000101101

Bit	Reset	Description
13:8	0x0	UTMIP_BIAS_DEBOUNCE_TIMESCALE: Debouncer time scaling, factor-1 to slow down debouncing by. So 0 is 1, 1 is 2, etc.
7:3	0x5	UTMIP_BIAS_PDTRK_COUNT: Control the BIAS cell power down lag. The lag should be 20us. For a Xtal clock of 13MHz it should be set a 5.
2	0x1	UTMIP_VBUS_WAKEUP_POWERDOWN: Reserved. Refer to the PMC registers for this feature.
1	0x0	UTMIP_FORCE_PDTRK_POWERUP: Force PDTRK input into power up.
0	0x1	UTMIP_FORCE_PDTRK_POWERDOWN: Force PDTRK input into power down. (Overrides FORCE_PDTRK_POWERUP.)

21.5.3.17 USB1_UTMIP_BIAS_STS0_0

UTMIP Bias cell status register 0

Offset: 840h | Read/Write: RO | Reset: 0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx

Bit	Reset	Description
31:16	X	UTMIP_TCTRL: Thermal encoding output from USB bias pad.
15:0	X	UTMIP_RCTRL: Thermal encoding output from USB bias pad.

21.5.3.18 USB1_UTMIP_CHRG_DEB_CFG0_0

UTMIP VDcd_Det and VDat_Det debounce

Debounce values VDcd_Det and VDat_Det. Each of these signals have their own debouncer and for each of those one out of 2 debouncing times can be chosen (CHRG_DEBOUNCE_PERIOD_A or CHRG_DEBOUNCE_PERIOD_B)

The values of DEBOUNCE_PERIOD_A and DEBOUNCE_PERIOD_B are calculated as follows:

- 0xffff -> No debouncing at all
- ms = *1000 / (1/19.2MHz) / 4

So to program a 1 ms debounce for CHG_DEBOUNCE_PERIOD, we have:

- CHG_DEBOUNCE_PERIOD[15:0] = 1000 * 19.2 / 4 = 4800 = 0x12c0

Offset: 844h | Read/Write: R/W | Reset: 0b11111111111111111111111111111111

Bit	Reset	Description
31:16	0xffff	UTMIP_CHRG_DEBOUNCE_PERIOD_B: simulation value -- Used for interrupts
15:0	0xffff	UTMIP_CHRG_DEBOUNCE_PERIOD_A: simulation value -- Used for interrupts

21.5.3.19 USB1_UTMIP_MISC_STS0_0

UTMIP MISC status register

Offset: 848h | Read/Write: RO | Reset: 0bxxxxxxxxxxxxxxxxxxxxxxx

Bit	Reset	Description
21	X	UTMIP_FS_DRV_EN: Indicates when the controller is driving on the bus
20:0	X	UTMIP_SPARE_FUSES: Spare fuses value, to keep the connections preserved

21.5.3.20 USB1_UTMIP_PMC_WAKEUP0_0

UTMIP PMC Wakeup value

Offset: 84ch | Read/Write: R/W | Reset: 0bx0

Bit	R/W	Reset	Description
1	RO	X	UTMIP_LINE_WAKEUP_EVENT_INT_STS: Indicates the status of the PMC wakeup event
0	RW	0x0	UTMIP_LINE_WAKEUP_EVENT_INT_ENB: Interrupt mask for the PMC wakeup event

21.5.3.21 USB2_QH_USB2D_QH_EP_0_OUT_0

USB2D Queue Head for OUT endpoint 0

Offset: 1000h | Read/Write: R/W | Reset: 0b00000000000000000000000000000000

Bit	Reset	Description
31:0	0x0	USB2D_QH: Queue Head for OUT endpoint 0. This is used to store a local Queue Head data structure for either device mode or host mode. In device mode, it holds the Queue Head for OUT endpoint 0.

21.5.3.22 USB2_QH_USB2D_QH_EP_0_IN_0

USB2D Queue Head for IN endpoint 0

Offset: 1040h | Read/Write: R/W | Reset: 0b00000000000000000000000000000000

Bit	Reset	Description
31:0	0x0	USB2D_QH: Queue Head for IN endpoint 0. This is used to store a local Queue Head data structure for either device mode or host mode. In device mode, it holds the Queue Head for IN endpoint 0.

21.5.3.23 USB2_QH_USB2D_QH_EP_1_OUT_0

USB2D Queue Head for OUT endpoint 1

Offset: 1080h | Read/Write: R/W | Reset: 0b00000000000000000000000000000000

Bit	Reset	Description
31:0	0x0	USB2D_QH: Queue Head for OUT endpoint 1. This is used to store a local Queue Head data structure for either device mode or host mode. In device mode, it holds the Queue Head for OUT endpoint 1.

21.5.3.24 USB2_QH_USB2D_QH_EP_1_IN_0

USB2D Queue Head for IN endpoint 1

Offset: 10c0h | Read/Write: R/W | Reset: 0b00000000000000000000000000000000

Bit	Reset	Description
31:0	0x0	USB2D_QH: Queue Head for IN endpoint 1. This is used to store a local Queue Head data structure for either device mode or host mode. In device mode, it holds the Queue Head for IN endpoint 1.

21.5.3.25 USB2_QH_USB2D_QH_EP_2_OUT_0

USB2D Queue Head for OUT endpoint 2

Offset: 1100h | Read/Write: R/W | Reset: 0b00000000000000000000000000000000

Bit	Reset	Description
31:0	0x0	USB2D_QH: Queue Head for OUT endpoint 2. This is used to store a local Queue Head data structure for either device mode or host mode. In device mode, it holds the Queue Head for OUT endpoint 2.

21.5.3.26 USB2_QH_USB2D_QH_EP_2_IN_0

USB2D Queue Head for IN endpoint 2

Offset: 1140h | Read/Write: R/W | Reset: 0b00000000000000000000000000000000

Bit	Reset	Description
31:0	0x0	USB2D_QH: Queue Head for IN endpoint 2. This is used to store a local Queue Head data structure for either device mode or host mode. In device mode, it holds the Queue Head for IN endpoint 2.

21.5.3.27 USB2_QH_USB2D_QH_EP_3_OUT_0

USB2D Queue Head for OUT endpoint 3

Offset: 1180h | Read/Write: R/W | Reset: 0b00000000000000000000000000000000

Bit	Reset	Description
31:0	0x0	USB2D_QH: Queue Head for OUT endpoint 3. This is used to store a local Queue Head data structure for either device mode or host mode. In device mode, it holds the Queue Head for OUT endpoint 3.

21.5.3.28 USB2_QH_USB2D_QH_EP_3_IN_0

USB2D Queue Head for IN endpoint 3

Offset: 11c0h | Read/Write: R/W | Reset: 0b00000000000000000000000000000000

Bit	Reset	Description
31:0	0x0	USB2D_QH: Queue Head for IN endpoint 3. This is used to store a local Queue Head data structure for either device mode or host mode. In device mode, it holds the Queue Head for IN endpoint 3.

21.5.3.29 USB2_QH_USB2D_QH_EP_4_OUT_0

21.5.4 USB2 Controller Registers

21.5.4.1 USB2_CONTROLLER_1_USB2D_ID_0

USB2D Identification Register

Offset: 000h | Read/Write: RO | Reset: 0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx

Bit	Reset	Description
31:29	X	CIVERSION: Identifies the CI version
28:25	X	VERSION: Identifies the version of the core
24:21	X	REVISION: Revision number of the USB controller. This is set to 0x0.
20:16	X	TAG: Identifies the tag of the core
15:8	X	NID: Ones complement version of ID. This field is set to 0xF9.
7:0	X	ID: Configuration number. This field is set to 0x06

21.5.4.2 USB2_CONTROLLER_1_USB2D_HW_HOST_0

USB2D Hardware Host Register

Offset: 008h | Read/Write: RO | Reset: 0bxxxx

Bit	Reset	Description
3:1	X	NPORT: VUSB_HS_NUM_PORT-1: This host controller has only 1 port. So this field will always be 0.
0	X	HC: VUSB_HS_HOST: Indicates support for host mode. Set to 1.

21.5.4.3 USB2_CONTROLLER_1_USB2D_HW_DEVICE_0

USB2D Hardware Device Register

Offset: 00ch |Read/Write: RO | Reset: 0bxxxxxx

Bit	Reset	Description
5:1	X	DEVEP: VUSB_HS_DV_EP: No. of endpoints supported by this device controller. Set to 16. This includes control endpoint 0.
0	X	DC: Device capable: Set to 1 indicating support for device mode.

21.5.4.4 USB2_CONTROLLER_1_USB2D_HW_TXBUF_0

USB2D Hardware TX Buffer Register

Offset: 010h | Read/Write: RO | Reset: 0bxxxxxxxxxxxxxxxxxxxxxxxx

Bit	Reset	Description
23:16	X	TXCHANADD: VUSB_HS_TX_CHAN_ADD: Total number of address bits for the transmit buffer of each transmit endpoint. Set to 7. Each transmit buffer is 128 words deep.
15:8	X	TXADD: VUSB_HS_TX_ADD: Total number of address bits for the transmit buffer. Set to 11. The total depth of the transmit buffer is 2048 words.
7:0	X	TCBURST: VUSB_HS_TX_BURST: Maximum burst size supported by the transmit endpoints for data transfers. Set to 8.

21.5.4.5 USB2_CONTROLLER_1_USB2D_HW_RXBUF_0

USB2D RX Buffer HW Parameters Register

Offset: 014h | Read/Write: RO | Reset: 0bxxxxxxxxxxxxxxxx

Bit	Reset	Description
15:8	X	RXADD: VUSB_HS_RX_ADD: Total number of address bits for the receive buffer. Set to 7. The total depth of the receive buffer is 128 words
7:0	X	RXBURST: VUSB_HS_RX_BURST: Maximum burst size supported by the receive endpoints for data transfers. Set to 8.

21.5.4.6 USB2_CONTROLLER_1_USB2D_CAPLENGTH_0

USB2D Capability Register Length Register

Offset: 100h | Read/Write: RO | Reset: 0bxxxxxxxx

Bit	Reset	Description
7:0	X	CAPLENGTH: Indicates which offset to add to the register base address at the beginning of the Operational Register. Set to 0x40.

21.5.4.7 USB2_CONTROLLER_1_USB2D_HCIVERSON_0

USB2D Host Interface Version Number Register

Offset: 102h | Read/Write: RO | Reset: 0bxxxxxxxxxxxxxxxx

Bit	Reset	Description
15:0	X	HCIVERSION: Contains a BCD encoding of the EHCI revision number supported by this host controller. The most significant byte of this register represents a major revision and the least significant byte is the minor revision. This host controller supports EHCI revision 1.00.

21.5.4.8 USB2_CONTROLLER_1_USB2D_HCSPARAMS_0

USB2D Host Control Structural Parameters Register

Offset: 104h | Read/Write: RO | Reset: 0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx

Bit	Reset	Description
27:24	X	N_TT: Number of Transaction Translators: indicates the number of embedded transaction translators associated with the USB2.0 host controller. This field is always set to 1 indicating only 1 embedded TT is implemented in this implementation. This is a non-EHCI field to support embedded TT.
23:20	X	N_PTT: Number of Ports per Transaction Translator: indicates the number of ports assigned to each transaction translator within the USB2.0 host controller. Field always equals N_PORTS. This is a non-EHCI field to support embedded TT.
15:12	X	N_CC: Number of Companion Controller: indicates the number of companion controllers. This field is set to 0.
11:8	X	N_PCC: Number of Ports per Companion Controller: indicates the number of ports supported per internal companion controller. This field is set to 0.
4	X	PPC: Port Power Control: indicates whether the host controller implementation includes port power control. 1 = Ports have port power switches 0= Ports do not have port power switches. This field affects the functionality of the port Power field in each port status and control register. This field is set to 1.
3:0	X	N_PORTS: Number of downstream ports. This field specifies the number of physical downstream ports implemented on this host controller. This field is fixed to 1, since this host controller only supports 1 port.

21.5.4.9 USB2_CONTROLLER_1_USB2D_HCCPARAMS_0

USB2D Host Control Capability Parameters Register

Offset: 108h | Read/Write: RO | Reset: 0bxxxxxxxxxxxxxxxxxx

Bit	Reset	Description
18	X	PPC: Per-Port Change Event Capability - RO. Default = 1b. This field indicates the support for per-port change events. This field is related with USBCMD PPE field, USBSTS PPCI field and USBINTR PPCE field.
17	X	LEN: Link Power Management Capability - RO. Default = 1b. This field indicates the support for LPM L1 state. This field is related with USBCMD HIRD field, POSTSCx SSTS and DA fields and HOSTPCx LEN, BA, and EPLPM fields.
15:8	X	EECP: EHCI Extended Capabilities Pointer: indicates a capabilities list exists. A value of 00h indicates no extended capabilities are implemented. For this implementation this field is always "0".
7:4	X	IST: Isochronous Scheduling Threshold. This field indicates, relative to the current position of the executing host controller, where software can reliably update the isochronous schedule. When bit [7] is zero, the value of the least significant 3 bits indicates the number of micro-frames a host controller can hold a set of isochronous data structures (one or more) before flushing the state. When bit [7] is a one, then host software assumes the host controller may cache an isochronous data structure for an entire frame. This field will always be "0".
2	X	ASP: Asynchronous Schedule Park Capability. 1 = (Default) the host controller supports the park feature for high-speed queue heads in the Asynchronous Schedule. The feature can be disabled or enabled and set to a specific level by using the Asynchronous Schedule Park Mode Enable and Asynchronous Schedule Park Mode Count fields in the USBCMD register. This field is always 1.

Bit	Reset	Description
1	X	PFL: Programmable Frame List Flag. 0 = System software must use a frame list length of 1024 elements with this host controller. The USBCMD register Frame List Size field is a read-only register and must be set to zero. 1 = System software can specify and use a smaller frame list and configure the host controller via the USBCMD register Frame List Size field. The frame list must always be aligned on a 4K-page boundary. This requirement ensures that the frame list is always physically contiguous. This field will always be "1".

21.5.4.10 USB2_CONTROLLER_1_USB2D_DCIVERSION_0

USB2D Device Interface Version Number Register

Offset: 120h | Read/Write: RO | Reset: 0bxxxxxxxxxxxxxxxx

Bit	Reset	Description
15:0	X	DCIVERSION: The device controller interface conforms to the two-byte BCD encoding of the interface version number contained in this register.

21.5.4.11 USB2_CONTROLLER_1_USB2D_DCCPARAMS_0

USB2D Device Control Capabilities Register

Offset: 124h | Read/Write: RO | Reset: 0bxxxxxxxxx

Bit	Reset	Description
8	X	HC: Host Capable: 1 = This controller is capable of operating as an EHCI compatible USB 2 0 host controller operating as an EHCI compatible USB 2.0 host controller. This field is set to 1.
7	X	DC: Device Capable: 1 = Controller is capable of operating as USB 2.0 device. This field is set to 1
5	X	LEN: Link Power Management Capability - RO. Default = 1b. This field indicates the support for LPM L1 state. This field is related with DEVLCx ASUS, STL,BA and NYT fields.
4:0	X	DEN: Device Endpoint Number: Number of endpoints built into the device controller. This is set to 16.

21.5.4.12 USB2_CONTROLLER_1_USB2D_EXTSTS_0

USB2D EXTSTS Register

Offset: 128h | Read/Write: R/W | Reset: 0b0000x

Bit	R/W	Reset	Description
4	RW	0x0	TI1: General Purpose Timer Interrupt 1 - RWC. Default = 0b. This bit is set when the counter in the GPTIMER1CTRL register transitions to zero. Writing a one to this bit will clear it.
3	RW	0x0	TI0: General Purpose Timer Interrupt 0 - RWC. Default = 0b. This bit is set when the counter in the GPTIMER1CTRL register transitions to zero. Writing a one to this bit will clear it.
2	RW	0x0	UPA: USB Host Periodic Interrupt (USBHSTPERINT) R/WC. This bit is set by the Host Controller when the cause of an interrupt is a completion of a USB transaction where the Transfer Descriptor (TD) has an interrupt on complete (IOC) bit set and the TD was from the periodic schedule. This bit is also set by the Host Controller when a short packet is detected AND the packet is on the periodic schedule. A short packet is when the actual number of bytes received was less than the expected number of bytes. This bit is not used by the device controller and will always be zero. 0 = DISABLE 1 = ENABLE
1	RW	0x0	UAI: USB Host Asynchronous Interrupt (USBHSTASYNCINT) R/WC. This bit is set by the Host Controller when the cause of an interrupt is a completion of a USB transaction where the Transfer

Bit	R/W	Reset	Description
			Descriptor (TD) has an interrupt on complete (IOC) bit set AND the TD was from the asynchronous schedule. This bit is also set by the Host when a short packet is detected AND the packet is on the asynchronous schedule. A short packet is when the actual number of bytes received was less than the expected number of bytes. This bit is not used by the device controller and will always be zero. 0 = DISABLE 1 = ENABLE
0	RO	X	NAKI: NAK Interrupt Bit Read Only. This bit is readonly. It is set by hardware when for a particular endpoint both the TX/RX Endpoint NAK bit and the corresponding TX/RX Endpoint NAK Enable bit are set. This bit is automatically cleared by hardware when the all the enabled TX/RX Endpoint NAK bits are cleared. 0 = DISABLE 1 = ENABLE

21.5.4.13 USB2_CONTROLLER_1_USB2D_USBEXTINTR_0

USB2D EXTINTR Register

Offset: 12ch | Read/Write: R/W | Reset: 0b00000

Bit	Reset	Description
4	0x0	TIE1: General Purpose Timer Interrupt Enable 1 - RWC. Default = 0b. When this bit is a one, and the TI1 bit in the EXTSTS register is a one, the controller will issue an interrupt. The interrupt is acknowledged by software clearing the TI1 bit.
3	0x0	TIE0: General Purpose Timer Interrupt Enable 0 - RWC. Default = 0b. When this bit is a one, and the TI1 bit in the EXTSTS register is a one, the controller will issue an interrupt. The interrupt is acknowledged by software clearing the TI1 bit.
2	0x0	UPIE: UPIE Interrupt Enable. 1 = USB controller issues an interrupt if UPA bit in USBSTS register transitions. 0 = DISABLE 1 = ENABLE
1	0x0	UAIE: UAIE Interrupt Enable. 1 = USB controller issues an interrupt if UAI bit in USBSTS register transitions. 0 = DISABLE 1 = ENABLE
0	0x0	NAKE: NAK Interrupt Enable. 1 = USB controller issues an interrupt if NAKI bit in USBSTS register transitions. 0 = DISABLE 1 = ENABLE

21.5.4.14 USB2_CONTROLLER_1_USB2D_USBCMD_0

USB2D USB Command Register

Offset: 130h | Read/Write: R/W | Reset: 0b000000001000000x1x11x0000000

Bit	R/W	Reset	Description
27:24	RW	0x0	HIRD: Host Initiated Resume Duration RW. Default = 0000b. This has the same behavior as bits 7:4 of BA field of HOSTPCx register. When writing to this field all BA[7:4] fields of all HOSTPCx registers will be set to this value. This field is used by system software to specify the minimum amount of time the host controller will drive the K-state during a host-initiated resume from a LPM state (e.g. L1), and is conveyed to each LPM-enabled device (via the HIRD bits within an LPM Tokens bmAttributes field) upon entry into a low-power state. Note the host controller is required to drive resume signaling for at least the amount of time specified in the HIRD value conveyed to the device during any proceeding host-initiated resume. Also note that the host controller is not required to observe this requirement during device-initiated resumes. Encoding for this field is identical to the definition for the similarly named HIRD field within an LPM Token, specifically: a value 0000b equals 50µs and each additional increment adds 75µs. For example, the value

Bit	R/W	Reset	Description
			0001b equals 125µs, and a value 1111b equals 1,175µs (~1.2ms).
23:16	RW	0x8	ITC: Interrupt Threshold Control .Read/Write. Default 08h. The system software uses this field to set the maximum rate at which the host/device controller will issue interrupts. ITC contains the maximum interrupt interval measured in micro-frames. Valid values are shown below. Value Maximum Interrupt Interval 00h Immediate (no threshold) 01h 1 micro-frame 02h 2 micro-frames 04h 4 micro-frames 08h 8 micro-frames 10h 16 micro-frames 20h 32 micro-frames 40h 64 micro-frames 0 = IMMEDIATE 2 = ONE_MF 4 = TWO_MF 8 = EIGHT_MF 16 = SIXTEEN_MF 32 = THIRTY_TWO_MF 64 = SIXTY_FOUR_MF
15	RW	0x0	FS2: Bit 2 of Frame List Size.
14	RW	0x0	ATDTW: Add DTD Tripwire. This bit is used as a semaphore when a dTD is added to an active (primed) endpoint. This bit is set and cleared by software and will be cleared by hardware when a hazard exists such that adding a dTD to a primed endpoint may go unnoticed. 0 = CLEAR 1 = SET
13	RW	0x0	SUTW: Setup Tripwire. This bit is used as a semaphore when the 8 bytes of setup data read extracted by the firmware. If the setup lockout mode is off, then there exists a hazard when new setup data arrives and firmware is copying setup data from the QH for a previous setup packet. This bit is set and cleared by software and will be cleared by hardware when a hazard exists. 0 = CLEAR 1 = SET
11	RW	0x1	ASPE: Asynchronous Schedule Park mode Enable. Software uses this bit to enable or disable Park mode. When this bit is one, Park mode is enabled. When this bit is a zero, Park mode is disabled. This field is set to "1" in this implementation. 0 = DISABLE 1 = ENABLE
9:8	RW	0x3	ASP1_ASP0: Asynchronous Schedule Park Mode Count (OPTIONAL) Read/Write. If the Asynchronous Park Capability bit in the HCCPARAMS register is a one, then this field defaults to 3h and is R/W. Otherwise it defaults to zero and is RO. It contains a count of the number of successive transactions the host controller is allowed to execute from a high-speed queue head on the Asynchronous schedule before continuing traversal of the Asynchronous schedule. Valid values are 1h to 3h. Software must not write a zero to this bit when Park Mode Enable is a one as this will result in undefined behavior. This field is set to 3h in this implementation and is Read/Write capable.
7	RO	X	LR: Light Host/Device Controller Reset (OPTIONAL) . Read Only. Not Implemented. This field will always be "0".
6	RW	0x0	IAA: Interrupt on Async Advance Doorbell. When the host controller has evicted all appropriate cached schedule states, it sets the Interrupt on Async Advance status bit in the USBSTS register. If the Interrupt on Sync Advance Enable bit in the USBINTR register is one, then the host controller will assert an interrupt at the next interrupt threshold. The host controller sets this bit to zero after it has set the Interrupt on Sync Advance status bit in the USBSTS register to one. Software should not write a one to this bit when the asynchronous schedule is inactive. Doing so will yield undefined results. This bit is only used in host mode. Writing a one to this bit when device mode is selected will have undefined results. 0 = CLEAR 1 = SET
5	RW	0x0	ASE: Asynchronous Schedule Enable. This bit controls whether the host controller skips processing the Asynchronous Schedule. 0 = Do not process the Asynchronous Schedule. 1 = Use the ASYNCLISTADDR register to access the Asynchronous Schedule. Only the host controller uses this bit. 0 = DISABLE 1 = ENABLE
4	RW	0x0	PSE: Periodic Schedule Enable.This bit controls whether the host controller skips processing the

Bit	R/W	Reset	Description
			Periodic Schedule. 0 = Do not process the Periodic Schedule 1 = Use the PERIODICLISTBASE register to access the Periodic Schedule. Only the host controller uses this bit. 0 = DISABLE 1 = ENABLE
3:2	RW	0x0	FS1_FS0: Frame List Size . (Read/Write). 000 = Default This field is Read/Write only if Programmable Frame List Flag in the HCCPARAMS registers is set to one. Hence this field is Read/Write for this implementation. This field specifies the size of the frame list that controls which bits in the Frame Index Register should be used for the Frame List Current index. Note that this field is made up from USBCMD bits 15, 3 and 2. 000 = 1024 elements (4096 bytes) Default value 001 = 512 elements (2048 bytes) 010 = 256 elements (1024 bytes) 011 = 128 elements (512 bytes) 100 = 64 elements (256 bytes) 101 = 32 elements (128 bytes) 110 = 16 elements (64 bytes) 111 = 8 elements (32 bytes) Only the host controller uses this field.
1	RW	0x0	RST: Controller Reset. Software uses this bit to reset the controller. This bit is set to zero by the Host/Device Controller when the reset process is complete. Software cannot terminate the reset process early by writing a zero to this register. Host Controller: When software writes a one to this bit, the Host Controller resets its internal pipelines, timers, counters, state machines etc. to their initial value. Any transaction currently in progress on USB is immediately terminated. A USB reset is not driven on downstream ports. Software should not set this bit to a one when the HCHalted bit in the USBSTS register is a zero. Attempting to reset an actively running host controller results in undefined behavior. Device Controller: When software writes a one to this bit, the Device Controller resets its internal pipelines, timers, counters, state machines etc. to their initial value. Any transaction currently in progress on USB is immediately terminated. Writing a one to this bit in device mode is not recommended. 0 = CLEAR 1 = SET
0	RW	0x0	RS: Run/Stop: Host Controller: When set to a 1, the Host Controller proceeds with the execution of the schedule. The Host Controller continues execution as long as this bit is set to a one. When this bit is set to 0, the Host Controller completes the current transaction on the USB and then halts. The HCHalted bit in the status register indicates when the Host Controller has finished the transaction and has entered the stopped state. Software should not write a one to this field unless the host controller is in the Halted state (i.e. HCHalted in the USBSTS register is a one). Device Controller: Writing a one to this bit will cause the device controller to enable a pull-up on D+ and initiate an attach event. This control bit is not directly connected to the pull-up enable, as the pull-up will become disabled upon transitioning into high-speed mode. Software should use this bit to prevent an attach event before the device controller has been properly initialized. Writing a 0 to this will cause a detach event. 0 = STOP 1 = RUN

21.5.4.15 USB2_CONTROLLER_1_USB2D_USBSTS_0

USB2D USB Status Register

Offset: 134h | Read/Write: R/W | Reset: 0b00000000000000000x1x0x0000x0000

Bit	R/W	Reset	Description
31:16	RW	0x0	PPCI: Port-n Change Detect - RW. Default = 0000h. The definition for each bit is identical to the Port Change Detect field (bit 2 of this register) except these bits are specific to a given port, where bit 16 = Port 1, 17 = Port 2, etc. For example, if bit 17 is set to a one then a port change event was detected on Port 2. The N_PORTS field in HCSPARAMS specifies how many ports are exposed by the host controller and thus how many bits in this field are valid.
15	RW	0x0	AS: Asynchronous Schedule Status. This bit reports the current real status of the Asynchronous Schedule. When set to zero the asynchronous schedule status is disabled and if set to one the status is enabled. The Host Controller is not required to immediately disable or enable the Asynchronous Schedule when software transitions the Asynchronous Schedule Enable bit in the USBCMD register. If AS = ASE: 1= Enable Asynchronous Schedule 0= Disable Asynchronous Schedule Only used by the host controller. 0 = DISABLE 1 = ENABLE
14	RW	0x0	PS: Periodic Schedule Status. This bit reports the current real status of the Periodic Schedule.

Bit	R/W	Reset	Description
			When set to zero the periodic schedule is disabled, and if set to one the status is enabled. The Host Controller is not required to immediately disable or enable the Periodic Schedule when software transitions the Periodic Schedule Enable bit in the USBCMD register. If PS = PSE then: 1 = Periodic Schedule is enabled or 0 = Periodic Schedule is disabled Only used by the host controller. 0 = DISABLE 1 = ENABLE
13	RO	X	RCL: Reclamation. This is a read-only status bit used to detect an empty asynchronous schedule. Only used by the host controller. 0 = DISABLE 1 = ENABLE
12	RW	0x1	HCH: HCHalted. 1 = Default. This bit is a zero whenever the Run/Stop bit is a one. The Host Controller sets this bit to one after it has stopped executing because of the Run/Stop bit being set to 0, either by software or by the Host Controller hardware (e.g. internal error). Only used by the host controller. 0 = UNHALTED 1 = HALTED
10	RW	0x0	ULPI_INT: ULPI Interrupt. This bit is set whenever an interrupt is received from ULPI PHY. Software writes 1 to clear it. 0 = NOT_ULPI_INT 1 = ULPI_INT
8	RW	0x0	SLI: DCSuspend. When a device controller enters a suspend state from an active state, this bit will be set to a 1. The device controller clears the bit upon exiting from a suspend state. Only used by the device controller. 0 = NOTSUSPEND 1 = SUSPENDED
7	RW	0x0	SRI: SOF Received. When the device controller detects a Start Of (micro) Frame, this bit will be set to a one. When a SOF is extremely late, the device controller will automatically set this bit to indicate that an SOF was expected. Therefore, this bit will be set roughly every 1ms in device FS mode and every 125µs in HS mode and will be synchronized to the actual SOF that is received. Since device controller is initialized to FS before connect, this bit Will be set at an interval of 1ms during the prelude to the connect and chirp. In host mode, this bit will be set every 125µs and can be used by host controller driver as a time base. Software writes a 1 to this bit to clear it. This is a non-EHCI status bit. 0 = SOF_NOT_RCVD 1 = SOF_RCVD
6	RW	0x0	URI: USB Reset Received. When the device controller detects a USB Reset and enters the default state, this bit is set to a 1. Software can write a 1 to this bit to clear the USB Reset Received status bit. Only used by the device controller. 0 = NO_USB_RESET 1 = USB_RESET
5	RW	0x0	AAI: Interrupt and Asynchronous Advance. System software can force the host controller to issue an interrupt the next time the host controller advances the asynchronous schedule by writing a one to the Interrupt on Async Advance Doorbell bit in the USBCMD register. This status bit indicates the assertion of that interrupt source. Only used by the host controller 0 = NOT_ADVANCED 1 = ADVANCED
4	RO	X	SEI: System Error. This bit is not used in this implementation and will always be set to "0". 0 = NO_ERROR 1 = ERROR
3	RW	0x0	FRI: Frame List Rollover. The Host Controller sets this bit to a 1 when the Frame List Index rolls over from its maximum value to 0. The exact value at which the rollover occurs depends on the frame list size. For example. If the frame list size (as programmed in the Frame List Size field of the USBCMD register) is 1024, the Frame Index Register rolls over every time FRINDEX [1 3] toggles. Similarly, if the size is 512, the Host Controller sets this bit to a 1 every time FHINDEX [12] toggles. Only used by the host controller. 0 = NO_ROLLOVER 1 = ROLLOVER

Bit	R/W	Reset	Description
2	RW	0x0	PCI: Port Change Detect. The Host Controller sets this bit to a 1 when on any port a Connect Status occurs, a Port Enable/Disable Change occurs, or the Force Port Resume bit is set as the result of a J-K transition on the suspended port. The Device Controller sets this bit to a one when the port controller enters the full or high-speed operational state. When the port controller exits the full or high-speed operational states due to Reset or Suspend events, the notification mechanisms are the USB Reset Received bit and the DCSuspend bits respectively. This bit is not EHCI compatible. 0 = NO_PORT_CHANGE 1 = PORT_CHANGE
1	RW	0x0	UEI: USB Error Interrupt. This bit gets set by the Host/Device controller when completion of a USB transaction results in an error condition. This bit is set along with the USBINT bit, if the TD on which the error interrupt occurred also ad its interrupt on complete (IOC) bit set. 0 = NO_ERROR 1 = ERROR
0	RW	0x0	UI: USB Interrupt. This bit is set by the Host/Device Controller when the cause of an interrupt is a completion of a USB transaction where the Transfer Descriptor (TD) as an interrupt on complete (IOC) bit set. This bit is also set by the Host/Device Controller when a short packet is detected. A short packet is when the actual number of bytes received was less than the expected number of bytes. 0 = NO_INT 1 = INT

21.5.4.16 USB2_CONTROLLER_1_USB2D_USBINTR_0

USB2D USB Interrupt Enable Register

Offset: 138h | Read/Write: R/W | Reset: 0b0000000000000000xxxxx0x000000000

Bit	Reset	Description
31:16	0x0	PPCE: Port-n Change Detect Enable - RW. Default = 0000h. The definition for each bit in this field is identical to bit 2 of this register (Port Change Interrupt Enable) except these bits are specific to a given port, where bit 16 = Port 1, 17 = Port 2, etc. For example, if bit 17 is set (1b) then a port change event was detected on Port 2. When a bit in this field is a one, and the corresponding Port-n Change Detect bit in the USBSTS register is a one, the host controller will issue an interrupt. The interrupt is acknowledged by software clearing the Port-n Change Detect bit.
10	0x0	ULPIE: ULPI Interrupt Enable. 1 = USB controller issues an interrupt if ULPI_INT bit in USBSTS register transitions. The interrupt is acknowledged by SW by writing a 1 to the ULPI_INT bit. 0 = DISABLE 1 = ENABLE
8	0x0	SLE: Sleep Enable. 1 = Device controller issues an interrupt if DCSuspend bit in USBSTS register transitions. The interrupt is acknowledged by SW by writing a 1 to the DCSuspend bit. Only used by the device controller. 0 = DISABLE 1 = ENABLE
7	0x0	SRE: SOF Received Enable. 1 = Device controller issues an interrupt if SOF Received bit in USBSTS register = 1. The interrupt is acknowledged by software clearing the SOF Received bit. 0 = DISABLE 1 = ENABLE
6	0x0	URE: USB Reset Enable.1 = Device controller issues an interrupt if USB Reset Received bit in USBSTS register = 1 The interrupt is acknowledged by software clearing the USB Reset Received bit. Only used by the device controller. 0 = DISABLE 1 = ENABLE
5	0x0	AAE: Interrupt on Asynchronous Advance Enable. 1 = the host controller issues an interrupt at the next interrupt threshold if Interrupt on Async Advance bit in USBSTS register = 1. The interrupt is acknowledged by software clearing the Interrupt on Async Advance bit. Only used by the host controller. 0 = DISABLE

Bit	Reset	Description
		1 = ENABLE
4	0x0	SEE: System Error Enable. 1 = Host/device controller issues an interrupt if the System Error bit in USBSTS register = 1. The interrupt is acknowledged by software clearing the System Error bit. 0 = DISABLE 1 = ENABLE
3	0x0	FRE: Frame List Rollover Enable. 1 = Host controller issues an interrupt if Frame List Rollover bit in the USBSTS register = 1. The interrupt is acknowledged by software clearing the Frame List Rollover bit. Only used by the host controller. 0 = DISABLE 1 = ENABLE
2	0x0	PCE: Port Change Detect Enable. 1 = Host/device controller issues an interrupt if Port Change Detect bit in USBSTS register = 1. The interrupt is acknowledged by software clearing the Port Change Detect bit. 0 = DISABLE 1 = ENABLE
1	0x0	UEE: USB Error Interrupt Enable. 1 = Host controller issues an interrupt at the next interrupt threshold if the USBERRINT bit in USBSTS = 1. The interrupt is acknowledged by software clearing the USBERRINT bit in the USBSTS register. 0 = DISABLE 1 = ENABLE
0	0x0	UE: USB Interrupt Enable. 1 = Host/device issues an interrupt at the next interrupt threshold if the USBINT bit in USBSTS = 1. The interrupt is acknowledged by software clearing the USBINT bit. 0 = DISABLE 1 = ENABLE

21.5.4.17 USB2_CONTROLLER_1_USB2D_FRINDEX_0

USB2D USB Frame Index Register

Offset: 13ch | Read/Write: RO | Reset: 0bxxxxxxxxxxxxxx

Bit	Reset	Description
13:0	X	FRINDEX: Frame Index. The value in this register increments at the end of each time frame (micro-frame). Bits [N: 3] are used for the Frame List current index. Each location of the frame list is accessed 8 times (frames or micro-frames) before moving to the next index. The following illustrates values of N based on the value of the Frame List Size field in the USBCMD register, when used in host mode. USBCMD [Frame List Size] Number Elements N 000b (1024) 12 001b (512) 11 010b (256) 10 011b (128) 9 100b (64) 8 101b (32) 7 110b (16) 6 111b (8) 5 In device mode the value is the current frame number of the last frame transmitted. It is not used as an index. In either mode bits 2:0 indicate the current micro-frame.

21.5.4.18 USB2_CONTROLLER_1_USB2D_PERIODICLISTBASE_0

USB2D Host Controller Frame List Base Address Register

Offset: 144h | Read/Write: R/W | Reset: 0b00000000000000000000

Bit	Reset	Description
31:25	0x0	USBADR: Device mode. The upper seven bits of this register represent the device address. After any controller reset or a USB reset, the device address is set to the default address (0). The default address will match all incoming addresses. Software shall reprogram the address after receiving a SET_ADDRESS request.
24	0x0	USBADRA: Device Address Advance. Default=0. When this bit is 0, any writes to USBADR are instantaneous. When this bit is written to a 1 at the same time or before USBADR is written, the write to the USBADR field is staged and held in a hidden register. After an IN occurs on endpoint 0 and is ACKed, USBADR will be loaded from the holding register. Hardware will automatically clear this bit on

Bit	Reset	Description
		the following conditions: 1) IN is ACKed to endpoint 0. (USBADR is updated from staging register). 2) OUT/SETUP occur to endpoint 0. (USBADR is not updated). 3) Device Reset occurs (USBADR is reset to 0). Note: After the status phase of the SET_ADDRESS descriptor, the DCD has 2 ms to program the USBADR field. This mechanism will ensure this specification is met when the DCD can not write of the device address within 2ms from the SET_ADDRESS status phase. If the DCD writes the USBADR with USBADRA=1 after the SET_ADDRESS data phase (before the prime of the status phase), the USBADR will be programmed instantly at the correct time and meet the 2ms USB requirement.
31:12	0x0	BASEADR: Host mode: This 32-bit register contains the beginning address of the Periodic Frame List in the system memory. HCD loads this register prior to starting the schedule execution by the Host Controller. The memory structure referenced by this physical memory pointer is assumed to be 4-Kbyte aligned. The contents of this register are combined with the Frame Index Register (FRINDEX) to enable the Host Controller to step through the Periodic Frame List in sequence. Base Address (Low). These bits correspond to memory address signals [31:12], respectively. Only used by the host controller.

21.5.4.19 USB2_CONTROLLER_1_USB2D_ASYNCLISTADDR_0

USB2D Next Asynchronous List Address Register

Offset: 148h | Read/Write: R/W | Reset: 0b00000000000000000000000000000000

Bit	Reset	Description
31:11	0x0	EPBASE: Device mode. This register contains the address of the top of the endpoint list in system memory. These bits correspond to memory address signals [31:11], respectively. This field will reference a list of up to 32 Queue Heads (QH). Only used by the device controller.
31:5	0x0	ASYBASE: Host mode. This 32-bit register contains the address of the next asynchronous queue head to be executed by the host. Link Pointer Low (LPL). These bits correspond to memory address signals [31:5], respectively. This field may only reference a Queue Head (OH). Only used by the host controller.

21.5.4.20 USB2_CONTROLLER_1_USB2D_ASYNCTTSTS_0

USB2D Asynchronous Buffer Status for Embedded TT Register

Offset: 14ch | Read/Write: R/W | Reset: 0b0x

Bit	R/W	Reset	Description
1	RW	0x0	TTAC: Embedded TT Async Buffers Clear. (Read/Write to set) This field will clear all pending transactions in the embedded TT Async Buffer(s). The clear will take as much time as necessary to clear buffer without interfering with a transaction in progress. TTAC will return to zero after being set by software only after the actual clear occurs.
0	RO	X	TTAS: Embedded TT Async Buffers Status. (Read Only) This read only bit will be 1 if one or more transactions are being held in the embedded TT Async. Buffers. When this bit is a zero, then all outstanding transactions in the embedded TT have been flushed.

21.5.4.21 USB2_CONTROLLER_1_USB2D_BURSTSIZE_0

USB2D Burst Size register

Offset: 150h | Read/Write: R/W | Reset: 0b0000100000001000

Bit	Reset	Description
15:8	0x8	TXPBURST: Programmable TX Burst Length. (Read/Write) This register represents the maximum length of a burst in 32-bit words while moving data from system memory to the USB bus.
7:0	0x8	RXPBURST: Programmable RX Burst Length. (Read/Write) This register represents the maximum length of a burst in 32-bit words while moving data from the USB bus to system memory.

21.5.4.22 USB2_CONTROLLER_1_USB2D_TXFILLTUNING_0

USB2D Transmit fill tuning register

Offset: 154h | Read/Write: R/W | Reset: 0b000010xxx0000000000000

Bit	Reset	Description
21:16	0x2	TXFIFOTHRES: FIFO Burst Threshold. (Read/Write) This register controls the number of data bursts that are posted to the TX latency FIFO in host mode before the packet begins on to the bus. The minimum value is 2 and this value should be a low as possible to maximize USB performance. A higher value can be used in systems with unpredicable latency and/or insufficient bandwidth where the FIFO may underrun because the data transferred from the latency FIFO to USB occurs before it can be replenished from system memory. This value is ignored if the Stream Disable bit in USBMODE register is set.
12:8	0x0	TXSCHHEALTH: Scheduler Health Counter. (Read/Write To Clear) [Default = 0] This register increments when the host controller fails to fill the TX latency FIFO to the level programmed by TXFIFOTHRES before running out of time to send the packet before the next Start-Of-Frame. This health counter measures the number of times this occurs to provide feedback to selecting a proper TXSCHOH. Writing to this register will clear the counter and this counter will max. at 31.
7:0	0x0	TXSCHOH: Scheduler Overhead. (Read/Write) [Default = 0] This register adds an additional fixed offset to the schedule time estimator described above as Tff. As an approximation, the value chosen for this register should limit the number of back-off events captured in the TXSCHHEALTH to less than 10 per second in a highly utilized bus. Choosing a value that is too high for this register is not desired as it can needlessly reduce USB utilization. The time unit represented in this register is 1.267us when a device is connected in High-Speed Mode. The time unit represented in this register is 6.333us when a device is connected in Low/Full Speed Mode

21.5.4.23 USB2_CONTROLLER_1_USB2D_ICUSB_CTRL_0

USB2D ICUSB control register

This register enables and controls the ICUSB FS/LS transceiver.

Offset: 15ch | Read/Write: R/W | Reset: 0b0000

Bit	Reset	Description
3	0x0	IC_ENB1: ICUSB transceiver enable. This bit enables the ICUSB transceiver . To enable the interface, the bits PTS must be set to 11 in the PORTSCx. Writing a '1' to this bit selects the IC_USB interface. 0 = DISABLE 1 = ENABLE
2:0	0x0	IC_VDD1: ICUSB voltage select. It selects which voltage is being supplied to the ICUSB peripheral. 000 -> No voltage 001 -> 1.0V - reserved 010 -> 1.2V - reserved 011 -> 1.5V - reserved 100 -> 1.8V 101 -> 3.0V 110 -> reserved 111 -> reserved The Voltage negotiation should happen between enabling port power (PP) and asserting the run/stop bit in register.

21.5.4.24 USB2_CONTROLLER_1_USB2D_ULPI_VIEWPORT_0

This register provides indirect access to the ULPI PHY register set. Although the USB controller performs access to the ULPI PHY register set, there may be extraordinary circumstances where software may need direct access.

Note: WRITES TO THE ULPI THROUGH THE VIEWPORT CAN SUBSTANTIALLY HARM STANDARD USB OPERATIONS. CURRENTLY NO USAGE MODEL HAS BEEN DEFINED WHERE SOFTWARE SHOULD NEED TO EXECUTE WRITES DIRECTLY TO THE ULPI PHY. SEE EXCEPTION REGARDING OPTIONAL FEATURES BELOW.

Note: EXECUTING READ OPERATIONS THROUGH THE ULPI VIEWPORT SHOULD HAVE NO HARMFUL SIDE EFFECTS TO STANDARD USB OPERATIONS.

There are two operations that can be performed with the ULPI Viewport-- wakeup and read /write operations.

The wakeup operation is used to put the ULPI interface into normal operation mode and reenable the clock if necessary. A wakeup operation is required before accessing the registers when the ULPI interface is operating in low power mode, serial mode, or carkit mode.

The ULPI state can be determined by reading the sync. state bit (ULPI_SYNC_STATE). If this bit is a one, then ULPI interface is running in normal operation mode and can accept read/write operations. If the ULPI_SYNC_STATE indicates a 0 then then read/write operations will not be able to execute. Undefined behavior will result if ULPI_SYNC_STATE = 0 and a read or write operation is performed.

To execute a wakeup operation, write all 32-bits of the ULPI Viewport where ULPI_PORT is constructed appropriately and the ULPI_WAKEUP bit is a 1 and ULPI_RUN bit is a 0. Poll the ULPI Viewport until ULPI_WAKEUP is zero for the operation to complete.

To execute a read or write operation, write all 32-bits of the ULPI Viewport where ULPI_DATA_WR, ULPI_REG_ADDR, ULPI_PORT, ULPI_RD_WR are constructed appropriately and the ULPI_RUN bit is a 1. Poll the ULPI Viewport until ULPI_RUN is zero for the operation to complete. Once ULPI_RUN is zero, the ULPI_DATA_RD will be valid if the operation was a read.

The polling method above can be changed to interrupt driven using the ULPI interrupt defined in the USBSTS and USBINTR registers. When a wakeup or read/write operation is complete, the ULPI_INT interrupt will be set.

There are several optional features that may need to be enabled or disabled by system software as part of system configuration. These bits are contained in the Interface and OTG Control registers of the ULPI PHY register set. These registers also contain bits which are controlled by the link dynamically and therefore should be only modified by system software using the Set/Clear access method. Direct writes to these registers could have harmful side effects to the standard USB operations. The optional bits are as follows: Bits 3 through 7 in the Interface Control register and Bits 6 and 7 in the OTG Control register.

Please refer to the ULPI Specification Revision 1.1 for further information on the use of the optional features.

USB2D ULPI viewport register

Offset: 160h | Read/Write: R/W | Reset: 0b000xx00000000000xxxxxxxx00000000

Bit	R/W	Reset	Description
31	RW	0x0	ULPI_WAKEUP: ULPI Wakeup. Writing the 1 to this bit will begin the wakeup operation. The bit will automatically transition to 0 after the wakeup is complete. Once this bit is set, the driver can not set it back to 0. Note: The driver must never execute a wakeup and a read/write operation at the same time. 0 = CLEAR 1 = SET
30	RW	0x0	ULPI_RUN: ULPI read/write Run. Writing the 1 to this bit will begin the read/write operation. The bit will automatically transition to 0 after the read/write is complete. Once this bit is set, the driver can not set it back to 0. Note: The driver must never execute a wakeup and a read/write operation at the same time. 0 = CLEAR 1 = SET
29	RW	0x0	ULPI_RD_WR: ULPI read/write control. (0) Read; (1) Write. This bit selects between running a read or write operation. 0 = READ 1 = WRITE
27	RO	X	ULPI_SYNC_STATE: ULPI sync state. (1) Normal Sync. State. (0) In another state (i.e. carkit, serial, low power) This bit represents the state of the ULPI interface. 0 = NOT_NORMAL 1 = NORMAL
26:24	RW	0x0	ULPI_PORT: ULPI PHY port no. This field should be always written as 0.

Bit	R/W	Reset	Description
23:16	RW	0x0	ULPI_REG_ADDR: ULPI PHY register address. When doing a read or write operation to the ULPI PHY, the address of the ULPI PHY register being accessed is written to this field.
15:8	RO	X	ULPI_DATA_RD: ULPI PHY data read. The data from the ULPI PHY register can be read from here after the read operation completes.
7:0	RW	0x0	ULPI_DATA_WR: ULPI PHY data write. The data to write to the ULPI PHY register is written here.

21.5.4.25 USB2_CONTROLLER_1_USB2D_PORTSC1_0

USB2D Port Status/Control 1 Register

Offset: 174h | Read/Write: R/W | Reset: 0b0000000xx0000000xxx1xx00x0xx010x

Bit	R/W	Reset	Description
31:25	RW	0x0	DA: Device Address - RW. Default = 0000000b. The 7-bit USB device address for the device attached to an immediately downstream of the associated root port. A value of zero indicates no device is present or software support for this feature is not present. This is used by the Controller when sending the LPM token. This field is only valid when the core is operating in host mode. If in device mode it will be read only and always equal to 0000000b.
24:23	RO	X	SSTS: Suspend Status - RO. Default = 00b. These two bits are used by software to determine whether an L1-based suspend request was successful, specifically: 00b - L1 state entered with success. ACK received from peripheral. 01b - NYET received from peripheral. It was not able to enter L1 state this time. 10b - L1 state not supported by peripheral. STALL received. 11b - Peripheral didn't respond or an error occurred. The value of this field is only valid when the port resides in the L0 state - that is, the meaning of these bits are invalid whenever bit 7 of this register (SUSP) is one. Ideally, the Controller driver should read this register if it receives an interrupt after issuing a suspend using L1 support. In case of a non-success a port change interrupt will be fired and this field should be checked for a possible L1 failure. This field is only valid when the core is operating in host mode. If in device mode it will be always equal to 00b. 0 = L1STATE_ENTERED 1 = NYET_PERIPH 2 = L1STATE_NOT_SUPPORTED 3 = PERIPH_NORESP_ERR
22	RW	0x0	WKOC: Default = 0b. Wake on Over-current Enable: Writing this bit to a one enables the port to be sensitive to over-current conditions as wake-up events. This field is zero if Port Power(PP) is zero. This bit should only be used when operating in Host mode. Writing this bit to 1 while the controller is working in device mode can result in undefined behavior. 0 = DISBLE 1 = ENABLE
21	RW	0x0	WKDS: Wake on Disconnect Enable: Writing this bit to a one enables the port to be sensitive to device disconnects as wake-up events. This field is zero if Port Power(PP) is zero or in device mode. This bit should only be used when operating in Host mode. Writing this bit to 1 while the controller is working in device mode can result in undefined behaviour. This bit should not be written to 1 if there is no device connected. After the device disconnect is detected, this bit should be cleared to 0. 0 = DISBLE 1 = ENABLE
20	RW	0x0	WKCN: Wake on Connect Enable: Writing this bit to a one enables the port to be sensitive to device connects as wake-up events. This field is zero if Port Power(PP) is zero or in device mode. This bit should only be used when operating in Host mode. Writing this bit to 1 while the controller is working in device mode can result in undefined behaviour. This bit should not be written to 1 while the device is connected. After the device connection is detected, this bit should be cleared to 0. 0 = DISBLE 1 = ENABLE
19:16	RW	0x0	PTC: Port Test Control: Any other value than zero indicates that the port is operating in test mode. Value Specific Test 0000b Not enabled 0001b J_ STATE 0010b K_STATE 0011b SEQ_NAK 0100b Packet 0101b FORCE_ENABLE 0110b to 1111b Reserved Refer to Chapter 7

Bit	R/W	Reset	Description
			of the USB Specification Revision 2.0 for details on each test mode. 0 = NORMAL_OP 1 = TEST_J 2 = TEST_K 3 = TEST_SE0_NAK 4 = TEST_PKT 5 = TEST_FORCE_ENABLE
15:14	RO	X	PIC: Port Indicator Control: This field is not supported in the current implementation. Please use a GPIO if you wish to use Port Indicators.
13	RO	X	PO: Port Owner. Port owner handoff is not implemented in this design, therefore this bit will always be 0.
12	RW	0x1	PP: Port Power: The function of this bit depends on the value of the Port Power Switching (PPC) field in the HCSPARAMS register. The behavior is as follows: PPC PP Operation 0b 0b Read Only. A device controller with no OTG capability does not have port power control switches. 1b 1b/0b RW. Host/OTG controller requires port power control switches. This bit represents the current setting of the switch (0=off, 1=on). When power is not available on a port (i.e. PP equals a 0), the port is non-functional and will not report attaches, detaches, etc. When an over-current condition is detected on a powered port and PPC is a one, the PP bit in each affected port may be transitioned by the host controller driver from a one to a zero (removing power from the port). 0 = NOT_POWERED 1 = POWERED
11:10	RO	X	LS: Line state. These bits reflect the current logical levels of the D+ (bit 10) and D- (bit 11) signal lines. The encoding of the bits are: 00b = SE0 01b = J-state 10b = K-state 11b = Undefined The value of this field is undefined if Port Power(PP) is zero in host mode. In host mode, the use of line-state by the host controller driver is not necessary (unlike EHCI), because the port controller state machine and the port routing manage the connection of LS and FS. In device mode, the use of line-state by the device controller driver is not necessary. 0 = SE0 1 = J_STATE 2 = K_STATE 3 = UNDEFINED
9	RW	0x0	SLP: Suspend using L1 - RW. Default = 0b. When this bit is set to '1' and a non-zero Device Address (DA) is specified Controller will instigate L1 entry during suspend (bit 7) and L1 exit during resume (bit 6). When set to zero the Controller will use the legacy (L2) mechanism. Software should only set this bit when the device attached immediately downstream supports L1 transitions. When acting as device, this bit is read-only and set to '1' by the hardware when the Controller enters is L1 state (LPM token received and accepted). Note: HSP is redundant with PSPD(27:26). This bit is not defined in the EHCI specification.
8	RW	0x0	PR: This field is zero if Port Power(PP) is zero. In Host Mode: Read/Write. 1=Port is in Reset. 0=Port is not in Reset. When software writes a one to this bit the bus-reset sequence as defined in the USB Specification Revision 2.0 is started. This bit will automatically change to zero after the reset sequence is complete. This behavior is different from EHCI where the host controller driver is required to set this bit to a zero after the reset duration is timed in the driver. In Device Mode: This bit is a read only status bit. Device reset from the USB bus is also indicated in the USBSTS register. 0 = NOT_USB_RESET 1 = USB_RESET
7	RO	X	SUSP: Port suspend. 1=Port in suspend state. 0=Port not in suspend state. In Host Mode: Read/Write. Port Enabled Bit and Suspend bit of this register define the port states as follows: Bits [Port Enabled, Suspend] Port State 0x Disable 10 Enable 11 Suspend When in suspend state, downstream propagation of data is blocked on this port, except for port reset. The blocking occurs at the end of the current transaction if a transaction was in progress when this bit was written to 1. In the suspend state, the port is sensitive to resume detection. Note that the bit status does not change until the port is suspended and that there may be a delay in suspending a port if there is a transaction currently in progress on the USB. The host controller will unconditionally set this bit to zero when software sets the Force Port Resume bit to zero. A write of zero to this bit is ignored by the host controller. If host software sets this bit to a one when the port is not enabled (i.e. Port enabled bit is a zero) the results are undefined. This field is zero if Port Power(PP) is zero in host mode. In Device Mode: Read Only. This bit is a read only status bit. 0 = NOT_SUSPEND 1 = SUSPEND

Bit	R/W	Reset	Description
6	RW	0x0	FPR: Force Port Resume. 1= Resume detected/driven on port. 0=No resume (K state) detected/driven on port. In Host Mode: Software sets this bit to one to drive resume signaling. The Host Controller sets this bit to one if a J-to-K transition is detected while the port is in the Suspend state. When this bit transitions to a one because a J-to-K transition is detected, the Port Change Detect bit in the USBSTS register is also set to one. This bit will automatically change to zero after the resume sequence is complete. This behavior is different from EHCI where the host controller driver is required to set this bit to a zero after the resume duration is timed in the driver. Note that when the Host controller owns the port, the resume sequence follows the defined sequence documented in the USB Specification Revision 2.0. The resume signaling (Full-speed 'K') is driven on the port as long as this bit remains a one. This bit remains a one until the port has switched to the high-speed idle. Writing a zero has no effect because the port controller will time the resume operation to clear the bit when the port control state switches to HS or FS idle. This field is zero if Port Power(PP) is zero in host mode. This bit is not-EHCI compatible. In Device mode: After the device has been in Suspend State for 5ms or more, software must set this bit to one to drive resume signaling before clearing. The Device Controller will set this bit to one if a J-to-K transition is detected while the port is in the Suspend state. The bit will be cleared when the device returns to normal operation. Also, when this bit transitions to a one because a J-to-K transition is detected, the Port Change Detect bit in the USBSTS register is also set to one. Software should ensure that the PHY clock is operational before writing a 1 to this bit to start the resume sequence. This is true for both Device and Host modes. 0 = NO_RESUME 1 = RESUME
5	RO	X	OCC: Over-current Change: Not supported 0 = NO_CHANGE 1 = CHANGE
4	RO	X	OCA: Over-current Active: Not supported 0 = NO_OVER_CURRENT 1 = OVER_CURRENT
3	RW	0x0	PEC: Port Enable/Disable Change: 1=Port enabled/disabled status has changed. 0=No change. In Host Mode: For the root hub, this bit gets set to a one only when a port is disabled due to disconnect on the port or due to the appropriate conditions existing at the EOF2 point (See Chapter 11 of the USB Specification). Software clears this by writing a one to it. This field is zero if Port Power(PP) is zero. In Device mode: The device port is always enabled. (This bit will be zero) 0 = NO_CHANGE 1 = CHANGE
2	RW	0x1	PE: Port Enabled/Disabled: 1=Enable. 0=Disable (default) In Host Mode: Ports can only be enabled by the host controller as a part of the reset and enable. Software cannot enable a port by writing a one to this field. Ports can be disabled by either a fault condition (disconnect event or other fault condition) or by the host software. Note that the bit status does not change until the port state actually changes. There may be a delay in disabling or enabling a port due to other host controller and bus events. When the port is disabled, (0b) downstream propagation of data is blocked except for reset. This field is zero if Port Power(PP) is zero in host mode. In Device Mode: The device port is always enabled. (This bit will be one) 0 = PORT_DISABLED 1 = PORT_ENABLED
1	RW	0x0	CSC: Connect Status Change: 1 =Change in Current Connect Status. 0=No change (default) In Host Mode: Indicates a change has occurred in the port's Current Connect Status. The host/device controller sets this bit for all changes to the port device connect status, even if system software has not cleared an existing connect status change. For example, the insertion status changes twice before system software has cleared the changed condition, hub hardware will be 'setting' an already-set bit (i.e., the bit will remain set). Software clears this bit by writing a one to it. This field is zero if Port Power(PP) is zero in host mode. This bit is undefined in device controller mode. 0 = NO_CHANGE 1 = CHANGE
0	RO	X	CCS: Current Connect Status: In Host Mode: 1=Device is present on port. 0=No device is present (default) This value reflects the current state of the port, and may not correspond directly to the event that caused the Connect Status Change bit (Bit 1) to be set. This field is zero if Port Power(PP) is zero in host mode. In Device Mode: 1=Attached 0=Not Attached (default) A one indicates that the device successfully attached and is operating in either high speed or full speed as indicated by the High Speed Port bit in this register. A zero indicates that the device did not

Bit	R/W	Reset	Description
			attach successfully or was forcibly disconnected by the software writing a zero to the Run bit in the USBCMD register. It does not state the device being disconnected or suspended. 0 = NOT_CONNECTED 1 = CONNECTED

21.5.4.26 USB2_CONTROLLER_1_USB2D_HOSTPC1_DEVLC_0

USB2D Device Mode LPM Behav and Control Register

This register controls the LPM behavior and controls the behavior of each USB port. Only available when in device mode. This register shares the same address with the HOSTPC1 register (which is used only in host mode).

USB2D Host Mode LPM Behav and Control Register

This register controls the LPM behavior and controls the behavior of each USB port. Only available when in host mode. This register shares the same address with the DEVLC register (which is used only in device mode).

Offset: 1b4h | Read/Write: R/W | Reset: 0b0000xxxx000000000000xxxxxxxxxxx0

Bit	R/W	Reset	Description
31:29	RW	0x0	PTS: Parallel transceiver select. This bit is not defined in the EHCI specification. 0 = UTMI 1 = RESERVED 2 = ULPI 3 = ICUSB_SER 4 = HSIC
28	RW	0x0	STS: Serial transceiver not selected. This is the only value supported. This bit is not defined in the EHCI specification. 0 = PARALLEL_IF 1 = SERIAL_IF
27	RO	X	PTW: Parallel Transceiver Width. Fixed to 0. This bit is not defined in the EHCI specification. 0 = EIGHT_BIT 1 = RESERVED
26:25	RO	X	PSPD: This register field indicates the speed at which the port is operating. 00 = Full Speed 01 = Low Speed 10 = High Speed. This bit is not defined in the EHCI specification. 0 = FULL_SPEED 1 = LOW_SPEED 2 = HIGH_SPEED 3 = RESERVED
23	RW	0x0	PFSC: Port Force Full Speed Connect - RW. Default = 0b. Writing this bit to a '1b' will force the port to only connect at Full Speed. It disables the chirp sequence that allows the port to identify itself as High Speed. This is useful for testing FS configurations with a HS host, hub or device. This bit is not defined in the EHCI specification. 0 = DONT_FORCE_FULL_SPEED 1 = FORCE_FULL_SPEED
22	RW	0x0	PHCD: PHY Low Power Suspend - Clock disable: Writing this bit to a 1 will disable the PHY clock. Write a 0 enables it. Reading this bit will indicate the status of the PHY clock. NOTE: The PHY clock cannot be disabled if it is being used as the system clock. In device mode, the PHY can be put into Low Power Clock Disable when the device is not running (USBCMD RS=0b) or the host has signaled suspend (PORTSCx SUSP=1b). Low Power Clock Disable will be cleared automatically when the host has signaled resume. Before forcing a resume from the device, the Controller driver must clear this bit. In host mode, the PHY can be put into Low Power Suspend Clock Disable when the downstream device has been put into suspend mode or when no downstream device is connected. Low Power Clock Disable is completely under the control of software. 0 = DISABLE 1 = ENABLE

Bit	R/W	Reset	Description
21:20	RW	0x0	LPMX: Auto LPM set - RW. Default = 00b. This bit field is **valid during Host Mode Only**. For Device Mode this is reserved. Value Meaning 00b Disables auto LPM. 01b If there is no activity for a certain number of SOFs the controller will send a LPM token, enter in suspend and issue a port change interrupt. 10b Same as above but without issuing an interrupt. 11b Reserved for futures LPM enhancements. The detection of no activity is based on the absence of response from the downstream device. Because of this limitation this feature should not be used if ISO OUT endpoints are being used (as no handshake is expected).
17	RW	0x0	ASUS: Auto Low Power - RW. Default = 0b. This bit field is **valid during Device Mode Only**. In Host Mode it is part of ELPM field. This bit is used to control the auto low power feature. If set, the auto low power feature will be enabled and every time the port enters in suspend state it will also enter in low power state, disabling the transceiver clock. The behavior will be the same as if the PHCD bit was enabled (in fact this bit will be set to '1' as soon as low power mode is enabled). 0 = DISABLE 1 = ENABLE
19:16	RW	0x0	EPLPM: Endpoint for LPM token - RW. Default = 0000b. This bit field is **valid during Host Mode Only**. For Device Mode [19:18] is reserved and 17 is ASUS, while 16 is STL. This sets the endpoint number to which the LPM token will be sent. It will be directly mapped to the ENDP field in the LPM token with the EXT PID.
16	RW	0x0	STL: STALL reply to LPM token - RW. Default = 0b. This bit field is **valid during Device Mode Only**. In Host Mode it is a part of ELPM field. When this bit is set to '1', the Controller will reply always with STALL to all incoming LPM tokens. This bit overrides the LPM NYET bit (NYT). 0 = DISABLE 1 = ENABLE
15:12	RW	0x0	LPMFRM: Auto LPM SOF Threshold - RW. Default = 0000b. This bit field is **valid during Host Mode Only**. For Device Mode this is reserved. This holds the SOF counter threshold. When the number of SOF with no activity in between reaches this threshold and the auto LPM is enabled, a LPM token will be sent and the port will enter in suspend state. The SOF counter for this threshold is incremented each 125us, even if the port is not in HS operation.
11:1	RO	X	BA: BmAttributtes - RO. Default = 00000000000b. This holds the bmAttributes field of the LPM sub-token received, after the EXT PID token.
0	RW	0x0	NYT_ASUS: NYET reply to LPM token - RW. Default = 0b. This bit is NYT during Device Mode. Details follows: When this bit is to '1', the device controller will NYET all the LPM tokens. When this bit is set to '0', the Controller will ACK all the LPM tokens if the STALL bit (STL) is also set to '0'. This bit is ASUS in Host Mode. Details follows: This bit is used to control the auto low power feature. If set, the auto low power feature will be enabled and every time the port enters in suspend state it will also enter in low power state, disabling the transceiver clock. The behavior will be the same as if the PHCD bit was enabled (in fact this bit will be set to '1' as soon as low power mode is enabled). 0 = DISABLE 1 = ENABLE

21.5.4.27 USB2_CONTROLLER_1_USB2D_OTGSC_0

USB2D On-The-Go (OTG) Status and Control Register

Offset: 1f4h | Read/Write: R/W | Reset: 0b0000000x0000000xxxxxxxxxx000x00

Bit	R/W	Reset	Description
30	RW	0x0	DPIE: Data Pulse Interrupt Enable. Setting this bit enables the Data pulse interrupt. 0 = DISABLE 1 = ENABLE
29	RW	0x0	ONEMSE: 1 millisecond timer Interrupt enable. Setting this bit enables the 1 millisecond timer interrupt. 0 = DISABLE 1 = ENABLE
28	RW	0x0	BSEIE: B Session End Interrupt Enable. Setting this bit enables the B session end interrupt 0 = DISABLE

Bit	R/W	Reset	Description
			1 = ENABLE
27	RW	0x0	BSVIE: B Session Valid Interrupt Enable. Setting this bit enables the B session valid interrupt 0 = DISABLE 1 = ENABLE
26	RW	0x0	ASVIE: A Session Valid Interrupt Enable. Setting this bit enables the A session valid interrupt 0 = DISABLE 1 = ENABLE
25	RW	0x0	AVVIE: A VBus Valid Interrupt Enable. Setting this bit enables the A VBus valid interrupt 0 = DISABLE 1 = ENABLE
24	RW	0x0	IDIE: USB ID Interrupt Enable. Setting this bit enables the USB ID interrupt 0 = DISABLE 1 = ENABLE
22	RW	0x0	DPIS: Data Pulse Interrupt Status. This bit is set when data bus pulsing occurs on DP or DM. Data bus pulsing is only detected when USBMODE.CM = Host (11) and PORTSC(0).PortPower = Off (0). Software writes a 1 to clear this bit. 0 = INT_CLEAR 1 = INT_SET
21	RW	0x0	ONEMSS: 1 millisecond timer Interrupt Status: This bit is set once every millisecond. Software writes a 1 to clear it. 0 = INT_CLEAR 1 = INT_SET
20	RW	0x0	BSEIS: B Session End Interrupt Status. This bit is set when VBus has fallen below the B session end threshold. Software writes a 1 to clear this bit . 0 = INT_CLEAR 1 = INT_SET
19	RW	0x0	BSVIS: B Session Valid Interrupt Status. This bit is set when VBus has either risen above or fallen below the B session valid threshold (0.8 VDC). Software writes a 1 to clear this bit. 0 = INT_CLEAR 1 = INT_SET
18	RW	0x0	ASVIS: A Session Valid Interrupt Status. This bit is set when VBus has either risen above or fallen below the A session valid threshold (0.8 VDC). Software writes a one to clear this bit. 0 = INT_CLEAR 1 = INT_SET
17	RW	0x0	AVVIS: A VBus Valid Interrupt Status. This bit is set when VBus has either risen above or fallen below the VBus valid threshold (4.4 VDC) on an A device. Software writes a 1 to clear this bit. 0 = INT_CLEAR 1 = INT_SET
16	RW	0x0	IDIS: USB ID Interrupt Status. This bit is set when a change on the ID input has been detected. Software writes a 1 to clear this bit. 0 = INT_CLEAR 1 = INT_SET
14	RO	X	DPS: Data Bus Pulsing Status. A 1 indicates data bus pulsing is being detected on the port. 0 = STS_CLEAR 1 = STS_SET
13	RO	X	ONEMST: 1 millisecond timer toggle. This bit toggles once per millisecond 0 = STS_CLEAR 1 = STS_SET
12	RO	X	BSE: B session End. Indicates VBus is below the B session end threshold 0 = STS_CLEAR 1 = STS_SET
11	RO	X	BSV: B Session Valid. Indicates VBus is above the B session valid threshold 0 = STS_CLEAR

Bit	R/W	Reset	Description
			1 = STS_SET
10	RO	X	ASV: A Session Valid. Indicates VBus is above the A session valid threshold 0 = STS_CLEAR 1 = STS_SET
9	RO	X	AVV: A VBus Valid. Indicates VBus is above the A VBus valid threshold 0 = STS_CLEAR 1 = STS_SET
8	RO	X	ID: USB ID: 0 = A-device 1 = B-device 0 = A_DEV 1 = B_DEV
5	RW	0x0	IDPU: USB ID Pullup 0 = CLEAR 1 = SET
4	RW	0x0	DP: Data Pulsing. Setting this bit causes the pull-up on DP to be asserted for data pulsing during SRP. 0 = NO_DATA_PULSE 1 = DATA_PULSE
3	RW	0x0	OT: OTG Termination. This bit must be set when the OTG device is in device mode, this controls the pulldown on DM. 0 = NO_OTG_TERM 1 = OTG_TERM
1	RW	0x0	VC: VBUS Charge. Setting this bit causes the VBus line to be charged. This is used for VBus pulsing during SRP. 0 = NO_VBUS_CHRG 1 = VBUS_CHRG
0	RW	0x0	VD: VBUS_Discharge. Read/write. Setting this bit causes Vbus to discharge through a resistor. 0 = NO_VBUS_DISCHRG 1 = VBUS_DISCHRG

21.5.4.28 USB2_CONTROLLER_1_USB2D_USBMODE_0

USB2D USB Device Mode Register

Offset: 1f8h | Read/Write: R/W | Reset: 0b0xxxxxxxxx0xxxxx

Bit	R/W	Reset	Description
15	RW	0x0	SRT: Shorten USB Reset Time. Software should never set this to 1.
5	RW	0x0	VBPS: VBUS Power Select This can be used by logic that selects between an on-chip Vbus power source (charge pump) and an off-chip source in systems when both are available. Only to be used in Host Mode No functionality implemented for this, so SW should not use this.
4	RO	X	SDIS: Stream disbable: 1 Streaming is disabled - helpful to avoid overrun/underruns when system load is too high. 0 = STREAM_ENABLE 1 = STREAM_DISABLE
3	RO	X	SLOM: Setup Lockout Mode: In device mode, this bit controls the behavior of the setup lockout mechanism. 0 - Setup lockout is ON (default) 1 Setup lockout is OFF. Firmware requires the use of setup tripwire semaphore in USB2D_USBCMD register. 0 = LOCKOUT_ON 1 = LOCKOUT_OFF
2	RO	X	ES: Endian Select: Note: For this implementation, this should be always set to 0 (little endian). 0 = LITTLE_ENDIAN 1 = RESERVED

Bit	R/W	Reset	Description
1:0	RO	X	CM: Controller Mode: The controller mode will default to an idle state and will need to be initialized to the desired operating mode after reset. This register can only be written once after reset. If it is necessary to switch modes, software must reset the controller by writing to the RESET bit in the USBCMD register before reprogramming this register. 00 = Idle [Default] 01 = Reserved 10 = Device Controller 11 = Host Controller 0 = IDLE 1 = RESERVED 2 = DEVICE_MODE 3 = HOST_MODE

21.5.4.29 USB2_CONTROLLER_1_USB2D_ENDPTNAK_0

USB2D Endpoint NAK register

Offset: 200h | Read/Write: R/W | Reset: 0b00000000000000000000000000000000

Bit	Reset	Description
31:16	0x0	EPTN: TX Endpoint NAK R/WC. Each TX endpoint has 1 bit in this field. The bit is set when the device sends a NAK handshake on a received IN token for the corresponding endpoint. 0 = CLEAR 1 = SET
15:0	0x0	EPRN: RX Endpoint NAK R/WC. Each RX endpoint has 1 bit in this field. The bit is set when the device sends a NAK handshake on a received OUT or PING token for the corresponding endpoint. 0 = CLEAR 1 = SET

21.5.4.30 USB2_CONTROLLER_1_USB2D_ENDPTNAK_ENABLE_0

USB2D Endpoint NAK Enable register

Offset: 204h | Read/Write: R/W | Reset: 0b00000000000000000000000000000000

Bit	Reset	Description
31:16	0x0	EPTNE: TX Endpoint NAK Enable R/W. Each bit is an enable bit for the corresponding TX Endpoint NAK bit. If this bit is set and the corresponding TX Endpoint NAK bit is set, the NAK Interrupt bit is set. 0 = DISABLE 1 = ENABLE
15:0	0x0	EPRNE: RX Endpoint NAK Enable R/W. Each bit is an enable bit for the corresponding RX Endpoint NAK bit. If this bit is set and the corresponding RX Endpoint NAK bit is set, the NAK Interrupt bit is set. 0 = DISABLE 1 = ENABLE

21.5.4.31 USB2_CONTROLLER_1_USB2D_ENDPTSETUPSTAT_0

USB2D Endpoint Setup Status Register

Offset: 208h | Read/Write: R/W | Reset: 0b0000000000000000

Bit	Reset	Description
15	0x0	ENDPTSETUPSTAT15: Endpoint 15 Setup Status: For every setup transaction that is received, this bit is set to 1. Software must clear or acknowledge the setup transfer by writing a 1 to it after it has read the setup data from Queue head. The response to a setup packet (as in the order of operations and total response time) is crucial to limit bus time-outs while the setup lock-out mechanism is engaged. This register is only used in device mode. 0 = NOT_RCVD 1 = SETUP_RCVD

21.5.4.34 USB2_CONTROLLER_1_USB2D_ENDPTSTATUS_0

USB2D Endpoint Status Register

Offset: 214h | Read/Write: RO | Reset: 0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx

Bit	Reset	Description
31	X	ETBR15: Endpoint Transmit Buffer Ready: One bit for each endpoint indicates status of the respective endpoint buffer. This bit is set to a one by the hardware as a response to receiving a command from a corresponding bit in the ENDPTPRIME register. There will always be a delay between setting a bit in the ENDPTPRIME register and endpoint indicating ready. This delay time varies based upon the current USB traffic and the number of bits set in the ENDPTPRIME register. Buffer ready is cleared by USB reset, by the USB DMA system, or through the ENDPTFLUSH register. This is only used in device mode. 0 = NOT_READY 1 = READY
30	X	ETBR14: Endpoint Transmit Buffer Ready: One bit for each endpoint indicates status of the respective endpoint buffer. This bit is set to a one by the hardware as a response to receiving a command from a corresponding bit in the ENDPTPRIME register. There will always be a delay between setting a bit in the ENDPTPRIME register and endpoint indicating ready. This delay time varies based upon the current USB traffic and the number of bits set in the ENDPTPRIME register. Buffer ready is cleared by USB reset, by the USB DMA system, or through the ENDPTFLUSH register. This is only used in device mode. 0 = NOT_READY 1 = READY
29	X	ETBR13: Endpoint Transmit Buffer Ready: One bit for each endpoint indicates status of the respective endpoint buffer. This bit is set to a one by the hardware as a response to receiving a command from a corresponding bit in the ENDPTPRIME register. There will always be a delay between setting a bit in the ENDPTPRIME register and endpoint indicating ready. This delay time varies based upon the current USB traffic and the number of bits set in the ENDPTPRIME register. Buffer ready is cleared by USB reset, by the USB DMA system, or through the ENDPTFLUSH register. This is only used in device mode. 0 = NOT_READY 1 = READY
28	X	ETBR12: Endpoint Transmit Buffer Ready: One bit for each endpoint indicates status of the respective endpoint buffer. This bit is set to a one by the hardware as a response to receiving a command from a corresponding bit in the ENDPTPRIME register. There will always be a delay between setting a bit in the ENDPTPRIME register and endpoint indicating ready. This delay time varies based upon the current USB traffic and the number of bits set in the ENDPTPRIME register. Buffer ready is cleared by USB reset, by the USB DMA system, or through the ENDPTFLUSH register. This is only used in device mode. 0 = NOT_READY 1 = READY

21.5.5 USB2 Controller Interface Registers

These are used to generate the actual RTL registers for USB2 controller interface.

ULPIS2S resets to be used as follows:

- Assert ULPIS2S_SLV0_CLAMP_XMIT to ensure that the signals between SLV0 and the line simulator are clean.
- Assert ULPIS2S_SLV0_RESET
- Do a functional asynchronous reset of the ChipIdea controller

- Deassert ULPIS2S_SLV0_RESET
- Deassert ULPIS2S_SLV0_CLAMP_XMIT

NULPI_SLV1_RESET should be used in the same way if there is some explicit way to reset the external ULPI controller (which is not necessarily the case.) There is usually no reason whatsoever to assert ULPIS2S_LINE_RESET.

21.5.5.1 USB2_IF_USB_SUSP_CTRL_0

This register controls the suspend and reusume behavior of USB controller/PHY.

USB suspend control register

Offset: 400h | Read/Write: R/W | Reset: 0b00111110000x1001000xx000000

Bit	R/W	Reset	Description
26	RW	0x0	FAST_WAKEUP_RESP: Enable Fast Response from UTMIP PHY for a Remote Wakeup request from device. This is used only for cases where wakeup response needs to be within 1ms of spec. Used for Host mode ONLY. 0 = DISABLE 1 = ENABLE
25	RW	0x0	UTMIP_SUSPL1_SET: Enable SuspendL1 for UTMIP PHY Enabling this will only cutoff clocks to the utmip logic. The USB plls, PllU and UTMIP PLL will still be running. 0 = DISABLE 1 = ENABLE
24	RW	0x1	ULPI_PADS_CLKEN_RESET: Async reset for the synchronizers that are used in the external and loopback ULPI 60 MHz clock. 0 = DISABLE 1 = ENABLE
23	RW	0x1	ULPI_PADS_RESET: Async reset for trimmers and line state logic that's implemented in the pad macros. 0 = DISABLE 1 = ENABLE
22	RW	0x1	ULPIS2S_LINE_RESET: Async reset of the line simulator logic that sits between the two virtual PHYs (active high). The ULPI PHY registers should be programmed while ULPI is in reset. 0 = DISABLE 1 = ENABLE
21	RW	0x1	ULPIS2S_SLV1_RESET: Async reset of the SLV1 ULPI logic. This corresponds to resetting the virtual PHY that is connected to the internal ULPI controller (active high). The ULPI PHY registers should be programmed while ULPI is in reset. 0 = DISABLE 1 = ENABLE
20	RW	0x1	ULPIS2S_SLV0_RESET: Async reset of the SLV0 ULPI logic. This corresponds to resetting the virtual PHY that is connected to the external ULPI controller. (active high). The ULPI PHY registers should be programmed while ULPI is in reset. 0 = DISABLE 1 = ENABLE
19	RW	0x0	UHSIC_PHY_ENB: Enable UHSIC PHY mode. Set this to 1 if using UHSIC PHY. Otherwise set this to 0. 0 = DISABLE 1 = ENABLE
18:16	RW	0x0	USB_WAKEUP_DEBOUNCE_COUNT: USB PHY wakeup debounce counter USB will debounce any wakeup event by the number of clocks programmed in this counter. A value of 0 results in no debounce.
14	RW	0x1	UHSIC_RESET: Reset going to UHSIC PHY (active high). This should be set to 1 whenever programming the UHSIC config registers. It should be cleared to 0 after the programming of UHSIC config registers is done. UHSIC config registers should be programmed only once before doing any transactions on UHSIC. The UHSIC PHY registers should be programmed while

Bit	R/W	Reset	Description
			UHSIC is in reset. 0 = DISABLE 1 = ENABLE
13	RW	0x0	ULPI_PHY_ENB: Enable ULPI PHY mode. Set this to 1 if using null or link ULPI PHY. Otherwise set this to 0. 0 = DISABLE 1 = ENABLE
12	RW	0x0	UTMIP_PHY_ENB: Enable UTMIP PHY mode Set this to 1 if using UTMIP PHY. Otherwise set this to 0. 0 = DISABLE 1 = ENABLE
11	RW	0x1	UTMIP_RESET: Reset going to UTMIP PHY (active high). This should be set to 1 whenever programming the UTMIP config registers. It should be cleared to 0 after the programming of UTMIP config registers is done. UTMIP config registers should be programmed only once before doing any transactions on UTMIP. The UTMIP PHY registers should be programmed while UTMIP is in reset. 0 = DISABLE 1 = ENABLE
10	RW	0x0	USB_SUSP_POL: Polarity of the suspend signal going to UHSIC PHY. 0 = Active low (default) 1 = Active high This should not be changed by software. 0 = ACTIVE_LOW 1 = ACTIVE_HIGH
9	RW	0x0	USB_PHY_CLK_VALID_INT_ENB: USB PHY clock valid interrupt enable. If this bit is enabled, interrupt is generated whenever USB clocks are resumed from a suspend. 0 = DISABLE 1 = ENABLE
8	RO	0x0	USB_PHY_CLK_VALID_INT_STS: USB PHY clock valid interrupt status. This bit is set whenever USB PHY clock is waked up from suspend. Software must write a 1 to clear this bit. 0 = UNSET 1 = SET
7	RO	X	USB_PHY_CLK_VALID: USB PHY clock valid status. This bit indicates whether the USB PHY is generating a valid clock to the USB controller. If USB PHY clock is running, this bit is set to 1, else it is set to 0. 0 = UNSET 1 = SET
6	RO	X	USB_CLKEN: USB AHB clock enable status. Indicates whether the AHB clock to the USB controller is enabled or not. If AHB clock to USB controller is enabled, this bit is set to 1, else it is set to 0. NOTE: even when this is set to 0, all essential blocks that are required to resume USB clocks from suspend will be active and their AHB clock will not be suspended. 0 = UNSET 1 = SET
5	RW	0x0	USB_SUSP_CLR: Suspend Clear Software must write a 1 to this bit to bring the PHY out of suspend mode. This is used when the software stops the PHY clock during suspend and then wants to initiate a resume. Software should also write 0 to clear it. NOTE: It is required that software generate a positive pulse on this bit to guarantee proper operation. 0 = UNSET 1 = SET
4	RW	0x0	USB_WAKE_ON_DISCON_EN_DEV: Wake on Disconnect Enable (device mode) When enabled (1), USB device will wakeup from suspend on a disconnect event. This is only valid when USB controller is in device mode, it is not applicable when USB controller is in host mode. 0 = DISABLE 1 = ENABLE
3	RW	0x0	USB_WAKE_ON_CNNT_EN_DEV: Wake on Connect Enable (device mode) When enabled (1), USB device will wakeup from suspend on a connect event. This is only valid when USB controller is in device mode, it is not applicable when USB controller is in host mode. 0 = DISABLE 1 = ENABLE

Bit	R/W	Reset	Description
2	RW	0x0	USB_WAKE_ON_RESUME_EN: Wake on resume enable. If this bit is enabled, USB will wakeup from suspend whenever a resume event is detected on USB. This is valid for both USB device and USB host modes. 0 = DISABLE 1 = ENABLE
1	RW	0x0	USB_WAKEUP_INT_ENB: USB wakeup interrupt enable. If this bit is enabled, interrupt is generated whenever USB wakeup event is generated. 0 = DISABLE 1 = ENABLE
0	RO	0x0	USB_WAKEUP_INT_STS: USB wakeup interrupt status. This bit is set whenever USB wakes up from suspend (a wakeup event is generated). Software must write a 1 to clear this bit. Note that during the wakeup sequence, PHY clocks will be resumed from suspend. Software can check when the PHY clocks are resumed by reading the bit USB_PHY_CLK_VALID. There is also a separate interrupt generated when PHY clock is resumed if USB_PHY_CLK_VALID_INT_EN is set. During the wakeup sequence, first USB_WAKEUP_INT_STS will be set, and it will take some time for the PHY clock to resume, which can be detected by checking USB_PHY_CLK_VALID. 0 = UNSET 1 = SET

21.5.5.2 USB2_IF_USB_PHY_VBUS_SENSORS_0

USB PHY VBUS SENSORS control register

This register controls the OTG VBUS sensors in the USB PHY. We have the following 4 VBUS sensors:

- A_VBUS_VLD
- A_SESS_VLD
- B_SESS_VLD
- B_SESS_END

The debounced status of each sensor can be read from _STS. The field _CHG_DET is set to 1 whenever a change is detected in the value of. If _INT_EN is set, then an interrupt is generated to the processor. This interrupt can be routed to CPU/COP by appropriately writing the USBD bits in the interrupt controller registers.

In case Software wants to override the value for a , it can set _SW_EN to 1, and set _SW_VALUE to 1 or 0 as per the requirement.

We have two debouncers for each sensor - DEBOUNCE_A and DEBOUNCE_B. The debounce values for them are controlled by the register UTMIP_DEBOUNCE_CFG0, fields UTMIP_BIAS_DEBOUNCE_A and UTMIP_BIAS_DEBOUNCE_B. For each sensor, we can select whether to use DEBOUNCE_A or DEBOUNCE_B by setting the field _DEB_SEL_B to apprORpriate value (SEL_A or SEL_B).

Note: Do not set either UTMIP_BIAS_DEBOUNCE_A or UTMIP_BIAS_DEBOUNCE_B to 0x0. If not using one of the debouncers, keep it at the default value of 0xFFFF.

Note: The source for A_SESS_VLD sensor can be programmed according to the setting of USB1_VBUS_SENSE_CTL in register USB1_LEGACY_CTRL.

0	RW	0x0	B_SESS_END_INT_EN: B_SESS_END interrupt enable. If this field is set to 1, an interrupt is generated whenever B_SESS_END_CHG_DET is set to 1. 0 = DISABLE 1 = ENABLE

21.5.5.3 USB2_IF_USB_PHY_VBUS_WAKEUP_ID_0

USB PHY VBUS wakeup and ID control register

This register controls the battery charger (VDCD_DET, VDAT_DET), VBUS_WAKEUP and ID sensors. We have the following sensors in this register:

- VBUS_WAKEUP
- ID
- VDAT_DET
- VDCD_DET

The debounced status of each sensor can be read from _STS. The field _CHG_DET is set to 1 whenever a change is detected in the value of. If _INT_EN is set, then an interrupt is generated to the processor. This interrupt can be routed to CPU/COP by appropriately writing the USBD bits in the interrupt controller registers.

In case Software wants to override the value for a , it can set _SW_EN to 1, and set _SW_VALUE to 1 or 0 as per the requirement.

We have two debouncers for each sensor - DEBOUNCE_A and DEBOUNCE_B. The debounce values for them are controlled by the register UTMIP_DEBOUNCE_CFG0, fields UTMIP_BIAS_DEBOUNCE_A and UTMIP_BIAS_DEBOUNCE_B. For each sensor, we can select whether to use DEBOUNCE_A or DEBOUNCE_B by setting the field _DEB_SEL_B to approrpriate value (SEL_A or SEL_B).

> **Note:** Do not set either UTMIP_BIAS_DEBOUNCE_A or UTMIP_BIAS_DEBOUNCE_B to 0x0. If not using one of the debouncers, keep it at the default value of 0xFFFF.

There are debouncers for VDAT_DET and VDCD_DET. These use separate debouncers - CHRG_DEBOUNCE_PERIOD_A and CHRG_DEBOUNCE_PERIOD_B. The debounce values for them are controlled by the register UTMIP_CHRG_DEB_CFG0, fields UTMIP_CHRG_DEBOUNCE_PERIOD_A and UTMIP_CHRG_DEBOUNCE_PERIOD_B. For each sensor, we can select whether to use CHRG_DEBOUNCE_PERIOD_A or CHRG_DEBOUNCE_PERIOD_B by setting the field _DEB_SEL_B to appropriate value (SEL_A or SEL_B).

> **Note:** Do not set either UTMIP_CHRG_DEBOUNCE_PERIOD_A or UTMIP_CHRG_DEBOUNCE_PERIOD_B to 0x0. If not using one of the debouncers, keep it at the default value of 0xFFFF.

Bit	R/W	Reset	Description
30	RW	0x0	VBUS_WAKEUP_WAKEUP_EN: VBUS_WAKEUP wakeup enable. If this bit is enabled, USB will wakeup from suspend whenever a change is detected on VBUS_WAKEUP. 0 = DISABLE 1 = ENABLE
29	RW	0x0	VDCD_DET_DEB_SEL_B: VCDT_DET debounce A/B select. Selects the debounce value from UTMIP_CHRG_DEBOUNCE_PERIOD_A or UTMIP_CHRG_DEBOUNCE_PERIOD_B from the

Bit	R/W	Reset	Description
			register UTMIP_CHRG_DEB_CFG0. 0 = SEL_A 1 = SEL_B
28	RW	0x0	VDCD_DET_SW_VALUE: VDCD_DET software value. Software should write the appropriate value (1/0) to set/unset the VDCD_DET status. This is only valid when VDCD_DET_SW_EN is set. 0 = UNSET 1 = SET
27	RW	0x0	VDCD_DET_SW_EN: VDCD_DET software enable. Enable Software Controlled VDCD_DET. Software sets this bit to drive the value in VDCD_DET_SW_VALUE to the USB controller 0 = DISABLE 1 = ENABLE
26	RO	X	VDCD_DET_STS: VDCD_DET status. This is set to 1 whenever VDCD_DET sensor output is 1. 0 = UNSET 1 = SET
25	RO	0x0	VDCD_DET_CHG_DET: VDCD_DET change detect. This field is set by hardware whenever a change is detected in the value of VDCD_DET. software writes a 1 to clear it 0 = UNSET 1 = SET
24	RW	0x0	VDCD_DET_INT_EN: VDCD_DET interrupt enable. If this field is set to 1, an interrupt is generated whenever VDCD_DET_CHG_DET is set to 1. 0 = DISABLE 1 = ENABLE
21	RW	0x0	VDAT_DET_DEB_SEL_B: VDAT_DET debounce A/B select. Selects between the two debounce values UTMIP_CHRG_DEBOUNCE_PERIOD_A or UTMIP_CHRG_DEBOUNCE_PERIOD_B from the register UTMIP_DEBOUNCE_CFG0. 0 = SEL_A 1 = SEL_B
20	RW	0x0	VDAT_DET_SW_VALUE: VDAT_DET software value. Software should write the appropriate value (1/0) to set/unset the VDAT_DET status. This is only valid when VDAT_DET_SW_EN is set. 0 = UNSET 1 = SET
19	RW	0x0	VDAT_DET_SW_EN: VDAT_DET software enable. Enable Software Controlled VDAT_DET. Software sets this bit to drive the value in VDAT_DET_SW_VALUE to the USB controller 0 = DISABLE 1 = ENABLE
18	RO	X	VDAT_DET_STS: VDAT_DET status. This is set to 1 whenever VDAT_DET sensor output is 1. 0 = UNSET 1 = SET
17	RO	0x0	VDAT_DET_CHG_DET: VDAT_DET change detect. This field is set by hardware whenever a change is detected in the value of VDAT_DET. software writes a 1 to clear it 0 = UNSET 1 = SET
16	RW	0x0	VDAT_DET_INT_EN: VDAT_DET interrupt enable. If this field is set to 1, an interrupt is generated whenever VDAT_DET_CHG_DET is set to 1. 0 = DISABLE 1 = ENABLE
13	RW	0x0	VBUS_WAKEUP_DEB_SEL_B: VBUS_WAKEUP debounce A/B select. Selects between the two debounce values UTMIP_BIAS_DEBOUNCE_A or UTMIP_BIAS_DEBOUNCE_B from the register UTMIP_DEBOUNCE_CFG0. 0 = SEL_A 1 = SEL_B
12	RW	0x0	VBUS_WAKEUP_SW_VALUE: VBUS wakeup software value. Software should write the appropriate value (1/0) to set/unset the VBUS_WAKEUP status. This is only valid when VBUS_WAKEUP_SW_EN is set. 0 = UNSET

Bit	R/W	Reset	Description
			1 = SET
11	RW	0x0	VBUS_WAKEUP_SW_EN: VBUS wakeup software enable. Enable Software Controlled VBUS_WAKEUP. Software sets this bit to drive the value in VBUS_WAKEUP_SW_VALUE to the USB controller. 0 = DISABLE 1 = ENABLE
10	RO	X	VBUS_WAKEUP_STS: VBUS wakeup status. This is set to 1 whenever VBUS_WAKEUP sensor output is 1. 0 = UNSET 1 = SET
9	RO	0x0	VBUS_WAKEUP_CHG_DET: VBUS wakeup change detect. This field is set by hardware whenever a change is detected in the value of VBUS_WAKEUP. software writes a 1 to clear it 0 = UNSET 1 = SET
8	RW	0x0	VBUS_WAKEUP_INT_EN: VBUS wakeup interrupt enable. If this field is set to 1, an interrupt is generated whenever VBUS_WAKEUP_CHG_DET is set to 1. 0 = DISABLE 1 = ENABLE
7	RO	X	STATIC_GPI: Static GPI status 0 = UNSET 1 = SET
6	RW	0x1	ID_PU: ID pullup enable. Set to 1. 0 = DISABLE 1 = ENABLE
5	RW	0x0	ID_DEB_SEL_B: ID debounce A/B select. Selects between the two debounce values UTMIP_BIAS_DEBOUNCE_A or UTMIP_BIAS_DEBOUNCE_B from the register UTMIP_DEBOUNCE_CFG0. 0 = SEL_A 1 = SEL_B
4	RW	0x0	ID_SW_VALUE: ID software value. Software should write the appropriate value (1/0) to set/unset the ID status. This is only valid when ID_SW_EN is set. 0 = UNSET 1 = SET
3	RW	0x0	ID_SW_EN: ID software enable. Enable Software Controlled ID. Software sets this bit to drive the value in ID_SW_VALUE to the USB controller 0 = DISABLE 1 = ENABLE
2	RO	X	ID_STS: ID status. This is set to 1 whenever ID sensor output is 1. 0 = UNSET 1 = SET
1	RO	0x0	ID_CHG_DET: ID change detect. This field is set by hardware whenever a change is detected in the value of ID. software writes a 1 to clear it 0 = UNSET 1 = SET
0	RW	0x0	ID_INT_EN: ID interrupt enable. If this field is set to 1, an interrupt is generated whenever ID_CHG_DET is set to 1. 0 = DISABLE 1 = ENABLE

21.5.5.4 USB2_IF_USB_PHY_ALT_VBUS_STS_0

USB PHY Alternate VBUS status register

Offset: 40ch | Read/Write: RO | Reset: 0bxxxxxxxxx

Bit	Reset	Description
8	X	VDCD_DET_ALT: VDCD_DET alternate status 0 = UNSET 1 = SET
7	X	VDAT_DET_ALT: VDAT_DET alternate status 0 = UNSET 1 = SET
6	X	A_SESS_VLD_ALT: A_SESS_VLD alternate status 0 = UNSET 1 = SET
5	X	B_SESS_VLD_ALT: B_SESS_VLD alternate status 0 = UNSET 1 = SET
4	X	ID_DIG_ALT: ID alternate status 0 = UNSET 1 = SET
3	X	B_SESS_END_ALT: B_SESS_END alternate status 0 = UNSET 1 = SET
2	X	STATIC_GPI_ALT: Static GPI alternate status 0 = UNSET 1 = SET
1	X	A_VBUS_VLD_ALT: A_VBUS_VLD alternate status 0 = UNSET 1 = SET
0	X	VBUS_WAKEUP_ALT: Vbus wakeup alternate status 0 = UNSET 1 = SET

21.5.5.5 USB2_IF_USB_ULPIS2S_CTRL_0

This register is used to setup parameters for ULPI null PHY mode.

Note: Current ULPI configuration registers use settings that support NV software drivers and should NOT be modified. If designing custom drivers, consult your NV representative prior to modifying these registers

ULPI NULL PHY control register

Offset: 418h | Read/Write: R/W | Reset: 0b0000xx0000000000xxxx0000

Bit	Reset	Description
23:20	0x0	ULPIS2S_CLAMP_LINE_DRIVE: The line drive value that should be sent into the line simulator during xmit clamping. The suggested value is 0x1: tri-state.
17	0x0	ULPIS2S_SLV1_CLAMP_XMIT: When set to 1, the outputs of the SLV1 xmit statemachine are clamped to 0. This bit should be set before the SLV0 async reset is asserted to prevent meta-stability issues in the line simulator.
16	0x0	ULPIS2S_SLV0_CLAMP_XMIT: When set to 1, the outputs of the SLV0 xmit statemachine are clamped to 0. This bit should be set before the SLV0 async reset is asserted to prevent meta-stability issues in the line simulator.
15	0x0	ULPIS2S_DISABLE_STP_PU: When set to 1 and in ULPIS2S mode, the pullup on the STP pin will NOT be active, even if the remote LINK asks to do so. In this case, an external pullup resistor would be required to ensure valid levels when the remote link is not powered.

Bit	Reset	Description
14	0x0	ULPIS2S_SUPPORT_HS_KEEP_ALIVE: When enabled, the PHY will support HS KeepAlive packets. In that case, this would be the only thing that's supported in Opmode3. All other Opmode3 generate packets are not supported under any circumstances. 0 = DISABLE 1 = ENABLE
13	0x0	ULPIS2S_DISCON_DONT_CHECK_SE0: When enabled, the disconnect detection logic will only check that that the other side is 'driving' tri-state. It won't check whether or not the local side is driving SE0. 0 = DISABLE 1 = ENABLE
12	0x0	ULPIS2S_FORCE_ULPI_CLK_OUT: When enabled and ULPIS2S_ENA is ENABLED, the external ULPI_CLOCK pad will always carry the internal 60MHz clock, even if the interface is in shutdown mode. 0 = DISABLE 1 = ENABLE
11:8	0x0	ULPIS2S_SPARE: Reserved bits bit 0: Vbus. Set to 1 to set the Vbus State field to 2'b11 in the RxCmd byte. bit 1: IdGnd. Set to 1 to set the ID field to 1'b1 in the RxCmd byte.
3	0x0	ULPIS2S_PLLU_MASTER_BLASTER60: When enabled, the PLLU 60MHz clock will be forced on. 0 = DISABLE 1 = ENABLE
2	0x0	ULPIS2S_SUPPORT_DISCONNECT: When disabled, the PHY will never detect a Disconnect. 0 = DISABLE 1 = ENABLE
1	0x0	ULPIS2S_SLV1_FORCE_DEVICE: When disabled, the slave port that's connected to the pins can be programmed to be host or a device depending on the value of the DpPulldown and DmPulldown bits in the OTG_CTRL ULPI register. When enables, the values of those bits in the OTG_CTRL register is ignored and the port will always behave like a device. 0 = DISABLE 1 = ENABLE
0	0x0	ULPIS2S_ENA: When enabled, the ULPI link interface coming out of the usb2 controller enters a NULL phy with two slaves. As a result the external pins will have a slave ULPI interface. When disabled, the ULPI link interface coming out of the usb2 controller go straight to the pins. 0 = DISABLE 1 = ENABLE

21.5.5.6 USB2_IF_USB_ULPIS2S_SLV1_ID_0

This register controls the product and vendor ID fields for ULPI null PHY presented to external ULPI master.

Note: Current ULPI configuration registers use settings that support NV software drivers and should NOT be modified. If designing custom drivers, consult your NV representative prior to modifying these registers

Offset: 41ch | Read/Write: R/W | Reset: 0b00000000000000000000000000000000

Bit	Reset	Description
31:16	0x0	ULPIS2S_SLV1_VENDOR_ID: PHY vendor_id as seen by external ULPI master
15:0	0x0	ULPIS2S_SLV1_PRODUCT_ID: PHY product_id as seen by external ULPI master

21.5.5.7 USB2_IF_USB_INTER_PKT_DELAY_CTRL_0

Inter packet delay control.

This controls the interpacket delay between two consecutive transmit packets in HS mode. This only applies to host mode as device never transmits two packets in a row.

Offset: 420h | Read/Write: R/W | Reset: 0b010010

Bit	Reset	Description
5:0	0x12	IP_DELAY_TX2TX_HS: HS Tx to Tx inter-packet delay. This is valid only for UHSIC PHY. Software should not change this.

21.5.5.8 USB2_IF_USB_RSM_DLY_0

USB Controller Resume Signalling Delay

Offset: 490h | Read/Write: R/W | Reset: 0b0110100101111000

Bit	Reset	Description
15:0	0x6978	TIME_TO_RESUME: Send the resume back in no. of 60 MHz cycles. Default gives 900 usec delay. Only applicable in host mode.

21.5.5.9 USB2_IF_SPARE_0

For ICUSB PADCTLS

Spare Register

Offset: 498h | Read/Write: R/W | Reset: 0b11111111111111110000000000000000

Bit	Reset	Description
31:16	0xffff	SPARE_HI: Spare register bits, defaulted to 1
15:0	0x0	SPARE_LO: Spare register bits, defaulted to 0. SPARE_LO[4] - usb_hs_rsm_eop_fix_en, Enable HS_RESUME EOP fix.

21.5.6 USB 2 UTMIP Configuration Registers

Note: Current UTMIP configuration registers use settings that support NV software drivers and should NOT be modified. If designing custom drivers, consult your NV representative prior to modifying these registers

21.5.6.1 USB2_UTMIP_PLL_CFG0_0

USB_PHY PLL Configuration Register 0 The data sampling frequency relies on a 960MHz clock, so the goal of the PLL is to have: In_Frequency*(PLL_VCOMULTBY2+1)*(PLL_NDIV/PLL_MDIV) = 960MHz With a 12MHz input from PLL_U, the default setting of PLL_VCOMULTBY2=1, PLL_NDIV=40 and PLL_MDIV=1 results in a correct output.

Note: This register has been moved to the CAR Section of this document. PROGRAMMING THIS REGISTER HERE WILL HAVE NO EFFECT WHATSOEVER !!!

This register was used to configure PLL inside UTMIP block prior to Tegra 3. This has been de-featured from utmip space and moved to car space.

This register is used to configure the PHY PLL contained in the UTMIP module.

Offset: 800h | Read/Write: R/W | Reset: 0b00000000010100000000000110000000

Bit	Reset	Description
30:28	0x0	UTMIP_PLL_SELECT: Selects which of the eight 60MHz clock phases to produce at the output of the USB PHY PLL. This is for a test mode. See cell specification.
27	0x0	UTMIP_PLL_PDIVRST: PDIVRST of the UTMIP PHY PLL. Reserved. Keep at 0x0. Currently there is no post divider on this PLL. See cell specification.

Bit	Reset	Description
26:24	0x0	UTMIP_PLL_PDIV: PDIV[2:0] input of the USB_PHY PLL. Reserved. Keep at 0x0. Currently there is no post divider on this PLL. See cell specification.
23:16	0x28	UTMIP_PLL_NDIV: NDIV[7:0] input of USB_PHY PLL. This is the feedback divider on the VCO feedback. 0x0 is not allowed. See cell specification.
15:8	0x1	UTMIP_PLL_MDIV: MDIV[7:0] input of the USB_PHY PLL. This is the predivide on the PLL. 0x0 is not allowed. See cell specification.
7	0x1	UTMIP_PLL_VCOMULTBY2: VCOMULTBY2 control of the UTMIP PHY PLL. Recommended setting is on. Additional divide by 2 on the VCO feedback. Which is setting the bit to 1. See cell spec.
6:1	0x0	UTMIP_PLL_LOCKSEL: LOCKSEL[5:0] input of USB_PHY PLL. Used in test modes only. See cell specification.
0	0x0	UTMIP_PLL_LOCKENABLE: LOCK_ENABLE input of USB_PHY PLL. Normally only used during test. See cell specification.

21.5.6.2 USB2_UTMIP_PLL_CFG1_0

UTMIP PLL and PLLU configuration register 1

Note: This register has been moved to the CAR Section of this document. PROGRAMMING THIS REGISTER HERE WILL HAVE NO EFFECT WHATSOEVER !!!

This register was used to configure PLL inside UTMIP block prior to Tegra 3. This has been de-featured from UTMIP space and moved to CAR space.

PLL CONFIGURATION & PARAMETERS

In normal operation, the following clock generators are in play for USB:

Xtal clock -> enters PLL_U to generate 12MHz clock -> enters USB_PHY PLL to generate 480/60 MHz clock

The following parameters control the bringup of the plls:

Coming out of reset or suspend

- -> PllUOnState: start pllu_enable_count and pll_lock_count
- -> Wait ~1us to actually enable the PLL_U (pllu_enable_count == ClkXtal * PLLU_ENABLE_DLY_COUNT * 8)
- -> Wait ~1ms until PLL_U is actually stable (pll_lock_count == ClkXtal * PLLU_STABLE_COUNT * 256) => USB_PHY PLL_ENABLE

pll_active_count = 0

- -> Wait 5us to enable pll_active: pll_active_count == ClkXtal * PLL_ACTIVE_DLY_COUNT * 16 => USB_PHY PLL_ACTIVE
- -> Wait ~2.5ms until USB_PHY is actually stable (pll_lock_count == ClkXtal * XTAL_FREQ_COUNT * 256) => USB_PHY

Numbers for a 19.2MHz Xtal clock

- PLLU_ENABLE_DLY_COUNT[4:0] = 1 * 19.2 / 8 = 2.4 = 3 = 0x03
- PLLU_STABLE_COUNT[11:0] = 1000 * 19.2 / 256 = 75 = 0x4b (Note: currently defaults to 0x600)
- PLL_ACTIVE_DLY_COUNT[4:0] = 5 * 19.2 / 16 = 6 = 0x06
- XTAL_FREQ_COUNT[11:0] = 2500 * 19.2 / 256 = 187 = 0xbb

Offset: 804h | Read/Write: R/W | Reset: 0b00011000001000000000000011000000

Bit	Reset	Description
31:27	0x3	UTMIP_PLLU_ENABLE_DLY_COUNT: Controls the wait time to enable PLL_U when coming out of suspend or reset.
26:18	0x8	UTMIP_PLL_SETUP: SETUP[8:0] input of USB_PHY PLL.
17	0x0	UTMIP_FORCE_PLLU_POWERUP: Force PLL_U into power up.
16	0x0	UTMIP_FORCE_PLLU_POWERDOWN: Force PLL_U into power down. (Overrides FORCE_PLLU_POWERUP.)
15	0x0	UTMIP_FORCE_PLL_ENABLE_POWERUP: Force USB_PHY PLL pll_enable input on.
14	0x0	UTMIP_FORCE_PLL_ENABLE_POWERDOWN: Force USB_PHY PLL pll_enable input off. (Overrides FORCE_PLL_ENABLE_POWERUP.)
13	0x0	UTMIP_FORCE_PLL_ACTIVE_POWERUP: Force USB_PHY PLL pll_active input on.
12	0x0	UTMIP_FORCE_PLL_ACTIVE_POWERDOWN: Force USB_PHY PLL pll_active input off. (Overrides FORCE_PLL_ACTIVE_POWERUP.)
11:0	0xc0	UTMIP_XTAL_FREQ_COUNT: Determines the time to wait until the output of USB_PHY PLL is considered stable.

21.5.6.3 USB2_UTMIP_XCVR_CFG0_0

UTMIP transceiver cell configuration register 0

Offset: 808h | Read/Write: R/W | Reset: 0b00100000001001010110010100000000

Bit	Reset	Description
31:25	0x10	UTMIP_XCVR_HSSLEW_MSB: Most significant bits of HS_SLEW.
24:22	0x0	UTMIP_XCVR_SETUP_MSB: Most significant bits of SETUP.
21	0x1	UTMIP_XCVR_LSBIAS_SEL: Low speed bias selection method for usb transceiver pad
20	0x0	UTMIP_XCVR_DISCON_METHOD: Disconnect method on the usb transceiver pad
19	0x0	UTMIP_FORCE_PDZI_POWERUP: Force PDZI input into power up.
18	0x1	UTMIP_FORCE_PDZI_POWERDOWN: Force PDZI input into power down. (Overrides FORCE_PDZI_POWERUP.)
17	0x0	UTMIP_FORCE_PD2_POWERUP: Force PD2 input into power up.
16	0x1	UTMIP_FORCE_PD2_POWERDOWN: Force PD2 input into power down. (Overrides FORCE_PD2_POWERUP.)
15	0x0	UTMIP_FORCE_PD_POWERUP: Force PD input into power up.
14	0x1	UTMIP_FORCE_PD_POWERDOWN: Force PD input into power down. (Overrides FORCE_PD_POWERUP.)
13	0x1	UTMIP_XCVR_TERMEN: Enable HS termination.
12	0x0	UTMIP_XCVR_HSLOOPBACK: Internal loopback inside XCVR cell. Used for IOBIST.
11:10	0x1	UTMIP_XCVR_LSFSLEW: LS falling slew rate control.
9:8	0x1	UTMIP_XCVR_LSRSLEW: LS rising slew rate control.
7:6	0x0	UTMIP_XCVR_FSSLEW: FS slew rate control.

Bit	Reset	Description
5:4	0x0	UTMIP_XCVR_HSSLEW: HS slew rate control. The two LSBs.
3:0	0x0	UTMIP_XCVR_SETUP: SETUP[3:0] input of XCVR cell. HS driver output control. 4 LSBs.

21.5.6.4 USB2_UTMIP_BIAS_CFG0_0

UTMIP Bias cell configuration register 0

Offset: 80ch | Read/Write: R/W | Reset: 0b01100000000000110000000000

Bit	Reset	Description
24	0x0	UTMIP_HSDISCON_LEVEL_MSB: Most significant bit of UTMIP_HSDISCON_LEVEL, bit 2
23	0x1	UTMIP_IDPD_VAL: See IDPD_SEL.
22	0x1	UTMIP_IDPD_SEL: 0: Reserved. Refer to the PMC registers for this feature.
21	0x0	UTMIP_IDDIG_VAL: See IDDIG_SEL.
20	0x0	UTMIP_IDDIG_SEL: 0: IdDig = IdDig. 1: IdDig = IDDIG_VAL.
19	0x0	UTMIP_GPI_VAL: See GPI_SEL.
18	0x0	UTMIP_GPI_SEL: 0: StaticGpi = IdDig. 1: StaticGpi = GPI_VAL.
17:15	0x0	UTMIP_ACTIVE_TERM_OFFSET: Active termination control offset.
14:12	0x0	UTMIP_ACTIVE_PULLUP_OFFSET: Active 1.5K pullup control offset.
11	0x1	UTMIP_OTGPD: Power down OTG circuit.
10	0x1	UTMIP_BIASPD: Power down bias circuit.
9:8	0x0	UTMIP_VBUS_LEVEL_LEVEL: Vbus detector level.
7:6	0x0	UTMIP_SESS_LEVEL_LEVEL: SessionEnd detector level.
5:4	0x0	UTMIP_HSCHIRP_LEVEL: HS chirp detector level.
3:2	0x0	UTMIP_HSDISCON_LEVEL: HS disconnect detector level.
1:0	0x0	UTMIP_HSSQUELCH_LEVEL: HS squelch detector level.

21.5.6.5 USB2_UTMIP_HSRX_CFG0_0

UTMIP High speed receive config 0

Offset: 810h | Read/Write: R/W | Reset: 0b10010000101100101001101000000000

Bit	Reset	Description
31:30	0x2	UTMIP_KEEP_PATT_ON_ACTIVE: Keep the stay alive pattern on active
29	0x0	UTMIP_ALLOW_CONSEC_UPDN: Allow consecutive ups and downs on the bits, debug only, set to 0.
28	0x1	UTMIP_REALIGN_ON_NEW_PKT: Realign the inertia counters on a new packet
27:24	0x1	UTMIP_PCOUNT_UPDN_DIV: The number of (edges-1) needed to move the sampling point
23:21	0x3	UTMIP_SQUELCH_EOP_DLY: Limit the delay of the squelch at EOP time

Bit	Reset	Description
20	0x0	UTMIP_NO_STRIPPING: Do not strip incoming data
19:15	0xa	UTMIP_IDLE_WAIT: Number of cycles of idle to declare IDLE.
14:10	0xd	UTMIP_ELASTIC_LIMIT: Depth of elastic input store
9	0x0	UTMIP_ELASTIC_OVERRUN_DISABLE: Do not declare overrun errors until overflow of FIFO
8	0x0	UTMIP_ELASTIC_UNDERRUN_DISABLE: Do not declare underrun errors
7	0x0	UTMIP_PASS_CHIRP: When in Chirp Mode, allow chirp rx data through
6	0x0	UTMIP_PASS_FEEDBACK: Pass through the feedback, do not block it.
5:4	0x0	UTMIP_PCOUNT_INERTIA: Retime the path.
3:2	0x0	UTMIP_PHASE_ADJUST: Based on incoming edges and current sampling position, adjust phase
1	0x0	UTMIP_THREE_SYNCBITS: Sync pattern detection needs 3 consecutive samples instead of 4
0	0x0	UTMIP_USE4SYNC_TRAN: Require 4 sync pattern transitions (01) instead of 3

21.5.6.6 USB2_UTMIP_HSRX_CFG1_0

UTMIP High speed receive config 1

Offset: 814h | Read/Write: R/W | Reset: 0b010011

Bit	Reset	Description
5:1	0x9	UTMIP_HS_SYNC_START_DLY: How long to wait before start of sync launches RxActive
0	0x1	UTMIP_HS_ALLOW_KEEP_ALIVE: Allow Keep Alive packets

21.5.6.7 USB2_UTMIP_FSLSRX_CFG0_0

UTMIP full and Low speed receive config 0

Offset: 818h | Read/Write: R/W | Reset: 0b11111101010101001000010000101001

Bit	Reset	Description
31	0x1	UTMIP_FSLS_SE1_DRIBBLE_FILTER: One SE1, don't allow dribble
30	0x1	UTMIP_FSLS_SE1_FILTER: Filter SE1
29	0x1	UTMIP_FSLS_SERIAL_SE0_RCV
28:26	0x7	UTMIP_FSLS_UPR_DRIBBLE_SIZE: Do not allow <= dribble bits
25:23	0x2	UTMIP_FSLS_LWR_DRIBBLE_SIZE: Do not allow >= dribble bits
22	0x1	UTMIP_FSLS_EOP_ENDS_AT_SE0: Only look for transitioning out of EOP
21:16	0x14	UTMIP_FSLS_KCOUNT_MAX: Number of K bits in question
15	0x1	UTMIP_FSLS_KCOUNT_LIMIT: Limit the number of bit times a K can last
14	0x0	UTMIP_FSLS_ACTIVE_ON_FULL_SYNC: Require a full sync pattern to declare the data received
13:8	0x4	UTMIP_FSLS_IDLE_WAIT_MAX: 4 bits of of SEO should exceed the time limit

Bit	Reset	Description
7	0x0	UTMIP_FSLS_IDLE_WAIT_LIMIT: Enable the reset of the state machine on extended SE0
6:1	0x14	UTMIP_FSLS_IDLE_COUNT_MAX: 20 bits of idle should end the packet if FsLsIdleCountLimitCfg=1.
0	0x1	UTMIP_FSLS_IDLE_COUNT_LIMIT: Give up on packet if a long sequence of J

21.5.6.8 USB2_UTMIP_FSLSRX_CFG1_0

UTMIP full and Low speed receive config 1

Offset: 81ch | Read/Write: R/W | Reset: 0b01000100110011101000000000000

Bit	Reset	Description
26	0x0	UTMIP_EARLY_LINE_STATE_FILTER: Assumes line state filtering table is inclusive, not exclusive
25:23	0x4	UTMIP_LS_BOUNCE_LENGTH: Number of clock cycle of LS stable
22:17	0x13	UTMIP_LS_EXTRACTION_COUNT: Phase count on which LS bits are extracted
16:11	0xe	UTMIP_LS_EOP_START_COUNT: Number of SEO clock cycles to block bit extraction
10:5	0x20	UTMIP_LS_SE0_COUNT: Only for this number of 60MHz of SEO and Idle to end packet
4	0x0	UTMIP_LS_LENIENT_DRIBBLE: Allow for large dribble in low speed mode
3	0x0	UTMIP_FS_LENIENT_DRIBBLE: Allow for large dribble in full speed mode
2	0x0	UTMIP_FS_WEAK_SYNC: Only look for a KK pattern, instead of KJKK
1	0x0	UTMIP_FS_DEBOUNCE: Whether full speed uses debouncing
0	0x0	UTMIP_FS_EOP_LENGTH: Whether full speed EOP is determined within 3(0) or 4(1) 60MHz cycles

21.5.6.9 USB2_UTMIP_TX_CFG0_0

UTMIP transmit config signals

Offset: 820h | Read/Write: R/W | Reset: 0b00010000001000000000

Bit	Reset	Description
19	0x0	UTMIP_FS_PREAMBLE_J: output enable sends an initial J before sync pattern

21.5.6.12 USB2_UTMIP_DEBOUNCE_CFG0_0

UTMIP Avalid and Bvalid debounce

Debounce values IdDig, Avalid, Bvalid, VbusValid, VbusWakeUp, and SessEnd.

Each of these signals have their own debouncer and for each of those one out of 2 debouncing times can be chosen (BIAS_DEBOUNCE_A or BIAS_DEBOUNCE_B.)

The values of DEBOUNCE_A and DEBOUNCE_B are calculated as follows:

- 0xffff -> No debouncing at all
- ms = *1000 / (1/19.2MHz) / 4

So to program a 1 ms debounce for BIAS_DEBOUNCE_A, we have: BIAS_DEBOUNCE_A[15:0] = 1000 * 19.2 / 4 = 4800 = 0x12c0

Offset: 82ch | Read/Write: R/W | Reset: 0b11111111111111111111111111111111

Bit	Reset	Description
31:16	0xffff	UTMIP_BIAS_DEBOUNCE_B: simulation value -- Used for interrupts
15:0	0xffff	UTMIP_BIAS_DEBOUNCE_A: simulation value -- Used for interrupts

21.5.6.13 USB2_UTMIP_BAT_CHRG_CFG0_0

UTMIP battery charger configuration

Offset: 830h | Read/Write: R/W | Reset: 0b000000xx000001

Bit	Reset	Description
13:8	0x0	UTMIP_CHRG_DEBOUNCE_TIMESCALE: Debouncer time scaling, factor-1 to slow down debouncing by. So 0 is 1, 1 is 2, etc.
5	0x0	UTMIP_OP_I_SRC_EN
4	0x0	UTMIP_ON_SRC_EN
3	0x0	UTMIP_OP_SRC_EN

1	0x0	UTMIP_OP_SINK_EN
0	0x1	UTMIP_PD_CHRG: Power down charger circuit

21.5.6.14 USB2_UTMIP_SPARE_CFG0_0

Utmip spare configuration bits

Offset: 834h | Read/Write: R/W | Reset: 0b11111111111111110000000000000000

Bit	Reset	Description
31:0	-65536	UTMIP_SPARE: Spare register bits 0: HS_RX_IPG_ERROR_ENABLE 1: HS_RX_FLUSH_ALAP. Flush as late as possible 2: HS_RX_LATE_SQUELCH. Delay Squelch by 1 CLK480 cycle. 3: FUSE_SETUP_SEL. Select between regular CFG value and JTAG values for UX_SETUP 4: FUSE_TERM_RANGE_ADJ_SEL. Select between regular CFG value and JTAG values for UX_TERM_RANGE_ADJ 31 to 5: Reserved Note: 4:3 stand for using fused termination and setup value.

21.5.6.15 USB2_UTMIP_XCVR_CFG1_0

UTMIP transceiver cell configuration register 1

Offset: 838h | Read/Write: R/W | Reset: 0b00011000100000010000010101

Bit	Reset	Description
23:22	0x0	UTMIP_XCVR_SPARE: Spare bits for USB transceiver pad.
21:18	0x6	UTMIP_XCVR_TERM_RANGE_ADJ: Range adjustment on terminations.
17	0x0	UTMIP_RCTRL_SW_SET: Use a software override on RCTRL instead of automatic bias control
16:12	0x8	UTMIP_RCTRL_SW_VAL: Encoded value to use on RCTRL when software override is enabled, 0 to 16 only
11	0x0	UTMIP_TCTRL_SW_SET: Use a software override on TCTRL instead of automatic bias control
10:6	0x8	UTMIP_TCTRL_SW_VAL: Encoded value to use on TCTRL when software override is enabled, 0 to 16 only
5	0x0	UTMIP_FORCE_PDDR_POWERUP: Force PDDR input into power up.
4	0x1	UTMIP_FORCE_PDDR_POWERDOWN: Force PDDR input input into power down. (Overrides FORCE_PDDR_POWERUP.)
3	0x0	UTMIP_FORCE_PDCHRP_POWERUP: Force PDCHRP input into power up.
2	0x1	UTMIP_FORCE_PDCHRP_POWERDOWN: Force PDCHRP input input into power down. (Overrides FORCE_PDCHRP_POWERUP.)
1	0x0	UTMIP_FORCE_PDDISC_POWERUP: Force PDDISC input into power up.
0	0x1	UTMIP_FORCE_PDDISC_POWERDOWN: Force PDDISC input into power down. (Overrides FORCE_PDDISC_POWERUP.)

21.5.6.16 USB2_UTMIP_BIAS_CFG1_0

UTMIP Bias cell configuration register 1

Offset: 83ch | Read/Write: R/W | Reset: 0b00000000101101

Bit	Reset	Description
13:8	0x0	UTMIP_BIAS_DEBOUNCE_TIMESCALE: Debouncer time scaling, factor-1 to slow down debouncing by. So 0 is 1, 1 is 2, etc.
7:3	0x5	UTMIP_BIAS_PDTRK_COUNT: Control the BIAS cell power down lag. The lag should be 20us. For a Xtal clock of 13MHz it should be set a 5.
2	0x1	UTMIP_VBUS_WAKEUP_POWERDOWN: Force VBUS_WAKEUP input into power down. Reserved. Refer to the PMC registers for this feature.
1	0x0	UTMIP_FORCE_PDTRK_POWERUP: Force PDTRK input into power up.
0	0x1	UTMIP_FORCE_PDTRK_POWERDOWN: Force PDTRK input into power down. (Overrides FORCE_PDTRK_POWERUP.)

21.5.6.17 USB2_UTMIP_BIAS_STS0_0

UTMIP Bias cell status register 0

Offset: 840h | Read/Write: RO | Reset: 0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx

Bit	Reset	Description
31:16	X	UTMIP_TCTRL: Thermal encoding output from USB bias pad.
15:0	X	UTMIP_RCTRL: Thermal encoding output from USB bias pad.

21.5.6.18 USB2_UTMIP_CHRG_DEB_CFG0_0

UTMIP VDcd_Det and VDat_Det debounce

Debounce values VDcd_Det and VDat_Det

Each of these signals have their own debouncer and for each of those one out of 2 debouncing times can be chosen (CHRG_DEBOUNCE_PERIOD_A or CHRG_DEBOUNCE_PERIOD_B)

The values of DEBOUNCE_PERIOD_A and DEBOUNCE_PERIOD_B are calculated as follows:

- 0xffff -> No debouncing at all
- ms = *1000 / (1/19.2MHz) / 4

So to program a 1 ms debounce for CHG_DEBOUNCE_PERIOD, we have: CHG_DEBOUNCE_PERIOD[15:0] = 1000 * 19.2 / 4 = 4800 = 0x12c0

Offset: 844h | Read/Write: R/W | Reset: 0b11111111111111111111111111111111

Bit	Reset	Description
31:16	0xffff	UTMIP_CHRG_DEBOUNCE_PERIOD_B: simulation value -- Used for interrupts
15:0	0xffff	UTMIP_CHRG_DEBOUNCE_PERIOD_A: simulation value -- Used for interrupts

21.5.6.19 USB2_UTMIP_MISC_STS0_0

UTMIP MISC status reg

Offset: 848h | Read/Write: RO | Reset: 0bxxxxxxxxxxxxxxxxxxxxxxx

Bit	Reset	Description
21	X	UTMIP_FS_DRV_EN: Indicates when the controller is driving on the bus
20:0	X	UTMIP_SPARE_FUSES: Spare Fuses value, to keep the connections preserved

21.5.6.20 USB2_UTMIP_PMC_WAKEUP0_0

UTMIP PMC Wakeup value

Offset: 84ch | Read/Write: R/W | Reset: 0bx0

Bit	R/W	Reset	Description
1	RO	X	UTMIP_LINE_WAKEUP_EVENT_INT_STS: Indicates the status of the pmc wakeup event
0	RW	0x0	UTMIP_LINE_WAKEUP_EVENT_INT_ENB: Interrupt mask for the pmc wakeup event

21.5.7 UHSIC Configuration Registers

Note: Current HSIC configuration registers use settings that support NV software drivers and should NOT be modified. If designing custom drivers, consult your NV representative prior to modifying these registers

21.5.7.1 USB2_UHSIC_PLL_CFG0_0

UHSIC PHY PLL Configuration Register 0

This register is used to configure the PHY PLL contained in the UHSIC module.

Offset: c00h | Read/Write: R/W | Reset: 0b0

Bit	Reset	Description
0	0x0	UHSIC_PLL_SPARE: Reserved

21.5.7.2 USB2_UHSIC_PLL_CFG1_0

UHSIC PLL and PLLU configuration register 1

PLL CONFIGURATION & PARAMETERS

In normal operation, the following clock generators are in play for USB:

Xtal clock -> enters PLLU to generate 12MHz clock -> enters USB_PHY PLL to generate 480/60 MHz clock

The following parameters control the bringup of the plls:

Coming out of reset or suspend

- -> PllUOnState: start pllu_enable_count and pll_lock_count
- -> Wait ~1us to actually enable the PLLU (pllu_enable_count == ClkXtal * PLLU_ENABLE_DLY_COUNT * 8)
- -> Wait ~1ms until PLLU is actually stable (pll_lock_count == ClkXtal * PLLU_STABLE_COUNT * 256) => USB_PHY PLL_ENABLE

Number for a 19.2MHz Xtal clock

- PLLU_ENABLE_DLY_COUNT[4:0] = 1 * 19.2 / 8 = 2.4 = 3 = 0x03
- PLLU_STABLE_COUNT[11:0] = 1000 * 19.2 / 256 = 75 = 0x4b (Note: currently defaults to 0x600)
- XTAL_FREQ_COUNT[11:0] = 2500 * 19.2 / 256 = 187 = 0xbb

This register is used to configure the PHY PLL contained in the UHSIC module as well as the PLLU power up and down.

Offset: c04h | Read/Write: R/W | Reset: 0b00011000000011000000

Bit	Reset	Description
18:14	0x3	UHSIC_PLLU_ENABLE_DLY_COUNT: 1 us / (1/19.2MHz) = 19 / 8 = 2.36 = 3

12	0x0	UHSIC_FORCE_PLLU_POWERDOWN
11:0	0xc0	UHSIC_XTAL_FREQ_COUNT: 2.5ms / (1/19.2MHz) = 48000 / 256 = 187 = 0xBB

21.5.7.3 USB2_UHSIC_HSRX_CFG0_0

UHSIC High speed receive config 0

Offset: c08h | Read/Write: R/W | Reset: 0b00101001110000111000

Bit	Reset	Description
18	0x0	UHSIC_NO_STRIPPING: Do not strip incoming data
17:13	0xa	UHSIC_IDLE_WAIT: Number of cycles of idle to declare IDLE.
12:8	0xe	UHSIC_ELASTIC_OVERRUN_LIMIT
7	0x0	UHSIC_ELASTIC_OVERRUN_DISABLE: Do not declare overrun errors until overflow of FIFO
6:2	0xe	UHSIC_ELASTIC_UNDERRUN_LIMIT
1	0x0	UHSIC_ELASTIC_UNDERRUN_DISABLE: Do not declare underrun errors
0	0x0	UHSIC_PASS_FEEDBACK: Pass through the feedback, do not block it.

21.5.7.4 USB2_UHSIC_HSRX_CFG1_0

UHSIC High speed receive config 1

Offset: c0ch | Read/Write: R/W | Reset: 0b10001000001010010001010011

Bit	Reset	Description
23:20	0x8	UHSIC_TX_BLOCK_CNT: Controls how long after the end of transmission the receive path is blocked
19:14	0x20	UHSIC_RX_STROBE_DLY_TRIMMER: Nr of delays cells between UH_RX_STROBE and RxStrobeClk in zero cycle path
13:9	0x14	UHSIC_INPUT_FIFO_DEPTH: Depth of the 2-bit wide input FIFO. Maximum depth is 20. Can be tuned
8	0x1	UHSIC_LINE_STATE_RESUME_FAKE_SE0: When enabled, send an SE0 for 2 LS symbols at the end of ResumeK
7	0x0	UHSIC_LINE_STATE_BYPASS: Bypass LineState reclocking logic
6	0x0	UHSIC_EARLY_LINE_STATE_FILTER: Assumes line state filtering table is inclusive, not exclusive
5:1	0x9	UHSIC_HS_SYNC_START_DLY: How long to wait before start of sync launches RxActive
0	0x1	UHSIC_HS_ALLOW_KEEP_ALIVE: Allow Keep Alive packets

21.5.7.5 USB2_UHSIC_TX_CFG0_0

UHSIC transmit config signals

Offset: c10h | Read/Write: R/W | Reset: 0b1000000000

Bit	Reset	Description
9	0x1	UHSIC_HS_READY_WAIT_FOR_VALID
8	0x0	UHSIC_PACKET_INVERT_DATA: Invert data during a regular packet
7	0x0	UHSIC_PACKET_FORCE_STROBE_LOW: Force STROBE low during a regular instead of toggling it
6	0x0	UHSIC_HS_POSTAMBLE_OUTPUT_ENABLE: output enable turns off 1 cycle after

Bit	Reset	Description
5	0x0	UHSIC_SIE_RESUME_ON_LINESTATE: SIE, not macrocell, detects LineState change to resume
4	0x0	UHSIC_SOF_ON_NO_STUFF: Sof when OpMode 3 -- perhaps, when sending controller made packets
3	0x0	UHSIC_SOF_ON_NO_ENCODE: Sof when OpMode 2 -- not likely, for Chirp
2	0x0	UHSIC_NO_STUFFING: No bit stuffing, static programming
1	0x0	UHSIC_NO_ENCODING: No encoding, static programming
0	0x0	UHSIC_NO_SYNC_NO_EOP: Do not sent SYNC or EOP

21.5.7.6 USB2_UHSIC_MISC_CFG0_0

UHSIC miscellaneous configurations

Offset: c14h | Read/Write: R/W | Reset: 0b00100001001110100011110

Bit	Reset	Description
20	0x0	UHSIC_DISABLE_BUSRESET: When 1, the PHY will not send out BusReset during XcvrSelect0, TermSelect0 and Opmode2. It will send out a non-bit-stuffed, non-encoded packet instead.
19	0x0	UHSIC_FORCE_TERMSEL: Value to be forced on TermSelect when FORCE_XCVR_MODE is set.
18	0x1	UHSIC_EXTEND_BK_ACTIVE: Drive buskeeper one cycle longer when going out of IDLE
17:16	0x0	UHSIC_FORCE_XCVRSEL: Value to be forced on XcvrSelect when FORCE_XCVR_MODE is set.
15	0x0	UHSIC_FORCE_XCVR_MODE: 1: Force the values of XcvrSelect and TermSelect via config bits instead of via the controller
14	0x1	UHSIC_SYMMETRIC_CONNECT_DATA: 0: DATA goes high before STROBE goes low and low before STROBE goes high. 1: DATA goes high before STROBE goes low and goes low *after* STROBE goes high.
13	0x0	UHSIC_ASYNC_CONNECT_DATA: 0: DATA keeps setup and hold requirements during CONNECT. 1: DATA moves together with STROBE
12	0x0	UHSIC_LONG_CONNECT_STROBE: 0: STROBE is 2 periods long during connect. 1: STROBE is 3 periods long during connect
11	0x1	UHSIC_ACTIVE_BK_DRIVE_RX: 1: Use RX state (EOP etc) to determine starting time to drive bus keeper instead of waiting for IDLE detection.
10	0x1	UHSIC_ACTIVE_BK_DRIVE_TX: 1: Use TX state to determine starting time to drive bus keeper instead of waiting for IDLE detection.
9	0x1	UHSIC_DETECT_SHORT_IDLE: 0: use 3 edges (negative and positive) to detect a idle state on the line. 1: use 4 edges.
8	0x0	UHSIC_DETECT_SHORT_CONNECT: 0: use 3 edges (negative and positive) to detect a connect state on the line. 1: use 4 edges.
7	0x1	UHSIC_SUSPEND_EXIT_ON_EDGE: Suspend exit requires edge or simply a value...
6:5	0x0	UHSIC_INJECT_ERROR_TYPE: Force error insertion into RX path. (Used for IOBIST.) 0 = DISABLE 1 = BIT_ERR 2 = RX_ERR 3 = BIT_RX_ERR
4:2	0x3	UHSIC_STABLE_COUNT: Number of cycles of crystal clock of signal not changing to consider stable.
1	0x1	UHSIC_STABLE_ALL: Determines if all signal need to be stable to not change a config.

Bit	Reset	Description
0	0x0	UHSIC_COMB_TERMS: Use combinational terminations or synced through CLKXTAL

21.5.7.7 USB2_UHSIC_MISC_CFG1_0

UHSIC miscellaneous configurations

Offset: c18h | Read/Write: R/W | Reset: 0b100001100000000010

Bit	Reset	Description
17	0x1	UHSIC_PHY_XTAL_CLOCKEN: Selects whether to enable the crystal clock in the module.
16:15	0x0	UHSIC_OBS_SEL: Select which one of 4 observation vectors is presented on the observation bus
14	0x0	UHSIC_FORCE_IOBIST_CLK_ON: Always enable IoBist CLK60. This would be required when you want to use RX_ERROR_CNT_EN.
13:2	0x600	UHSIC_PLLU_STABLE_COUNT: WRONG! This should be 1ms -> 0x50
1	0x1	UHSIC_RX_ERROR_CNT_CLR: Clear IOBST RxError counter
0	0x0	UHSIC_RX_ERROR_CNT_EN: Enable IOBIST RxError counter when not in IOBIST mode. Allows one to read out the number of errors via JTAG during normal operation

4	0x1	UHSIC_PD_TRK: Power down tracking circuit
3	0x1	UHSIC_PD_TX: Power down transmitter
2	0x1	UHSIC_PD_BG: Power down band-gap and bias generator
1	0x0	UHSIC_IDDQ: Shut down analog blocks for IDDQ testing
0	0x1	UHSIC_AUTO_RTERM_EN: Enable auto-termination

21.5.7.10 USB2_UHSIC_CMD_CFG0_0

Determine startup behavior.

When AUTO_NEGOTIATE = 0

- Firmware is supposed to take care of things.

HOST

if Opmode1: do not drive anything

else

Initial power up:

- Asynchronously drive 00

- After a few Xtal clocks, enable bus keepers

Offset: c24h | Read/Write: R/W | Reset: 0b0000101

Bit	Reset	Description
6	0x0	UHSIC_FORCE_ACTIVATED: Force PHY into activated state without connect handshake (both host and device)
5	0x0	UHSIC_PRETEND_CONNECT_DETECT: While in HOST mode, act as if the input stage has seen a CONNECT pulse from the external PHY
4	0x0	UHSIC_FORCE_RESET: While in HOST mode, force global state machine into RESET state
3	0x0	UHSIC_FORCE_CONNECT: Upon rising value of this bit, force device to send connect. Only useful when AUTO_CONNECT is disabled.
2	0x1	UHSIC_AUTO_CONNECT: As device, automatically send Connect during activation.
1	0x0	UHSIC_FORCE_ACTIVATE: Upon rising value of this bit, instruct state machine to go into activation mode. Only useful when AUTO_ACTIVATE is disabled.
0	0x1	UHSIC_AUTO_ACTIVATE: Upon power up, automatically move to activation mode and start going through connect procedure.

21.5.7.11 USB2_UHSIC_STAT_CFG0_0

Offset: c28h | Read/Write: R/W | Reset: 0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx0

31:0	0x0	USB2D_QH: Queue Head for IN endpoint 14. This is used to store a local Queue Head data structure for either device mode or host mode. In device mode, it holds the Queue Head for IN endpoint 14.

21.5.7.45 USB2_QH_USB2D_QH_EP_15_OUT_0

USB2D Queue Head for OUT endpoint 15

Offset: 1780h | Read/Write: R/W | Reset: 0b00000000000000000000000000000000

Bit	Reset	Description
31:0	0x0	USB2D_QH: Queue Head for OUT endpoint 15 This is used to store a local Queue Head data structure for either device mode or host mode. In device mode, it holds the Queue Head for OUT endpoint 15.

21.5.7.46 USB2_QH_USB2D_QH_EP_15_IN_0

USB2D Queue Head for IN endpoint 15

Offset: 17c0h | Read/Write: R/W | Reset: 0b00000000000000000000000000000000

Bit	Reset	Description
31:0	0x0	USB2D_QH: Queue Head for IN endpoint 15. This is used to store a local Queue Head data structure for either device mode or host mode. In device mode, it holds the Queue Head for IN endpoint 15.

21.5.8 USB3 Controller Registers

21.5.8.1 USB2_CONTROLLER_2_USB2D_ID_0

USB2D Identification Register

Offset: 000h | Read/Write: RO | Reset: 0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx

Bit	Reset	Description
31:29	X	CIVERSION: Identifies the CI version
28:25	X	VERSION: Identifies the version of the core
24:21	X	REVISION: Revision number of the USB controller. This is set to 0x0.
20:16	X	TAG: Identifies the tag of the core
15:8	X	NID: Ones complement version of ID. This field is set to 0xF9.
7:0	X	ID: Configuration number. This field is set to 0x06

21.5.8.2 USB2_CONTROLLER_2_USB2D_HW_HOST_0

USB2D Hardware Host Register

Offset: 008h | Read/Write: RO | Reset: 0bxxxx

Bit	Reset	Description
3:1	X	NPORT: VUSB_HS_NUM_PORT-1: This host controller has only 1 port. So this field will always be 0.
0	X	HC: VUSB_HS_HOST: Indicates support for host mode. Set to 1.

21.5.8.3 USB2_CONTROLLER_2_USB2D_HW_DEVICE_0

USB2D Hardware Device Register

Offset: 00ch | Read/Write: RO | Reset: 0bxxxxxx

Bit	Reset	Description
5:1	X	DEVEP: VUSB_HS_DV_EP: No. of endpoints supported by this device controller. Set to 16. This includes control endpoint 0.
0	X	DC: Device capable: Set to 1 indicating support for device mode.

21.5.8.4 USB2_CONTROLLER_2_USB2D_HW_TXBUF_0

USB2D Hardware TX Buffer Register

Offset: 010h | Read/Write: RO | Reset: 0bxxxxxxxxxxxxxxxxxxxxxxxx

Bit	Reset	Description
23:16	X	TXCHANADD: VUSB_HS_TX_CHAN_ADD: Total no. of address bits for the transmit buffer of each transmit endpoint. Set to 7. Each transmit buffer is 128 words deep.
15:8	X	TXADD: VUSB_HS_TX_ADD: Total no. of address bits for the transmit buffer. Set to 11. The total depth of the transmit buffer is 2048 words.
7:0	X	TCBURST: VUSB_HS_TX_BURST: Maximum burst size supported by the transmit endpoints for data transfers. Set to 8.

21.5.8.5 USB2_CONTROLLER_2_USB2D_HW_RXBUF_0

USB2D RX Buffer HW Parameters Register

Offset: 014h | Read/Write: RO | Reset: 0bxxxxxxxxxxxxxxxx

Bit	Reset	Description
15:8	X	RXADD: VUSB_HS_RX_ADD: Total no. of address bits for the receive buffer. Set to 7. The total depth of the receive buffer is 128 words
7:0	X	RXBURST: VUSB_HS_RX_BURST: Maximum burst size supported by the receive endpoints for data transfers. Set to 8.

21.5.8.6 USB2_CONTROLLER_2_USB2D_CAPLENGTH_0

USB2D Capability Register Length Register

Offset: 100h | Read/Write: RO | Reset: 0bxxxxxxxx

Bit	Reset	Description
7:0	X	CAPLENGTH: Indicates which offset to add to the register base address at the beginning of the Operational Register. Set to 0x40.

21.5.8.7 USB2_CONTROLLER_2_USB2D_HCIVERSON_0

USB2D Host Interface Version Number Register

Offset: 102h | Read/Write: RO | Reset: 0bxxxxxxxxxxxxxxxx

Bit	Reset	Description
15:0	X	HCIVERSION: Contains a BCD encoding of the EHCI revision number supported by this host controller. The most significant byte of this register represents a major revision and the least significant byte is the minor revision. This host controller supports EHCI revision 1.00.

21.5.8.8 USB2_CONTROLLER_2_USB2D_HCSPARAMS_0

USB2D Host Control Structural Parameters Register

Offset: 104h | Read/Write: RO | Reset: 0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx

Bit	Reset	Description
27:24	X	N_TT: Number of Transaction Translators: indicates the number of embedded transaction translators associated with the USB2.0 host controller. This field is always set to 1 indicating only 1 embedded TT is implemented in this implementation. This is a non-EHCI field to support embedded TT.
23:20	X	N_PTT: Number of Ports per Transaction Translator: indicates the number of ports assigned to each transaction translator within the USB2.0 host controller. Field always equals N_PORTS. This is a non-EHCI field to support embedded TT.
15:12	X	N_CC: Number of Companion Controller: indicates the number of companion controllers. This field is set to 0.
11:8	X	N_PCC: Number of Ports per Companion Controller: indicates the number of ports supported per internal companion controller. This field is set to 0.
4	X	PPC: Port Power Control: indicates whether the host controller implementation includes port power control. 1 = Ports have port power switches 0= Ports do not have port power switches. This field affects the functionality of the port Power field in each port status and control register. This field is set to 1.
3:0	X	N_PORTS: Number of downstream ports. This field specifies the number of physical downstream ports implemented on this host controller. This field is fixed to 1, since this host controller only supports 1 port.

21.5.8.9 USB2_CONTROLLER_2_USB2D_HCCPARAMS_0

USB2D Host Control Capability Parameters Register

Offset: 108h | Read/Write: RO | Reset: 0bxxxxxxxxxxxxxxxxxx

Bit	Reset	Description
18	X	PPC: Per-Port Change Event Capability - RO. Default = 1b. This field indicates the support for per-port change events. This field is related with USBCMD PPE field, USBSTS PPCI field and USBINTR PPCE field.
17	X	LEN: Link Power Management Capability - RO. Default = 1b. This field indicates the support for LPM L1 state. This field is related with USBCMD HIRD field, POSTSCx SSTS and DA fields and HOSTPCx LEN, BA, and EPLPM fields.
15:8	X	EECP: EHCI Extended Capabilities Pointer: indicates a capabilities list exists. A value of 00h indicates no extended capabilities are implemented. For this implementation this field is always "0".
7:4	X	IST: Isochronous Scheduling Threshold. This field indicates, relative to the current position of the executing host controller, where software can reliably update the isochronous schedule. When bit [7] is zero, the value of the least significant 3 bits indicates the number of micro-frames a host controller can hold a set of isochronous data structures (one or more) before flushing the state. When bit [7] is a one, then host software assumes the host controller may cache an isochronous data structure for an entire frame. This field will always be "0".
2	X	ASP: Asynchronous Schedule Park Capability. 1 = (Default) the host controller supports the park feature for high-speed queue heads in the Asynchronous Schedule. The feature can be disabled or enabled and set to a specific level by using the Asynchronous Schedule Park Mode Enable and Asynchronous Schedule Park Mode Count fields in the USBCMD register. This field is always 1.
1	X	PFL: Programmable Frame List Flag. 0 = System software must use a frame list length of 1024 elements with this host controller. The USBCMD register Frame List Size field is a read-only register and must be set to zero. 1 = System software can specify and use a smaller frame list and configure the host controller via the USBCMD register Frame List Size field. The frame list must always be aligned on a 4K-page boundary. This requirement ensures that the frame list is always physically contiguous. This field will always be "1".

21.5.8.10 USB2_CONTROLLER_2_USB2D_DCIVERSION_0

USB2D Device Interface Version Number Register

Offset: 120h | Read/Write: RO | Reset: 0bxxxxxxxxxxxxxxxx

Bit	Reset	Description
15:0	X	DCIVERSION: The device controller interface conforms to the two-byte BCD encoding of the interface version number contained in this register.

21.5.8.11 USB2_CONTROLLER_2_USB2D_DCCPARAMS_0

USB2D Device Control Capabilities Register

Offset: 124h | Read/Write: RO | Reset: 0bxxxxxxxxx

Bit	Reset	Description
8	X	HC: Host Capable: 1 = This controller is capable of operating as an EHCI compatible USB 2 0 host controller operating as an EHCI compatible USB 2.0 host controller. This field is set to 1.
7	X	DC: Device Capable: 1 = Controller is capable of operating as USB 2.0 device. This field is set to 1
5	X	LEN: Link Power Management Capability - RO. Default = 1b. This field indicates the support for LPM L1 state. This field is related with DEVLCx ASUS, STL,BA and NYT fields.
4:0	X	DEN: Device Endpoint Number: Number of endpoints built into the device controller. This is set to 16.

21.5.8.12 USB2_CONTROLLER_2_USB2D_EXTSTS_0

USB2D EXTSTS Register

Offset: 128h | Read/Write: R/W | Reset: 0b0000x

Bit	R/W	Reset	Description
4	RW	0x0	TI1: General Purpose Timer Interrupt 1 - RWC. Default = 0b. This bit is set when the counter in the GPTIMER1CTRL register transitions to zero. Writing a one to this bit will clear it.
3	RW	0x0	TI0: General Purpose Timer Interrupt 0 - RWC. Default = 0b. This bit is set when the counter in the GPTIMER1CTRL register transitions to zero. Writing a one to this bit will clear it.
2	RW	0x0	UPA: USB Host Periodic Interrupt (USBHSTPERINT) R/WC. This bit is set by the Host Controller when the cause of an interrupt is a completion of a USB transaction where the Transfer Descriptor (TD) has an interrupt on complete (IOC) bit set and the TD was from the periodic schedule. This bit is also set by the Host Controller when a short packet is detected AND the packet is on the periodic schedule. A short packet is when the actual number of bytes received was less than the expected number of bytes. This bit is not used by the device controller and will always be zero. 0 = DISABLE 1 = ENABLE
1	RW	0x0	UAI: USB Host Asynchronous Interrupt (USBHSTASYNCINT) R/WC. This bit is set by the Host Controller when the cause of an interrupt is a completion of a USB transaction where the Transfer Descriptor (TD) has an interrupt on complete (IOC) bit set AND the TD was from the asynchronous schedule. This bit is also set by the Host when a short packet is detected AND the packet is on the asynchronous schedule. A short packet is when the actual number of bytes received was less than the expected number of bytes. This bit is not used by the device controller and will always be zero. 0 = DISABLE 1 = ENABLE
0	RO	X	NAKI: NAK Interrupt Bit Read Only. This bit is readonly. It is set by hardware when for a particular endpoint both the TX/RX Endpoint NAK bit and the corresponding TX/RX Endpoint NAK Enable bit are set. This bit is automatically cleared by hardware when the all the enabled TX/RX Endpoint NAK bits are cleared. 0 = DISABLE 1 = ENABLE

21.5.8.13 USB2_CONTROLLER_2_USB2D_USBEXTINTR_0

USB2D EXTINTR Register

Offset: 12ch | Read/Write: R/W | Reset: 0b00000

Bit	Reset	Description
4	0x0	TIE1: General Purpose Timer Interrupt Enable 1 - RWC. Default = 0b. When this bit is a one, and the TI1 bit in the EXTSTS register is a one, the controller will issue an interrupt. The interrupt is acknowledged by software clearing the TI1 bit.
3	0x0	TIE0: General Purpose Timer Interrupt Enable 0 - RWC. Default = 0b. When this bit is a one, and the TI1 bit in the EXTSTS register is a one, the controller will issue an interrupt. The interrupt is acknowledged by software clearing the TI1 bit.
2	0x0	UPIE: UPIE Interrupt Enable. 1 = USB controller issues an interrupt if UPA bit in USBSTS register transitions. 0 = DISABLE 1 = ENABLE
1	0x0	UAIE: UAIE Interrupt Enable. 1 = USB controller issues an interrupt if UAI bit in USBSTS register transitions. 0 = DISABLE 1 = ENABLE
0	0x0	NAKE: NAK Interrupt Enable. 1 = USB controller issues an interrupt if NAKI bit in USBSTS register transitions. 0 = DISABLE 1 = ENABLE

21.5.8.14 USB2_CONTROLLER_2_USB2D_USBCMD_0

USB2D USB Command Register

Offset: 130h | Read/Write: R/W | Reset: 0b000000001000000x1x11x0000000

Bit	R/W	Reset	Description
27:24	RW	0x0	HIRD: Host Initiated Resume Duration RW. Default = 0000b. This has the same behavior as bits 7:4 of BA field of HOSTPCx register. When writing to this field all BA[7:4] fields of all HOSTPCx registers will be set to this value. This field is used by system software to specify the minimum amount of time the host controller will drive the K-state during a host-initiated resume from a LPM state (e.g. L1), and is conveyed to each LPM-enabled device (via the HIRD bits within an LPM Tokens bmAttributes field) upon entry into a low-power state. Note the host controller is required to drive resume signaling for at least the amount of time specified in the HIRD value conveyed to the device during any proceeding host-initiated resume. Also note that the host controller is not required to observe this requirement during device-initiated resumes. Encoding for this field is identical to the definition for the similarly named HIRD field within an LPM Token, specifically: a value 0000b equals 50µs and each additional increment adds 75µs. For example, the value 0001b equals 125µs, and a value 1111b equals 1,175µs (~1.2ms).
23:16	RW	0x8	ITC: Interrupt Threshold Control .Read/Write. Default 08h. The system software uses this field to set the maximum rate at which the host/device controller will issue interrupts. ITC contains the maximum interrupt interval measured in micro-frames. Valid values are shown below. Value Maximum Interrupt Interval 00h Immediate (no threshold) 01h 1 micro-frame 02h 2 micro-frames 04h 4 micro-frames 08h 8 micro-frames 10h 16 micro-frames 20h 32 micro-frames 40h 64 micro-frames 0 = IMMEDIATE 2 = ONE_MF 4 = TWO_MF 8 = EIGHT_MF 16 = SIXTEEN_MF 32 = THIRTY_TWO_MF 64 = SIXTY_FOUR_MF
15	RW	0x0	FS2: Bit 2 of Frame List Size.

Bit	R/W	Reset	Description
14	RW	0x0	ATDTW: Add DTD Tripwire. This bit is used as a semaphore when a dTD is added to an active (primed) endpoint. This bit is set and cleared by software and will be cleared by hardware when a hazard exists such that adding a dTD to a primed endpoint may go unnoticed. 0 = CLEAR 1 = SET
13	RW	0x0	SUTW: Setup Tripwire. This bit is used as a semaphore when the 8 bytes of setup data read extracted by the firmware. If the setup lockout mode is off, then there exists a hazard when new setup data arrives and firmware is copying setup data from the QH for a previous setup packet. This bit is set and cleared by software and will be cleared by hardware when a hazard exists. 0 = CLEAR 1 = SET
11	RW	0x1	ASPE: Asynchronous Schedule Park mode Enable. Software uses this bit to enable or disable Park mode. When this bit is one, Park mode is enabled. When this bit is a zero, Park mode is disabled. This field is set to "1" in this implementation. 0 = DISABLE 1 = ENABLE
9:8	RW	0x3	ASP1_ASP0: Asynchronous Schedule Park Mode Count (OPTIONAL) Read/Write. If the Asynchronous Park Capability bit in the HCCPARAMS register is a one, then this field defaults to 3h and is R/W. Otherwise it defaults to zero and is RO. It contains a count of the number of successive transactions the host controller is allowed to execute from a high-speed queue head on the Asynchronous schedule before continuing traversal of the Asynchronous schedule. Valid values are 1h to 3h. Software must not write a zero to this bit when Park Mode Enable is a one as this will result in undefined behavior. This field is set to 3h in this implementation and is Read/Write capable.
7	RO	X	LR: Light Host/Device Controller Reset (OPTIONAL) . Read Only. Not Implemented. This field will always be "0".
6	RW	0x0	IAA: Interrupt on Async Advance Doorbell. When the host controller has evicted all appropriate cached schedule states, it sets the Interrupt on Async Advance status bit in the USBSTS register. If the Interrupt on Sync Advance Enable bit in the USBINTR register is one, then the host controller will assert an interrupt at the next interrupt threshold. The host controller sets this bit to zero after it has set the Interrupt on Sync Advance status bit in the USBSTS register to one. Software should not write a one to this bit when the asynchronous schedule is inactive. Doing so will yield undefined results. This bit is only used in host mode. Writing a one to this bit when device mode is selected will have undefined results. 0 = CLEAR 1 = SET
5	RW	0x0	ASE: Asynchronous Schedule Enable. This bit controls whether the host controller skips processing the Asynchronous Schedule. 0 = Do not process the Asynchronous Schedule. 1 = Use the ASYNCLISTADDR register to access the Asynchronous Schedule. Only the host controller uses this bit. 0 = DISABLE 1 = ENABLE
4	RW	0x0	PSE: Periodic Schedule Enable.This bit controls whether the host controller skips processing the Periodic Schedule. 0 = Do not process the Periodic Schedule 1 = Use the PERIODICLISTBASE register to access the Periodic Schedule. Only the host controller uses this bit. 0 = DISABLE 1 = ENABLE
3:2	RW	0x0	FS1_FS0: Frame List Size . (Read/Write). 000 = Default This field is Read/Write only if Programmable Frame List Flag in the HCCPARAMS registers is set to one. Hence this field is Read/Write for this implementation. This field specifies the size of the frame list that controls which bits in the Frame Index Register should be used for the Frame List Current index. Note that this field is made up from USBCMD bits 15, 3 and 2. 000 = 1024 elements (4096 bytes) Default value 001 = 512 elements (2048 bytes) 010 = 256 elements (1024 bytes) 011 = 128 elements (512 bytes) 100 = 64 elements (256 bytes) 101 = 32 elements (128 bytes) 110 = 16 elements (64 bytes) 111 = 8 elements (32 bytes) Only the host controller uses this field.
1	RW	0x0	RST: Controller Reset. Software uses this bit to reset the controller. This bit is set to zero by the Host/Device Controller when the reset process is complete. Software cannot terminate the reset process early by writing a zero to this register. Host Controller: When software writes a one to this bit, the Host Controller resets its internal pipelines, timers, counters, state machines etc. to their

Bit	R/W	Reset	Description
			initial value. Any transaction currently in progress on USB is immediately terminated. A USB reset is not driven on downstream ports. Software should not set this bit to a one when the HCHalted bit in the USBSTS register is a zero. Attempting to reset an actively running host controller results in undefined behavior. Device Controller: When software writes a one to this bit, the Device Controller resets its internal pipelines, timers, counters, state machines etc. to their initial value. Any transaction currently in progress on USB is immediately terminated. Writing a one to this bit in device mode is not recommended. 0 = CLEAR 1 = SET
0	RW	0x0	RS: Run/Stop: Host Controller: When set to a 1, the Host Controller proceeds with the execution of the schedule. The Host Controller continues execution as long as this bit is set to a one. When this bit is set to 0, the Host Controller completes the current transaction on the USB and then halts. The HCHalted bit in the status register indicates when the Host Controller has finished the transaction and has entered the stopped state. Software should not write a one to this field unless the host controller is in the Halted state (i.e. HCHalted in the USBSTS register is a one). Device Controller: Writing a one to this bit will cause the device controller to enable a pull-up on D+ and initiate an attach event. This control bit is not directly connected to the pull-up enable, as the pull-up will become disabled upon transitioning into high-speed mode. Software should use this bit to prevent an attach event before the device controller has been properly initialized. Writing a 0 to this will cause a detach event. 0 = STOP 1 = RUN

21.5.8.15 USB2_CONTROLLER_2_USB2D_USBSTS_0

USB2D USB Status Register

Offset: 134h | Read/Write: R/W | Reset: 0b00000000000000000x1x0x0000x0000

Bit	R/W	Reset	Description
31:16	RW	0x0	PPCI: Port-n Change Detect - RW. Default = 0000h. The definition for each bit is identical to the Port Change Detect field (bit 2 of this register) except these bits are specific to a given port, where bit 16 = Port 1, 17 = Port 2, etc. For example, if bit 17 is set to a one then a port change event was detected on Port 2. The N_PORTS field in HCSPARAMS specifies how many ports are exposed by the host controller and thus how many bits in this field are valid.
15	RW	0x0	AS: Asynchronous Schedule Status. This bit reports the current real status of the Asynchronous Schedule. When set to zero the asynchronous schedule status is disabled and if set to one the status is enabled. The Host Controller is not required to immediately disable or enable the Asynchronous Schedule when software transitions the Asynchronous Schedule Enable bit in the USBCMD register. If AS = ASE: 1= Enable Asynchronous Schedule 0= Disable Asynchronous Schedule Only used by the host controller. 0 = DISABLE 1 = ENABLE
14	RW	0x0	PS: Periodic Schedule Status. This bit reports the current real status of the Periodic Schedule. When set to zero the periodic schedule is disabled, and if set to one the status is enabled. The Host Controller is not required to immediately disable or enable the Periodic Schedule when software transitions the Periodic Schedule Enable bit in the USBCMD register. If PS = PSE then: 1 = Periodic Schedule is enabled or 0 = Periodic Schedule is disabled Only used by the host controller. 0 = DISABLE 1 = ENABLE
13	RO	X	RCL: Reclamation. This is a read-only status bit used to detect an empty asynchronous schedule. Only used by the host controller. 0 = DISABLE 1 = ENABLE
12	RW	0x1	HCH: HCHalted. 1 = Default. This bit is a zero whenever the Run/Stop bit is a one. The Host Controller sets this bit to one after it has stopped executing because of the Run/Stop bit being set to 0, either by software or by the Host Controller hardware (e.g. internal error). Only used by the host controller. 0 = UNHALTED

Bit	R/W	Reset	Description
			1 = HALTED
10	RW	0x0	ULPI_INT: ULPI Interrupt. This bit is set whenever an interrupt is received from ULPI PHY. Software writes 1 to clear it. 0 = NOT_ULPI_INT 1 = ULPI_INT
8	RW	0x0	SLI: DCSuspend. When a device controller enters a suspend state from an active state, this bit will be set to a 1. The device controller clears the bit upon exiting from a suspend state. Only used by the device controller. 0 = NOTSUSPEND 1 = SUSPENDED
7	RW	0x0	SRI: SOF Received. When the device controller detects a Start Of (micro) Frame, this bit will be set to a one. When a SOF is extremely late, the device controller will automatically set this bit to indicate that an SOF was expected. Therefore, this bit will be set roughly every 1ms in device FS mode and every 125us in HS mode and will be synchronized to the actual SOF that is received. Since device controller is initialized to FS before connect, this bit Will be set at an interval of 1ms during the prelude to the connect and chirp. In host mode, this bit will be set every 125us and can be used by host controller driver as a time base. Software writes a 1 to this bit to clear it. This is a non-EHCI status bit. 0 = SOF_NOT_RCVD 1 = SOF_RCVD
6	RW	0x0	URI: USB Reset Received. When the device controller detects a USB Reset and enters the default state, this bit is set to a 1. Software can write a 1 to this bit to clear the USB Reset Received status bit. Only used by the device controller. 0 = NO_USB_RESET 1 = USB_RESET
5	RW	0x0	AAI: Interrupt and Asynchronous Advance. System software can force the host controller to issue an interrupt the next time the host controller advances the asynchronous schedule by writing a one to the Interrupt on Async Advance Doorbell bit in the USBCMD register. This status bit indicates the assertion of that interrupt source. Only used by the host controller 0 = NOT_ADVANCED 1 = ADVANCED
4	RO	X	SEI: System Error. This bit is not used in this implementation and will always be set to "0". 0 = NO_ERROR 1 = ERROR
3	RW	0x0	FRI: Frame List Rollover. The Host Controller sets this bit to a 1 when the Frame List Index rolls over from its maximum value to 0. The exact value at which the rollover occurs depends on the frame list size. For example. If the frame list size (as programmed in the Frame List Size field of the USBCMD register) is 1024, the Frame Index Register rolls over every time FRINDEX [1 3] toggles. Similarly, if the size is 512, the Host Controller sets this bit to a 1 every time FHINDEX [12] toggles. Only used by the host controller. 0 = NO_ROLLOVER 1 = ROLLOVER
2	RW	0x0	PCI: Port Change Detect. The Host Controller sets this bit to a 1 when on any port a Connect Status occurs, a Port Enable/Disable Change occurs, or the Force Port Resume bit is set as the result of a J-K transition on the suspended port. The Device Controller sets this bit to a one when the port controller enters the full or high-speed operational state. When the port controller exits the full or high-speed operational states due to Reset or Suspend events, the notification mechanisms are the USB Reset Received bit and the DCSuspend bits respectively. This bit is not EHCI compatible. 0 = NO_PORT_CHANGE 1 = PORT_CHANGE
1	RW	0x0	UEI: USB Error Interrupt. This bit gets set by the Host/Device controller when completion of a USB transaction results in an error condition. This bit is set along with the USBINT bit, if the TD on which the error interrupt occurred also ad its interrupt on complete (IOC) bit set. 0 = NO_ERROR 1 = ERROR
0	RW	0x0	UI: USB Interrupt. This bit is set by the Host/Device Controller when the cause of an interrupt is a completion of a USB transaction where the Transfer Descriptor (TD) as an interrupt on complete

Bit	R/W	Reset	Description
			(IOC) bit set. This bit is also set by the Host/Device Controller when a short packet is detected. A short packet is when the actual number of bytes received was less than the expected number of bytes. 0 = NO_INT 1 = INT

21.5.8.16 USB2_CONTROLLER_2_USB2D_USBINTR_0

USB2D USB Interrupt Enable Register

Offset: 138h | Read/Write: R/W | Reset: 0b0000000000000000xxxxx0x000000000

Bit	Reset	Description
31:16	0x0	PPCE: Port-n Change Detect Enable - RW. Default = 0000h. The definition for each bit in this field is identical to bit 2 of this register (Port Change Interrupt Enable) except these bits are specific to a given port, where bit 16 = Port 1, 17 = Port 2, etc. For example, if bit 17 is set (1b) then a port change event was detected on Port 2. When a bit in this field is a one, and the corresponding Port-n Change Detect bit in the USBSTS register is a one, the host controller will issue an interrupt. The interrupt is acknowledged by software clearing the Port-n Change Detect bit.
10	0x0	ULPIE: ULPI Interrupt Enable. 1 = USB controller issues an interrupt if ULPI_INT bit in USBSTS register transitions. The interrupt is acknowledged by SW by writing a 1 to the ULPI_INT bit. 0 = DISABLE 1 = ENABLE
8	0x0	SLE: Sleep Enable. 1 = Device controller issues an interrupt if DCSuspend bit in USBSTS register transitions. The interrupt is acknowledged by SW by writing a 1 to the DCSuspend bit. Only used by the device controller. 0 = DISABLE 1 = ENABLE
7	0x0	SRE: SOF Received Enable. 1 = Device controller issues an interrupt if SOF Received bit in USBSTS register = 1. The interrupt is acknowledged by software clearing the SOF Received bit. 0 = DISABLE 1 = ENABLE
6	0x0	URE: USB Reset Enable.1 = Device controller issues an interrupt if USB Reset Received bit in USBSTS register = 1 The interrupt is acknowledged by software clearing the USB Reset Received bit. Only used by the device controller. 0 = DISABLE 1 = ENABLE
5	0x0	AAE: Interrupt on Asynchronous Advance Enable. 1 = the host controller issues an interrupt at the next interrupt threshold if Interrupt on Async Advance bit in USBSTS register = 1. The interrupt is acknowledged by software clearing the Interrupt on Async Advance bit. Only used by the host controller. 0 = DISABLE 1 = ENABLE
4	0x0	SEE: System Error Enable. 1 = Host/device controller issues an interrupt if the System Error bit in USBSTS register = 1. The interrupt is acknowledged by software clearing the System Error bit. 0 = DISABLE 1 = ENABLE
3	0x0	FRE: Frame List Rollover Enable. 1 = Host controller issues an interrupt if Frame List Rollover bit in the USBSTS register = 1. The interrupt is acknowledged by software clearing the Frame List Rollover bit. Only used by the host controller. 0 = DISABLE 1 = ENABLE
2	0x0	PCE: Port Change Detect Enable. 1 = Host/device controller issues an interrupt if Port Change Detect bit in USBSTS register = 1. The interrupt is acknowledged by software clearing the Port Change Detect bit. 0 = DISABLE 1 = ENABLE

Bit	Reset	Description
1	0x0	UEE: USB Error Interrupt Enable. 1 = Host controller issues an interrupt at the next interrupt threshold if the USBERRINT bit in USBSTS = 1. The interrupt is acknowledged by software clearing the USBERRINT bit in the USBSTS register. 0 = DISABLE 1 = ENABLE
0	0x0	UE: USB Interrupt Enable. 1 = Host/device issues an interrupt at the next interrupt threshold if the USBINT bit in USBSTS = 1. The interrupt is acknowledged by software clearing the USBINT bit. 0 = DISABLE 1 = ENABLE

21.5.8.17 USB2_CONTROLLER_2_USB2D_FRINDEX_0

USB2D USB Frame Index Register

Offset: 13ch | Read/Write: RO | Reset: 0bxxxxxxxxxxxxxx

Bit	Reset	Description
13:0	X	FRINDEX: Frame Index. The value in this register increments at the end of each time frame (micro-frame). Bits [N: 3] are used for the Frame List current index. Each location of the frame list is accessed 8 times (frames or micro-frames) before moving to the next index. The following illustrates values of N based on the value of the Frame List Size field in the USBCMD register, when used in host mode. USBCMD [Frame List Size] Number Elements N 000b (1024) 12 001b (512) 11 010b (256) 10 011b (128) 9 100b (64) 8 101b (32) 7 110b (16) 6 111b (8) 5 In device mode the value is the current frame number of the last frame transmitted. It is not used as an index. In either mode bits 2:0 indicate the current micro-frame.

21.5.8.18 USB2_CONTROLLER_2_USB2D_PERIODICLISTBASE_0

USB2D Host Controller Frame List Base Address Register

Offset: 144h | Read/Write: R/W | Reset: 0b00000000000000000000

Bit	Reset	Description
31:25	0x0	USBADR: Device mode. The upper seven bits of this register represent the device address. After any controller reset or a USB reset, the device address is set to the default address (0). The default address will match all incoming addresses. Software shall reprogram the address after receiving a SET_ADDRESS request.
24	0x0	USBADRA: Device Address Advance. Default=0. When this bit is 0, any writes to USBADR are instantaneous. When this bit is written to a 1 at the same time or before USBADR is written, the write to the USBADR field is staged and held in a hidden register. After an IN occurs on endpoint 0 and is ACKed, USBADR will be loaded from the holding register. Hardware will automatically clear this bit on the following conditions: 1) IN is ACKed to endpoint 0. (USBADR is updated from staging register). 2) OUT/SETUP occur to endpoint 0. (USBADR is not updated). 3) Device Reset occurs (USBADR is reset to 0). Note: After the status phase of the SET_ADDRESS descriptor, the DCD has 2 ms to program the USBADR field. This mechanism will ensure this specification is met when the DCD can not write of the device address within 2ms from the SET_ADDRESS status phase. If the DCD writes the USBADR with USBADRA=1 after the SET_ADDRESS data phase (before the prime of the status phase), the USBADR will be programmed instantly at the correct time and meet the 2ms USB requirement.
31:12	0x0	BASEADR: Host mode: This 32-bit register contains the beginning address of the Periodic Frame List in the system memory. HCD loads this register prior to starting the schedule execution by the Host Controller. The memory structure referenced by this physical memory pointer is assumed to be 4-Kbyte aligned. The contents of this register are combined with the Frame Index Register (FRINDEX) to enable the Host Controller to step through the Periodic Frame List in sequence. Base Address (Low). These bits correspond to memory address signals [31:12], respectively. Only used by the host controller.

21.5.8.19 USB2_CONTROLLER_2_USB2D_ASYNCLISTADDR_0

USB2D Next Asynchronous List Address Register

Offset: 148h | Read/Write: R/W | Reset: 0b00000000000000000000000000000000

Bit	Reset	Description
31:11	0x0	EPBASE: Device mode. This register contains the address of the top of the endpoint list in system memory. These bits correspond to memory address signals [31:11], respectively. This field will reference a list of up to 32 Queue Heads (QH). Only used by the device controller.
31:5	0x0	ASYBASE: Host mode. This 32-bit register contains the address of the next asynchronous queue head to be executed by the host. Link Pointer Low (LPL). These bits correspond to memory address signals [31:5], respectively. This field may only reference a Queue Head (OH). Only used by the host controller.

21.5.8.20 USB2_CONTROLLER_2_USB2D_ASYNCTTSTS_0

USB2D Asynchronous Buffer Status for Embedded TT Register

Offset: 14ch | Read/Write: R/W | Reset: 0b0x

Bit	R/W	Reset	Description
1	RW	0x0	TTAC: Embedded TT Async Buffers Clear. (Read/Write to set) This field will clear all pending transactions in the embedded TT Async Buffer(s). The clear will take as much time as necessary to clear buffer without interfering with a transaction in progress. TTAC will return to zero after being set by software only after the actual clear occurs.
0	RO	X	TTAS: Embedded TT Async Buffers Status. (Read Only) This read only bit will be 1 if one or more transactions are being held in the embedded TT Async. Buffers. When this bit is a zero, then all outstanding transactions in the embedded TT have been flushed.

21.5.8.21 USB2_CONTROLLER_2_USB2D_BURSTSIZE_0

USB2D Burst Size register

Offset: 150h | Read/Write: R/W | Reset: 0b0000100000001000

Bit	Reset	Description
15:8	0x8	TXPBURST: Programmable TX Burst Length. (Read/Write) This register represents the maximum length of a burst in 32-bit words while moving data from system memory to the USB bus.
7:0	0x8	RXPBURST: Programmable RX Burst Length. (Read/Write) This register represents the maximum length of a burst in 32-bit words while moving data from the USB bus to system memory.

21.5.8.22 USB2_CONTROLLER_2_USB2D_TXFILLTUNING_0

USB2D Transmit fill tuning register

Offset: 154h | Read/Write: R/W | Reset: 0b000010xxx0000000000000

Bit	Reset	Description
21:16	0x2	TXFIFOTHRES: FIFO Burst Threshold. (Read/Write) This register controls the number of data bursts that are posted to the TX latency FIFO in host mode before the packet begins on to the bus. The minimum value is 2 and this value should be a low as possible to maximize USB performance. A higher value can be used in systems with unpredicable latency and/or insufficient bandwidth where the FIFO may underrun because the data transferred from the latency FIFO to USB occurs before it can be replenished from system memory. This value is ignored if the Stream Disable bit in USBMODE register is set.

Bit	Reset	Description
12:8	0x0	TXSCHHEALTH: Scheduler Health Counter. (Read/Write To Clear) [Default = 0] This register increments when the host controller fails to fill the TX latency FIFO to the level programmed by TXFIFOTHRES before running out of time to send the packet before the next Start-Of-Frame. This health counter measures the number of times this occurs to provide feedback to selecting a proper TXSCHOH. Writing to this register will clear the counter and this counter will max. at 31.
7:0	0x0	TXSCHOH: Scheduler Overhead. (Read/Write) [Default = 0] This register adds an additional fixed offset to the schedule time estimator described above as Tff. As an approximation, the value chosen for this register should limit the number of back-off events captured in the TXSCHHEALTH to less than 10 per second in a highly utilized bus. Choosing a value that is too high for this register is not desired as it can needlessly reduce USB utilization. The time unit represented in this register is 1.267us when a device is connected in High-Speed Mode. The time unit represented in this register is 6.333us when a device is connected in Low/Full Speed Mode

21.5.8.23 USB2_CONTROLLER_2_USB2D_ICUSB_CTRL_0

USB2D ICUSB control register

This register enables and controls the ICUSB FS/LS transceiver.

Offset: 15ch | Read/Write: R/W | Reset: 0b0000

Bit	Reset	Description
3	0x0	IC_ENB1: ICUSB transceiver enable. This bit enables the ICUSB transceiver . To enable the interface, the bits PTS must be set to 11 in the PORTSCx. Writing a '1' to this bit selects the IC_USB interface. 0 = DISABLE 1 = ENABLE
2:0	0x0	IC_VDD1: ICUSB voltage select. It selects which voltage is being supplied to the ICUSB peripheral. 000 -> No voltage 001 -> 1.0V - reserved 010 -> 1.2V - reserved 011 -> 1.5V - reserved 100 -> 1.8V 101 -> 3.0V 110 -> reserved 111 -> reserved The Voltage negotiation should happen between enabling port power (PP) and asserting the run/stop bit in register.

21.5.8.24 USB2_CONTROLLER_2_USB2D_ULPI_VIEWPORT_0

USB2D ULPI viewport register

This register provides indirect access to the ULPI PHY register set. Although the USB controller performs access to the ULPI PHY register set, there may be extraordinary circumstances where software may need direct access.

Note: WRITES TO THE ULPI THROUGH THE VIEWPORT CAN SUBSTANTIALLY HARM STANDARD USB OPERATIONS. CURRENTLY NO USAGE MODEL HAS BEEN DEFINED WHERE SOFTWARE SHOULD NEED TO EXECUTE WRITES DIRECTLY TO THE ULPI PHY. SEE EXCEPTION REGARDING OPTIONAL FEATURES BELOW.

Note: EXECUTING READ OPERATIONS THROUGH THE ULPI VIEWPORT SHOULD HAVE NO HARMFUL SIDE EFFECTS TO STANDARD USB OPERATIONS.

There are two operations that can be performed with the ULPI Viewport, wakeup and read /write operations.

The wakeup operation is used to put the ULPI interface into normal operation mode and reenable the clock if necessary. A wakeup operation is required before accessing the registers when the ULPI interface is operating in low power mode, serial mode, or carkit mode.

The ULPI state can be determined by reading the sync. state bit (ULPI_SYNC_STATE). If this bit is a one, then ULPI interface is running in normal operation mode and can accept read/write operations. If the ULPI_SYNC_STATE indicates a 0 then then read/write operations will not be able to execute. Undefined behavior will result if ULPI_SYNC_STATE = 0 and a read or write operation is performed.

To execute a wakeup operation, write all 32-bits of the ULPI Viewport where ULPI_PORT is constructed appropriately and the ULPI_WAKEUP bit is a 1 and ULPI_RUN bit is a 0. Poll the ULPI Viewport until ULPI_WAKEUP is zero for the operation to complete.

To execute a read or write operation, write all 32-bits of the ULPI Viewport where ULPI_DATA_WR, ULPI_REG_ADDR, ULPI_PORT, ULPI_RD_WR are constructed appropriately and the ULPI_RUN bit is a 1. Poll the ULPI Viewport until ULPI_RUN is zero for the operation to complete. Once ULPI_RUN is zero, the ULPI_DATA_RD will be valid if the operation was a read.

The polling method above can be changed to interrupt driven using the ULPI interrupt defined in the USBSTS and USBINTR registers. When a wakeup or read/write operation is complete, the ULPI_INT interrupt will be set.

There are several optional features that may need to be enabled or disabled by system software as part of system configuration. These bits are contained in the Interface and OTG Control registers of the ULPI PHY register set. These registers also contain bits which are controlled by the link dynamically and therefore should be only modified by system software using the Set/Clear access method. Direct writes to these registers could have harmful side effects to the standard USB operations. The optional bits are as follows: Bits 3 through 7 in the Interface Control register and Bits 6 and 7 in the OTG Control register.

Please refer to the ULPI Specification Revision 1.1 for further information on the use of the optional features.

Offset: 160h | Read/Write: R/W | Reset: 0b000xx00000000000xxxxxxxx00000000

Bit	R/W	Reset	Description
31	RW	0x0	ULPI_WAKEUP: ULPI Wakeup. Writing the 1 to this bit will begin the wakeup operation. The bit will automatically transition to 0 after the wakeup is complete. Once this bit is set, the driver cannot set it back to 0. Note: The driver must never execute a wakeup and a read/write operation at the same time. 0 = CLEAR 1 = SET
30	RW	0x0	ULPI_RUN: ULPI read/write Run. Writing the 1 to this bit will begin the read/write operation. The bit will automatically transition to 0 after the read/write is complete. Once this bit is set, the driver cannot set it back to 0. Note: The driver must never execute a wakeup and a read/write operation at the same time. 0 = CLEAR 1 = SET
29	RW	0x0	ULPI_RD_WR: ULPI read/write control. (0) Read; (1) Write. This bit selects between running a read or write operation. 0 = READ 1 = WRITE
27	RO	X	ULPI_SYNC_STATE: ULPI sync state. (1) Normal Sync. State. (0) In another state (i.e. carkit, serial, low power) This bit represents the state of the ULPI interface. 0 = NOT_NORMAL 1 = NORMAL
26:24	RW	0x0	ULPI_PORT: ULPI PHY port no. This field should be always written as 0.
23:16	RW	0x0	ULPI_REG_ADDR: ULPI PHY register address. When doing a read or write operation to the ULPI PHY, the address of the ULPI PHY register being accessed is written to this field.
15:8	RO	X	ULPI_DATA_RD: ULPI PHY data read. The data from the ULPI PHY register can be read from here after the read operation completes.
7:0	RW	0x0	ULPI_DATA_WR: ULPI PHY data write. The data to write to the ULPI PHY register is written here.

21.5.8.25 USB2_CONTROLLER_2_USB2D_PORTSC1_0

USB2D Port Status/Control 1 Register

Offset: 174h | Read/Write: R/W | Reset: 0b0000000xx0000000xxx1xx00x0xx010x

Bit	R/W	Reset	Description
31:25	RW	0x0	DA: Device Address - RW. Default = 0000000b. The 7-bit USB device address for the device attached to an immediately downstream of the associated root port. A value of zero indicates no device is present or software support for this feature is not present. This is used by the Controller when sending the LPM token. This field is only valid when the core is operating in host mode. If in device mode it will be read only and always equal to 0000000b.
24:23	RO	X	SSTS: Suspend Status - RO. Default = 00b. These two bits are used by software to determine whether an L1-based suspend request was successful, specifically: 00b - L1 state entered with success. ACK received from peripheral. 01b - NYET received from peripheral. It was not able to enter L1 state this time. 10b - L1 state not supported by peripheral. STALL received. 11b - Peripheral didn't respond or an error occurred. The value of this field is only valid when the port resides in the L0 state - that is, the meaning of these bits are invalid whenever bit 7 of this register (SUSP) is one. Ideally, the Controller driver should read this register if it receives an interrupt after issuing a suspend using L1 support. In case of a non-success a port change interrupt will be fired and this field should be checked for a possible L1 failure. This field is only valid when the core is operating in host mode. If in device mode it will be always equal to 00b. 0 = L1STATE_ENTERED 1 = NYET_PERIPH 2 = L1STATE_NOT_SUPPORTED 3 = PERIPH_NORESP_ERR
22	RW	0x0	WKOC: Default = 0b. Wake on Over-current Enable: Writing this bit to a one enables the port to be sensitive to over-current conditions as wake-up events. This field is zero if Port Power(PP) is zero. This bit should only be used when operating in Host mode. Writing this bit to 1 while the controller is working in device mode can result in undefined behavior. 0 = DISBLE 1 = ENABLE
21	RW	0x0	WKDS: Wake on Disconnect Enable: Writing this bit to a one enables the port to be sensitive to device disconnects as wake-up events. This field is zero if Port Power(PP) is zero or in device mode. This bit should only be used when operating in Host mode. Writing this bit to 1 while the controller is working in device mode can result in undefined behaviour. This bit should not be written to 1 if there is no device connected. After the device disconnect is detected, this bit should be cleared to 0. 0 = DISBLE 1 = ENABLE
20	RW	0x0	WKCN: Wake on Connect Enable: Writing this bit to a one enables the port to be sensitive to device connects as wake-up events. This field is zero if Port Power(PP) is zero or in device mode. This bit should only be used when operating in Host mode. Writing this bit to 1 while the controller is working in device mode can result in undefined behaviour. This bit should not be written to 1 while the device is connected. After the device connection is detected, this bit should be cleared to 0. 0 = DISBLE 1 = ENABLE
19:16	RW	0x0	PTC: Port Test Control: Any other value than zero indicates that the port is operating in test mode. Value Specific Test 0000b Not enabled 0001b J_ STATE 0010b K_STATE 0011b SEQ_NAK 0100b Packet 0101b FORCE_ENABLE 0110b to 1111b Reserved Refer to Chapter 7 of the USB Specification Revision 2.0 for details on each test mode. 0 = NORMAL_OP 1 = TEST_J 2 = TEST_K 3 = TEST_SE0_NAK 4 = TEST_PKT 5 = TEST_FORCE_ENABLE
15:14	RO	X	PIC: Port Indicator Control: This field is not supported in the current implementation. Please use a GPIO if you wish to use Port Indicators.
13	RO	X	PO: Port Owner. Port owner handoff is not implemented in this design, therefore this bit will

Bit	R/W	Reset	Description
			always be 0.
12	RW	0x1	PP: Port Power: The function of this bit depends on the value of the Port Power Switching (PPC) field in the HCSPARAMS register. The behavior is as follows: PPC PP Operation 0b 0b Read Only. A device controller with no OTG capability does not have port power control switches. 1b 1b/0b RW. Host/OTG controller requires port power control switches. This bit represents the current setting of the switch (0=off, 1=on). When power is not available on a port (i.e. PP equals a 0), the port is non-functional and will not report attaches, detaches, etc. When an over-current condition is detected on a powered port and PPC is a one, the PP bit in each affected port may be transitioned by the host controller driver from a one to a zero (removing power from the port). 0 = NOT_POWERED 1 = POWERED
11:10	RO	X	LS: Line state. These bits reflect the current logical levels of the D+ (bit 10) and D- (bit 11) signal lines. The encoding of the bits are: 00b = SE0 01b = J-state 10b = K-state 11b = Undefined The value of this field is undefined if Port Power(PP) is zero in host mode. In host mode, the use of line-state by the host controller driver is not necessary (unlike EHCI), because the port controller state machine and the port routing manage the connection of LS and FS. In device mode, the use of line-state by the device controller driver is not necessary. 0 = SE0 1 = J_STATE 2 = K_STATE 3 = UNDEFINED
9	RW	0x0	SLP: Suspend using L1 - RW. Default = 0b. When this bit is set to '1' and a non-zero Device Address (DA) is specified Controller will instigate L1 entry during suspend (bit 7) and L1 exit during resume (bit 6). When set to zero the Controller will use the legacy (L2) mechanism. Software should only set this bit when the device attached immediately downstream supports L1 transitions. When acting as device, this bit is read-only and set to '1' by the hardware when the Controller enters is L1 state (LPM token received and accepted). Note: HSP is redundant with PSPD(27:26). This bit is not defined in the EHCI specification.
8	RW	0x0	PR: This field is zero if Port Power(PP) is zero. In Host Mode: Read/Write. 1=Port is in Reset. 0=Port is not in Reset. When software writes a one to this bit the bus-reset sequence as defined in the USB Specification Revision 2.0 is started. This bit will automatically change to zero after the reset sequence is complete. This behavior is different from EHCI where the host controller driver is required to set this bit to a zero after the reset duration is timed in the driver. In Device Mode: This bit is a read only status bit. Device reset from the USB bus is also indicated in the USBSTS register. 0 = NOT_USB_RESET 1 = USB_RESET
7	RO	X	SUSP: Port suspend. 1=Port in suspend state. 0=Port not in suspend state. In Host Mode: Read/Write. Port Enabled Bit and Suspend bit of this register define the port states as follows: Bits [Port Enabled, Suspend] Port State 0x Disable 10 Enable 11 Suspend When in suspend state, downstream propagation of data is blocked on this port, except for port reset. The blocking occurs at the end of the current transaction if a transaction was in progress when this bit was written to 1. In the suspend state, the port is sensitive to resume detection. Note that the bit status does not change until the port is suspended and that there may be a delay in suspending a port if there is a transaction currently in progress on the USB. The host controller will unconditionally set this bit to zero when software sets the Force Port Resume bit to zero. A write of zero to this bit is ignored by the host controller. If host software sets this bit to a one when the port is not enabled (i.e. Port enabled bit is a zero) the results are undefined. This field is zero if Port Power(PP) is zero in host mode. In Device Mode: Read Only. This bit is a read only status bit. 0 = NOT_SUSPEND 1 = SUSPEND
6	RW	0x0	FPR: Force Port Resume. 1= Resume detected/driven on port. 0=No resume (K state) detected/driven on port. In Host Mode: Software sets this bit to one to drive resume signaling. The Host Controller sets this bit to one if a J-to-K transition is detected while the port is in the Suspend state. When this bit transitions to a one because a J-to-K transition is detected, the Port Change Detect bit in the USBSTS register is also set to one. This bit will automatically change to zero after the resume sequence is complete. This behavior is different from EHCI where the host controller driver is required to set this bit to a zero after the resume duration is timed in the driver. Note that when the Host controller owns the port, the resume sequence follows the defined sequence documented in the USB Specification Revision 2.0. The resume signaling (Full-speed 'K') is driven on the port as long as this bit remains a one. This bit remains a one until the port has switched to the high-speed idle. Writing a zero has no effect because the port controller will time

Bit	R/W	Reset	Description
			the resume operation to clear the bit when the port control state switches to HS or FS idle. This field is zero if Port Power(PP) is zero in host mode. This bit is not-EHCI compatible. In Device mode: After the device has been in Suspend State for 5ms or more, software must set this bit to one to drive resume signaling before clearing. The Device Controller will set this bit to one if a J-to-K transition is detected while the port is in the Suspend state. The bit will be cleared when the device returns to normal operation. Also, when this bit transitions to a one because a J-to-K transition is detected, the Port Change Detect bit in the USBSTS register is also set to one. Software should ensure that the PHY clock is operational before writing a 1 to this bit to start the resume sequence. This is true for both Device and Host modes. 0 = NO_RESUME 1 = RESUME
5	RO	X	OCC: Over-current Change: Not supported 0 = NO_CHANGE 1 = CHANGE
4	RO	X	OCA: Over-current Active: Not supported 0 = NO_OVER_CURRENT 1 = OVER_CURRENT
3	RW	0x0	PEC: Port Enable/Disable Change: 1=Port enabled/disabled status has changed. 0=No change. In Host Mode: For the root hub, this bit gets set to a one only when a port is disabled due to disconnect on the port or due to the appropriate conditions existing at the EOF2 point (See Chapter 11 of the USB Specification). Software clears this by writing a one to it. This field is zero if Port Power(PP) is zero. In Device mode: The device port is always enabled. (This bit will be zero) 0 = NO_CHANGE 1 = CHANGE
2	RW	0x1	PE: Port Enabled/Disabled: 1=Enable. 0=Disable (default) In Host Mode: Ports can only be enabled by the host controller as a part of the reset and enable. Software cannot enable a port by writing a one to this field. Ports can be disabled by either a fault condition (disconnect event or other fault condition) or by the host software. Note that the bit status does not change until the port state actually changes. There may be a delay in disabling or enabling a port due to other host controller and bus events. When the port is disabled, (0b) downstream propagation of data is blocked except for reset. This field is zero if Port Power(PP) is zero in host mode. In Device Mode: The device port is always enabled. (This bit will be one) 0 = PORT_DISABLED 1 = PORT_ENABLED
1	RW	0x0	CSC: Connect Status Change: 1 =Change in Current Connect Status. 0=No change (default) In Host Mode: Indicates a change has occurred in the port's Current Connect Status. The host/device controller sets this bit for all changes to the port device connect status, even if system software has not cleared an existing connect status change. For example, the insertion status changes twice before system software has cleared the changed condition, hub hardware will be 'setting' an already-set bit (i.e., the bit will remain set). Software clears this bit by writing a one to it. This field is zero if Port Power(PP) is zero in host mode. This bit is undefined in device controller mode. 0 = NO_CHANGE 1 = CHANGE
0	RO	X	CCS: Current Connect Status: In Host Mode: 1=Device is present on port. 0=No device is present (default) This value reflects the current state of the port, and may not correspond directly to the event that caused the Connect Status Change bit (Bit 1) to be set. This field is zero if Port Power(PP) is zero in host mode. In Device Mode: 1=Attached 0=Not Attached (default) A one indicates that the device successfully attached and is operating in either high speed or full speed as indicated by the High Speed Port bit in this register. A zero indicates that the device did not attach successfully or was forcibly disconnected by the software writing a zero to the Run bit in the USBCMD register. It does not state the device being disconnected or suspended. 0 = NOT_CONNECTED 1 = CONNECTED

21.5.8.26 USB2_CONTROLLER_2_USB2D_HOSTPC1_DEVLC_0

USB2D Device Mode LPM Behav and Control Register

This register controls the LPM behavior and controls the behavior of each USB port. Only available when in device mode. This register shares the same address with the HOSTPC1 register (which is used only in host mode).

USB2D Host Mode LPM Behav and Control Register

This register controls the LPM behavior and controls the behavior of each USB port. Only available when in host mode. This register shares the same address with the DEVLC register (which is used only in device mode).

Offset: 1b4h | Read/Write: R/W | Reset: 0b0000xxxx000000000000xxxxxxxxxxx0

Bit	R/W	Reset	Description
31:29	RW	0x0	PTS: Parallel transceiver select. This bit is not defined in the EHCI specification. 0 = UTMI 1 = RESERVED 2 = ULPI 3 = ICUSB_SER 4 = HSIC
28	RW	0x0	STS: Serial transceiver not selected. This is the only value supported. This bit is not defined in the EHCI specification. 0 = PARALLEL_IF 1 = SERIAL_IF
27	RO	X	PTW: Parallel Transceiver Width. Fixed to 0. This bit is not defined in the EHCI specification. 0 = EIGHT_BIT 1 = RESERVED
26:25	RO	X	PSPD: This register field indicates the speed at which the port is operating. 00 = Full Speed 01 = Low Speed 10 = High Speed. This bit is not defined in the EHCI specification. 0 = FULL_SPEED 1 = LOW_SPEED 2 = HIGH_SPEED 3 = RESERVED
23	RW	0x0	PFSC: Port Force Full Speed Connect - RW. Default = 0b. Writing this bit to a '1b' will force the port to only connect at Full Speed. It disables the chirp sequence that allows the port to identify itself as High Speed. This is useful for testing FS configurations with a HS host, hub or device. This bit is not defined in the EHCI specification. 0 = DONT_FORCE_FULL_SPEED 1 = FORCE_FULL_SPEED
22	RW	0x0	PHCD: PHY Low Power Suspend - Clock disable: Writing this bit to a 1 will disable the PHY clock. Write a 0 enables it. Reading this bit will indicate the status of the PHY clock. NOTE: The PHY clock cannot be disabled if it is being used as the system clock. In device mode, the PHY can be put into Low Power Clock Disable when the device is not running (USBCMD RS=0b) or the host has signaled suspend (PORTSCx SUSP=1b). Low Power Clock Disable will be cleared automatically when the host has signaled resume. Before forcing a resume from the device, the Controller driver must clear this bit. In host mode, the PHY can be put into Low Power Suspend Clock Disable when the downstream device has been put into suspend mode or when no downstream device is connected. Low Power Clock Disable is completely under the control of software. 0 = DISABLE 1 = ENABLE
21:20	RW	0x0	LPMX: Auto LPM set - RW. Default = 00b. This bit field is valid during Host Mode Only. For Device Mode this is reserved. Value Meaning 00b Disables auto LPM. 01b If there is no activity for a certain number of SOFs the controller will send a LPM token, enter in suspend and issue a port change interrupt. 10b Same as above but without issuing an interrupt. 11b Reserved for futures LPM enhancements. The detection of no activity is based on the absence of response from the downstream device. Because of this limitation this feature should not be used if ISO OUT endpoints are being used (as no handshake is expected).

Bit	R/W	Reset	Description
17	RW	0x0	ASUS: Auto Low Power - RW. Default = 0b. This bit field is valid during Device Mode Only. In Host Mode it is part of ELPM field. This bit is used to control the auto low power feature. If set, the auto low power feature will be enabled and every time the port enters in suspend state it will also enter in low power state, disabling the transceiver clock. The behavior will be the same as if the PHCD bit was enabled (in fact this bit will be set to '1' as soon as low power mode is enabled). 0 = DISABLE 1 = ENABLE
19:16	RW	0x0	EPLPM: Endpoint for LPM token - RW. Default = 0000b. This bit field is valid during Host Mode Only. For Device Mode [19:18] is reserved and 17 is ASUS, while 16 is STL. This sets the endpoint number to which the LPM token will be sent. It will be directly mapped to the ENDP field in the LPM token with the EXT PID.
16	RW	0x0	STL: STALL reply to LPM token - RW. Default = 0b. This bit field is valid during Device Mode Only. In Host Mode it is a part of ELPM field. When this bit is set to '1', the Controller will reply always with STALL to all incoming LPM tokens. This bit overrides the LPM NYET bit (NYT). 0 = DISABLE 1 = ENABLE
15:12	RW	0x0	LPMFRM: Auto LPM SOF Threshold - RW. Default = 0000b. This bit field is valid during Host Mode Only. For Device Mode this is reserved. This holds the SOF counter threshold. When the number of SOF with no activity in between reaches this threshold and the auto LPM is enabled, a LPM token will be sent and the port will enter in suspend state. The SOF counter for this threshold is incremented each 125us, even if the port is not in HS operation.
11:1	RO	X	BA: BmAttributtes - RO. Default = 00000000000b. This holds the bmAttributes field of the LPM sub-token received, after the EXT PID token.
0	RW	0x0	NYT_ASUS: NYET reply to LPM token - RW. Default = 0b. This bit is NYT during Device Mode. Details follows: When this bit is to '1', the device controller will NYET all the LPM tokens. When this bit is set to '0', the Controller will ACK all the LPM tokens if the STALL bit (STL) is also set to '0'. This bit is ASUS in Host Mode. Details follows: This bit is used to control the auto low power feature. If set, the auto low power feature will be enabled and every time the port enters in suspend state it will also enter in low power state, disabling the transceiver clock. The behavior will be the same as if the PHCD bit was enabled (in fact this bit will be set to '1' as soon as low power mode is enabled). 0 = DISABLE 1 = ENABLE

21.5.8.27 USB2_CONTROLLER_2_USB2D_OTGSC_0

USB2D On-The-Go (OTG) Status and Control Register

Offset: 1f4h | Read/Write: R/W | Reset: 0b0000000x0000000xxxxxxxxxx000x00

Bit	R/W	Reset	Description
30	RW	0x0	DPIE: Data Pulse Interrupt Enable. Setting this bit enables the Data pulse interrupt. 0 = DISABLE 1 = ENABLE
29	RW	0x0	ONEMSE: 1 millisecond timer Interrupt enable. Setting this bit enables the 1 millisecond timer interrupt. 0 = DISABLE 1 = ENABLE
28	RW	0x0	BSEIE: B Session End Interrupt Enable. Setting this bit enables the B session end interrupt 0 = DISABLE 1 = ENABLE
27	RW	0x0	BSVIE: B Session Valid Interrupt Enable. Setting this bit enables the B session valid interrupt 0 = DISABLE 1 = ENABLE
26	RW	0x0	ASVIE: A Session Valid Interrupt Enable. Setting this bit enables the A session valid interrupt 0 = DISABLE

Bit	R/W	Reset	Description
			1 = ENABLE
25	RW	0x0	AVVIE: A VBus Valid Interrupt Enable. Setting this bit enables the A VBus valid interrupt 0 = DISABLE 1 = ENABLE
24	RW	0x0	IDIE: USB ID Interrupt Enable. Setting this bit enables the USB ID interrupt 0 = DISABLE 1 = ENABLE
22	RW	0x0	DPIS: Data Pulse Interrupt Status. This bit is set when data bus pulsing occurs on DP or DM. Data bus pulsing is only detected when USBMODE.CM = Host (11) and PORTSC(0).PortPower = Off (0). Software writes a 1 to clear this bit. 0 = INT_CLEAR 1 = INT_SET
21	RW	0x0	ONEMSS: 1 millisecond timer Interrupt Status: This bit is set once every millisecond. Software writes a 1 to clear it. 0 = INT_CLEAR 1 = INT_SET
20	RW	0x0	BSEIS: B Session End Interrupt Status. This bit is set when VBus has fallen below the B session end threshold. Software writes a 1 to clear this bit . 0 = INT_CLEAR 1 = INT_SET
19	RW	0x0	BSVIS: B Session Valid Interrupt Status. This bit is set when VBus has either risen above or fallen below the B session valid threshold (0.8 VDC). Software writes a 1 to clear this bit. 0 = INT_CLEAR 1 = INT_SET
18	RW	0x0	ASVIS: A Session Valid Interrupt Status. This bit is set when VBus has either risen above or fallen below the A session valid threshold (0.8 VDC). Software writes a one to clear this bit. 0 = INT_CLEAR 1 = INT_SET
17	RW	0x0	AVVIS: A VBus Valid Interrupt Status. This bit is set when VBus has either risen above or fallen below the VBus valid threshold (4.4 VDC) on an A device. Software writes a 1 to clear this bit. 0 = INT_CLEAR 1 = INT_SET
16	RW	0x0	IDIS: USB ID Interrupt Status. This bit is set when a change on the ID input has been detected. Software writes a 1 to clear this bit. 0 = INT_CLEAR 1 = INT_SET
14	RO	X	DPS: Data Bus Pulsing Status. A 1 indicates data bus pulsing is being detected on the port. 0 = STS_CLEAR 1 = STS_SET
13	RO	X	ONEMST: 1 millisecond timer toggle. This bit toggles once per millisecond 0 = STS_CLEAR 1 = STS_SET
12	RO	X	BSE: B session End. Indicates VBus is below the B session end threshold 0 = STS_CLEAR 1 = STS_SET
11	RO	X	BSV: B Session Valid. Indicates VBus is above the B session valid threshold 0 = STS_CLEAR 1 = STS_SET
10	RO	X	ASV: A Session Valid. Indicates VBus is above the A session valid threshold 0 = STS_CLEAR 1 = STS_SET
9	RO	X	AVV: A VBus Valid. Indicates VBus is above the A VBus valid threshold 0 = STS_CLEAR

Bit	R/W	Reset	Description
			1 = STS_SET
8	RO	X	ID: USB ID: 0 = A-device 1 = B-device 0 = A_DEV 1 = B_DEV
5	RW	0x0	IDPU: USB ID Pullup 0 = CLEAR 1 = SET
4	RW	0x0	DP: Data Pulsing. Setting this bit causes the pull-up on DP to be asserted for data pulsing during SRP. 0 = NO_DATA_PULSE 1 = DATA_PULSE
3	RW	0x0	OT: OTG Termination. This bit must be set when the OTG device is in device mode, this controls the pulldown on DM. 0 = NO_OTG_TERM 1 = OTG_TERM
1	RW	0x0	VC: VBUS Charge. Setting this bit causes the VBus line to be charged. This is used for VBus pulsing during SRP. 0 = NO_VBUS_CHRG 1 = VBUS_CHRG
0	RW	0x0	VD: VBUS_Discharge. Read/write. Setting this bit causes Vbus to discharge through a resistor. 0 = NO_VBUS_DISCHRG 1 = VBUS_DISCHRG

21.5.8.28 USB2_CONTROLLER_2_USB2D_USBMODE_0

USB2D USB Device Mode Register

Offset: 1f8h | Read/Write: R/W | Reset: 0b0xxxxxxxxx0xxxxx

Bit	R/W	Reset	Description
15	RW	0x0	SRT: Shorten USB Reset Time. Software should never set this to 1.
5	RW	0x0	VBPS: VBUS Power Select This can be used by logic that selects between an on-chip Vbus power source (charge pump) and an off-chip source in systems when both are available. Only to be used in Host Mode No functionality implemented for this, so SW should not use this.
4	RO	X	SDIS: Stream disbable: 1 Streaming is disabled - helpful to avoid overrun/underruns when system load is too high. 0 = STREAM_ENABLE 1 = STREAM_DISABLE
3	RO	X	SLOM: Setup Lockout Mode: In device mode, this bit controls the behavior of the setup lockout mechanism. 0 - Setup lockout is ON (default) 1 Setup lockout is OFF. Firmware requires the use of setup tripwire semaphore in USB2D_USBCMD register. 0 = LOCKOUT_ON 1 = LOCKOUT_OFF
2	RO	X	ES: Endian Select: Note: For this implementation, this should be always set to 0 (little endian). 0 = LITTLE_ENDIAN 1 = RESERVED
1:0	RO	X	CM: Controller Mode: The controller mode will default to an idle state and will need to be initialized to the desired operating mode after reset. This register can only be written once after reset. If it is necessary to switch modes, software must reset the controller by writing to the RESET bit in the USBCMD register before reprogramming this register. 00 = Idle [Default] 01 = Reserved 10 = Device Controller 11 = Host Controller 0 = IDLE 1 = RESERVED 2 = DEVICE_MODE

Bit	R/W	Reset	Description
			3 = HOST_MODE

21.5.8.29 USB2_CONTROLLER_2_USB2D_ENDPTNAK_0

USB2D Endpoint NAK register

Offset: 200h | Read/Write: R/W | Reset: 0b00000000000000000000000000000000

Bit	Reset	Description
31:16	0x0	EPTN: TX Endpoint NAK R/WC. Each TX endpoint has 1 bit in this field. The bit is set when the device sends a NAK handshake on a received IN token for the corresponding endpoint. 0 = CLEAR 1 = SET
15:0	0x0	EPRN: RX Endpoint NAK R/WC. Each RX endpoint has 1 bit in this field. The bit is set when the device sends a NAK handshake on a received OUT or PING token for the corresponding endpoint. 0 = CLEAR 1 = SET

21.5.8.30 USB2_CONTROLLER_2_USB2D_ENDPTNAK_ENABLE_0

USB2D Endpoint NAK Enable register

Offset: 204h | Read/Write: R/W | Reset: 0b00000000000000000000000000000000

Bit	Reset	Description
31:16	0x0	EPTNE: TX Endpoint NAK Enable R/W. Each bit is an enable bit for the corresponding TX Endpoint NAK bit. If this bit is set and the corresponding TX Endpoint NAK bit is set, the NAK Interrupt bit is set. 0 = DISABLE 1 = ENABLE
15:0	0x0	EPRNE: RX Endpoint NAK Enable R/W. Each bit is an enable bit for the corresponding RX Endpoint NAK bit. If this bit is set and the corresponding RX Endpoint NAK bit is set, the NAK Interrupt bit is set. 0 = DISABLE 1 = ENABLE

21.5.8.31 USB2_CONTROLLER_2_USB2D_ENDPTSETUPSTAT_0

USB2D Endpoint Setup Status Register

Offset: 208h | Read/Write: R/W | Reset: 0b0000000000000000

Bit	Reset	Description
15	0x0	ENDPTSETUPSTAT15: Endpoint 15 Setup Status: For every setup transaction that is received, this bit is set to 1. Software must clear or acknowledge the setup transfer by writing a 1 to it after it has read the setup data from Queue head. The response to a setup packet (as in the order of operations and total response time) is crucial to limit bus time-outs while the setup lock-out mechanism is engaged. This register is only used in device mode. 0 = NOT_RCVD 1 = SETUP_RCVD
14	0x0	ENDPTSETUPSTAT14: Endpoint 14 Setup Status: For every setup transaction that is received, this bit is set to 1. Software must clear or acknowledge the setup transfer by writing a 1 to it after it has read the setup data from Queue head. The response to a setup packet (as in the order of operations and total response time) is crucial to limit bus time-outs while the setup lock-out mechanism is engaged. This register is only used in device mode. 0 = NOT_RCVD 1 = SETUP_RCVD

Bit	Reset	Description
13	0x0	ENDPTSETUPSTAT13: Endpoint 13 Setup Status: For every setup transaction that is received, this bit is set to 1. Software must clear or acknowledge the setup transfer by writing a 1 to it after it has read the setup data from Queue head. 21.5.8.34 USB2_CONTROLLER_2_USB2D_ENDPTSTATUS_0

USB2D Endpoint Status Register

Offset: 214h | Read/Write: RO | Reset: 0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx

Bit	Reset	Description
31	X	ETBR15: Endpoint Transmit Buffer Ready: One bit for each endpoint indicates status of the respective endpoint buffer. This bit is set to a one by the hardware as a response to receiving a command from a corresponding bit in the ENDPTPRIME register. There will always be a delay between setting a bit in the ENDPTPRIME register and endpoint indicating ready. This delay time varies based upon the current USB traffic and the number of bits set in the ENDPTPRIME register. Buffer ready is cleared by USB reset, by the USB DMA system, or through the ENDPTFLUSH register. This is only used in device mode. 0 = NOT_READY 1 = READY
30	X	ETBR14: Endpoint Transmit Buffer Ready: One bit for each endpoint indicates status of the respective endpoint buffer. This bit is set to a one by the hardware as a response to receiving a command from a corresponding bit in the ENDPTPRIME register. There will always be a delay between setting a bit in the ENDPTPRIME register and endpoint indicating ready. This delay time varies based upon the current USB traffic and the number of bits set in the ENDPTPRIME register. Buffer ready is cleared by USB reset, by the USB DMA system, or through the ENDPTFLUSH register. This is only used in device mode. 0 = NOT_READY 1 = READY
29	X	ETBR13: Endpoint Transmit Buffer Ready: One bit for each endpoint indicates status of the respective endpoint buffer. This bit is set to a one by the hardware as a response to receiving a command from a corresponding bit in the ENDPTPRIME register. There will always be a delay between setting a bit in the ENDPTPRIME register and endpoint indicating ready. This delay time varies based upon the current USB traffic and the number of bits set in the ENDPTPRIME register. Buffer ready is cleared by USB reset, by the USB DMA system, or through the ENDPTFLUSH register. This is only used in device mode. 0 = NOT_READY 1 = READY
28	X	ETBR12: Endpoint Transmit Buffer Ready: One bit for each endpoint indicates status of the respective endpoint buffer. This bit is set to a one by the hardware as a response to receiving a command from a corresponding bit in the ENDPTPRIME register. There will always be a delay between setting a bit in the ENDPTPRIME register and endpoint indicating ready. This delay time varies based upon the current USB traffic and the number of bits set in the ENDPTPRIME register. Buffer ready is cleared by USB reset, by the USB DMA system, or through the ENDPTFLUSH register. This is only used in device mode. 0 = NOT_READY 1 = READY
27	X	ETBR11: Endpoint Transmit Buffer Ready: One bit for each endpoint indicates status of the respective endpoint buffer. This bit is set to a one by the hardware as a response to receiving a command from a corresponding bit in the ENDPTPRIME register. There will always be a delay between setting a bit in the ENDPTPRIME register and endpoint indicating ready. This delay time varies based upon the current USB traffic and the number of bits set in the ENDPTPRIME register. Buffer ready is cleared by USB reset, by the USB DMA system, or through the ENDPTFLUSH register. This is only used in device mode. 0 = NOT_READY 1 = READY
26	X	ETBR10: Endpoint Transmit Buffer Ready: One bit for each endpoint indicates status of the respective endpoint buffer. This bit is set to a one by the hardware as a response to receiving a command from a corresponding bit in the ENDPTPRIME register. There will always be a delay between setting a bit in the ENDPTPRIME register and endpoint indicating ready. This delay time varies based upon the current USB traffic and the number of bits set in the ENDPTPRIME register. Buffer ready is cleared by USB reset, by the USB DMA system, or through the ENDPTFLUSH register. This is only used in device mode. 0 = NOT_READY 1 = READY
25	X	ETBR9: Endpoint Transmit Buffer Ready: One bit for each endpoint indicates status of the respective endpoint buffer. This bit is set to a one by the hardware as a response to receiving a command from a corresponding bit in the ENDPTPRIME register. There will always be a delay between setting a bit in the ENDPTPRIME register and endpoint indicating ready. This delay time varies based upon the current USB traffic and the number of bits set in the ENDPTPRIME register. Buffer ready is cleared by USB reset, by the USB DMA system, or through the ENDPTFLUSH register. This is only used in device mode. 0 = NOT_READY

26	RW	0x0	FAST_WAKEUP_RESP: Enable Fast Response from UTMIP PHY for a Remote Wakeup request from device. This is used only for cases where wakeup response needs to be within 1ms of spec. Used for Host mode ONLY. 0 = DISABLE 1 = ENABLE
25	RW	0x0	UTMIP_SUSPL1_SET: Enable SuspendL1 for UTMIP PHY Enabling this will only cutoff clocks to

Bit	R/W	Reset	Description
			the utmip logic. The USB plls, PllU and UTMIP PLL will still be running. 0 = DISABLE 1 = ENABLE
18:16	RW	0x0	USB_WAKEUP_DEBOUNCE_COUNT: USB PHY wakeup debounce counter USB will debounce any wakeup event by the number of clocks programmed in this counter. A value of 0 results in no debounce.
15	RW	0x0	ICUSB_MOD_CLK_ENB: ICUSB module clock enable. Enables transceiver clock to USB controller when in ICUSB mode. After setting ICUSB_PHY_ENB, software needs to wait until PLLU output is stable before setting ICUSB_MOD_CLK_ENB to ENABLE. This will be reset to DISABLE whenever ICUSB is in suspend. Software needs to enable it after ICUSB comes out of suspend after waiting for PLLU output to be stable again. 0 = DISABLE 1 = ENABLE
13	RW	0x0	ICUSB_PHY_ENB: Enable ICUSB PHY mode Setting this will enable the PLLU output clock when ICUSB is not in suspend 0 = DISABLE 1 = ENABLE
12	RW	0x0	UTMIP_PHY_ENB: Enable UTMIP PHY mode Set this to 1 if using UTMIP PHY. Otherwise set this to 0. 0 = DISABLE 1 = ENABLE
11	RW	0x1	UTMIP_RESET: Reset going to UTMIP PHY (active high). This should be set to 1 whenever programming the UTMIP config registers. It should be cleared to 0 after the programming of UTMIP config registers is done. UTMIP config registers should be programmed only once before doing any transactions on USB. The UTMIP PHY registers should be programmed while UTMIP is in reset. 0 = DISABLE 1 = ENABLE
10	RW	0x0	USB_SUSP_POL: Polarity of the suspend signal going to USB PHY. 0 = Active low (default) 1 = Active high This should not be changed by software. 0 = ACTIVE_LOW 1 = ACTIVE_HIGH
9	RW	0x0	USB_PHY_CLK_VALID_INT_ENB: USB PHY clock valid interrupt enable. If this bit is enabled, interrupt is generated whenever USB clocks are resumed from a suspend. 0 = DISABLE 1 = ENABLE
8	RO	0x0	USB_PHY_CLK_VALID_INT_STS: USB PHY clock valid interrupt status. This bit is set whenever USB PHY clock is waked up from suspend. Software must write a 1 to clear this bit. 0 = UNSET 1 = SET
7	RO	X	USB_PHY_CLK_VALID: USB PHY clock valid status. This bit indicates whether the USB PHY is generating a valid clock to the USB controller. If USB PHY clock is running, this bit is set to 1, else it is set to 0. 0 = UNSET 1 = SET
6	RO	X	USB_CLKEN: USB AHB clock enable status. Indicates whether the AHB clock to the USB controller is enabled or not. If AHB clock to USB controller is enabled, this bit is set to 1, else it is set to 0. NOTE: even when this is set to 0, all essential blocks that are required to resume USB clocks from suspend will be active and their AHB clock will not be suspended. 0 = UNSET 1 = SET
5	RW	0x0	USB_SUSP_CLR: Suspend Clear Software must write a 1 to this bit to bring the PHY out of suspend mode. This is used when the software stops the PHY clock during suspend and then wants to initiate a resume. Software should also write 0 to clear it. NOTE: It is required that software generate a positive pulse on this bit to guarantee proper operation. 0 = UNSET 1 = SET

Bit	R/W	Reset	Description
4	RW	0x0	USB_WAKE_ON_DISCON_EN_DEV: Wake on Disconnect Enable (device mode) When enabled (1), USB device will wakeup from suspend on a disconnect event. This is only valid when USB controller is in device mode, it is not applicable when USB controller is in host mode. 0 = DISABLE 1 = ENABLE
3	RW	0x0	USB_WAKE_ON_CNNT_EN_DEV: Wake on Connect Enable (device mode) When enabled (1), USB device will wakeup from suspend on a connect event. This is only valid when USB controller is in device mode, it is not applicable when USB controller is in host mode. 0 = DISABLE 1 = ENABLE
2	RW	0x0	USB_WAKE_ON_RESUME_EN: Wake on resume enable. If this bit is enabled, USB will wakeup from suspend whenever a resume event is detected on USB. This is valid for both USB device and USB host modes. 0 = DISABLE 1 = ENABLE
1	RW	0x0	USB_WAKEUP_INT_ENB: USB wakeup interrupt enable. If this bit is enabled, interrupt is generated whenever USB wakeup event is generated. 0 = DISABLE 1 = ENABLE
0	RO	0x0	USB_WAKEUP_INT_STS: USB wakeup interrupt status. This bit is set whenever USB wakes up from suspend (a wakeup event is generated). Software must write a 1 to clear this bit. Note that during the wakeup sequence, PHY clocks will be resumed from suspend. Software can check when the PHY clocks are resumed by reading the bit USB_PHY_CLK_VALID. There is also a separate interrupt generated when PHY clock is resumed if USB_PHY_CLK_VALID_INT_EN is set. During the wakeup sequence, first USB_WAKEUP_INT_STS will be set, and it will take some time for the PHY clock to resume, which can be detected by checking USB_PHY_CLK_VALID. 0 = UNSET 1 = SET

21.5.9.2 USB3_IF_USB_PHY_VBUS_SENSORS_0

USB PHY VBUS SENSORS control register

This register controls the OTG VBUS sensors in the USB PHY. We have the following 4 VBUS sensors:

- A_VBUS_VLD
- A_SESS_VLD
- B_SESS_VLD
- B_SESS_END

The debounced status of each sensor can be read from _STS. The field _CHG_DET is set to 1 whenever a change is detected in the value of . If _INT_EN is set, then an interrupt is generated to the processor. This interrupt can be routed to CPU/COP by appropriately writing the USBD bits in the interrupt controller registers.

In case Software wants to override the value for a , it can set _SW_EN to 1, and set _SW_VALUE to 1 or 0 as per the requirement.

We have two debouncers for each sensor - DEBOUNCE_A and DEBOUNCE_B. The debounce values for them are controlled by the register UTMIP_DEBOUNCE_CFG0, fields UTMIP_BIAS_DEBOUNCE_A and UTMIP_BIAS_DEBOUNCE_B. For each sensor, we can select whether to use DEBOUNCE_A or DEBOUNCE_B by setting the field _DEB_SEL_B to approrpriate value (SEL_A or SEL_B).

Note: Do not set either UTMIP_BIAS_DEBOUNCE_A or UTMIP_BIAS_DEBOUNCE_B to 0x0. If not using one of the debouncers, keep it at the default value of 0xFFFF.

Note: The source for A_SESS_VLD sensor can be programmed according to the setting of USB1_VBUS_SENSE_CTL in register USB1_LEGACY_CTRL.

0	RW	0x0	B_SESS_END_INT_EN: B_SESS_END interrupt enable. If this field is set to 1, an interrupt is generated whenever B_SESS_END_CHG_DET is set to 1. 0 = DISABLE 1 = ENABLE

21.5.9.3 USB3_IF_USB_PHY_VBUS_WAKEUP_ID_0

USB PHY VBUS wakeup and ID control register

This register controls the battery charger (VDCD_DET, VDAT_DET), VBUS_WAKEUP and ID sensors. We have the following sensors in this register:

- VBUS_WAKEUP
- ID
- VDAT_DET
- VDCD_DET

The debounced status of each sensor can be read from _STS. The field _CHG_DET is set to 1 whenever a change is detected in the value of . If _INT_EN is set, then an interrupt is generated to the processor. This interrupt can be routed to CPU/COP by appropriately writing the USBD bits in the interrupt controller registers.

In case Software wants to override the value for a , it can set _SW_EN to 1, and set _SW_VALUE to 1 or 0 as per the requirement.

We have two debouncers for each sensor - DEBOUNCE_A and DEBOUNCE_B. The debounce values for them are controlled by the register UTMIP_DEBOUNCE_CFG0, fields UTMIP_BIAS_DEBOUNCE_A and UTMIP_BIAS_DEBOUNCE_B. For each sensor, we can select whether to use DEBOUNCE_A or DEBOUNCE_B by setting the field _DEB_SEL_B to apprORpriate value (SEL_A or SEL_B).

Note: Do not set either UTMIP_BIAS_DEBOUNCE_A or UTMIP_BIAS_DEBOUNCE_B to 0x0. If not using one of the debouncers, keep it at the default value of 0xFFFF.

There are debouncers for VDAT_DET and VDCD_DET. These use separate debouncers - CHRG_DEBOUNCE_PERIOD_A and CHRG_DEBOUNCE_PERIOD_B. The debounce values for them are controlled by the register UTMIP_CHRG_DEB_CFG0, fields UTMIP_CHRG_DEBOUNCE_PERIOD_A and UTMIP_CHRG_DEBOUNCE_PERIOD_B. For each sensor, we can select whether to use HRG_DEBOUNCE_PERIOD_A or CHRG_DEBOUNCE_PERIOD_B by setting the field _DEB_SEL_B to appropriate value (SEL_A or SEL_B).

Note: Do not set either UTMIP_CHRG_DEBOUNCE_PERIOD_A or UTMIP_CHRG_DEBOUNCE_PERIOD_B to 0x0. If not using one of the debouncers, keep it at the default value of 0xFFFF.

21.5.10 USB 3 UTMIP Configuration Registers

Note: Current UTMIP configuration registers use settings that support NV software drivers and should NOT be modified. If designing custom drivers, consult your NV representative prior to modifying these registers

21.5.10.1 USB3_UTMIP_PLL_CFG0_0

USB_PHY PLL Configuration Register 0 The data sampling frequency relies on a 960MHz clock, so the goal of the PLL is to have: In_Frequency*(PLL_VCOMULTBY2+1)*(PLL_NDIV/PLL_MDIV) = 960MHz With a 12MHz input from PLL_U, the default setting of PLL_VCOMULTBY2=1, PLL_NDIV=40 and PLL_MDIV=1 results in a correct output.

Note: This register has been moved to the CAR section of this document. PROGRAMMING THIS REGISTER HERE WILL HAVE NO EFFECT WHATSOEVER!

This register was used to configure PLL inside utmip block prior to Tegra 3. This has been de-featured from utmip space and moved to car space.

This register is used to configure the PHY PLL contained in the UTMIP module.

Offset: 800h | Read/Write: R/W | Reset: 0b00000000010100000000000110000000

Bit	Reset	Description
30:28	0x0	UTMIP_PLL_SELECT: Selects which of the eight 60MHz clock phases to produce at the output of the USB PHY PLL. This is for a test mode. See cell specification.
27	0x0	UTMIP_PLL_PDIVRST: PDIVRST of the UTMIP PHY PLL. Reserved. Keep at 0x0. Currently there is no post divider on this PLL. See cell specification.
26:24	0x0	UTMIP_PLL_PDIV: PDIV[2:0] input of the USB_PHY PLL. Reserved. Keep at 0x0. Currently there is no post divider on this PLL. See cell specification.
23:16	0x28	UTMIP_PLL_NDIV: NDIV[7:0] input of USB_PHY PLL. This is the feedback divider on the VCO feedback. 0x0 is not allowed. See cell specification.
15:8	0x1	UTMIP_PLL_MDIV: MDIV[7:0] input of the USB_PHY PLL. This is the predivide on the PLL. 0x0 is not allowed. See cell specification.
7	0x1	UTMIP_PLL_VCOMULTBY2: VCOMULTBY2 control of the UTMIP PHY PLL. Recommended setting is

Bit	Reset	Description
		on. Additional divide by 2 on the VCO feedback. Which is setting the bit to 1. See cell spec.
6:1	0x0	UTMIP_PLL_LOCKSEL: LOCKSEL[5:0] input of USB_PHY PLL. Used in test modes only. See cell specification.
0	0x0	UTMIP_PLL_LOCKENABLE: LOCK_ENABLE input of USB_PHY PLL. Normally only used during test. See cell specification.

21.5.10.2 USB3_UTMIP_PLL_CFG1_0

UTMIP PLL and PLLU configuration register 1

Note: This register has been moved to the CAR section of this document. PROGRAMMING THIS REGISTER HERE WILL HAVE NO EFFECT WHATSOEVER!

This register was used to configure PLL inside utmip block prior to Tegra 3. This has been de-featured from utmip space and moved to car space.

PLL CONFIGURATION & PARAMETERS

In normal operation, the following clock generators are in play for USB:

Xtal clock -> enters PLL_U to generate 12MHz clock -> enters USB_PHY PLL to generate 480/60 MHz clock

The following parameters control the bringup of the plls:

Coming out of reset or suspend

- -> PllUOnState: start pllu_enable_count and pll_lock_count
- -> Wait ~1us to actually enable the PLL_U (pllu_enable_count == ClkXtal * PLLU_ENABLE_DLY_COUNT * 8)
- -> Wait ~1ms until PLL_U is actually stable (pll_lock_count == ClkXtal * PLLU_STABLE_COUNT * 256) => USB_PHY PLL_ENABLE

pll_active_count = 0

- -> Wait 5us to enable pll_active: pll_active_count == ClkXtal * PLL_ACTIVE_DLY_COUNT * 16 => USB_PHY PLL_ACTIVE
- -> Wait ~2.5ms until USB_PHY is actually stable (pll_lock_count == ClkXtal * XTAL_FREQ_COUNT * 256) => USB_PHY

Numbers for a 19.2MHz Xtal clock

- PLLU_ENABLE_DLY_COUNT[4:0] = 1 * 19.2 / 8 = 2.4 = 3 = 0x03
- PLLU_STABLE_COUNT[11:0] = 1000 * 19.2 / 256 = 75 = 0x4b (Note: currently defaults to 0x600)
- PLL_ACTIVE_DLY_COUNT[4:0] = 5 * 19.2 / 16 = 6 = 0x06
- XTAL_FREQ_COUNT[11:0] = 2500 * 19.2 / 256 = 187 = 0xbb

Offset: 804h | Read/Write: R/W | Reset: 0b00011000001000000000000011000000

Bit	Reset	Description
31:27	0x3	UTMIP_PLLU_ENABLE_DLY_COUNT: Controls the wait time to enable PLL_U when coming out of suspend or reset.
26:18	0x8	UTMIP_PLL_SETUP: SETUP[8:0] input of USB_PHY PLL.
17	0x0	UTMIP_FORCE_PLLU_POWERUP: Force PLL_U into power up.

Bit	Reset	Description
16	0x0	UTMIP_FORCE_PLLU_POWERDOWN: Force PLL_U into power down. (Overrides FORCE_PLLU_POWERUP.)
15	0x0	UTMIP_FORCE_PLL_ENABLE_POWERUP: Force USB_PHY PLL pll_enable input on.
14	0x0	UTMIP_FORCE_PLL_ENABLE_POWERDOWN: Force USB_PHY PLL pll_enable input off. (Overrides FORCE_PLL_ENABLE_POWERUP.)
13	0x0	UTMIP_FORCE_PLL_ACTIVE_POWERUP: Force USB_PHY PLL pll_active input on.
12	0x0	UTMIP_FORCE_PLL_ACTIVE_POWERDOWN: Force USB_PHY PLL pll_active input off. (Overrides FORCE_PLL_ACTIVE_POWERUP.)
11:0	0xc0	UTMIP_XTAL_FREQ_COUNT: Determines the time to wait until the output of USB_PHY PLL is considered stable.

21.5.10.3 USB3_UTMIP_XCVR_CFG0_0

UTMIP transceiver cell configuration register 0

Offset: 808h | Read/Write: R/W | Reset: 0b00100000001001010110010100000000

Bit	Reset	Description
31:25	0x10	UTMIP_XCVR_HSSLEW_MSB: Most significant bits of HS_SLEW.
24:22	0x0	UTMIP_XCVR_SETUP_MSB: Most significant bits of SETUP.
21	0x1	UTMIP_XCVR_LSBIAS_SEL: Low speed bias selection method for usb transceiver pad
20	0x0	UTMIP_XCVR_DISCON_METHOD: Disconnect method on the usb transceiver pad
19	0x0	UTMIP_FORCE_PDZI_POWERUP: Force PDZI input into power up.
18	0x1	UTMIP_FORCE_PDZI_POWERDOWN: Force PDZI input into power down. (Overrides FORCE_PDZI_POWERUP.)
17	0x0	UTMIP_FORCE_PD2_POWERUP: Force PD2 input into power up.
16	0x1	UTMIP_FORCE_PD2_POWERDOWN: Force PD2 input into power down. (Overrides FORCE_PD2_POWERUP.)
15	0x0	UTMIP_FORCE_PD_POWERUP: Force PD input into power up.
14	0x1	UTMIP_FORCE_PD_POWERDOWN: Force PD input into power down. (Overrides FORCE_PD_POWERUP.)
13	0x1	UTMIP_XCVR_TERMEN: Enable HS termination.
12	0x0	UTMIP_XCVR_HSLOOPBACK: Internal loopback inside XCVR cell. Used for IOBIST.
11:10	0x1	UTMIP_XCVR_LSFSLEW: LS falling slew rate control.
9:8	0x1	UTMIP_XCVR_LSRSLEW: LS rising slew rate control.
7:6	0x0	UTMIP_XCVR_FSSLEW: FS slew rate control.
5:4	0x0	UTMIP_XCVR_HSSLEW: HS slew rate control. The two LSBs.
3:0	0x0	UTMIP_XCVR_SETUP: SETUP[3:0] input of XCVR cell. HS driver output control. 4 LSBs.

21.5.10.4 USB3_UTMIP_BIAS_CFG0_0

UTMIP Bias cell configuration register 0

Offset: 80ch | Read/Write: R/W | Reset: 0b01100000000000110000000000

Bit	Reset	Description
24	0x0	UTMIP_HSDISCON_LEVEL_MSB: Most significant bit of UTMIP_HSDISCON_LEVEL, bit 2
23	0x1	UTMIP_IDPD_VAL: See IDPD_SEL.
22	0x1	UTMIP_IDPD_SEL: 0: Reserved. Refer to the PMC registers for this feature.
21	0x0	UTMIP_IDDIG_VAL: See IDDIG_SEL.
20	0x0	UTMIP_IDDIG_SEL: 0: IdDig = IdDig. 1: IdDig = IDDIG_VAL.
19	0x0	UTMIP_GPI_VAL: See GPI_SEL.
18	0x0	UTMIP_GPI_SEL: 0: StaticGpi = IdDig. 1: StaticGpi = GPI_VAL.
17:15	0x0	UTMIP_ACTIVE_TERM_OFFSET: Active termination control offset.
14:12	0x0	UTMIP_ACTIVE_PULLUP_OFFSET: Active 1.5K pullup control offset.
11	0x1	UTMIP_OTGPD: Power down OTG circuit.
10	0x1	UTMIP_BIASPD: Power down bias circuit.
9:8	0x0	UTMIP_VBUS_LEVEL_LEVEL: Vbus detector level.
7:6	0x0	UTMIP_SESS_LEVEL_LEVEL: SessionEnd detector level.
5:4	0x0	UTMIP_HSCHIRP_LEVEL: HS chirp detector level.
3:2	0x0	UTMIP_HSDISCON_LEVEL: HS disconnect detector level.
1:0	0x0	UTMIP_HSSQUELCH_LEVEL: HS squelch detector level.

21.5.10.5 USB3_UTMIP_HSRX_CFG0_0

UTMIP High speed receive config 0

Offset: 810h | Read/Write: R/W | Reset: 0b10010001011001010011010000000000

Bit	Reset	Description
31:30	0x2	UTMIP_KEEP_PATT_ON_ACTIVE: Keep the stay alive pattern on active
29	0x0	UTMIP_ALLOW_CONSEC_UPDN: Allow consecutive ups and downs on the bits, debug only, set to 0.
28	0x1	UTMIP_REALIGN_ON_NEW_PKT: Realign the inertia counters on a new packet
27:24	0x1	UTMIP_PCOUNT_UPDN_DIV: The number of (edges-1) needed to move the sampling point
23:21	0x3	UTMIP_SQUELCH_EOP_DLY: Limit the delay of the squelch at EOP time
20	0x0	UTMIP_NO_STRIPPING: Do not strip incoming data
19:15	0xa	UTMIP_IDLE_WAIT: Number of cycles of idle to declare IDLE.
14:10	0xd	UTMIP_ELASTIC_LIMIT: Depth of elastic input store
9	0x0	UTMIP_ELASTIC_OVERRUN_DISABLE: Do not declare overrun errors until overflow of FIFO

Bit	Reset	Description
8	0x0	UTMIP_ELASTIC_UNDERRUN_DISABLE: Do not declare underrun errors
7	0x0	UTMIP_PASS_CHIRP: When in Chirp Mode, allow chirp rx data through
6	0x0	UTMIP_PASS_FEEDBACK: Pass through the feedback, do not block it.
5:4	0x0	UTMIP_PCOUNT_INERTIA: Retime the path.
3:2	0x0	UTMIP_PHASE_ADJUST: Based on incoming edges and current sampling position, adjust phase
1	0x0	UTMIP_THREE_SYNCBITS: Sync pattern detection needs 3 consecutive samples instead of 4
0	0x0	UTMIP_USE4SYNC_TRAN: Require 4 sync pattern transitions (01) instead of 3

21.5.10.6 USB3_UTMIP_HSRX_CFG1_0

UTMIP High speed receive config 1

Offset: 814h | Read/Write: R/W | Reset: 0b010011

Bit	Reset	Description
5:1	0x9	UTMIP_HS_SYNC_START_DLY: How long to wait before start of sync launches RxActive
0	0x1	UTMIP_HS_ALLOW_KEEP_ALIVE: Allow Keep Alive packets

21.5.10.7 USB3_UTMIP_FSLSRX_CFG0_0

UTMIP full and Low speed receive config 0

Offset: 818h | Read/Write: R/W | Reset: 0b11111101010101001000010000101001

Bit	Reset	Description
31	0x1	UTMIP_FSLS_SE1_DRIBBLE_FILTER: One SE1, don't allow dribble
30	0x1	UTMIP_FSLS_SE1_FILTER: Filter SE1
29	0x1	UTMIP_FSLS_SERIAL_SE0_RCV
28:26	0x7	UTMIP_FSLS_UPR_DRIBBLE_SIZE: Do not allow <= dribble bits
25:23	0x2	UTMIP_FSLS_LWR_DRIBBLE_SIZE: Do not allow >= dribble bits
22	0x1	UTMIP_FSLS_EOP_ENDS_AT_SE0: Only look for transitioning out of EOP
21:16	0x14	UTMIP_FSLS_KCOUNT_MAX: Number of K bits in question
15	0x1	UTMIP_FSLS_KCOUNT_LIMIT: Limit the number of bit times a K can last
14	0x0	UTMIP_FSLS_ACTIVE_ON_FULL_SYNC: Require a full sync pattern to declare the data received
13:8	0x4	UTMIP_FSLS_IDLE_WAIT_MAX: 4 bits of of SEO should exceed the time limit
7	0x0	UTMIP_FSLS_IDLE_WAIT_LIMIT: Enable the reset of the state machine on extended SE0
6:1	0x14	UTMIP_FSLS_IDLE_COUNT_MAX: 20 bits of idle should end the packet if FsLsIdleCountLimitCfg=1.
0	0x1	UTMIP_FSLS_IDLE_COUNT_LIMIT: Give up on packet if a long sequence of J

21.5.10.8 USB3_UTMIP_FSLSRX_CFG1_0

UTMIP full and Low speed receive config 1

Offset: 81ch | Read/Write: R/W | Reset: 0b01000100110011101010000000000

Bit	Reset	Description
26	0x0	UTMIP_EARLY_LINE_STATE_FILTER: Assumes line state filtering table is inclusive, not exclusive
25:23	0x4	UTMIP_LS_BOUNCE_LENGTH: Number of clock cycle of LS stable
22:17	0x13	UTMIP_LS_EXTRACTION_COUNT: Phase count on which LS bits are extracted
16:11	0xe	UTMIP_LS_EOP_START_COUNT: Number of SEO clock cycles to block bit extraction
10:5	0x20	UTMIP_LS_SE0_COUNT: Only for this number of 60MHz of SEO and Idle to end packet
4	0x0	UTMIP_LS_LENIENT_DRIBBLE: Allow for large dribble in low speed mode
3	0x0	UTMIP_FS_LENIENT_DRIBBLE: Allow for large dribble in full speed mode
2	0x0	UTMIP_FS_WEAK_SYNC: Only look for a KK pattern, instead of KJKK
1	0x0	UTMIP_FS_DEBOUNCE: Whether full speed uses debouncing
0	0x0	UTMIP_FS_EOP_LENGTH: Whether full speed EOP is determined within 3(0) or 4(1) 60MHz cycles

21.5.10.9 USB3_UTMIP_TX_CFG0_0

UTMIP transmit config signals

Offset: 820h | Read/Write: R/W | Reset: 0b00010000001000000000

Bit	Reset	Description
19	0x0	UTMIP_FS_PREAMBLE_J: output enable sends an initial J before sync pattern
18	0x0	UTMIP_FS_POSTAMBLE_OUTPUT_ENABLE: output enable turns off 1/2 cycle after
17	0x0	UTMIP_FS_PREAMBLE_OUTPUT_ENABLE: output enable turns on 1/2 cycle before
16	0x1	UTMIP_FSLS_ALLOW_SOP_TX_STUFF_ERR: Allow SOP to be source of transmit error stuffing
15	0x0	UTMIP_HS_READY_WAIT_FOR_VALID
14:10	0x0	UTMIP_HS_TX_IPG_DLY
9	0x1	UTMIP_HS_DISCON_EOP_ONLY: Only check during EOP
8	0x0	UTMIP_HS_DISCON_DISABLE: Disable high speed disconnect
7	0x0	UTMIP_HS_POSTAMBLE_OUTPUT_ENABLE: output enable turns off 1 cycle after
6	0x0	UTMIP_HS_PREAMBLE_OUTPUT_ENABLE: output enable turns on 1 cycle before
5	0x0	UTMIP_SIE_RESUME_ON_LINESTATE: SIE, not macrocell, detects LineState change to resume
4	0x0	UTMIP_SOF_ON_NO_STUFF: Sof when OpMode 3 -- perhaps, when sending controller made packets
3	0x0	UTMIP_SOF_ON_NO_ENCODE: Sof when OpMode 2 -- not likely, for Chirp
2	0x0	UTMIP_NO_STUFFING: No bit stuffing, static programming
1	0x0	UTMIP_NO_ENCODING: No encoding, static programming

Bit	Reset	Description
0	0x0	UTMIP_NO_SYNC_NO_EOP: Do not sent SYNC or EOP

21.5.10.10 USB3_UTMIP_MISC_CFG0_0

UTMIP miscellaneous configurations

Offset: 824h | Read/Write: R/W | Reset: 0b00000111110000000000000001111000

Bit	Reset	Description
30:27	0x0	UTMIP_DPDM_OBSERVE_SEL: Select DP/DM obs signals
26	0x0	UTMIP_DPDM_OBSERVE: Use DP/DM as obs bus
25	0x1	UTMIP_KEEP_XCVR_PD_ON_SOFT_DISCON
24	0x1	UTMIP_ALLOW_LS_ON_SOFT_DISCON
23	0x1	UTMIP_FORCE_FS_DISABLE_ON_DEV_CHIRP
22	0x1	UTMIP_SUSPEND_EXIT_ON_EDGE: Suspend exit requires edge or simply a value...
21	0x1	UTMIP_LS_TO_FS_SKIP_4MS: Don't block changes for 4ms when going from LS to FS (should not happen)
20:19	0x0	UTMIP_INJECT_ERROR_TYPE: Force error insertion into RX path. (Used for IOBIST.) 0 = DISABLE 1 = BIT_ERR 2 = RX_ERR 3 = BIT_RX_ERR
18	0x0	UTMIP_FORCE_HS_CLOCK_ON: Force HS clock always on.
17	0x0	UTMIP_DISABLE_HS_TERM: Force HS termination inactive.
16	0x0	UTMIP_FORCE_HS_TERM: Force HS termination active.
15	0x0	UTMIP_DISABLE_PULLUP_DP: Force DP pullup inactive. (Overrides FORCE_PULLUP_DP.)
14	0x0	UTMIP_DISABLE_PULLUP_DM: Force DM pullup inactive. (Overrides FORCE_PULLUP_DM.)
13	0x0	UTMIP_DISABLE_PULLDN_DP: Force DP pulldown inactive. (Overrides FORCE_PULLDN_DP.)
12	0x0	UTMIP_DISABLE_PULLDN_DM: Force DM pulldown inactive. (Overrides FORCE_PULLDN_DM.)
11	0x0	UTMIP_FORCE_PULLUP_DP: Force DP pullup active.
10	0x0	UTMIP_FORCE_PULLUP_DM: Force DM pullup active.
9	0x0	UTMIP_FORCE_PULLDN_DP: Force DP pulldown active.
8	0x0	UTMIP_FORCE_PULLDN_DM: Force DM pulldown active.
7:5	0x3	UTMIP_STABLE_COUNT: Number of cycles of crystal clock of signal not changing to consider stable.
4	0x1	UTMIP_STABLE_ALL: Determines if all signal need to be stable to not change a config.
3	0x1	UTMIP_NO_FREE_ON_SUSPEND: Don't use free running terminations during suspend.
2	0x0	UTMIP_NEVER_FREE_RUNNING_TERMS: Ignore free running terminations, even when no clock
1	0x0	UTMIP_ALWAYS_FREE_RUNNING_TERMS: Use free running terminations at all time
0	0x0	UTMIP_COMB_TERMS: Use combinational terminations or synced through CLKXTAL

21.5.10.11 USB3_UTMIP_MISC_CFG1_0

UTMIP miscellaneous configurations

Offset: 828h | Read/Write: R/W | Reset: 0b10000000001100110000000000100100

Bit	Reset	Description
30	0x1	UTMIP_PHY_XTAL_CLOCKEN: Selects whether to enable the crystal clock in the module.
29	0x0	UTMIP_LINESTATE_BYPASS: Bypass LineState reclocking logic

3	0x0	UTMIP_FLIP_FSLS_POLARITY
2	0x1	UTMIP_SUSPEND_TERMSEL
1:0	0x0	UTMIP_XCVRSEL3: Bit 0: 0: 0xa5 -> treat as KeepAlive 1: treat as regular packet Bit 1: 0: Turn on FS EOP detection 1: Turn off FS EOP detection

21.5.10.12 USB3_UTMIP_DEBOUNCE_CFG0_0

UTMIP Avalid and Bvalid debounce

Debounce values IdDig, Avalid, Bvalid, VbusValid, VbusWakeUp, and SessEnd. Each of these signals have their own debouncer and for each of those one out of 2 debouncing times can be chosen (BIAS_DEBOUNCE_A or BIAS_DEBOUNCE_B.)

The values of DEBOUNCE_A and DEBOUNCE_B are calculated as follows:

- 0xffff -> No debouncing at all
- ms = *1000 / (1/19.2MHz) / 4

So to program a 1 ms debounce for BIAS_DEBOUNCE_A, we have: BIAS_DEBOUNCE_A[15:0] = 1000 * 19.2 / 4 = 4800 = 0x12c0

Offset: 82ch | Read/Write: R/W | Reset: 0b11111111111111111111111111111111

Bit	Reset	Description
31:16	0xffff	UTMIP_BIAS_DEBOUNCE_B: simulation value -- Used for interrupts
15:0	0xffff	UTMIP_BIAS_DEBOUNCE_A: simulation value -- Used for interrupts

21.5.10.13 USB3_UTMIP_BAT_CHRG_CFG0_0

UTMIP battery charger configuration

Offset: 830h | Read/Write: R/W | Reset: 0b000000xx000001

Bit	Reset	Description
13:8	0x0	UTMIP_CHRG_DEBOUNCE_TIMESCALE: Debouncer time scaling, factor-1 to slow down debouncing by. So 0 is 1, 1 is 2, etc.
5	0x0	UTMIP_OP_I_SRC_EN
4	0x0	UTMIP_ON_SRC_EN
3	0x0	UTMIP_OP_SRC_EN

1	0x0	UTMIP_OP_SINK_EN
0	0x1	UTMIP_PD_CHRG: Power down charger circuit

21.5.10.14 USB3_UTMIP_SPARE_CFG0_0

Utmip spare configuration bits

Offset: 834h | Read/Write: R/W | Reset: 0b11111111111111110000000000000000

Bit	Reset	Description
31:0	-65536	UTMIP_SPARE: Spare register bits 0: HS_RX_IPG_ERROR_ENABLE 1: HS_RX_FLUSH_ALAP. Flush as late as possible 2: HS_RX_LATE_SQUELCH. Delay Squelch by 1 CLK480 cycle. 3: FUSE_SETUP_SEL. Select between regular CFG value and JTAG values for UX_SETUP 4: FUSE_TERM_RANGE_ADJ_SEL. Select between regular CFG value and JTAG values for UX_TERM_RANGE_ADJ 31 to 5: Reserved Note: 4:3 stand for using fused termination and setup value.

21.5.10.15 USB3_UTMIP_XCVR_CFG1_0

UTMIP transceiver cell configuration register 1

Offset: 838h | Read/Write: R/W | Reset: 0b00011000100000010000010101

Bit	Reset	Description
23:22	0x0	UTMIP_XCVR_SPARE: Spare bits for USB transceiver pad.
21:18	0x6	UTMIP_XCVR_TERM_RANGE_ADJ: Range adjustment on terminations.
17	0x0	UTMIP_RCTRL_SW_SET: Use a software override on RCTRL instead of automatic bias control
16:12	0x8	UTMIP_RCTRL_SW_VAL: Encoded value to use on RCTRL when software override is enabled, 0 to 16 only
11	0x0	UTMIP_TCTRL_SW_SET: Use a software override on TCTRL instead of automatic bias control

Bit	Reset	Description
10:6	0x8	UTMIP_TCTRL_SW_VAL: Encoded value to use on TCTRL when software override is enabled, 0 to 16 only
5	0x0	UTMIP_FORCE_PDDR_POWERUP: Force PDDR input into power up.
4	0x1	UTMIP_FORCE_PDDR_POWERDOWN: Force PDDR input input into power down. (Overrides FORCE_PDDR_POWERUP.)
3	0x0	UTMIP_FORCE_PDCHRP_POWERUP: Force PDCHRP input into power up.
2	0x1	UTMIP_FORCE_PDCHRP_POWERDOWN: Force PDCHRP input input into power down. (Overrides FORCE_PDCHRP_POWERUP.)
1	0x0	UTMIP_FORCE_PDDISC_POWERUP: Force PDDISC input into power up.
0	0x1	UTMIP_FORCE_PDDISC_POWERDOWN: Force PDDISC input into power down. (Overrides FORCE_PDDISC_POWERUP.)

21.5.10.16 USB3_UTMIP_BIAS_CFG1_0

UTMIP Bias cell configuration register 1

Offset: 83ch | Read/Write: R/W | Reset: 0b00000000101101

Bit	Reset	Description
13:8	0x0	UTMIP_BIAS_DEBOUNCE_TIMESCALE: Debouncer time scaling, factor-1 to slow down debouncing by. So 0 is 1, 1 is 2, etc.
7:3	0x5	UTMIP_BIAS_PDTRK_COUNT: Control the BIAS cell power down lag. The lag should be 20us. For a Xtal clock of 13MHz it should be set a 5.
2	0x1	UTMIP_VBUS_WAKEUP_POWERDOWN: Force VBUS_WAKEUP input into power down. Reserved. Refer to the PMC registers for this feature.
1	0x0	UTMIP_FORCE_PDTRK_POWERUP: Force PDTRK input into power up.
0	0x1	UTMIP_FORCE_PDTRK_POWERDOWN: Force PDTRK input into power down. (Overrides FORCE_PDTRK_POWERUP.)

21.5.10.17 USB3_UTMIP_BIAS_STS0_0

UTMIP Bias cell status register 0

Offset: 840h | Read/Write: RO | Reset: 0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx

Bit	Reset	Description
31:16	X	UTMIP_TCTRL: Thermal encoding output from USB bias pad.
15:0	X	UTMIP_RCTRL: Thermal encoding output from USB bias pad.

21.5.10.18 USB3_UTMIP_CHRG_DEB_CFG0_0

UTMIP VDcd_Det and VDat_Det debounce

Debounce values VDcd_Det and VDat_Det. Each of these signals have their own debouncer and for each of those one out of 2 debouncing times can be chosen (CHRG_DEBOUNCE_PERIOD_A or CHRG_DEBOUNCE_PERIOD_B)

The values of DEBOUNCE_PERIOD_A and DEBOUNCE_PERIOD_B are calculated as follows:

- 0xffff -> No debouncing at all
- ms = *1000 / (1/19.2MHz) / 4

So to program a 1 ms debounce for CHG_DEBOUNCE_PERIOD, we have: CHG_DEBOUNCE_PERIOD[15:0] = 1000 * 19.2 / 4 = 4800 = 0x12c0

Offset: 844h | Read/Write: R/W | Reset: 0b11111111111111111111111111111111

Bit	Reset	Description
31:16	0xffff	UTMIP_CHRG_DEBOUNCE_PERIOD_B: simulation value -- Used for interrupts
15:0	0xffff	UTMIP_CHRG_DEBOUNCE_PERIOD_A: simulation value -- Used for interrupts

21.5.10.19 USB3_UTMIP_MISC_STS0_0

UTMIP MISC status reg

Offset: 848h | Read/Write: RO | Reset: 0bxxxxxxxxxxxxxxxxxxxxxxxx

Bit	Reset	Description
21	X	UTMIP_FS_DRV_EN: Indicates when the controller is driving on the bus
20:0	X	UTMIP_SPARE_FUSES: Spare Fuses value, to keep the connections preserved

21.5.10.20 USB3_UTMIP_PMC_WAKEUP0_0

UTMIP PMC Wakeup value

Offset: 84ch | Read/Write: R/W | Reset: 0bx0

Bit	R/W	Reset	Description
1	RO	X	UTMIP_LINE_WAKEUP_EVENT_INT_STS: Indicates the status of the pmc wakeup event
0	RW	0x0	UTMIP_LINE_WAKEUP_EVENT_INT_ENB: Interrupt mask for the pmc wakeup event

21.5.10.21 USB2_QH_USB2D_QH_EP_0_OUT_0

USB2D Queue Head for OUT endpoint 0

Offset: 1000h | Read/Write: R/W | Reset: 0b00000000000000000000000000000000

Bit	Reset	Description
31:0	0x0	USB2D_QH: Queue Head for OUT endpoint 0 This is used to store a local Queue Head data structure for either device mode or host mode. In device mode, it holds the Queue Head for OUT endpoint 0.

21.5.10.22 USB2_QH_USB2D_QH_EP_0_IN_0

USB2D Queue Head for IN endpoint 0

Offset: 1040h | Read/Write: R/W | Reset: 0b00000000000000000000000000000000

Bit	Reset	Description
31:0	0x0	USB2D_QH: Queue Head for IN endpoint 0. This is used to store a local Queue Head data structure for either device mode or host mode. In device mode, it holds the Queue Head for IN endpoint 0.

Bit	Reset	Description
31:0	0x0	USB2D_QH: Queue Head for IN endpoint 15. This is used to store a local Queue Head data structure for either device mode or host mode. In device mode, it holds the Queue Head for IN endpoint 15.

21.5.11 CLK_RST_CONTROLLER_UTMIP_PLL_CFG0_0

This register is also a part of the CAR section of this document.

The data sampling frequency relies on a 960MHz clock, so the goal of the PLL is to have: In_Frequency*(PLL_VCOMULTBY2+1)*(PLL_NDIV/PLL_MDIV) = 960MHz With a 12MHz input from PLL_U, the default setting of PLL_VCOMULTBY2=1, PLL_NDIV=40 and PLL_MDIV=1 results in a correct output.

This register is used to configure the PHY PLL contained in the UTMIP module.

UTMIP PLL Configuration Register 0

Offset: 480h | Read/Write: R/W | Reset: 0b00000000010100000000000110000000

Bit	Reset	Description
30:28	0x0	UTMIP_PLL_SELECT: Selects which of the eight 60MHz clock phases to produce at the output of the USB PHY PLL. This is for a test mode. See cell specification.
27	0x0	UTMIP_PLL_PDIVRST: PDIVRST of the UTMIP PHY PLL. Reserved. Keep at 0x0. Currently there is no post divider on this PLL. See cell specification.
26:24	0x0	UTMIP_PLL_PDIV: PDIV[2:0] input of the UTMIP PLL. Reserved. Keep at 0x0. Currently there is no post divider on this PLL. See cell specification.
23:16	0x28	UTMIP_PLL_NDIV: NDIV[7:0] input of UTMIP PLL. This is the feedback divider on the VCO feedback. 0x0 is not allowed. See cell specification.
15:8	0x1	UTMIP_PLL_MDIV: MDIV[7:0] input of the UTMIP PLL. This is the predivide on the PLL. 0x0 is not allowed. See cell specification.
7	0x1	UTMIP_PLL_VCOMULTBY2: VCOMULTBY2 control of the UTMIP PHY PLL. Recommended setting is on. Additional divide by 2 on the VCO feedback. Which is setting the bit to 1. See cell spec.
6:1	0x0	UTMIP_PLL_LOCKSEL: LOCKSEL[5:0] input of UTMIP PLL. Used in test modes only. See cell specification.
0	0x0	UTMIP_PLL_LOCKENABLE: LOCK_ENABLE input of UTMIP PLL. Normally only used during test. See cell specification.

21.5.12 CLK_RST_CONTROLLER_UTMIP_PLL_CFG1_0

PLL Configuration and Parameters

This register is also a part of the CAR section of this document.

In normal operation, the following clock generators are in play for USB:

Xtal clock -> enters PLL_U to generate 12MHz clock -> enters USB_PHY PLL to generate 480/60 MHz clock

The following parameters control the bringup of the plls:

Coming out of reset or suspend

-> PllUOnState: start pllu_enable_count and pll_lock_count

-> Wait ~1us to actually enable the PLL_U (pllu_enable_count == ClkXtal * PLLU_ENABLE_DLY_COUNT * 8)

-> Wait ~1ms until PLL_U is actually stable (pll_lock_count == ClkXtal * PLLU_STABLE_COUNT * 256) => USB_PHY PLL_ENABLE pll_active_count = 0

-> Wait 5us to enable pll_active: pll_active_count == ClkXtal * PLL_ACTIVE_DLY_COUNT * 16 => USB_PHY PLL_ACTIVE

-> Wait ~2.5ms until USB_PHY is actually stable (pll_lock_count == ClkXtal * XTAL_FREQ_COUNT * 256) => USB_PHY

Numbers for a 19.2MHz Xtal clock

- PLLU_ENABLE_DLY_COUNT[4:0] = 1 * 19.2 / 8 = 2.4 = 3 = 0x03

- PLLU_STABLE_COUNT[11:0] = 1000 * 19.2 / 256 = 75 = 0x4b
- PLL_ACTIVE_DLY_COUNT[4:0] = 10 * 19.2 / 16 = 12 = 0x0c
- XTAL_FREQ_COUNT[11:0] = 2500 * 19.2 / 256 = 187 = 0xbb

UTMIP PLL and PLLU configuration register 1

Offset: 484h | Read/Write: R/W | Reset: 0b00011000001000010101000011000000

Bit	Reset	Description
31:27	0x3	UTMIP_PLLU_ENABLE_DLY_COUNT: Controls the wait time to enable PLL_U when coming out of suspend or reset.
26:18	0x8	UTMIP_PLL_SETUP: SETUP[8:0] input of USB_PHY PLL.
17	0x0	UTMIP_FORCE_PLLU_POWERUP: Force PLL_U into power up.
16	0x1	UTMIP_FORCE_PLLU_POWERDOWN: Force PLL_U into power down. (Overrides FORCE_PLLU_POWERUP.)
15	0x0	UTMIP_FORCE_PLL_ENABLE_POWERUP: Force UTMIP PLL pll_enable input on.
14	0x1	UTMIP_FORCE_PLL_ENABLE_POWERDOWN: Force UTMIP PLL pll_enable input off. (Overrides FORCE_PLL_ENABLE_POWERUP.)
13	0x0	UTMIP_FORCE_PLL_ACTIVE_POWERUP: Force UTMIP PLL pll_active input on.
12	0x1	UTMIP_FORCE_PLL_ACTIVE_POWERDOWN: Force UTMIP PLL pll_active input off. (Overrides FORCE_PLL_ACTIVE_POWERUP.)
11:0	0xc0	UTMIP_XTAL_FREQ_COUNT: Determines the time to wait until the output of UTMIP PLL is considered stable.

21.5.13 CLK_RST_CONTROLLER_UTMIP_PLL_CFG2_0

This register is also a part of the CAR section of this document.

UTMIP Miscellaneous Configurations

Offset: 488h | Read/Write: R/W | Reset: 0b10101xx00110001100000000010101

Bit	Reset	Description

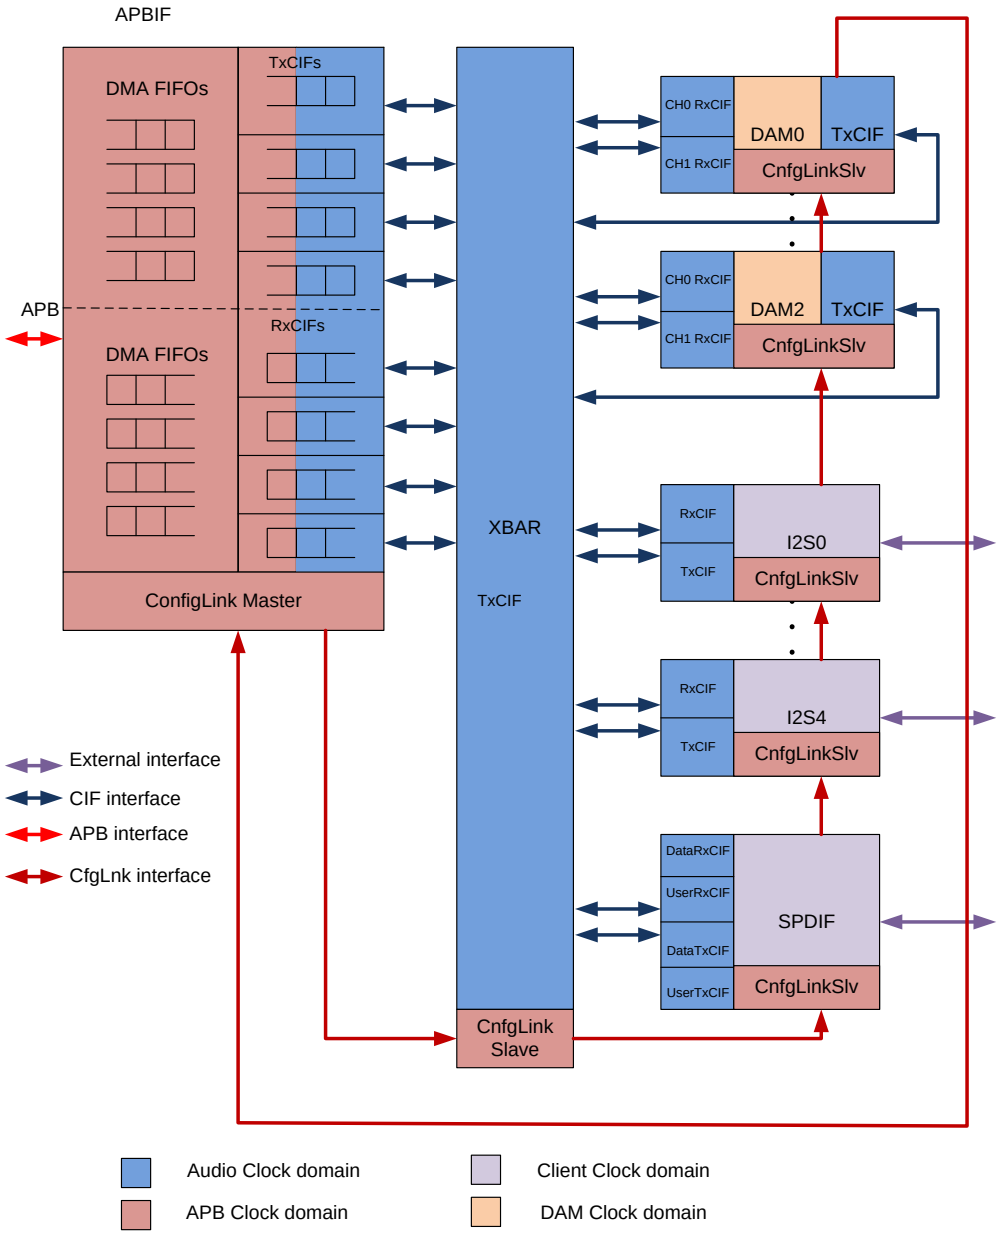
22.0 AUDIO HUB

The Tegra® 3 processor defines several audio interface modules to support various types of audio protocols and data formats. To provide a flexible audio streaming environment, it is essential to implement a versatile audio fabric to connect audio modules independently and simultaneously.

The Audio Hub (AHUB) is a crossbar switch matrix connecting various audio modules such as I2S and SPDIF. AHUB is attached to the APB bus and is programmable through the bus. APBIF is the agent for the APB control flow and DMA operation, which sends or receives data from/to Memory. The figure below shows the audio subsystem in Tegra 3 devices.

Figure 38. Audio Subsystem in Tegra 3 Devices



Features

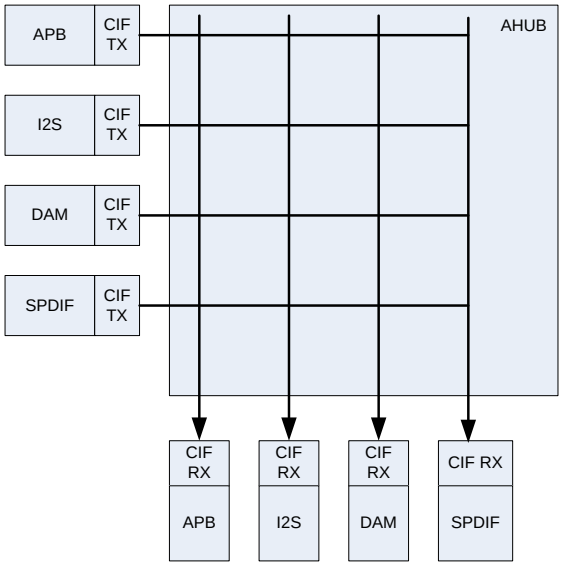
- Concurrent switching between audio clients
  - The audio clients are I2S, DAM, SPDIF, APBIF
  - A TX client can talk to multiple RX clients simultaneously
- Scalable MxN crossbar switch, where
  - M is the number of TX clients
  - N is the number of RX clients
- A native protocol, AHUB protocol, is defined and used between AHUB and AHUB clients
- Programmable clock
  - Typically 12 MHz from crystal
- Supports multi-channel APB DMA operations
- AHUBCIF provides the interface to AHUB in the AHUB clients
  - One or more AHUBCIF can be instantiated in an AHUB client for RX and TX
  - Data conversion between various bit formats, 8/16/24/32
  - Mono/Stereo conversion
  - Asynchronous clock boundary between AHUB clock and client clock

22.1 Audio Hub Functionality

AHUB is a MxN full crossbar switch with unidirectional data flow, where M and N are the number of TX and RX clients, respectively. A TX client can send audio data to multiple RX clients, while a RX client can receive data from only one TX at a time. A session is created by binding a transmitting TX client and a receiving RX client. At any point, a TX or RX client can be bound to no more than one session. Multiple sessions can be active at a time and work independent of each other. Figure 39 shows a simple diagram of the AHUB crossbar switch.

One or more AHUBCIFs are instantiated in an AHUB client to transmit and/or receive audio data through AHUB. The AHUBCIF generate audio data frames with the AHUB protocol, which will be discussed later. It also performs a common data conversion in most of the clients, data width conversion (8/16/24/32) and channel conversion (mono/stereo).

Figure 39. AHUB Crossbar Switch and Clients



22.1.1 AHUB signals

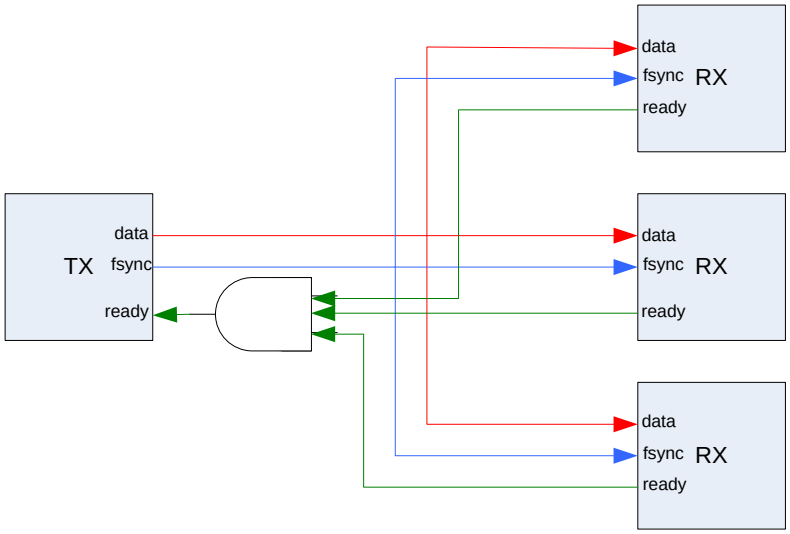
An AHUB session has 3 signals to transmit audio data from a TX client to RX clients. Table 37 shows the signals. Figure 40 shows the connectivity between the Tx and Rx clients through the AHUB.

The data signal transmits one bit each clock. The fsync signal is asserted when a new frame starts. A frame consists of samples from multiple channels. When a RX client asserts the Ready signal, a buffer of at least one frame should be ready in the RX client's AHUBCIF. The Tx client samples 'Ready' only when the fsync is asserted. If the ready signal is de-asserted when the fsync is active (indicting that the Rx client is not ready to receive data), the TX client should hold the first data and fsync until the Ready signal is asserted.

Table 37. AHUB signals

signal	Width	direction	Description
data	1	TX->RX	serial audio data
fsync	1	TX->RX	a pulse frame sync for each frame
ready	1	TX<-RX	Ready from RX clients

Figure 40. Signals exchange between TX and RX clients



22.1.2 Frame Length

The frame length is simply a product of bits per sample and the number of channels in an audio frame. Before starting data transfer, Bits per sample and the number of channels of the Tx and Rx clients should be programmed to be identical, to avoid incorrect frame parsing. Table 38 show the min and max length of frames that AHUB carries.

Table 38. Frame length

	Bits	channels	frame length	typical usecase
min frame	8	1	8	mono voice stream from baseband
max frame	24	8	192	HIFI multi-channel audio in HDMI

22.1.3 Clocking

When multiple sessions are in progress, AHUB clock should be fast enough to support the session with the highest data rate. If a session is used for sending 8 kHz 16 bit stereo stream, the AHUB clock should be at least 256 kHz. While a faster clock is better for data transmission, it is not necessarily good for power consumption. Using the clock directly from the crystal without going through PLLs is recommended for typical audio application like MP3 music playback. Depending on the applications, you can program the clock registers to satisfy the requirement of clock frequency. Table 39 shows the various clock frequencies for AHUB.

Table 39. AHUB Clock Frequencies

clock freq	Description
64 kHz	Slowest clock to carry 8 bit mono voice data in 8 kHz sampling
1.4112 Mhz	Clock to carry 16 bit stereo audio data in 44.1 kHz sampling
1.536 Mhz	Clock to carry 16 bit stereo audio data in 48k Hz sampling
4.608 Mhz	Clock to carry 24 bit stereo audio data in 96 kHz sampling or 16 bit 6 channel audio data in 48 kHz sampling
12 Mhz	Minimum crystal frequency
18.432 Mhz	Clock to carry 24 bit 8 channel audio data in 96 kHz sampling
36.864 Mhz	Clock to carry 24 bit 8 channel audio data in 192 kHz sampling (HDMI max)

22.1.4 AHUBCIF

The main function of AHUBCIF is to serialize an audio sample to a serial data stream or de-serialize a serial data stream to be an audio sample. The configuration register is programmed to specify the bit width and the number of channels for parsing incoming stream or serializing outgoing stream. An asynchronous FIFO is used to cross the clock boundary between *ahub_clk* and *client_clk*.

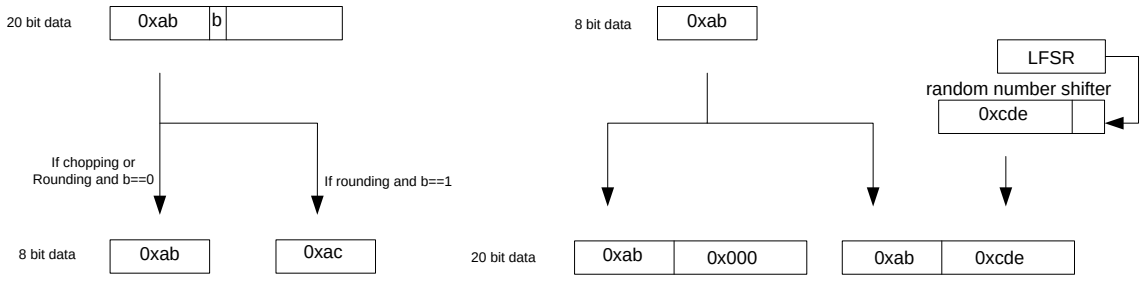
Besides serialization/de-serialization, other common format conversions performed in AHUBCIF optionally by the register configuration include data width conversion and channel conversion.

AHUB and AHUBCIF support 8, 16, 24, and 32 bit wide data. When converting from a larger width to a smaller width, a configuration option is provided to chop off the least significant bits and a randomly generated bit can be added to the least significant bit to make audio stream sound more natural. When converting a smaller width to a larger width, the blank region can be either filled with 0's or 1's or randomly generated numbers. AHUBCIF maintains a 16 bit LSFR to generate random numbers, x**16 + x**12 + x**5 + 1.

LFSR = ((LFSR << 1) ^ ((LFSR & 0x8000)? 0x1021: 0x0000)) & 0xFFFF

Figure 41 shows how AHUBCIF converts different widths of data with randomly generated numbers.

Figure 41. Data format conversion



AHUBCIF supports mono-to-stereo and stereo-to-mono conversion. Mono data is converted to stereo by duplicating the data into the second channel. The stereo to mono conversion has the following options: copying the first channel data into the mono channel, copying the second channel data into the mono channel, or averaging two channel data, (L + R)/2.

While 16/24 bit PCM samples are represented by 2's complements, 8 bit samples are different.

8 bit sample	actual value
0xFF	127
0x80	0
0x00	-128

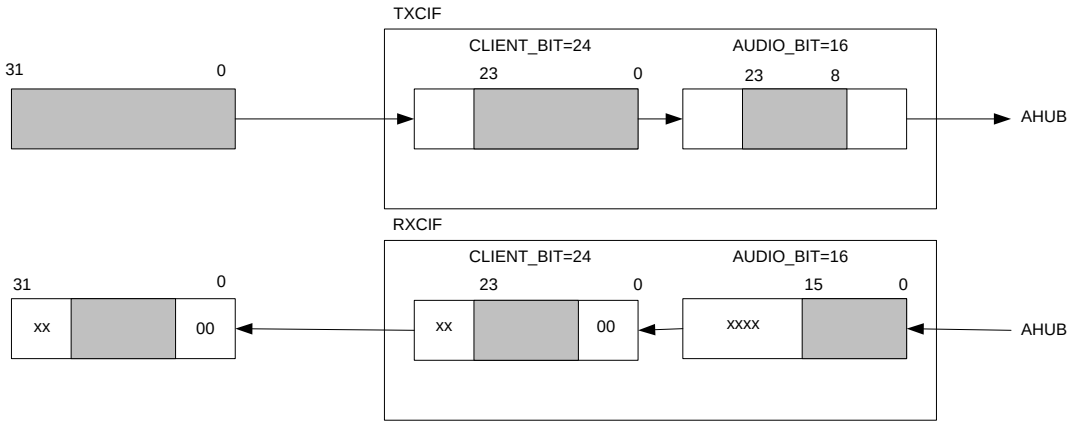
When an 8 bit sample A[7:0] is extended into a 16 bit sample B[15:0],

B[15:8] = 0x80 ^ A[7:0]

B[7:0] = 0's or 1's or 8 bit LFSR

When a 16 bit sample is converted to an 8 bit sample, the process should be reversed.

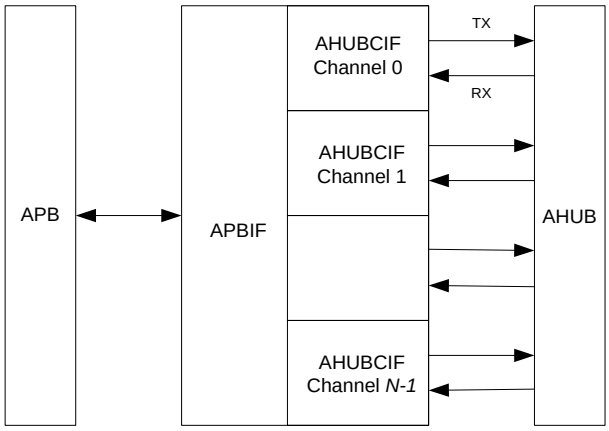
Bit width of audio sample on AHUB side is specified by AUDIO_BITS field. Bit width of audio samples in client domain is specified by CLIENT_BITS field. Since AHUBCIF has 32 bit data interface, the maximum value of CLIENT_BITS and AUDIO_BITS is 32. When the bus is defined to be DATA[31:0], CLIENT_BITS specifies how many bits are valid from LSB in the client. If CLIENT_BITS=24, DATA[23:0] is valid, while DATA[31:24] may be unused. If the client data is serialized with AUDIO_BITS=24, all 24 bits of the client data is transmitted or received through AHUB. However, if AHUB_BITS is less than CLIENT_BITS (for example AHUB_BITS=16), the lower 8 bits are discarded for transmission and only DATA[23:8] will be transmitted to AHUB. The figure below shows the conversion.



22.2 APBIF

APBIF is the agent for the APB control flow and DMA operation, which sends or receives data from/to Memory. APBIF is composed of *N* instances of AHUBIF and APB interface as shown in the figure below.

Figure 42. AHUB crossbar switch and clients



Features

- Separate APB DMA operations for all AHUB clients
- Each channel is bidirectional and needs one TX and one RX AHUBCIF.
- Scalable *N* channel design
- Maintain interrupt registers for AHUB clients

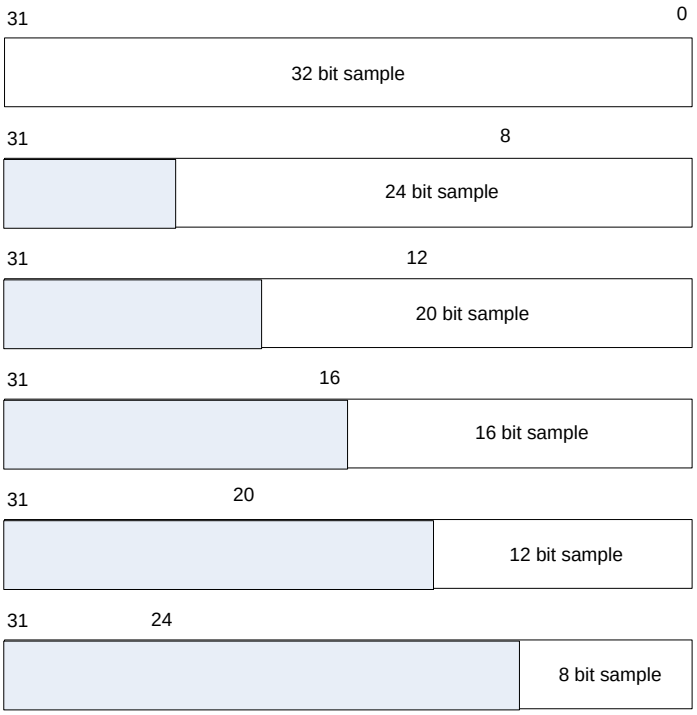
22.2.1 APBIF Functionality

22.2.1.1 Number of channels

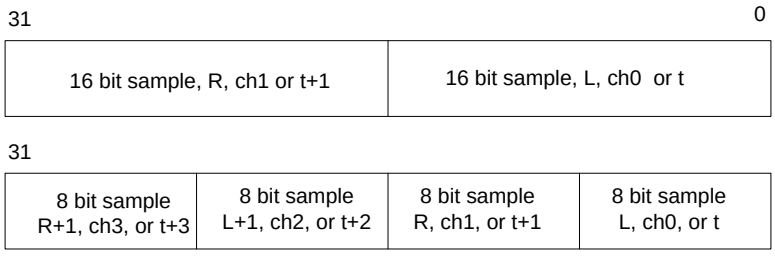
Tegra 3 supports 4 full duplex DMA channels.

22.2.1.2 Data Packing

When an audio sample is saved in the memory, it is right justified in a D-word configuration, regardless of its bit width. The next figure shows how a sample is stored in the memory without packing.



APBIF supports two types of packing, 2x16bits and 4x8bits on a dword boundary. The figure shows the packing modes. When the samples are packed, the sample in the LSB is either the first channel sample (channel 0) or the earlier sample (time T) compared to T+1, T+2 etc. In case of 4x8bits configuration, the one in the LSB is the earlier left channel sample or the earliest sample in case of single channel stream.



22.3 Digital Audio Mixer (DAM)

Tegra® 3 Digital Audio Mixer (DAM) has four inputs and one output. The inputs are from AHUB through AHUBCIF, while the output also goes to AHUB through AHUBCIF. One input is for voice stream, while the others are for high-fidelity audio streams. Typically for the cellular communication, the voice stream comes from a baseband processor through an I2S unit and AHUB. The voice stream is normally up-converted to a high sampling rate, either 44.1 or 48 kHz before it is mixed with another audio stream. The down-conversion is also possible when high sample rate needs to be converted to low sample rate.

Features

- DAM takes two input sources, typically one for voice data from a baseband (BB) and the others for music from an internal source.
  - 2 input sources with 2 RX AHUBCIFs
  - 1 output with 1 TX AHUBCIF
- Sample rate conversion for voice stream
  - One input for Low-Latency-Filter(LLF) SRC

- Low-Latency-Filter(LLF) SRC
  - input: 8/16/44.1/48 kHz mono audio
  - up-conversion from 8/16 -> 44.1/48 kHz
  - down-conversion from 44.1/48 -> 8/16 kHz
  - 16 bit audio data
  - 4th order Farrow filter for interpolation
  - 10th order elliptic filter for anti-aliasing
  - fixed latency on round trip between baseband and CODEC of ~1msec.
- DAM mixes the two audio input through SRC and the programmable gain controller.
- Configuration register programming

22.3.1 DAM Functionality

22.3.1.1 AHUBCIF RX

DAM has 2 AHUBCIF instances for stream inputs. AHUBCIF can perform simple format conversion for bit-width and/or multiple-channels. LLF SRC only handles 16 bit mono stream

22.3.1.2 Low Latency Filter (LLF)

SRC performs up and down sample conversion, which addresses the conversion between 8/16 kHz and 44.1/48 kHz sampling rates. LLF is composed of two pipeline stages, interpolation and anti-aliasing. A Farrow filter is used for interpolation. An IIR filter is used for anti-aliasing.

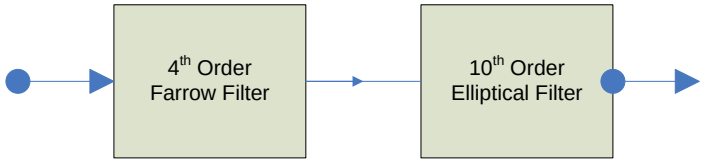
Up sampling

The interpolation filter is applied to generate more samples per unit time and the anti-aliasing filter is applied to sort out unwanted frequency signals. Suppose the input and the output sample rates are M and N kHz, respectively, where M < N.

```
                step_size = S
                current_step = 0x8000;
for each sample (0 .. STEP_RESET-1) {
                calculate step_index and step_frag from current_step
        step_index = (current_step & 0x8000) >> 15
        step_frag = current_step & 0x7FFF
                if(step_index == 1) {
                     pop a sample from the flow control FIFO and add it into Q
                     current_step = current_step - 0x8000;
                }
    apply Farrow Filter with Q and step_frag
    time = time + step_size
    apply Elliptic Filter and generate a sample to output
}
```

The coefficients are generated based on a step size and an index value of the current time. The tables below show the step sizes and index values for up-sampling and down-sampling, respectively.

up-sampling	step index	step fractional(hex)
8kHz -> 44.1kHz	0	0x1738
8kHz -> 48 kHz	0	0x1555
16kHz -> 44.1kHz	0	0x2E70
16kHz -> 48kHz	0	0x2AAA



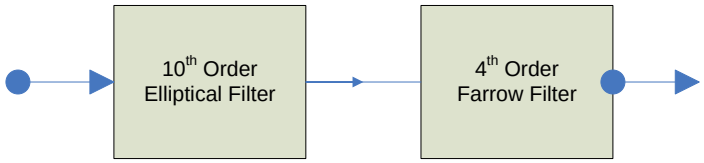
Down Sampling

The anti-aliasing filter is applied first and the interpolation filter is applied to generate less number of samples per unit time. Suppose the input and the output sample rates are M and N kHz, respectively, where M > N.

```
                step_size = S
                current_step = 0x0000
                              for each sample (0 ..  STEP_RESET-1) {
                                  pop a sample from the flow control FIFO, apply Elliptic Filter and add
it into Q
                    calculate step_index and step_frag from current_step
                        step_index = (current_step & 0xF8000) >> 15
                        step_frag = current_step & 0x7FFF
                    if(step_index  == 0) {
                        if(step_flag == 0)
                                send the middle sample in Q to output
                        else
                          apply Farrow Filter with Q and step flag and generate a sample to output
                        current_step  = current_step + step_size
                    }
                    current_step = current_step – 0x8000
                 }
```

The coefficients are generated based on a step size and an index value of the current time. The tables below show the step size and index values for up-sampling and down-sampling, respectively.

down-sampling	step index	step fractional(hex)
8kHz -> 44.1kHz	5	0x4199
8kHz -> 48 kHz	6	0x0
16kHz -> 44.1kHz	2	0x60cc
16kHz -> 48kHz	3	0x0

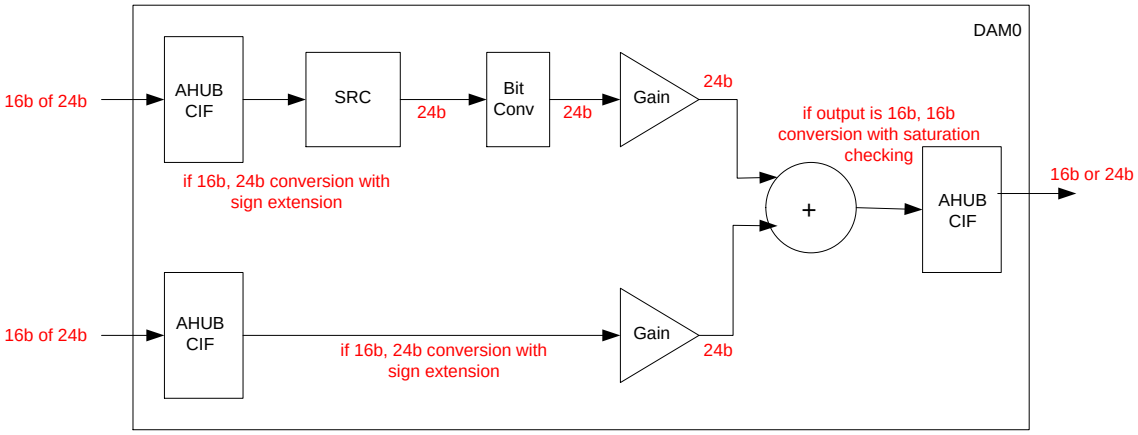


Multiplier Precision

While the input data and the step constants are 16 bit wide, the internal data is kept in the 24 bit format. For the multiplication, 24x16 multiplier is implemented. The width of accumulator is 43 bits for 40 bit + 3 guard bits for accumulation. Note that all data is signed.

While 16 bit samples are the only input format specified by P0, SRC can handle 24 bit input samples since the internal structure supports 24 bit samples. If RXCIF gets 16 bit input samples, it passes the samples untouched to the DAM core logic. The DAM core logic converts upgrades their precision to 24 bits with sign extension automatically before those samples are used in computation. If RXCIF gets 24 bits input samples, it can still forward those samples untouched to DAM. DAM will identify the bit width of the samples and use those as is without sign extension.

The reverse conversion should happen in the output stage of TXCIF. The internal 24 bit samples are converted to 16 bits with saturation checking before they are passed to TXCIF by the signal merger. If the output format is 24 bits, the samples can be forwarded to TXCIF untouched.



22.3.1.3 Channel Conversion

LLF SRC only supports 16 bit input mono streams.

22.3.1.4 Gain Controller

The gain controller supports a 16-bit volume level; and performs a 24x16 multiply with 24 bit output. While the LLF path only supports 16 bit data, the HQF will generate 24 bit output. To reuse the gain controller both in the LLF and the HQF paths, the input and output bit width is fixed to 24 bits. Also, the gain controller should support multi-channel stream, up to 8. Each gain controller has its own gain value.

The gain value is specified in the Q12 unsigned fractional format. In the binary representation,

iiii.ffffffffffff

where *i* and *f* represent integer and fractional binary numbers, respectively.

With the format, 0x1000 means 1 in linear gain, while 0x0800 means 0.5 in linear gain. Note that the 24 bit input data is signed data, while the gain value is unsigned.

The accumulator output is shifted right 14 bit to generate normalized output.

22.3.1.5 Mixer

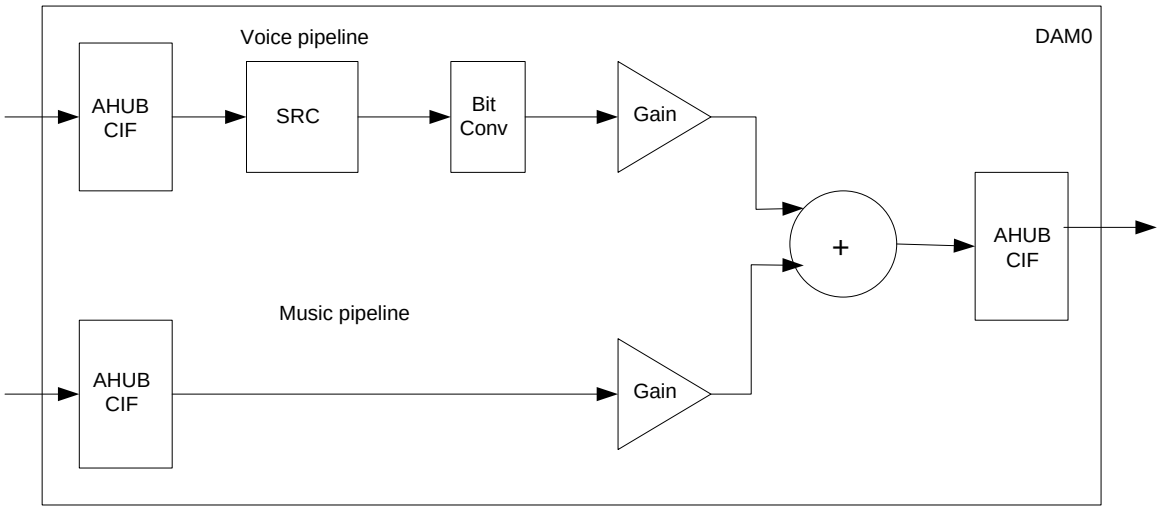
The mixer is simply a 24 bit adder. The output data from the gain controllers is added to generate a 24 bit value, which is sent to AHUBCIF TX. AHUBCIF converts the stream into user-specified bit format.

When the mixer tries to pick up the data from each channel, it is possible that one channel has data available, while the other channel doesn't. While this data synchronization can be specified in the configuration register, it is recommended to use a certain values for the field of each channel. Mostly, the data for the LLF channel is a stream input, while the data for the second channel comes from memory via DMA. In this scenario, the data in the second channel fills the channel pipeline, FIFOs, while the pipeline of the first channel is empty. Normally, the sample in the second channel should wait for the first channel for mixing, but the sample in the first channel should not wait for the second channel because the latency is critical in the first channel. The synchronization between the samples can be controlled by the configuration register settings.

When the mixer merges samples from multiple channels, the sum can get out of precision limit due to inappropriate gain values in the gain controller. Due to the bit with limitation, those out-of-limit samples will be clipped to the maximum values that the precision allows. If this happens frequently, the sound quality will be greatly degraded. To avoid this kind of situation, DAM notifies CPU to adjust the gain values through keeping the number clipped samples and an interrupt.

22.3.1.6 Error handling

While DAM expects constant data streams from CIFs, it may encounter some erroneous situations such as FIFO empty or FIFO full in its pipelines. Those can happen due to external issues somewhere in the system. A good example is APB DMA runs out of data when a system bus is congested so that CPU cannot access the DMA for the next batch of data for transmission. The FIFOs in DAM will be depleted, but it should still generate output stream.



The diagram shows a conversion case where a voice stream and a HIFI stream are mixed in DAM. SRC is the only one that can change the sampling frequency and all other module just obey the incoming sampling rate. There are some corner cases that should be carefully described.

- Whenever any sample is ready in AHUBCIF TX, it should send it to AHUB. If AHUBCIF TX doesn't get the ready signal when it has a sample to send, it will backpressure the rest of the pipeline.
- The mixer unit merges two samples from both pipelines. If both samples are ready, it mixes them and send it to AHUBCIF. If a sample from the the voice pipeline is ready, while the music pipeline is not, the mixer takes NULL data for the music pipeline and mixes it with the voice sample. If a sample from the music pipeline is ready, while the voice sample is not, it should wait for a sample from the voice pipeline. This only applies when both pipeline is turned on. If only one pipeline is turned on, the mixer sends out a sample whenever it is ready from the previous stage. The synchronization behavior is controlled by the configuration register.
- Depending on the configuration register programming, SRC generates an output sample stream from an input sample stream with different frequencies. If it gets backpressure from the next stage, it just stop generating samples until the condition changes. Also, if the input stream is not ready for SRC, it will just wait for the next sample.

If AHUBCIF RX gets backpressure from the next stage, it'll just hold the incoming AHUB bus until the condition changes.

22.4 I2S

The I^2S Controller has been designed to transfer streaming audio-data between the system memory and an audio-codec (audio-codec is an analog-to-digital (A/D) and/or digital-to-analog (D/A) converter). The controller supports I^2S format, Left Justified Mode format, Right Justified Mode format, and DSP mode format, as defined in the Philips® inter-IC-sound (I^2S) bus specification (a simple serial link specifically designed for digital audio).

The I^2S controller supports point-to-point serial interface for the I^2S digital audio streams. I^2S-compatible products, such as compact disc players, digital audio tape devices, digital sound processors, and those with digital TV sound may be directly connected to the I2S controller. Controller also supports the PCM, telephony (network) and TDM mode of data-transfer. Pulse-Code-Modulation (PCM) is a standard method used to digitize audio (particularly voice) patterns for transmission over digital communication channels. The Telephony (network) mode will be used to transmit and receive data to/from an external mono CODEC in a slot-based scheme of time-division multiplexing. TDM mode is same as network mode, but in TDM mode, all or any of the slots are active. All these modes are synced up by a frame-sync signal (same as left-right-channel-clock –LRCK—in case of normal I2S communication).

I2S can be hooked up to any audio modules through AHUB. If I2S needs to access the system memory, it can transmit/receive transactions to/from APBIF, which can trigger the APB-bridge DMA to transfer data to and from its FIFOs. Controller supports two-FIFOs, FIFO-1 and FIFO-2 which can operate bi-directional in normal I2S modes but only uni-directional in PCM/NW/TDM modes.

Features

- Philips inter-IC-sound (I^2S) bus specification compliant
- PCM and NW mode support
- Can operate in both Master and Slave modes
- Supports I^2S, RJM, LJM and DSP mode data-formats.
- Supports non- 50:50 mark-space ratio in both Master and Slave modes of I2S, RJM, and LJM.
- Two FIFOs and control logic. In I2S basic modes, both the FIFOs can be configured for Tx or Rx. In PCM/NW mode, FIFO-1 will act as Tx-FIFO and FIFO-2 as Rx-FIFO.
- Buffer memory optimized for peripheral bus utilization, allowing multiple sets of data being stored for both incoming and outgoing data stream per slot (Data-Packed mode in both FIFOs)
- Supports PCM-mode mono and NW-mode with independent slot-selection for Tx-and-Rx.
- PCM mode supports short and long FSYNC. Long FSYNC can be only 2-clocks wide in Master mode and can be any number of clocks in slave-mode.
- Supports TDM mode with programmability in number of slots, active slots and slot size.
- Same LRCK/FSYNC for both Transmission and reception of data.
- 6-bit clock divisor to support single- and double-speed for the following rates: 8 KHz, 32 KHz, 44.1 KHz, 48 KHz, 96 KHz, and 128 KHz
- Maximum frequency of device clock supported is 48 MHz
- The number of slots can be programmed from 1 to maximum 8 in TDM mode.

The I^2S controller supports bidirectional audio streams. It can operate in half-duplex or full-duplex mode; that is, it can transmit or receive data on both the I2S_DIN and I2S_DOUT pins, based on the register-configuration. The I^2S controller supports input word lengths of 16, 20, 24, or 32 bits. In TDM mode, the word length can be supported multiple of 4 starts from 8 bit.

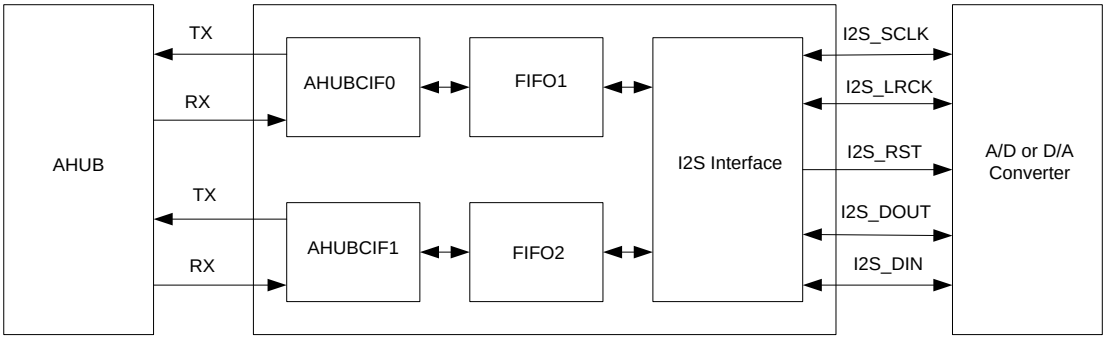
In Master mode, the I^2S controller signals the synchronization of all I^2S data transactions. The I^2S controller module generates the SCLK bit clock (I2S_SCLK,) and Left-Right channel clock LRCK (I2S_LRC) to the A/D or D/A converter. The A/D or D/A converter synchronizes the input or output audio data based on these clock signals.

In Slave mode, the external A/D or D/A converter provides the synchronization clocks, bit clock (I2S_SCLK) and Left-Right channel clock (I2S_LRCK) to the I^2S controller. The I^2S controller synchronizes the input/output audio data to these clocks.

I^2S has two AHUBCIFs, which can be configured to either RX or TX depending on the direction of FIFOx and DOUT/DIN.

Note: Legacy naming of FIFO1 and FIFO2 are still used in the figure below, while AHUBCIFs are numbered from 0 to 1.

Figure 43. I2S Functional Block Diagram



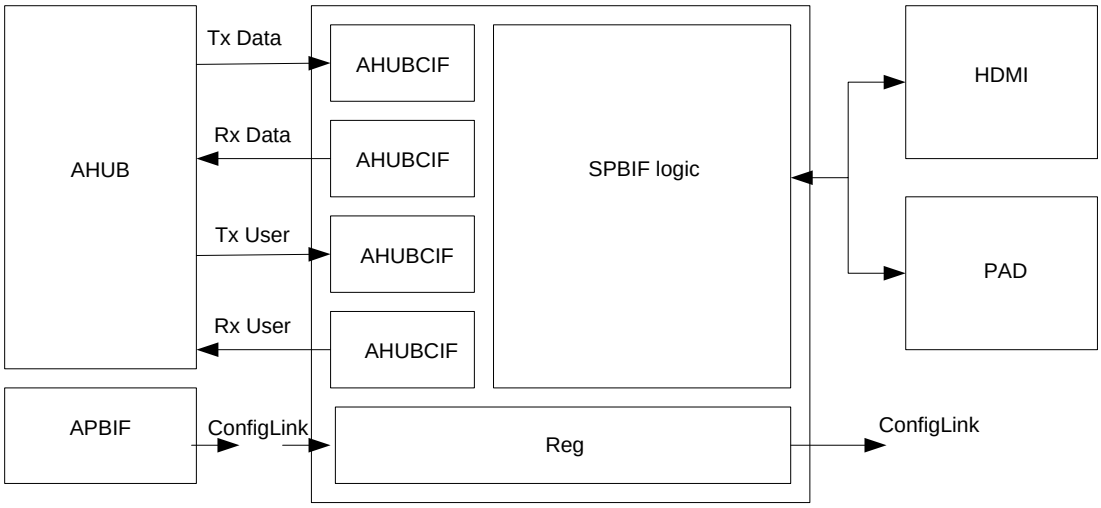
The configuration registers are programmed through a serial link from APBIF, ConfigLink. The interface has 1 bit data line for input and output and runs under the APB clock domain.

In order to avoid empty/full FIFO, a flow control mechanism is necessary in I2S. In the TX FIFO, an empty FIFO can cause sample dropping in the output stream. I2S should either add samples as specified by the configuration register or try to avoid the situation from the beginning. Also, if the RX FIFO is full in I2S, it should either drop some samples until there is room for new samples in the FIFO or try to avoid the situation with flow controlling.

22.5 SPDIF

The SPDIF interface is intended to support both professional and consumer applications, and therefore is a complete IEC-958 standard interface. When used in a professional application, the interface is primarily intended to carry monophonic or stereophonic programs, at a 48 kHz sampling frequency and with a resolution of up to 24 bits per sample; it may alternatively be used to carry signals sampled at 32 kHz or 44.1 kHz. When used in a consumer application, the interface is primarily intended to carry stereophonic programs, with a resolution of up to 20 bits per sample, an extension to 24 bits per sample being possible. When used for other purposes, the interface is primarily intended to carry audio data coded other than as linear PCM coded audio samples. Provision is also made to allow the interface to carry data related to computer software or signals coded using non-linear PCM. The format specification for these applications is not part of this standard.

SPDIF receives and/or transits data through AHUB from/to other AHUB clients. The register programming is performed through the ConfigLink interface, which is a daisy chain of a serial data line.



Features

- Support five data format.
  - 16-bit.
  - 20-bit.
  - 24-bit.
  - Raw.
  - 16-bit packed.
- Support “autolock” mode to automatically detect the “spdifin” sample rate and lock onto the data stream.
- Support “override” mode to provide a manual control to sample the “spdifin” data stream.
- Provide a loopback mode to route the “spdifout” back to “spdifin” for self-testing.
- SPDIFOUT (transmitter).
  - 16-word data FIFO for storage of outgoing audio data. (AHUBCIF)
  - 4-word user FIFO for storage of outgoing user data. (AHUBCIF)
  - 6-word page buffer for storage of outgoing channel status. (Config Reg)
- SPDIFIN (receiver).
  - 16-word data FIFO for storage of incoming audio data. (AHUBCIF)
  - 4-word user FIFO for storage of incoming user data. (AHUBCIF)
- 6-word page buffer for storage of incoming channel status. (Config Reg)

22.5.1 SPDIF Functionality

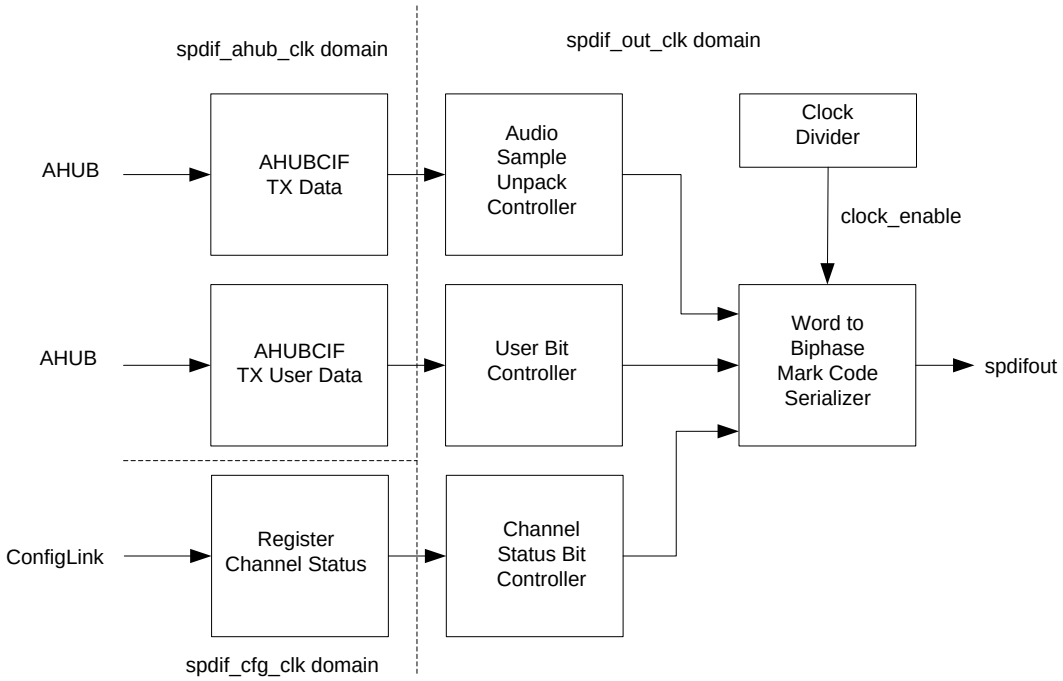
22.5.1.1 SPDIFOUT

The SPDIFOUT module contains the following sub-blocks:

- A clock divider.
- A 16-word data FIFO.
- An audio sample unpack controller.
- A 4-word user FIFO.
- A user bit controller.

- A channel status bit controller.
- A word to biphase mark code serializer

Figure 44. SPDIFOUT Block Diagram



Data FIFO

This 16-word deep FIFO is used to store audio samples written by the system; in raw mode, it also stores non-audio data such as parity, channel status, user, validity, and preamble bits.

Audio sample unpack controller

Based on the **PACK** register field, this controller will either break-up the packed data from the data FIFO or just let the data FIFO's data flow through unmodified to the "word to biphase mark code serializer" module. Also, this controller handles when to pop an entry out of the data FIFO.

User FIFO

This 4-word deep FIFO is used to store user data written by the system; in raw mode, data from this FIFO will not be used.

User bit controller

When in 16, 20, 24-bit, or pack mode (**PACK** = 1 or **BIT.MODE** ≠ 11) and user data transmit is enabled (**TXU.E** = 1), this controller will temporary store an entry out of the user FIFO and feed user data, one bit **per subframe**, to the "word to biphase mark code serializer" module. Of course, this controller handles when to pop an entry out of the user FIFO. If user data transmit is disabled (**TXU.E** = 0), the user bit will be force to 0.

Channel status bit controller

When in 16, 20, 24-bit, or pack mode (**PACK** = 1 or **BIT.MODE** ≠ 11) and channel status transmit is enabled (**TXC.E** = 1), this controller will temporary store an entry out of the channel data TX page buffer and feed channel status, one bit **per frame**, to

the “word to biphase mark code serializer” module. Also, it provides control to advance the channel data TX page buffer pointer to the next entry. If channel status transmit is disabled (**TXC.E** = 0), the channel status bit will be force to 0.

Word to Biphase Mark Code Serializer

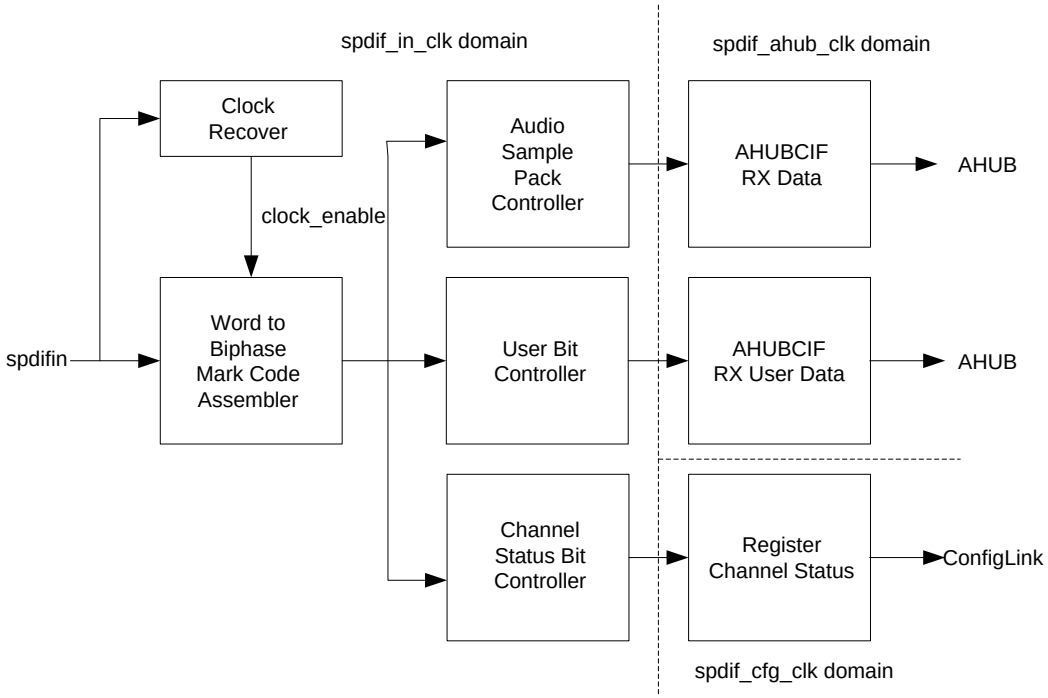
Based on the **PACK** and **BIT.MODE** register fields, this controller assembles a 32-bit word from the “Audio sample unpack controller” module, and/or “User bit controller” module, and/or “channel status bit controller” module. This 32-bit word will then be converted to the IEC 60958-3 biphase-mark code format and send out through the ‘spdifout’ signal. This controller also provides various status signals (i.e. end of transmitting a subframe, etc) back to the “unpack”, “user”, and “channel status” controllers.

22.5.1.2 SPDIFIN

The SPDIFIN module contains the following sub-blocks:

- A biphase mark code to word assembler.
- An audio sample pack controller.
- A 16-word data FIFO.
- A user bit controller.
- A 4-word user FIFO.
- A channel status bit controller.
- A clock recovery.

Figure 45. SPDIFIN Block Diagram



Pulse Counter

The purpose of this module is to perform the following three tasks, (1) count the number of “spdifin_clk” within the “spdifin” pulse, (2) generate a pulse to indicate that “spdifin” has toggled, and (3) indicate “spdifin” input is inactive.

Clk recover algorithm

Based on the inputs from the ‘Pulse counter’, this module calculate both, (1) the “spdifin” biphase period, and (2) the mid-point within the biphase period, in term of the number of “spdifin_clk”; the algorithm used is based on the 3 biphase period and 1 biphase period wide pulse in the “spdifin” data stream’s preamble phase. If the “override” mode is selected instead, the number of “spdifin_clk” within the biphase period and mid-point within the biphase period will be controlled by the **BIPHASE_DAT_STRB** and **BIPHASE_CLK_PERIOD** configuration register fields instead.

Clock enable decode (pre- and post-)

This module, which is used twice, contains the following functions, (1) to generate a “clk_enable” pulse in the middle of a “spdifin” biphase period for other modules to have a safe point for storing data from the “spdifin” data stream, and (2) to keep track of the bit position within a SPDIF subframe for the current “clk_enable” pulse. The reason why this module is used twice is because the “pre-“ module is used to search or re-lock to the “spdifin” data stream if the logic ever lost lock to the data stream. Once acquired lock for the first time, the “post-“ module will continue to use the previous saved biphase period and mid-point clock count to generate “clk_enable” even though the “pre-“ logic lost lock to the data stream and is in the process of re-locking (re-establishing the new biphase period and mid-point clock count) to the “spdifin” data stream.

Preamble decode (pre- and post-)

Based on the inputs from the ‘Clock enable decode’, this module provides miscellaneous decode such as, (1) when a preamble is detected from the “spdifin” data stream, (2) the beginning of a block, (3) whether the current subframe is channel A or channel B, and (4) when is the end of a subframe, etc. to other modules. This module is also used twice, one for each of the ‘Clock enable decode’ modules.

Lock checking

The purpose of this module is to act as a watcher/checker to the entire clock recovery logic. It determines, (1) when a lock to the “spdifin” data stream is established, (2) when a lock to the “spdifin” data stream is lost so that a re-lock is needed, (3) when to update the new biphase period and mid-point clock count values within both of the ‘clock enable decode’ modules.

22.5.1.3 Biphase mark code to word assembler

Based on the clock enable pulse from the “clock recovery” module, this controller reads the ‘spdifin’ data stream in IEC 60958-3 biphase-mark code format and convert/assemble the bit data into a 32-bit word. This 32-bit word will then be read by “audio sample pack controller”, “user bit controller”, and “channel status bit controller” modules for further processing. This controller also provides various status signals (i.e. end of receiving a subframe, etc) to the “pack”, “user”, and “channel status” controller.

22.5.1.4 Audio sample pack controller

Based on the **PACK** register field, this controller will either combine two audio data or just let the audio data flow through unmodified from the “biphase mark code to word assembler” module to the data FIFO. Also, this controller handles when to push an entry into the data FIFO.

22.5.1.5 Data FIFO

This 16-word deep FIFO is used to store audio samples written by the “audio sample pack controller” module; in 16, 20, 24-bit, or pack mode, it also stores non-audio data such as parity, channel status, user, validity, and preamble bits. Furthermore, this FIFO serves as a bridge between the ‘spdif_in_clk’ and ‘spdif_ahub_clk’ domain.

22.5.1.6 User bit controller

This controller will save the user bit from each subframe and assemble them into a 32-bit word before pushing an entry into the user FIFO.

22.5.1.7 User FIFO

This 4-word deep FIFO is used to store user data written by the “user bit controller” module. Also, this FIFO serves as a bridge between the ‘spdif_in_clk’ and ‘spdif_ahub_clk’ domain.

22.5.1.8 Channel status bit controller

This controller handles saving the channel status bit from channel A (subframe 1) **only** and assemble them into a 32-bit word before writing into the 6-word channel status page buffer which is also resided within this controller.

22.5.1.9 Flow Controller

The flow controller is implemented in both I2S and SPDIF to match each other’s output. A common sub-module should be implemented and instantiated as needed.

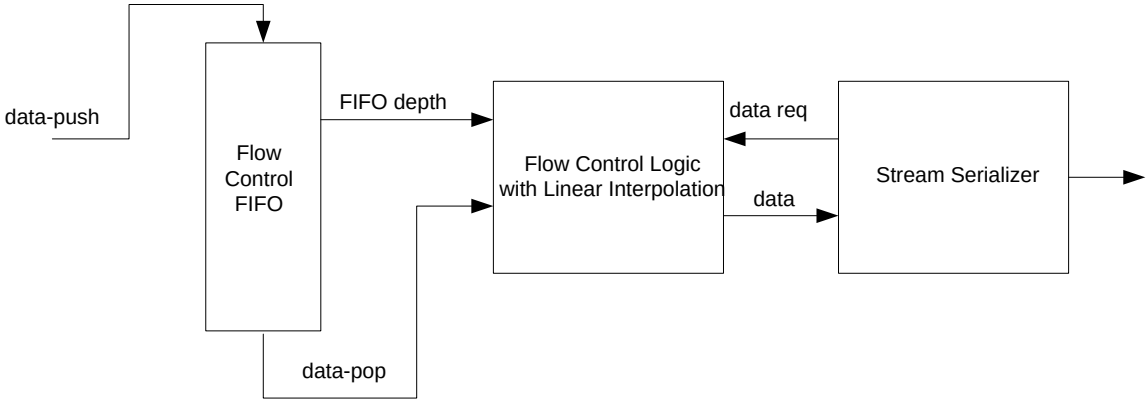
When communicating with a baseband processor and a CODEC, their operating clock frequencies can be a little bit different and not accurately synchronized to each other even their nominal frequencies are the same. Also, when sampling rate conversion is performed, the converted sampling rate frequency can be a little off from the SPDIF interface clock rate. For example, the sample rate conversion between 8 kHz and 44.1 kHz can leads to either data skipping or blanking, because 44.1 kHz output cannot be exactly aligned with 8 kHz input. Even the rate conversion is between 8 kHz and 48 kHz, their actual frequencies may not be ratio-synchronized because their clock sources can be different. If the error from the clock difference accumulates, the audio quality eventually suffers from skipping or blanking.

There are two exceptional events that SPDIF should pay special attention to, FIFO empty in the SPDIF TX and FIFO full in the SPDIF RX. The other cases, FIFO full in the SPDIF TX and FIFO empty in the SPDIF RX are not the critical events and the AHUB subsystem can minimize the impact through back-pressuring the pipeline or simply idling.

These events can happen in two different types of operations, DMA operations and stream operations. With the DMA operations, the exceptions rarely happens because SW programs DMA properly to avoid those and the DMA transactions are much faster than the external SPDIF transactions. However, with the stream transactions, there are good chances of those exceptions happening due to the asynchronous nature of the AHUB subsystem and the external SPDIF interface. Therefore, two different types of flow control mechanism are proposed in SPDIF to handle them appropriately.

The first one is a simple replication and drop. With the SPDIF RX, if FIFO is full, next incoming samples are simply dropped until FIFO has some room for new samples. With the SPDIF TX, if FIFO is empty, SPDIF can either replicate the last known sample or send out just 0’s depending on the register configuration. When either of these exceptions happen, SPDIF should log the situation and trigger an corresponding interrupt, if un-masked, to the master as soon as possible. This scheme usually can be used when SPDIF is pipelined with DMA.

The other scheme is to implement a linear interpolation filter to smooth out the samples in case of empty or full FIFO. This is used in SPDIF TX only, but not in SPDIF RX. SW specifies a pre-determined threshold in FIFO to control flow. If the FIFO depth is greater than the threshold, SPDIF increases the step size to reduce the number of sample per time unit, which will decrease the FIFO depth gradually. When the FIFO depth becomes the threshold value, the step size is back to normal. If the FIFO depth is less than the threshold, SPDIF decreases the step size to produce more samples per time unit, which will increase the FIFO depth gradually. This scheme is useful for the use case where a voice stream comes in an SPDIF interface and the processed stream go out from other I2S interfaces. A block diagram is shown below.



If the FIFO status is normal, the interpolation filter uses the regular step size, which will generates the identical output sample. If the input rate is faster than the output rate, the more symbols will be in the FIFO, which can cause eventual FIFO overflow. To avoid overflow, SPDIF takes a bigger step size to generate less output symbols per unit time. The range of the step sizes for each clock frequency is SW programmable. If the input rate is slow than the output rate, FIFO will underflow eventually. In that case, a smaller step is used to generate more output symbols per unit time. While we assume the worst clock difference is 100 ppm (0.01%), the step size variance is programmable for the optimal adjustment.

Normally, SPDIF takes the standard step size *S* to process input audio signals. If the FIFO level becomes greater than the pre-defined (programmable) threshold level, SRC replaces step size *S* with $S + \Delta$ to control the sample rate conversion flow. When SPDIF eventually catches up the input rate and the FIFO levels goes down to the level, it replaces back step size $S + \Delta$ with *S*. To avoid underflow, SPDIF takes $S - \Delta$. The threshold level and the various step sizes are SW programmable. Since both filters need to execute several 24x16 multiplication, a 24x16 multiply-accumulate (MAC) is used and can be shared, if possible. Note that both input to and output can be multi-channel PCMs.

In order to avoid accumulation of error through adding step size, a register programmable can be used to reset the current time every N samples. After SPDIF takes N input samples, it should reset the current time value and send out the input sample intact. If the FIFO depth is not at the threshold level, the adjusted step size is applied again from the reset state.

22.5.2 SPDIF Programming Guidelines

22.5.2.1 16-, 20-, 24-bit Mode

During transmission, the audio data is taken from the TXdata FIFO, the channel status bit is taken from the TXchannel status page buffer and the user status bit is from the TX user FIFO. The preamble bits are generated by the hardware. The Valid bit is always zero.

During reception, the audio data is stored in the RX data FIFO, the channel status bit is stored in the RX channel status page buffer and the user status bit is stored in the RX user FIFO.

In addition to storing the audio data, the RX data FIFO also stores the preamble bits, channel status bit, user status bit and the valid bit. The reception of the channel bits start after the B-preamble is detected.

The audio-data sample has 16-, 20-, or 24-bits of data. Firmware has to transmit 16-, 20-, or 24-bit data and read 16-, 20-, or 24-bit data.

22.5.2.2 Raw Mode

During transmission, the audio-data, the preamble bits, channel status bits, the user bits and the valid bits are transmitted from the RX data FIFO. The firmware has to provide the correct preamble bits for the receiving device to synchronize with the transmitter. The firmware has to provide preambles according to the following table:

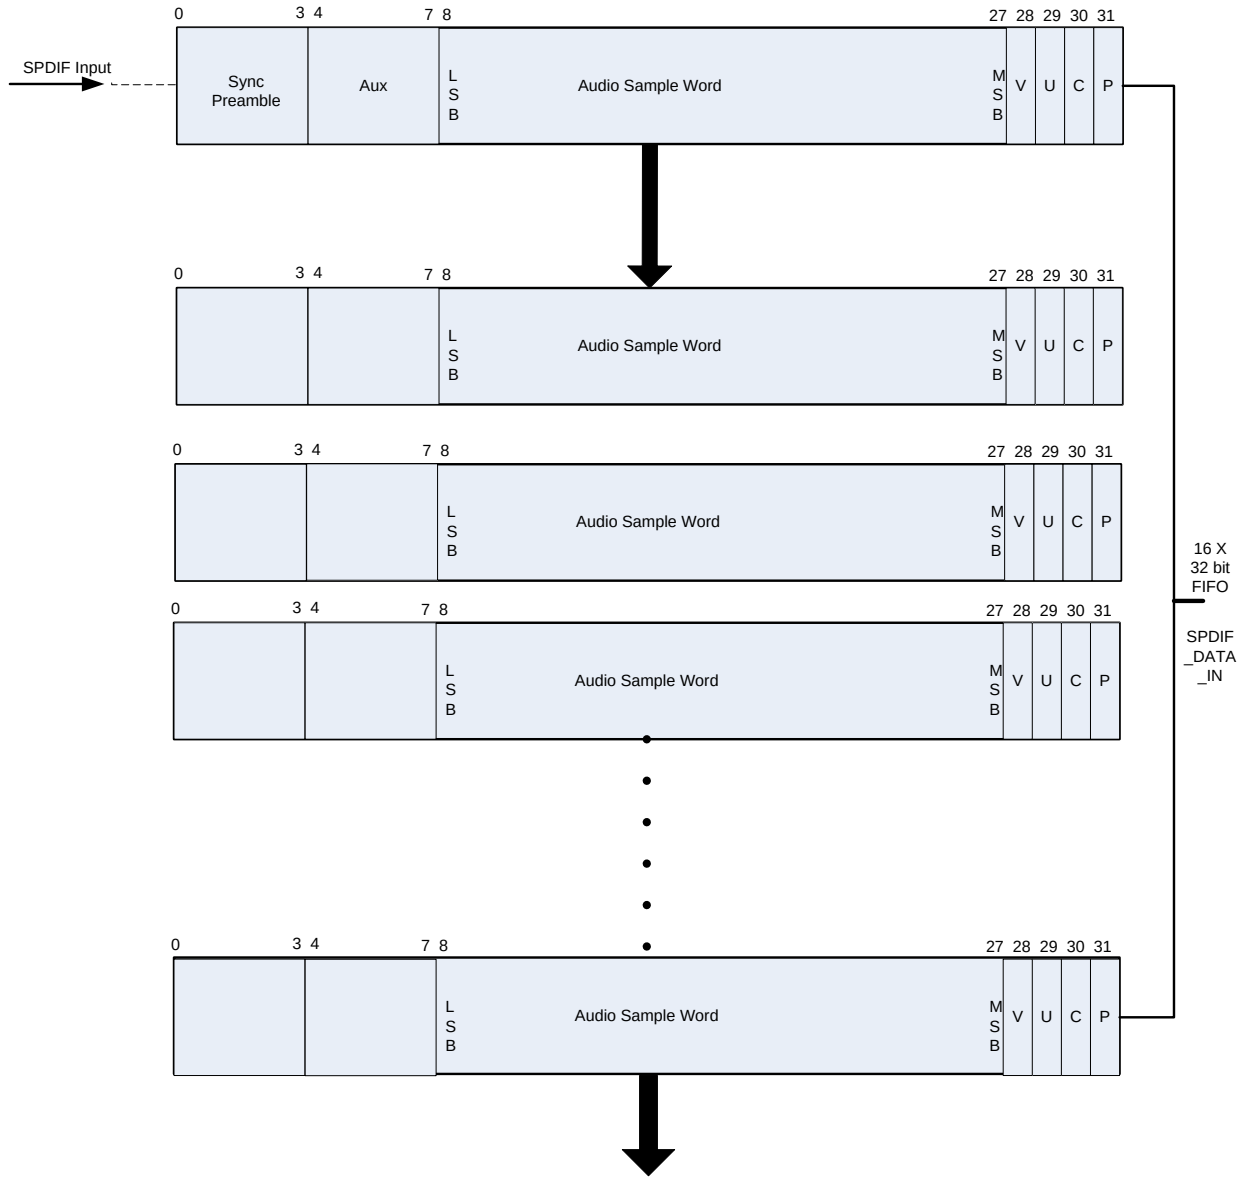
Preceding State in the Parity Bit: 0/1

Figure 46. Preamble bits

Symbol	Preamble Code	Channel Coding	Description
"B" (or "Z")	0001/0001	11101000/00010111	Start of a block.
"M" (or "X")	0010/0010	11100010/00011101	Start of sub-frame 1.
"W" (or "Y")	0011/0011	11100100/00011011	Start of sub-frame 2.

During reception, the audio-data, the preamble bits, channel status bits, the user bits and the valid bits are stored in the RX data FIFO. The user bit is also stored in the RX user FIFO. The channel bit is also stored in the RX channel status page buffer. But the channel status bits are stored in the RX channel status page buffer only after the B-preamble is detected.

Figure 47. S/PDIF Data Format for Raw Mode



22.5.2.3 Pack Mode

During transmission, the audio data is taken from TX data FIFO which contains two 16-bit data (the upper 16-bit is for channel B or sub-frame 2, the lower 16-bit is for channel A or sub-frame 1, the channel status bits are taken from TX channel status page buffer and the user status bits are from TX user FIFO. The preamble bits are generated by the hardware. The Valid bit is always zero.

During reception, the audio data is stored in the RX data FIFO which contains two 16-bit data (the upper 16-bit being channel B data and the lower 16-bit being channel A data), the channel status bits are stored in the RX channel status page buffer and the user status bits are stored in the RX user FIFO. The reception of the channel bits start after the B-preamble is detected.

22.5.2.4 Module Reset

The application may initialize or reset the S/P-DIF module via the clock and reset (CAR) control's RST_DEVICES_L_0 register.

22.5.2.5 Clock Source/Divider Control

The SPDIFOUT clock source/divider can be selected by programming CAR's CLK_SOURCE_SPDIF register. Refer to the SPDIF registers below for the needed input frequency for the desire output audio sample rate.

The SPDIFIN clock source/divider can be selected by programming CAR's CLK_SOURCE_SPDIF register. Refer to the SPDIF registers below for the needed over-sample frequency.

22.5.2.6 Clock Enable Control

The application may enable the S/P-DIF clocks by programming CAR's CLK_OUT_ENB_L_0 register.

22.5.2.7 Detecting Incoming Sampling Rate

The SPDIFIN is capable of detecting and locking onto the 'spdifin' data stream regardless of the sample rate. It achieves this by using over-sampling technique

In addition to reading the sampling rate from the channel status information, one can also read the PERIOD field in register STROBE_CTRL_0 to estimate the incoming sample rate. The last two digits of PERIOD indicates the fractional clock period.

Sample rate ≈ ('spdifin' clock frequency * 1000) / (PERIOD * 128)

If using the PERIOD method, it is better to read this field toward the end of the song or just before turning off the SPDIFIN. Although the hardware can lock onto the SPDIFIN data stream in as little as 2 sub frame of time, the hardware is actually constantly re-adjusting itself (due to jitter, synchronization loss, etc. in the data stream) to provide the strobe point to the center of the biphase data stream. As time goes by, the strobe point will vary less and less because the hardware has already adjusted to all the variations seen in the data stream.

22.5.2.8 S/P-DIF Transmit Data Flow

Make sure that the TX_FIFO is filled before enabling the transmission by setting TX_EN field of CTRL_0 register. Never allow the TX_FIFO to go empty at any time during transmission. The interrupt is generated when Tx DATA FIFO empty count is greater than the Tx DATA attention value (TX_ATN_LVL field of DATA_FIFO_CSR_0 register) if the Tx interrupt enable is set.

22.5.2.9 S/P-DIF Receive Data Flow

To enable the reception of RX_FIFO set (RX_EN field of CTRL_0 register). Never allow the RX_FIFO to become full at any time during reception. The interrupt is generated when Rx DATA FIFO data count is greater than the Rx DATA attention value (RX_ATN_LVL field of DATA_FIFO_CSR register) if the Rx interrupt enable bit is set.

22.5.2.10 Method of Filling/Retrieve Data from TX/RX User/Data FIFO

Use DMA method by programming the APBDMA and APBIF Registers. With this method, the FIFO attention levels need to be set in APBIF just like in method 2. But instead of enabling interrupts when the FIFO attention level is reached, one should program the APBDMA registers. Now, every time the attention level is reached, a DMA request will be generated by the APBIF to the APBDMA and the APBDMA will perform the data moving task from/to APBIF FIFOs to the AHB bus.

22.6 Audio Hub Registers

Control Register for AUDIOCIF for both TX and RX

MONO_CONV : Convert mono to stereo

ZERO -> zero out the second channel

COPY -> copy the first channel to the second channel

valid only in 1 channel to 2 channels conversion

TRUNCATE : rounding method on LSB when deleting lower bits

CHOP -> chop off the lower bits; if 1, just chop off lower bits (truncate)

ROUND -> if immediate lower bit is 1, add 1 to the significant bits

ROUND should be chosen for signed numbers because rounding is toward positive infinite. Also, in case of the max positive number, the lower bits are just chopped off.

For example with 8 -> 4 bit rounding for signed numbers

0x7F -> 0x7

0x0F -> 0x1

0xFF -> 0x0

0x8F -> 0x9

DIRECTION : Direction of CIF

TXCIF -> TX port to AUDIO

RXCIF -> RX port from AUDIO

REPLICATE : When FIFO underflows, if replicate bit is set then previous frame is repeated.

In Tegra 3 we only support replicating for mono and stereo frames due to the FIFO size limitation. If it's more than 2 channels, the samples in FIFO is used to fill other muti-channels.

DISABLE -> Disable replication. All zero's will be used.

ENABLE -> Previous frame is repeated.

STEREO_CONV : Convert stereo to mono

CH0 -> pick the first channel

CH1 -> pick the second channel

AVG -> (ch0 + ch1) / 2

valid only in 2 channels to 1 channel conversion

EXPAND : Expand the additional bits with the following method

ZERO -> zero out the expanded field

ONE -> fill the expanded field with 1's

LSFR -> fill the expanded field with a random number

CLIENT_BITS : The number of bits in a sample in the client side

CIF_BITS : The number of bits in a sample in the AUDIO side

CLIENT_CHANNELS : The number of channels in the client side

the actual channels = CLIENT_CHANNELS + 1 i.e. 0 -> 1 channel

CIF_CHANNELS : The number of channels in the AUDIO side

the actual channels = CIF_CHANNELS + 1 i.e. 0 -> 1 channel

FIFO_THRESHOLD : This specifies the number of words that need to be present in the FIFO before a CIF starts transfers.

0 : start transfer when 1 word is received.

1 : start transfer when 2 words is received.

i : start transfer when i words is received.

For example, if FIFO_THRESHOLD is set to 3, then RxCif gives rd_req to I2S/SPDIF/DAM core only after 4 words have been written into the FIFO. It is recommended that a non-zero value be set only for rx_cifs of I2S and SPDIF. For all other cases default value of zero is the appropriate setting.

22.6.1.37 APBIF_I2S_INT_MASK_0

Since the config registers of the AUDIO clients are daisy-chained, their read latency can be high. To avoid unnecessary latency, the clients provide signals to APBI, mostly interrupt signals so that CPU/AVP can access them promptly.

These registers should be detailed further with AUDIO clients.

Interrupt mask and status for AUDIO clients

22.6.1.41 APBIF_I2S_INT_STATUS_0

Bits in this register are high after the interrupt condition is satisfied. A write to this register clears the bits corresponding to the data bits that are high in the write data.

2	0x0	APBIF_CH1_RXCIF_UNDERRUN: 0 = DISABLE 1 = ENABLE
1	0x0	APBIF_CH0_TXCIF_OVERRUN: 0 = DISABLE 1 = ENABLE
0	0x0	APBIF_CH0_RXCIF_UNDERRUN: 0 = DISABLE 1 = ENABLE

Packet is Big Endian and HEADER is transmitted first. This packet is not used for Tegra 3.

22.6.2 Audio Registers

22.6.2.1 AUDIO_APBIF_RX0_0

The following macro defines a register for each RX port. No more than one field can be 1 in a register because a RX port can receive from only one TX port.

Example:

```
reg DAM0 RX0 incr4
0:0          DAM0 TX0           rw         i=0
1:1          I2S0 TX0           rw         i=0
2:2          I2S1 TX0           rw         i=0
;
```

22.6.4 I2S Registers

The I2S Controller is designed to transport streaming audio-data between the system memory and an audio-codec. The controller supports I2S format, Left Justified Mode format, Right Justified Mode format, and DSP mode format, as defined in the Philips inter-IC-sound (I2S) bus specification.

The Controller also supports the PCM and telephony (network) mode of data-transfer. Pulse-Code-Modulation (PCM) is a standard method used to digitize audio (particularly voice) patterns for transmission over digital communication channels.

The Telephony (network) mode is used to transmit and receive data to/from an external mono codec in a slot-based scheme of time-division multiplexing.

The controller has one transmit and one receive interface. The controller can be configured to operate either as a master or a slave.

22.6.4.1 I2S_CTRL_0

This is I2S control register where we can configure bit formats (I2S, LJM, RJM, DSP, PCM, NW, TDM), bit sizes(8, 16, 20, 24 and 32), FIFO formats, Master/slave selection, LR polarity and error interrupt enables.

I2S Control Register

Offset: 000h | Read/Write: R/W |Reset: 0b00000000xxxxxxxxx000x000xx00x000

Bit	Reset	Description

22.6.4.2 I2S_TIMING_0

The CHANNEL_BIT_CNT field of this register is used to program the number of bit-clks per channel of LRCK (sampling rate) the I2S controller needs to send out in Master mode. This value is interpreted as follows:

a) DSP mode:- Number of bit clocks (sclk) within (LEFT +RIGHT) channel width.

b) Basic/LJM/RJM modes:- Number of bit clocks (sclk) within each individual channel width (LEFT or RIGHT).

c) PCM/NW/TDM modes:- Number of bit clocks (sclk) per frame.

The NON_SYM.EN can be used to program the I2S controller to output a non-50:50 mark-space ratio on to the I2S bus. When the NON_SYM.EN Bit[12] is enabled, the Controller sends out exactly the programmed number of clock cycles on the left channel and one bit-clk greater on the right channel. This is used in Basic/LJM/RJM modes.

When NON_SYM.EN is enabled, the channel-bit-count should be programmed with the number of bit clocks required in the left channel. This will ensure that the non-50:50 mark-space ratio is achieved with

R_BCLK = L_BCLK + 1

The PCM/NW/TDM modes channel_bit-cnt can be calculated using the relation:

Channel_bit_cnt = ((frequency of bit_clk) / (2 * required sampling rate)) - 1;

If this calculation returns a fractional value, the non-symmetry feature of the controller should be used to attain the required sampling rate.

I2S Timing Register

22.6.4.8 I2S_FLOWCTL_0

This register controls the flow control mechanism and is valid only with the TX mode. The flow control is only useful when the input stream to I2S/SPDIF is already real-time spaced such as a live stream from Baseband through another I2S_RX. If the input stream is from DMA directly, the flow control should be disabled.

FLOWCTRL

Offset: 01ch | Read/Write: R/W | Reset: 0b1

Bit	Reset	Description
31	QUAD	FILTER: to use linear or quadratic filter. Tegra 3 supports quadratic filter only. 0 = LINEAR 1 = QUAD

22.6.4.9 I2S_TX_STEP_0

Offset: 020h | Read/Write: R/W | Reset: 0b1000000000000000

Bit	Reset	Description
15:0	0x8000	STEP_SIZE: This is a compensation value for the clock difference between input and output. To catch up the clock difference quickly, this value is supposed to be bigger than clock difference in terms of STEP_SIZE, but to avoid the sound quality degradation it should not be greater than the clock difference too much. For example, the input frame sampling rate is 44.095kHz and the output frame sampling rate is 44.100kHz, the clock error rate is (44100 - 44095) / 44100 = 0.000113. The step size used in the linear interpolation is 0x8000 (32768) step_size = 0.000113 * 32768 = 3.7. A threshold of 4 is a recommended value. If the value is less than 3 in the above example the adjusted step size wont be able to catch up // the flow control FIFO will eventually become empty. This will lead to either NULL or replicating the last sample.

22.6.4.10 I2S_FLOW_STATUS_0

When the flow controller is used, the step size should be properly chosen depending on the clock frequency difference.

The step size should be small enough not to degrade sound quality, but big enough to converge the FIFO depth.

If the step size is not big enough, the FIFO depth will either increase or decrease, which will cause FIFO overflow/underflow eventually. The flow controller monitor and counter can be used to fine-tune the step size. When the flow controller is enabled and a proper step size is chosen, the FIFO depth should be in [threshold -1 : threshold + 1].

When the flow controller monitor is enabled and the FIFO depth is deviated from the range, either FLOW_OVERFLOW or FLOW_UNDERFLOW will be set. Also, the interrupt signal will be asserted, ifMONITOR_INT_EN is enabled. MONITOR_CLR clears the FLOW_OVERFLOW/UNDERFLOW as well as the interrupt signal to APBIF.

When the flow controller counter is enabled, it records how many samples are processed and how many times the step size is applied to either lower or raise the time step. In case of stereo samples, it counts as 1.

- FLOW_NORMAL - the total number of samples (only count left channel samples).
- FLOW_OVER - the number of samples with adding STEP_SIZE to the time step.
- FLOW_UNDER - the number of samples with subtracting STEP_SIZE o the time step.

Flow Controller Monitor/Counter

22.6.5 SPDIF Registers

The SPDIF consists of the following two major modules:

(1) The SPDIFOUT sub-module, responsible for sending data to the "spdifout" port in IEC 60958-3 biphase-mark code format.

(2) The SPDIFIN sub-module, responsible for retrieving data to the "spdifin" port in IEC 60958-3 biphase-mark code format.

Clock rates required by each sub-controller for given sample rate:

Sample Rate (KHz)	SPDIFOUT clock freq (exact freq. MHz)	Period (ns)	SPDIFIN clock freq. (min. freq but <= 100MHz)
32.0	4.0960	244.141	16.3840 (48MHz typical)
44.1	5.6448	177.154	22.5790 (48MHz typical)
48.0	6.1440	162.760	24.5760 (48MHz typical)
88.2	11.2896	88.577	45.1584 (72MHz typical)
96.0	12.2880	81.380	49.1520 (72MHz typical)
176.4	22.5792	44.289	90.3168 (108MHz typical)
192.0	24.5760	40.690	98.3040 (108MHz typical)

SPDIF Control Register

Note: Changing the state of TC_EN, TU_EN, LBK_EN, PACK, BIT_MODE while RX_EN and/or TX_EN and/or RX_BSY and/or TX_BSY is set can cause unexpected behavior and therefore shall not be attempted.

22.6.5.7 SPDIF_CH_STA_RX_A_0

This 6-words receive channel data page buffer holds a block (192 frames) of channel status information. The order of receive is from LSB bit to MSB bit, and from CH_STA_RX_A to CH_STA_RX_F and back to CH_STA_RX_A.

Note: Only channel status bit from channel A (subframe 1) will be saved into this page buffer.

SPDIF Channel Status Rx Page Buffer Register

Offset: 018h | Read/Write: RO | Reset: 0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx

Bit	Reset	Description
31:0	X	RX_C31_RX_C0: Channel status bits [31:0]; one bit per audio sample

22.6.5.19 SPDIF_FLOWCTL_CTRL_0

This register controls the flow control mechanism and is valid only with the TX mode. The flow control is only useful when the input stream to I2S/SPDIF is already real-time spaced such as a live stream from Baseband through another I2S_RX. If the input stream is from DMA directly, the flow control should be disabled.

Offset: 070h | Read/Write: R/W | Reset: 0b1

Bit	Reset	Description
31	QUAD	FILTER: to use linear or quadratic filter. Tegra 3 supports quadratic filter only. 0 = LINEAR 1 = QUAD

22.6.5.20 SPDIF_TX_STEP_0

Offset: 074h | Read/Write: R/W | Reset: 0b1000000000000000

Bit	Reset	Description
15:0	0x8000	STEP_SIZE: This is a compensation value for the clock difference between input and output. To catch up the clock difference quickly, this value is supposed to be bigger than clock difference in terms of STEP_SIZE, but to avoid the sound quality degradation it should not be greater than the clock difference too much. For example, the input frame sampling rate is 44.095kHz and the output frame sampling rate is 44.100kHz, the clock error rate is (44100 - 44095) / 44100 = 0.000113 The step size used in the linear interpolation is 0x8000 (32768) step_size = 0.000113 * 32768 = 3.7. A threshold of 4 is a recommended value. If the value is less than 3 in the above example the adjusted step size won't be able to catch up // the flow control FIFO will eventually become empty. This will lead to either NULL or replicating the last sample.

22.6.5.21 SPDIF_FLOW_STATUS_0

When the flow controller is used, the step size should be properly chosen depending on the clock frequency difference. The step size should be small enough not to degrade sound quality, but big enough to converge the FIFO depth.

If the step size is not big enough, the FIFO depth will either increase or decrease, which will cause FIFO overflow/underflow eventually. The flow controller monitor and counter can be used to fine-tune the step size. When the flow controller is enabled and a proper step size is chosen, the FIFO depth should be in [threshold -1 : threshold + 1].

When the flow controller monitor is enabled and the FIFO depth is deviated from the range, either FLOW_OVERFLOW or FLOW_UNDERFLOW will be set. Also, the interrupt signal will be asserted, if MONITOR_INT_EN is enabled. MONITOR_CLR clears the FLOW_OVERFLOW/UNDERFLOW as well as the interrupt signal to APBIF.

When the flow controller counter is enabled, it records how many samples are processed and how many times the step size is applied to either lower or raise the time step. In case of stereo samples, it counts as 1.

- FLOW_NORMAL - the total number of samples (only count left channel samples).
- FLOW_OVER - the number of samples with adding STEP_SIZE to the time step.
- FLOW_UNDER - the number of samples with subtracting STEP_SIZE o the time step.

Flow Controller Monitor/Counter

Offset: 078h | Read/Write: R/W | Reset: 0b00xxxxxxxxxxxxxxxxxxxxxxxxxx0xx00

Bit	Reset	Description

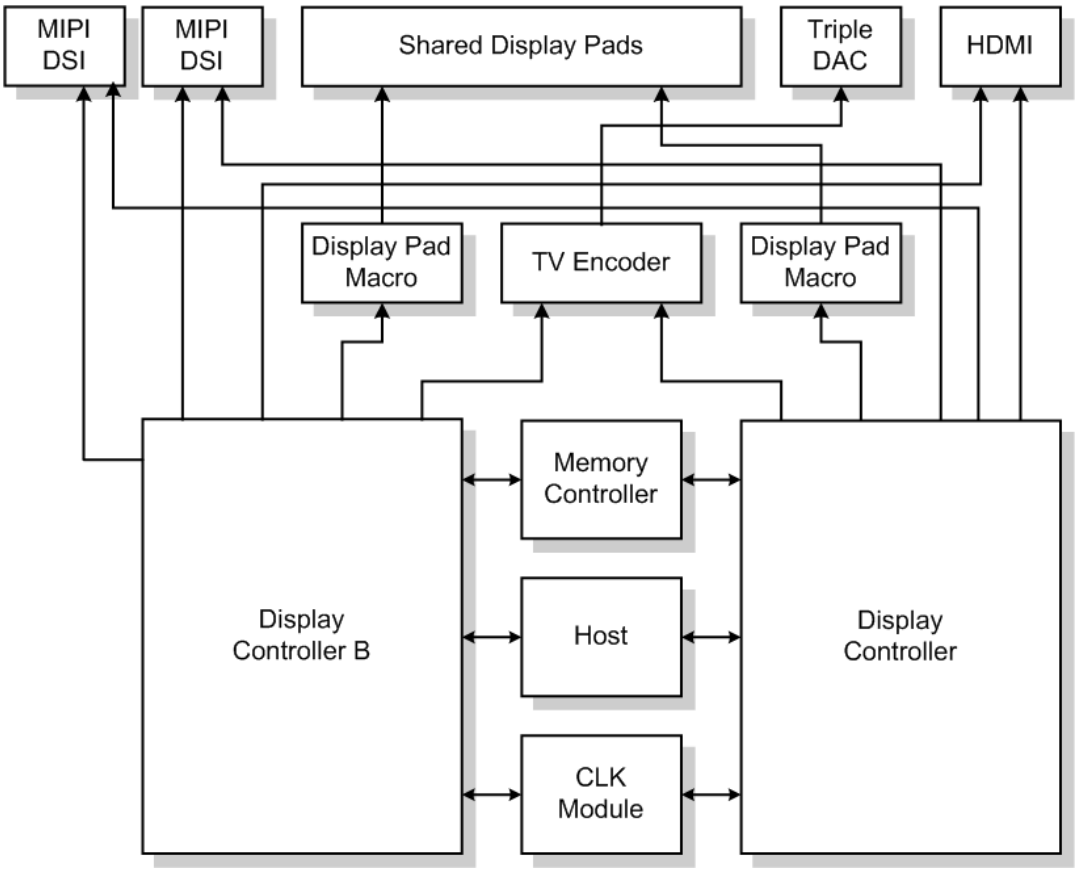
23.0 DISPLAY CONTROLLER

The Display Controller Complex integrates two independent display controllers. Each display controller is capable of interfacing to an external display device, which can be a parallel interface or SPI LCD, DVI, an HDMI® HDTV, RGB monitor or a MIPI DSI LCD. Direct interface is supported directly to most LCD displays with TFT or TFT-like interface.

There are two independent display controllers, so the module described here is instantiated twice.

Each of the two display controllers shares access to the various output resources. There are two instances of the MIPI DSI: one HDMI and one DAC. Only one display controller may access one of these outputs at any given time.

Figure 48. Display Controller



Display maximum performance is ultimately determined by the availability of memory bandwidth. The line buffer for the DSI transmitter is 1920 bytes in size. This is enough to hold 640 pixels with a pixel depth of 24-bits per pixel, or 960 pixels with a pixel depth of 16-bits per pixel. This will limit the maximum burst rate on the DSI interface for a given pixel clock frequency. However, the buffer has been sized to cope with most reasonable combinations of screen resolution, pixel clock and burst rate.

The line buffer for error diffusion dithering is limited to 1280 pixels per line. This limits the maximum horizontal active area size to 1280 pixels when error diffusion dithering is enabled. For larger displays either full 24-bit color pixel resolution output is required or ordered dithering may be used since it does not require a line buffer.

> **Note:** Display maximum resolution is not limited by counter resolution. The display raster timing generator supports 12-bit counter resolution.

Features

- Three display windows (1 graphics window A and 2 overlay windows B and C)
- Hardware surface blending
- Hardware cursor
- Fully programmable display timing and resolution
- 'Hysteresis' latency FIFO to minimize DRAM power for display refresh in an idle system

Clocking

The Display source clock can be selected from a number of sources. The SHIFT_CLK_DIVIDER register value divides the source clock to generate dcsclk, the shift clock. PIXEL_CLK_DIVIDER register value further divides down the shift to generate dcpclk, pixel clock. One pixel is processed every pixel clock and PIXEL_CLK_DIVIDER is programmed such that the correct number of shift clocks per pixel clock is available for the pixel data to be transferred to the LCD.

Display has first, second, and third level clock gating. First level clock gating is controlled by a host register bit. Display has extensive second level clock gating controlled by hardware, and based on activity.

When TVO is enabled, the TVO controls the frame rate of the Display Controller by stalling the Display Controller. TVO sends a stall signal to the Display Controller that qualifies the pixel clock enable, essentially stopping Display Controller's processing until TVO is ready for more data. When HDMI is enabled, the Display and HDMI source clocks and frequencies must be the same. Similarly, when DSI is enabled, the Display and DSI source clocks must be the same.

23.1 Hardware Interface

23.1.3 Interface to Host

The display controller interfaces to the host with a similar architecture as other modules. Display's host interface contains a read FIFO and a write FIFO, allowing an asynchronous boundary between host clock and display clock. Display registers are synchronously written and read in display's clock domain. Class and register writes are treated identically.

Display controller supports several different sync points, allowing software to synchronize events properly. Refer to the display specification files for the sync points that are supported.

Display controller supports several interrupts that can be used for synchronization or for notifying the host of corruption (underflow/overflow). All interrupts are programmable to be level or edge sensitive. Refer to the Interrupt Controllers section for the interrupts that are supported.

23.1.4 Interface to Memory

Display has five memory clients: one block read client for window A (128-bit x 128 deep read FIFO), two block read clients for window B (128-bit x 64-deep read FIFO), one block read client for window C (128-bit x 128 deep read FIFO), and one single read client for the cursor. For display controller purposes, the block read client is used as a line read since display controller needs data on a line by line basis to do vertical scaling. In addition, the read memory clients for window B and C support reading YUV data.

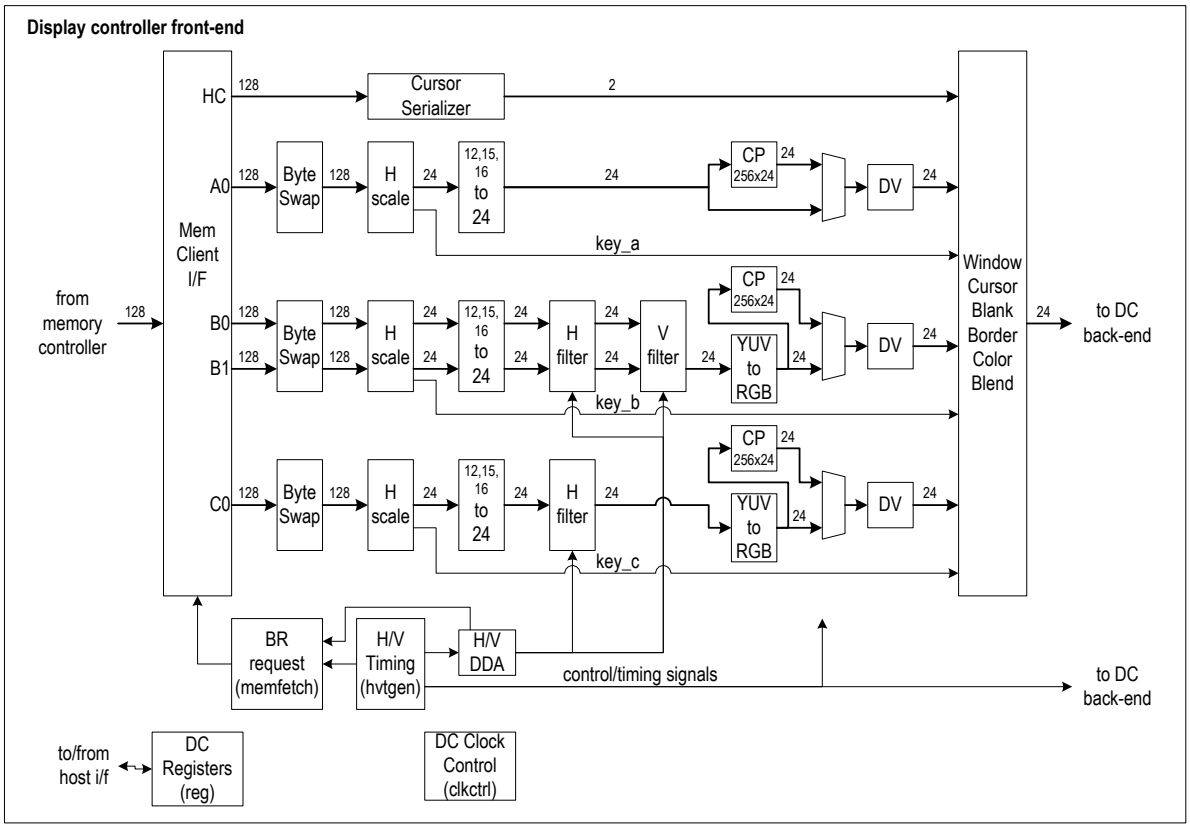
Display controller requires a constant bandwidth and can withstand only a limited latency. For this reason, display controller has the highest priority for memory controller requests. An underflow in memory data will result in a visual corruption on the LCD panel.

23.2 Functionality

23.2.1 Block Diagram

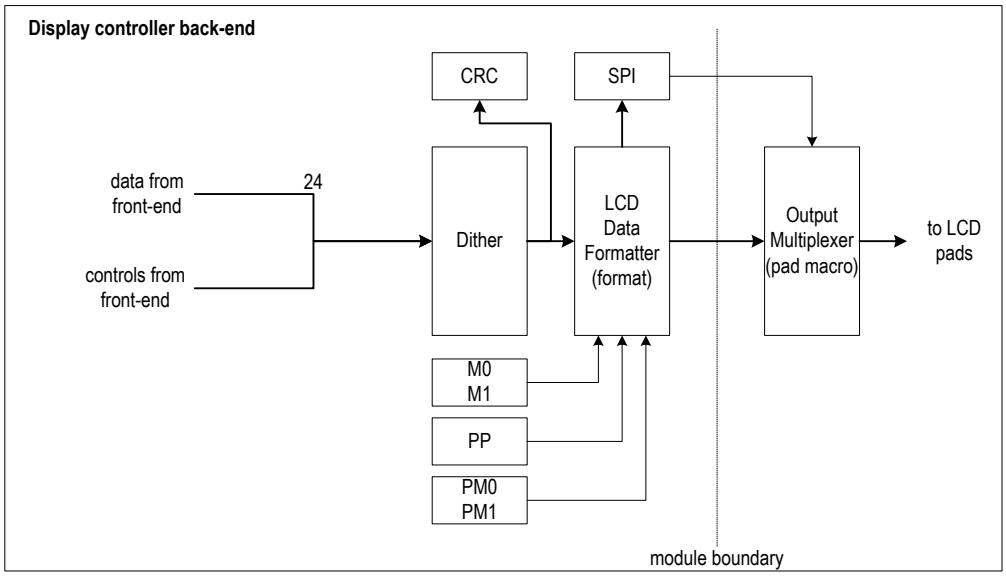
The following shows a block diagram of the display controller module front-end:

Figure 49. Display Controller Front-End Block Diagram



A block diagram of the display controller module back-end is shown in the next figure:

Figure 50. Display Controller Back-end Block Diagram



23.2.2 Color Key and Overlay Blend

When more than one active window is overlapping, the color key multiplexer selects between blended window data and pure window data. There are 3 windows (A, B, C) and therefore there are potentially 3 regions (A, B, C) where there is no window overlap and 4 regions (AB, AC, BC, ABC) where there is window overlap.

Blended data is the sum of the weighted active window data. The weight is determined from register programming and is based on a color key match, a fixed weight, an alpha weight, or a weight dependent on the other active window(s). There are separate registers defined for each possible overlap condition.

Color key can be defined in any of the overlapping window. Typically color key is enabled in one of the overlapping windows only. If color key is enabled in more than one of the overlapping windows then the color key multiplexer uses a priority encoder to select the window to use for color key compare. The order of priority is Window A, then B, then C when multiple windows are enabled for color key.

Figure 51 Keying Example with Key Region Values

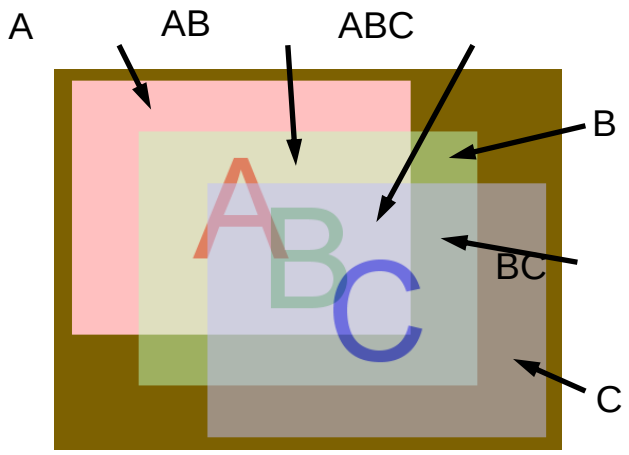


Table 47: Key Region Values for Keying Example

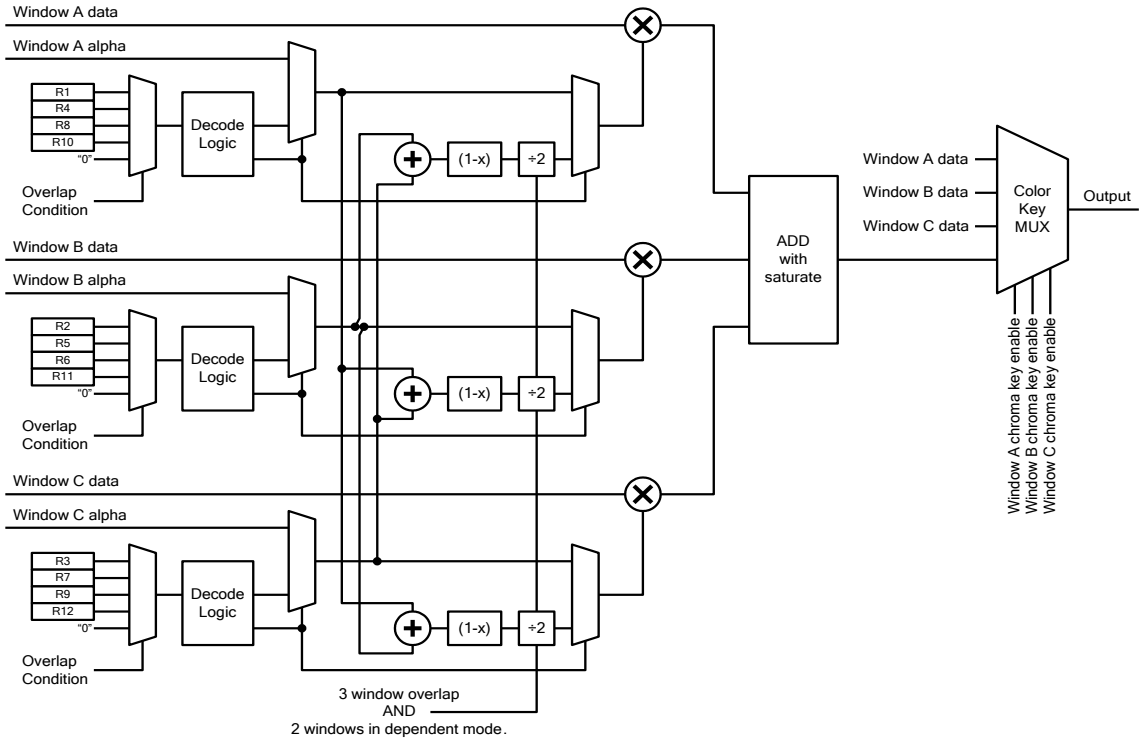
Region	A	B	C
A	100		
B		50	
C			50
AB	50	50	
AC	n/a	n/a	n/a
BC		25	50
ABC	25	25	50

Figure 52. Block Diagram of the Key Logic



23.2.3 Display Transformation

The Display is responsible for incrementing (and/or) decrementing *x*-direction scanning, and incrementing (and/or) decrementing *y*-direction scanning. By itself, the Display is not capable of doing the line scanning in the *y*-direction, which is needed for 90-degree or 270-degree display rotation.

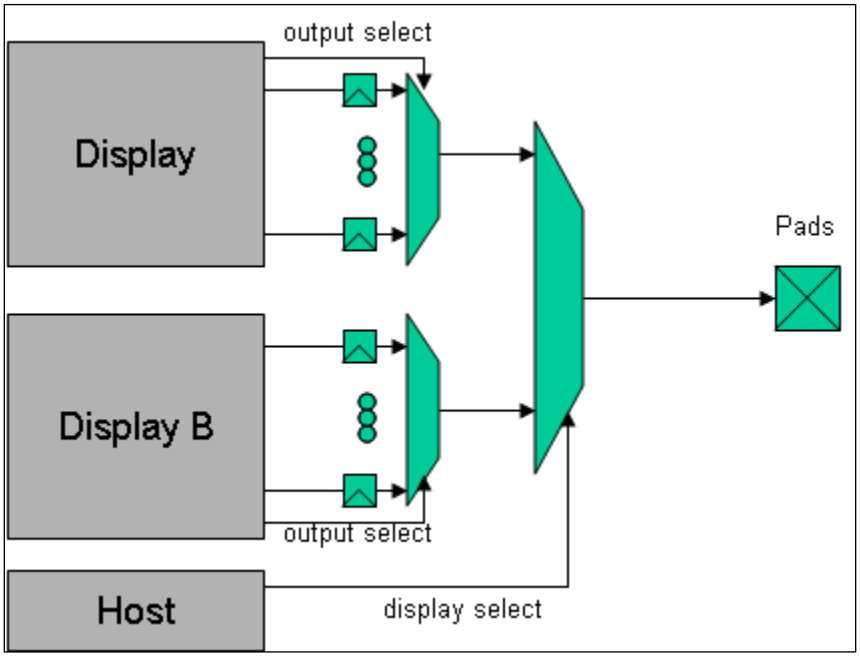
23.2.4 Dual Display

There are two identical Display controllers, Display and Display B, instantiated in the chip, allowing the chip to drive two panels simultaneously. Because of pad limitation, Display B only supports a subset of the LCD interfaces that Display supports when used simultaneously. In dual display mode, Display and Display B may be programmed to non 1-clock/1-pixel modes such that the maximum data pins needed is 9-bit (refer to table).

For dual LCD display, there are two identical pad macros, one for each instance of display. By duplicating the pad macro, each display can drive the same type of interfaces as long as the pin is available. Register bits from within the host control whether the pin is driven by Display or Display B.

Each display controller may drive any of the available outputs, allowing such combinations as (but not limited to) LCD + TV or LCD + DSI.

Figure 53. Dual Display Block Diagram



The next table shows which pairs of primary and secondary LCDs support independent simultaneous refresh of both LCDs.

Table 48: Display Pairs

Primary	Secondary	Simultaneous Dual Refresh?	Primary	Secondary	Simultaneous Dual Refresh?	Primary	Secondary	Simultaneous Dual Refresh?
24-bit RGB	9-bit CPU	No	16-bit RGB	9-bit CPU	Yes	9-bit CPU	9-bit CPU	Yes
	8-bit CPU	No		8-bit CPU	Yes		8-bit CPU	Yes

	8-bit CPU	Yes		8-bit CPU	Yes			
	5-wire SPI	Yes		5-wire SPI	Yes			

23.3 VESA Timings

The VESA standard timings for Personal Computer Monitors can be roughly divided – for practical purposes – into two distinct groups: “Standard” and “Reduced Blanking”. Standard timing is used for CRT monitors and LCD panels. Reduced Blanking timings are used only for LCD panels that can accept Reduced Blanking timings.

The purpose of Reduced Blanking is to acknowledge the redundancy of the requirement of a large Horizontal Blanking period when outputting a video raster to an LCD panel. The Original purpose of the HB period was to allow a CRT time to move the electron beam from the right side of the screen to the left side of the screen prior to starting the next line. This takes a finite amount of time.

However, in an LCD, this time can be made arbitrarily small with suitable care in the design of the panel. The advantage that Reduced Blanking gives is that the pixel clock frequency can be reduced for a given H. Total, V. Total and Vertical Frequency (refresh rate). This in turn results in the ability to either lower power consumption for a given resolution, or increase the resolution without exceeding the capabilities of the interface between the Display Controller and the Display Device. Both sets of timing parameters are provided in the following sections.

23.4 Programming

23.4.1 Raster Generator

The following is a list of register names that correspond to the abbreviations used throughout this document.

Table 49: Abbreviation / Register Field Mapping

Abbreviation	Method/Register	Field
HFP	FRONT_PORCH	H_FRONT_PORCH
HS	SYNC_WIDTH	H_SYNC_WIDTH
HBP	BACK_PORCH	H_BACK_PORCH
HA	DISP_ACTIVE	H_DISP_ACTIVE
VFP	FRONT_PORCH	V_FRONT_PORCH
VS	SYNC_WIDTH	V_SYNC_WIDTH
VBP	BACK_PORCH	V_BACK_PORCH
VA	DISP_ACTIVE	V_DISP_ACTIVE

HT and VT are derived from the other registers by summing together all the related periods:

HT = HFP + HS + HBP + HA

VT = VFP + VS + VBP + VA

23.5 Display Controller Register Definition

Display supports three windows: Window A, Window B, Window C

Window A is a graphics only window (does not support YUV data format) and it supports only simple non-filtered up/down scaling via pixel and line replication/deletion.

Window B is an overlay window which supports both RGB and YUV data format and it supports filtered up/down scaling. Vertical filter is 2 tap with 16-phase resolution and horizontal filter is 6-tap with 16-phase resolution. Performance is optimized for YUV formats, and has performance limitations at 32-bit RGB formats.

Window C is an overlay window which supports both RGB and YUV data format and it supports filtered up/down scaling. Horizontal filter is 6-tap with 16-phase resolution.

The Display Controller register consists of two template files:

- ardisplay_TEMPLATE.spec: these registers are applicable to all display windows
- ardisplay_b_TEMPLATE.spec: these registers are applicable to windows, A, B, or C. There are three copies of these registers in DISPLAY. Window A, B, and C registers are copies of each other, except for differences in window features. Each copy is available at two different addresses. When using window address offset 0x500 (via the ardisplay_a, b, c header files), the copies of a register in window A, B, and C share the same address; register field DISPLAY_WINDOW_HEADER is used to control whether the subsequent programming goes to window A, B, or C registers, or any combination of them. Before reading these registers, DISPLAY_WINDOW_HEADER must be programmed to enable only one window, so that DISPLAY knows which register copy is being read. When using window-direct address ranges at 0xa00, 0xc00, and 0xe00 (via the ardisplay_ad, bd, cd header files), DISPLAY_WINDOW_HEADER is not used. Each window has a separate address.

Color Palette

These appear as three instances of 256 32-bit registers with each register consisting of one RGB pixel so not all 32 bits in the registers are used. One instance is used for window A, another instance is used for window B, and the third instance is used for window C. In reality, each instance is implemented as triple 256-words dual-port register file (2P RF) with one read port and one write port (1R1W) and with each word consisting of 1 red/green/blue component. Read port of the color palettes are used for the corresponding window A, window B, or window C and write port of the color palettes are used for host write.

Note that the host cannot read these color palettes so it must cache this color palette somewhere else to be able to read them. This is done to reduce area.

23.5.1 Display Shadow Registers

Display registers have three shadow types:

1. Not Shadowed

   Writes to these registers take effect immediately.

2. Double Buffered

   Each register has two copies: ASSEMBLY and ACTIVE. ACTIVE is the working copy.

   These two copies share the same address/offset.

   WRITE_MUX can be programmed to choose which copy the subsequent register writes goes to:

   - When set to ACTIVE, both ACTIVE and ASSEMBLY copies will be written
   - When set to ASSEMBLY, only ASSEMBLY copy will be written

   READ_MUX can be programmed to choose which copy the subsequent register reads comes from.

   If display is in STOP mode, ASSEMBLY copy is latched into ACTIVE copy immediately after

   (GENERAL/WIN_A/WIN_B/WIN_C)_ACT_REQ is programmed. In other modes the latching happens on the next frame boundary after (GENERAL/WIN_A/WIN_B/WIN_C)_ACT_REQ is programmed.

3. Triple buffered

   Each register has three copies: ASSEMBLY, ARM, and ACTIVE. ACTIVE is the working copy.

   ASSEMBLY and ACTIVE copies share the same address/offset, the ARM copy is located at the address/offset one bigger than the ASSEMBLY/ACTIVE copy.

   WRITE_MUX can be programmed to choose which copy the subsequent register writes goes to:

   - When set to ACTIVE, all three copies will be written
   - When set to ASSEMBLY, only ASSEMBLY copy will be written

   READ_MUX can be programmed to choose which copy the subsequent register reads comes from.

   - To read back ASSEMBLY or ACTIVE copy, set READ_MUX correctly before register reads.

These two copies share the same address.

- To read back ARM copy, do not set READ_MUX, but read back the register/register-field with "_NS" in their names, the offset of which is 1 bigger than its ASSEMBLY/ACTIVE counterpart.

ASSEMBLY copy is latched into ARM copy immediately after GENERAL/WIN_A/WIN_B/WIN_C)_UPDATE is programmed.

If display is in STOP mode, ARM copy is latched into ACTIVE copy immediately after (GENERAL/WIN_A/WIN_B/WIN_C)_ACT_REQ is programmed. In other modes the latching happens on the next frame boundary after (GENERAL/WIN_A/WIN_B/WIN_C)_ACT_REQ is programmed.

23.5.2 Display Control Modes

The DISPLAY_COMMAND is used to set display control mode (**CONTINUOUS**, **ONE-SHOT**, or **STOP**).

Display switches mode when CONTROL_MODE is programmed to shadow register and then activated.

Display enters a mode when the register activation happens, either on frame boundary when entering **STOP** mode, or immediately when exiting **STOP** mode.

In **STOP** mode, display is in idle. Pixel clock is not running.

In **CONTINUOUS** mode, display keeps refreshing the output frame by frame. This mode is mostly used for the panels without internal frame buffer.

In **ONE-SHOT** mode, display waits for a trigger before refreshing each frame. Between those frames, display is in idle. This mode is usually for the panels with internal frame buffer.

(TVO is an exception. Since TV does not have internal frame buffer, TVO works in continuous mode and controls the pace. DISPLAY is thus set to ONE-SHOT mode to work as slave of TVO. Other than that, it works much like CONTINUOUS mode.)

In ONE-SHOT mode, there are different types of triggers as follows:

- Input triggers

  Input trigger is to notify DISPLAY that a new memory surface is ready to be displayed.
- Host Trigger

  Host trigger is requested when NC_HOST_TRIG_ENABLE is programmed. This register field is in the same register as shadow registers UPDATE/ACT_REQ so that the trigger can happen atomically with register updates for the new frame. When host trigger is requested within a frame, the requested frame will start immediately after the end of the current frame.
- Output Triggers

  Output trigger is to notify DISPLAY that a panel is ready to receive data from DISPLAY.
- TVO Triggers

  When TVO is enabled, DISPLAY waits until TVO sends over a vsync pulse, then sends a new frame, regardless of whether an input trigger has happened.
- Tear Effect Signal Triggers

  When MSF/SSF register field is set to ENABLE, DISPLAY holds off a frame requested by input triggers until DISPALY receives a "ready" from the pins that connect to the tearing effect signals from the panel, then sends a new frame to panel. However, if no input trigger has been requested, DISPLAY does not send a new frame. That is different from the behavior of TVO triggers.

In CONTINUOUS mode, the meaning of the triggers is different.

- Input Triggers

  Since in CONTINUOUS mode trigger happen automatically and repeatedly, trigger here only affects the buffer address change on a window.

- Host Trigger

  Host can change the buffer address and then write WIN_A/B/C_ACT_REQ to request the buffer address change. Note that for syncpt logic, it cannot tell if a WIN_A/B/C register activation indicates the change of address, so it behaves always like a change of address happens on any register activation requested by WIN_A/B/C_ACT_REQ. As the result, RD_DONE/OP_DONE is returned.

- Output triggers

  These triggers are not applicable in CONTINUOUS mode. TVO_ENABLE and MSF/SSF_ENABLE should never be set in CONTINUOUS mode.

23.5.3 Sync Points

DISPLAY has 4 syncpt clients:

- GENERAL

  Conditions

  - 0: IMMEDIATE return INDX immediately
  - 1: OP_DONE not meaningful, same as IMMEDIATE
  - 2: RD_DONE not meaningful, same as IMMEDIATE
  - 3: REG_WR_SAFE returns INDX whenever it is safe to program GENERAL shadow registers (when all previous GENERAL activation has happened)
  - 4: HSPI returns INDX whenever it is safe to send HSPI data (when all HSPI_*** registers are safe to be programmed)
  - 5: FRAME_DONE returns INDX on the next frame end
  - 6: VPULSE3 returns INDX on the next vpulse3 leading edge (for timing sensitive operations if needed)
  - 7: FRAME_START returns INDX on the next frame start (currently for hardware testing, but can be used if needed)

- WIN_A

  Conditions

  - 0: IMMEDIATE return INDX immediately
  - 1: OP_DONE same as RD_DONE
  - 2: RD_DONE returns INDX when all WIN_A reads for frames activated before the INCR_SYNCPT are complete. In ONE-SHOT mode with TVO disabled, this happens after the last row of window A display. In CONTINUOUS mode, or in ONE-SHOT mode with TVO enabled, this happens on the last row of window A or on frame end (depending if the INCR_SYNCPT is issued before or after the window A last row).
  - 3: REG_WR_SAFE returns INDX whenever it is safe to program WIN_A shadow registers (when all previous WIN_A activation has happened)

- WIN_B

  Similar to WIN_A

- WIN_C

  Similar to WIN_A

- DISPLAY Continuous syncpt

  VSYNC: When enabled, return syncpt whenever a vblank start happens.

23.5.4 Raise Actions (Legacy)

The Raise action is used to check the state of the display's command execution. The Raise action can be enabled by itself or with other actions.

The raise value is returned to the host controller if the current and all previous commands have completed execution. If the command is executed with the delayed mode, the raise is not returned till that command is executed at the end of the frame.

If there is no pending command when the Raise is issued, the raise value is returned immediately. The raise value is a 4-bit number included in the command.

Context switch acknowledge, register reads, and raises are returned to the host through a read FIFO. However, because there may be more than one raise, read, or acknowledge available for writing to the FIFO in a certain cycle, there must be a priority encoder. Here is the priority:

1. Context switch
2. Register read
3. SIGNAL_RAISE
4. SIGNAL_RAISE1
5. SIGNAL_RAISE2
6. SIGNAL_RAISE3
7. DISP_COMMAND_RAISE
8. HSPI_RAISE
9. Refcount

23.6 Display CMD Registers

23.6.1 DC_CMD_GENERAL_INCR_SYNCPT_0

Offset: 000h | Read/Write: R/W | Reset: 0b0000000000000000

Bit	Reset	Description
15:8	0x0	GENERAL_COND: Condition mapped from raise/wait 0 = IMMEDIATE 1 = OP_DONE 2 = RD_DONE 3 = REG_WR_SAFE 4 = HSPI 5 = FRAME_DONE 6 = VPULSE3 7 = FRAME_START 8 = COND_8 9 = COND_9 10 = COND_10 11 = COND_11 12 = COND_12 13 = COND_13 14 = COND_14 15 = COND_15
7:0	0x0	GENERAL_INDX: syncpt index value

23.6.2 DC_CMD_GENERAL_INCR_SYNCPT_CNTRL_0

Offset: 001h | Read/Write: R/W | Reset: 0b0xxxxxxx0

Bit	Reset	Description
8	0x0	GENERAL_INCR_SYNCPT_NO_STALL: If NO_STALL is 1, then when fifos are full, INCR_SYNCPT methods will be dropped and the INCR_SYNCPT_ERROR[COND] bit will be set. If NO_STALL is 0, then when fifos are full, the client host interface will be stalled.
0	0x0	GENERAL_INCR_SYNCPT_SOFT_RESET: If SOFT_RESET is set, then all internal state of the client syncpt block will be reset. To do soft reset, first set SOFT_RESET of all host1x clients affected, then clear all SOFT_RESETs.

23.6.3 DC_CMD_GENERAL_INCR_SYNCPT_ERROR_0

Offset: 002h | Read/Write: R/W | Reset: 0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx

Bit	Reset	Description
31:0	_NONE_	GENERAL_COND_STATUS: COND_STATUS[COND] is set if the FIFO for COND overflows This bit is sticky and will remain set until overwritten with a zero

23.6.4 DC_CMD_WIN_A_INCR_SYNCPT_0

Offset: 008h | Read/Write: R/W | Reset: 0b0000000000000000

Bit	Reset	Description
15:8	0x0	WIN_A_COND: Condition mapped from raise/wait 0 = IMMEDIATE 1 = OP_DONE 2 = RD_DONE 3 = REG_WR_SAFE 4 = COND_4 5 = COND_5 6 = COND_6 7 = COND_7 8 = COND_8 9 = COND_9 10 = COND_10 11 = COND_11 12 = COND_12 13 = COND_13 14 = COND_14 15 = COND_15
7:0	0x0	WIN_A_INDX: syncpt index value

23.6.5 DC_CMD_WIN_A_INCR_SYNCPT_CNTRL_0

Offset: 009h | Read/Write: R/W | Reset: 0b0xxxxxx0

Bit	Reset	Description
8	0x0	WIN_A_INCR_SYNCPT_NO_STALL: If NO_STALL is 1, then when fifos are full, INCR_SYNCPT methods will be dropped and the INCR_SYNCPT_ERROR[COND] bit will be set. If NO_STALL is 0, then when fifos are full, the client host interface will be stalled.
0	0x0	WIN_A_INCR_SYNCPT_SOFT_RESET: If SOFT_RESET is set, then all internal state of the client syncpt block will be reset. To do soft reset, first set SOFT_RESET of all host1x clients affected, then clear all SOFT_RESETs.

23.6.6 DC_CMD_WIN_A_INCR_SYNCPT_ERROR_0

Offset: 00ah | Read/Write: R/W | Reset: 0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx

Bit	Reset	Description
31:0	_NONE_	WIN_A_COND_STATUS: COND_STATUS[COND] is set if the fifo for COND overflows This bit is sticky and will remain set until overwritten with a zero

23.6.7 DC_CMD_WIN_B_INCR_SYNCPT_0

Offset: 010h | Read/Write: R/W | Reset: 0b0000000000000000

Bit	Reset	Description
15:8	0x0	WIN_B_COND: Condition mapped from raise/wait 0 = IMMEDIATE 1 = OP_DONE 2 = RD_DONE 3 = REG_WR_SAFE 4 = COND_4 5 = COND_5 6 = COND_6 7 = COND_7 8 = COND_8 9 = COND_9 10 = COND_10 11 = COND_11 12 = COND_12 13 = COND_13 14 = COND_14 15 = COND_15
7:0	0x0	WIN_B_INDX: syncpt index value

23.6.8 DC_CMD_WIN_B_INCR_SYNCPT_CNTRL_0

Offset: 011h | Read/Write: R/W | Reset: 0b0xxxxxx0

Bit	Reset	Description
8	0x0	WIN_B_INCR_SYNCPT_NO_STALL: If NO_STALL is 1, then when FIFOs are full, INCR_SYNCPT methods will be dropped and the INCR_SYNCPT_ERROR[COND] bit will be set. If NO_STALL is 0, then when FIFOs are full, the client host interface will be stalled.
0	0x0	WIN_B_INCR_SYNCPT_SOFT_RESET: If SOFT_RESET is set, then all internal state of the client syncpt block will be reset. To do soft reset, first set SOFT_RESET of all host1x clients affected, then clear all SOFT_RESETs.

23.6.9 DC_CMD_WIN_B_INCR_SYNCPT_ERROR_0

Offset: 012h | Read/Write: R/W | Reset: 0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx

Bit	Reset	Description
31:0	_NONE_	WIN_B_COND_STATUS: COND_STATUS[COND] is set if the FIFO for COND overflows This bit is sticky and will remain set until overwritten with a zero

23.6.10 DC_CMD_WIN_C_INCR_SYNCPT_0

Offset: 018h | Read/Write: R/W | Reset: 0b0000000000000000

Bit	Reset	Description
15:8	0x0	WIN_C_COND: Condition mapped from raise/wait 0 = IMMEDIATE 1 = OP_DONE 2 = RD_DONE 3 = REG_WR_SAFE 4 = COND_4 5 = COND_5 6 = COND_6 7 = COND_7 8 = COND_8 9 = COND_9 10 = COND_10 11 = COND_11 12 = COND_12 13 = COND_13 14 = COND_14 15 = COND_15
7:0	0x0	WIN_C_INDX: syncpt index value

23.6.11 DC_CMD_WIN_C_INCR_SYNCPT_CNTRL_0

Offset: 019h | Read/Write: R/W | Reset: 0b0xxxxxxx0

Bit	Reset	Description
8	0x0	WIN_C_INCR_SYNCPT_NO_STALL: If NO_STALL is 1, then when FIFOs are full, INCR_SYNCPT methods will be dropped and the INCR_SYNCPT_ERROR[COND] bit will be set. If NO_STALL is 0, then when FIFOs are full, the client host interface will be stalled.
0	0x0	WIN_C_INCR_SYNCPT_SOFT_RESET: If SOFT_RESET is set, then all internal state of the client syncpt block will be reset. To do soft reset, first set SOFT_RESET of all host1x clients affected, then clear all SOFT_RESETs.

23.6.12 DC_CMD_WIN_C_INCR_SYNCPT_ERROR_0

Offset: 01ah | Read/Write: R/W | Reset: 0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx

Bit	Reset	Description
31:0	_NONE_	WIN_C_COND_STATUS: COND_STATUS[COND] is set if the FIFO for COND overflows This bit is sticky and will remain set until overwritten with a zero

23.6.13 DC_CMD_CONT_SYNCPT_VSYNC_0

Offset: 028h | Read/Write: R/W | Reset: 0b0xxxxxxxx

Bit	Reset	Description
8	0x0	VSYNC_EN: on host read bus every time VSYNC (V-blank leading edge) happens and VSYNC_EN is set 0 = DISABLE 1 = ENABLE
7:0	_NONE_	VSYNC_INDX: return INDX (set HOST_CLRD packet TYPE field to SYNCPT)

23.6.14 DC_CMD_CTXSW_0

Context switch registers for class and channel

Should be common to all modules. Includes the current channel/class (which is writable by SW) and the next channel/class (which the hardware sets when it receives a context switch).

Context switching works like this:

Any context switch request triggers an interrupt to the host and causes the new channel/class to be stored in NEXT_CHANNEL/NEXT_CLASS. SW sees that there is a context switch interrupt and does the necessary operations to make the module ready to receive traffic from the new context. It clears the context switch interrupt and writes CURR_CHANNEL/CLASS to the same value as NEXT_CHANNEL/CLASS, which causes a context switch acknowledge packet to be sent to the host. This completes the context switch and allows the host to continue sending data to the module.

Context switches can also be pre-loaded. If CURR_CLASS/CHANNEL are written and updated to the next CLASS/CHANNEL before the context switch request occurs, an acknowledge will be generated by the module and no interrupt will be triggered. This is one way for software to avoid dealing with context switch interrupts.

Another way to avoid context switch interrupts is to set the AUTO_ACK bit.

This bit tells the module to automatically acknowledge any incoming context switch requests without triggering an interrupt. CURR_* and NEXT_* will be updated by the module so they will always be current.

Offset: 030h | Read/Write: R/W | Reset: 0bxxxxxxxxxxxxxxxxx11111x0000000000

Bit	Reset	Description
31:28	0xf	NEXT_CHANNEL: Next requested channel
25:16	0x0	NEXT_CLASS: Next requested class
15:12	0xf	CURR_CHANNEL: Current working channel, reset to 'invalid'
11	0x1	AUTO_ACK: Automatically acknowledge any incoming context switch requests 0 = MANUAL 1 = AUTOACK
9:0	0x0	CURR_CLASS: Current working class

23.6.15 DC_CMD_DISPLAY_COMMAND_OPTION0_0

Display Controller Option 0. This register is not effective until DISPLAY_COMMAND is written.

Class: Display Command

Offset: 031h | Read/Write: R/W | Reset: 0b000xxxxxxxx00000000

Bit	Reset	Description
18	0x0	WINDOW_C_NC_DISPLAY: Window C Non-Continuous Display This is effective only in Non-Continuous Display mode when window B buffer switching is not controlled by host. If this bit is enabled, a frame is sent whenever Window B buffer is switched. 0 = DISABLE 1 = ENABLE
17	0x0	WINDOW_B_NC_DISPLAY: Window B Non-Continuous Display This is effective only in Non-Continuous Display mode when window B buffer switching is not controlled by host. If this bit is enabled, a frame is sent whenever Window B buffer is switched. 0 = DISABLE 1 = ENABLE
16	0x0	WINDOW_A_NC_DISPLAY: Window A Non-Continuous Display This is effective only in Non-Continuous Display mode when window A buffer switching is not controlled by host. If this bit is enabled, a frame is sent whenever Window A buffer is switched. 0 = DISABLE 1 = ENABLE
7:6	0x0	SSF_SOURCE: Source pin for the SSF input Controls which pin will be used as the source for the trigger input when MSF mode is enabled. Note that although the same pins are available for both MSF and SSF, the order in the enum and hence the values differ between the pins. This is to maintain backwards compatibility with previous chips, which had a fixed mapping. The init value and the first value in the enum reflects this historical mapping. 0= LCD_DC pin (legacy default) 1= LCD_SPI pin 2= LCD_SDI pin 3= RESERVED for future use. 0 = SSF_LDC 1 = SSF_LSPI 2 = SSF_LSDI
5	0x0	SSF_ENABLE: Sub-Display Stop Frame (SSF) input This is effective only in Non-Continuous Display mode 0= Disabled 1= Enabled When enabled, SSF signal can be input through LDC pin. When SSF is enabled a trigger to send a frame in Non-Continuous Display mode will be delayed until SSF is active. 0 = DISABLE 1 = ENABLE
4	0x0	SSF_POLARITY: Sub-Display Stop Frame (SSF) Polarity 0= Active high 1= Active low
3:2	0x0	MSF_SOURCE: Source pin for the MSF input Controls which pin will be used as the source for the trigger input when MSF mode is enabled. Note that although the same pins are available for both MSF and SSF, the order in the enum and hence the values differ between the pins. This is to maintain backwards compatibility with previous chips, which had a fixed mapping. The init value and the first value in the enum reflects this historical mapping. 0= LCD_SPI pin (legacy default) 1= LCD_DC pin 2= LCD_SDI pin 3= RESERVED for future use. 0 = MSF_LSPI 1 = MSF_LDC 2 = MSF_LSDI

When MSF is enabled a trigger to send a frame in Non-Continuous Display mode will be delayed until MSF is active. 0 = DISABLE 1 = ENABLE

Bit	Reset	Description
0	0x0	MSF_POLARITY: Main-Display Stop Frame (MSF) Polarity 0= Active high 1= Active low

23.6.16 DC_CMD_DISPLAY_COMMAND_0

Display Command

Offset: 032h | Read/Write: R/W | Reset: 0bxxxxxxxxxxxxxxxxxxxxxxxxx00xxxx0

Bit	Reset	Description
30:27	X	DISP_COMMAND_RAISE_CHANNEL_ID: Display Command Channel ID
26:22	X	DISP_COMMAND_RAISE_VECTOR: Display Command Raise Vector This raise vector is at the next line or frame boundary, depending on GENERAL_ACT_CNTR_SEL
6:5	0x0	DISPLAY_CTRL_MODE: Display Controller Mode 0= Stop Display, this can be used to stop sending frame at the next frame boundary. This is automatically generated in Non-Continuous Display after sending one frame. If this is issued when display controller is already stopped then there is no frame sent. Raise vector (if raise is enabled) is also returned immediately. This command can also be used in non-continuous display mode to stop accepting non-host trigger conditions from other clients. 1= Continuous Display, the display controller will continuously send frame. Continuous display mode can be stopped by switching to Non-Continuous Display or by issuing Stop Display. 2= Non-Continuous Display, the display controller is forced to send one frame of each active display and then wait for the next time this command is issued or for other (non-host) trigger conditions to send frame. The sending of frames may be delayed by MSF or SSF input signals from the display device. If a Stop Display is issued while in non-continuous display mode then non-host trigger conditions will no longer be accepted until the next time Non-Continuous Display is issued 0 = STOP 1 = C_DISPLAY 2 = NC_DISPLAY
0	0x0	DISP_COMMAND_RAISE: Display Command Raise. Raise vector will be returned at the end of command completion 0 = DISABLE 1 = ENABLE

23.6.17 DC_CMD_SIGNAL_RAISE_0

When written, next occurrence of the selected SIGNAL will cause a RAISE to be sent to the host. Software must not write this register if a previous request (from previous write) is still outstanding. Added SIGNAL_RAISE_TYPE option so that multiple raises can be returned without software intervention. SIGNAL_RAISE1, SIGNAL_RAISE2, or SIGNAL_RAISE3 can be used if more than one source signal is needed.

Offset: 033h | Read/Write: R/W | Reset: 0bxxxxxxx0xxxxxxxxxxx

Bit	Reset	Description
19:16	X	SIGNAL_RAISE_CHANNEL_ID: Signal Raise Channel ID
12	0x0	SIGNAL_RAISE_TYPE: 0= Oneshot, single raise returned 1= Continuous, raise is returned persistently whenever raise event is true until this register is reprogrammed such that SIGNAL_RAISE_SELECT=NONE or SIGNAL_RAISE_TYPE=ONESHOT 0 = ONESHOT 1 = CONT

Bit	Reset	Description
10:8	X	SIGNAL_RAISE_SELECT: which signal to raise on 0= none, no raise sent back 1= Frame End signal 2= V Blank signal 3= V Pulse 3 signal 4= Rising edge of V Blank signal 5= Falling edge of V Blank signal 6= Rising edge of V Pulse 3 signal 7= Falling edge of V Pulse 3 signal 0 = NONE 1 = FRAME_END 2 = VBLANK 3 = VPULSE3 4 = VBLANK_START 5 = VBLANK_END 6 = VPULSE3_START 7 = VPULSE3_END
4:0	X	SIGNAL_RAISE_VECTOR: bit number to raise

23.6.18 DC_CMD_DISPLAY_POWER_CONTROL_0

Display Power Control

Offset: 036h | Read/Write: R/W | Reset: 0b00xxxxx0x0xxxxxxx0x0x0x0x0

Bit	Reset	Description
25	0x0	HSPI_ENABLE: Host SPI write cycle Enable. SPI_ENABLE must be enabled also for this bit to be effective. 0 = DISABLE 1 = ENABLE
24	0x0	SPI_ENABLE: SPI interface Enable. This enables clock to SPI interface logic for Host SPI, IS SPI, and LCD SPI. 0 = DISABLE 1 = ENABLE
18	0x0	PM1_ENABLE: PM1 signal Enable 0 = DISABLE 1 = ENABLE
16	0x0	PM0_ENABLE: PM0 signal Enable 0 = DISABLE 1 = ENABLE
8	0x0	PW4_ENABLE: PW4 signal Enable. This signal can be output at the pad for display power sequencing. 0 = DISABLE 1 = ENABLE
6	0x0	PW3_ENABLE: PW3 signal Enable. This signal can be output at the pad for display power sequencing. 0 = DISABLE 1 = ENABLE
4	0x0	PW2_ENABLE: PW2 signal Enable. This signal controls pixel data processing. It should be enabled during V blank time. This signal also controls the time when pin polarity takes effect at the pad. This signal can be output at the pad for display power sequencing. 0 = DISABLE 1 = ENABLE
2	0x0	PW1_ENABLE: PW1 signal Enable. This signal can be output at the pad for display power sequencing. 0 = DISABLE 1 = ENABLE

Bit	Reset	Description
0	0x0	PW0_ENABLE: PW0 signal Enable. This signal controls the display H and V counters. It must be enabled first and disabled last during display power sequencing. This signal can be output at the pad for display power sequencing. 0 = DISABLE 1 = ENABLE

23.6.19 DC_CMD_INT_STATUS_0

This reflects status of all pending interrupts which is valid as long as the interrupt is not cleared even if the interrupt is masked. A pending interrupt can be cleared by writing a '1' to this the corresponding interrupt status bit in this register.

Display Interrupt and Status

Offset: 037h | Read/Write: R/W | Reset: 0bxxxxxxxxxxxxxxxxxxxxxx

Bit	Reset	Description
20	X	GPIO_2_INT: GPIO 2 Interrupt Status, connected to LCD_PWR2 0= interrupt not pending 1= interrupt pending
19	X	GPIO_1_INT: GPIO 1 Interrupt Status, connected to LCD_PWR1 0= interrupt not pending 1= interrupt pending

0	0x0	CTXSW_INT_MASK: Context Switch Interrupt Mask 0 = MASKED 1 = NOTMASKED

23.6.21 DC_CMD_INT_ENABLE_0

Setting bits in this register enable the corresponding interrupt event to generate a pending interrupt. Interrupt output signal will be activated only if the corresponding interrupt is not masked.

Disabling an interrupt will not clear a corresponding pending interrupt - it only prevents a new interrupt event to generate a pending interrupt.

Interrupt Enable

Offset: 039h | Read/Write: R/W | Reset: 0b000x00000x0000xx00001

Bit	Reset	Description
20	0x0	GPIO_2_INT_ENABLE: Display GPIO_2 Interrupt Enable, connected to LCD_PWR2 0 = DISABLE 1 = ENABLE

Offset: 040h | Read/Write: R/W | Reset: 0b0x0

Bit	Reset	Description
2	0x0	WRITE_MUX: Write access control 0= write assembly state 1= write active state When set to ACTIVE, register writes also propagate to assembly set for double buffered registers, to both assembly and arm set for triple buffered registers. 0 = ASSEMBLY 1 = ACTIVE

Bit	Reset	Description
0	0x0	READ_MUX: Read access control 0= read assembly state 1= read active state Arm state register read is not controlled by this mux, but by reading the registers with "_NS" suffix 0 = ASSEMBLY 1 = ACTIVE

23.6.28 DC_CMD_STATE_CONTROL_0

State Control for Activating/Arming New Register State

Restrictions: ACT_REQ cannot be programmed at the same time the corresponding "UPDATE" is programmed.

If so desired, it should be split into two consecutive writes to this register.

Offset: 041h | Read/Write: R/W | Reset: 0b0xxxxxxxxxxxx0000xxxx0000

Bit	Reset	Description
24	0x0	NC_HOST_TRIG_ENABLE: Host trigger enable. Effective only in Non-continuous mode. The exception is that when TVO is enabled, this trigger is ignored so as not to corrupt TV output. Note that when this field is enabled, GENERAL_ACT_REQ must be enabled at the same time. 0= disable: no frame is triggered 0 = DISABLE 1 = ENABLE
11	0x0	WIN_C_UPDATE: Trigger for arming state (from assembly to armed state) for the win C subset of the triple buffered registers. This register is also known as "Update Register" 0 = DISABLE 1 = ENABLE
10	0x0	WIN_B_UPDATE: Trigger for arming state (from assembly to armed state) for the win B subset of the triple buffered registers. This register is also known as "Update Register" 0 = DISABLE 1 = ENABLE
9	0x0	WIN_A_UPDATE: Trigger for arming state (from assembly to armed state) for the win A subset of the triple buffered registers. This register is also known as "Update Register" 0 = DISABLE 1 = ENABLE
8	0x0	GENERAL_UPDATE: Trigger for arming state (from assembly to armed state) for a subset of the triple buffered registers. This register is also known as "Update Register" 0 = DISABLE 1 = ENABLE
3	0x0	WIN_C_ACT_REQ: Window C activation request 0= no req pending/req completed 1= activation requested/pending 0 = DISABLE 1 = ENABLE
2	0x0	WIN_B_ACT_REQ: Window B activation request 0= no req pending/req completed 1= activation requested/pending 0 = DISABLE 1 = ENABLE

Bit	Reset	Description
1	0x0	WIN_A_ACT_REQ: Window A activation request 0= no req pending/req completed 1= activation requested/pending 0 = DISABLE 1 = ENABLE
0	0x0	GENERAL_ACT_REQ: Non-window-specific 0= no req pending/req completed 1= activation requested/pending 0 = DISABLE 1 = ENABLE

23.6.29 DC_CMD_DISPLAY_WINDOW_HEADER_0

Display Window Header for programming display windows and their corresponding buffer start addresses.

Class: Display Window Programming Header

Offset: 042h | Read/Write: R/W | Reset: 0b000

Bit	Reset	Description
6	0x0	WINDOW_C_SELECT: Window C Select 0= disable window C programming 1= enable window C programming 0 = DISABLE 1 = ENABLE
5	0x0	WINDOW_B_SELECT: Window B Select 0= disable window B programming 1= enable window B programming 0 = DISABLE 1 = ENABLE
4	0x0	WINDOW_A_SELECT: Window A Select 0= disable window A programming 1= enable window A programming 0 = DISABLE 1 = ENABLE

23.6.30 DC_CMD_REG_ACT_CONTROL_0

Register activation options

Offset: 043h | Read/Write: R/W | Reset: 0b0x0x0x0

Bit	Reset	Description
6	0x0	WIN_C_ACT_CNTR_SEL: Select which counter to use for window C activation 0 = VCOUNTER 1 = HCOUNTER
4	0x0	WIN_B_ACT_CNTR_SEL: Select which counter to use for window B activation 0 = VCOUNTER 1 = HCOUNTER
2	0x0	WIN_A_ACT_CNTR_SEL: Select which counter to use for window A activation 0 = VCOUNTER 1 = HCOUNTER

Bit	Reset	Description
0	0x0	GENERAL_ACT_CNTR_SEL: Select which counter to use for general activation 0 = VCOUNTER 1 = HCOUNTER

23.7 Display COM Registers

23.7.1 DC_COM_CRC_CONTROL_0

CRC Control

CRC is provided for at speed testing and diagnostic. When CRC is enabled, the CRC logic waits for the next VSync pulse or the one after that (depending on CRC_WAIT) and then it captures one frame of data at the end of display pipeline and computes the CRC value.

After one frame of data is captured, the CRC logic will stop capturing data.

When CRC_INTPU_DATA = FULL_FRAME, DISPLAY_COMMAND.DISPLAY_CTRL_MODE should be programmed to C_DISPLAY so that CRC works properly.

When CRC_INTPU_DATA = ACTIVE_DATA, it can work on both NC_DISPLAY and C_DISPLAY modes, and can work for multiple frames if CRC is checked, disabled, and re-enabled after the end of frame v-active area and before next vsync.

CRC logic takes 8-bit of control signals and 24-bit RGB pixel after dither and after display color (R and B) swap option.

Input [31:0] into CRC depends on CRC_INPUT_DATA. If programmed as FULL_FRAME, input data is {LCD_D20, LPV0, LCD_D19, LCD_D18, LCD_D21, VSYNC, HSYNC, ACTIVE, R[7:0], G[7:0], B[7:0]} and CRC runs over the entire frame (including blank). If programmed as ACTIVE_DATA, input data is {R[7:0], G[7:0], B[7:0]} and CRC runs only during active display area.

Offset: 300h | Read/Write: R/W | Reset: 0b0000

Bit	Reset	Description
3	0x0	CRC_ALWAYS: CRC always: calculate CRC for every following frame. Must use with CRC_INPUT_DATA = ACTIVE_DATA if enabled, CRC_WAIT field is ignored. 0 = DISABLE 1 = ENABLE
2	0x0	CRC_INPUT_DATA: CRC input data 0= Full frame (RGB data and control) 1= Active display (Only RGB data) 0 = FULL_FRAME 1 = ACTIVE_DATA
1	0x0	CRC_WAIT: CRC Wait 0= 1 Vsync 1= 2 Vsyncs
0	0x0	CRC_ENABLE: CRC Enable 0 = DISABLE 1 = ENABLE

23.7.2 DC_COM_CRC_CHECKSUM_0

CRC Checksum

This register can be read by host after CRC logic stops capturing data.

Offset: 301h | Read/Write: RO | Reset: 0x00000000

Bit	Reset	Description
31:0	0x0	CRC_CHECKSUM: CRC Checksum

23.7.3 DC_COM_PIN_OUTPUT_ENABLE0_0

Notes:

1. LD[23-0] contain pixel data for 1-pixel/1-clock parallel interface

2. LPD[17-0] contain pixel data for non 1-pixel/1-clock parallel interface

3. If output select is set to 1, then corresponding Pin Output Data register value is output (pin is used as general purpose output).

*4. If output select is set to 1 AND display is in DF2P1C18B (aka notebook) mode, then all output are overloaded. See table below. This doesn't apply to LSC0 (PCLK) which must be programmed to output-select==0.

5. For dual display, each display has its own instance of the above pad macro. Set up each display according to the panel interface and insure that pins are used by only one display. A set of registers outside of display, PIN_MUX_CTL_**, control which one out of 4 inputs, including display and displayb, go to the pads.

Dual Pixel Formats Table

Regarding note 4 above, in 2P1C18B mode, output-select==1 pin assignments are modified to accommodate two pixels' data per clock. Note that DF2P1C18B must be used with DIV2.

Pin Miscellaneous Control

Offset: 31bh | Read/Write: R/W | Reset: 0b0

Bit	Reset	Description
2	0x0	DISP_CLOCK_OUTPUT: Display Clock (DCLK) Enable 0= disable 1= enable display clock to be output on LCD_DE pin (LCD_DE output select must be appropriately programmed for this to be effective) 0 = DISABLE 1 = ENABLE

23.7.25 DC_COM_PM0_CONTROL_0

PM0 Signal Control

Class: Pulse Width Modulation

PM0 signal is programmable pulse width modulation signal that can be output on several pins. The control register should be initialized once before PM0 is enabled.

> **Note:** The period is expressed as multiples of 4 times the divider value.
> The actual period - in clock cycles - is given by:
> period = (1 + PM0_CLOCK_DIVIDER) * ((PM0_PERIOD + 1) * 4)

Offset: 31ch | Read/Write: R/W | Reset: 0bxxxxxxxxxxxxxxxxxxxxxxxxxx

Bit	Reset	Description
23:18	X	PM0_PERIOD: PM0 Period (4, 8, ... , 256 clock cycles)
9:4	X	PM0_CLOCK_DIVIDER: PM0 Clock Divider (1 to 16384)

Bit	Reset	Description
1:0	X	PM0_CLOCK_SELECT: PM0 Clock Select 0= output of shift clock divider 1= pixel clock 2= line clock 3= frame clock Notes: 1) Pixel clock, line clock, and frame clock is running only when PW0 signal is enabled. 2) In non-continuous mode, shift clock and pixel clock run continuously, but line clock and frame clock only run while a frame is being sent.

23.7.26 DC_COM_PM0_DUTY_CYCLE_0

PM0 Duty Cycle

A counter repeatedly counts up from 0 to ((PM0_PERIOD << 2) + 3) pre-scaled cycles.

The period always starts with the output value == 1. After DUTY_CYCLE number of pre-scaled cycles, the output value is cleared for the remainder of the period. In order to output constant 0, simply set the DUTY_CYCLE to 0. To output a constant 1, set DUTY_CYCLE to be any value greater than ((PM0_PERIOD << 2) + 3).

Offset: 31dh | Read/Write: R/W | Reset: 0bxxxxxxxxx

Bit	Reset	Description
8:0	X	PM0_DUTY_CYCLE: PM0 Duty Cycle (or D). From 1/P to D/P pulse high time where P is the period. This must not be larger than the period.

23.7.27 DC_COM_PM1_CONTROL_0

PM1 signal Control

PM1 signal is programmable pulse width modulation signal that can be output on several pins.

The control register should be initialized once before PM1 is enabled.

The actual period (in clock cycles) is given by:

PERIOD = (1 + PM1_CLOCK_DIVIDER) * ((PM1_PERIOD + 1) * 4)

Offset: 31eh | Read/Write: R/W | Reset: 0bxxxxxxxxxxxxxxxxxxxxxxxxxx

Bit	Reset	Description
23:18	X	PM1_PERIOD: PM1 Period (4, 8, ... , 256 clock cycles)
9:4	X	PM1_CLOCK_DIVIDER: PM1 Clock Divider (1 to 16384)
1:0	X	PM1_CLOCK_SELECT: PM1 Clock Select 0= output of shift clock divider 1= pixel clock 2= line clock 3= frame clock Notes: 1) Pixel clock, line clock, and frame clock is running only when PW0 signal is enabled. 2) In non-continuous mode, shift clock and pixel clock run continuously, but line clock and frame clock only run while a frame is being sent.

23.7.28 DC_COM_PM1_DUTY_CYCLE_0

PM1 Duty Cycle

A counter repeatedly counts up from 0 to ((PM1_PERIOD << 2) + 3) pre-scaled cycles.

The period always starts with the output value == 1. After DUTY_CYCLE number of pre-scaled cycles, the output value is cleared for the remainder of the period. In order to output constant 0, simply set the DUTY_CYCLE to 0. To output a constant 1, set DUTY_CYCLE to be any value greater than ((PM1_PERIOD << 2) + 3).

Offset: 31fh | Read/Write: R/W | Reset: 0bxxxxxxxxx

Bit	Reset	Description
8:0	X	PM1_DUTY_CYCLE: PM1 Duty Cycle from 1/P to P/P pulse high time where P is the period. This must not be larger than the period.

23.7.29 DC_COM_SPI_CONTROL_0

SPI Control

Class: Serial Peripheral Interface (SPI)

SPI interface is a 3-pin or 4-pin serial interface which is typically used to program registers in display device. However, for display with built-in frame buffer, it can also be used to write pixel data to the built-in frame buffer. Currently only write cycles are supported.

LCD SPI interface signal consists of:

- SPI Clock (SCK) which can be output on LCD_SCK pin.
- SPI Data (SDA) which can be output on LCD_SDOUT pin.
- Optional SPI Data/Command (SDC) which can be output on LCD_DC0 pin.
- Main-Display SPI Chip Select (Main SCS_) signal which can be output on LCS_ pin
- Sub-Display SPI Chip Select (Sub SCS_) signal which can be output on LCD_CS1_N or LCD_D22 or LCD_SDOUT pins - this is only used only if there is a sub display

Theoretically if two LCD panels (main and sub displays) are connected, then SPI interface can be connected to both LCD panels and shared between the two panels.

In this case two Chip Select pins are required and LCS_ should be connected to the main display and other pin has to be selected to output the sub display SCS_.

Internally two SPI chip select signals (lmscs_ and lsscs_ for main and sub display SPI chip select) are generated.

When SPI is enabled, there are three possible SPI transactions:

- SPI write can be triggered by host by writing to HSPI_CS_DC register
- SPI write can be triggered to send pixel data from frame buffer
- SPI write can be triggered to send Initialization Sequence (IS). Frame initialization sequence is sent one line prior to active display line.

For LCD SPI, pixel data can only be sent to either Main-Display or Sub-Display but not to both but host SPI and IS SPI can be sent to both Main and Sub displays simultaneously.

In case a. and c. the SPI root clock is derived from output of shift clock divider which is then further divided by SPI_CLK_DIVIDER. For both cases, the SPI number of bits/cycle is determined by SPI_BITS_PER_CYCLE and the SPI data direction is determined by SPI_DATA_DIRECTION.

In case b. the SPI root clock is derived from output of shift clock divider with no further division. For this case, the SPI number of bits/cycle is determined by correct programming of pixel clock divider.

If case a. is enabled at the same time with case b. and c. then host SPI triggers is delayed to the beginning of horizontal display active time of a line that does not have IS SPI or LCD SPI cycles. This means that if all cases are enabled, the vertical blank time must be at least 2 lines otherwise host SPI cycles cannot be executed.

Offset: 320h | Read/Write: R/W | Reset: 0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx

Bit	Reset	Description
25:24	X	SPI_STATUS_ENABLE: SPI Status Enable 00= SPI status disable 01= SPI status enabled for host SPI only 10= SPI status enabled for IS and LCD SPI only 11= SPI status enabled for all SPI cycles SPI status is reflected in SPI_BUSY bit and can generate interrupt. SPI status indicates when SPI module is busy (SPI write cycles are in progress) so its falling edge should be used to generate interrupt. SPI status can also be output on LCD_DE pin. When Host SPI is triggered, the SPI busy is asserted within three display clock cycles after the end of the host write cycle. SPI status is disabled when SPI_ENABLE bit is disabled.
20:16	X	SPI_CLK_DIVIDER: SPI Clock Divider (1 to 32). This clock divider is used only if SPI is enabled for host writes (Host SPI) or for sending initialization sequence (IS SPI). Programmed value is 1 less than the desired (actual) clock divider value. This parameter is forced to 0 (clock divide by 1) for LCD SPI.
7:4	X	SPI_BITS_PER_CYCLE: SPI Bits per Cycle. This is valid for Host and IS SPI only. This parameter determines the number of bits/cycle when SPI is used for host write or for sending initialization sequence. If SPI is used for sending pixel data to the display then pixel clock divider determines the SPI bits/cycle. SPI8DC is 8-bit SPI plus data/command bit SPI16DC is 16-bit SPI plus data/command bit SPI16SB is 16-bit SPI plus an 8-bit start byte preceding the 16-bit data. 0 = SPI8 1 = SPI8DC 2 = SPI12 3 = SPI16 4 = SPI16DC 5 = SPI16SB 6 = SPI18 7 = SPI24
3	X	SPI_DATA_DIRECTION: SPI Data Direction. This is valid for Host SPI and for sending initialization sequence (IS SPI) only. Note that data direction does not affect the start byte direction (always msb to lsb) and position (always first 8-bit of serial data) for SPI16SB mode. 0 = MSB2LSB 1 = LSB2MSB
1:0	X	SPI_SERIAL_CLK_CONTROL: SPI Serial Clock Control 0= SCK rising edge is active edge 1-clock chip select and no SCK clock edge to latch chip select 1= SCK rising edge is active edge 2-clock chip select with SCK rising clock edge to latch it 2= SCK falling edge is active edge 1-clock chip select and no SCK clock edge to latch chip select 3= SCK falling edge is active edge 2-clock chip select with SCK falling clock edge to latch it This is valid for Host, IS, and LCD SPI

23.7.30 DC_COM_SPI_START_BYTE_0

SPI Start Byte

SPI Start Bytes are used only for SPI16SB mode (start byte plus 16-bit data). Data direction does not affect the start byte direction (always msb to lsb) and position (always the first 8 bits of serial data).

Offset: 321h | Read/Write: R/W | Reset: 0bxxxxxxxxxxxxxxxx

Bit	Reset	Description
15:8	X	SPI_COMMAND_START_BYTE: SPI Command Start Byte This is valid for Host, IS, and LCD SPI.
7:0	X	SPI_DATA_START_BYTE: SPI Data Start Byte. This is valid for Host, IS, and LCD SPI.

23.7.31 DC_COM_HSPI_WRITE_DATA_AB_0

Host SPI Write Data A & B

These registers are used to send write data for Host SPI write cycles (HSPI_ENABLE = 1).

For the tables below, these abbreviations of the registers are used:

- HSPIWDA = HSPI_WRITE_DATA_A
- HSPIWDB = HSPI_WRITE_DATA_B
- HSPIWDC = HSPI_WRITE_DATA_C
- HSPIWDD = HSPI_WRITE_DATA_D
- HSPIMCS = HSPI_MAIN_CS
- HSPISCS = HSPI_SUB_CS
- HSPIDC = HSPI_DC

For 8-bit SPI, up to 4 write cycles can be performed (SPI_BITS_PER_CYCLE equals SPI8)

Write cycle	0	1	2	3
Data	HSPIWDA[7-0]	HSPIWDA[15-8]	HSPIWDB[7-0]	HSPIWDB[15-8]
Main SCS_	HSPIMCS[0]	HSPIMCS[1]	HSPIMCS[2]	HSPIMCS[3]
Sub SCS_	HSPISCS[0]	HSPISCS[1]	HSPISCS[2]	HSPICSC[3]
SDC	HSPIDC[0]	HSPIDC[1]	HSPIDC[2]	HSPIDC[3]

For SPI8DC mode, a 9-bit SPI, the first data bit sent comes from HSPI_DC register and the other eight bits come as shown in the table below. Up to 4 write cycles can be performed.

Write cycle	0	1
Data	HSPIDC[0], HSPIWDA[7-0]	HSPIDC[1], HSPIWDA[15-8]
Main SCS_	HSPIMCS[0]	HSPIMCS[1]
Sub SCS_	HSPISCS[0]	HSPISCS[1]
SDC	HSPIDC[0]	HSPIDC[1]
Write cycle	**2**	**3**
Data	HSPIDC[2], HSPIWDB[7-0]	HSPIDC[3], HSPIWDB[15-8]
Main SCS_	HSPIMCS[2]	HSPIMCS[3]
Sub SCS_	HSPISCS[2]	HSPICSC[3]
SDC	HSPIDC[2]	HSPIDC[3]

For 12-bit SPI, up to 4 write cycles can be performed (SPI12)

Write cycle	0	1	2	3
Data	HSPIWDA[11-0]	HSPIWDB[11-0]	HSPIWDC[11-0]	HSPIWDD[11-0]
Main SCS_	HSPIMCS[0]	HSPIMCS[1]	HSPIMCS[2]	HSPIMCS[3]
Sub SCS_	HSPISCS[0]	HSPISCS[1]	HSPISCS[2]	HSPISCS[3]
SDC	HSPIDC[0]	HSPIDC[1]	HSPIDC[2]	HSPIDC[3]

For 16-bit SPI, up to 4 write cycles can be performed (SPI16, SPI16SB). Note for SPI16SB mode, the first write cycle will be the start byte, followed by write cycle 0, as shown in the table below.

Write cycle	0	1	2	3
Data	HSPIWDA[15-0]	HSPIWDB[15-0]	HSPIWDC[15-0]	HSPIWDD[15-0]

23.7.33 DC_COM_HSPI_CS_DC_0

Host SPI Chip Select and Data/Command

A write to this register will trigger the Host SPI write cycle if SPI_ENABLE and HSPI_ENABLE are both enabled. Writing to this register with HSPI_RAISE enabled will cause the raise vector to be returned after all the host SPI cycles are completed. Up to four host SPI cycles can be executed with a single trigger.

This register should not be written if previous host SPI write cycle is in progress. HSPI_MAIN_CS and HSPI_SUB_CS controls the main and sub display chip selects and therefore also determine how many SPI write cycles to main and sub displays and the write data position.

HSPI_MAIN_CS or HSPI_SUB_CS should be programmed to have at least one valid cycle when programming HSPI_CS_DC register.

Offset: 324h | Read/Write: R/W | Reset: 0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx0

0	0x0	GPIO_0_DEBOUNCE_ENABLE: maps to display pin LCD_PWR0 0 = DISABLE 1 = ENABLE

23.7.37 DC_COM_GPIO_DEBOUNCE_COUNTER_0

Display GPIO Debounce Counter

Provides mark_en to debounce logic.

MARKER

The MARKER value sets the interval at which the debounce finite state machines associated with each GPIO input pin evaluate input transitions. An input transition must be stable for at least 4 consecutive MARKER ticks before it is propagated through the debounce circuit.

MARKER is in display clock tick units. The actual 'gravity delay' of a debounce FSM is 4 * Tmarker, where Tmarker = MARKER * (APB clock duration). For a 100 MHz display clock, a MARKER setting of 10,000,000 results in a gravity delay of 4x100 ms.

Offset: 328h | Read/Write: R/W | Reset: 0b00000000000000000000010000000000

Bit	Reset	Description
31:0	0x400	DEBOUNCE_COUNTER

23.7.38 DC_COM_CRC_CHECKSUM_LATCHED_0

CRC Checksum latched

This register is a latched version of CRC_CHECKSUM. Latching happens at frame end.

Note: CRC_INPUT_DATA needs to be set to ACTIVE_DATA if this register is used. In full frame mode, CRC is frozen two cycles after frame end due to pipelining, so only in active area mode, CRC is consistent and independent of display control mode, and can be checked continuously frame by frame.

Offset: 329h | Read/Write: RO | Reset: 0x00000000

Bit	Reset	Description
31:0	0x0	CRC_CHECKSUM_LATCHED: CRC Checksum latched

23.8 Display DISP Registers

These registers control DISP display only; not including the DISP display window parameters.

23.8.1 DC_DISP_DISP_SIGNAL_OPTIONS0_0

Offset: 402h | Read/Write: R/W | Reset: 0b000xxxxxxxxxx0

Bit	Reset	Description
30	0x0	HDMI_ENABLE: HDMI interface. The HDMI unit must also be separately enabled in its own register space in order to use HDMI functionality. 0 = DISABLE 1 = ENABLE
29	0x0	DSI_ENABLE: MIPI Display Serial Interface Enable. The DSI unit must also be separately enabled in its own register space in order to use DSI functionality. 0 = DISABLE 1 = ENABLE
28	0x0	TVO_ENABLE: TVO Enable. Steps to start displaying on TV (The order of the first 3 steps can freely change): -- Program and enable TVO module -- Program DISPLAY_CTRL_MODE to NC_DISPLAY -- Program the ASSEMBLY shadow copy of this register field with ENABLE -- Program GENERAL_ACT_REQ to activate the shadow 0 = DISABLE 1 = ENABLE
16	0x0	CURSOR_ENABLE: Cursor Enable 0 = DISABLE 1 = ENABLE

23.8.4 DC_DISP_MEM_HIGH_PRIORITY_0

Memory High Priority request control

Display Memory High Priority Threshold

This controls high priority request for memory read access for each display window and for cursor. High priority request threshold should be increased in scenarios where memory access latency is high.

> **Note:** High Priority Threshold is no longer supported by the MCCIF clients. Registers are retained for software compatibility, but are not used by the hardware.

Offset: 403h | Read/Write: R/W | Reset: 0b00000000000x000000000000000

Bit	Reset	Description
26:24	0x0	CSR_DISPLAYHC2MC_HPTH: Cursor Memory High Priority enable 0= memory access for cursor is normal priority 1= memory access for cursor is high priority
23:16	0x0	CBR_DISPLAY0C2MC_HPTH: Window C Memory High Priority threshold Memory access for this window is high priority if the number of filled entries in the return data fifo is less than or equal to this value. Setting this parameter to 0 disables high priority memory request.
14:8	0x0	CBR_DISPLAYB2MC_HPTH: Window B Memory High Priority threshold Memory access for this window is high priority if the number of filled entries in the return data fifo is less than or equal to this value. Setting this parameter to 0 disables high priority memory request. This register is used for both window B0 and B1
7:0	0x0	CBR_DISPLAY0A2MC_HPTH: Window A Memory High Priority threshold Memory access for this window is high priority if the number of filled entries in the return data fifo is less than or equal to this value. Setting this parameter to 0 disables high priority memory request.

23.8.5 DC_DISP_MEM_HIGH_PRIORITY_TIMER_0

Memory High Priority request control

Display Memory High Priority Timer

The high-priority assertion can be delayed by a number of memory clock cycles indicated by the timer. This creates an hysteresis effect, avoiding setting the high-priority for very short periods of time, which may or may not be desirable.

> **Note:** High Priority Timer is no longer supported by the MCCIF clients. Registers are retained for software compatibility, but are not used by the hardware.

Offset: 404h | Read/Write: R/W | Reset: 0b000000xx000000xx000000xx000000

Bit	Reset	Description
29:24	0x0	CSR_DISPLAYHC2MC_HPTM: Cursor Memory High Priority timer

13:8	0x0	CBR_DISPLAYB2MC_HPTM: Window B Memory High Priority timer This register is used for both window B0 and B1
5:0	0x0	CBR_DISPLAY0A2MC_HPTM: Window A Memory High Priority timer

23.8.6 DC_DISP_DISP_TIMING_OPTIONS_0

Display Timing Options

Class: Display Standard Timings

Programming of display timing registers must meet these restrictions:

Constraint 1: H_REF_TO_SYNC + H_SYNC_WIDTH + H_BACK_PORCH > 11.

Constraint 2: V_REF_TO_SYNC + V_SYNC_WIDTH + V_BACK_PORCH > 1.

Constraint 3: V_FRONT_PORCH + V_SYNC_WIDTH + V_BACK_PORCH > 1 (vertical blank).

Constraint 4: V_SYNC_WIDTH >= 1

H_SYNC_WIDTH >= 1

Constraint 5: V_REF_TO_SYNC >= 1

H_REF_TO_SYNC >= 0

Constraint 6: V_FRONT_PORCH >= (V_REF_TO_SYNC + 1)

H_FRONT_PORCH >= (H_REF_TO_SYNC + 1)

Constraint 7: H_DISP_ACTIVE >= 16

V_DISP_ACTIVE >= 16

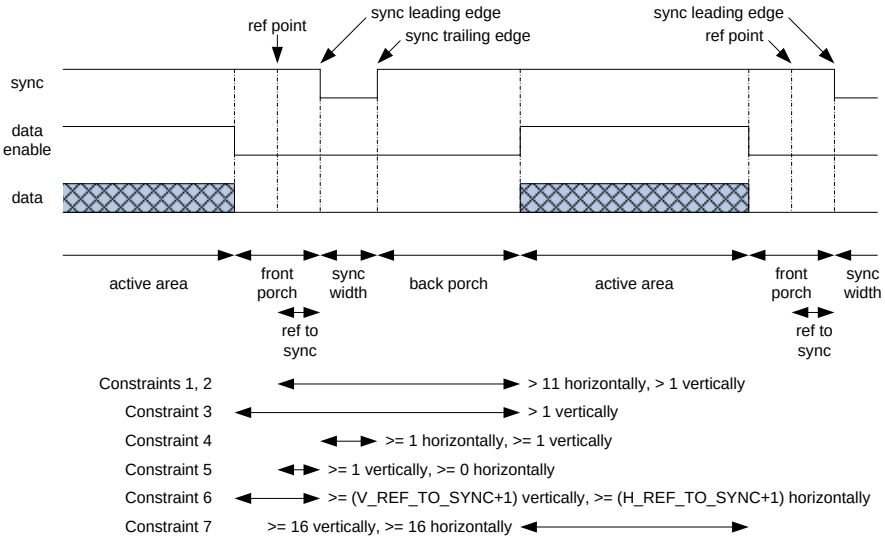
Only the back porch can be a negative value, though it is typically positive. Note that the back porch is defined as the distance between the trailing edge of the sync and the beginning of the active area. Some LCD specifications define the back porch from the leading edge of the sync rather than the trailing edge. Front porch is defined as the distance between the end of the active area and the leading edge of the sync. Vertical timing is in terms of lines and horizontal timing is in terms of pixels.

Sync polarity is in terms of the sync width; active low means the sync width pulse will be low, as in the diagram. Pixel clock polarity is in terms of when data will transition; an active low pixel clock means that the data changes on the falling edge of the clock, to be latched on the rising edge. Data enable (also called display enable or DE) polarity selects the level of the signal during the active area of display. The diagram has DE active high.

Timing Diagram

- This diagram applies to both vertical and horizontal timing
- Back porch is the only parameter that can be negative

Figure 54 Display Timing Options Timing Diagram



This register specifies display timing options for HSYNC and VSYNC

Offset: 405h | Read/Write: R/W | Reset: 0b0000000000000

Bit	Reset	Description
12:0	0x0	VSYNC_H_POSITION: VSYNC Horizontal Position This parameter specifies the position where VSYNC can toggle with respect to H reference point.

23.8.7 DC_DISP_REF_TO_SYNC_0

H/V Reference to Sync

This register specifies the start position of HSYNC and VSYNC with respect to H and V reference point (line and frame start) correspondingly. The H and V reference points correspond to the time when H and V display timing counter is re-initialized to zero correspondingly.

The H reference point also determines the point where V display timing counter is incremented so this points the horizontal relationship between HSYNC and VSYNC.

Note: VSYNC's rising/falling edge is fixed at H reference point zero. In the future, we may want to add a horizontal position offset so that VSYNC can occur after HSYNC.

Offset: 406h | Read/Write: R/W | Reset: 0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx

Bit	Reset	Description
28:16	X	V_REF_TO_SYNC: V reference to VSYNC (minimum 1 line clock)
12:0	X	H_REF_TO_SYNC: H reference to HSYNC (minimum 0 pixel clock)

23.8.8 DC_DISP_SYNC_WIDTH_0

H/V SYNC Pulse Width

This register specifies the width of HSYNC and VSYNC pulses. Check the comment for REF_TO_SYNC for programming restrictions.

Offset: 407h | Read/Write: R/W | Reset: 0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx

Bit	Reset	Description
28:16	X	V_SYNC_WIDTH: VSYNC pulse width (minimum 1 line clock)
12:0	X	H_SYNC_WIDTH: HSYNC pulse width (minimum 1 pixel clock)

23.8.9 DC_DISP_BACK_PORCH_0

H/V Back Porch

This register specifies the distance between H/V SYNC trailing edge to beginning of display active area. This is 2's complement value and negative value indicates that H/V SYNC overlaps with the corresponding display active area. Check the comment for REF_TO_SYNC for programming restrictions.

Offset: 408h | Read/Write: R/W | Reset: 0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx

Bit	Reset	Description
28:16	X	V_BACK_PORCH: V back porch
12:0	X	H_BACK_PORCH: H back porch

23.8.10 DC_DISP_DISP_ACTIVE_0

H/V Display Active width

This register specifies the width of H/V display active area. Check the comment for REF_TO_SYNC for programming restrictions.

Offset: 409h | Read/Write: R/W | Reset: 0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx

Bit	Reset	Description
28:16	X	V_DISP_ACTIVE: V display active width (minimum 16 lines)
12:0	X	H_DISP_ACTIVE: H display active width (minimum 16 pixels)

23.8.11 DC_DISP_FRONT_PORCH_0

H/V Front Porch

This register specifies the distance between end of H/V display active area to the leading edge of the corresponding H/V SYNC.

Design Note: H/V active end plus the H/V front porch value minus the H/V reference to H/VSYNC determines the H/V total (final H/V count value for the H/V display counter). Check the comment for REF_TO_SYNC for programming restrictions.

Offset: 40ah | Read/Write: R/W | Reset: 0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx

Bit	Reset	Description
28:16	X	V_FRONT_PORCH: VSYNC front porch (minimum -=PS_=-V_REF_TO_SYNC + 1)
12:0	X	H_FRONT_PORCH: HSYNC front porch (minimum -=PS_=-H_REF_TO_SYNC + 1)

23.8.12 DC_DISP_H_PULSE0_CONTROL_0

H Pulse 0 Control

Class: Display Extended Timings

Horizontal pulse 0 is programmable pulse that repeats every line.

In the NORMAL mode, this signal can have several pulses (A to D) per line with programmable width as defined by the pairs of start and end positions. The pulses must not overlap and must occur in sequence: pulse A, then pulse B, etc. In this case, the Enable field must be set to one of the End position. If the Enable field is set to one of the Start position then the pulse generator will stop as if the Enable field is set to the previous End position. If Enable field is set to Start A position then no pulse is generated.

In the ONE_CLOCK mode this signal can have up to twice the number of pulses per line with each pulse having a width of 1 pixel clock. In this mode, the position of the one-clock pulses corresponds to the enabled Start and End positions.

Regardless of the mode, the pulse generator processes the pairs of start and end position sequentially in the order of: Start A, End A, Start B, End B, etc.

So these start/end positions should be programmed in increasing order. If any of the positions are programmed in non-increasing order (has invalid value) then the pulse generator will stop at the last valid position.

Polarity adjustment is made prior to V display qualification. This register specifies options for Horizontal pulse 0.

23.8.22 DC_DISP_H_PULSE2_CONTROL_0

H Pulse 2 Control

Horizontal pulse 2 is programmable pulse that repeats every line.

In the NORMAL mode, this signal can have several pulses (A to D) per line with programmable width as defined by the pairs of start and end positions. The pulses must not overlap and must occur in sequence: pulse A, then pulse B, etc. In this case, the Enable field must be set to one of the End position. If the Enable field is set to one of the Start position then the pulse generator will stop as if the Enable field is set to the previous End position. If Enable field is set to Start A position then no pulse is generated.

In the ONE_CLOCK mode this signal can have up to twice the number of pulses per line with each pulse having a width of 1 pixel clock. In this mode, the position of the one-clock pulses corresponds to the enabled Start and End positions.

Regardless of the mode, the pulse generator processes the pairs of start and end position sequentially in the order of: Start A, End A, Start B, End B, etc. So these start/end positions should be programmed in increasing order. If any of the positions are programmed in non-increasing order (has invalid value) then the pulse generator will stop at the last valid position. Polarity adjustment is made prior to V display qualification. This register specifies options for Horizontal pulse 2.

M1 Control

Display M1 signal. M1 signal can be generated either using a line (horizontal) or a frame (vertical) clock and it can be horizontally positioned with respect to H reference point. This signal is typically output on LCD_M1 pin. This register specifies options for M1 signal.

Offset: 427h | Read/Write: R/W | Reset: 0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx

Bit	Reset	Description
28:16	X	M1_H_POSITION: M1 Horizontal Position. This parameter specifies the position where M0 can toggle with respect to H reference point.
12:8	X	M1_PERIOD: M1 Period. This should be program to the half of the desired M1 period (in lines) minus 1.
7	X	M1_POLARITY: M1 Polarity. Polarity adjustment is applied last after phase control is applied. 0 = HIGH 1 = LOW

Bit	Reset	Description
6	X	M1_PHASE_RESET: M1 Phase Reset. This bit is effective only when M1 is not free running. 0= frequency (phase) counter is not reset 1= frequency (phase) counter is reset at beginning of vertical active display if phase control is set to VACTIVE_RESTART or at beginning of frame if phase control is set to FRAME_INVERT 0 = DISABLE 1 = ENABLE
5:4	X	M1_PHASE_CONTROL: M1 Phase Control 00= free-running 01= reserved 10= reset at beginning of vertical active display 11= invert at beginning of frame This should be set to free-running if frame clock is used. 0 = FREE_RUN 2 = VACTIVE_RESTART 3 = FRAME_INVERT
1:0	X	M1_CLOCK_SELECT: M1 Clock Select 00= pixel clock (for diagnostic) 01= synchronous to M0 provided that M0 is generated using line clock. This will not work if M0 is not generated using line clock. In this case, M1 is controlled by -=PS_=-M0_PHASE_RESET and -=PS_=-M0_PERIOD, -=PS_=-M1_PHASE_CONTROL and -=PS_=-M1_POLARITY. 10= line clock 11= frame clock 0 = PCLK 1 = M0SYNC 2 = LCLK 3 = FCLK

23.8.41 DC_DISP_DI_CONTROL_0

DI Control

Display Data Inversion (DI) signal generation.

This signal is typically needed to control data inversion for PWM panels and is typically output on LCD_D22 pin.

Horizontal position of this signal with respect to horizontal reference point can be programmed. DI signal together with M0 may also be used to control the actual pixel data inversion.

Pixel data may be controlled by either DI only or by (DI ^ M0) as specified by -=PS_=-PIXDATA_INV_SELECT. The inversion control signal is then used to control pixel data inversion as specified by -=PS_=-PIXDATA_INV_CONTROL. Note that even if the DI signal is disabled, pixel data inversion could still occur depending on the setting of -=PS_=-PIXDATA_INV_CONTROL.

Data inversion is limited to only active area. For the purpose of pixel data inversion, DI and M0 signals are used before the corresponding horizontal positioning so that these signals are always stable during active area.

In case M0 signal is used to control data inversion then it should be generated using line clock. M0 polarity control is not accounted when M0 is used to generate DI signal or to control pixel data inversion.

This register specifies options for DI signal as well as pixel data inversion.

Offset: 428h | Read/Write: R/W | Reset: 0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx

Bit	Reset	Description
28:16	X	DI_H_POSITION: DI signal Horizontal Position. This parameter specifies the position where DI signal can toggle with respect to H reference point. It should not be programmed larger than -=PS_=-PP_H_POSITION if DI is used to control PP signal generation.

Bit	Reset	Description
7:6	X	PIXDATA_INV_CONTROL: Pixel Data Inversion Control. The control signal for pixel data inversion is defined by -=PS_=-PIXDATA_INV_SELECT 00= no pixel data inversion regardless of control signal state. 01= Pixels 0, 2, 4 ... are inverted if control signal is high. Pixels 1, 3, 5 ... are inverted if control signal is low. 10= Pixels 1, 3, 5 ... are inverted if control signal is high. Pixels 0, 2, 4 ... are inverted if control signal is low. 11= all pixel data is inverted if control signal is high. NOTE: Pixel data inversion is NOT supported for 2-pixel/3-clock 12-bit parallel display data format! 0 = NOINV 1 = EVENINV 2 = ODDINV 3 = ALLINV
4	X	PIXDATA_INV_SELECT: Pixel Data Inversion Select 0= DI signal controls pixel data inversion 1= (DI xor M0) controls pixel data inversion. 0 = DI 1 = DIXORM0
1:0	X	DI_MODE: DI signal Mode 00= DI is always low 01= DI is always high 10= DI is forced high every time M0 (before polarity adjustment) toggles from low to high; otherwise then DI toggles every line 11= DI has same frequency (phase) as M0 (before M0 polarity adjustment)

23.8.42 DC_DISP_PP_CONTROL_0

PP Control

Display Programmable Pulse (PP) signal generation

PP signal generation logic can generate up to 128 pulses per line internally and the PP pulse select registers determines which of the 128 pulses will be output. Any of the 128 internally generated pulse can be independently selected as output if they occur within one line time.

PP signal is typically output on LCD_D23 pin. Note that DI signal may impact PP generation as controlled by -=PS_=-PP_REVERSAL_CONTROL.

PP signal generation may be delayed (positioned) from H reference point (line start) controlled by -=PS_=-PP_H_DELAY. Delaying PP may cause the last few internal PP pulses to overflow to the next line.

PP is always generated using the display clock after the shift clock divider.

This register specifies options for PP signal.

Offset: 429h | Read/Write: R/W | Reset: 0bxxxxxxxxxxxxxxxx

Bit	Reset	Description
15:12	X	PP_LOW_PULSE: PP Low Pulse width (1 to 16)
11:8	X	PP_HIGH_PULSE: PP High Pulse width (1 to 16)
7:4	X	PP_H_DELAY: PP signal Horizontal Delay (0 to 15). This parameter specifies the position where PP signal generation starts with respect to H reference point. If DI is used to generate PP signal then this parameter should not be smaller than -=PS_=-DI_H_POSITION.

23.8.47 DC_DISP_DISP_CLOCK_CONTROL_0

Display Clock Control

Shift clock divider is used to divide root clock for display controller module to generate internal shift clock for shifting data to the display. Output of this divider is typically used to generate the external shift clock which is sent to the display (SC0 and/or SC1) except for 1-pixel/1-clock parallel display.

The output of this divider is also used to generate Programmable Pulse (PP) signal. For 1-pixel/1-clock parallel display, SC0 and SC1 are generated using the output of pixel clock divider which can be set to 1, 2, or 4 for 1-pixel/1-clock parallel display.

The reason pixel clock divider 2 and 4 are allowed for 1-pixel/1-clock parallel display interface is so that the clock that generates PP can be generated with 2x or 4x higher frequency than pixel clock and therefore can produce higher resolution PP pulse positions. For all cases of parallel display, SC0 and SC1 can be further divided by 1, 2 or 4.

Class: Display Interface Settings

This register controls generation of shift clock to the display and internal pixel clock. Internal display pipeline runs with pixel clock and processes 1 pixel per clock.

Offset: 42eh | Read/Write: R/W | Reset: 0b000000000110

Bit	Reset	Description
11:8	0x0	PIXEL_CLK_DIVIDER: Pixel Clock Divider 0000= divide by 1 0001= divide by 1.5 0010= divide by 2 0011= divide by 3 0100= divide by 4 0101= divide by 6 0110= divide by 8 0111= divide by 9 1000= divide by 12 1001= divide by 16 1010= divide by 18 1011= divide by 24 1100= divide by 13 other= reserved 0 = PCD1 1 = PCD1H 2 = PCD2 3 = PCD3 4 = PCD4 5 = PCD6 6 = PCD8 7 = PCD9 8 = PCD12 9 = PCD16 10 = PCD18 11 = PCD24 12 = PCD13

Bit	Reset	Description
7:0	0x6	SHIFT_CLK_DIVIDER: Shift Clock Divider 0 = divide by 1 1 = divide by 1.5 2 = divide by 2 3 = divide by 2.5 4 = divide by 3 : : : : 254 = divide by 128 255 = divide by 128.5 Pixel clock divider is used to divide output of internal shift clock divider to generate internal pixel clock which is used to clock the internal horizontal and vertical counters. This divider also determines the output format for parallel interface, serial interface, and LCD SPI interface in conjunction with Display Data Format parameter. For 1-pixel/1-clock parallel display interface, valid settings are PCD1, PCD2, and PCD4. Note that the main reason to use PCD2 and PCD4 is to get higher frequency PP clock because the PP clock is always generated from the output of shift clock divider. For non 1-pixel/1-clock parallel display interface, valid settings are, PCD1H (2-pixel/3-clock), PCD2 (1-pixel/2-clock), and PCD3 (1-pixel/3-clock). For 1-channel serial display interface, valid settings are PCD3 (3-bpp 1-ch), PCD4 (3-bpp 1-ch), PCD6 (6-bpp 1-ch), PCD9 (9-bpp 1-ch), PCD12 (12-bpp 1-ch), PCD16 (16-bpp 1-ch), PCD18 (18-bpp 1-ch). For 2-channel serial display interface, valid settings are PCD2 (3-bpp 2-ch), PCD3 (6-bpp 2-ch), PCD6 (12-bpp 2-ch), PCD8 (16-bpp 2-ch), PCD9 (18-bpp 2-ch). For 3-channel serial display interface, valid settings are PCD1 (3-bpp 3-ch), PCD2 (6-bpp 3-ch), PCD3 (9-bpp 3-ch), PCD4 (12-bpp 3-ch), PCD6 (18-bpp 3-ch). For LCD SPI interface, valid settings are PCD12 (B4G4R4), PCD16 (B5G6R5), PCD18 (B6G6R6), PCD24 (B8G8R8), PCD8 (B5G6R5 with data/command bit), PCD6 (B5G6R5 with data/command start byte - depending on data/command bit), PCD4 (P8 for spi8), PCD9 (B5G6R5 with chip select de-assertion at 8-bit boundary, spi16x2), PCD3 (P8 for spidc), PCD2 (B5G6R5 with data/command bit and chip select de-assertion at 9-bit boundary, spi16x2dc), and PCD13 (spi12p2, no chip select de-assertion between pairs of pixels).

23.8.48 DC_DISP_DISP_INTERFACE_CONTROL_0

Display Interface Control

This register specifies display interface options

Offset: 42fh | Read/Write: R/W | Reset: 0b00xxxx0000

Bit	Reset	Description
9	0x0	DISP_DATA_ORDER: Display Data Order. This is effective only for 1-pixel/2-clock 16-/18-/24- bit parallel interface. 0= Red pixel is output in the first clock and blue pixel is output in the second cycle 1= Blue pixel is output in the first clock cycle and red pixel is output in the second clock cycle 0 = RED_BLUE 1 = BLUE_RED

Bit	Reset	Description
8	0x0	DISP_DATA_ALIGNMENT: Display Data Alignment. This is effective for parallel display data format and the associated Initialization Sequence (IS). 0= Output data is MSB-aligned. For 1-pixel/1-clock parallel display the output data ordering is the same regardless of display Base Color Size. For 1-pixel/1-clock parallel display data alignment is optimized for 18-bpp so the 24-bit data ordering is: LD[5:0] is blue data bits 7-2, LD[11:6] is green data bits 7-2, LD[17:12] is red data bits 7-2, LD[19:18] is blue data bits 1-0, LD[21:20] is green data bits 1-0, LD[23:22] is red data bits 1-0. Note that LD18 to LD23 signals are multiplexed with control pins (see Pin Output Select definition) 1= Output data is LSB-aligned. For 1-pixel/1-clock parallel display the output data ordering is determined by display Base Color Size. For 1-pixel/1-clock parallel display data alignment is optimized for 24-bpp as follows: LD[7:0] is blue data bits 7-0, LD[15:8] is green data bits 7-0, LD[23:16] is red data bits 7-0. Note that LD18 to LD23 signals are multiplexed with control pins (see Pin Output Select definition) 0 = MSB 1 = LSB
3:0	0x0	DISP_DATA_FORMAT: Display Data Format Pixel Clock Divider is used together with this parameter to determine the exact display data format. 0 = DF1P1C : 0= 1-pixel/1-clock up to 24-bit parallel 1 = DF1P2C24B : Not supported 2 = DF1P2C18B : Not supported 3 = DF1P2C16B : Not supported 4 = DF1S : 4= 1-channel serial NOTE: 1-/2-/3-channel serial display interface supported is a low-voltage differential serial interface. 5 = DF2S : 5= 2-channel serial 6 = DF3S : 6= 3-channel serial 7 = DFSPI : 7= SPI serial 8 = DF1P3C24B : Not supported 9 = DF2P1C18B : 9= 2-pixel/1-clock 18-bit parallel 10 = DFDUAL1P1C18B: Not supported

23.8.49 DC_DISP_DISP_COLOR_CONTROL_0

Display Color Control

Offset: 430h | Read/Write: R/W | Reset: 0b0000xxxxx0x0xx00xxxxxxxx0000

Bit	Reset	Description
27	0x0	LCD_MD3: LCD Mode 3 signal 0 = LOW 1 = HIGH
26	0x0	LCD_MD2: LCD Mode 2 signal 0 = LOW 1 = HIGH
25	0x0	LCD_MD1: LCD Mode 1 signal 0 = LOW 1 = HIGH
24	0x0	LCD_MD0: LCD Mode 0 signal 0 = LOW 1 = HIGH

Bit	Reset	Description
18	0x0	NON_BASE_COLOR: Non Base Color. 0= zeros 1= ones MD0-3 signals are general purpose mode signals that can be output in various pins (see Pin Output Select) to configure the display device. These bits are effective at the start of frame. Typically these can be programmed in shadow register which takes effect on the next frame.
17	X	BLANK_COLOR: Blank Color. 0= zeros 1= ones Non Base Color applies to the least significant color bits which are not part of the base color, and it has higher priority over Border Color but lower priority over Blank color.
16	0x0	DISP_COLOR_SWAP: Display Color Swap 0= RGB (normal) 1= BGR (red-blue reverse) 0 = RGB 1 = BGR
13:12	0x0	ORD_DITHER_ROTATION: Ordered Dither Frame Rotation. This parameter specifies the rotation frequency of the dither matrix in terms of number of frames. If programmed to 0, there is no dither matrix rotation. If programmed to N where N is larger than 0, the dither matrix is rotated clockwise every N frame.
9:8	X	DITHER_CONTROL: Dither Control 00= dither disabled 01= reserved 10= ordered dither 11= error-diffusion dither (maximum line width is 1280) Design Note: initial dither matrix (where d is 2 dither bits) d=00 d=01 d=10 d=11 --------- --------- --------- --------- 0 0 1 0 0 1 0 1 --------- --------- --------- --------- 0 0 0 0 1 0 1 1 --------- --------- --------- --------- Note: 0 in the matrix specifies no addition to base color 1 in the matrix specifies incrementation of base color (with saturation) 0 = DISABLE 2 = ORDERED 3 = ERRDIFF
3:0	0x0	BASE_COLOR_SIZE: Display Base Color Size. This parameter determines the number of bits per color after dither. 0= 6 bits 1= 1 bit 2= 2 bits 3= 3 bits 4= 4 bits 5= 5 bits 6= 5 bits for R,B and 6 bits for G 7= 3 bits for R,G and 2 bits for B 8= 8 bits, this also forces dither to be disabled. This setting can be used to output 24-bit data in 1-pixel/clock parallel display data format. 0 = BASE666 1 = BASE111 2 = BASE222 3 = BASE333 4 = BASE444 5 = BASE555 6 = BASE565 7 = BASE332 8 = BASE888

23.8.50 DC_DISP_SHIFT_CLOCK_OPTIONS_0

Shift Clock options

This register specifies options for both display shift clock 0 (SC0) and display shift clock 1 (SC1). SC0 signal is typically output on LCD_PCLK pin and SC1 signal is typically output on LCD_WR_N pin.

Offset: 431h | Read/Write: R/W | Reset: 0b00000000xxxxxxxx00000000

Bit	Reset	Description
23:22	0x0	SC1_CLK_DIVIDER: SC1 Clock Divider 0= divide by 1 - this is valid for all display interfaces 1= divide by 2 - this is valid only for 1-pixel/1-clock parallel display and 2-pixel/1-clock parallel display 2= divide by 4 - this is valid only for 1-pixel/1-clock parallel display 3= divide by 2, aligned with data (2p1c mode only) 0 = DIV1 1 = DIV2 2 = DIV4 3 = DIV2_ALIGNED
21:19	0x0	SC1_V_QUALIFIER: SC1 Vertical Qualifier 0= no vertical qualifier 2= vertical display active 3= 1-line extended vertical display active 4= V Pulse 1 (VP1) 5= 1-line extended V Pulse 1 others= reserved If SC1 is divided by 2 then it is synchronously reset at the beginning of the horizontal qualifier such that rising edge of SC1 is generated for the first horizontally qualified 'pixel'. If SC1 is divided by 4 then it is synchronously reset at the beginning of the horizontal qualifier such that rising edge of LCD_WR_N is generated for the second horizontally qualified 'pixel'. In the case where there is no horizontal qualifier start of horizontal display active will be used to generate the synchronous reset. If Initialization Sequence (IS) is enabled on parallel interface then only divide by 1 is allowed for SC1 Clock Divider and SC1 must have vertical and horizontal qualifiers enabled. 0 = NO_VQUAL 1 = RESERVED 2 = VACTIVE 3 = EXT_VACTIVE 4 = VPULSE1 5 = EXT_VPULSE1

23.8.51 DC_DISP_DATA_ENABLE_OPTIONS_0

Data Enable options

DE signal is display Data Enable signal which can be used to indicate valid data area and it can be output on LCD_WR_N pin if needed.

This signal can also be used to generate PCS (Parallel mode panel Chip Selecter)

- 0 = Deasserted during both VBlank and HBlank, except for the IS sequence and the gap between IS and the first active line if IS is enabled.
- 1 = Deasserted during VBlank, except for the IS line (whole IS line) if IS is enabled.
- 2 = Always asserted during refresh

Option 0 can be achieved by: DE_SELECT=ACTIVE_IS; DE_CONTROL=NORMAL

Option 1 can be achieved by: DE_SELECT=ACTIVE_IS; DE_CONTROL=ACTIVE_BLANK

Option 2 can be achieved by: DE_SELECT=ACTIVE_BLANK; DE_CONTROL=ACTIVE_BLANK

Offset: 432h | Read/Write: R/W | Reset: 0b00000

Bit	Reset	Description
4:2	0x0	DE_CONTROL: DE (Data Enable) horizontal coverage control 0= 1-pixel clock pulse preceding active line (1-clock DE) 1= LDE active for horizontal display active time (normal DE) 2= LDE starts 1-pixel clock preceding active line but stays high on horizontal display active (early and extended DE) 3= 1-pixel clock early horizontal display active (early DE) 4= DE is active for the whole line, covering both active data and h blank (active and blank) 0 = ONECLK 1 = NORMAL 2 = EARLY_EXT 3 = EARLY 4 = ACTIVE_BLANK
1:0	0x0	DE_SELECT: DE (Data Enable) vertical coverage control 0= DE is generated on every lines (active & blank) 1= DE is generated only for active lines 2= DE is generated for active lines and Initialization sequence (if IS is enabled). DE is also asserted in the time gap between the IS and the first active line. This bit also controls STH for serial display interface in the same manner. 0 = ACTIVE_BLANK 1 = ACTIVE 2 = ACTIVE_IS

23.8.52 DC_DISP_SERIAL_INTERFACE_OPTIONS_0

Serial Display Interface Options

Controls signals for the low-voltage differential serial display interface consists of: SDT, STP and STH signals. SDT and STP are asserted high if current pixel is same as previous pixel; in this case,

SDT is toggled low sometime later but STP is either toggled low at same time as SDT (if next pixel is different than current pixel) or remains high if next pixel is same as current pixel.

When doing pixel comparison, output of dither is used, so pixel comparison depends on the base color (which maybe different than the number of output data bits).

Both SDT and STP are always low (disabled) if the pixel clock divider is 4 or less.

STH is used to indicate the beginning of line and it is asserted high once at the beginning of each line. The STH pulse exact timing width is dependent on the exact mode. STH is generated from Data Enable therefore Data Enable Select bit also controls STH generation and can be used to generate STH either only for active lines or both for active and blank lines. If STH is sent during blank lines then the blank lines are also transmitted.

Offset: 433h | Read/Write: R/W | Reset: 0b00000000

Bit	Reset	Description
7	0x0	STP_CONTROL: STP signal control 0= STP is not ORed with H Pulse 2 and vertical blank 1= STP is ORed with H Pulse 2 and vertical blank This may be set to 1 when STP needs to be forced high during blank time in which case H Pulse 2 should be programmed when STP needs to be forced high. Vertical blank is the area outside vertical display active. 0 = NORMAL 1 = EXTENDED

Bit	Reset	Description
6	0x0	STH_DURATION: STH signal duration 0= STH is high for 1 pixel clock in all cases except for 3-bit 2-channel and 6-bit 3-channel where STH is 1.5 pixel clock and for 3-bit 3-channel STH is 3 pixel clocks. 1= STH is high for 2 pixel clock in all cases except for 3-bit 3-channel STH is 4 pixel clocks. 0 = ONE_CLOCK 1 = TWO_CLOCK
5:2	0x0	SDT_STP_DURATION: SDT and STP signal duration 0= 1 shift clock 1= 1 pixel clock 2= 1 pixel clock - 1 shift clock 3= 1 pixel clock - 2 shift clock 4= 1 pixel clock - 3 shift clock 5= 1 pixel clock - 4 shift clock : : : F= 1 pixel clock - 14 shift clock STP active duration is same as SDT if next pixel is not the same as current pixel; else, STP active duration is always 1 pixel clock. Maximum valid setting is pixel clock divider - 1 for pixel clock divider > 4. If pixel clock divider is 4 or less, SDT and STP is always low.
1:0	0x0	SDT_STP_MODE: SDT and STP modes 0= SDT and STP disabled 1= reserved 2= SDT & STP enabled, duplicate data sent 3= SDT & STP enabled, duplicate data not sent 0 = DISABLE 1 = RESERVED 2 = ENABLE_DUP 3 = ENABLE

23.8.53 DC_DISP_LCD_SPI_OPTIONS_0

LCD SPI Interface Options

LCD SPI interface signals consists of:

1. SPI Clock (SCK) which can be output on LCD_SCK pin.

2. SPI Data (SDA) which can be output on LCD_SDOUT pin.

3. Optional SPI Data/Command (SDC) which can be output on LCD_DC0 pin.

4. Main-Display SPI Chip Select (Main SCS_) signal which can be output on LCS_ pin.

5. Sub-Display SPI Chip Select (Sub SCS_) signal which can be optionally output on several pins (see pin output select) - this is optional and it is used only if there is a sub display.

For LCD SPI, pixel data can only be sent to either Main-Display or Sub-Display but not to both.

Main SCS_ or Sub SCS_ signal is always active low and is typically controlled by SPI logic but can also be forced active one line prior to display active (for SIS SPI) and during vertical display active area (for LCD SPI).

Offset: 434h | Read/Write: R/W | Reset: 0b00000

Bit	Reset	Description
4	0x0	LCD_SPI_DIRECTION: LCD SPI Data Direction. Note that data direction does not affect the start byte direction (which is always msb to lsb) and position (always first 8-bit of serial data) for SPI16SB mode. 0 = MSB2LSB 1 = LSB2MSB

Bit	Reset	Description

23.8.59 DC_DISP_CURSOR_FOREGROUND_0

Cursor Foreground color

Class: Hardware Cursor

Hardware cursor is supported for 32x32 or for 64x64 2-bpp cursor.

Cursor start address is aligned to 1 KB boundary. All cursor registers except for cursor foreground and background colors are triple buffered.

GENERAL_UPDATE controls ASSEMBLY->ARM latching, GENERAL_ACT_REQ controls ARM->ACTIVE latching.

Cursor scaling and flipping are not implemented so this must be done by software if needed. Cursor H/V positions are signed number with respect to one of the display windows or with respect to upper left position of display active area as specified by cursor clipping parameter which also determines cursor clipping boundary. If cursor position is with respect to one of the display window and the corresponding display window is disabled then cursor will also be disabled.

Offset: 43ch | Read/Write: R/W | Reset: 0bxxxxxxxxxxxxxxxxxxxxxxxxxx

23.8.65 DC_DISP_INIT_SEQ_CONTROL_0

Initialization Sequence Control

Class: Initialization Sequence (IS)

Display initialization sequence may have to be written to the display if the display has built-in frame buffer. This initialization sequence is used typically to reinitialize the display buffer start address and maybe needed once per frame (frame initialization sequence) and/or once per line (line initialization sequence).

Frame initialization sequence is sent during the horizontal active time of the line just before the first active display line. Line initialization sequence is currently NOT supported.

Initialization sequence can be done through parallel LCD interface or through SPI serial interface. Software is responsible in making sure that the active line time is sufficient to send initialization sequence.

For parallel interface initialization, the signals used as chip selects (typically these are one of the vertical signals) must be programmed to be active one line just before the first active display line.

Also SC0/SC1 clock divider must be programmed to divide by 1 if initialization sequence is enabled.

Offset: 442h | Read/Write: R/W | Reset: 0bxxxxxxxxxx00

Bit	Reset	Description
11:8	X	FRAME_INIT_SEQ_CYCLES: Frame Initialization Sequence Cycles. This parameter specifies the number of frame initialization sequence cycles to send. If programmed to 0, there is no frame initialization cycle generated.
7	X	INIT_SEQ_DC_CONTROL: Initialization Sequence DC Pin. This bit is used only for the parallel initialization sequence, and it controls how data/command is added to the vertical signal selected by -=PS_=-INIT_SEQ_DC_SIGNAL 0= parallel IS DC is inverted and then AND-ed to the vertical signal 1= parallel IS DC is ORed to the vertical signal
6:4	X	INIT_SEQ_DC_SIGNAL: Frame Initialization Sequence DC Pin. This parameter is used only for parallel initialization sequence and it specifies which signal carries the data/command signal. 0= parallel IS DC signal is not needed 1= parallel IS DC on Vertical Sync 2= parallel IS DC on Vertical Pulse 0 3= parallel IS DC on Vertical Pulse 1 4= parallel IS DC on Vertical Pulse 2 5= parallel IS DC on Vertical Pulse 3 other= reserved 0 = NODC 1 = VSYNC 2 = VPULSE0 3 = VPULSE1 4 = VPULSE2 5 = VPULSE3

Bit	Reset	Description
1	0x0	INIT_SEQUENCE_MODE: Initialization Sequence Mode 0= Send init sequence through parallel LCD interface 1= Send init sequence through SPI serial interface 0 = PLCD_INIT 1 = SPI_INIT
0	0x0	SEND_INIT_SEQUENCE: Send Initialization Sequence (IS) 0 = DISABLE 1 = ENABLE

23.8.66 DC_DISP_SPI_INIT_SEQ_DATA_A_0

SPI Init Sequence Write Data A

For parallel initialization sequence there are two possible data widths: 9 bits or 18 bits.

If parallel IS is selected, the number of bits per cycle depend on the DISP_DATA_FORMAT register programming. 18-bit parallel IS cycles are performed for 1-pixel/1-clock parallel interface (DF1P1C). 9-bit parallel IS cycles are performed for non 1-pixel/1-clock parallel interface.

Parallel IS cycles must be completed prior to the end of horizontal active of the line where IS cycles are sent. If all the cycles have been completed prior to the end of horizontal active, control signals are held inactive and last output data is held till end of horizontal active. For 9-bit parallel initialization sequence, the data is output in either LCD_D[8:0] pins or LCD_D[17:9] pins depending on display data alignment.

For serial initialization sequence using SPI (IS SPI) there are six possible data widths: 8 bits, 9 bits, 12 bits, 16 bits, 16 bits data plus start byte (24 bits), 18 bits, or 24 bits. Parameters in SPI_CONTROL register and SPI_START_BYTE register is also used for serial initialization sequence using SPI.

Serial IS cycles must also be completed prior to the end of horizontal active of the line where initialization cycles are sent. The programmer needs to make sure that register programming is such that this is true. If all the cycles have been completed prior to the end of horizontal active, SPI signals will be forced inactive until the next SPI cycles.

The following shows how initialization sequence data bits are used when sending initialization sequence:

For 9-bit parallel initialization - up to 10 initialization cycles can be done:

Init cycle	1	2	3	4	5	6	7	8	9	10
Data	8-0	17-9	26-18	35-27	44-36	53-45	62-54	71-63	80-72	89-81
LCD_PCLK enable	90	93	96	99	102	105	108	111	114	117
LCD_WR_N enable	91	94	97	100	103	106	109	112	115	118
data/command	92	95	98	101	104	107	110	113	116	119

For 18-bit parallel initialization - up to 6 initialization cycles can be done:

Init cycle	1	2	3	4	5	6
Data	17-0	35-18	53-36	71-54	89-72	107-90
LCD_PCLK enable	108	111	114	117	120	123
LCD_WR_N enable	109	112	115	118	121	124
data/command	110	113	116	119	122	125

For serial initialization using SPI, main display SPI chip select (Main SCS_) is always output on LCS_ pin while sub display SPI chip select (Sub SCS_) can be optionally output on several pins (see pin output select definition).

Initialization cycle through SPI interface can only be sent to either main or sub display but not to both and the selection bits are specified in the tables below.

Note that 0 indicates main display initialization and 1 indicates sub display initialization.

For 8-bit SPI initialization - up to 12 initialization cycles can be done:

Init cycle	1	2	3	4	5	6	7	8	9	10	11	12
Data	7-0	15-8	23-16	31-24	39-32	47-40	55-48	63-56	71-64	79-72	87-80	95-88
Main/Sub SCS_	96	98	100	102	104	106	108	110	112	114	116	118
SDC	97	99	101	103	105	107	109	111	113	115	117	119

For 12-bit SPI initialization - up to 9 initialization cycles can be done:

Init cycle	1	2	3	4	5	6	7	8	9
Data	11-0	23-12	35-24	47-36	59-48	71-60	83-72	95-84	107-96
Main/Sub SCS_	109	111	113	115	117	119	121	123	125
LCD_DC0	110	112	114	116	118	120	122	124	126

For 16-bit SPI initialization - up to 7 initialization cycles can be done:

Init cycle	1	2	3	4	5	6	7
Data	15-0	31-16	47-32	63-48	79-64	95-80	111-96
Main/Sub SCS_	112	114	116	118	120	122	124
SDC	113	115	117	119	121	123	125

For 18-bit SPI initialization - up to 6 initialization cycles can be done:

Init cycle	1	2	3	4	5	6
Data	17-0	35-18	53-36	71-54	89-72	107-90
Main/Sub SCS_	108	110	112	114	116	118
SDC	109	111	113	115	117	119

For 24-bit SPI initialization - up to 4 initialization cycles can be done:

Init cycle	1	2	3	4
Data	23-0	47-24	71-48	95-72
Main/Sub SCS_	96	98	100	102
SDC	97	99	101	103

23.8.70 DC_DISP_DC_MCCIF_FIFOCTRL_0

Memory Client Interface FIFO Control Register

Note: The FIFO timing aspects of this register are no longer supported, but retained for software compatibility. The clockenable fields of this register control the 2nd level clock gating for the MC side of the MCCIF.

A '1' written to the override field will result in that clock reverting to the legacy mode of operation (where the msc*clk is on whenever the client clk is enabled).

Offset: 480h | Read/Write: R/W | Reset: 0b00xxxxxxxxxxxx0000

23.8.76 DC_DISP_DISP_MISC_CONTROL_0

Miscellaneous controls.

Offset: 4c1h | Read/Write: R/W | Reset: 0b10

Bit	Reset	Description
1	0x1	UF_LINE_FLUSH: Enable underflow line flush, as opposed to end-of-frame flush. underflow line flush 0 = DISABLE 1 = ENABLE
0	0x0	PHASE_SHIFT_2P1C18B: Enable phase shift for 2P1C format phase shift SC0/SC1 will be delayed for one pixel clock cycle. In 2P1C format, data will hold for 2 pixel clocks, so either choice should work 0 = DISABLE 1 = ENABLE

23.9 Window A (WINC_A) Registers

These registers control window A parameters.

> **Note:** There are three copies of these registers for window A, B, and C. Window A, B, and C support different features

Window A: color palette, digital vibrance

Window B: color palette, digital vibrance, color space conversion, horizontal/vertical filtering

Window C: color palette, digital vibrance, color space conversion, horizontal filtering. The registers under DC_WINC are usually not shadowed.

23.9.1 DC_WINC_A_COLOR_PALETTE_0

This is used for palletized data format (color depth of 8-bpp or less) or for gamma correction for non-palletized data formats (color depth of more than 8-bpp).

Each window has its own color palette which consists of three 256x8 register file which can be written by host and indexed (read) by the window.

For palletized data format less than 8-bpp, the pixel data is aligned to least significant bits of the palette index (address) and the remaining upper bits are filled with the corresponding bits of the Palette Color Extension. For example, for 4-bpp mode, the pixel data occupies bits 3-0 of the palette index and bits 7-4 of the palette index are set to bits 7-4 of the Palette Color Extension.

Note that host read is assumed to be not needed - software can cache the color palette in system memory.

This is an array of 256 identical register entries; the register fields below apply to each entry.

Window A Color Palette

Offset: 500h..5ffh | Read/Write: WO | Reset: 0bxxxxxxxxxxxxxxxxxxxxxxxx

Bit	Reset	Description
23:16	X	A_COLOR_PALETTE_B: Blue Color Palette
15:8	X	A_COLOR_PALETTE_G: Green Color Palette
7:0	X	A_COLOR_PALETTE_R: Red Color Palette

23.9.2 DC_WINC_A_PALETTE_COLOR_EXT_0

Palette extension for 1-bpp, 2-bpp, and 4-bpp. These bits provide the upper most significant bits for indexing the color palette. Supported for window A only.

Window A Palette Color Extension

Offset: 600h | Read/Write: R/W | Reset: 0bxxxxxxx

Bit	Reset	Description
7:1	X	A_PALETTE_COLOR_EXT: Window A Palette Color Extension. Bits 7-1 are used for 1-bpp mode. Bits 7-2 are used for 2-bpp mode. Bits 7-4 are used for 4-bpp mode.

Horizontal Scaling Filter Coefficients

Horizontal scaling filter is a 6-tap filter with 4-bit positional phase.

- Coefficients 0 and 5 are 3-bit signed value ranging from -4 to 3.
- Coefficients 1 and 4 are 5-bit signed value ranging from -16 to 15.
- Coefficients 2 and 3 are 8-bit unsigned value ranging from 0 to 128.
- Coefficient 0 is the multiplier for the earliest pixel (P0) in the group of 6-pixel and
- Coefficient 5 is the multiplier for the latest pixel (P5) in the group. The output pixel positional phase is defined as centered in P2 if the positional phase is 0 or proportionally in between P2 and P3 if the positional phase is larger than 0.

Sum of all coefficients for each phase should be 128 typically and software should never program the sum of all coefficients for a phase to be more than 128.

For each horizontal positional phase, the 6 filter coefficients require 32 register bits.

Note that color value ranges from 0 to 255 for Y, R, G, B and -128 to 127 for U and V.

Color Space Conversion coefficients

The CSC can be used for YUV to RGB conversion with brightness and hue/saturation control. The CSC can only be enabled for window A controlled by CSC_ENABLE register bits.

For Y color, the Y offset is applied first and saturation (clipping) is performed immediately after the Y offset is applied.

R = sat(KYRGB * sat(Y + YOF) + KUR * U + KVR * V)

G = sat(KYRGB * sat(Y + YOF) + KUG * U + KVG * V)

B = sat(KYRGB * sat(Y + YOF) + KUB * U + KVB * V)

Saturation and rounding is performed in the range of 0 to 255 for the above equations.

Typical values are:

YOF = -16.000, KYRGB = 1.1644

KUR = 0.0000, KVR = 1.5960

KUG = -0.3918, KVG = -0.8130

KUB = 2.0172, KVB = 0.0000

KUR and KVB are typically 0.0000 but they may be programmed non-zero for hue rotation.

The CSC can also take RGB input, in which case YOF, KVB, KUG, KUR should be programmed to 0 and KYRGB will be forced to 0 by the hardware for generating R and B. KYRGB will not be forced to 0 for generating G. KVR, KYRGB, and KUB can be programmed to 1.0 or used as gain control for R, G, B, correspondingly.

Note that color value ranges from 0 to 255 for Y, R, G, B and -128 to 127 for U and V.

Vertical scaling filter coefficients

Vertical scaling filter is a 2-tap filter with 4-bit positional phase. Coefficients 0 and 1 are 8-bit unsigned value ranging from 0 to 128.

Coefficient 0 is the multiplier for the earlier pixel (P0) in the group of 2-pixel and coefficient 1 is the multiplier for the later pixel (P1) in the group. The output pixel positional phase is defined as centered in P0 if the positional phase is 0 or proportionally in between P0 and P1 if the positional phase is larger than 0.

Sum of all coefficients for each phase should be 128 typically therefore coefficient 1 can be calculated from (1 - coefficient 0) and therefore only coefficient 0 is programmed. For each vertical positional phase, the filter coefficient requires 8 reg bits. Note that color value ranges from 0 to 255 for Y, R, G, B and -128 to 127 for U and V.

The registers under DC_WIN are double buffered.

23.9.3 DC_WIN_A_WIN_OPTIONS_0

Window A Options

Class: Display Window Settings

Display Window A parameters

Offset: 700h | Read/Write: R/W | Reset: 0b0xxxxxxxxxxxxx0xxxxxxxxxxxxxxx

Bit	Reset	Description
30	0x0	A_WIN_ENABLE: Window A Window enable 0 = DISABLE 1 = ENABLE
20	X	A_DV_ENABLE: Window A Digital Vibrance Enable 0 = DISABLE 1 = ENABLE
16	0x0	A_CP_ENABLE: Window A Color Palette Enable. This controls the color palette and should be enabled for palletized color modes. For non-palletized color modes, the color palette can be enabled for gamma correction. 0 = DISABLE 1 = ENABLE
6	X	A_COLOR_EXPAND: Window A 12/15/16/18-to-24 bpp color expansion. This bit should be enabled only for 12-bpp B4G4R4A4, 15-bpp B5G5R5A, 16-bpp B5G6R5, 18-bpp B6G6R6 color modes. If enabled the color conversion is performed prior to horizontal scaling. 0 = DISABLE 1 = ENABLE
2	X	A_V_DIRECTION: Window A Vertical (Y) drawing Direction 0 = INCREMENT 1 = DECREMENT
0	X	A_H_DIRECTION: Window A Horizontal (X) drawing Direction 0 = INCREMENT 1 = DECREMENT

23.9.4 DC_WIN_A_BYTE_SWAP_0

Window A Byte Swap

Offset: 701h | Read/Write: R/W | Reset: 0bxx

Bit	Reset	Description
1:0	X	A_BYTE_SWAP: Window A Byte Swap. This controls byte swap of frame data read from memory prior to any data processing in the display module. 00= no byte swap (3 2 1 0) 01= byte swap for each 2-byte word (2 3 0 1) 10= byte swap for each 4-byte word (0 1 2 3) 11= word swap for each 4-byte word (1 0 3 2) 0 = NOSWAP 1 = SWAP2 2 = SWAP4 3 = SWAP4HW

23.9.5 DC_WIN_A_BUFFER_CONTROL_0

Window A Buffer Control

Offset: 702h | Read/Write: R/W | Reset: 0b000

Bit	Reset	Description
2:0	0x0	A_BUFFER_CONTROL: Window A Buffer Control 0= Host (software) controlled 1= Video Input controlled 2= Encoder Pre-Processor controlled 3= MPEG Encoder controlled 4= StretchBLT or 2D other= reserved If window buffer selection is not controlled by the host (software), then buffer start indexes are sent by the respective module specified by this parameter, and in this case, the buffer start address registers are used to specify frame stride and buffer offset for the calculated start address. 0 = HOST 1 = VI 4 = SB2D 3 = MPEGE

23.9.6 DC_WIN_A_COLOR_DEPTH_0

Window A Color Depth. For YCbCr data format, Cb and Cr are 8-bit unsigned values. For YUV data format, U and V are 8-bit signed values.

YCbCr422R is similar to YCbCr422P but the Cb and Cr are shared vertically.

YUV422R is similar to YUV422P but the U and V are shared vertically.

YCbCr422RA is the same as YCbCr422R in memory and YUV422RA is the same as YUV422R in memory but while reading from memory, for YCbCr422RA and YUV422RA, chroma averaging is applied for each pixel pair so that they can be processed as YUV422 by the display pipeline.

For YCbCr422R and YUV422R, every other chroma pixels are not used (discarded) by the display pipeline. B6x2G6x2R6x2A8 is similar to B8G8R6A8 but with the 2 LSBs zeroed out.

R6x2G6x2B6x2A8 is similar to R8G8B6A8 but with the 2 LSBs zeroed out.

Offset: 703h | Read/Write: R/W | Reset: 0bxxxxx

Bit	Reset	Description
4:0	X	A_COLOR_DEPTH: Window A Color Depth Supported color depths are: P1 = 1-bpp (palletized), P2 = 2-bpp (palletized), P4 = 4-bpp (palletized), P8 = 8-bpp (palletized), B4G4R4A4 = 12-bpp B4G4R4 B5G5R5A = 15-bpp B5G5R5 AB5G5R5 = 15-bpp B5G5R5 B5G6R5 = 16-bpp B5G6R5 B8G8R8A8 = 32-bpp B8G8R8A8 R8G8B8A8 = 32-bpp R8G8B8A8 B6x2G6x2R6x2A8 = 32-bpp B6G6R6A8 R6x2G6x2B6x2A8 = 32-bpp R6G6B6A8 0 = P1 1 = P2 2 = P4 3 = P8 4 = B4G4R4A4 5 = B5G5R5A 6 = B5G6R5 7 = AB5G5R5 12 = B8G8R8A8 13 = R8G8B8A8 14 = B6x2G6x2R6x2A8 15 = R6x2G6x2B6x2A8 16 = YCbCr422 17 = YUV422 18 = YCbCr420P 19 = YUV420P 20 = YCbCr422P 21 = YUV422P 22 = YCbCr422R 23 = YUV422R 24 = YCbCr422RA 25 = YUV422RA

23.9.7 DC_WIN_A_POSITION_0

Window A Position

This register defines H position and size of Window A after scaling (if there is any)

Offset: 704h | Read/Write: R/W | Reset: 0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx

Bit	Reset	Description
28:16	X	A_V_POSITION: Window A V Position. This is specified with respect to the top edge of active display area.
12:0	X	A_H_POSITION: Window A H Position. This is specified with respect to the left edge of active display area.

23.9.8 DC_WIN_A_SIZE_0

Window A Size

This register defines the V position and size of Window A after scaling (if there is any)

Note: programming on window size should guarantee the whole window is inside the active area, otherwise extra rows/columns will be fetched and discarded which affects performance.

Offset: 705h | Read/Write: R/W | Reset: 0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx

Bit	Reset	Description
28:16	X	A_V_SIZE: Window A V Size (lines). This is the vertical size after scaling.
12:0	X	A_H_SIZE: Window A H Size (pixels). This is the horizontal size after scaling.

23.9.9 DC_WIN_A_PRESCALED_SIZE_0

Window A Pre-scaled Size

This register defines Window A pre-scaled size.

The H pre-scaled size is needed to determine how many bytes to fetch from memory per line and this parameter must be programmed exactly as needed taking into account the scaling factor. For planar YUV or YCbCr data formats, this parameter refer to the H pre-scaled of the Y plane.

The total number of lines to be fetched from memory is determined by post-scale V size but V pre-scaled size is needed to 'clamp' the last valid line if the vertical DDA is exactly or slightly beyond the specified V pre-scaled size.

Design Note: H pre-scaled size ideally should be in terms of pixel but then hardware needs to convert this precisely to bytes to determine the amount of data to request from memory.

This could be a risky calculation - maybe this should be made optional on whether we use internal hardware to calculate or left it to software to calculate.

Offset: 706h | Read/Write: R/W | Reset: 0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx

Bit	Reset	Description
28:16	X	A_V_PRESCALED_SIZE: Window A V Pre-scaled Size (lines). In 420P/422R/422RA formats, it must be even.
14:0	X	A_H_PRESCALED_SIZE: Window A H Pre-scaled Size (bytes). In 420P and 422P formats, it must be even.

23.9.10 DC_WIN_A_H_INITIAL_DDA_0

Window A H Initial DDA

Design Note: the first pixel of pre-scaled image is always used to output the first pixel so essentially this is the same as forcing the H Initial DDA integer portion to 1 initially even though user typically programs this to 0. If it makes the implementation easier, it is possible to force software to program the Initial DDA integer portion to 1. Similarly with the V Initial DDA.

Offset: 707h | Read/Write: R/W | Reset: 0bxxxxxxxxxxxxxxxx

Bit	Reset	Description
15:0	X	A_H_INITIAL_DDA: Window A H Initial DDA (4.12). This is typically programmed to 0.0

23.9.11 DC_WIN_A_V_INITIAL_DDA_0

Window A V Initial DDA

Offset: 708h | Read/Write: R/W | Reset: 0bxxxxxxxxxxxxxxxx

Bit	Reset	Description
15:0	X	A_V_INITIAL_DDA: Window A V Initial DDA (4.12). This is typically programmed to 0.0 for both non-interlaced and interlaced sources.

23.9.12 DC_WIN_A_DDA_INCREMENT_0

Window A DDA Increment

DDA increment is typically calculated by dividing (Pre-scaled size in pixels - 1) by (Post-scaled size in pixels - 1). The result should be rounded up and expressed as 4.12 format (4-bit integer and 12-bit fraction). For non-filtered image this value can be slightly larger so that it is not missing the last row/column. Reference programming values (H and V should be calculated separately depending on filter on/off and sizes):

- Filter on: min(round((prescaled_size_in_pixels - 1) * 0x1000 / (post_scaled_size_in_pixels - 1)), MAX)

- Filter off: min(round(prescaled_size_in_pixels * 0x1000 / (post_scaled_size_in_pixels - 1) - 0.5), MAX)

Where the value of MAX is as follows:

For V_DDA_INCREMENT: 15.0 (0xF000)

For H_DDA_INCREMENT: 4.0 (0x4000) for 4 Bytes/pix formats.

8.0 (0x8000) for 2 Bytes/pix formats.

They are theoretically the biggest values that guarantee not displaying beyond an image boundary. If the DDA increment is less than 1.0 then image will be up-scaled and if the DDA increment is more than 1.0 then image will be down-scaled.

Offset: 709h | Read/Write: R/W | Reset: 0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx

Bit	Reset	Description
31:16	X	A_V_DDA_INCREMENT: Window A Vertical DDA Increment (4.12). This should be set to 1.0 if there is no scaling. Maximum value is 15.0 regardless of the number of bytes per pixel.
15:0	X	A_H_DDA_INCREMENT: Window A Horizontal DDA Increment (4.12). This should be set to 1.0 if there is no scaling. The maximum value for downscaling depends on the number of bytes per pixel. For 4-byte/pixel modes (32-bpp) the maximum value is 4.0 and for all other modes the maximum value is 8.0.

23.9.13 DC_WIN_A_LINE_STRIDE_0

Window A Line Stride

Offset: 70ah | Read/Write: R/W | Reset: 0bxxxxxxxxxxxxxxxx

Bit	Reset	Description
15:0	X	A_LINE_STRIDE: Window A Line Stride. This is stride (in bytes) for all non-planar data formats. If the memory surface is tiled, the stride needs to be a multiple of 16. If H_DIRECTION of window A is set to DECREMENT, the stride also needs to be a multiple of 16. For planar YUV or YCbCr data formats, this is stride (in bytes) for the luma plane with the restriction that it must be multiples of 8 (16 if tiled or in horizontal flipping) For tiled surface this value may affect starting address of a window. Refer to the comment of START_ADDR for detail.

23.9.14 DC_WIN_A_BUF_STRIDE_0

Window A Buffer stride

Offset: 70bh | Read/Write: R/W | Reset: 0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx

Bit	Reset	Description
31:0	X	A_BUF_STRIDE: Window A Buffer stride. Buffer stride is used to calculate the buffer addresses when the window is triggered by non-host modules. Refer to the comment of START_ADDR for programming guide. For YUV planar pixel format, this specifies buffer stride for the Y plane. The value is in bytes.

23.9.15 DC_WIN_A_BUFFER_ADDR_MODE_0

Memory Controller Tiling definitions

Offset: 70dh | Read/Write: R/W | Reset: 0b0

Bit	Reset	Description
0	0x0	A_TILE_MODE: Window A Memory surface tiling mode. For YUV planar pixel format, this specifies tiling mode for the Y plane. 0 = LINEAR 1 = TILED

23.9.16 DC_WIN_A_DV_CONTROL_0

Window A Digital Vibrance Control

If enabled, Digital Vibrance is applied after H and V scaling and after color palette or color space conversion logic but before color keying multiplexer and before cursor multiplexer.

- After DV, new R = R + (2R - G - B) * FR, where FR is fraction from 0 to 7/8
- After DV, new G = G + (2G - R - B) * FG, where FG is fraction from 0 to 7/8
- After DV, new B = B + (2B - R - G) * FB, where FB is fraction from 0 to 7/8

Offset: 70eh | Read/Write: R/W | Reset: 0bxxxxxxxxxxxxxxxxxx

Bit	Reset	Description
18:16	X	A_DV_CONTROL_B: Digital Vibrance control for B

Bit	Reset	Description
10:8	X	A_DV_CONTROL_G: Digital Vibrance control for G
2:0	X	A_DV_CONTROL_R: Digital Vibrance control for R

23.9.17 DC_WIN_A_BLEND_NOKEY_0

Blend Control for this window area where color key is enabled but the pixel color is not within the color key range (color key not match). This is valid for all overlapping condition but only if there is no overlap with other window with higher priority color key enabled and color key not match.

Class: Display Color Keying and Blending

Color keying and blending of the display windows are done prior to cursor blending.

Cursor always goes on top of the blended windows. Blending is controlled independently on each possible overlap area of the display windows. If 3 windows are enabled there are 7 possible overlap area combinations. For every window in each overlap area combination, color key can be disabled or enabled. Also, for every window in each overlap area combination, there is a corresponding window blend control parameter and a window blend weight parameter. The window blend control parameter is always effective but the window blend weight is not always used. The window blend weight can also be derived from pixel alpha value or from the reverse of other overlapping windows weight.

Color keying has the highest priority for display window blending. Color key consists of a range of color which is searched independently for each window. If more than 1 windows color keys are enabled then Window A color key has the highest priority, followed by

Window B color key, and then followed by Window C color key. Two sets of color key range (Color Key 0 and Color Key 1) can be defined and they are shared for all windows. It is possible to use both color key sets for the same window or for two separate windows.

The two sets of color key ranges should not overlap and if they do the overlap colors are treated as if they are part of Color Key 0 and not part of Color Key 1.

Assuming that there is no overlap with other higher priority window with color key not matched, if a window color key is enabled for any overlap condition and the window pixel is not within the color key range (key not match), then the window pixel will not be blended with other overlapping window pixels but it will be weighted. The weight is not dependent on the overlap condition it is controlled by the same set of parameters for all overlapping condition.

Assuming that there is no overlap with other higher priority window with color key not matched, if a window color key is enabled for a particular overlap condition and the window pixel is within the color key range (key match), then the window pixel will be weighted and blended with other overlapping pixels and this is controlled separately for each overlap condition.

Assuming that there is no overlap with other higher priority window with color key not matched, if a window color key is disabled then the window pixel will be blended with other overlapping pixels and this is controlled separately for each overlap condition.

Display Color Key parameters

For B4G4R4A4, B5G6R5A, B5G6R5 mode, color key should be compared prior to color conversion to 24-bpp and unused least significant bits of the pixel are filled with zeros.

For palletized mode, color key is compared prior to color palette and the palletized color is compared against the green color key values/mask.

For YUV mode, U and V are offset by +128 before performing the color key comparison. In all cases, color key is compared prior to horizontal/vertical scaling filter and prior to digital vibrance control.

Both upper and lower values are inclusive.

Offset: 70fh | Read/Write: R/W | Reset: 0bxxxxxxxxxxxxxxxxxxxxxxxx

Bit	Reset	Description
23:16	X	A_BLEND_WEIGHT1_NOKEY: Window blend weight 1 for color key not match areas. This is used only for alpha weight with 1-bit alpha and alpha value of 1.
15:8	X	A_BLEND_WEIGHT0_NOKEY: Window blend weight 0 for color key not match areas. For alpha weight, this is used for 1-bit alpha with value of 0.
0	X	A_BLEND_CONTROL_NOKEY: Window blend control for color key not match areas. 0 = Fix weight using window blend weight 0 for color key not matched. 1 = Alpha weight using the alpha value. This is only valid if the window color format includes an alpha value. For 1-bit alpha value, if the alpha is 0 window blend weight 0 is used and if alpha is 1, window blend weight 1 is used. 0 = FIX_WEIGHT 1 = ALPHA_WEIGHT

23.9.18 DC_WIN_A_BLEND_1WIN_0

Blend Control for this window area where it does not overlap with other windows.

Offset: 710h | Read/Write: R/W | Reset: 0bxxxxxxxxxxxxxxxxxxxxxxxx

Bit	Reset	Description
23:16	X	A_BLEND_WEIGHT1_1WIN: Window blend weight 1 for color key disabled or color key enabled with key matched areas. This is used only for alpha weight with 1-bit alpha and alpha value of 1.
15:8	X	A_BLEND_WEIGHT0_1WIN: Window blend weight 0 for color key disabled or color key enabled with key matched areas. For alpha weight, this is used for 1-bit alpha with value of 0.
2	X	A_BLEND_CONTROL_1WIN: Window blend control in area where it does not overlap with other windows and either color key disabled or color key enabled with key matched. 0 = Fix weight using the window blend weight 0 if color key disabled or color key 0 enabled with key matched, or using the window blend weight 1 if color key 1 enabled with key matched. 1 = Alpha weight using the alpha value. This is only valid if the window color format includes an alpha value. For 1-bit alpha value, if the alpha is 0 window blend weight 0 is used and if alpha is 1, window blend weight 1 is used. 0 = FIX_WEIGHT 1 = ALPHA_WEIGHT
1:0	X	A_CKEY_ENABLE_1WIN: Window color key enable 0 = Color Key 0 and 1 Disable 1 = Color Key 0 Enable 2 = Color Key 1 Enable 3 = Color Key 0 and 1 Enable 0 = NOKEY 1 = CKEY0 2 = CKEY1 3 = CKEY01

23.9.19 DC_WIN_A_BLEND_2WIN_B_0

Blend Control for this window area that overlaps with window B only.

Offset: 711h | Read/Write: R/W | Reset: 0bxxxxxxxxxxxxxxxxxxxxxxxxxx

Bit	Reset	Description
23:16	X	A_BLEND_WEIGHT1_2WIN_B: Window blend weight 1 for color key disabled or color key enabled with key matched areas. This is used only for alpha weight with 1-bit alpha and alpha value of 1.
15:8	X	A_BLEND_WEIGHT0_2WIN_B: Window blend weight 0 for color key disabled or color key enabled with key matched areas. For alpha weight, this is used for 1-bit alpha with value of 0.
3:2	X	A_BLEND_CONTROL_2WIN_B: Window blend control in area where either color key disabled or color key enabled with key matched. 0 = Fix weight using the window blend weight 0 if color key disabled or color key 0 enabled with key matched, or using the window blend weight 1 if color key 1 enabled with key matched. 1 = Alpha weight using the alpha value. This is only valid if the window color format includes an alpha value. For 1-bit alpha value, if the alpha is 0 window blend weight 0 is used and if alpha is 1, window blend weight 1 is used. 2 = Dependent weight, in this case, the window blend weight is 1 - the weights of the other window that overlaps with this window. Only 1 of the overlapping windows may have this setting. 0 = FIX_WEIGHT 1 = ALPHA_WEIGHT 2 = DEPENDENT_WEIGHT
1:0	X	A_CKEY_ENABLE_2WIN_B: Window color key enable 0 = Color Key 0 and 1 Disable 1 = Color Key 0 Enable 2 = Color Key 1 Enable 3 = Color Key 0 and 1 Enable 0 = NOKEY 1 = CKEY0 2 = CKEY1 3 = CKEY01

23.9.20 DC_WIN_A_BLEND_2WIN_C_0

Blend Control for this window area that overlaps with window C only.

Offset: 712h | Read/Write: R/W | Reset: 0bxxxxxxxxxxxxxxxxxxxxxxxxxx

Bit	Reset	Description
23:16	X	A_BLEND_WEIGHT1_2WIN_C: Window blend weight 1 for color key disabled or color key enabled with key matched areas. This is used only for alpha weight with 1-bit alpha and alpha value of 1.
15:8	X	A_BLEND_WEIGHT0_2WIN_C: Window blend weight 0 for color key disabled or color key enabled with key matched areas. For alpha weight, this is used for 1-bit alpha with value of 0.

Bit	Reset	Description
3:2	X	A_BLEND_CONTROL_2WIN_C: Window blend control in area where either color key disabled or color key enabled with key matched. 0 = Fix weight using the window blend weight 0 if color key disabled or color key 0 enabled with key matched, or using the window blend weight 1 if color key 1 enabled with key matched. 1 = Alpha weight using the alpha value. Only valid if the window color format includes an alpha value. For 1-bit alpha value, if the alpha is 0 window blend weight 0 is used and if alpha is 1, window blend weight 1 is used. 2 = Dependent weight, in this case, the window blend weight is 1 - the weights of the other window that overlaps with this window. 1:0	X	A_CKEY_ENABLE_2WIN_C: Window color key enable 0 = Color Key 0 and 1 Disable 1 = Color Key 0 Enable 2 = Color Key 1 Enable 3 = Color Key 0 and 1 Enable 0 = NOKEY 1 = CKEY0 2 = CKEY1 3 = CKEY01

23.9.21 DC_WIN_A_BLEND_3WIN_BC_0

Blend Control for this window area that overlaps with windows B and C only.

Offset: 713h | Read/Write: R/W | Reset: 0bxxxxxxxxxxxxxxxxxxxxxxxxxx

Bit	Reset	Description
23:16	X	A_BLEND_WEIGHT1_3WIN_BC: Window blend weight 1 for color key disabled or color key enabled with key matched areas. This is used only for alpha weight with 1-bit alpha and alpha value of 1.
15:8	X	A_BLEND_WEIGHT0_3WIN_BC: Window blend weight 0 for color key disabled or color key enabled with key matched areas. For alpha weight, this is used for 1-bit alpha with value of 0.
3:2	X	A_BLEND_CONTROL_3WIN_BC: Window blend control in area where either color key disabled or color key enabled with key matched. 0 = Fix weight using the window blend weight 0 if color key disabled or color key 0 enabled with key matched, or using the window blend weight 1 if color key 1 enabled with key matched. 1 = Alpha weight using the alpha value. This is only valid if the window color format includes an alpha value. For 1-bit alpha value, if the alpha is 0 window blend weight 0 is used and if alpha is 1, window blend weight 1 is used. 2 = Dependent weight, in this case, the window blend weight is 1 - the weights of the other window that overlaps with this window. Only 1 of the overlapping windows may have this setting. 0 = FIX_WEIGHT 1 = ALPHA_WEIGHT 2 = DEPENDENT_WEIGHT
1:0	X	A_CKEY_ENABLE_3WIN_BC: Window color key enable 0 = Color Key 0 and 1 Disable 1 = Color Key 0 Enable 2 = Color Key 1 Enable 3 = Color Key 0 and 1 Enable 0 = NOKEY 1 = CKEY0 2 = CKEY1 3 = CKEY01

23.9.22 DC_WIN_A_HP_FETCH_CONTROL_0

Window A High Priority Avoidance Fetch Parameters

This register gives extra information to the Memory Controller Client Interface (MCCIF) about the number of memory words that will be fetched per scan line and about the rate at which those words are consumed. This allows the MCCIF to more accurately arbitrate memory accesses to prevent the use of the High Priority signal. Use of this signal causes all other client accesses to be blocked in preference to the client asserting HP.

This is a state which is sometime necessary for Display as it is an isochronous client and MUST be serviced in a timely manner. However, use of this signal should be avoided if possible. These parameters help the MCCIF avoid the over-use of HP.

Note: HP fetch control is no longer supported by the MCCIF clients. Registers are retained for software compatibility, but are not used by the hardware.

Offset: 714h | Read/Write: R/W | Reset: 0b0xxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx

Bit	Reset	Description
31	0x0	A_FETCH_INFO_ENABLE: Enables the sending of the Window A fetch information. For compatibility with earlier devices, this defaults to DISABLE. 0 = DISABLE : This bit should be enabled only for 12-bpp 1 = ENABLE
30:16	X	A_WORDS_PER_LINE: Window A memory fetch words per scan line. This value is in memory fetch words: Multiples of 16 bytes for Tegra 3 devices. It is computed as follows: A_WORDS_PER_LINE = (A_SIZE.A_H_SIZE * (bytes per pixel) + 15) >> 4 bytes per pixel is determined by the pixel format.
15:0	X	A_CYCLES_PER_WORD: Window A clock cycles per memory fetch word. The value of this field is essentially a measure of the data consumption rate for window A. It is computed as follows: A_CYCLES_PER_WORD = A_DDA_INCREMENT.A_H_DDA_INCREMENT / (bytes per pixel). Note that the format for this value is a fixed-point fractional value with 8 bits of integer precision and 8 bits of fractional precision. In other words, it is an '8.8' number. For example, if there is no scaling of the input image, the DDA increment will be 4096. With 32-bit RGBA pixels there will be 4 bytes per pixel, so CYCLES_PER_WORD will be ... 4096 / 4 = 1024, or 4.0 expressed in the 8.8 format. Any scaling performed on the pixels will change the rate at which pixels are consumed. Scaling up will increase the value of DDA increment and will therefore increase the number of cycles between memory fetches. Conversely, scaling down will decrease the value of DDA increment and memory fetches will occur more frequently.

23.9.23 DC_WIN_A_GLOBAL_ALPHA_0

Window A Global Alpha

When enabled, per pixel alpha values are scaled by GLOBAL_ALPHA before blending: a’ = a * GLOBAL_ALPHA/255. When per pixel alpha is not used in blending, global alpha has no affect.

Note: 1- and 4-bit per pixel alpha are quantized back to 1- and 4-bits, respectively, after scaling. For 1-bit alpha case, finer scaling can be achieved by changing BLEND_WEIGHT* instead.

Offset: 715h | Read/Write: R/W | Reset: 0b0xxxxxxxxxxxxxxx

Bit	Reset	Description
16	DISABLE	A_GLOBAL_ALPHA_ENABLE: When enabled, color palette *must* also be enabled and programmed. 0 = DISABLE 1 = ENABLE

Bit	Reset	Description
7:0	X	A_GLOBAL_ALPHA: Global alpha: 0..255 map to 0.0 – 1.0. I.e., 255 yields no-operation. For power, better to set GLOBAL_ALPHA_ENABLE=DISABLE when GLOBAL_ALPHA=255.

23.10 WINBUF_A Registers

The registers under DC_WINBUF are triple-buffered.

23.10.1 DC_WINBUF_A_START_ADDR_0

Window A Start Address

Overview

START_ADDR, BUF_STRIDE, LINE_STRIDE, ADDR_H_OFFSET, ADDR_V_OFFSET combined, specify the starting address of a window buffer in the memory surface. Generally START_ADDR is programmed with the starting address of the memory surface. H/V_OFFSET specify the address offsets of the pixel at the beginning of the window, with respect to the starting address of the memory surface. (There is an exception to that when memory surface is not well aligned, see 3-ii below.)

Note that "beginning of the window" here means the top-left corner of a window in normal mode, top-right corner in horizontal flipping, bottom-left corner in vertical flipping, and bottom-right in horizontal+vertical flipping.

Starting address calculation

These formulae are same for both tiled or linear mode. However, for linear mode, the addresses calculated are real physical addresses, but for tile mode, these addresses will be translated to the real physical addresses by the memory controller client before used.

- When a window is host triggered, starting address of a window is calculated as follows by HW.
  - non-YUV-planar modes:

    starting-address = START_ADDR + ADDR_V_OFFSET * LINE_STRIDE + ADDR_H_OFFSET
  - YUV-planar modes:

    y-starting-address = START_ADDR + ADDR_V_OFFSET * LINE_STRIDE + ADDR_H_OFFSET

    u-starting-address = START_ADDR_U + ADDR_V_OFFSET * UV_LINE_STRIDE / denom1 + ADDR_H_OFFSET / denom2

    v-starting-address = START_ADDR_V + ADDR_V_OFFSET * UV_LINE_STRIDE / denom1 + ADDR_H_OFFSET / denom2 where denom1/denom2 equal to 1 or 2 depending on the actual planar format, derived natively by HW.
- When a window is non-host triggered, starting address of a window buffer is calculated as below.
  - non-YUV-planar mode:

    starting-address = START_ADDR + BUF_STRIDE * buf_index + ADDR_V_OFFSET * LINE_STRIDE + ADDR_H_OFFSET
  - YUV-planar mode:

    y-starting-address = START_ADDR + BUF_STRIDE * buf_index + ADDR_V_OFFSET * LINE_STRIDE + ADDR_H_OFFSET

    u-starting-address = START_ADDR_U + UV_BUF_STRIDE * buf_index + ADDR_V_OFFSET * UV_LINE_STRIDE / denom1 + ADDR_H_OFFSET / denom2

v-starting-address = START_ADDR_V + UV_BUF_STRIDE * buf_index + ADDR_V_OFFSET * UV_LINE_STRIDE / denom1 + ADDR_H_OFFSET / denom2 where denom1/denom2 equal to 1 or 2 depending on the actual planar format, derived natively by HW.

buf_index is the index transmitted by the triggering module pointing to the first buffer of a frame.

Programming Restrictions

i. For tiled address mode:

Image surface can only aligned to multiples of 256, thus the following restrictions.

- START_ADDR, START_ADDR_U, START_ADDR_V need to be multiples of 256.

- BUF_STRIDE, UV_BUF_STRIDE need to be multiples of 256

- LINE_STRIDE, UV_LINE_STRIDE need to be multiples of 16

- ADDR_H_OFFSET needs to be multiple of 2 in yuv planar format (the last bit is ignored), but with no restrictions on other color formats.

- ADDR_V_OFFSET has no restrictions

ii. For linear address mode:

Image surface can be aligned 2, 4 or 8 bytes, depending on the color formats.

As an additional restriction for display, START_ADDR, START_ADDR_U and START_ADDR_V need to be multiples of 16.

When a surface is not aligned to 16 bytes, program START_ADDR with the memory surface address with its least 4 significant bits zeroed out and add these 4 address bits to the original H_OFFSET. (So the formula in 2-i,ii still hold)

- For all formats:

-- START_ADDR, START_ADDR_U and START_ADDR_V need to be multiples of 16.

- For 16-bpp formats,

-- (START_ADDR+H_OFFSET) need to be multiple of 2. The least significant bit of H_OFFSTE is ignored.

- For 32-bpp formats,

-- (START_ADDR+H_OFFSTE) needs to be multiple of 4. The least two significant bits of H_OFFSTE are ignored.

- For yuv planar formats:

-- BUF_STRIDE, UV_BUF_STRIDE:

BUF_STRIDE[2:1]=UV_BUF_STRIDE[1:0]

or as a stricter constraint: BUF_STRIDE be multiple of 8, UV_BUF_STRIDE be multiple of 4.

-- LINE_STRIDE, UV_LINE_STRIDE:

LINE_STRIDE and UV_LINE_STRIDE need to be at least 16.

LINE_STRIDE needs to be multiple of 8, UV_LINE_STRIDE needs to be multiple of 4.

-- ADDR_H_OFFSET: Needs to be multiple of 2. If needs to point to odd pixel position, program ADDR_H_OFFSET to be the previous position (or the next position if H-flipped) and program H_INITIAL_DDA bit 12 to 1.

-- ADDR_V_OFFSET: Needs to be multiple of 2. If needs to point to odd line number, program ADDR_V_OFFSTE to be the previous line number (or next line number if V-flipped) and program V_INITIAL_DDA bit 12 to 1.

iii. Memory allocation for non-host triggered case:

When a window buffer is not controlled by host (software) then a frame may be stored in multiple buffers. In this case, the buffers must be contiguous in the memory because display will use the same luma or chroma line strides for all lines in the frame. Also buffer wraparound must not occur in the middle of the displayed part of the frame.

The controlling module will send frame start and frame end indicators (flags) to display module to indicate the beginning and end of frame. Buffer start address is latched when frame start flag is active but the actual buffer start address is not switched until frame end flag is active. In the case where one buffer corresponds to one frame then frame start and frame end flag are active every time a buffer index is sent.

Offset: 800h | Read/Write: R/W | Reset: 0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx

Bit	Reset	Description
31:0	X	A_START_ADDR: Window A Start Address. This is a byte address. The LSB is not used for 16-bpp non-planar pixel format and the last 2 LSBs are not used for 32-bpp non-planar pixel format. For YUV planar pixel format, this specifies start address for the Y plane.

23.10.2 DC_WINBUF_A_START_ADDR_NS_0

Window A Shadowed Start Address

Offset: 801h | Read/Write: R/W | Reset: 0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx

Bit	Reset	Description
31:0	X	A_START_ADDR_NS: Window A Shadowed Start Address. This is ARM set shadow of Start Address.

23.10.3 DC_WINBUF_A_ADDR_H_OFFSET_0

Window A Horizontal address offset

Offset: 806h | Read/Write: R/W | Reset: 0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx

Bit	Reset	Description
31:0	X	A_ADDR_H_OFFSET: Window A Horizontal address offset. This is a byte address. The LSB is not used for 16-bpp non-planar pixel format and the last 2 LSBs are not used for 32-bpp non-planar pixel format. For YUV planar pixel format, this specifies horizontal offset of Y plane. The horizontal offsets of U/V plane is derived by HW.

23.10.4 DC_WINBUF_A_ADDR_H_OFFSET_NS_0

Window A Shadowed Horizontal address offset

Offset: 807h | Read/Write: R/W | Reset: 0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx

Bit	Reset	Description
31:0	X	A_ADDR_H_OFFSET_NS: Window A Shadowed Horizontal address offset. This is ARM set shadow of ADDR_H_OFFSET

23.10.5 DC_WINBUF_A_ADDR_V_OFFSET_0

Window A Vertical address offset

Offset: 808h | Read/Write: R/W | Reset: 0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx

Bit	Reset	Description
31:0	X	A_ADDR_V_OFFSET: Window A Vertical address offset. This is a line number. The LSB is not used for 16-bpp non-planar pixel format and the last 2 LSB are not used for 32-bpp non-planar pixel format. For YUV planar pixel format, this specifies vertical offset of Y plane. The vertical offsets of U/V plane is derived by HW.

23.10.6 DC_WINBUF_A_ADDR_V_OFFSET_NS_0

Window A Shadowed Vertical address offset

Offset: 809h | Read/Write: R/W | Reset: 0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx

Bit	Reset	Description
31:0	X	A_ADDR_V_OFFSET_NS: Window A Shadowed Vertical address offset. This is ARM set shadow of ADDR_V_OFFSET

23.10.7 DC_WINBUF_A_UFLOW_STATUS

Window A FIFO Underflow Status Register

Offset: 80ah | Read/Write: R/W | Reset: 0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx

Bit	Reset	Description
30	X	COUNT_OFLOW: Flag bit that indicates that the underflow event counter has overflowed. There were too many events. If COUNT_OFLOW is set, UFLOW_COUNT is meaningless. Cleared on write.
23:0	X	UFLOW_COUNT: Underflow count. This field indicates the number of contiguous groups of output pixels for which there was no data in the FIFO. For example, if the valid from the FIFO is low for 10 consecutive cycles and then goes high, the counter will increment by one. Reset to zero on write.

23.11 Window B (WINC_B) Registers

These registers control window B parameters

23.11.1 DC_WINC_B_COLOR_PALETTE_0

Window B Color Palette

This is used for palletized data format (color depth of 8-bpp or less) or for gamma correction for non-palletized data formats (color depth of more than 8-bpp).

Each window has its own color palette which consists of three 256x8 register file which can be written by host and indexed (read) by the window.

For palletized data format less than 8-bpp the pixel data is aligned to least significant bits of the palette index (address) and the remaining upper bits are filled with the corresponding bits of the Palette Color Extension. For example, for 4-bpp mode, the pixel data occupies bits 3-0 of the palette index and bits 7-4 of the palette index are set to bits 7-4 of the Palette Color Extension.

Note that host read is assumed to be not needed - software can cache the color palette in system memory.

This is an array of 256 identical register entries; the register fields below apply to each entry.

Offset: 500h..5ffh | Read/Write: WO | Reset: 0bxxxxxxxxxxxxxxxxxxxxxxxx

Bit	Reset	Description
23:16	X	B_COLOR_PALETTE_B: Blue Color Palette
15:8	X	B_COLOR_PALETTE_G: Green Color Palette
7:0	X	B_COLOR_PALETTE_R: Red Color Palette

23.11.2 DC_WINC_B_PALETTE_COLOR_EXT_0

Window B Palette Color Extension

Palette extension for 1-bpp, 2-bpp, and 4-bpp. These bits provide the upper most significant bits for indexing the color palette. Supported for window A only.

Offset: 600h | Read/Write: R/W | Reset: 0bxxxxxxx

Bit	Reset	Description
7:1	X	B_PALETTE_COLOR_EXT: Window B Palette Color Extension. Bits 7-1 are used for 1-bpp mode, bits 7-2 are used for 2-bpp mode, and bits 7-4 are used for 4-bpp mode.

23.11.3 DC_WINC_B_H_FILTER_P00_0

Window B Horizontal Filter phase 00

Horizontal scaling filter coefficients

Horizontal scaling filter is a 6-tap filter with 4-bit positional phase.

- Coefficients 0 and 5 are 3-bit signed value ranging from -4 to 3.
- Coefficients 1 and 4 are 5-bit signed value ranging from -16 to 15.
- Coefficients 2 and 3 are 8-bit unsigned value ranging from 0 to 128.

- Coefficient 0 is the multiplier for the earliest pixel (P0) in the group of 6-pixel and coefficient 5 is the multiplier for the latest pixel (P5) in the group. The output pixel positional phase is defined as centered in P2 if the positional phase is 0 or proportionally in between P2 and P3 if the positional phase is larger than 0.

Sum of all coefficients for each phase should be 128 typically, and software should never program the sum of all coefficients for a phase to be more than 128. For each horizontal positional phase, the 6 filter coefficients require 32 register bits. Note that color value ranges from 0 to 255 for Y, R, G, B and -128 to 127 for U and V.

23.11.19 DC_WINC_B_CSC_YOF_0

Window B CSC Y Offset

Color Space Conversion coefficients.

The CSC can be used for YUV to RGB conversion with brightness and hue/saturation control.

The CSC can only be enabled for window B controlled by CSC_ENABLE register bits.

For Y color, the Y offset is applied first and saturation (clipping) is performed immediately after the Y offset is applied.

R = sat(KYRGB * sat(Y + YOF) + KUR * U + KVR * V)

G = sat(KYRGB * sat(Y + YOF) + KUG * U + KVG * V)

B = sat(KYRGB * sat(Y + YOF) + KUB * U + KVB * V)

Saturation and rounding is performed in the range of 0 to 255 for the above equations.

Typical values are:

YOF = -16.000, KYRGB = 1.1644

KUR = 0.0000, KVR = 1.5960

KUG = -0.3918, KVG = -0.8130

KUB = 2.0172, KVB = 0.0000

KUR and KVB are typically 0.0000 but they may be programmed non-zero for hue rotation.

The CSC can also take RGB input, in which case YOF, KVB, KUG, KUR should be programmed to 0 and KYRGB will be forced to 0 by the hardware for generating R and B. KYRGB will not be forced to 0 for generating G. KVR, KYRGB, and KUB can be programmed to 1.0 or used as gain control for R, G, B correspondingly.

Note that color value ranges from 0 to 255 for Y, R, G, B and -128 to 127 for U and V.

23.11.27 DC_WINC_B_V_FILTER_P00_0

Window B Vertical Filter phase 00

Vertical scaling filter coefficients

Vertical scaling filter is a 2-tap filter with 4-bit positional phase.

Coefficients 0 and 1 are 8-bit unsigned value ranging from 0 to 128.

Coefficient 0 is the multiplier for the earlier pixel (P0) in the group of 2-pixel and coefficient 1 is the multiplier for the later pixel (P1) in the group. The output pixel positional phase is defined as centered in P0 if the positional phase is 0 or proportionally in between P0 and P1 if the positional phase is larger than 0.

Sum of all coefficients for each phase should be 128 typically therefore coefficient 1 can be calculated from (1 - coefficient 0) and therefore only coefficient 0 is programmed.

For each vertical positional phase, the filter coefficient requires 8 register bits. Note that color value ranges from 0 to 255 for Y, R, G, B and -128 to 127 for U and V.

12	X	B_V_FILTER_OPTIMIZE: Window B V Filter Optimization. This is effective only when vertical scaling filter is enabled. This can be used (enabled) to temporarily disable the vertical scaling filter when the vertical scaling DDA fraction is zero. In this case the next line is not fetched from memory to save bandwidth and power. This feature cannot be used in 420P/422R/422RA formats. 0 = DISABLE 1 = ENABLE
10	X	B_V_FILTER_ENABLE: Window B V Filter Enable. This controls V scaling filter and is effective only for non-palletized color modes. If V filter is disabled, only one line is read from memory for each output line. 0 = DISABLE 1 = ENABLE
8	X	B_H_FILTER_ENABLE: Window B H Filter Enable. This controls H scaling filter and is effective only for non-palletized color modes. 0 = DISABLE 1 = ENABLE
6	X	B_COLOR_EXPAND: Window B 12/15/16/18-to-24 bpp color expansion. This bit should be enabled only for 12-bpp B4G4R4A4, 15-bpp B5G5R5A, 16-bpp B5G6R5, 18-bpp B6G6R6 color modes. If enabled the color conversion is performed prior to horizontal scaling. 0 = DISABLE 1 = ENABLE
2	X	B_V_DIRECTION: Window B Vertical (Y) drawing Direction 0 = INCREMENT 1 = DECREMENT
0	X	B_H_DIRECTION: Window B Horizontal (X) drawing Direction 0 = INCREMENT 1 = DECREMENT

23.11.44 DC_WIN_B_BYTE_SWAP_0

Window B Byte Swap

Offset: 701h | Read/Write: R/W | Reset: 0bxx

Bit	Reset	Description
1:0	X	B_BYTE_SWAP: Window B Byte Swap. This controls byte swap of frame data read from memory prior to any data processing in the display module. 00= no byte swap (3 2 1 0) 01= byte swap for each 2-byte word (2 3 0 1) 10= byte swap for each 4-byte word (0 1 2 3) 11= word swap for each 4-byte word (1 0 3 2) 0 = NOSWAP 1 = SWAP2 2 = SWAP4 3 = SWAP4HW

23.11.45 DC_WIN_B_BUFFER_CONTROL_0

Window B Buffer Control

Offset: 702h | Read/Write: R/W | Reset: 0b000

Bit	Reset	Description
2:0	0x0	B_BUFFER_CONTROL: Window B Buffer Control 0= Host (software) controlled 1= Video Input controlled 2= Encoder Pre-Processor controlled 3= MPEG Encoder controlled 4= StretchBLT or 2D other= reserved If window buffer selection is not controlled by host (software) then buffer start indexes are sent by the respective module specified by this parameter, and in this case, the buffer start address registers are used to specify frame stride and buffer offset for the calculated start address. 0 = HOST 1 = VI 2 = EPP 4 = SB2D 3 = MPEGE

23.11.46 DC_WIN_B_COLOR_DEPTH_0

Window B Color Depth for YCbCr data format, Cb and Cr are 8-bit unsigned values. For YUV data format, U and V are 8-bit signed values. YCbCr422R is similar to YCbCr422P but the Cb and Cr are shared vertically.

YUV422R is similar to YUV422P but the U and V are shared vertically. YCbCr422RA is same as YCbCr422R in memory and YUV422RA is same as YUV422R in memory but while reading from memory, for YCbCr422RA and YUV422RA, chroma averaging is applied for each pixel pair so that they can be processed as YUV422 by the display pipeline.

For YCbCr422R and YUV422R, every other chroma pixels are not used (discarded) by the display pipeline. B6x2G6x2R6x2A8 is similar to B8G8R6A8 but with the 2 LSBs zeroed out. R6x2G6x2B6x2A8 is similar to R8G8B6A8 but with the 2 LSBs zeroed out.

Offset: 703h | Read/Write: R/W | Reset: 0bxxxxx

Bit	Reset	Description
4:0	X	B_COLOR_DEPTH: Window B Color Depth. Supported color depths are: P8 = 8-bpp (palletized) B4G4R4A4 = 12-bpp B4G4R4 B5G5R5A = 15-bpp B5G5R5 AB5G5R5 = 15-bpp B5G5R5 B5G6R5 = 16-bpp B5G6R5 B8G8R8A8 = 32-bpp B8G8R8A8 R8G8B8A8 = 32-bpp R8G8B8A8 B6x2G6x2R6x2A8 = 32-bpp B6G6R6A8 R6x2G6x2B6x2A8 = 32-bpp R6G6B6A8 YCbCr422 = 16-bpp YCbCr422 packed YUV422 = 16-bpp YUV422 YCbCr420P = 16-bpp YCbCr420 planar YUV420P = 16-bpp YUV420 planar YCbCr422P = 16-bpp YCbCr422 planar YUV422P = 16-bpp YUV422 planar YCbCr422R = 16-bpp YCbCr422 rotated planar YUV422R = 16-bpp YUV422 rotated planar YCbCr422RA= 16-bpp YCbCr422 rotated planar with chroma averaging YUV422RA = 16-bpp YUV422 rotated planar with chroma averaging 0 = P1 1 = P2 2 = P4 3 = P8 4 = B4G4R4A4 5 = B5G5R5A 6 = B5G6R5 7 = AB5G5R5 12 = B8G8R8A8 13 = R8G8B8A8 14 = B6x2G6x2R6x2A8 15 = R6x2G6x2B6x2A8 16 = YCbCr422 17 = YUV422 18 = YCbCr420P 19 = YUV420P 20 = YCbCr422P 21 = YUV422P 22 = YCbCr422R 23 = YUV422R 24 = YCbCr422RA 25 = YUV422RA

23.11.47 DC_WIN_B_POSITION_0

Window B Position

This register defines H position and size of Window B after scaling (if there is any)

Offset: 704h | Read/Write: R/W | Reset: 0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx

Bit	Reset	Description
28:16	X	B_V_POSITION: Window B V Position. This is specified with respect to the top edge of active display area.
12:0	X	B_H_POSITION: Window B H Position. This is specified with respect to the left edge of active display area.

23.11.48 DC_WIN_B_SIZE_0

Window B Size

This register defines V position and size of Window B after scaling (if there is any)

Note: programming on window size should guarantee the whole window is inside the active area, otherwise extra rows/columns will be fetched and discarded which affects performance.

Offset: 705h | Read/Write: R/W | Reset: 0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx

Bit	Reset	Description
28:16	X	B_V_SIZE: Window B V Size (lines). This is the vertical size after scaling.
12:0	X	B_H_SIZE: Window B H Size (pixels). This is the horizontal size after scaling.

23.11.49 DC_WIN_B_PRESCALED_SIZE_0

Window B Pre-scaled Size

This register defines Window B pre-scaled size.

The H pre-scaled size is needed to determine how many bytes to fetch from memory per line and this parameter must be programmed exactly as needed taking into account the scaling factor. For planar YUV or YCbCr data formats, this parameter refer to the H pre-scaled of the Y plane.

The total number of lines to be fetched from memory is determined by post-scale V size but V pre-scaled size is needed to 'clamp' the last valid line if the vertical DDA is exactly or slightly beyond the specified V pre-scaled size.

Design Note: H pre-scaled size ideally should be in terms of pixel but then hardware needs to convert this precisely to bytes to determine the amount of data to request from memory.

This could be a risky calculation - maybe this should be made optional on whether we use internal hardware to calculate or left it to software to calculate.

Offset: 706h | Read/Write: R/W | Reset: 0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx

Bit	Reset	Description
28:16	X	B_V_PRESCALED_SIZE: Window B V Pre-scaled Size (lines). In 420P/422R/422RA formats, it must be even.
14:0	X	B_H_PRESCALED_SIZE: Window B H Pre-scaled Size (bytes). In 420P and 422P formats, it must be even.

23.11.50 DC_WIN_B_H_INITIAL_DDA_0

Window B H Initial DDA

Design Note: the first pixel of pre-scaled image is always used to output the first pixel so essentially this is the same as forcing the H Initial DDA integer portion to 1 initially even though user typically programs this to 0. If it makes the implementation easier, it is possible to force software to program the Initial DDA integer portion to 1. Similar with the V Initial DDA.

Offset: 707h | Read/Write: R/W | Reset: 0bxxxxxxxxxxxxxxxx

Bit	Reset	Description
15:0	X	B_H_INITIAL_DDA: Window B H Initial DDA (4.12). This is typically programmed to 0.0

23.11.51 DC_WIN_B_V_INITIAL_DDA_0

Window B V Initial DDA

Offset: 708h | Read/Write: R/W | Reset: 0bxxxxxxxxxxxxxxxx

Bit	Reset	Description
15:0	X	B_V_INITIAL_DDA: Window B V Initial DDA (4.12). This is typically programmed to 0.0 for both non-interlaced and interlaced sources.

23.11.52 DC_WIN_B_DDA_INCREMENT_0

Window B DDA Increment

DDA increment is typically calculated by dividing (Pre-scaled size in pixels - 1) by (Post-scaled size in pixels - 1). The result should be rounded up and expressed as 4.12 format (4-bit integer and 12-bit fraction). For non-filtered image this value can be slightly larger so that it is not missing the last row/column. Reference programming values (H and V should be calculated separately depending on filter on/off and sizes):

- Filter on: min(round((prescaled_size_in_pixels - 1) * 0x1000 / (post_scaled_size_in_pixels - 1)), MAX)
- Filter off: min(round(prescaled_size_in_pixels * 0x1000 / (post_scaled_size_in_pixels - 1) - 0.5), MAX)

Where the value of MAX is as follows:

For V_DDA_INCREMENT: 15.0 (0xF000)

For H_DDA_INCREMETN: 4.0 (0x4000) for 2 Bytes/pix formats.

8.0 (0x8000) for 4 Bytes/pix formats.

They are theoretically the biggest values that guarantee not displaying beyond an image boundary.

If the DDA increment is less than 1.0 then image will be up-scaled and if DDA increment is more than 1.0 then image will be down-scaled.

Offset: 709h | Read/Write: R/W | Reset: 0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx

Bit	Reset	Description
31:16	X	B_V_DDA_INCREMENT: Window B Vertical DDA Increment (4.12). This should be set to 1.0 if there is no scaling. Maximum value is 15.0 regardless of the number of bytes per pixel.
15:0	X	B_H_DDA_INCREMENT: Window B Horizontal DDA Increment (4.12). This should be set to 1.0 if there is no scaling. The maximum value for downscaling depends on the number of bytes per pixel. For 4-byte/pixel modes (32-bpp) the maximum value is 4.0 and for all other modes the maximum value is 8.0.

23.11.53 DC_WIN_B_LINE_STRIDE_0

Window B Line Stride

Offset: 70ah | Read/Write: R/W | Reset: 0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx

Bit	Reset	Description
31:16	X	B_UV_LINE_STRIDE: Window B Line Stride for Chroma. This is stride (in bytes) for planar YUV or YCbCr data formats for the chroma plane, with the restriction that it must be programmed to be multiples of 4 (16 if tiled or in horizontal flipping) This is not used (ignored) for other non-planar data formats.

Bit	Reset	Description
15:0	X	B_LINE_STRIDE: Window B Line Stride. This is stride (in bytes) for all non-planar data formats. If the memory surface is tiled, the stride needs to be a multiple of 16. If H_DIRECTION of window B is set to DECREMENT, the stride also needs to be a multiple of 16. For planar YUV or YCbCr data formats, this is stride (in bytes) for the luma plane with the restriction that it must be multiples of 8 (16 if tiled or in horizontal flipping) For tiled surface this value may affect starting address of a window. Refer to the comment of START_ADDR for details.

23.11.54 DC_WIN_B_BUF_STRIDE_0

Window B Buffer stride

Offset: 70bh | Read/Write: R/W | Reset: 0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx

Bit	Reset	Description
31:0	X	B_BUF_STRIDE: Window B Buffer stride. Buffer stride is used to calculate the buffer addresses when the window is triggered by non-host modules. Refer to the comment of of START_ADDR for programming guide. For YUV planar pixel format, this specifies buffer stride for the Y plane. The value is in bytes.

23.11.55 DC_WIN_B_UV_BUF_STRIDE_0

Window B Buffer stride for U/V plane

Offset: 70ch | Read/Write: R/W | Reset: 0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx

Bit	Reset	Description
31:0	X	B_UV_BUF_STRIDE: Window B. This value is in bytes. For YUV planar pixel format, this specifies buffer stride for the U/V plane.

23.11.56 DC_WIN_B_BUFFER_ADDR_MODE_0

Memory Controller Tiling definitions

Offset: 70dh | Read/Write: R/W | Reset: 0b0xxxxxxxxxxxxxxx0

Bit	Reset	Description
16	0x0	B_UV_TILE_MODE: Window B Memory surface tiling mode. For YUV planar pixel format, this specifies tiling mode for the U/V plane. 0 = LINEAR 1 = TILED
0	0x0	B_TILE_MODE: Window B Memory surface tiling mode. For YUV planar pixel format, this specifies tiling mode for the Y plane. 0 = LINEAR 1 = TILED

23.11.57 DC_WIN_B_DV_CONTROL_0

Window B Digital Vibrance Control

If enabled, Digital Vibrance is applied after H and V scaling and after color palette or color space conversion logic but before color keying multiplexer and before cursor multiplexer.

- After DV, new R = R + (2R - G - B) * FR, where FR is fraction from 0 to 7/8
- After DV, new G = G + (2G - R - B) * FG, where FG is fraction from 0 to 7/8
- After DV, new B = B + (2B - R - G) * FB, where FB is fraction from 0 to 7/8

Offset: 70eh | Read/Write: R/W | Reset: 0bxxxxxxxxxxxxxxxxxxx

Bit	Reset	Description
18:16	X	B_DV_CONTROL_B: Digital Vibrance control for B
10:8	X	B_DV_CONTROL_G: Digital Vibrance control for G
2:0	X	B_DV_CONTROL_R: Digital Vibrance control for R

23.11.58 DC_WIN_B_BLEND_NOKEY_0

Blend Control for this window area where color key is enabled but the pixel color is not within the color key range (color key not match). This is valid for all overlapping condition but only if there is no overlap with other window with higher priority color key enabled and color key not match.

Class: Display Color Keying and Blending

Color keying and blending of the display windows are done prior to cursor blending.

Cursor always goes on top of the blended windows. Blending is controlled independently on each possible overlap area of the display windows. If 3 windows are enabled there are 7 possible overlap area combinations. For every window in each overlap area combination, color key can be disabled or enabled. Also, for every window in each overlap area combination, there is a corresponding window blend control parameter and a window blend weight parameter. The window blend control parameter is always effective but the window blend weight is not always used. The window blend weight can also be derived from pixel alpha value or from the reverse of other overlapping windows weight.

Color keying has the highest priority for display window blending. Color key consists of a range of color which is searched independently for each window. If more than 1 windows color keys are enabled then Window A color key has the highest priority, followed by Window B color key, and then followed by Window C color key. Two sets of color key range (Color Key 0 and Color Key 1) can be defined and they are shared for all windows. It is possible to use both color key sets for the same window or for two separate windows.

The two sets of color key ranges should not overlap and if they do the overlap colors are treated as if they are part of Color Key 0 and not part of Color Key 1.

Assuming that there is no overlap with other higher priority window with color key not matched, if a window color key is enabled for any overlap condition and the window pixel is not within the color key range (key not match), then the window pixel will not be blended with other overlapping window pixels but it will be weighted. The weight is not dependent on the overlap condition it is controlled by the same set of parameters for all overlapping condition.

Assuming that there is no overlap with other higher priority window with color key not matched, if a window color key is enabled for a particular overlap condition and the window pixel is within the color key range (key match), then the window pixel will be weighted and blended with other overlapping pixels and this is controlled separately for each overlap condition.

Assuming that there is no overlap with other higher priority window with color key not matched, if a window color key is disabled then the window pixel will be blended with other overlapping pixels and this is controlled separately for each overlap condition.

Display Color Key Parameters

For B4G4R4A4, B5G6R5A, B5G6R5 mode, color key should be compared prior to color conversion to 24-bpp and unused least significant bits of the pixel are filled with zeros.

For palletized mode, color key is compared prior to color palette and the palletized color is compared against the green color key values/mask.

For YUV mode, U and V are offset by +128 before performing the color key comparison.

In all cases, color key is compared prior to horizontal/vertical scaling filter and prior to digital vibrance control. Both upper and lower values are inclusive.

Offset: 70fh | Read/Write: R/W | Reset: 0bxxxxxxxxxxxxxxxxxxxxxxxxxx

Bit	Reset	Description
23:16	X	B_BLEND_WEIGHT1_NOKEY: Window blend weight 1 for color key not match areas. This is used only for alpha weight with 1-bit alpha and alpha value of 1.
15:8	X	B_BLEND_WEIGHT0_NOKEY: Window blend weight 0 for color key not match areas. For alpha weight, this is used for 1-bit alpha with value of 0.
0	X	B_BLEND_CONTROL_NOKEY: Window blend control for color key not match areas. 0 = Fix weight using window blend weight 0 for color key not matched. 1 = Alpha weight using the alpha value. This is only valid if the window color format includes an alpha value. For 1-bit alpha value, if the alpha is 0 window blend weight 0 is used and if alpha is 1, window blend weight 1 is used. 0 = FIX_WEIGHT 1 = ALPHA_WEIGHT

23.11.59 DC_WIN_B_BLEND_1WIN_0

Blend Control for this window area where it does not overlap with other windows.

Offset: 710h | Read/Write: R/W | Reset: 0bxxxxxxxxxxxxxxxxxxxxxxxxxx

Bit	Reset	Description
23:16	X	B_BLEND_WEIGHT1_1WIN: Window blend weight 1 for color key disabled or color key enabled with key matched areas. This is used only for alpha weight with 1-bit alpha and alpha value of 1.
15:8	X	B_BLEND_WEIGHT0_1WIN: Window blend weight 0 for color key disabled or color key enabled with key matched areas. For alpha weight, this is used for 1-bit alpha with value of 0.
2	X	B_BLEND_CONTROL_1WIN: Window blend control in area where it does not overlap with other windows and either color key disabled or color key enabled with key matched. 0 = Fix weight using the window blend weight 0 if color key disabled or color key 0 enabled with key matched, or using the window blend weight 1 if color key 1 enabled with key matched. 1 = Alpha weight using the alpha value. This is only valid if the window color format includes an alpha value. For 1-bit alpha value, if the alpha is 0 window blend weight 0 is used and if alpha is 1, window blend weight 1 is used. 0 = FIX_WEIGHT 1 = ALPHA_WEIGHT

23.11.63 DC_WIN_B_HP_FETCH_CONTROL_0

Window B High Priority Avoidance Fetch Parameters

This register gives extra information to the Memory Controller Client Interface (MCCIF) about the number of memory words that will be fetched per scan line and about the rate at which those words are consumed. This allows the MCCIF to more accurately arbitrate memory accesses to prevent the use of the High Priority signal. Use of this signal causes all other client accesses to be blocked in preference to the client asserting HP. Obviously, this is a state which is sometime necessary for Display since it is an isochronous client and MUST be serviced in a timely manner. However, use of this signal should be avoided if possible. These parameters help the MCCIF avoid the over-use of HP.

Note: HP fetch control is no longer supported by the MCCIF clients. Registers are retained for software compatibility, but are not used by the hardware.

Offset: 714h | Read/Write: R/W | Reset: 0b0xxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx

Bit	Reset	Description
31	0x0	B_FETCH_INFO_ENABLE: Enables the sending of the Window B fetch information. For compatibility with earlier devices, this defaults to DISABLE. 0 = DISABLE : This bit should be enabled only for 12-bpp 1 = ENABLE
30:16	X	B_WORDS_PER_LINE: Window B memory fetch words per scan line. This value is in memory fetch words: Multiples of 16 bytes for Tegra 3 devices. It is computed as follows: B_WORDS_PER_LINE = (B_SIZE.B_H_SIZE * (bytes per pixel) + 15) >> 4 bytes per pixel is determined by the pixel format.
15:0	X	B_CYCLES_PER_WORD: Window B clock cycles per memory fetch word. The value of this field is essentially a measure of the data consumption rate for window B. It is computed as follows: B_CYCLES_PER_WORD = B_DDA_INCREMENT.B_H_DDA_INCREMENT / (bytes per pixel). Note that the format for this value is a fixed-point fractional value with 8 bits of integer precision and 8 bits of fractional precision. In other words, it is an '8.8' number. For example, if there is no scaling of the input image, the DDA increment will be 4096. With 32-bit RGBA pixels there will be 4 bytes per pixel, so CYCLES_PER_WORD will be ... 4096 / 4 = 1024, or 4.0 expressed in the 8.8 format. Any scaling performed on the pixels will change the rate at which pixels are consumed. Scaling up will increase the value of DDA increment and will therefore increase the number of cycles between memory fetches. Conversely, scaling down will decrease the value of DDA increment and memory fetches will occur more frequently.

23.11.64 DC_WIN_B_GLOBAL_ALPHA_0

Window B Global Alpha

When enabled, per pixel alpha values are scaled by GLOBAL_ALPHA before blending: a' = a * GLOBAL_ALPHA/255. When per pixel alpha is not used in blending, global alpha has no affect.

Note: 1- and 4-bit per pixel alpha are quantized back to 1- and 4-bits, respectively, after scaling. For 1-bit alpha case, finer scaling can be achieved by changing BLEND_WEIGHT* instead.

Offset: 715h | Read/Write: R/W | Reset: 0b0xxxxxxxxxxxxxxx

Bit	Reset	Description
16	DISABLE	B_GLOBAL_ALPHA_ENABLE: When enabled, the color palette *must* also be enabled and programmed. 0 = DISABLE 1 = ENABLE
7:0	X	B_GLOBAL_ALPHA: Global alpha: 0..255 map to 0.0 – 1.0. I.e., 255 yields no-operation. For power, better to set GLOBAL_ALPHA_ENABLE=DISABLE when GLOBAL_ALPHA=255.

23.12 WINBUF_B Registers

The registers under DC_WINBUF are triple-buffered.

23.12.1 DC_WINBUF_B_START_ADDR_0

Window B Start Address

Overview

START_ADDR, BUF_STRIDE, LINE_STRIDE, ADDR_H_OFFSET, ADDR_V_OFFSET combined, specify the starting address of a window buffer in the memory surface. Generally START_ADDR is programmed with the starting address of the memory surface. H/V_OFFSET specify the address offsets of the pixel at the beginning of the window, with respect to the starting address of the memory surface. (There is an exception to that when memory surface is not well aligned, see 3-ii below.)

Note that "beginning of the window" here means the top-left corner of a window in normal mode, top-right corner in horizontal flipping, bottom-left corner in vertical flipping, and bottom-right in horizontal+vertical flipping.

Starting Address Calculation

These formulae are same for both tiled or linear mode. However, for linear mode, the addresses calculated are real physical addresses, but for tile mode, these addresses will be translated to the real physical addresses by the memory controller client before used.

- When a window is host triggered, starting address of a window is calculated as follows by HW.
  - non-YUV-planar modes:

    starting-address = START_ADDR + ADDR_V_OFFSET * LINE_STRIDE + ADDR_H_OFFSET
  - YUV-planar modes:

    y-starting-address = START_ADDR + ADDR_V_OFFSET * LINE_STRIDE + ADDR_H_OFFSET

    u-starting-address = START_ADDR_U + ADDR_V_OFFSET * UV_LINE_STRIDE / denom1 + ADDR_H_OFFSET / denom2

    v-starting-address = START_ADDR_V + ADDR_V_OFFSET * UV_LINE_STRIDE / denom1 + ADDR_H_OFFSET / denom2 where denom1/denom2 equal to 1 or 2 depending on the actual planar format, derived natively by HW.
- When a window is non-host triggered, starting address of a window buffer is calculated as below.
  - non-YUV-planar mode:

    starting-address = START_ADDR + BUF_STRIDE * buf_index + ADDR_V_OFFSET * LINE_STRIDE + ADDR_H_OFFSET
  - YUV-planar mode:

    y-starting-address = START_ADDR + BUF_STRIDE * buf_index + ADDR_V_OFFSET * LINE_STRIDE + ADDR_H_OFFSET

    u-starting-address = START_ADDR_U + UV_BUF_STRIDE * buf_index + ADDR_V_OFFSET * UV_LINE_STRIDE / denom1 + ADDR_H_OFFSET / denom2

    v-starting-address = START_ADDR_V + UV_BUF_STRIDE * buf_index + ADDR_V_OFFSET * UV_LINE_STRIDE / denom1 + ADDR_H_OFFSET / denom2 where denom1/denom2 equal to 1 or 2 depending on the actual planar format, derived natively by HW.

    buf_index is the index transmitted by the triggering module pointing to the first buffer of a frame.

Programming Restrictions

- For tiled address mode:

  Image surface can only aligned to multiples of 256, thus the following restrictions.

  - START_ADDR, START_ADDR_U, START_ADDR_V need to be multiples of 256.
  - BUF_STRIDE, UV_BUF_STRIDE need to be multiples of 256
  - LINE_STRIDE, UV_LINE_STRIDE need to be multiples of 16
  - ADDR_H_OFFSET needs to be multiple of 2 in yuv planar format (the last bit is ignored), but with no restrictions on other color formats.
  - ADDR_V_OFFSET has no restrictions

- For linear address mode:

  Image surface can be aligned 2, 4 or 8 bytes, depending on the color formats.

  As an additional restriction for display, START_ADDR, START_ADDR_U and START_ADDR_V need to be multiples of 16.

  When a surface is not aligned to 16 bytes, program START_ADDR with the memory surface address with its least 4 significant bits zeroed out and add these 4 address bits to the original H_OFFSET. (So the formula in 2-i,ii still hold)

  - For all formats:

    START_ADDR, START_ADDR_U and START_ADDR_V need to be multiples of 16.
  - For 16-bpp formats,

    (START_ADDR+H_OFFSET) need to be multiple of 2. The least significant bit of H_OFFSTE is ignored.
  - For 32-bpp formats,

    (START_ADDR+H_OFFSTE) needs to be multiple of 4. The least two significant bits of H_OFFSTE are ignored.
  - For yuv planar formats:

    BUF_STRIDE, UV_BUF_STRIDE:

    BUF_STRIDE[2:1]=UV_BUF_STRIDE[1:0]

    or as a stricter constraint: BUF_STRIDE be multiple of 8, UV_BUF_STRIDE be multiple of 4.

    LINE_STRIDE, UV_LINE_STRIDE:

    LINE_STRIDE and UV_LINE_STRIDE need to be at least 16.

    LINE_STRIDE needs to be multiple of 8, UV_LINE_STRIDE needs to be multiple of 4.

    ADDR_H_OFFSET:

    Needs to be multiple of 2. If needs to point to odd pixel position, program ADDR_H_OFFSET to be the previous position (or the next position if H-flipped) and program H_INITIAL_DDA bit 12 to 1.

    ADDR_V_OFFSET:

    Needs to be multiple of 2. If needs to point to odd line number, program ADDR_V_OFFSTE to be the previous line number (or next line number if V-flipped) and program V_INITIAL_DDA bit 12 to 1.

- Memory allocation for non-host triggered case

  When a window buffer is not controlled by host (software) then a frame may be stored in multiple buffers. In this case, the buffers must be contiguous in the memory because display will use the same luma or chroma line strides for all lines in the frame.

  Also buffer wraparound must not occur in the middle of the displayed part of the frame. The controlling module will send frame start and frame end indicators (flags) to display module to indicate the beginning and end of frame. Buffer start address is latched when frame start flag is active but the actual buffer start address is not switched until frame end flag is active. In the case where one buffer corresponds to one frame, the frame start and frame end flag are active every time a buffer index is sent.

Offset: 800h | Read/Write: R/W | Reset: 0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx

Bit	Reset	Description
31:0	X	B_START_ADDR: Window B Start Address. This is a byte address. The LSB is not used for 16-bpp non-planar pixel format and the last 2 LSB are not used for 32-bpp non-planar pixel format. For YUV planar pixel format, this specifies start address for the Y plane.

23.12.2 DC_WINBUF_B_START_ADDR_NS_0

Window B Shadowed Start Address

Offset: 801h | Read/Write: R/W | Reset: 0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx

Bit	Reset	Description
31:0	X	B_START_ADDR_NS: Window B Shadowed Start Address. This is ARM set shadow of Start Address.

23.12.3 DC_WINBUF_B_START_ADDR_U_0

Window B Start Address for U plane

Offset: 802h | Read/Write: R/W | Reset: 0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx

Bit	Reset	Description
31:0	X	B_START_ADDR_U: Window B Start Address for U plane. This is a byte address.

23.12.4 DC_WINBUF_B_START_ADDR_U_NS_0

Window B Shadowed Start Address for U plane

Offset: 803h | Read/Write: R/W | Reset: 0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx

Bit	Reset	Description
31:0	X	B_START_ADDR_U_NS: Window B Shadowed Start Address for U plane. This is ARM set shadow register of U start address

23.12.5 DC_WINBUF_B_START_ADDR_V_0

Window B Start Address for V plane

Offset: 804h | Read/Write: R/W | Reset: 0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx

Bit	Reset	Description
31:0	X	B_START_ADDR_V: Window B Start Address for V plane. This is a byte address.

23.12.6 DC_WINBUF_B_START_ADDR_V_NS_0

Window B Shadowed Start Address for V plane

Offset: 805h | Read/Write: R/W | Reset: 0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx

Bit	Reset	Description
31:0	X	B_START_ADDR_V_NS: Window B Shadowed Start Address for V plane This is ARM set shadow register of U start address

23.12.7 DC_WINBUF_B_ADDR_H_OFFSET_0

Window B Horizontal address offset

Offset: 806h | Read/Write: R/W | Reset: 0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx

Bit	Reset	Description
31:0	X	B_ADDR_H_OFFSET: Window B Horizontal address offset. This is a byte address. The LSB is not used for 16-bpp non-planar pixel format and the last 2 LSB are not used for 32-bpp non-planar pixel format. For YUV planar pixel format, this specifies horizontal offset of Y plane. The horizontal offsets of U/V plane is derived by HW.

23.12.8 DC_WINBUF_B_ADDR_H_OFFSET_NS_0

Window B Shadowed Horizontal address offset

Offset: 807h | Read/Write: R/W | Reset: 0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx

Bit	Reset	Description
31:0	X	B_ADDR_H_OFFSET_NS: Window B Shadowed Horizontal address offset. This is ARM set shadow of ADDR_H_OFFSET

23.12.9 DC_WINBUF_B_ADDR_V_OFFSET_0

Window B Vertical address offset

Offset: 808h | Read/Write: R/W | Reset: 0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx

Bit	Reset	Description
31:0	X	B_ADDR_V_OFFSET: Window B Vertical address offset. This is a byte address. The LSB is not used for 16-bpp non-planar pixel format and the last 2 LSB are not used for 32-bpp non-planar pixel format. For YUV planar pixel format, this specifies vertical offset of Y plane. Vertical offsets of U/V plane is derived by HW.

23.12.10 DC_WINBUF_B_ADDR_V_OFFSET_NS_0

Window B Shadowed Vertical address offset

Offset: 809h | Read/Write: R/W | Reset: 0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx

Bit	Reset	Description
31:0	X	B_ADDR_V_OFFSET_NS: Window B Shadowed Vertical address offset This is ARM set shadow of ADDR_V_OFFSET

23.12.11 DC_WINBUF_B_UFLOW_STATUS_0

Window B FIFO Underflow Status Register

Offset: 80ah | Read/Write: R/W | Reset: 0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx

Bit	Reset	Description
30	X	COUNT_OFLOW: Flag bit that indicates that the underflow event counter has overflowed. There were too many events. If COUNT_OFLOW is set, UFLOW_COUNT is meaningless. Cleared on write.
23:0	X	UFLOW_COUNT: Underflow count. This field indicates the number of contiguous groups of output pixels for which there was no data in the FIFO. For example, if the valid from the FIFO is low for 10 consecutive cycles and then goes high, the counter will increment by one. Reset to zero on write.

23.13 Window C (WIN_C) Registers

These registers control window C parameters

23.13.1 DC_WINC_C_COLOR_PALETTE_0

Window C Color Palette

This is used for palletized data format (color depth of 8-bpp or less) or for gamma correction for non-palletized data formats (color depth of more than 8-bpp). Each window has its own color palette which consists of three 256x8 register file which can be written by host and indexed (read) by the window.

For palletized data format less than 8-bpp the pixel data is aligned to least significant bits of the palette index (address) and the remaining upper bits are filled with the corresponding bits of the Palette Color Extension. For example, for 4-bpp mode, the pixel data occupies bits 3-0 of the palette index, and bits 7-4 of the palette index are set to bits 7-4 of the Palette Color Extension. Host read is assumed to be not needed - software can cache the color palette in system memory. This is an array of 256 identical register entries; the register fields below apply to each entry.

Color palette

Offset: 500h..5ffh | Read/Write: WO | Reset: 0bxxxxxxxxxxxxxxxxxxxxxxxxxx

Bit	Reset	Description
23:16	X	C_COLOR_PALETTE_B: Blue Color Palette
15:8	X	C_COLOR_PALETTE_G: Green Color Palette
7:0	X	C_COLOR_PALETTE_R: Red Color Palette

23.13.2 DC_WINC_C_PALETTE_COLOR_EXT_0

Window C Palette Color Extension

Palette extension for 1-bpp, 2-bpp, and 4-bpp. These bits provide the upper most significant bits for indexing the color palette. Supported for window A only.

Offset: 600h | Read/Write: R/W | Reset: 0bxxxxxxx

Bit	Reset	Description
7:1	X	C_PALETTE_COLOR_EXT: Window C Palette Color Extension. Bits 7-1 are used for 1-bpp mode, bits 7-2 are used for 2-bpp mode, and bits 7-4 are used for 4-bpp mode.

23.13.3 DC_WINC_C_H_FILTER_P00_0

Window C Horizontal Filter phase 00

Horizontal scaling filter coefficients.

Horizontal scaling filter is a 6-tap filter with 4-bit positional phase.

- Coefficients 0 and 5 are 3-bit signed values ranging from -4 to 3.
- Coefficients 1 and 4 are 5-bit signed values ranging from -16 to 15.
- Coefficients 2 and 3 are 8-bit unsigned values ranging from 0 to 128.
- Coefficient 0 is the multiplier for the earliest pixel (P0) in the group of 6-pixel and coefficient 5 is the multiplier for the latest pixel (P5) in the group. The output pixel positional phase is defined as centered in P2 if the positional phase is 0 or proportionally in between P2 and P3 if the positional phase is larger than 0.

Sum of all coefficients for each phase should be 128 typically and software should never program the sum of all coefficients for a phase to be more than 128.

For each horizontal positional phase, the 6 filter coefficients require 32 register bits. Note that color value ranges from 0 to 255 for Y, R, G, B and -128 to 127 for U and V.

Offset: 601h | Read/Write: R/W | Reset: 0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx

Bit	Reset	Description
31:29	X	C_H_FILTER_P00C5: Phase 00 coefficient 5 (typically 0)

23.13.19 DC_WINC_C_CSC_YOF_0

Window C CSC Y Offset

Color Space Conversion coefficients

The CSC can be used for YUV to RGB conversion with brightness and hue/saturation control. The CSC can only be enabled for window C controlled by CSC_ENABLE register bits.

For Y color, the Y offset is applied first and saturation (clipping) is performed immediately after the Y offset is applied.

- R = sat(KYRGB * sat(Y + YOF) + KUR * U + KVR * V)
- G = sat(KYRGB * sat(Y + YOF) + KUG * U + KVG * V)
- B = sat(KYRGB * sat(Y + YOF) + KUB * U + KVB * V)

Saturation and rounding is performed in the range of 0 to 255 for the above equations.

Typical values are:

- YOF = -16.000, KYRGB = 1.1644
- KUR = 0.0000, KVR = 1.5960
- KUG = -0.3918, KVG = -0.8130
- KUB = 2.0172, KVB = 0.0000

KUR and KVB are typically 0.0000 but they may be programmed non-zero for hue rotation.

The CSC can also take RGB input, in which case YOF, KVB, KUG, KUR should be programmed to 0 and KYRGB will be forced to 0 by the hardware for generating R and B. KYRGB will not be forced to 0 for generating G. KVR, KYRGB, and KUB can be programmed to 1.0 or used as gain control for R, G, B correspondingly. Note that color value ranges from 0 to 255 for Y, R, G, B and -128 to 127 for U and V.

Vertical scaling filter coefficients

Vertical scaling filter is a 2-tap filter with 4-bit positional phase. Coefficients 0 and 1 are 8-bit unsigned value ranging from 0 to 128.

Coefficient 0 is the multiplier for the earlier pixel (P0) in the group of 2-pixel and coefficient 1 is the multiplier for the later pixel (P1) in the group. The output pixel positional phase is defined as centered in P0 if the positional phase is 0 or proportionally in between P0 and P1 if the positional phase is larger than 0.

Sum of all coefficients for each phase should be 128 typically therefore coefficient 1 can be calculated from (1 - coefficient 0) and therefore only coefficient 0 is programmed.

For each vertical positional phase, the filter coefficient requires 8 register bits. Note that color value ranges from 0 to 255 for Y, R, G, B and -128 to 127 for U and V.

The registers under DC_WIN are double buffered.

23.13.27 DC_WIN_C_WIN_OPTIONS_0

Window C Options

Class: Display Window Settings

23.13.31 DC_WIN_C_POSITION_0

Window C Position

This register defines H position and size of Window C after scaling (if there is any)

Offset: 704h | Read/Write: R/W | Reset: 0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx

Bit	Reset	Description
28:16	X	C_V_POSITION: Window C V Position. This is specified with respect to the top edge of active display area.
12:0	X	C_H_POSITION: Window C H Position. This is specified with respect to the left edge of active display area.

23.13.32 DC_WIN_C_SIZE_0

Window C Size

This register defines V position and size of Window C after scaling (if there is any)

> **Note:** Programming on window size should guarantee the whole window is inside the active area, otherwise extra rows/columns will be fetched and discarded which affects performance.

Programming on window size should guarantee the whole window is inside the active area, otherwise extra rows/columns will be fetched and discarded which affects performance.

Offset: 705h | Read/Write: R/W | Reset: 0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx

Bit	Reset	Description
28:16	X	C_V_SIZE: Window C V Size (lines). This is the vertical size after scaling.
12:0	X	C_H_SIZE: Window C H Size (pixels). This is the horizontal size after scaling.

23.13.33 DC_WIN_C_PRESCALED_SIZE_0

Window C Pre-scaled Size

This register defines Window C pre-scaled size.

The H pre-scaled size is needed to determine how many bytes to fetch from memory per line and this parameter must be programmed exactly as needed taking into account the scaling factor. For planar YUV or YCbCr data formats, this parameter refer to the H pre-scaled of the Y plane.

The total number of lines to be fetched from memory is determined by post-scale V size but V pre-scaled size is needed to 'clamp' the last valid line if the vertical DDA is exactly or slightly beyond the specified V pre-scaled size.

Design Note: H pre-scaled size ideally should be in terms of pixel but then hardware needs to convert this precisely to bytes to determine the amount of data to request from memory.

This could be a risky calculation - maybe this should be made optional on whether we use internal hardware to calculate or left it to software to calculate.

Offset: 706h | Read/Write: R/W | Reset: 0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx

Bit	Reset	Description
28:16	X	C_V_PRESCALED_SIZE: Window C V Pre-scaled Size (lines). In 420P/422R/422RA formats, it must be even.
14:0	X	C_H_PRESCALED_SIZE: Window C H Pre-scaled Size (bytes). In 420P and 422P formats, it must be even.

23.13.34 DC_WIN_C_H_INITIAL_DDA_0

Window C H Initial DDA

Design Note: the first pixel of pre-scaled image is always used to output the first pixel so essentially this is the same as forcing the H Initial DDA integer portion to 1 initially even though user typically programs this to 0. If it makes the implementation easier, it is possible to force software to program the Initial DDA integer portion to 1. Similarly with the V Initial DDA.

Offset: 707h | Read/Write: R/W | Reset: 0bxxxxxxxxxxxxxxxx

Bit	Reset	Description
15:0	X	C_H_INITIAL_DDA: Window C H Initial DDA (4.12) This is typically programmed to 0.0

23.13.35 DC_WIN_C_V_INITIAL_DDA_0

Window C V Initial DDA

Offset: 708h | Read/Write: R/W | Reset: 0bxxxxxxxxxxxxxxxx

Bit	Reset	Description
15:0	X	C_V_INITIAL_DDA: Window C V Initial DDA (4.12) This is typically programmed to 0.0 for both non-interlaced and interlaced sources.

23.13.36 DC_WIN_C_DDA_INCREMENT_0

Window C DDA Increment

DDA increment is typically calculated by dividing (Pre-scaled size in pixels - 1) by (Post-scaled size in pixels - 1). The result should be rounded up and expressed as 4.12 format (4-bit integer and 12-bit fraction). For non-filtered image this value can be slightly larger so that it is not missing the last row/column. Reference programming values (H and V should be calculated separately depending on filter on/off and sizes):

- Filter on: min(round((prescaled_size_in_pixels - 1) * 0x1000 /(post_scaled_size_in_pixels - 1)), MAX)

- Filter off: min(round(prescaled_size_in_pixels * 0x1000 / post_scaled_size_in_pixels - 1) - 0.5), MAX)

Where the value of MAX is as follows:

For V_DDA_INCREMENT: 15.0 (0xF000)

For H_DDA_INCREMENT: 4.0 (0x4000) for 2 Bytes/pix formats.

8.0 (0x8000) for 4 Bytes/pix formats.

They are theoretically the biggest values that guarantee not displaying beyond an image boundary. If the DDA increment is less than 1.0 then image will be up-scaled and if DDA increment is more than 1.0 then image will be down-scaled.

Offset: 709h | Read/Write: R/W | Reset: 0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx

Bit	Reset	Description
31:16	X	C_V_DDA_INCREMENT: Window C Vertical DDA Increment (4.12). This should be set to 1.0 if there is no scaling. Maximum value is 15.0 regardless of the number of bytes per pixel.
15:0	X	C_H_DDA_INCREMENT: Window C Horizontal DDA Increment (4.12). This should be set to 1.0 if there is no scaling. The maximum value for downscaling depends on the number of bytes per pixel. For 4-byte/pixel modes (32-bpp) the maximum value is 4.0 and for all other modes the maximum value is 8.0.

23.13.37 DC_WIN_C_LINE_STRIDE_0

Window C Line Stride

Offset: 70ah | Read/Write: R/W | Reset: 0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx

Bit	Reset	Description
31:16	X	C_UV_LINE_STRIDE: Window C Line Stride for Chroma. This is stride (in bytes) for planar YUV or YCbCr data formats for the chroma plane, with the restriction that it must be programmed to be multiples of 4 (16 if tiled or in horizontal flipping) This is not used (ignored) for other non-planar data formats.
15:0	X	C_LINE_STRIDE: Window C Line Stride. This is stride (in bytes) for all non-planar data formats. If the memory surface is tiled, the stride needs to be a multiple of 16. If H_DIRECTION of window C is set to DECREMENT, the stride also needs to be a multiple of 16. For planar YUV or YCbCr data formats, this is stride (in bytes) for the luma plane with the restriction that it must be multiples of 8 (16 if tiled or in horizontal flipping) For tiled surface this value may affect starting address of a window. Refer to the comment of START_ADDR for detail.

23.13.38 DC_WIN_C_BUF_STRIDE_0

Window C Buffer stride

Offset: 70bh | Read/Write: R/W | Reset: 0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx

Bit	Reset	Description
31:0	X	C_BUF_STRIDE: Window C Buffer stride. Buffer stride is used to calculate the buffer addresses when the window is triggered by non-host modules. Refer to the comment of START_ADDR for programming guide. For YUV planar pixel format, this specifies buffer stride for the Y plane. The value is in bytes.

23.13.39 DC_WIN_C_UV_BUF_STRIDE_0

Window C Buffer stride for U/V plane

Offset: 70ch | Read/Write: R/W | Reset: 0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx

Bit	Reset	Description
31:0	X	C_UV_BUF_STRIDE: Window C. This value is in bytes. For YUV planar pixel format, this specifies buffer stride for the U/V plane.

23.13.41 DC_WIN_C_DV_CONTROL_0

Window C Digital Vibrance Control

If enabled, Digital Vibrance is applied after H and V scaling and after color palette or color space conversion logic but before color keying multiplexer and before cursor multiplexer.

- After DV, new R = R + (2R - G - B) * FR, where FR is fraction from 0 to 7/8
- After DV, new G = G + (2G - R - B) * FG, where FG is fraction from 0 to 7/8
- After DV, new B = B + (2B - R - G) * FB, where FB is fraction from 0 to 7/8

Offset: 70eh | Read/Write: R/W | Reset: 0bxxxxxxxxxxxxxxxxxxx

Bit	Reset	Description
18:16	X	C_DV_CONTROL_B: Digital Vibrance control for B
10:8	X	C_DV_CONTROL_G: Digital Vibrance control for G
2:0	X	C_DV_CONTROL_R: Digital Vibrance control for R

23.13.42 DC_WIN_C_BLEND_NOKEY_0

Blend Control for this window area where color key is enabled but the pixel color is not within the color key range (color key not match). This is valid for all overlapping condition but only if there is no overlap with other window with higher priority color key enabled and color key not match.

Class: Display Color Keying and Blending

Color keying and blending of the display windows are done prior to cursor blending. Cursor always goes on top of the blended windows. Blending is controlled independently on each possible overlap area of the display windows. If 3 windows are enabled there are 7 possible overlap area combinations. For every window in each overlap area combination, color key can be disabled or enabled. Also, for every window in each overlap area combination, there is a corresponding window blend control parameter and a window blend weight parameter. The window blend control parameter is always effective but the window blend weight is not always used. The window blend weight can also be derived from pixel alpha value or from the reverse of other overlapping windows weight.

Color keying has the highest priority for display window blending. Color key consists of a range of color which is searched independently for each window. If more than 1 windows color keys are enabled then Window A color key has the highest priority, followed by Window B color key, and then followed by Window C color key. Two sets of color key range (Color Key 0 and Color Key 1) can be defined and they are shared for all windows. It is possible to use both color key sets for the same window or for two separate windows.

The two sets of color key ranges should not overlap and if they do the overlap colors are treated as if they are part of Color Key 0 and not part of Color Key 1.

Assuming that there is no overlap with other higher priority window with color key not matched, if a window color key is enabled for any overlap condition and the window pixel is not within the color key range (key not match), then the window pixel

will not be blended with other overlapping window pixels but it will be weighted. The weight is not dependent on the overlap condition it is controlled by the same set of parameters for all overlapping condition.

Assuming that there is no overlap with other higher priority window with color key not matched, if a window color key is enabled for a particular overlap condition and the window pixel is within the color key range (key match), then the window pixel will be weighted and blended with other overlapping pixels and this is controlled separately for each overlap condition.

Assuming that there is no overlap with other higher priority window with color key not matched, if a window color key is disabled then the window pixel will be blended with other overlapping pixels and this is controlled separately for each overlap condition.

Display Color Key Parameters

For B4G4R4A4, B5G6R5A, B5G6R5 mode, color key should be compared prior to color conversion to 24-bpp and unused least significant bits of the pixel are filled with zeros.

For palletized mode, color key is compared prior to color palette and the palletized color is compared against the green color key values/mask.

For YUV mode, U and V are offset by +128 before performing the color key comparison.

In all cases, color key is compared prior to horizontal/vertical scaling filter and prior to digital vibrance control.

Both upper and lower values are inclusive.

Offset: 70fh | Read/Write: R/W | Reset: 0bxxxxxxxxxxxxxxxxxxxxxxxxxx

Bit	Reset	Description
23:16	X	C_BLEND_WEIGHT1_NOKEY: Window blend weight 1 for color key not match areas. This is used only for alpha weight with 1-bit alpha and alpha value of 1.
15:8	X	C_BLEND_WEIGHT0_NOKEY: Window blend weight 0 for color key not match areas. For alpha weight, this is used for 1-bit alpha with value of 0.
0	X	C_BLEND_CONTROL_NOKEY: Window blend control for color key not match areas. 0 = Fix weight using window blend weight 0 for color key not matched. 1 = Alpha weight using the alpha value. This is only valid if the window color format includes an alpha value. For 1-bit alpha value, if the alpha is 0 window blend weight 0 is used, and if alpha is 1, window blend weight 1 is used. 0 = FIX_WEIGHT 1 = ALPHA_WEIGHT

23.13.43 DC_WIN_C_BLEND_1WIN_0

Blend Control for this window area where it does not overlap with other windows.

Offset: 710h | Read/Write: R/W | Reset: 0bxxxxxxxxxxxxxxxxxxxxxxxxxx

Bit	Reset	Description
23:16	X	C_BLEND_WEIGHT1_1WIN: Window blend weight 1 for color key disabled or color key enabled with key matched areas. This is used only for alpha weight with 1-bit alpha and alpha value of 1.
15:8	X	C_BLEND_WEIGHT0_1WIN: Window blend weight 0 for color key disabled or color key enabled with key matched areas. For alpha weight, this is used for 1-bit alpha with value of 0.
2	X	C_BLEND_CONTROL_1WIN: Window blend control in area where it does not overlap with other windows and either color key disabled or color key enabled with key matched. 0 = Fix weight using the window blend weight 0 if color key disabled or color key 0 enabled with key matched, or using the window blend weight 1 if color key 1 enabled with key matched.

Bit	Reset	Description
		1 = Alpha weight using the alpha value. This is only valid if the window color format includes an alpha value. For 1-bit alpha value, if the alpha is 0 window blend weight 0 is used and if alpha is 1, window blend weight 1 is used. 0 = FIX_WEIGHT 1 = ALPHA_WEIGHT

23.13.44 DC_WIN_C_BLEND_2WIN_A_0

Blend Control for this window area that overlaps with window A only.

Offset: 711h | Read/Write: R/W | Reset: 0bxxxxxxxxxxxxxxxxxxxxxxxxxx

Bit	Reset	Description
23:16	X	C_BLEND_WEIGHT1_2WIN_A: Window blend weight 1 for color key disabled or color key enabled with key matched areas. This is used only for alpha weight with 1-bit alpha and alpha value of 1.
15:8	X	C_BLEND_WEIGHT0_2WIN_A: Window blend weight 0 for color key disabled or color key enabled with key matched areas. For alpha weight, this is used for 1-bit alpha with value of 0.
3:2	X	C_BLEND_CONTROL_2WIN_A: Window blend control in area where either color key disabled or color key enabled with key matched. 0 = Fix weight using the window blend weight 0 if color key disabled or color key 0 enabled with key matched, or using the window blend weight 1 if color key 1 enabled with key matched. 1 = Alpha weight using the alpha value. This is only valid if the window color format includes an alpha value. For 1-bit alpha value, if the alpha is 0 window blend weight 0 is used and if alpha is 1, window blend weight 1 is used. 2 = Dependent weight, in this case, the window blend weight is 1 - the weights of the other window that overlaps with this window. Only 1 of the overlapping windows may have this setting. 0 = FIX_WEIGHT 1 = ALPHA_WEIGHT 2 = DEPENDENT_WEIGHT
1:0	X	C_CKEY_ENABLE_2WIN_A: Window color key enable 0 = Color Key 0 and 1 Disable 1 = Color Key 0 Enable 2 = Color Key 1 Enable 3 = Color Key 0 and 1 Enable 0 = NOKEY 1 = CKEY0 2 = CKEY1 3 = CKEY01

23.13.45 DC_WIN_C_BLEND_2WIN_B_0

Blend Control for this window area that overlaps with window B only.

Offset: 712h | Read/Write: R/W | Reset: 0bxxxxxxxxxxxxxxxxxxxxxxxxxx

Bit	Reset	Description
23:16	X	C_BLEND_WEIGHT1_2WIN_B: Window blend weight 1 for color key disabled or color key enabled with key matched areas. This is used only for alpha weight with 1-bit alpha and alpha value of 1.
15:8	X	C_BLEND_WEIGHT0_2WIN_B: Window blend weight 0 for color key disabled or color key enabled with key matched areas. For alpha weight, this is used for 1-bit alpha with value of 0.
3:2	X	C_BLEND_CONTROL_2WIN_B: Window blend control in area where either color key disabled or color key enabled with key matched. 0 = Fix weight using the window blend weight 0 if color key disabled or color key 0 enabled with key matched, or using the window blend weight 1 if color key 1 enabled with key matched. 1 = Alpha weight using the alpha value. This is only valid if the window color format includes an alpha value. For 1-bit alpha value, if the alpha is 0 window blend weight 0 is used and if alpha is 1, window blend weight 1 is used. 2 = Dependent weight, in this case, the window blend weight is 1 - the weights of the other window that overlaps with this window. Only 1 of the overlapping windows may have this setting. 0 = FIX_WEIGHT 1 = ALPHA_WEIGHT 2 = DEPENDENT_WEIGHT
1:0	X	C_CKEY_ENABLE_2WIN_B: Window color key enable 0 = Color Key 0 and 1 Disable 1 = Color Key 0 Enable 2 = Color Key 1 Enable 3 = Color Key 0 and 1 Enable 0 = NOKEY 1 = CKEY0 2 = CKEY1 3 = CKEY01

23.13.46 DC_WIN_C_BLEND_3WIN_AB_0

Blend Control for this window area that overlaps with windows A & B only.

Offset: 713h | Read/Write: R/W | Reset: 0bxxxxxxxxxxxxxxxxxxxxxxxxxx

Bit	Reset	Description
23:16	X	C_BLEND_WEIGHT1_3WIN_AB: Window blend weight 1 for color key disabled or color key enabled with key matched areas. This is used only for alpha weight with 1-bit alpha and alpha value of 1.
15:8	X	C_BLEND_WEIGHT0_3WIN_AB: Window blend weight 0 for color key disabled or color key enabled with key matched areas. For alpha weight, this is used for 1-bit alpha with value of 0.
3:2	X	C_BLEND_CONTROL_3WIN_AB: Window blend control in area where either color key disabled or color key enabled with key matched. 0 = Fix weight using the window blend weight 0 if color key disabled or color key 0 enabled with key matched, or using the window blend weight 1 if color key 1 enabled with key matched. 1 = Alpha weight using the alpha value. This is only valid if the window color format includes an alpha value. For 1-bit alpha value, if the alpha is 0 window blend weight 0 is used and if alpha is 1, window blend weight 1 is used. 2 = Dependent weight, in this case, the window blend weight is 1 - the weights of the other window that overlaps with this window. Only 1 of the overlapping windows may

Bit	Reset	Description
		have this setting. 0 = FIX_WEIGHT 1 = ALPHA_WEIGHT 2 = DEPENDENT_WEIGHT
1:0	X	C_CKEY_ENABLE_3WIN_AB: Window color key enable 0 = Color Key 0 and 1 Disable 1 = Color Key 0 Enable 2 = Color Key 1 Enable 3 = Color Key 0 and 1 Enable 0 = NOKEY 1 = CKEY0 2 = CKEY1 3 = CKEY01

23.13.47 DC_WIN_C_HP_FETCH_CONTROL_0

Window C High Priority Avoidance Fetch Parameters

This register gives extra information to the Memory Controller Client Interface (MCCIF) about the number of memory words that will be fetched per scan line and about the rate at which those words are consumed. This allows the MCCIF to more accurately arbitrate memory accesses to prevent the use of the High Priority signal.

Use of this signal causes all other client accesses to be blocked in preference to the client asserting HP. Obviously, this is a state which is sometime necessary for Display since it is an isochronous client and MUST be serviced in a timely manner. However, use of this signal should be avoided if possible. These parameters help the MCCIF avoid the over-use of HP.

Note: HP fetch control is no longer supported by the MCCIF clients. Registers are retained for software compatibility, but are not used by the hardware.

Offset: 714h | Read/Write: R/W | Reset: 0b0xxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx

Bit	Reset	Description
31	0x0	C_FETCH_INFO_ENABLE: Enables the sending of the Window C fetch information. For compatibility with earlier devices, this defaults to DISABLE. 0 = DISABLE : This bit should be enabled only for 12-bpp 1 = ENABLE
30:16	X	C_WORDS_PER_LINE: Window C memory fetch words per scan line. This value is in memory fetch words: Multiples of 16 bytes for Tegra 3 devices. It is computed as follows: C_WORDS_PER_LINE = (C_SIZE.C_H_SIZE * (bytes per pixel) + 15) >> 4 bytes per pixel is determined by the pixel format.
15:0	X	C_CYCLES_PER_WORD: Window C clock cycles per memory fetch word. The value of this field is essentially a measure of the data consumption rate for window C. It is computed as follows: C_CYCLES_PER_WORD = C_DDA_INCREMENT.C_H_DDA_INCREMENT / (bytes per pixel). Note that the format for this value is a fixed-point fractional value with 8 bits of integer precision and 8 bits of fractional precision. In other words, it is an '8.8' number. For example, if there is no scaling of the input image, the DDA increment will be 4096. With 32-bit RGBA pixels there will be 4 bytes per pixel, so CYCLES_PER_WORD will be ... 4096 / 4 = 1024, or 4.0 expressed in the 8.8 format. Any scaling performed on the pixels will change the rate at which pixels are consumed. Scaling up will increase the value of DDA increment and will therefore increase the number of cycles between memory fetches. Conversely, scaling down will decrease the value of DDA increment and memory fetches will occur more frequently.

23.13.48 DC_WIN_C_GLOBAL_ALPHA_0

Window C Global Alpha

When enabled, per pixel alpha values are scaled by GLOBAL_ALPHA before blending: a' = a * GLOBAL_ALPHA/255. When per pixel alpha is not used in blending, global alpha has no affect.

Note: 1 and 4 bits per pixel alpha are quantized back to 1 and 4 bits, respectively, after scaling. For 1-bit alpha case, finer scaling can be achieved by changing BLEND_WEIGHT* instead.

Offset: 715h | Read/Write: R/W | Reset: 0b0xxxxxxxxxxxxxxx

Bit	Reset	Description
16	DISABLE	C_GLOBAL_ALPHA_ENABLE: When enabled, color palette *must* also be enabled and programmed. 0 = DISABLE 1 = ENABLE
7:0	X	C_GLOBAL_ALPHA: Global alpha: 0..255 map to 0.0 – 1.0. I.e., 255 yields no-operation. For power, better to set GLOBAL_ALPHA_ENABLE=DISABLE when GLOBAL_ALPHA=255.

23.14 WINBUF_C Registers

The registers under DC_WINBUF are triple-buffered.

23.14.1 DC_WINBUF_C_START_ADDR_0

Window C Start Address

Overview

START_ADDR, BUF_STRIDE, LINE_STRIDE, ADDR_H_OFFSET, ADDR_V_OFFSET combined, specify the starting address of a window buffer in the memory surface. Generally START_ADDR is programmed with the starting address of the memory surface. H/V_OFFSET specifies the address offsets of the pixel at the beginning of the window, with respect to the starting address of the memory surface. (There is an exception to that when memory surface is not well aligned, see 3-ii below.)

Note that "beginning of the window" here means the top-left corner of a window in normal mode, top-right corner in horizontal flipping, bottom-left corner in vertical flipping, and bottom-right in horizontal+vertical flipping.

Starting Address Calculation

These formulae are same for both tiled or linear mode. However, for linear mode, the addresses calculated are real physical addresses, but for tile mode, these addresses will be translated to the real physical addresses by the memory controller client before used.

- When a window is host triggered, starting address of a window is calculated as follows by HW.
  - non-YUV-planar modes

    starting-address = START_ADDR + ADDR_V_OFFSET * LINE_STRIDE + ADDR_H_OFFSET
  - YUV-planar modes

    y-starting-address = START_ADDR + ADDR_V_OFFSET * LINE_STRIDE + ADDR_H_OFFSET

    u-starting-address = START_ADDR_U + ADDR_V_OFFSET * UV_LINE_STRIDE / denom1 + ADDR_H_OFFSET / denom2

v-starting-address = START_ADDR_V + ADDR_V_OFFSET * UV_LINE_STRIDE / denom1 + ADDR_H_OFFSET / denom2 where denom1/denom2 equal to 1 or 2 depending on the actual planar format, derived natively by HW.

- When a window is non-host triggered, starting address of a window buffer is calculated as below.
  - non-YUV-planar mode

    starting-address = START_ADDR + BUF_STRIDE * buf_index + ADDR_V_OFFSET * LINE_STRIDE + ADDR_H_OFFSET
  - YUV-planar mode:

    y-starting-address = START_ADDR + BUF_STRIDE * buf_index + ADDR_V_OFFSET * LINE_STRIDE + ADDR_H_OFFSET

    u-starting-address = START_ADDR_U + UV_BUF_STRIDE * buf_index + ADDR_V_OFFSET * UV_LINE_STRIDE / denom1 + ADDR_H_OFFSET / denom2

    v-starting-address = START_ADDR_V + UV_BUF_STRIDE * buf_index + ADDR_V_OFFSET * UV_LINE_STRIDE / denom1 + ADDR_H_OFFSET / denom2 where denom1/denom2 equal to 1 or 2 depending on the actual planar format, derived natively by HW.

    buf_index is the index transmitted by the triggering module pointing to the first buffer of a frame.

Programming Restrictions

- For tiled address mode

  Image surface can only aligned to multiples of 256, thus the following restrictions.
  - START_ADDR, START_ADDR_U, START_ADDR_V need to be multiples of 256.
  - BUF_STRIDE, UV_BUF_STRIDE need to be multiples of 256
  - LINE_STRIDE, UV_LINE_STRIDE need to be multiples of 16
  - ADDR_H_OFFSET needs to be multiple of 2 in yuv planar format (the last bit is ignored), but with no restrictions on other color formats.
  - ADDR_V_OFFSET has no restrictions
- For linear address mode

  Image surface can be aligned 2, 4, or 8 bytes, depending on the color formats.

  As an additional restriction for display, START_ADDR, START_ADDR_U and START_ADDR_V need to be multiples of 16. When a surface is not aligned to 16 bytes, program START_ADDR with the memory surface address with its least 4 significant bits zeroed out and add these 4 address bits to the original H_OFFSET. (So the formula in 2-i,ii still hold)
  - For all formats:

    START_ADDR, START_ADDR_U, and START_ADDR_V need to be multiples of 16.

    For 16-bpp formats,

    (START_ADDR+H_OFFSET) need to be multiple of 2. The least significant bit of H_OFFSTE is ignored.

    For 32-bpp formats,

    (START_ADDR+H_OFFSTE) needs to be multiple of 4. The least two significant bits of H_OFFSTE are ignored.
  - For YUV planar formats:

    BUF_STRIDE, UV_BUF_STRIDE:

    BUF_STRIDE[2:1]=UV_BUF_STRIDE[1:0]

    or as a stricter constraint: BUF_STRIDE be multiple of 8, UV_BUF_STRIDE be multiple of 4.

    LINE_STRIDE, UV_LINE_STRIDE:

LINE_STRIDE and UV_LINE_STRIDE need to be at least 16.

LINE_STRIDE needs to be multiple of 8, UV_LINE_STRIDE needs to be multiple of 4.

ADDR_H_OFFSET:

Needs to be a multiple of 2. If needs to point to odd pixel position, program ADDR_H_OFFSET to be the previous position (or the next position if H-flipped) and program H_INITIAL_DDA bit 12 to 1.

ADDR_V_OFFSET:

Needs to be a multiple of 2. If needs to point to odd line number, program ADDR_V_OFFSTE to be the previous line number (or next line number if V-flipped) and program V_INITIAL_DDA bit 12 to 1.

- Memory allocation for non-host triggered case:

  When a window buffer is not controlled by host (software) then a frame may be stored in multiple buffers. In this case, the buffers must be contiguous in the memory because display will use the same luma or chroma line strides for all lines in the frame.

  Also buffer wraparound must not occur in the middle of the displayed part of the frame. The controlling module will send frame start and frame end indicators (flags) to display module to indicate the beginning and end of frame. Buffer start address is latched when frame start flag is active but the actual buffer start address is not switched until frame end flag is active. In the case where one buffer corresponds to one frame, the frame start and frame end flag are active every time a buffer index is sent.

Offset: 800h | Read/Write: R/W | Reset: 0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx

Bit	Reset	Description
31:0	X	C_START_ADDR: Window C Start Address. This is a byte address. The LSB is not used for 16-bpp non-planar pixel format and the last 2 LSB are not used for 32-bpp non-planar pixel format. For YUV planar pixel format, this specifies start address for the Y plane.

23.14.2 DC_WINBUF_C_START_ADDR_NS_0

Window C Shadowed Start Address

Offset: 801h | Read/Write: R/W | Reset: 0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx

Bit	Reset	Description
31:0	X	C_START_ADDR_NS: Window C Shadowed Start Address. This is ARM set shadow of Start Address.

Window C Start Address for V plane

Offset: 804h | Read/Write: R/W | Reset: 0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx

Bit	Reset	Description
31:0	X	C_START_ADDR_V: Window C Start Address for V plane. This is a byte address.

23.14.6 DC_WINBUF_C_START_ADDR_V_NS_0

Window C Shadowed Start Address for V plane

Offset: 805h | Read/Write: R/W | Reset: 0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx

Bit	Reset	Description
31:0	X	C_START_ADDR_V_NS: Window C Shadowed Start Address for V plane. This is ARM set shadow register of U start address

23.14.7 DC_WINBUF_C_ADDR_H_OFFSET_0

Window C Horizontal address offset

Offset: 806h | Read/Write: R/W | Reset: 0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx

Bit	Reset	Description
31:0	X	C_ADDR_H_OFFSET: Window C Horizontal address offset. This is a byte address. The LSB is not used for 16-bpp non-planar pixel format and the last 2 LSB are not used for 32-bpp non-planar pixel format. For YUV planar pixel format, this specifies horizontal offset of Y plane. The horizontal offsets of U/V plane is derived by HW.

23.14.8 DC_WINBUF_C_ADDR_H_OFFSET_NS_0

Window C Shadowed Horizontal address offset

Offset: 807h | Read/Write: R/W | Reset: 0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx

Bit	Reset	Description
31:0	X	C_ADDR_H_OFFSET_NS: Window C Shadowed Horizontal address offset. This is ARM set shadow of ADDR_H_OFFSET

23.14.9 DC_WINBUF_C_ADDR_V_OFFSET_0

Window C Vertical address offset

Offset: 808h | Read/Write: R/W | Reset: 0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx

Bit	Reset	Description
31:0	X	C_ADDR_V_OFFSET: Window C Vertical address offset. This is a byte address. The LSB is not used for 16-bpp non-planar pixel format and the last 2 LSB are not used for 32-bpp non-planar pixel format. For YUV planar pixel format, this specifies vertical offset of Y plane. The vertical offsets of U/V plane is derived by HW.

23.14.10 DC_WINBUF_C_ADDR_V_OFFSET_NS_0

Window C Shadowed Vertical address offset

Offset: 809h | Read/Write: R/W | Reset: 0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx

Bit	Reset	Description
31:0	X	C_ADDR_V_OFFSET_NS: Window C Shadowed Vertical address offset. This is ARM set shadow of ADDR_V_OFFSET

23.14.11 DC_WINBUF_C_UFLOW_STATUS_0

Window C FIFO Underflow Status Register

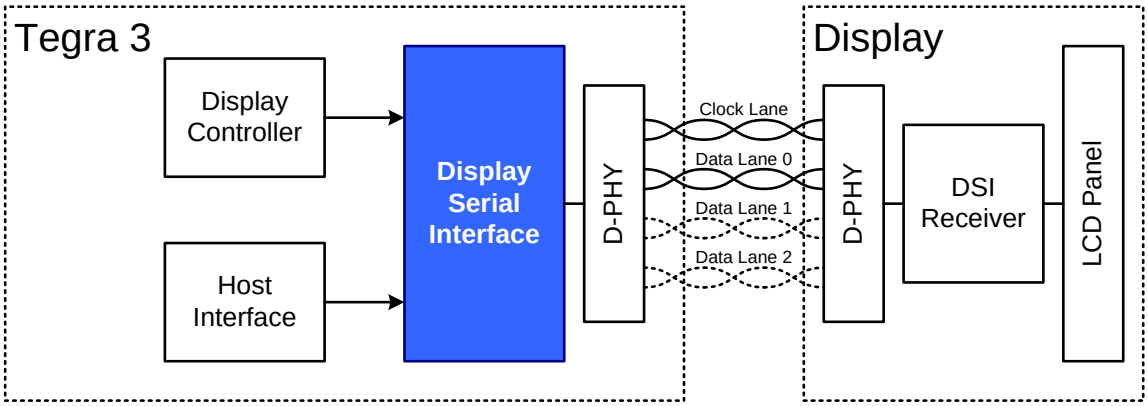
Offset: 80ah | Read/Write: R/W | Reset: 0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx

Bit	Reset	Description
30	X	COUNT_OFLOW: Flag bit that indicates that the underflow event counter has overflowed. There were too many events. If COUNT_OFLOW is set, UFLOW_COUNT is meaningless. Cleared on write.
23:0	X	UFLOW_COUNT: Underflow count. This field indicates the number of contiguous groups of output pixels for which there was no data in the FIFO. For example, if the valid from the FIFO is low for 10 consecutive cycles and then goes high, the counter will increment by one. Reset to zero on write.

24.0 MIPI-DSI (DISPLAY SERIAL INTERFACE)

The Display Serial Interface (DSI) is a MIPI standard serial bitstream, intended to provide a low pin count interface to a display panel. DSI reduces both package pin-count and I/O power consumption compared to parallel solutions. It transfers pixel data from either one of the display controllers (internal to Tegra® 3) to an external third-party LCD module. The physical positioning of the DSI module in relation to other units / devices in the system is shown in Figure 55.

Figure 55 System Block Diagram



DSI is a replacement for the MIPI DPI and DBI standards, and follows the use cases of these interfaces. From a data transport point of view, MIPI DPI is an interface similar to a traditional raster-based isochronous display interface, and DBI is an asynchronous packet based transfer mechanism. DSI behaves like MIPI DPI when in “Video Mode”, and implements a “Command Mode” to handle the DBI interface. Any implementation must implement both these modes of operation.

24.1 Clocking

- Host Clock = 166 MHz {Max frequency}
- Pixel Clock = 2.49 to 91.0 MHz for all modes.
- Application/Lane Management Byte Clock = function of lanes, pixel clock, pixel depth. 10 to 125 MHz.
- Fixed LP receive clock = 72 MHz
- Lane Bit clock = 40 to 500 MHz differential clock, DDR data (80 to 1000 bits/sec).

More details on pixel clock/byte_clock selection is explained in the next section.

24.1.1 Pixel Clock / DSI Byte Clock Ratios

When running the DSI interface in one of the two non-burst video modes, the relationship between the DSI D-PHY bit-rate clock, the DSI byte-rate lane clock and the display controller pixel clock must be exact. This will ensure that precise raster timing information is conveyed to the display peripheral.

There is always a fixed ratio of 8:1 between the D-PHY bit clock and the lane management layer byte clock since there are 8 bits in each byte that are serialized. Therefore, only relationships between pixel clock and byte clock and between pixel clock and bit clock will be discussed.

The relationship between pixel clock and byte clock is shown in Table 50. As can be seen, for some modes, these ratios are far from being simple powers of 2.

Table 50. Pixel Clock: Byte Clock for Various Modes.

Lanes	Pixel Data Format			
	16 bpp	18 bpp (packed)	18 bpp	24 bpp
1	1:2	4:9	1:3	1:3
2	1:1	8:9	2:3	2:3

Since the pixel clock is effectively derived from the D-PHY bit clock, it is perhaps more instructive to look at the number by which you must divide the bit clock to get the correct pixel clock. This information is shown in Table 51. Here, the numbers look reasonable except for the problematic cases of 16bpp over a 3-lane link and 18 bpp (packed) over a 4 lane link. For these two situations, you cannot simply divide the bit rate clock by some integer to arrive at the pixel clock. Moreover, if you need a 50:50 duty cycle for the pixel clock, then you will need to toggle the pixel clock every N/2 bit clock cycles, where N is the number in 2. However, if you do this, 18 bpp (packed) over 2 lanes also becomes a problem.

Table 51. Value to Divide Bit Clock by to Get Pixel Clock

Lanes	Pixel Data Format			
	16 bpp	18 bpp (packed)	18 bpp	24 bpp
1	16	18	24	24
2	8	9	12	12
3	16 / 3	6	8	8
4	4	9 / 2	6	6

To resolve these issues, derive the display controller pixel clock from a separate PLL and then lock that PLL to the DSI D-PHY PLL using a phase comparator and the appropriate divide ratios obtained from the tables. In the straightforward case where pixel clock is derived from PLLD, programming pixel clock divider using Table 51 above and PLLD programming will suffice clocking requirements. PLLD is covered in section 24.6.1 below.

24.2 Operating Modes

24.2.1 Video Mode

Communication with the peripheral is by isochronous data transfer similar to a typical video interface. There is no Bus Turn Around permitted in Video Mode, though there is a mandatory period of LP operation at least once per frame. There are three different sub-modes of Video Mode. These are outlined below:

24.2.1.1 Non-Burst Mode with Start and End

In this mode, the DSI must match the timing of a traditional video raster as closely as possible. This means all information about the start and end of parameters like vertical and horizontal sync, vertical and horizontal sync, front and back porches must be conveyed to the receiving peripherals via the timing of the transmission of the High-Speed sync packets.

24.2.1.2 Non-Burst Mode

This is like Non-Burst Mode with Start and End, except that the Sync-Active and Sync-End packets are not sent. Pixels must still be delivered at the correct rate.

24.2.1.3 Burst Mode

Only the timing of Sync-Start packets is required to be accurately conveyed in this mode. The data rate of the pixel data is arbitrary and is typically higher than the pixel rate of the peripheral. This allows time to transmit other information during the periods where no more pixels are needed.

24.2.2 Command Mode

Communication with the peripheral is by asynchronously timed and variable length packets. The packets may contain video data or control data. In Command Mode, return (read) data can be requested from the peripheral. The DSI will issue a Bus Turn Around (BTA) request and relinquish control of the bus to the peripheral.

24.3 Display Controller Interface

The interface between the display controller and the DSI unit consists of the following elements:

- 24-bit wide pixel bus with an associated valid signal. The valid will only be high during the active portion of a video line.
- 1-bit Horizontal Sync (HS) signal that will toggle once per line.
- 3-bit Lin-Type code. These bits should remain stable for at least 2 pixel clock periods prior to the Horizontal Sync signal changing state. This is to ensure that on the DSI side, the state of these 3 bits is correctly captured.

The DSI unit uses these signals in the following manner: When the display controller toggles the HS signal, the DSI captures the state of the line type code. This information is then used to look up a pre-programmed packet sequence that corresponds to that line type. There are several different line types to select from. Once the packet sequence has been selected, the DSI sends these packets into its internal packet FIFO. When a packet that requires data from the display controller is encountered, the DSI pauses the packet writing operation, until data arrives from the display controller on the pixel bus. When the data arrives – indicated by the assertion of the valid signals – the data is written into the FIFO. This process continues until all the packets for that line type have been written.

Separately, when the HS signal arrives, a counter is started. When the counter reaches a pre-programmed value, the logic on the read side of the DSI internal FIFO is instructed to start pulling packets out of the FIFO and transmit them over the DSI link to the display device.

24.4 Host Interface

Not all displays can accept a raster-based packet stream. For some low-bandwidth displays with small pixel and line dimensions, it is more efficient to have a frame store in the display device itself and to only update the contents of the frame store with occasional packet sequences. For these types of display, there is a SW accessible interface for sending command packets using DSI command mode operation. This mode should also be used to access control and status registers within the display device.

The Host interface consists of a small FIFO for holding packet information and a special register for writing data into the FIFO. In this way, several packets may be queued up by SW and sent in one HS burst. This is more efficient that sending the packets one at a time.

When very long sequences of packets are required to be sent – for example, when the host interface is emulating video mode, or where a large amount of data needs to be sent to the display device in one packet – it is possible for the host to use the large video line-store FIFO.

24.5 FIFO Buffers

24.5.1 Video Mode Operation

24.5.1.1 Writing Data

The following packets are written into the large data FIFO based on the various triggering events described.

Table 52 FIFO Trigger Events

Trigger Event	Packet
Leading edge of Vertical Sync.	V Sync Start
Trailing edge of Vertical Sync	V Sync End
Leading edge of Horizontal Sync, *unless* simultaneous with leading or trailing edge of vertical sync	H Sync Start
Trailing edge of Horizontal Sync	H Sync End
Immediately following VS, HS, VE or HE packets. Packet Word Count determined by display controller timing parameters.	Blanking packet
Immediately following blanking packet	Pixel Stream packet (16, 18 or 24 bits/pixel)

24.5.1.2 Reading Data

The initiation of the reading of the FIFO is triggered by a delayed version of the horizontal sync pulse from the display controller. The delay should be sufficient that the FIFO will not completely drain as reading of the FIFO continues. However, the delay should not be so long as to cause the FIFO to overflow with data.

24.5.2 Command Mode Operation

24.5.2.1 Writing Data from the Display Controller

Upon receipt of the leading edge of Vertical Sync, the display sends whatever DCS command packets are required to initialize the display to receive pixels. Then, as pixels start to arrive from the display controller, a DCS Long Write packet is sent – one per line – which contains the pixel data for that line. No synchronization or blanking packets should be sent. Data packets continue to be sent until the end of the active period. Like video mode packets, there is no need to calculate ECC or CRC words, as this is performed by the hardware on the other side of the data FIFO.

The Packet Sequence registers behave in the same manner as they do for Video Mode packet generation with the following exceptions:

- For Long packets, a DCS command ID byte must be inserted as the first byte of the data payload of the packet, ahead of the pixel data. The packet header Word Count must be 1 more than the number of bytes in the pixel data to take into account this extra byte, but it is the responsibility of SW to make sure the packet length is programmed correctly.
- For Line Type 4, any data contained in the Host Data FIFO should be appended to the end of any packets defined in the Packet Sequence for Line Type 4. In this way, the Host may send DCS commands to the Display Peripheral while the Display Controller is sending pixel information to the Display Peripheral.

24.5.2.2 Writing Data from the Host

Host should choose which data FIFO – small or large – to use prior to sending packet information. The large data FIFO is only available if the display controller is not currently using it. The software is responsible for constructing whatever packets are required for the desired operation and should be written into the FIFO via the host. There is no need for the software to compute ECC or CRC words, as this is performed by the hardware on the other side of the data FIFO.

24.5.2.3 Reading Data

The initiation of the reading of data from the FIFO is triggered by a FIFO threshold. Once the threshold is reached, the FIFO starts to be drained by the D-PHY and the packets are sent to the display. The threshold should be set such that there is no danger of either FIFO overflow from excessive data from the Host or display controller, nor FIFO underflow caused by a lack of sufficient data in the FIFO.

24.5.3 FIFO Sizing

FIFO Threshold Video Non-bust modes is calculated as

Threshold = (Length x OutRate) / (OutRate + InRate)

Where,

- InRate = pixClk
- OutRate = (ByteClk x NumOfLanes) / BytePerPix
- Length = input frame width
- Threshold = minimum fifo depth to start transfer data to CIL

Table 53 Output Rates and Thresholds for Width=800, ByteClk=128, InRate=44.

		Number of Lanes			
Bytes per pixel		1	2	3	4
2	Out Rate	64	128	192	256
2	Threshold	474	595	650	682
2.25	Out Rate	56	113	170	227
2.25	Threshold	448	575	635	670
3	Out Rate	42	85	128	170
3	Threshold	390	527	595	635

Table 54 Output Rates and Thresholds for Width=1024, ByteClk=128 InRate=44.

		Number of Lanes			
Bytes per pixel		1	2	3	4
2	Out Rate	64	128	192	256

24.6 Programming Guidelines

The packet timing diagrams in this section use the following key:

Figure 56 Video Mode Timing Diagram Key.

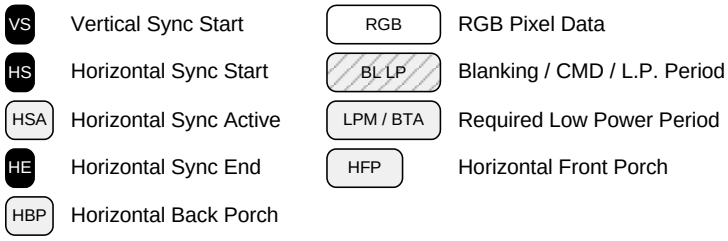

Table 55 Timing Diagram parameter list

Parameter	Description
tHBP	Horizontal Back Porch period
tHACT	Horizontal Active period
tVBP	Vertical Back Porch period
tVACT	Vertical Active period
tVFP	Vertical Front Porch period
tL	Total line period

Table 56 DSI Register Overview

Register	Description
DSI_RD_DATA	BTA read-return FIFO output
DSI_WR_DATA	Host Transmit FIFO input
DSI_POWER_CONTROL	
INT_ENABLE	Interrupt Enables
INT_STATUS	Interrupt Status
INT_MASK	Interrupt Mask
HOST_DSI_CONTROL	Host-specific DSI controls
DSI_CONTROL	General and Video DSI controls
DSI_SOL_DELAY	Start-Of-Line delay register
DSI_MAX_THRESHOLD	FIFO transmit start threshold
DSI_TRIGGER	Manual transmit trigger register
DSI_TX_CRC	Verification transmitted data CRC
DSI_INIT_SEQ_CONTROL	Initialization sequence control
DSI_INIT_SEQ_DATA_0	Initialization data 0
DSI_INIT_SEQ_DATA_1	Initialization data 1
DSI_INIT_SEQ_DATA_2	Initialization data 2
DSI_INIT_SEQ_DATA_3	Initialization data 3
DSI_PKT_SEQ_[0..5]_LO	Packet Sequence [0..5] (low)
DSI_PKT_SEQ_[0..5]_HI	Packet Sequence [0..5] (high)
DSI_DCS_CMDS	DCS commands for Line Type 3 and 5
DSI_PKT_LEN_0_1	Packet Lengths for packets 0 and 1
DSI_PKT_LEN_2_3	Packet Lengths for packets 2 and 3

Register	Description
DSI_PKT_LEN_4_5	Packet Lengths for packets 4 and 5
DSI_PKT_LEN_6_7	Packet Lengths for packets 6 and 7
DSI_PHY_TIMING_0	Low-level D-PHY timing control
DSI_PHY_TIMING_1	Low-level D-PHY timing control
DSI_BTA_TIMING	Low-level D-PHY timing control
DSI_TIMEOUT_0	HTX_TO and LRXH_TO durations
DSI_TIMEOUT_1	TA_TO and PR_TO durations
DSI_TO_TALLY	Count of how many TOs have occurred

24.6.1 Initialization

The start-up and shut-down procedures vary depending on what mode of operation is required. Examples of programming sequences for the main modes are given below.

24.6.1.1 PLLD Programming

The DSI PLL is called PLLD in the Tegra 3 Devices. Just like the other PLLs in the system, PLLD has an M, N and P register for programming the various divide ratios for the clock. When used to drive Display pixel clock and DSI byte clock, the P divider is not used. Instead, there is a second divider that is used specifically for obtaining the Display pixel clock. The division ratio is labeled as D in the code below, but the correct name of the register should be used when actually programming the PLL.

```
//**** Environment ... ****

const float Fomin = 80.0;   // Min. oscillator frequency (MHz)
const float Fomax = 1000.0; // Max. oscillator frequency (MHz)
const float Fcmin = 1.0;    // Min. PLL phase comparison frequency (MHz)
const float Fcmax = 6.5;    // Max. PLL phase comparison frequency (MHz)

// MIPI Pixel formats ...
typedef enum { BIT16P, BIT18P, BIT18NP, BIT24P } pixel fmt;

//**** PLL Programming Information ... ****

int   M;         // Value by which the Reference clock is divided
                 // to get the comparison frequency
int   N;         // Value by which the Oscillator clock is divided
                 // to get the comparison frequency
int   D;         // Ratio between D-PHY bit clock and pixel clock

float Fosc;      // PLL oscillator frequency, in MHz   (information only)
float Fcomp;     // Phase comparator frequency, in MHz (information only)

//**** Function that computes the values of M, N and D ... ****

bool calc M N D(float Fref, float Fpixel, float tolerance,
                pixel fmt fmt, int lanes)

/******************
  Fref      : Input Reference frequency - in MHz
  Fpixel    : Desired output pixel clock frequency
  tolerance : Fractional error allowed in the output frequency
```

```
  fmt       : Pixel format. One of BIT16P, BIT18P, BIT18NP and BIT24P
  lanes     : Number of DSI lanes in use
  Function returns “true” on success and “false” otherwise
*******************/

{
  float Nfrac;
  bool  done = false;

  // Compute the value of D ...

  switch (fmt) {
    case BIT16P  : D = 16; break;
    case BIT18P  : D = 18; break;
    case BIT18NP :
    case BIT24P  : D = 24; break;
    }

  D = D / lanes;
  Fosc = Fpixel * clk ratio; // Calculate the Oscillator Frequency

  // Compute the values of M and N ...

  if ((Fosc > Fomin) && (Fosc < Fomax)) {
   // If the oscillator frequency is "legal" ...
    M = (int)(0.99 + Fref / Fcmax);
    do {
      // For each value of M, compute the comparison frequency
      Fcomp = Fref / (float)(M);
      // Now compute the exact value of N ...
      Nfrac = Fosc / Fcomp;
      // Strip off the integer and fractional parts ...
      N     = (int)(Nfrac);
      Nfrac = Nfrac - (float)(N);
      if (N > 0) {
        if ((Nfrac / N) < tolerance)
          // If the error is less than the tolerance, then we're done
          done = true;
        else
          // Too much error, so try dividing the reference some more ...
          M++;
        }
      else // N too small, so divide the reference by some more ...
        M++;
      } while (!done && (M < 32) && (Fcomp > Fcmin));
    }

  return (done);
}
```

24.6.1.2 Video Mode Start-up

All 3 video modes – Burst, Non-Burst and Non-Burst with Sync Ends – essentially have the same start-up sequence, with a slight variation between Burst and Non-Burst modes:

- Set up the clocks. This involves configuring and enabling the DSI PLL (PLLD). For Non-Burst and Non-Burst with Sync End modes, the Display Controller must also be programmed to take its pixel clock from the DSI PLL. For Burst Mode, the Display Controller can take its pixel clock either from the DSI PLL or from another clock source. Program the PLLD registers with the correct OSC_FREQ and program the PLLD_BASE register. In addition, PLLP must be running in order to provide the LP receive clock. Program the PLLP registers with the correct OSC_FREQ and program the PLLP_BASE register.
- Depending on the sub-mode, the various Packet Sequence registers and Packet Length registers must be programmed.
- Set the `VID_TX_TRIG_SRC` field in the `DSI_CONTROL` register to `SOL`. Select which Display Controller will source the video data.
- Configure PHY timing registers and timeout registers
- Enable DSI
- Program the Display Controller to produce the raster size required.
- Enable the Display Controller.

When the Display Controller starts sending SOL and data, the DSI automatically starts creating and transmitting packets to the Display Device.

24.6.1.3 Command Mode start-up

Set up the clocks. Program and enable the DSI PLL (PLLD). In addition, PLLP must be running in order to provide the LP receive clock. Program the PLLP registers with the correct OSC_FREQ and program the PLLP_BASE register. Unlike the Video Modes, the selection of PLLD output clock frequency is essentially arbitrary. The suitability of the clock frequency should be based on the expected data throughput and the requirements of the particular Display Device. Program the PLLD registers with the correct OSC_FREQ and program the PLLD_BASE register. In addition, PLLP must be running in order to provide the LP receive clock. Program the PLLP registers with the correct OSC_FREQ and program the PLLP_BASE register.

- Set the `HOST_TX_TRIG_SRC` field in the `HOST_DSI_CONTROL` registers to `IMMEDIATE`. Set any other state required.
- Configure PHY timing registers and timeout registers
- Enable DSI.

The DSI should now be ready to accept Command Packets written to the `DSI_WR_DATA` register.

24.6.2 Video Mode Programming

Packet sequences for video mode are somewhat complex and there is on-going debate within the MIPI DSI workgroup regarding the precise sequences and whether or not certain packets are optional. In order to make the hardware flexible enough to cope with all current video mode sequences and any possible future sequences or sequence variations, a more-or-less open-ended programming model has been adopted.

The programming model is as follows:

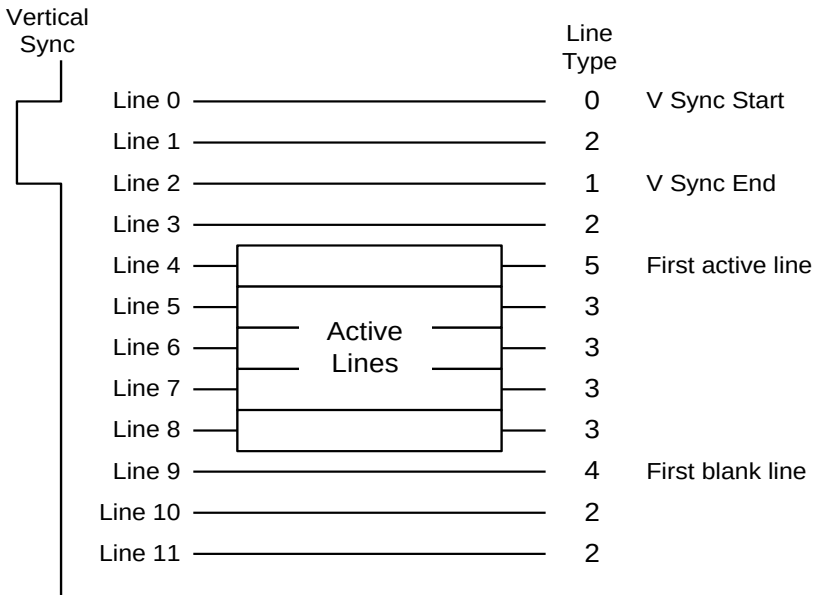
Each line of video output will have associated with it a “line type”. This line type is automatically generated by the display controller HW according to the following table:

Table 57 Line type descriptions

Line Type	Description	Typical raster position
0	Blank line starting with VS	First line of the raster
1	Blank line starting with VE	Line corresponding to V sync end.
2	Blank line starting with HS	Vertical blanking line
3	Active line starting with HS	Active line
4	First blank line after active	First blank line after active
5	First active line	First active line
6, 7	Reserved	

Figure 57 illustrates a typical raster showing the relationship between various events in the raster and the line types.

Figure 57 Example Video Raster Showing Line Types.



The line type acts like a pointer to a data structure containing the information about the "*packet sequence*" for that line type. The packet sequence information is actually held within a pair of registers. For example, the packet sequence for line type 0 is held in the pair of registers `DSI_PKT_SEQ_0_LO` and `DSI_PKT_SEQ_0_HI`. Each pair of packet sequence registers contains all the information required to generate up to 6 packets. This is sufficient to generate any packet sequence for any DSI video line. The information stored for each packet is shown in the following table:

Table 58 Packet Sequence Description Fields

Field	No. bits	Description
PKT_*_SIZE	3	Pointer to packet size register
PKT_*_ID	6	Packet ID as defined in the MIPI DSI spec.
PKT_*_EN	1	Enable. Determines which packets are active.

Using the same pair of registers as an example, Table 59 shows how all six packet descriptors fit into the pair of 32-bit packet sequence registers.

Table 59 Packet Sequence 0 registers

Register	Field	Bits	Description
DSI_PKT_SEQ_0_LO	PKT_00_SIZE	2:0	Packet 0 Size
	PKT_00_ID	8:3	Packet 0 ID
	PKT_00_EN	9	Packet 0 Enable
	PKT_01_SIZE	12:10	Packet 1 Size
	PKT_01_ID	18:13	Packet 1 ID
	PKT_01_EN	19	Packet 1 Enable
	PKT_02_SIZE	22:20	Packet 2 Size
	PKT_02_ID	28:23	Packet 2 ID
	PKT_02_EN	29	Packet 2 Enable
	SEQ_0_FORCE_LP	30	End in LP state
DSI_PKT_SEQ_0_HI	PKT_03_SIZE	2:0	Packet 3 Size
	PKT_03_ID	8:3	Packet 3 ID
	PKT_03_EN	9	Packet 3 Enable
	PKT_04_SIZE	12:10	Packet 4 Size
	PKT_04_ID	18:13	Packet 4 ID
	PKT_04_EN	19	Packet 4 Enable
	PKT_05_SIZE	22:20	Packet 5 Size
	PKT_05_ID	28:23	Packet 5 ID
	PKT_05_EN	29	Packet 5 Enable

Finally, the SIZE field in the packet descriptor is used as a pointer to a 16-bit "*packet length*" field in the packet length registers. The reason an indirect pointer is used, rather than storing the packet length directly in the packet descriptor is that the packet lengths are physically large – 16 bits – but there is a lot of re-use. There are actually only a few different lengths used in a typical raster layout. Thus, it is more efficient to hold the lengths in separate length registers and then to simply refer to them with a short pointer. This allows the storing of 36 packet descriptors in only 6 pairs of packet sequence registers.

It should be noted that one of the packet length registers is reserved for short packets. If a `SIZE` field in the packet descriptor is programmed to 0, this implies this packet is a short packet. Short packets are fixed in length to 4 bytes including the packet header byte and ECC byte. In the context of video mode, they are essentially reserved for timing packets. All other packet length registers can be used to determine the length of any associated long packet.

The `SEQ_0_FORCE_LP` bit is used to determine if the link should be placed in the LP state at the end of the packet transmission. In Burst Mode operation, the link always drops back into LP state at the end of the HS packet transmission on a line. However, for Non-Burst Modes, the HS transmission may continue to the next line. It is important the that the HW state machine that generates packets not attempt to go to the LP state, but should instead prepare for the next sequence of packets associated with the next video line and keep the line in the HS transmission state.

The packet length registers are shown in Table 60. The packet size pointer in the packet descriptor can point to any of the available length registers – with the one exception of short packets, whose `SIZE` field must point to length register 0. This open-ended possibility is very powerful, but may lead to confusion. It is therefore recommended that the suggested packet length assignment for various length registers is followed. This consistency will hopefully reduce confusion when debugging packet descriptors and packet sequences.

Table 60 Packet Length registers and assignments

Register	Field	Suggested Assignment
DSI_PKT_LEN_0_1	LENGTH_0	Must be used for short packets
	LENGTH_1	H sync active length (HSA)

Register	Field	Suggested Assignment
DSI_PKT_LEN_2_3	LENGTH_2	H back porch length (HBP)
	LENGTH_3	H active length (ACTIVE)
DSI_PKT_LEN_4_5	LENGTH_4	H front porch length (HFP)
	LENGTH_5	- reserved -
DSI_PKT_LEN_6_7	LENGTH_6	- reserved -
	LENGTH_7	- reserved -

When programming the length registers, it should be remembered that these are byte counts, not pixel counts. Therefore, the DSI pixel format, number of DSI lanes in use and the finite (non-zero) size of the packet header and CRC words should be taken into account when programming these values – especially for blanking packets since all of these parameters affect the number of bytes that should be used to emulate a specific blanking time. The equations required to determine the byte count in the packets is given in the examples that follow. The identification of the length given in the tables and equations has been included in braces in Table 60 so that the values in the examples can be easily tied to the registers.

24.6.3 SOL Delay Programming

In order to ensure that the pixel FIFO from display to DSI does not underflow when in video mode, it is necessary to delay the start of packet generation by the DSI, by a fixed amount from the arrival of the SOL signal from display. This is especially true of Burst-Mode, since the DSI byte clock can be very much faster than display pixel clock. If no delay is applied, the DSI will very quickly consume all the pixels in the FIFO and the FIFO will underflow. The `SOL_DELAY` registers is used to set this delay.

24.6.3.1 None-Burst Mode

In non-burst mode, the rate at which DSI consumes pixels is the same as the rate at which the display module produces them, so it is merely sufficient to ensure that enough pixels have been fed into the FIFO to overcome the internal latency. This internal latency is on the order of 8 pixel clock cycles. However, `SOL_DELAY` is programmed in DSI byte clocks, so the pixel format and the number of lanes being used should be taken into account when programming this value. Please contact your NVIDIA FAE for details on the relationship between display pixel clock and byte clock. These ratios are then used to determine the value of `SOL_DELAY` as follows:

$$SOL\_DELAY = 8 * F_{DSI} / F_{pixel}$$

Where F_{DSI} and F_{pixel} are the DSI byte and pixel clocks, respectively.

Alternatively, a fixed value of `SOL_DELAY` that will work for all pixel formats and numbers of lanes can be programming by taking the worst-case ratio of 1:3 (pixel:byte) clock and multiplying by 8 to give `SOL_DELAY` = 24.

24.6.3.2 Burst Mode

Burst mode is much more complex because not only must the pixel format, number of lanes and the DSI / pixel clock ratio be taken into account, but also the horizontal back porch time (including H sync) and the H active time. So, for Burst Mode:

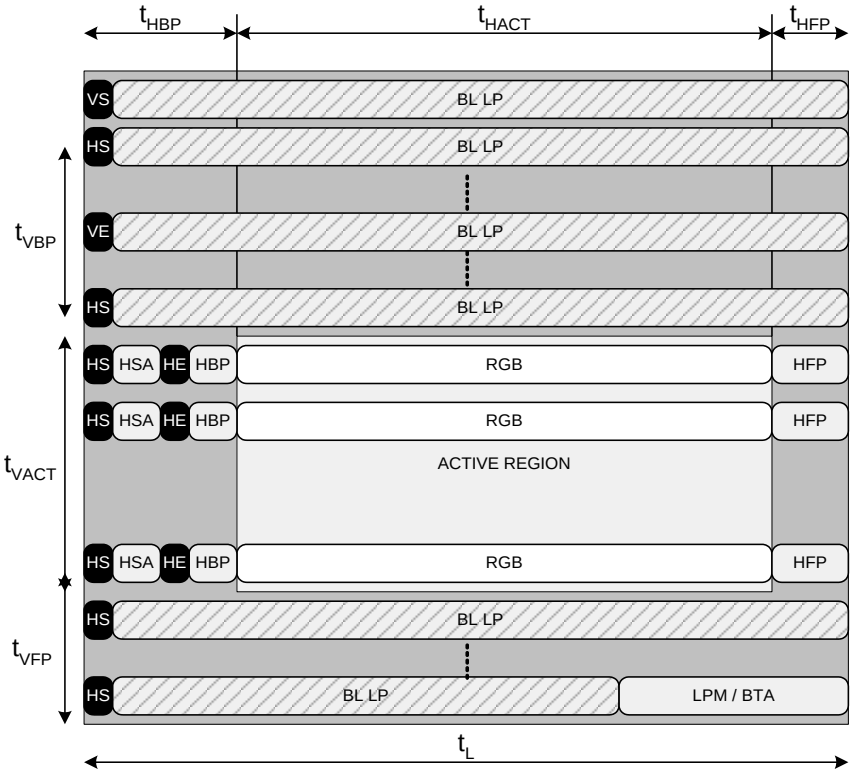
$$SOL\_DELAY = ((T_{HBP} + T_{active}) * F_{DSI} / F_{pixel}) – (T_{active} * F_{DSI\_NB} / F_{pixel\_NB})$$

Where the ratio $F_{DSI\_NB} / F_{pixel\_NB}$ is determined by the clock ratio tables for Non-Burst mode, according to the pixel format used and the number of active lanes.

24.6.4 Non-Burst Mode with Start and End

In this mode, an attempt is made to accurately convey traditional raster synchronization information across the link to the peripheral. This is achieved by sending both start and end sync packets.

Figure 58 Timing Diagram for Video Non-Burst Mode with Start and End



During the Vertical Active period, all packets should be concatenated into a single HS transmission for the duration of the Vertical Active period. There is some debate going on as to whether the HFP blank packet is required, or even desirable. This may get replaced by a period of Blanking / Low Power mode.

The detail of how a single line is constructed from multiple packets is shown in the figure below. In addition, it is necessary for the packet constructor on the display clock side of the display / DSI boundary FIFO to calculate the packet size for four different packets on the line.

It is also suggested that there is a running-disparity adjustment made to the packet sizes so that the average pixel rate on the DSI side matches the display output rate.

Figure 59 Non-Burst Mode with Start and End Packet Timing Detail

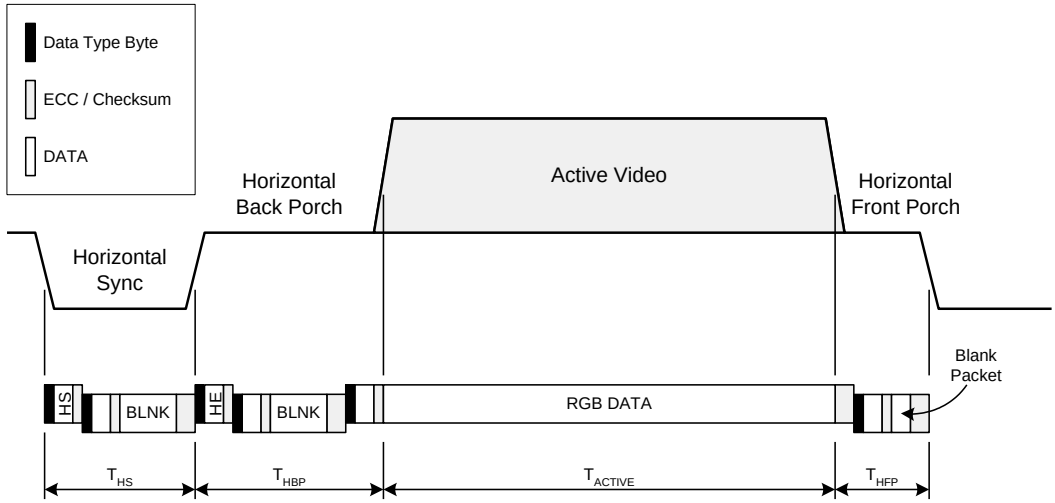


Table 61 Payload Size Table - Non-Burst Mode with Start and End

Packet	Payload Size (Bytes)
HSA	(T_{HS} * B) – 10
HBP	(T_{HBP} * B) – 14
ACTIVE	(T_{ACTIVE} * B)
HFP	(T_{HFP} * B) – 8

B = 2, 2.25 or 3, depending on pixel format.

N = Number of lanes used

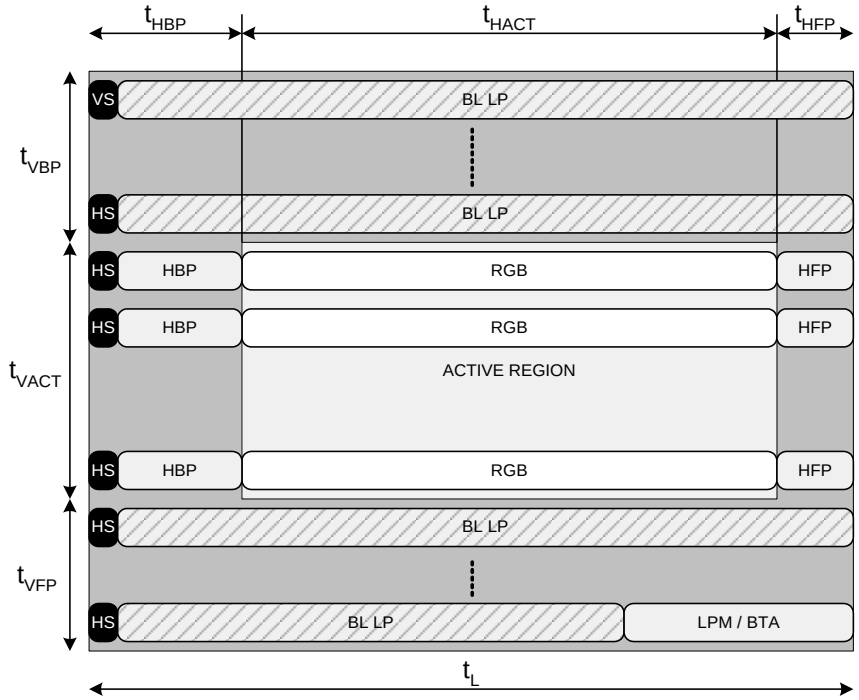
Table 62 Line Type Packet Sequences - Non-Burst with Sync Ends

LT	ID	Len	ID	Len	ID	Len	ID	Len	ID	Len	ID	Len
0	VS	0	EOT	0								
1	VE	0	EOT	0								
2	HS	0	EOT	0								
3	HS	0	BLNK	1	HE	0	BLNK	2	RGB	3	BLNK	4
4	HS	0	EOT	0								
5	HS	0	BLNK	1	HE	0	BLNK	2	RGB	3	BLNK	4

24.6.5 Non-Burst Mode (Without Ends)

This mode relaxes the requirement to mimic the generation of sync pulses and instead merely mandates that the start of the line is indicated and that the pixels appear at the same rate and in the same area of the raster as a tradition raster structure.

Figure 60 Timing Diagram for Video Non-Burst Mode



During the Vertical Active period, all packets should be concatenated into a single HS transmission for the duration of the Vertical Active period. As of writing, there is some debate as to whether the HFP blank packet is required, or even desirable. This may get replaced by a period of Blanking / Low Power mode.

The detail of how a single line is constructed from multiple packets is shown in the figure below. In addition, it will be necessary for the packet constructor on the display clock side of the display / DSI boundary FIFO to calculate the packet size for three different packets on the line. It is also suggested that there is a running-disparity adjustment made to the packet sizes so that the average pixel rate on the DSI side matches the display output rate.

Figure 61 Non-Burst Mode Packet Timing Detail

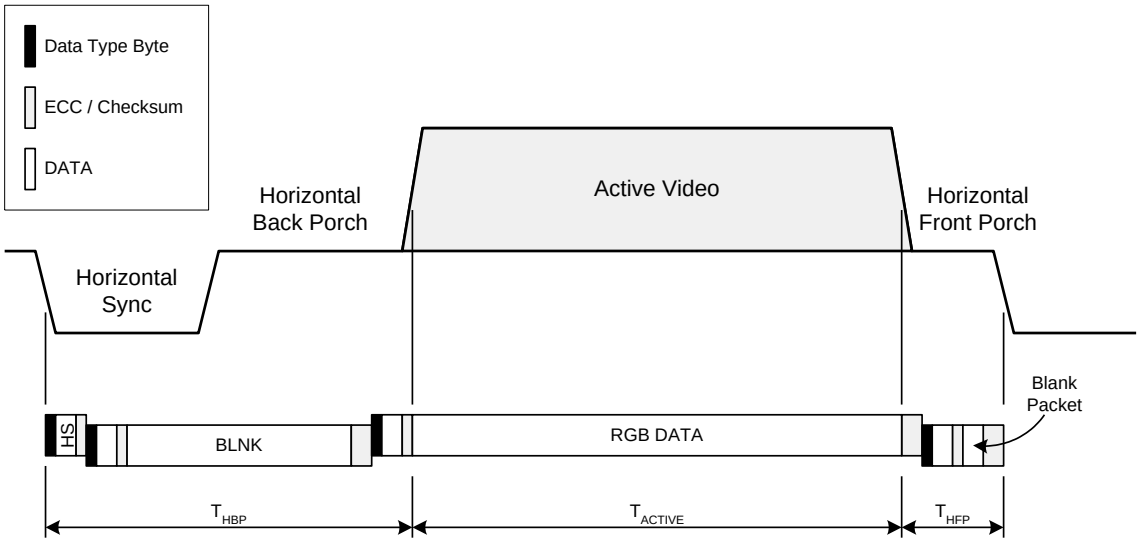


Table 63 Payload Size Table - Non-Burst Mode

Packet	Payload Size (Bytes)
HBP	(T_{HBP} * B) – 14
ACTIVE	(T_{ACTIVE} * B)
HFP	(T_{HFP} * B) – 8

B = 2, 2.25 or 3, depending on pixel format.

N = Number of Lanes used.

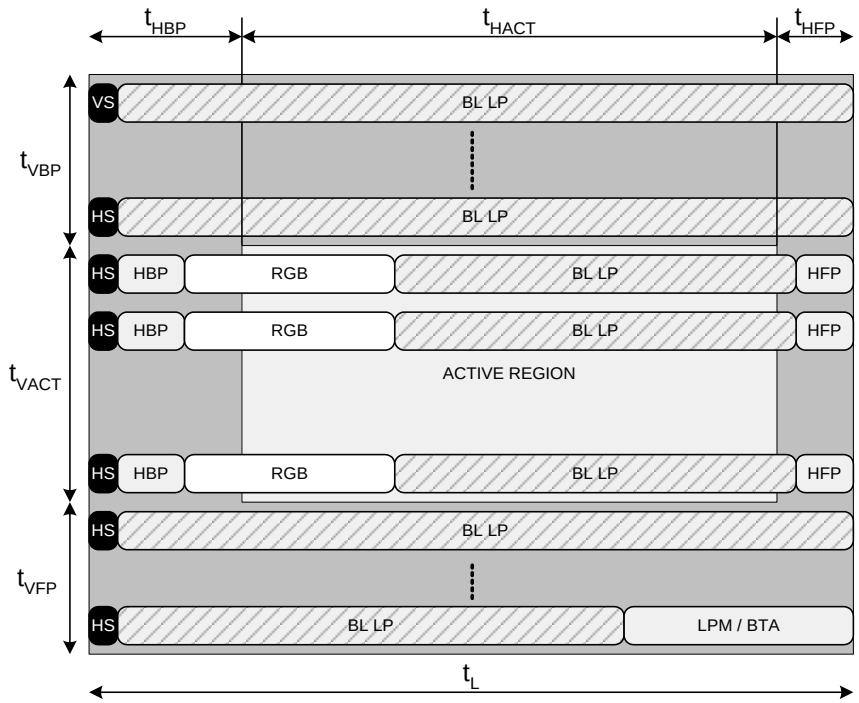
Table 64 Line Type Packet Sequences – Non Burst

LT	ID	Len	ID	Len	ID	Len	ID	Len	ID	Len	ID	Len
0	VS	0	EOT	0								
1	HS	0	EOT	0								
2	HS	0	EOT	0								
3	HS	0	BLNK	2	RGB	3	BLNK	4				
4	HS	0	EOT	0								
5	HS	0	BLNK	2	RGB	3	BLNK	4				

24.6.6 Burst Mode

In Burst Mode, the only attempt to match the raster structure is with the timing of the sync start events. The actual RGB pixel data is transmitted at whatever rate is convenient. This means that the HS, HBP and RGB packets become compressed with respect to the timing of the underlying raster. This allows some period of idle time each line that can be used for the transmission of other packets.

Figure 62 Timing Diagram for Video Burst Mode



During the Vertical Active period, packets on an individual line should be concatenated into a single HS transmission. However, unlike Non-Burst Mode, the bus should go idle – if possible – at the end of this transmission. This will allow additional non-video packets to be sent essentially simultaneously with the video stream. The NULL and HFP packets may be optional. Check the latest MIPI DSI specification for clarification.

Table 65 Line Type Packet Sequences - Bust Mode

LT	ID	Len	ID	Len	ID	Len	ID	Len	ID	Len	ID	Len
0	NULL	4	VS	0	EOT	0						
1	NULL	4	HS	0	EOT	0						
2	NULL	4	HS	0	EOT	0						
3	BLNK	4	HS	0	BLNK	2	RGB	3	EOT	0		
4	NULL	4	HS	0	EOT	0						
5	BLNK	4	HS	0	BLNK	2	RGB	3	EOT	0		

24.6.7 Command Mode Programming

There are two sources of command mode packet sequences:

- Display Controller
- Host Interface

Only one of these sources will be active at any particular time.

24.6.7.1 Command Mode from Host

In this mode of operation, all packets sent over the DSI interface are determined by Software. There may be hardware assistance in the generation of Error Correction Codes (ECC) and Cyclic Redundancy Checks (CRC), but all other data is passed un-altered to the DSI physical layer.

Host Packet Writes

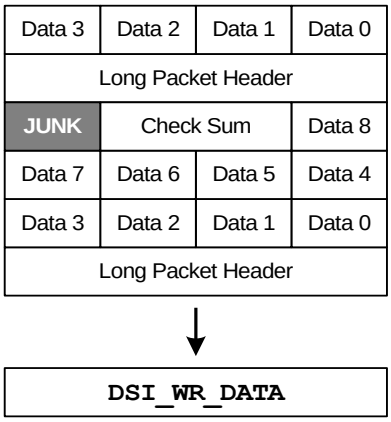
Packets are written to the HW by writing to the `DSI_WR_DATA` register. The data written is passed into the DSI Host transmit FIFO. If the data is a packet header and the `ECC_ENABLE` field in the `HOST_DSI_CONTROL` register is set to `ENABLE`, then the MSBs of the 32 bit packet header word is replaced with a Hardware computed ECC byte prior to being written into the FIFO. If this field is set to `DISABLE`, then no action is taken by the HW and the packet header is written unchanged.

If the packet is a long packet, then the packet payload should be written to the register after the packet header is written. If the `ECC_ENABLE` field of the `HOST_DSI_CONTROL` register is set to `ENABLE`, then the hardware computes the check-sum and appends it to the packet information. If this field is set to `DISABLE` then software must append the correctly computed check-sum to the packet data.

Rules:

1. Software should make sure packets are transmitted in their entirety and that once transmission starts, the FIFO contains enough data to finish a transition on a packet boundary. This can be achieved by only initiating a transmission – either explicitly, or indirectly – once all data required for a transmission has been written to the transmit FIFO.
2. Packets should be written such that the packet header is always written in one 32-bit word and is never split across writes. In other words, if the end of a packet does not fall on a 32-bit word boundary – if the payload has an odd length, for example – then the header for the next packet should not about the last packet, but should re-align with the register. See Figure 63 for an example.

Figure 63 Packet alignment for writes to DSI_WR_DATA



Host Packet Transmission

Control of when the Host write FIFO starts to drain (flush) can be programmed to come from several sources:

- Start Of Line signal from the Display Controller
- Once the FIFO has some programmable quantity of data in it.
- Explicit FLUSH bit in a control register

Start of Line (HOST_TX_TRIG_SRC == SOL **)**

This mode would typically be used when the Host is trying to emulate Video Mode to drive a raster-based display. Currently this mode of operation is a P1 feature.

Threshold (HOST_TX_TRIG_SRC == FIFO_LEVEL**)**

The FIFO can be programmed to automatically start transmission once a certain amount of data has been written to the FIFO. This is useful if the amount of data to be transmitted is already known and is essentially constant, or at least consistently more than the threshold amount. Software can then simply write to the `DSI_WR_DATA` register and transmission will start automatically. However, it should be ensured that if the threshold is set such that not all the data for a packet will have been written when the threshold is met, that software will write all the required data before the transmission has drained the FIFO completely.

Immediate (HOST_TX_TRIG_SRC == IMMEDIATE**)**

As the name implies – if a '1' is written to the `DSI_HOST_TRIGGER` field of the `DSI_TRIGGER` register, then transmission of the data in the Host write FIFO will start immediately. It it recommended that all data required for transmission is written to the `DSI_WR_DATA` register prior to setting this bit.

24.6.7.2 Command Mode from Display Controller

This mode of operation is intended to allow the display controller to write pixel data packets to a DBI-like device that does not require data to be sent in an isochronous raster structure like a DPI device. Of course, the data ***will*** be sent in an isochronous manner since it will be coming from the display controller, but the commands sent will be DCS control commands, rather than Video Mode timing and blanking packets.

Setup

There are four steps to operating in this mode:

1. Program the Peripheral display device using DCS commands via the Host Command interface. It is especially important to send the set_column_address, set_page_address and set_pixel_format commands. These effectively define the area to which we will be writing pixels.
2. Program the DSI_INIT_SEQ_CONTROL and DSI_INIT_SEQ_DATA_* registers in the DSI interface with appropriate values. Any commands required to be sent once per frame and *every* frame by way of set-up prior to the pixel data being sent should be put in here.
3. Program the DSI_DATA_FORMAT field of the DSI_CONTROL register to the required pixel format. Note that BIT18NP should not be programmed – see below on pixel format restrictions.
4. Program the DSI_PKT_SEQ_* registers. Program the registers in the flowing way:
    a. Packet Sequence registers for Line Types 0, 1, 2 and 4 should all be programmed with 0 in all the Packet Enable fields. In other words, there should not be any packets generated for these line types.
    b. Packet Sequence registers for Line Type 3 and 5 should be programmed with a DCS Long Write packet.
5. Program the DCS command ID register to have a write_start command associated with Line Type 5 (First line of active) and a write_continue command associated with Line Type 3 (all other active lines).
6. Enable the display. When Vertical syncs arrive from display, the initialization sequence should be sent and for every active line, the pixel data will be sent in a DCS Long Write packet.

Pixel Format Restrictions

The MIPI DCS specification allows for up to 6 different pixel data formats to be transmitted in a write_start or write_continue command. These pixel formats are listed in Table 66. Unfortunately, due to limitations in the current design of the DSI hardware, only 3 of the 6 formats can be supported.

The formats supported are also shown in the “supported” column of Table 66. Do not set BIT18NP as a pixel format. There is no DCS equivalent of this format, so undefined behavior may result if this format is set.

Table 66 DCS Pixel Format Support

DCS ID	DCS format	Supported	Name
0	reserved	N/A	-
1	3bpp	N	-
2	8bpp	N	-
3	12bpp	N	-
4	reserved	N/A	-
5	16bpp	Y	BIT16P
6	18bpp	Y	BIT18P
7	24bpp	Y	BIT24P

Simultaneous Host Command packets

It is necessary, from time to time, to send a DCS command to the display peripheral in a “side-band” fashion while the display controller is continuing to send DCS write commands with pixel information. To this end, Line Type 4 (First blank line) is reserved to indicate to the HW when it should attempt to send any DCS command packets requested by SW.

If it is desired to send a DCS command in this way, the DCS command packet should be written in its entirety (header, ECC, DCS command, payload, CSC) into the Host Command FIFO. The HOST_TX_TRIG_SRC field should then be set to IMMEDIATE.

The DSI HW will then send the entire contents of the FIFO out on the DSI interface on the first line of blanking. Sending the data on this line guarantees the Host packet transmission will have enough time to complete before the next packet generated by the Display Controller is generated.

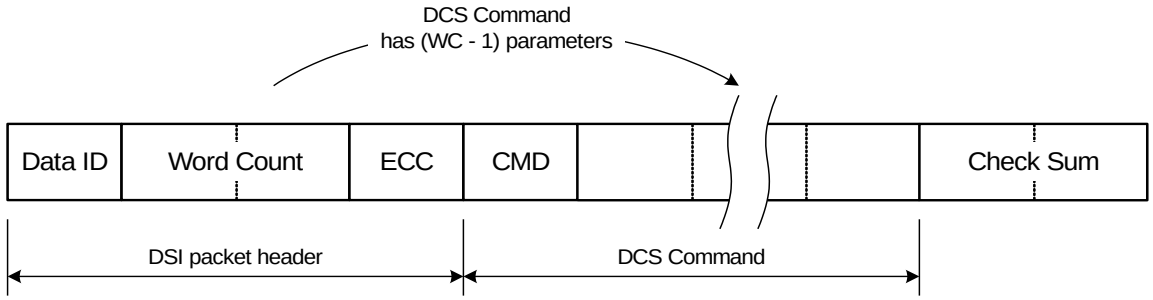
Note: There will be no BTA permitted in this mode, so no ACK, ACK with error report or read return data will be generated.

24.6.8 Display Command Set (DCS) Packets

DCS is a legacy control command set that is used to program various control registers present in typical LCD panels used in cell phones. Historically, the commands would be sent to the display over a MIPI DBI interface. Since MIPI DSI is meant to replace both DPI and DBI, it must also transport these control commands.

There are several DCS-specific commands in the MIPI DSI specification that can be used to send DCS commands to the Peripheral Display Device. However, the most useful is probably the DCS Long Write packet since it can be used to send commands with more than one parameter. The DCS command is embedded with an MIPI DSI Long Packet as follows: The DCS Command Byte and all the DCS Command Parameters (payload) are concatenated and sent in the Payload of the MIPI DSI Long Packet. The Word Count of the DSI packet conveys the total size of the DSC packet. As usual, a 2-byte CS footer is appended to the DSI Long Packet. A diagram of how a DCS Long Write packet is constructed is shown below in the next figure.

Figure 64 DCS command Placement in DSI Long Packet



24.6.9 Function Programming

24.6.9.1 ECC Generation

For precise details on the calculation of the ECC field of the packet header, reference should be made to the MIPI Alliance Standard for Display Serial Interface [2]. However, this is an overview of how the ECC can be created quite simply.

Each bit of the ECC byte is the result of XORing a number of bits from the packet header together. Which header bits contribute to which ECC bit is contained in a special table which can be used to calculate the ECC as follows:

```
const UCHAR ecc_parity[24] = { 0x07, 0x0b, 0x0d, 0x0e, 0x13, 0x15, 0x16, 0x19,
                               0x1a, 0x1c, 0x23, 0x25, 0x26, 0x29, 0x2a, 0x2c,
                               0x31, 0x32, 0x34, 0x38, 0x1f, 0x2f, 0x37, 0x3b
                             };
ULONG packet_header;
UCHAR ecc_byte;
UINT  i;

// Assume bottom 24 bits of packet_header
// contains header ID and byte count, then ...

ecc_byte = 0;
for (i = 0; i < 24; i++) {
  ecc_byte ^= ((packet_header >> i) & 1) ? ecc_parity[i] : 0x00;
}
```

```
packet header |= (ULONG)(ecc byte) << 24;
```

Note that the table in the DSI specification actually contains 64 entries. Since short packets have been fixed in length to be the same as a long packet header since the original specification was written, there will now always be just 24 data bits in the packet header, so only 24 entries are needed.

24.6.9.2 CRC Insertion

The DSI check sum used for long packets is derived using the generator polynomial $x^{16}+x^{12}+x^5+x^0$. Details of this can be found in section 9.6 of the MIPI DSI specification. To understand how the CRC is generated, it is easier to think of the packet data as consisting of a continuous serialized stream of bits, rather than a sequence of 8-bit bytes. When thought of in this way, it is relatively straight forward to generate the CRC. Reproduced below is an abridged version of the example C code contained in Appendix B of the MIPI DSI specification.

```
// Polynomial, bit reversed form (since DSI transmits LSB first) …
const unsigned short CRC16GenerationCode = 0x8408;

unsigned short CalculateCRC16( unsigned char *DataStream ptr, unsigned short NumberOfDataBytes)

{
  unsigned short ByteCounter;
  unsigned char  BitCounter;
  unsigned char  CurrentData;
  unsigned short CRC16Result = 0xFFFF;

  if (NumberOfDataBytes > 0) {
    for (ByteCounter = 0; ByteCounter < NumberOfDataBytes; ByteCounteer++) {
      CurrentData = DataStream ptr[ByteCounter];
      for (BitCounter = 0; BitCounter < 8; BitCounter++) {
        if ((CRC16Result & 0x0001) ^ (CurrentData ^ 0x0001))
          CRC16Result = ((CRC16Result >> 1) & 0x7FFF) ^ CRCGenerationCode;
        else
          CRC16Result =  (CRC16Result >> 1) & 0x7FFF;
        CurrentData = (CurrentData >> 1) & 0x7F;
      }
    }
  }
  return CRC16Result;
}
```

This code may not be very high-performance due to the inner for loop which iterates over bits, rather than bytes. While it is instructive and could form the basis of a reference piece of code, it is not recommended where performance is important. There are many documented methods of performing this calculation in parallel in order to speed up the computations. These methods are beyond the scope of this document.

24.6.10 Read Data Return

DSI is a bi-directional interface. Data is returned from the peripheral display device only after the display controller has requested information by issuing a Bust Turn Around (BTA). All returned data is written into a FIFO that can be read using Host reads of a DSI register.

24.6.10.1 Reading Peripheral Registers

A typical application of BTA would be in the reading of a register from the display peripheral. This is achieved in the following way:

1. Set up the DSI interface to be in Host-driven command mode.
2. Set the DSI_MAX_THRESHOLD to 3.
3. Set the HOST_TX_TRIG_SRC field of the HOST_DSI_CONTROL register to FIFO_LEVEL.
4. Set the PKT_BTA field of the HOST_DSI_CONTROL register to ENABLE.
5. Write a DCS READ command packet (see section 8.8.8.2 of the MIPI DSI specification) into the Command FIFO by writing to the DSI_WR_DATA register.

This will result in the transmission of a DCS READ packet to the peripheral, the initiation of a BTA and – assuming the peripheral received the packet without error – the return of the requested data to the Host Read Return FIFO. The data can then be read from the FIFO by reading the DSI_RD_DATA register.

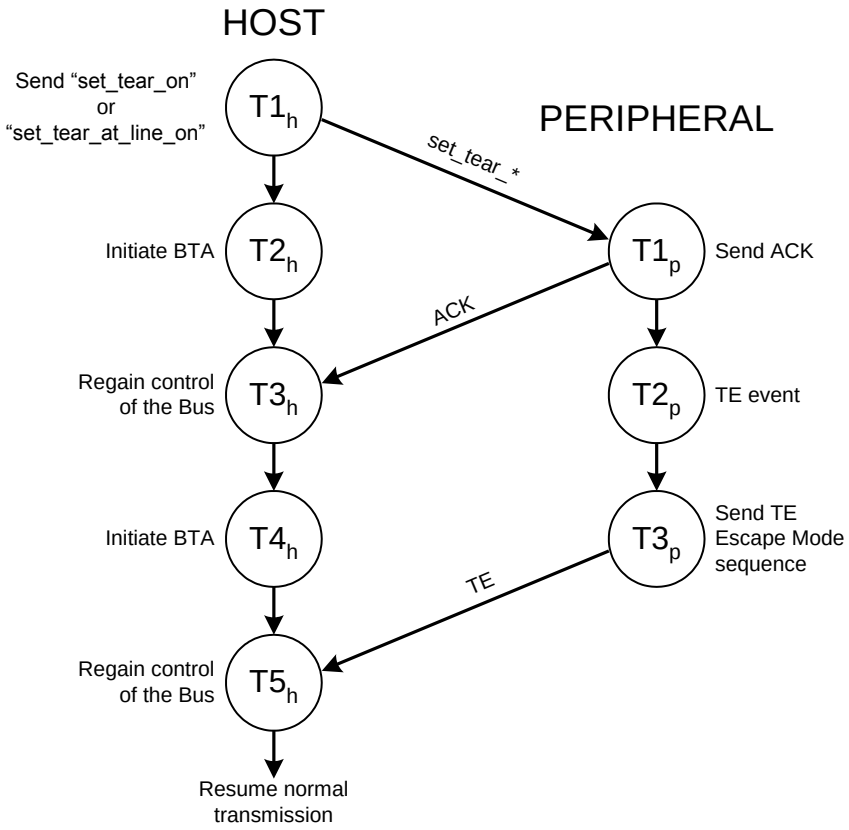
24.6.10.2 Bus Turn Around

- BTA is only supported for Host driven Command Mode interface. There will be no BTA during video mode transmission.
- Whether or not a BTA is initiated is controlled by the PKT_BTA field of the HOST_DSI_CONTROL register.
- The DSI Read Return FIFO is 4 bytes wide and 8 entries deep, so 32 bytes in total. this is enough to hold 8 short packets, or a mixture of short and long packets. Obviously, the length of long packets must be severely restricted.
- There will be no ECC or CS check performed by hardware on the read return data. Entire packets will simply be made available to software to perform whatever checks they desire.
- There will be the ability to increment a sync point counter on the arrival of the returned data or on the receipt of an error report in the event there was a problem with the read packet transaction.

24.6.11 Tearing Effect

In order to synchronize the update of a Command Mode display with data from the Host, a signal from the display can be sent to indicate when it is safe to proceed with the transmission of new data. This is the Tearing Effect reporting signal. Refer to section “8.12 TE Signaling in DSI” of the DSI specification for more details.

Figure 65. Tearing Effect State Transition Diagram



Programmatically, this is achieved in the following way:

1. Send SET_TEAR_ON or SET_TEAR_AT_LINE_ON command with the PKT_BTA field in the HOST_DSI_CONTROL register set to ENABLE. This is state $T1_h$.
2. Wait for ACK to come back from the peripheral. This is states $T2_h$ and $T3_h$.
3. Set the IMM_BTA field in the HOST_DSI_CONTROL register set to ENABLE. This will cause the D-PHY to go into BTA without having to send a command first. This is state $T4_h$.
4. Wait for TE return byte from the peripheral. This is state $T5_h$.

24.6.12 Error Reporting

There is no actual error recovery circuitry in the hardware, only error reporting. Any error that is reported via a protocol-level packet will be processed like all other return data and will be written to the data return FIFO for processing by the Host / Software.

Low level hardware errors such as bus contention will not be flagged, but will increment counters that can be queried by software so as to determine the reliability of the link.

24.6.12.1 Acknowledge with Error Report

The peripheral device (display) can be instructed to return an error report along with an acknowledge at the end of a transmission sequence. This is achieved by setting the PKT_BTA field in the HOST_DSI_CONTROL register to ENABLE. When this is done, there are several outcomes as shown in Table 67.

Table 67 Peripheral response to various conditions

Condition	Non-Read Packet	Read Packet
No error	ACK	Read Data
Corrected single bit error	ACK w/ERR	Read Data + ACK w/ERR
Non-corrected multi-bit error	ACK w/ERR	ACK w/ERR
SOT, EOT, VI ID or other D-PHY error	ACK w/ERR	ACK w/ERR

It is the responsibility of software to read this data from the packet returned in the packet return FIFO and process as required. No action will be taken by the hardware based on the error report returned in the ACK packet.

ACK Return

If a BTA request is enabled and there is no error, then the peripheral will return an ACK trigger to the DSI hardware. This is a single byte trigger and has the value 0x84. Since the return FIFO is 32 bits wide, the 0x84 value will be placed in the bottom 8 bits of the FIFO.

Read Data

If a read command packet is sent, then BTA request should be enabled to allow the peripheral to return the read data. If no error occurs in the transmission of the read packet, or a corrected single bit error occurs, then the read data will be returned to the host DSI hardware in the form of a read packet. The precise form will depend on the type of read packet transmitted. Refer to the MIPI DSI specification, section 8.10 for details.

If a corrected error occurs during the transmission of the read command, the requested read data will be returned in the normal way, but an ACK with Error report packet will be appended to the read return data packet.

ACK with Error Report

The error report is contained in the 16 payload bits of a special short packet returned by the peripheral. The bits allocations of the packet data are detailed in section 8.9.5 of the MIPI DSI specification but are repeated here for convenience.

Table 68 Error Report Bit Assignments

Bit	Description
0	SOT error
1	SOT sync error
2	EOT sync error
3	Escape Mode Entry Command error
4	Low-Power Transmit Sync Error
5	HS Receive Timeout error
6	False Control Error
7	RESERVED
8	ECC Error, single bit (corrected)
9	ECC Error, multi-bit (not corrected)
10	CS Error (long packet only)
11	DSI data type not recognized
12	DSI Virtual Channel ID invalid
13	RESERVED
14	RESERVED
15	RESERVED

24.6.13 Time Outs

There are three compulsory and one optional time out counters required by the MIPI DSI specification for Processors (display controller). Each timer will consist of a simple counter which will count DSI byte clocks. The counters will reset to 0 on an event and will then simply increment their count every DSI byte clock cycle. If the event that the time out is protecting occurs before the time out reaches its terminal count, the counter will simply stop counting and hold its value. If the counter reaches software programmed maximum count before the expected event occurs, the counter will stop counting and hold its count value. Any action that is required by the MIPI DSI specification upon reaching the time out will also be performed by the hardware.

Table 69 Time out counter summary

Time Out Name	Abbreviation	Start Condition	Length Greater Than	Action
HS Transmit TO	HTX_TO	SOT	Longest HS sequence	EOT + LP-11
LP Receive TO	LRXH_TO	LP Rx start	LTXP_TO (on periph.)	LP-11
Turn Around TO	TA_TO	BTA start	BTA response time	LP-11
Peripheral Reset	PR_TO	Reset Entry CMD	Peripheral resp. time	None.

In the table, the Peripheral Reset time out is the only timer that is optional. All the other timers are required by the MIPI DSI specification. Note that under “Action”, the listed operations are forced on the interface by the D-PHY under the instruction of the protocol layer (hardware). In the case of the optional Peripheral Reset time out, there is no action since this time out simply exists to issue a reset to the peripheral. Once the reset command is issued, the only further action required is to wait for an appropriate length of time to allow the peripheral to go through its reset sequence.

In the case of the HTX_TO, LRXH_TO and TA_TO time outs, the reaching of a terminal count will not only cause the action as listed in Table 69, but will also cause a tally counter to increment so that software can read the register and determine if any of the time outs have occurred. Software will be able to reset these tally counters to 0 by writing to the tally register. The value written will be irrelevant. The PR_TO will report its operation in a different manner. When the PR_TO counter is actually counting, there will be a status bit that reads as ‘0’. When the PR_TO terminal count is reached and time out ends, the status bit will become ‘1’. This will allow SW to determine when the peripheral has been reset.

Table 70 Time out and Tally registers

Register	Field	Description
DSI_TIMEOUT_0	HTX_TO	High Speed Transmit time out duration
	LRXH_TO	Low Power Receive time out duration
DSI_TIMEOUT_1	TA_TO	Turn Around time out duration
	PR_TO	Peripheral Reset duration
DSI_TO_TALLY	HTX_TALLY	High Speed Transmit time out Tally
	LRXH_TALLY	Low Power Receive time out Tally
	TA_TALLY	Turn Around time out Tally
	P_RESET_STATUS	Peripheral Reset Status: 0= Reset, 1 = Ready

24.7 MIPI-DSI Registers

24.7.1 DSI_INCR_SYNCPT_0

Offset: 000h | Read/Write: R/W | Reset: 0b0000000000000000

Bit	Reset	Description
15:8	0x0	COND: Condition mapped from raise/wait 0 = IMMEDIATE 1 = OP_DONE 2 = RD_DONE 3 = REG_WR_SAFE 4 = COND_4 5 = COND_5 6 = COND_6 7 = COND_7 8 = COND_8 9 = COND_9 10 = COND_10 11 = COND_11 12 = COND_12 13 = COND_13 14 = COND_14 15 = COND_15
7:0	0x0	INDX: syncpt index value

24.7.2 DSI_INCR_SYNCPT_CNTRL_0

Offset: 001h | Read/Write: R/W | Reset: 0b0xxxxxxx0

Bit	Reset	Description
8	0x0	INCR_SYNCPT_NO_STALL: If NO_STALL is 1, then when fifos are full, INCR_SYNCPT methods will be dropped and the INCR_SYNCPT_ERROR[COND] bit will be set. If NO_STALL is 0, then when fifos are full, the client host interface will be stalled.
0	0x0	INCR_SYNCPT_SOFT_RESET: If SOFT_RESET is set, then all internal state of the client syncpt block will be reset. To do soft reset, first set SOFT_RESET of all host1x clients affected, then clear all SOFT_RESETs.

24.7.3 DSI_INCR_SYNCPT_ERROR_0

Offset: 002h | Read/Write: R/W | Reset: 0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx

Bit	Reset	Description
31:0	X	COND_STATUS: COND_STATUS[COND] is set if the fifo for COND overflows. This bit is sticky and will remain set until cleared. Cleared by writing 1.

24.7.4 DSI_CTXSW_0

Context switch register (common to all modules). Includes the current channel/class (which is writable by SW) and the next channel/class (which the hardware sets when it receives a context switch).

Context switch works like this:

Any context switch request triggers an interrupt to the host and causes the new channel/class to be stored in NEXT_CHANNEL/NEXT_CLASS (see vmod/chexample). SW sees that there is a context switch interrupt and does the necessary operations to make the module ready to receive traffic from the new context. It clears the context switch interrupt and writes CURR_CHANNEL/CLASS to the same value as NEXT_CHANNEL/CLASS, which causes a context switch acknowledge packet to be sent to the host. This completes the context switch and allows the host to continue sending data to the module. Context switches can also be pre-loaded. If CURR_CLASS/CHANNEL are written and updated to the next CLASS/CHANNEL before the context switch request occurs, an acknowledge will be generated by the module and no interrupt will be triggered. This is one way for software to avoid dealing with context switch interrupts.

Another way to avoid context switch interrupts is to set the AUTO_ACK bit. This bit tells the module to automatically acknowledge any incoming context switch requests without triggering an interrupt. CURR_* and NEXT_* will be updated by the module so they will always be current.

Offset: 008h | Read/Write: R/W | Reset: 0bxxxxxxxxxxxxxxxx11111x0000000000

Bit	R/W	Reset	Description
31:28	RO	X	NEXT_CHANNEL: Next requested channel
25:16	RO	X	NEXT_CLASS: Next requested class
15:12	RW	0xf	CURR_CHANNEL: Current working channel, reset to 'invalid'
11	RW	0x1	AUTO_ACK: Automatically acknowledge any incoming context switch requests 0 = MANUAL 1 = AUTOACK
9:0	RW	0x0	CURR_CLASS: Current working class

Note: **PACKET DEFINITIONS**

Packet for Display Controller -> DSI communication:

Line Type is used to convey the type of video line from the display controller to the DSI block. The line type implies the generation of one of the associated packet sequences as defined in the DSI packet sequence registers (see below). Used to construct packet headers. All packet headers are now 32-bits wide regardless of whether they are short or long packets. Used for validation infrastructure only.

24.7.5 DSI_DSI_RD_DATA_0

DSI read return data

Offset: 009h | Read/Write: RO | Reset: 0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx

Bit	Reset	Description
31:0	X	DSI_RD_DATA: Each read to this register will pop 32 bits from the 32 bit wide read return data FIFO. FIFO has NV_DSI_HOST_DATA_RETURN_FIFO_DEPTH entries.

24.7.6 DSI_DSI_WR_DATA_0

Host FIFO write input

Offset: 00ah | Read/Write: R/W | Reset: 0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx

Bit	Reset	Description
31:0	X	DSI_WR_DATA: Each write to this register will puch 32 bits into the 32 bit wide Host data FIFO. FIFO has NV_DSI_HOST_DATA_FIFO_DEPTH entries

24.7.7 DSI_DSI_POWER_CONTROL_0

Display Power Control. DSI Enable

Offset: 00bh | Read/Write: R/W | Reset: 0b0

Bit	Reset	Description
0	0x0	LEG_DSI_ENABLE: DSI interface Enable 0 = DISABLE : Disable DSI 1 = ENABLE : Enable DSI

24.7.8 DSI_INT_ENABLE_0

Interrupt enable register

Offset: 00ch | Read/Write: R/W | Reset: 0b1

Bit	Reset	Description
0	0x1	CTXSW_INT_ENABLE: Context Switch Interrupt Enable 0 = DISABLE : interrupt disabled 1 = ENABLE : interrupt enabled

24.7.9 DSI_INT_STATUS_0

Interrupt Status register

Offset: 00dh | Read/Write: R/W | Reset: 0b0

Bit	Reset	Description
0	0x0	CTXSW_INT: Context switch interrupt status (clear on write)

24.7.10 DSI_INT_MASK_0

Setting bits in this register masked the corresponding interrupt but does not clear a pending interrupt and does not prevent a pending interrupt to be generated. Masking an interrupt also does not clear a pending interrupt status and does not prevent a pending interrupt status to be generated.

Interrupt Mask

Offset: 00eh | Read/Write: R/W | Reset: 0b0

Bit	Reset	Description
0	0x0	CTXSW_INT_MASK: Context Switch Interrupt Mask 0 = MASKED : interrupt masked 1 = NOTMASKED : interrupt not masked

24.7.11 DSI_HOST_DSI_CONTROL_0

DSI control register when input is from HOST

Offset: 00fh | Read/Write: R/W | Reset: 0b00x000xx00xx0000000011

Bit	Reset	Description
21	0x0	FIFO_STAT_RESET: write only bit to clear FIFO underflow/overflow flags. If there new underflow/overflow event occurs during the same time, current access cant clear the status bits
20	0x0	CRC_RESET: Write only bit. When written with a 1, causes the Verification CRC generator to reset to 0xFFFF_FFFF. If written with 0, it has no effect.
18:16	0x0	DSI_PHY_CLK_DIV: Phy clock divider value for byte clock 0 = DIV1 1 = DIV2
13:12	0x0	HOST_TX_TRIG_SRC: Controls the source of the trigger to start sending packets. 0 = SOL : Start of Line signal from the Display Controller. 1 = FIFO_LEVEL : How full the FIFO is. Level determined elsewhere. 2 = IMMEDIATE : Determined by a write to the DSI_HOST_TRIGGER field of the DSI_TRIGGER register
9:8	0x0	DSI_ULTRA_LOW_POWER: Ultra Low Power 0 = NORMAL 1 = ENTER_ULPM 2 = EXIT_ULPM
7	0x0	PERIPH_RESET: Initiate an Escape Mode Peripheral Reset. 0 = DISABLE 1 = ENABLE Causes an Escape Mode Command to be sent to reset the external display device. Also starts the PR_TO counter. PR_TO state can be checked with the P_RESET_STATUS field in the DSI_TO_TALLY register. HW clears this bit upon completion of issuing "Trigger Reset" OR called "Reset Entry" command is sent out.
6	0x0	RAW_DATA: Host raw data mode. In this mode. All data is sent exactly as written. No attempt to decode packet headers is made. This bit will also override the function of the ECC and CS ENABLE fields. No ECC or CS will be generated. This mode is intended as a debug / diagnostic workaround mode only. 0 = DISABLE : Normal mode. 1 = ENABLE : Enable raw data transmission.
5	0x0	DSI_HIGH_SPEED_TRANS: DSI high speed transmission of packets 0 = LOW : low speed - Note: Unlikely ever to be used. 1 = HIGH : high speed

Bit	Reset	Description
4	0x0	PKT_WR_FIFO_SEL: Host Write FIFO Select 0 = HOST : Write data to the small host data FIFO only. 1 = VIDEO : Write data to both the host and video line store FIFO, in series.
3	0x0	IMM_BTA: Generate BTA immediately, eg. for Tearing Effect reporting. Note: This will generate a BTA and pass control of the D-PHY to the remote peripheral without the need to send any packet. Once the BTA is initiated on interface this bit gets cleared. Later on Host syncpt opdone is returned when the remote peripheral has responded and relinquished control of the bus. 0 = DISABLE : Do not generate BTA 1 = ENABLE : Generate BTA immediately, without waiting for a packet.
2	0x0	PKT_BTA: Generate BTA at the end of Host packets 0 = DISABLE : Do not generate BTA 1 = ENABLE : Generate BTA after the next packet is sent.
1	0x1	CS_ENABLE: enable Hardware Check Sum (CS) for Host packets Note: when CS is disabled, Host is responsible for generating proper CRC and adding the 2-byte CRC to the end of the packet after the payload. 0 = DISABLE : disable HW generation of CS (Host must calculate CS). 1 = ENABLE : enable HW generation of CS.
0	0x1	ECC_ENABLE: enable Hardware Error Correction Code (ECC) for Host packets Note: when ECC is disabled, Host is responsible for generating proper ECC byte for header 0 = DISABLE : disable HW generation of ECC (Host must calculate ECC). 1 = ENABLE : enable HW generation of ECC.

24.7.12 DSI_DSI_CONTROL_0

General DSI Control register

Offset: 010h | Read/Write: R/W | Reset: 0b0xxxxxxxxxx0xx00xx00xx00xx000000

Bit	Reset	Description
31	0x0	DSI_DBG_ENABLE: Control signal to turn off clock monitoring when enabled for debug, on every DSI byte clock debug signal toggles. Also TX CRC computation aid will turn on
20	0x0	DSI_HS_CLK_CTRL: Control for the HS clock lane 0 = CONTINUOUS : HS clock is on all the time. 1 = TX_ONLY : HS clock is only active during HS transmissions.
17:16	0x0	DSI_VIRTUAL_CHANNEL: Virtual channel ID Virtual channel is sent as part of packet header and used to distinguish multiple displays.
13:12	0x0	DSI_DATA_FORMAT: Pixel Data format transmitted. Note that although the pixel format is specified in the packet header ID for RGB data packets, this information is ignored by the HW. Only the information used in this register is used in the construction of RGB data packets. 0 = BIT16P : 16 bpp RGB Packed. 2 bytes used per pixel 1 = BIT18NP : 18 bpp RGB Not-packed. 3 bytes used per pixel 2 = BIT18P : 18 bpp RGB Packed. 2.25 bytes used per pixel 3 = BIT24P : 24 bpp RGB Packed. 3 bytes used per pixel
9:8	0x0	VID_TX_TRIG_SRC: Controls the source of the trigger to start sending packets. 0 = SOL : Start of Line signal from the Display Controller. 1 = FIFO_LEVEL : How full the FIFO is. Level determined elsewhere. 2 = IMMEDIATE : Determined by a write to the DSI_VID_TRIGGER field of the DSI_TRIGGER register

Bit	Reset	Description
5:4	0x0	DSI_NUM_DATA_LANES: Number of D-PHY data lanes used by Display for HS transmission. 0 = ONE : 1 data lane. 1 = TWO : 2 data lanes. 2 = THREE : 3 data lanes. (NOTE: Currently, this is illegal) 3 = FOUR : 4 data lanes. (NOTE: Currently, this is illegal)
3	0x0	VID_DCS_ENABLE: Enable for insertion of DCS commands during Display Controller generated packets. When enabled, the DCS commands defined in the LT3_DCS_CMD and LT5_DCS_CMD fields of the DSI_DCS_CMDS register will be inserted in long packets defined in packet sequence 3 and 5. 0 = DISABLE : No DCS commands will be inserted. 1 = ENABLE : DCS command IDs will be inserted as described above.
2	0x0	DSI_VID_SOURCE: Source of video pixels 0 = DISPLAY_0 : pixels come from "display" 1 = DISPLAY_1 : pixels come from "displayb"
1	0x0	DSI_VID_ENABLE: Video DSI interface Enable 0 = DISABLE : disable 1 = ENABLE : enable
0	0x0	DSI_HOST_ENABLE: Host DSI interface Enable 0 = DISABLE : disable 1 = ENABLE : enable

24.7.13 DSI_DSI_SOL_DELAY_0

Number of byte-clock counts to wait after reception of.

Offset: 011h | Read/Write: R/W | Reset: 0bxxxxxxxxxxxxxxxx

Bit	Reset	Description
15:0	X	SOL_DELAY: Start Of Line before generating output packets.

24.7.14 DSI_DSI_MAX_THRESHOLD_0

Maximum threshold registers for DSI related packets.

Offset: 012h | Read/Write: R/W | Reset: 0bxxxxxxxxxxxxxxxx

Bit	Reset	Description
15:0	X	MAX_THRESHOLD: Start draining fifo once this threshold is met This register can be used for DBI mode when line packet data exceeds the size of the data fifo.

24.7.15 DSI_DSI_TRIGGER_0

Manual transmissions trigger register.

Offset: 013h | Read/Write: R/W | Reset: 0bxx

Bit	Reset	Description
1	X	DSI_HOST_TRIGGER: A 1 written to this bit will start host transmission when HOST_DSI_CONTROL.HOST_TX_TRIG_SRC is set to IMMEDIATE HW auto clears on operation completion

Bit	Reset	Description
0	X	DSI_VID_TRIGGER: A 1 written to this bit will start video transmission. when DSI_CONTROL.VID_TX_TRIG_SRC is set to IMMEDIATE HW auto clears on operation completion

24.7.16 DSI_DSI_TX_CRC_0

Transmission CRC

Offset: 014h | Read/Write: RO | Reset: 0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx

Bit	Reset	Description
31:0	X	TX_CRC: Long Packet CRC appended to the end of long packets. This CRC is that result of generating a CRC from all transmitted bytes. If DSI_HOST_ENABLE == ENABLE, then a CRC is generated from all bytes transmitted from the Host interface in Command Mode. If DSI_VID_ENABLE == ENABLE, then a CRC is generated from all bytes transmitted during a frame of video when in Video Mode. Note that the HW will capture the CRC into a separate internal register so that it can continue to calculate the CRC for the next frame without having to wait for SW to read the current result.

24.7.17 DSI_DSI_STATUS_0

DSI Status register

Offset: 015h | Read/Write: RO | Reset: 0bxxxxxxxxxxx

Bit	Reset	Description
10	x	DSI_IDLE: Indicated that DSI is IDLE
9	X	LB_UNDERFLOW: Indicates that Line buffer underflow event happened
8	X	LB_OVERFLOW: Indicates that Line buffer overflow event happened
4:0	X	RD_FIFO_COUNT: Count of how many data words are left in the Host Read Data Return FIFO. Typically, SW knows how much data to read from the DSI_RD_DATA register after a Read packet / BTA has been sent / requested, since these transactions are initiated by SW. However, under error conditions, insufficient data may have been read from the FIFO. SW should therefore check this field to make sure it is 0 after reading all the information it expected to get.

24.8 Initialization Sequence Registers

24.8.1 DSI_DSI_INIT_SEQ_CONTROL_0

DSI Initialization Sequence Control.

Offset: 01ah | Read/Write: R/W | Reset: 0bxxxxxxxxxxxxxx0

Bit	Reset	Description
13:8	X	DSI_FRAME_INIT_BYTE_COUNT: Frame Initialization Sequence Byte Count This parameter specifies the number of frame initialization sequence cycles to send. If programmed to 0, there is no frame initialization cycle generated. Valid programmable values: 0 to 32 Invalid programmable values: 33 to 63

Bit	Reset	Description
0	0x0	DSI_SEND_INIT_SEQUENCE: Send Initialization Sequence (IS) 0 = DISABLE : 1 = ENABLE :

24.8.2 DSI_DSI_INIT_SEQ_DATA_0_0

DSI Init Sequence Write Data 0.

Offset: 01bh | Read/Write: R/W | Reset: 0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx

Bit	Reset	Description
31:0	X	DSI_INIT_SEQ_DATA_0: DSI Init Sequence Write Data bits 31-0

24.8.3 DSI_DSI_INIT_SEQ_DATA_1_0

DSI Init Sequence Write Data 1.

Offset: 01ch | Read/Write: R/W | Reset: 0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx

Bit	Reset	Description
31:0	X	DSI_INIT_SEQ_DATA_1: DSI Init Sequence Write Data bits 31-0

24.8.4 DSI_DSI_INIT_SEQ_DATA_2_0

DSI Init Sequence Write Data 2.

Offset: 01dh | Read/Write: R/W | Reset: 0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx

Bit	Reset	Description
31:0	X	DSI_INIT_SEQ_DATA_2: DSI Init Sequence Write Data bits 31-0

24.8.5 DSI_DSI_INIT_SEQ_DATA_3_0

DSI Init Sequence Write Data 3.

Offset: 01eh | Read/Write: R/W | Reset: 0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx

Bit	Reset	Description
31:0	X	DSI_INIT_SEQ_DATA_3: DSI Init Sequence Write Data bits 31-0

24.8.6 DSI_DSI_INIT_SEQ_DATA_4_0

DSI Init Sequence Write Data 4

Offset: 01fh | Read/Write: R/W | Reset: 0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx

Bit	Reset	Description
31:0	X	DSI_INIT_SEQ_DATA_4: DSI Init Sequence Write Data bits 31-0

24.8.7 DSI_DSI_INIT_SEQ_DATA_5_0

DSI Init Sequence Write Data 5

Offset: 020h | Read/Write: R/W | Reset: 0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx

Bit	Reset	Description
31:0	X	DSI_INIT_SEQ_DATA_5: DSI Init Sequence Write Data bits 31-0

24.8.8 DSI_DSI_INIT_SEQ_DATA_6_0

DSI Init Sequence Write Data 6

Offset: 021h | Read/Write: R/W | Reset: 0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx

Bit	Reset	Description
31:0	X	DSI_INIT_SEQ_DATA_6: DSI Init Sequence Write Data bits 31-0

24.8.9 DSI_DSI_INIT_SEQ_DATA_7_0

DSI Init Sequence Write Data 7

Offset: 022h | Read/Write: R/W | Reset: 0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx

Bit	Reset	Description
31:0	X	DSI_INIT_SEQ_DATA_7: DSI Init Sequence Write Data bits 31-0

24.9 Packet Sequence Registers

24.9.1 DSI_DSI_PKT_SEQ_0_LO_0

These registers allow the construction of arbitrary packet sequences associated with various video line types as sent from the Display Controller to the DSI block.

The first digit of the pair of digits in each field below is the sequence number and second digit denotes the packet number within each sequence. For example, field PKT_23_ID, defines the ID for packet 3 in sequence 2.

DSI Packet Sequence 0 LO half

Offset: 023h | Read/Write: R/W | Reset: 0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx

Bit	Reset	Description
30	X	SEQ_0_FORCE_LP: For packet sequence 0, forces the D-PHY to go to LP mode after the last packet of the sequence has been transmitted. 0 = DISABLE 1 = ENABLE
29	X	PKT_02_EN: Packet 2 enable 0 = DISABLE 1 = ENABLE
28:23	X	PKT_02_ID: Packet 2 Packet ID
22:20	X	PKT_02_SIZE: Packet 2 size pointer

Bit	Reset	Description
19	X	PKT_01_EN: Packet 1 enable 0 = DISABLE 1 = ENABLE
18:13	X	PKT_01_ID: Packet 1 Packet ID
12:10	X	PKT_01_SIZE: Packet 1 size pointer
9	X	PKT_00_EN: Packet 0 enable 0 = DISABLE 1 = ENABLE
8:3	X	PKT_00_ID: Packet 0 Packet ID
2:0	X	PKT_00_SIZE: Packet 0 size pointer

24.9.2 DSI_DSI_PKT_SEQ_0_HI_0

DSI Packet Sequence 0 HI half

Note: Line Type 0 is associated with the first line in the frame and should contain a packet sequence that starts with a VS packet.

Offset: 024h | Read/Write: R/W | Reset: 0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx

Bit	Reset	Description
29	X	PKT_05_EN: Packet 5 enable 0 = DISABLE 1 = ENABLE
28:23	X	PKT_05_ID: Packet 5 Packet ID
22:20	X	PKT_05_SIZE: Packet 5 size pointer
19	X	PKT_04_EN: Packet 4 enable 0 = DISABLE 1 = ENABLE
18:13	X	PKT_04_ID: Packet 4 Packet ID
12:10	X	PKT_04_SIZE: Packet 4 size pointer
9	X	PKT_03_EN: Packet 3 enable 0 = DISABLE 1 = ENABLE
8:3	X	PKT_03_ID: Packet 3 Packet ID
2:0	X	PKT_03_SIZE: Packet 3 size pointer

24.9.3 DSI_DSI_PKT_SEQ_1_LO_0

DSI Packet Sequence 1 LO half

> **Note:** Line Type 1 is associated with the last line of Vertical Sync and should contain a packet sequence that starts with a VE packet.

Offset: 025h | Read/Write: R/W | Reset: 0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx

Bit	Reset	Description
30	X	SEQ_1_FORCE_LP: For packet sequence 1, forces the D-PHY to go to LP mode after the last packet of the sequence has been transmitted. 0 = DISABLE 1 = ENABLE
29	X	PKT_12_EN: Packet 2 enable 0 = DISABLE 1 = ENABLE
28:23	X	PKT_12_ID: Packet 2 Packet ID
22:20	X	PKT_12_SIZE: Packet 2 size pointer
19	X	PKT_11_EN: Packet 1 enable 0 = DISABLE 1 = ENABLE
18:13	X	PKT_11_ID: Packet 1 Packet ID
12:10	X	PKT_11_SIZE: Packet 1 size pointer
9	X	PKT_10_EN: Packet 0 enable 0 = DISABLE 1 = ENABLE
8:3	X	PKT_10_ID: Packet 0 Packet ID
2:0	X	PKT_10_SIZE: Packet 0 size pointer

24.9.4 DSI_DSI_PKT_SEQ_1_HI_0

DSI Packet Sequence 1 HI half

Offset: 026h | Read/Write: R/W | Reset: 0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx

Bit	Reset	Description
29	X	PKT_15_EN: Packet 5 enable 0 = DISABLE 1 = ENABLE
28:23	X	PKT_15_ID: Packet 5 Packet ID
22:20	X	PKT_15_SIZE: Packet 5 size pointer
19	X	PKT_14_EN: Packet 4 enable 0 = DISABLE 1 = ENABLE
18:13	X	PKT_14_ID: Packet 4 Packet ID

Bit	Reset	Description
12:10	X	PKT_14_SIZE: Packet 4 size pointer
9	X	PKT_13_EN: Packet 3 enable 0 = DISABLE 1 = ENABLE
8:3	X	PKT_13_ID: Packet 3 Packet ID
2:0	X	PKT_13_SIZE: Packet 3 size pointer

24.9.5 DSI_DSI_PKT_SEQ_2_LO_0

DSI Packet Sequence 2 LO half

Note: Line Type 2 is associated with any vertical blank line except the first one after active and should contain a packet sequence that starts with an HS packet.

Offset: 027h | Read/Write: R/W | Reset: 0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx

Bit	Reset	Description
30	X	SEQ_2_FORCE_LP: For packet sequence 2, forces the D-PHY to go to LP mode after the last packet of the sequence has been transmitted. 0 = DISABLE 1 = ENABLE
29	X	PKT_22_EN: Packet 2 enable 0 = DISABLE 1 = ENABLE
28:23	X	PKT_22_ID: Packet 2 Packet ID
22:20	X	PKT_22_SIZE: Packet 2 size pointer
19	X	PKT_21_EN: Packet 1 enable 0 = DISABLE 1 = ENABLE
18:13	X	PKT_21_ID: Packet 1 Packet ID
12:10	X	PKT_21_SIZE: Packet 1 size pointer
9	X	PKT_20_EN: Packet 0 enable 0 = DISABLE 1 = ENABLE
8:3	X	PKT_20_ID: Packet 0 Packet ID
2:0	X	PKT_20_SIZE: Packet 0 size pointer

24.9.6 DSI_DSI_PKT_SEQ_2_HI_0

DSI Packet Sequence 2 HI half

Offset: 028h | Read/Write: R/W | Reset: 0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx

Bit	Reset	Description
29	X	PKT_25_EN: Packet 5 enable 0 = DISABLE 1 = ENABLE
28:23	X	PKT_25_ID: Packet 5 Packet ID
22:20	X	PKT_25_SIZE: Packet 5 size pointer
19	X	PKT_24_EN: Packet 4 enable 0 = DISABLE 1 = ENABLE
18:13	X	PKT_24_ID: Packet 4 Packet ID
12:10	X	PKT_24_SIZE: Packet 4 size pointer
9	X	PKT_23_EN: Packet 3 enable 0 = DISABLE 1 = ENABLE
8:3	X	PKT_23_ID: Packet 3 Packet ID
2:0	X	PKT_23_SIZE: Packet 3 size pointer

24.9.7 DSI_DSI_PKT_SEQ_3_LO_0

DSI Packet Sequence 3 LO half

Note: Line Type 3 is associated with any active line except the first one and should contain a packet sequence that starts with an HS packet and includes an RGB data packet.

Offset: 029h | Read/Write: R/W | Reset: 0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx

Bit	Reset	Description
30	X	SEQ_3_FORCE_LP: For packet sequence 3, forces the D-PHY to go to LP mode after the last packet of the sequence has been transmitted. 0 = DISABLE 1 = ENABLE
29	X	PKT_32_EN: Packet 2 enable 0 = DISABLE 1 = ENABLE
28:23	X	PKT_32_ID: Packet 2 Packet ID
22:20	X	PKT_32_SIZE: Packet 2 size pointer
19	X	PKT_31_EN: Packet 1 enable 0 = DISABLE 1 = ENABLE
18:13	X	PKT_31_ID: Packet 1 Packet ID

Bit	Reset	Description
12:10	X	PKT_31_SIZE: Packet 1 size pointer
9	X	PKT_30_EN: Packet 0 enable 0 = DISABLE 1 = ENABLE
8:3	X	PKT_30_ID: Packet 0 Packet ID
2:0	X	PKT_30_SIZE: Packet 0 size pointer

24.9.8 DSI_DSI_PKT_SEQ_3_HI_0

DSI Packet Sequence 3 HI half

Offset: 02ah | Read/Write: R/W | Reset: 0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx

Bit	Reset	Description
29	X	PKT_35_EN: Packet 5 enable 0 = DISABLE 1 = ENABLE
28:23	X	PKT_35_ID: Packet 5 Packet ID
22:20	X	PKT_35_SIZE: Packet 5 size pointer
19	X	PKT_34_EN: Packet 4 enable 0 = DISABLE 1 = ENABLE
18:13	X	PKT_34_ID: Packet 4 Packet ID
12:10	X	PKT_34_SIZE: Packet 4 size pointer
9	X	PKT_33_EN: Packet 3 enable 0 = DISABLE 1 = ENABLE
8:3	X	PKT_33_ID: Packet 3 Packet ID
2:0	X	PKT_33_SIZE: Packet 3 size pointer

24.9.9 DSI_DSI_PKT_SEQ_4_LO_0

DSI Packet Sequence 4 LO half

> **Note:** Line Type 4 is associated with the first vertical blanking line after the last active line and should contain a packet sequence that starts with an HS packet. Ordinarily, this packet sequence should be identical to sequence 2.

Offset: 02bh | Read/Write: R/W | Reset: 0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx

Bit	Reset	Description
30	X	SEQ_4_FORCE_LP: For packet sequence 4, forces the D-PHY to go to LP mode after the last packet of the sequence has been transmitted. 0 = DISABLE 1 = ENABLE
29	X	PKT_42_EN: Packet 2 enable 0 = DISABLE 1 = ENABLE
28:23	X	PKT_42_ID: Packet 2 Packet ID
22:20	X	PKT_42_SIZE: Packet 2 size pointer
19	X	PKT_41_EN: Packet 1 enable 0 = DISABLE 1 = ENABLE
18:13	X	PKT_41_ID: Packet 1 Packet ID
12:10	X	PKT_41_SIZE: Packet 1 size pointer
9	X	PKT_40_EN: Packet 0 enable 0 = DISABLE 1 = ENABLE

24.9.13 DSI_DSI_DCS_CMDS_0

Note: DCS COMMAND AND PACKET LENGTH REGISTERS

DCS command IDs used for Line Type 3 and 5. These command IDs are inserted at the start of the data payload of DCS long packets when the Display Controller is being used to transmit DCS commands.

Offset: 033h | Read/Write: R/W | Reset: 0bxxxxxxxxxxxxxxxx

Bit	Reset	Description
15:8	X	LT5_DCS_CMD: DCS command for Line Type 5.
7:0	X	LT3_DCS_CMD: DCS command for Line Type 3.

24.9.14 DSI_DSI_PKT_LEN_0_1_0

DSI packet lengths 0 and 1

Offset: 034h | Read/Write: R/W | Reset: 0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx

Bit	Reset	Description
31:16	X	LENGTH_1: Packet length 1 (in bytes)
15:0	X	LENGTH_0: Packet length 0 (in bytes)

24.9.15 DSI_DSI_PKT_LEN_2_3_0

DSI packet lengths 2 and 3

Offset: 035h | Read/Write: R/W | Reset: 0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx

Bit	Reset	Description
31:16	X	LENGTH_3: Packet length 3 (in bytes)
15:0	X	LENGTH_2: Packet length 2 (in bytes)

24.9.16 DSI_DSI_PKT_LEN_4_5_0

DSI packet lengths 4 and 5

Offset: 036h | Read/Write: R/W | Reset: 0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx

Bit	Reset	Description
31:16	X	LENGTH_5: Packet length 5 (in bytes)
15:0	X	LENGTH_4: Packet length 4 (in bytes)

24.9.17 DSI_DSI_PKT_LEN_6_7_0

DSI packet lengths 6 and 7

Offset: 037h | Read/Write: R/W | Reset: 0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx

Bit	Reset	Description
31:16	X	LENGTH_7: Packet length 7 (in bytes)
15:0	X	LENGTH_6: Packet length 6 (in bytes)

24.10 Physical Interface Timing Registers

24.10.1 DSI_DSI_PHY_TIMING_0_0

DSI D-PHY timing register 0

Offset: 03ch | Read/Write: R/W | Reset: 0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx

Bit	Reset	Description
31:24	X	DSI_THSDEXIT: Time to drive LP11 after HS
23:16	X	DSI_THSTRAIL: Time to drive HS flipped bit at EOT
15:8	X	DSI_TDATZERO: Time to drive HS0 before SOT
7:0	X	DSI_THSPREPR: Time to drive LP00 before HS data

24.10.2 DSI_DSI_PHY_TIMING_1_0

DSI D-PHY timing register 1

Offset: 03dh | Read/Write: R/W | Reset: 0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx

Bit	Reset	Description
31:24	X	DSI_TCLKTRAIL: Time to drive HS0 before clock goes to LP1 1
23:16	X	DSI_TCLKPOST: Time to drive Clock after the last HS data
15:8	X	DSI_TCLKZERO: Time to drive LP00 before HS clock
7:0	X	DSI_TTLPX: LP period

24.10.3 DSI_DSI_PHY_TIMING_2_0

DSI D-PHY timing register 2

Offset: 03eh | Read/Write: R/W | Reset: 0bxxxxxxxxxxxxxxxxxxxxxxxx

Bit	Reset	Description
23:16	X	DSI_TCLKPREPARE: Time to drive LP0 before CLK_ZERO starts off on clock lane
15:8	X	DSI_TCLKPRE: Time to run clock before enabling data lane
7:0	X	DSI_TWAKEUP: LP period when exiting ULPM. in units of 512 byte clocks.

24.10.4 DSI_DSI_BTA_TIMING_0

DSI D-PHY Bus-Turn-Around timing

Offset: 03fh | Read/Write: R/W | Reset: 0bxxxxxxxxxxxxxxxxxxxxxxxx

Bit	Reset	Description
23:16	X	DSI_TTAGET: Time to Drive LP00 at end of BTA (5 * TTLPX)
15:8	X	DSI_TTASURE: Time to Receive LP00 at end of BTA (2 * TTLPX)
7:0	X	DSI_TTAGO: Time to drive LP00 at start of BTA (4 * TTLPX)

24.10.5 DSI_DSI_TIMEOUT_0_0

Note: CONTENTION RECOVERY TIMERS
These registers control the length of time - in units of 512 DSI byte clocks - that can elapse before the hardware will decide that a bus contention error has occurred. There are several counters to deal with various forms of error that may occur. For details, refer to MIPI DSI Spec. section 7.2.2

DSI Time out terminal count register 0

Offset: 044h | Read/Write: R/W | Reset: 0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx

Bit	Reset	Description
31:16	X	LRXH_TO: Low Power Receive (Host) Time Out terminal count
15:0	X	HTX_TO: High Speed Transmit Time Out terminal count

24.10.6 DSI_DSI_TIMEOUT_1_0

DSI Time out terminal count register 1

Offset: 045h | Read/Write: R/W | Reset: 0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx

Bit	Reset	Description
31:16	X	PR_TO: Peripheral Reset duration.
15:0	X	TA_TO: Turn Around Time Out terminal count

24.10.7 DSI_DSI_TO_TALLY_0

Each time one of the time out counters reaches its terminal count, it will increment the associated tally register.

DSI Time out tally register

Offset: 046h | Read/Write: R/W | Reset: 0bxxxxxxxxxxxxxxxxxxxxxxxxxxxx

Bit	R/W	Reset	Description
24	RO	X	P_RESET_STATUS: Peripheral Reset time out status 0 = IN_RESET 1 = READY
23:16	RW	X	TA_TALLY: Turn Around time out tally
15:8	RW	X	LRXH_TALLY: LP Rx time out tally
7:0	RW	X	HTX_TALLY: HS Tx time out tally

24.11 Physical Pad Control Registers

24.11.1 DSI_PAD_CONTROL_0

SW can program this register to work with different panels.

DSI PHY configuration register

Offset: 04bh | Read/Write: R/W | Reset: 0b00010000x00001110000x000x0000000

Bit	Reset	Description
31:30	0x0	DSI_PAD_HS_BSO: 1= enables BIAS and power regulators on for HS mode
29	0x0	DSI_PAD_HS_BSO_CLK: 1= enables BIAS and power regulators on for HS mode

Bit	Reset	Description
28	0x1	DSI_PAD_PULLDN_ENAB: 1= enable pad pulldn on power on
27	0x0	DSI_PAD_REV_CLK – Reverse clock polarity.
26:24	0x0	DSI_PAD_SLEWUPADJ – Pull up slew rate adjust. 0 = init 000 > 011 = slew rate increases 100 = same as 000 100 > 111 = slew rate decreases
22:20	0x0	DSI_PAD_SLEWDNADJ – Pull down slew rate adjust. 0 = init 000 > 011 = slew rate increases 100 = same as 000 100 > 111 = slew rate decreases
19	0x0	DSI_PAD_PREEMP_EN – HS driver pre-emphasis enable. 0 = init 1 = pre-emphasis enabled
18	0x1	DSI_PAD_PDIO_CLK – Power down for clock bit, drivers, receivers and contention detectors. 1 = init
17:16	0x3	DSI_PAD_PDIO – Power down for data bit,drivers,receivers and contention detectors. 3 = init
15:14	0x0	DSI_PAD_LPUPADJ – Driver pull up impedance control. 0 = init 00 = 130ohm (default) 01 = 110ohm 10 = 130ohm (same as 00) 11 = 150ohm
13:12	0x0	DSI_PAD_LPDNADJ – Driver pull down impedance control. 0 = init 00 = 130ohm (default) 01 = 110ohm 10 = 130ohm (same as 00) 11 = 150ohm
10:8	0x0	DSI_PAD_OUTADJCLK – Output trimmer delay for clock bit. Each tap delays 40ps. 0 = init
6:4	0x0	DSI_PAD_OUTADJ1 – Input delay trimmer for data bit 1. Each tap delays 40ps. 0 = init
3	0x0	DSI_PAD_BANDWD_IN – Increase bandwidth of differential receiver. 0 = init
2:0	0x0	DSI_PAD_OUTADJ0 – Input delay trimmer for data bit 0. Each tap delays 40ps. 0 = init

24.11.2 DSI_PAD_CONTROL_CD_0

Contention detection logic enable signals

Offset: 04ch | Read/Write: R/W | Reset: 0b000x000x000

Bit	Reset	Description

1:0	X	DSI_PAD_CDP

24.11.4 DSI_DSI_VID_MODE_CONTROL_0

Host Command Packet during Video Mode

Offset: 04eh | Read/Write: R/W | Reset: 0x00000000 (0b0000)

Bit	Reset	Description
3:1	0x0	DSI_LINE_TYPE: LINE TYPE on which host command packet to be transmitted 0 = ZERO : line type 0 1 = ONE : line type 1 2 = TWO : line type 2 3 = THREE : NA: host command packets on linetype 3 are invalid 4 = FOUR : line type 4 5 = FIVE : NA: host command packets on linetype 5 are invalid 6 = SIX : NA: host command packets on linetype 6 are invalid 7 = SEVEN : NA: host command packets on linetype 7 are invalid
0	0x0	DSI_CMD_PKT_VID_ENABLE: 0 = DISABLE : Disable host command packet during video mode 1 = ENABLE : Enable host command packet during video mode

[THIS PAGE INTENTIONALLY LEFT BLANK]

25.0 HIGH-DEFINITION MULTIMEDIA INTERFACE

The High-Definition Multimedia Interface (HDMI) receives pixels from the Display Controller and audio from HDA. It combines and transmits them together.

25.1 Programming Guidelines

The overall sequence to start up HDMI is:

- Program power, pin mux, clocks, resets, etc.
- Copy HDCP keys from KFUSE to HDMI
- Program display timing registers, etc.
- Program HDMI registers and SOR sequencer
- Start HDMI SOR (Serial Output Resource)
- Start display

Since audio is entirely asynchronous to HDMI or display, the SPDIF and HDA modules can be started any time.

25.1.1 Power

Turn on the necessary power supplies.

- MIPI_PLL: 1.2V
- HDMI_AVDD: 3.3V
- VHDCP: 2.8V (shared with LCD CORE, KeyPAD_LED, TouchPanel VDD)

These need to be enabled in PMU via I2C.

25.1.2 Clocks

The display controllers and HDMI have separate clock source registers. However, they must be programmed to the same source and the same frequency. Typical settings for 13 MHz oscillator, using PLLD, would be:

Pixel Clock MHz	PLLD Freq	PLL M	PLL N	HDMI_ CLK_ DIVISOR	Display SHIFT_ CLK_ DIVIDER	HDMI_ CLK_ SRC	DISP1_ CLK_ SRC
27	216/2	13	216	0x6 (/4)	0x6 (/4)	PLLD_OUT0	PLLD_OUT0
74.25	594/2	13	594	0x6 (/4)	0x6 (/4)	PLLD_OUT0	PLLD_OUT0
148.5	594/2	13	594	0x2 (/2)	0x2 (/2)	PLLD_OUT0	PLLD_OUT0

In addition, the spdif_out and HDA2CODEC_2X modules must derive from same oscillator as display and HDMI, since audio and video clock frequencies must be a fixed ratio. The HDA2CODEC_2X clock must be enabled and configured for 54 MHz. For HDA Audio, additionally, the HDA2HDMICODEC clock must be enabled. 6 clock use cases with permutations of 4 clock enables are defined in Tegra® 3 devices.

25.1.3 Display Timing

Frame timing is controlled by display. HDMI has certain requirements, however – imposed by both the module itself, and the HDMI standards.

HDMI gets the following signals from display:

- h_blank – derived in HW from h_ref_to_sync, h_sync_width, h_back_porch, h_disp_active, h_front_porch
- v_blank – derived in HW from v_ref_to_sync, v_sync_width, v_back_porch, v_disp_active, v_front_porch
- h_sync – derived from h_ref_to_sync, h_sync_width
- v_sync – derived from v_ref_to_sync, v_sync_width
- video_preamble – derived from h_pulse2_control, h_pulse2_position.

EIA/CEA-861-B format	ref_to_sync	sync_width	back_porch	disp_active	front_porch
480P_60 (2,3)					
horizontal	1	62	60	720	16
vertical	1	6	30	480	9
720P_60 (4)					
horizontal	1	40	220	1280	110
vertical	1	5	20	720	5
720P_50 (19)					
horizontal	1	40	220	1280	440
vertical	1	5	20	720	5
640x480_60 (1)					
horizontal	1	96	48	640	16
vertical	1	2	33	480	10
576p_50 (17/18)					
horizontal	1	64	68	720	12
vertical	1	5	39	576	5
1080p_60 (16)					
horizontal	1	44	148	1920	88
vertical	1	5	36	1080	4

The video_preamble uses h_pulse2, with following settings:

disp_signal_options0.h_pulse2_enable	ENABLE
h_pulse2_control.h_pulse2_mode	NORMAL
h_pulse2_control.h_pulse2_polarity	HIGH
h_pulse2_control.h_pulse2_v_qual	VACTIVE
h_pulse2_control.h_pulse2_last_end	END_A
h_pulse2_position.h_pulse2_start_a	h_ref_to_sync + h_sync_width + h_back_porch - 10
h_pulse2_position.h_pulse2_end_a	h_pulse2_start_a + 8

Miscellaneous registers required:

DISP_TIMING_OPTIONS.VSYNC_H_POSITION	1
DISP_CLOCK_CONTROL.PIXEL_CLK_DIVIDER	PCD1
DISP_COLOR_CONTROL.DITHER_CONTROL	DISABLE
DISP_WIN_OPTIONS.HDMI_ENABLE	ENABLE

Display Datapath

Dithering should be disabled, since HDMI uses full 8 bits per component.

For limited-range modes (i.e., everything except VGA 640x480), R/G/B should be scaled to lie in [16, 235] nominal range; this can be done in color palette and/or in CSC block. See the HDMI specification, section 6.6. For most HDMI modes, codes 0 and 255 must be removed; HDMI's NV_PDISP_INPUT_CONTROL.ARM_VIDEO_RANGE = LIMITED enables this.

25.1.4 HDMI Basics

- Select display source with NV_PDISP_HDMI_SRC_SELECT
- Program SOR reference clock, based on HDMI pixel clock – see NV_PDISP_SOR_REFCLK in spec. For example,

```
dispclk div 8 2 = int(dispclk freq / 1000000.0 * 4)
NV PDISP SOR REFCLK.DIV INT = dispclk div 8 2 >> 2
NV_PDISP_SOR_REFCLK.DIV_FRAC = dispclk_div_8_2 & 0x3
```

- Program SOR sequences for power up, power down.

25.1.5 TMDS Macro Configuration

The table below gives values for various modes. Registers not listed should use the initial (reset) values.

Register	480p	720p	1080p
SOR_LANE_DRIVE_CURRENT.LANE0..3	0xa	0xa	0xa
SOR_PLL1.TMDS_TERM	ENABLE	ENABLE	ENABLE
SOR_PLL1.TMDS_TERMADJ	0x0	0x0	0x0
SOR_PLL0.VCOCAP	0x3	0x3	0x3
SOR_PLL0.BG_V17_S	0x3	0x3	0x3
SOR_PLL1.PE_EN	ENABLE	ENABLE	ENABLE
PE_CURRENT0..3	0xa	0xa	0xa

Note: NV_PDISP_SOR_LANE_DRIVE_CURRENT.FUSE_OVERRIDE is TRUE.

25.1.6 HDA Controller Init

Basic operations:

- HDA IPFS init, FPCI, and HDA config and memory spaces allocated
- Deassert soft reset, bring up link. AZA.GCTL.CRST = DEASSERT, and wait for reset completion by spinning until CRST = DEASSERT. Wait 4 frame times (poll AZA.WALCLK for 2000 ticks to elapse)
- Verify internal codec (and external if desired) have been detected by reading AZA.WAKEEN.SDIWAKE3 for internal codec, and SDIWAKE1 for external.

25.1.7 HDA Audio Codec Init

When HDA is the audio source, the codec must be initialized before audio can flow. The internal codec uses industry-standard verbs, so in theory, out-of-box driver should correctly discover and configure the codec. See the HD Audio specification. A summary of necessary verbs:

1. AOC widget: SET_CONV_STREAM_CHAN with desired output stream ID
2. AOC widget: SET_CONV_FMT to desired audio format (sampling frequency, sample depth, number of channels)
3. AOC widget: SET_DIGITAL_CONV_CONTROL1
   a. Bit 0: 1 (DigEn=1)
   b. Bit 3..6: channel status pre/copy/audio/pro bits
   c. Bit 7: channel status CC bit 7 (called GEN_LEVEL)
4. AOC widget: SET_DIGITAL_CONV_CONTROL2:

a. Bit 6:0: channel status CC bits 6:0

5. Pin widget: SET_CONVERTER_CHANNEL_TO_DIGITAL_SLOT_MAPPING= 0x22 and SET_CONVERTER_CHANNEL_TO_DIGITAL_SLOT_MAPPING= 0x33 to undo default swap of channels 2 and 3
6. AOC widget: SET_STRIPE_CONTROL to select number of lanes. Recommend programming to 2 lanes all the time.
7. Pin widget: SET_PIN_WIDGET_CTRL = 0x40, to enable output and use PCM packets.
8. If desired to use HDA for info packets, program them with SET_DIP_INDEX/SET_DIP_DATA and enable with SET_DIP_XMIT_CTRL.

25.1.8 Audio

Both “Hardware CTS” and “Force SW CTS” modes must be used for generating ACR packets, Set NV_PDISP_HDMI_ACR_CTRL (all fields) to 0

1. Reset N counter: HDMI.NV_PDISP_AUDIO_N.RESETF = ASSERT, GENERATE=ALTERNATE, LOOKUP=DISABLE
2. Based on pixel clock and audio sample clock frequencies, program the appropriate ACR N value into NV_PDISP_HDMI_ACR_0441_SUBPACK_ HIGH (see HDMI 1.2a spec section 7.2.3). LSB of N goes in SB6, and MSB into SB4.
3. Likewise, program the appropriate ACR CTS value into NV_PDISP_HDMI_ACR_0441_SUBPACK_LOW. LSB of CTS goes in SB3 and MSB into SB1.
4. Program computed AVAL into appropriate SOR_AUDIO_AVAL_ register
5. Set NV_PDISP_AUDIO_N.VALUE = N – 1 (from above)
6. Set NV_PDISP_HDMI_ACR_0441_SUBPACK_HIGH.ENABLE = YES.
7. Set NV_PDISP_HDMI_SPARE = 0x10003
8. Bring N counter of of reset: set HDMI.NV_PDISP_AUDIO_N.RESETF = DEASSERT
9. Program audio source with SOR_AUDIO_CNTRL0.SOURCE_SELECT = SPDIF for spdif, HDAL for HDA, or AUTO. AUTO automatically selects HDA if HDMI’s internal HDA codec has been enumerated by HDA controller, else SPDIF
10. Enable HDMI audio: set HDMI_CTRL.ENABLE = EN, HDMI_GENERIC_CTRL.AUDIO = EN, AUDIO_ENGINE.PWRDWN=0

Note:	CTS and N values depend on the ratio of the actual pixel clock and audio clock rates. The chip’s clock generators cannot create every frequency exactly. For example 25.2 MHz (for 640x480p@60) cannot be exactly generated – 25.25 is the result. Thus CTS and N must be adjusted accordingly.

25.1.9 Other HDMI Configuration

1. Set HDMI_CTRL.MAX_AC_PACKET based on horizontal blanking width. Using display timing registers, MAX_AC_PACKET = floor((H_SYNC_WIDTH + H_BACK_PORCH + H_FRONT_PORCH – HDMI_CTRL.REKEY – 18) / 32)
2. Program and enable Audio InfoFrames:
   - Set HDMI_AUDIO_INFOFRAME_HEADER = 0x000A0184
   - Set PB4-7 = 0, typically, in HDMI_AUDIO_INFOFRAME_SUBPACK0_HIGH
   - Set PB1-3 and CRC in HDMI_AUDIO_INFOFRAME_SUBPACK0_LOW. Typically PB1 = 1, and PB2 and PB3 are 0. CRC = (256 – (0x0a + 0x01 + 0x84 + PB1 + PB2 …) & 0xff) & 0xff
   - Set HDMI_AUDIO_INFOFRAME_CTRL.ENABLE = EN
3. Program and enable AVI InfoFrames. When using HDA Audio, this *may* come from HDA Codec if desired, using one of its Generic packets. If so, don’t enable the HDMI one:

- Set HDMI_AVI_INFOFRAME_HEADER = 0x000D0282
- Program checksum, PB1, PB2, PB3 in HDMI_AVI_INFOFRAME_SUBPACK0_LOW. PB4 contains the video format code from CEA-861-D spec. See HDMI and EIA/CEA-861-D for all the fields. CRC is computed over header and PB1…PB13 as above.
- Program PB4…PB6 in HDMI_AVI_INFOFRAME_SUBPACK0_HIGH, and PB7..PB13 in HDMI_AVI_INFOFRAME_SUBPACK1_LOW / HIGH.
- Set HDMI_AVI_INFOFRAME_CTRL.ENABLE = EN

4. For HDMI 1.4 3D, program and enable GENERIC InfoFrame to send HDMI Vendor Specific Infoframe. When using HDA Audio, this *may* come from HDA Codec if desired, using one of its Generic packets. If so, don't enable the HDMI one.
   - Set HDMI_GENERIC_HEADER = 0x00LL0181 where LL is length of packet – 0x05 for the basic version described here.
   - HDMI_GENERIC_SUBPACK0_LOW.PB1/PB2/PB3 = 0x03/0c/00 (IEEE registration id)
   - PB4 = 0x40 (Hdmi_video_format = 3d_structure present)
   - PB5 = 0x00 (3D_Structure = Frame packing)
   - PB6...PB27 = 0 (no 3D_Ext_Data for Frame packing)
   - Compute checksum over header and PB1..PB27 and put in PB0, as above.
   - HDMI_GENERIC_CTRL.ENABLE=EN. OTHER, SINGLE, HBLANK= DIS.
   - Be sure to keep HDMI_GENERIC_CTRL.AUDIO = EN

25.1.10 Start HDMI SOR

1. Enable TMDS macro with SOR_PLL0.PWR=0, VCOPD=0, PULLDOWN=0.
2. write SOR_PWR with NORMAL_STATE = PU, SAFE_STATE = PD, SETTING_NEW = TRIGGER
3. write SOR_PWR with same but SETTING_NEW = DONE
4. poll SOR_PWR for SETTING_NEW = DONE
5. write SOR_STATE2 with ASY_OWNER=HEAD0, SUBOWNER=3, ASY_PROTOCOL=SINGLE_TMDS_A, ASY_HSYNCPOL=POSITIVE_TRUE, ASY_VSYNCPOL=POSITIVE_TRUE, ASY_DEPOL=POSITIVE_TRUE
6. write SOR_STATE1 with ASY_HEAD_OPMODE=AWAKE, ASY_ORMODE=NORMAL, ATTACHED=0, ARM_SHOW_VGA=0
7. write SOR_STATE0 with UPDATE=0
8. write SOR_STATE0 with UPDATE=1
9. write SOR_STATE1 with ATTACHED=1
10. write SOR_STATE0 with UPDATE=0

25.1.11 Start Display

- Set DISP_WIN_OPTIONS.HDMI_ENABLE = ENABLE
- Start display the usual way with DISPLAY_COMMAND.DISPLAY_CTRL_MODE and DISPLAY_POWER_CONTROL.

25.2 HDCP

HDCP requires the presence of a correctly programmed KFUSE, as well as upstream C keys provided by software. Two main sequences are downstream authentication and upstream authentication. Downstream authentication actually permits encryption of the HDMI output, and involves a handshake between HDMI module and the display device. Upstream

authentication is more of a software convention between the application and HDMI driver, although the HDMI module does perform KFUSE operations to assist.

Communication with downstream receiver uses DDC, which requires I2C.

25.2.1 HDCP KFUSE Key Copying

HDCP keys are stored encrypted in kfuse. Before starting HDCP, SW must copy the keys (576 bytes) from the KFUSE to HDMI registers.

1. To enable use of kfuse keys, set NV_PDISP_KEY_CTRL.LOCAL_KEYS = ENABLED.
2. Bring kfuse module out of reset and enable clock, if not already. This can be before or after HDMI is out of reset.
3. Wait for kfuse to read the keys from fuse to its SRAM and perform error correction and CRC checking:
   a. Poll for KFUSE.STATE.DONE == 1
   b. Check KFUSE.STATE.CRCPASS == 1
   c. Check that NV_PDISP_KEY_CTRL.PKEY_LOADED == TRUE
4. Prepare to copy:
   a. KFUSE.KEYADDR.ADDR = 0
   b. KFUSE.KEYADDR.AUTOINC = 1
5. For each line in 0 .. 35 # 576 bytes = 144 words / 4 words-per-line = 36 lines
   a. For each word in 0..3:

      data[word] = KFUSE.KEYS # auto-increments read address

   b. HDMI.NV_PDISP_KEY_HDCP_KEY_0 = data[0]
   c. HDMI.NV_PDISP_KEY_HDCP_KEY_1 = data[1]
   d. HDMI.NV_PDISP_KEY_HDCP_KEY_2 = data[2]
   e. HDMI.NV_PDISP_KEY_HDCP_KEY_3 = data[3]
   f. HDMI.NV_PDISP_KEY_HDCP_KEY_TRIG.LOAD_HDCP_KEY = TRIGGER # trigger decryption of 16 bytes
   g. If line == 0: HDMI.NV_PDISP_KEY_CTRL.AUTOINC = DISABLED. Else: HDMI.NV_PDISP_KEY_CTRL.AUTOINC = ENABLED
   h. HDMI. NV_PDISP_KEY_CTRL.WRITE16 = TRIGGER # wait for decrypt, and copy decrypted 16 bytes to local key store.
   i. Poll for HDMI. NV_PDISP_KEY_CTRL.WRITE16 == DONE
6. Write NV_PDISP_KEY_SKEY_INDEX.IDX_VALUE with the AES key selector that was used to encrypt the keyglob data. This is currently fixed at 0.

25.2.2 Downstream Authentication

This can be done before enabling transmission.

1. Set RG_HDCP_CTRL.ONEONE = ENABLE. RG_HDCP_CTRL.RUN = YES. Causes RTL to access HDCP keys and compute An and other parameters.
2. Poll for RG_HDCP_CTRL.AN = VALID
3. Read Aksv from RG_HDCP_AKSV_LSB/MSB and check validity (exactly 20 of 40 bits = 1). If invalid, the kfuse might be blank.
4. Read Bksv from receiver (via I2C), check validity (20 high bits), and write it into RG_HDCP_BKSV_LSB/MSB.
5. Read An from RG_HDCP_AN_LSB/MSB, and write to receiver via I2C.
6. Read Aksv from RG_HDCP_AKSV_LSB/MSB, check validity (20 high bits), and write to receiver via I2C.

7. Poll for RG_HDC_CTRL.R0 = VALID
8. Read RG_HDCP_RI and compare with receiver's RI – should match.

If the above is successful, then RG_HDCP_CTRL.CRYPT can be set to ENABLE.

To verify that encryption is enabled, check that RG_HDCP_CTRL.RUN == YES.

25.2.3 Upstream Authentication

The HDMI module does not handle the protocol itself. Rather, it provides primitives that SW can use. These primitives access HDCP keys and status, and compute values.

Typically, downstream authentication has been completed before doing the upstream.

The "Upstream Setup" sequence is:

1. set RG_HDCP_CMODE.MODE = READ_S
2. poll for RG_HDCP_CTRL.SPRIME = INVALID
3. program RG_HDCP_CN_LSB/MSB and RG_HDCP_CKSV_LSB/MSB with Cn and Cksv. NOTE: CKSV_MSB must be last since it's a trigger.
4. poll for HDCP_CTRL.SPRIME = VALID
5. read Dksv from RG_HDCP_DKSV_LSB/MSB and verify validity
6. read Cs from RG_HDCP_CS_LSB/MSB
7. read S' from RG_HDCP_SPRIME_LSB1/LSB2/MSB

SW uses these read values to perform the authentication handshake with application software.

The "Upstream M" sequence is:

1. set RG_HDCP_CMODE.MODE = READ_M
2. poll for RG_HDCP_CTRL.MPRIME = INVALID
3. program RG_HDCP_CN_LSB/MSB and RG_HDCP_CKSV_LSB/MSB with Cn and Cksv. NOTE: CKSV_MSB must be last since it's a trigger.
4. poll for HDCP_CTRL.MPRIME = VALID
5. read Dksv from RG_HDCP_DKSV_LSB/MSB and verify validity
6. read M' from RG_HDCP_MPRIME_LSB/MSB

25.3 Audio / Display Driver Communication

HDMI combines video and audio and so the display and audio drivers need to coordinate. The HDA Codec and HDMI implement the methods defined in the audio specs.

25.3.1 Hot-plug and ELD (EDID-like data)

When HDMI driver receives notification of hot-plug interrupt, it reads downstream TV's E-EDID ROM. The EDID contains audio-related data, so the audio driver needs it too. HDMI can send the hot-plug event and EDID buffer to Audio driver via HDA Codec.

Note:	See register comments in SOR_AUDIO_HDA_PRESENSE and SOR_AUDIO_HDA_ELD_BUFWR later in this section.

25.3.2 Copy-Protection

Audio driver can query copy-protection state (i.e., HDCP enabled), and request HDCP be enabled by the HDMI driver.

Note:	See SOR_AUDIO_HDA_CP register and CP_REQUEST interrupt in INT_STATUS later in this section.

25.3.3 InfoPacket

In HDA mode, the Audio Infoframe data is provided by internal HDA Codec, not by the HDMI_AUDIO_INFOFRAME* registers. The SET_DIP_INDEX/SET_DIP_DATA verbs write this data.

In addition, 3 additional generic infopackets are provided by HDA Codec, in addition to the exiting generic packet.

25.3.4 Miscellaneous

For Audio to HDMI signaling, HDA Codec has SCRATCH verbs that are reflected in HDMI SOR_AUDIO_HDA_CODEC_SCRATCH* registers, and CODEC_SCRATCH* interrupts.

For HDMI to Audio signaling, HDMI SOR_AUDIO_HDA_SCRATCH* registers, when written, are reflected to HDA Codec GET_NV_SCRATCH_REGN_FROM_DISP verb and cause an Unsolicited Response (interrupt in HDA Controller).

25.4 Clock Use Cases

Tegra 3 HDMI has the following clock sources. All five are required for HDMI operation.

DISP1 or DISP2	Display controller (pixel clock)
HDMI	HDMI controller (pixel clock)
HDA2CODEC_2X	HDA interface clock (48 MHz)
HDA2HDMICODEC	HDMI audio clock
HDA	HDA controller

25.5 CTS/N/AVAL Algorithm

```
void get_hda_cts_n(
// inputs:
NvU32 audio_freq_hz /* Fs */,
NvU32 pixclk_freq_hz /* Fpix */,
// outputs:
NvU32 &best_cts, NvU32 &best_n, NvU32 &best_a)
{
    // Ideal ACR interval is 1000 hz (1 ms);
    // acceptable is 300 hz .. 1500 hz
    const int min_n = 128 * audio_freq_hz / 1500;
    const int max_n = 128 * audio_freq_hz / 300;
    const int ideal_n = 128 * audio_freq_hz / 1000;

    float min_err = 100.0;

    best_n = 0;
    best_cts = 0;
    best_a = 0;

    for (int n = min_n; n <= max_n; n ++)
    {
```

```
        float cts_f = pixclk_freq_hz * (float)n / (128.0 * (float)audio_freq_hz);
        int cts = (int)(cts_f + 0.5); // round to nearest integer
        float err = fabs(cts_f - (float)cts);
        float aval_f = 24000000.0 * (float)n / (128.0 * (float)audio_freq_hz);
        int aval = (int)aval_f; // truncate (round toward zero)
        if ((float)aval == aval_f &&
(err < min_err ||
            ((err == min_err) && (abs(n - ideal_n) < abs((int)best_n - ideal_n)))))
        {
            min_err = err;
            best_n = (NvU32)n;
            best_cts = (NvU32)cts;
            best_a = (NvU32)aval;
        }
    }

    assert(best_n != 0 && best_cts != 0);
    assert((double)best_cts ==
     ((double)pixclk_freq_hz * best_n) / (128.0 * audio_freq_hz));

}
```

25.6 HDMI Registers

25.6.1 HDMI_CTXSW_0

Channel IDs

Context switch register. Should be common to all modules. Includes the current channel/class (which is writable by SW) and the next channel/class (which the hardware sets when it receives a context switch).

Context switch works like this: Any context switch request triggers an interrupt to the host and causes the new channel/class to be stored in NEXT_CHANNEL/NEXT_CLASS (see vmod/chexample). SW sees that there is a context switch interrupt and does the necessary operations to make the module ready to receive traffic from the new context. It clears the context switch interrupt and writes CURR_CHANNEL/CLASS to the same value as NEXT_CHANNEL/CLASS, which causes a context switch acknowledge packet to be sent to the host. This completes the context switch and allows the host to continue sending data to the module.

Context switches can also be pre-loaded. If CURR_CLASS/CHANNEL are written and updated to the next CLASS/CHANNEL before the context switch request occurs, an acknowledge will be generated by the module and no interrupt will be triggered. This is one way for software to avoid dealing with context switch interrupts. Another way to avoid context switch interrupts is to set the AUTO_ACK bit.

This bit tells the module to automatically acknowledge any incoming context switch requests without triggering an interrupt. CURR_* and NEXT_* will be updated by the module so they will always be current.

Offset: 000h | Read/Write: R/W | Reset: 0bxxxxxxxxxxxxxxxx11111x0000000000

Bit	R/W	Reset	Description
31:28	RO	X	NEXT_CHANNEL: Next requested channel
25:16	RO	X	NEXT_CLASS: Next requested class
15:12	RW	0xf	CURR_CHANNEL: Current working channel, reset to 'invalid'
11	RW	0x1	AUTO_ACK: Automatically acknowledge any incoming context switch requests

Bit	R/W	Reset	Description
			0 = MANUAL 1 = AUTOACK
9:0	RW	0x0	CURR_CLASS: Current working class

25.6.2 HDMI_NV_PDISP_SOR_STATE0_0

Writing a 1 to this field cause a 1cycle pulse which is used to activate the fields in registers NV_PDISP_SOR_STATE[12]. These fields are assembly registers; the active state is located in disp_sor_aa_core.v and disp_or_aaa_super.v

The "attached" field in SOR_STATE1 seems to be flopped to create read-only field "attached" in register NV_PDISP_SOR_TEST.

Offset: 001h | Read/Write: R/W | Reset: 0b0

Bit	Reset	Description
0	0x0	UPDATE

25.6.3 HDMI_NV_PDISP_SOR_STATE1_0

Offset: 002h | Read/Write: R/W | Reset: 0b00000

Bit	Reset	Description
4	0x0	ARM_SHOW_VGA
3	0x0	ATTACHED
2	SAFE	ASY_ORMODE: 0 = SAFE 1 = NORMAL
1:0	0x0	ASY_HEAD_OPMODE: 0 = SLEEP 1 = SNOOZE 2 = AWAKE

25.6.4 HDMI_NV_PDISP_SOR_STATE2_0

Offset: 003h | Read/Write: R/W | Reset: 0b000000101010001

Bit	Reset	Description
14	0x0	ASY_DEPOL: 0 = POSITIVE_TRUE 1 = NEGATIVE_TRUE
13	0x0	ASY_VSYNCPOL: 0 = POSITIVE_TRUE 1 = NEGATIVE_TRUE
12	0x0	ASY_HSYNCPOL: 0 = POSITIVE_TRUE 1 = NEGATIVE_TRUE
11:8	SINGLE_TMDS_A	ASY_PROTOCOL: 1 = SINGLE_TMDS_A 15 = CUSTOM
7:6	COMPLETE_RASTER	ASY_CRCMODE: 0 = ACTIVE_RASTER 1 = COMPLETE_RASTER 2 = NON_ACTIVE_RASTER

Bit	Reset	Description
5:4	SUBHEAD0	ASY_SUBOWNER: 0 = NONE 1 = SUBHEAD0 2 = SUBHEAD1 3 = BOTH
3:0	HEAD0	ASY_OWNER: 0 = NONE 1 = HEAD0

25.6.5 HDMI_NV_PDISP_RG_HDCP_AN_MSB_0

HDCP control registers in the pipeline

HDCP AN MSB REGISTER

The AN_MSB register holds the 32 most significant bits of the link encryption session random number. See the HDCP specification, the Upstream Link for HDCP specification for more information.

Usage: normal operation

Offset: 004h | Read/Write: RO | Reset: 0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx

Bit	Reset	Description
31:0	X	VALUE: 0 = ZERO

25.6.6 HDMI_NV_PDISP_RG_HDCP_AN_LSB_0

HDCP AN LSB REGISTER

The AN_LSB register holds the 32 least significant bits of the link encryption session random number. See the HDCP specification, the Upstream Link for HDCP specification for more information.

Usage: normal operation

Offset: 005h | Read/Write: RO | Reset: 0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx

Bit	Reset	Description
31:0	X	VALUE: 0 = ZERO

25.6.7 HDMI_NV_PDISP_RG_HDCP_CN_MSB_0

HDCP CN MSB REGISTER

The CN_MSB register holds the 32 most significant bits of the upstream exchange random number. See the HDCP specification, the Upstream Link for HDCP specification for more information.

Usage: normal operation

Offset: 006h | Read/Write: R/W | Reset: 0b00000000000000000000000000000000

Bit	Reset	Description
31:0	0x0	VALUE: 0 = ZERO

25.6.8 HDMI_NV_PDISP_RG_HDCP_CN_LSB_0

HDCP CN LSB REGISTER

The CN_LSB register holds the 32 least significant bits of the upstream exchange random number. See the HDCP specification, the Upstream Link for HDCP specification for more information.

Usage: normal operation

Offset: 007h | Read/Write: R/W | Reset: 0b00000000000000000000000000000000

Bit	Reset	Description
31:0	0x0	VALUE: 0 = ZERO

25.6.9 HDMI_NV_PDISP_RG_HDCP_AKSV_MSB_0

HDCP AKSV MSB REGISTER

The AKSV_MSB register holds the 8 most significant bits of the transmitter's downstream key selection vector (KSV). See the HDCP specification, the Upstream Link for HDCP specification for more information.

Usage: normal operation

Offset: 008h | Read/Write: RO | Reset: 0bxxxxxxxx

Bit	Reset	Description
7:0	X	VALUE: 0 = ZERO

25.6.10 HDMI_NV_PDISP_RG_HDCP_AKSV_LSB_0

HDCP AKSV LSB REGISTER

The AKSV_LSB register holds the 32 least significant bits of the transmitter's downstream key selection vector (KSV). See the HDCP specification, the Upstream Link for HDCP specification for more information.

Usage: normal operation

Offset: 009h | Read/Write: RO | Reset: 0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx

Bit	Reset	Description
31:0	X	VALUE: 0 = ZERO

25.6.11 HDMI_NV_PDISP_RG_HDCP_BKSV_MSB_0

HDCP BKSV MSB REGISTER

The BKSV_MSB register holds the 8 most significant bits of the receiver's key selection vector (KSV), as well as the receiver's REPEATER bit. See the HDCP specification, the Upstream Link for HDCP specification for more information.

Usage: normal operation

Offset: 00ah | Read/Write: R/W | Reset: 0b0xxxxxxxxxxxxxxxxxxxxxxxx00000000

Bit	Reset	Description
31	0x0	REPEATER: 0 = VALUE
7:0	0x0	VALUE: 0 = ZERO

25.6.12 HDMI_NV_PDISP_RG_HDCP_BKSV_LSB_0

HDCP BKSV LSB REGISTER

The BKSV_LSB register holds the 32 least significant bits of the receiver's key selection vector (KSV). See the HDCP specification, the Upstream Link for HDCP specification for more information.

Usage: normal operation

Offset: 00bh | Read/Write: R/W | Reset: 0b00000000000000000000000000000000

Bit	Reset	Description
31:0	0x0	VALUE: 0 = ZERO

25.6.13 HDMI_NV_PDISP_RG_HDCP_CKSV_MSB_0

HDCP CKSV MSB REGISTER

The CKSV_MSB register holds the 8 most significant bits of the software's key selection vector (KSV). See the HDCP specification, the Upstream Link for HDCP specification for more information.

> **Note:** Writing CKSV_MSB is the trigger for computing MPRIME and DKSV. It must be written last, after HDCP_CMODE, CN_MSB/LSB, and CKSV_LSB.

Usage: normal operation

Offset: 00ch | Read/Write: R/W | Reset: 0b00000000

Bit	Reset	Description
7:0	0x0	VALUE: 0 = ZERO

25.6.14 HDMI_NV_PDISP_RG_HDCP_CKSV_LSB_0

HDCP CKSV LSB REGISTER

The CKSV_LSB register holds the 32 least significant bits of the software's key selection vector (KSV). See the HDCP specification, the Upstream Link for HDCP specification for more information.

Usage: normal operation

Offset: 00dh | Read/Write: R/W | Reset: 0b00000000000000000000000000000000

Bit	Reset	Description
31:0	0x0	VALUE: 0 = ZERO

25.6.15 HDMI_NV_PDISP_RG_HDCP_DKSV_MSB_0

HDCP DKSV MSB REGISTER

The DKSV_MSB register holds the 8 most significant bits of the transmitter's upstream key selection vector (KSV). See the HDCP specification, the Upstream Link for HDCP specification for more information.

Usage: normal operation

Offset: 00eh | Read/Write: RO | Reset: 0bxxxxxxxx

Bit	Reset	Description
7:0	X	VALUE: 0 = ZERO

25.6.16 HDMI_NV_PDISP_RG_HDCP_DKSV_LSB_0

HDCP DKSV LSB REGISTER

The DKSV_LSB register holds the 32 least significant bits of the transmitter's upstream key selection vector (KSV). See the HDCP specification, the Upstream Link for HDCP specification for more information.

Usage: normal operation

Offset: 00fh | Read/Write: RO | Reset: 0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx

Bit	Reset	Description
31:0	X	VALUE: 0 = ZERO

25.6.17 HDMI_NV_PDISP_RG_HDCP_CTRL_0

HDCP CTRL REGISTER

The CTRL register is used to facilitate synchronization between the display driver and hardware.

- RUN: Set by driver to start or stop the downstream protocol
- CRYPT: Set by driver to turn encryption on.
- Write ENABLED to enable, but only after RUN == YES. Once enabled, is disabled by writing RUN=NO.
- DUAL_LINK_EN: Set by driver to turn dual-link mode on or off
- ONEONE: ONEONE_EN enables the HDCP 1.1 features. This enables HDCP EESS signaling and Advance_Cipher.
- Write ENABLED to enable, but only after RUN == YES.

Once enabled, is disabled by writing RUN=NO. This should be enabled if your receiver supports HDCP 1.1

See Chapter 2.7 in the HDCP 1.1 spec for EESS signaling. See Chapter 2.2 in the HDCP 1.1 spec for ADVANCE_CIPHER.

- AN: Set by hardware when a valid An value has been generated
- R0: Set by hardware when Km, Ks, M0, and R0 have been calculated
- SPRIME: Set by hardware when S' has been calculated
- MPRIME: Set by hardware when M' has been calculated
- SROM_EN: Set by hardware while the HDCP SROM is in use, cleared when not in use
- SROM_ERR: set by hardware when an error occurs while using the HDCP SROM

Usage: normal operation

Offset: 010h | Read/Write: R/W | Reset: 0bxxxxxxxxxx0000

Bit	R/W	Reset	Description
13	RO	X	SROM_ERR: 0 = NOERROR 1 = ERROR
12	RO	X	SROM_EN: 0 = DISABLED 1 = ENABLED
11	RO	X	MPRIME: 0 = INVALID 1 = VALID
10	RO	X	SPRIME: 0 = INVALID 1 = VALID
9	RO	X	R0: 0 = INVALID 1 = VALID
8	RO	X	AN: 0 = INVALID 1 = VALID
3	RW	0x0	ONEONE: 0 = DISABLED 1 = ENABLED
2	RW	0x0	DUAL_LINK_EN: 0 = DISABLED 1 = ENABLED
1	RW	0x0	CRYPT: 0 = DISABLED 1 = ENABLED
0	RW	0x0	RUN: 0 = NO 1 = YES

25.6.18 HDMI_NV_PDISP_RG_HDCP_CMODE_0

HDCP CMODE REGISTER

The CMODE register indicates to hardware which upstream protocol calculation to perform. See the HDCP specification, the Upstream Link for HDCP specification for more information.

Writing to the CMODE register kicks off a "Read Status" or a "Read M" operation. When performing a "Read Status" operation, use the CMODE_INDEX field to identify the port for which you wish to obtain status.

Usage: normal operation

Offset: 011h | Read/Write: R/W | Reset: 0b00000001

Bit	Reset	Description
7:4	0x0	INDEX: 0 = TMDS0_LINK1 1 = TMDS0_LINK0 2 = TMDS1_LINK1 3 = TMDS1_LINK0 4 = DVOA 5 = DVOB 6 = DAC1 7 = DAC2

Bit	Reset	Description
		8 = DAC3 9 = TMDS2_LINK1 10 = TMDS2_LINK0 11 = DP2_LINK1 12 = DP2_LINK0 13 = DP1_LINK1 14 = DP1_LINK0
3:0	0x1	MODE: 1 = READ_S 2 = READ_M

25.6.19 HDMI_NV_PDISP_RG_HDCP_MPRIME_MSB_0

HDCP MPRIME MSB REGISTER

The MPRIME_MSB register holds the 32 most significant bits of the encrypted M0 value. See the HDCP specification, the Upstream Link for HDCP specification for more information.

Usage: normal operation

Offset: 012h | Read/Write: RO | Reset: 0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx

Bit	Reset	Description
31:0	X	VALUE: 0 = ZERO

25.6.20 HDMI_NV_PDISP_RG_HDCP_MPRIME_LSB_0

HDCP MPRIME LSB REGISTER

The MPRIME_LSB register holds the 32 least significant bits of the encrypted M0 value. See the HDCP specification, the Upstream Link for HDCP specification document for more information.

Usage: normal operation

Offset: 013h | Read/Write: RO | Reset: 0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx

Bit	Reset	Description
31:0	X	VALUE: 0 = ZERO

25.6.21 HDMI_NV_PDISP_RG_HDCP_SPRIME_MSB_0

HDCP SPRIME MSB REGISTER

The SPRIME_MSB register holds the 8 most significant bits of the S' value. See the HDCP specification, the Upstream Link for HDCP specification for more information.

STATUS_READZ indicates whether or not this chip implements the HDCP Upstream Spec's "Read Z" operation. Currently, none of our chips implement "Read Z".

STATUS_CS indicates whether or not this chip implements the connection state (CS) register. If this field is set to STATUS_CS_NOT_IMPL, it means this chip will always follow the standard "Read Status" protocol when reporting status. If this field is set to STATUS_CS_IMPLMNTD, it means this chip will always follow the "Read Status With Connection State" protocol when reporting status. STATUS_SCOPE indicates how the chip will report the status for the STATUS_UNPROTECTED field. See the STATUS_UNPROTECTED description below for more information.

STATUS_INTPNL indicates if the port you are querying (identified by the CMode index) is transmitting to an internal panel on this head. If the port you are querying isn't transmitting on this head (see the ** note below), or if it is transmitting on this head but to a device other than an internal panel, then STATUS_INTPNL_INACTV will be returned.

STATUS_MAX_CMODE_IDX identifies the maximum CMode index allowed for requesting status.

> ****Note:** Unlike the STATUS_UNPROTECTED field, the other STATUS fields always use the _HA_ registers to report status for ports on head A and the _HB_ registers to report status on head B. If you use the _HA_ versions of the CMODE and SPRIME registers to query the status of a port that is actually being driven by head B, the status will indicate that the port isn't transmitting at all (everything will come back as INACTV).

Usage: normal operation

Offset: 014h | Read/Write: RO | Reset: 0bxxxxxxxx

Bit	Reset	Description
7	X	STATUS_READZ: 0 = NOT_IMPL 1 = IMPLMNTD
6	X	STATUS_CS: 0 = NOT_IMPL 1 = IMPLMNTD
5	X	STATUS_SCOPE: 0 = SCOPE_TWO_HEADS 1 = SCOPE_1_HEAD
4	X	STATUS_INTPNL: 0 = INACTV 1 = ACTV
3:0	X	STATUS_MAX_CMODE_IDX

25.6.22 HDMI_NV_PDISP_RG_HDCP_SPRIME_LSB2_0

HDCP SPRIME LSB2 REGISTER

The SPRIME_LSB2 register holds the 32 next-most significant bits of the S' value. See the HDCP specification, the Upstream Link for HDCP specification for more information.

STATUS_CMODE_IDX identifies the index of the port to which the status request was actually routed. STATUS_UNPROTECTED indicates whether the port you queried (identified by the CMode index) is transmitting unprotected data. If STATUS_SCOPE is set to STATUS_SCOPE_1_HEAD, then make sure to use the _HA_ registers to see if any ports on head A are unprotected, and use the _HB_ registers to see if any ports on head B are unprotected. If STATUS_SCOPE is set to STATUS_SCOPE_2_HEADS, then STATUS_UNPROTECTED combines the status of both heads. In this case, both the _HA_ registers and the _HB_ registers will report the same value for the STATUS_UNPROTECTED field.

Value of STATUS_SCOPE	Meaning of STATUS_UNPROTECTED
_1_HEAD	UNPROTECTED_Y means that at least one port driven by this head is transmitting "unprotected" data. UNPROTECTED_N means that none of the ports driven by this head are transmitting "unprotected" data.
_2_HEADS	UNPROTECTED_Y means that at least one port driven by either head is transmitting "unprotected" data. UNPROTECTED_N means that none of the ports driven by either head are transmitting "unprotected" data.

"Unprotected" data does not necessarily mean data that is not being encrypted. Data being transmitted out of a DAC is *always* considered unprotected. Data being transmitted out of a DVO is considered unprotected if it isn't being encrypted. Data being transmitted by a TMDS link is also considered unprotected if it isn't being encrypted,*except* for the case where

the link feeds the internal panel of a laptop. The HDCP spec dictates that since the bus feeding an internal panel is essentially inaccessible to users, it can be considered "protected" even when sending clear data.

STATUS_EXTPNL is set to STATUS_EXTPNL_ACTV if the port identified by the CMode index is a digital interface (i.e. a DVO or TMDS interface), and it is transmitting on this head to something *other* than an internal panel. The STATUS_INTPNL field and the STATUS EXTPNL field will never be both set to ACTV for the same port. If a digital port is transmitting on this head, and it is physically connected to an internal panel, then the STATUS_INTPNL bit is set to ACTV and the STATUS_EXTPNL is set to INACTV; if it is transmitting on this head but it is *not* connected to an internal panel (even if it isn't connected to anything at all), then STATUS_INTPNL is set to INACTV and STATUS_EXTPNL is set to ACTV.

STATUS_RPTR is set to STATUS_RPTR_ACTV if 1) the STATUS_EXTPNL field is set to ACTV, and 2) the REPEATER bit of the BKSV_MSB register is set to 0x1. This scenario should only occur after we are transmitting to an external HDCP-compliant device whose "repeater" bit is set.

STATUS_ENCRYPTING will be set to STATUS_ENCRYPTING_Y if the HDCP unit in this head is actually encrypting the data it receives. Note that if this bit is set, it means that *all* ports driven by this head whose data streams flow through the HDCP unit will be transmitting encrypted data, but any ports driven by this head whose data streams *bypass* the HDCP unit will be transmitting *clear* data. The DACs always use a data path that bypasses the HDCP unit and therefore must always be considered "unprotected".

Usage: normal operation

Offset: 015h | Read/Write: RO | Reset: 0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx

Bit	Reset	Description
31:28	X	STATUS_CMODE_IDX
27	X	STATUS_UNPROTECTED: 0 = N 1 = Y
26	X	STATUS_EXTPNL: 0 = INACTV 1 = ACTV
25	X	STATUS_RPTR: 0 = INACTV 1 = ACTV
24	X	STATUS_ENCRYPTING: 0 = N 1 = Y
23:0	X	VALUE: 0 = ZERO

25.6.23 HDMI_NV_PDISP_RG_HDCP_SPRIME_LSB1_0

HDCP SPRIME LSB1 REGISTER

The SPRIME_LSB1 register holds the 32 least significant bits of the S' value. See the HDCP specification, the Upstream Link for HDCP specification for more information.

Usage: normal operation

Offset: 016h | Read/Write: RO | Reset: 0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx

Bit	Reset	Description
31:0	X	VALUE: 0 = ZERO

25.6.24 HDMI_NV_PDISP_RG_HDCP_RI_0

HDCP RI REGISTER

The RI register holds the 16-bit link integrity check value. See the HDCP specification, the Upstream Link for HDCP specification for more information.

Usage: normal operation

Offset: 017h | Read/Write: RO | Reset: 0bxxxxxxxxxxxxxxxx

Bit	Reset	Description
15:0	X	VALUE: 0 = ZERO

25.6.25 HDMI_NV_PDISP_RG_HDCP_CS_MSB_0

HDCP CS MSB REGISTER

The CS_MSB register holds the 8 most significant bits of the connection state. See the HDCP specification, the Upstream Link for HDCP specification for more information.

Usage: normal operation

Offset: 018h | Read/Write: RO | Reset: 0bxxxxxxxx

Bit	Reset	Description
7:0	X	RESERVED

25.6.26 HDMI_NV_PDISP_RG_HDCP_CS_LSB_0

HDCP CS LSB REGISTER

The CS_LSB register holds the 32 least significant bits of the connection state. See the HDCP specification, and the Upstream Link for HDCP specification for more information.

Usage: normal operation

Offset: 019h | Read/Write: RO | Reset: 0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx

Bit	Reset	Description
31:0	X	RESERVED

25.6.27 HDMI_NV_PDISP_HDMI_AUDIO_INFOFRAME_CTRL_0

Please refer IEC60958-1 for general and IEC60958-3 for consumer spec, for related audio information.

Additional notes regarding the ACR packet:

There are several methods that can used to generate the N and CTS values in the Audio Clock Regeneration packet. The details of these methods are described here.

Full SW control: SW controls the contents of the possible ACR packets. SW writes the contents of the ACR_XXXX_SUBPACK_HIGH and ACR_XXXX_SUBPACK_LOW for all seven audio frequencies.

SW selects a method in ACR_CTRL to determine the audio sampling frequency

1. Measured in the audio block (MEASURE)

2. Read from the channel status information encoded in the audio stream (PACKET)

3. Defined by SW (FREQS)

SW writes _YES to the ENABLE field of the SUBPACK_HIGH registers to allow that pair of registers to be used as the ACR packet. The audio sampling frequency specified in ACR_CTRL will select one of the seven pairs of SUBPACK registers to use as the ACR packet. This packet is sent on every Frame 27 of the audio block if that pair's ENABLE field is _YES.

Hardware controlled CTS: SW provides the N value and the hardware measures the CTS value. This is described in the HDMI_SPARE comments and mentioned in all other affected registers.

SW writes _ENABLE to HDMI_SPARE_HW_CTS to enable this feature.

SW writes 1 to HDMI_SPARE_CTS_RESET_VAL. This controls what the internal CTS counter resets to when it starts the next round of measurement. Resetting to zero was not correct, and adding a few bits of control helped to fine tune the measurement.

SW sets all ENABLEs in ACR_CTRL to _NO. (The easy way to do this is just to write zero to the whole register.)

SW writes the value of N in two places.

1. ACR_0441_SUBPACK_HIGH_SB[4/5/6]: It is written here so that the ACR packet contains the correct information for N.

2. AUDIO_N_VALUE: It is written here so that the audio block knows what N to use while it is measuring CTS. (SW does not need to write N to these places if Hardware Selected N is used.)

SW enables the sending of ACR_0441_SUBPACK* by setting ACR_0441_SUBPACK_ENABLE to _YES. (This pair of registers is used for all audio frequencies when Hardware controlled CTS is enabled.)

SW writes _USE_HW_CTS_VAL to ACR_0441_SUBPACK_LOW_SB1.

Hardware selected N: SW provides the possible N values whenever the pixel clock frequency changes. Hardware looks up the correct N value from a table stored in priv registers.

SW writes the 7 possible N values into the 7 AUDIO_NVAL registers. This is based on pixel clock frequency.

SW enables this feature by setting AUDIO_N_LOOKUP to _ENABLE. HW will used the audio sampling frequency detected by the audio block to select the correct N value.

NOTE: This is not the audio sampling frequency reported by the channel status information in the audio stream. HW will ignore whatever if written in the SUBPACK_HIGH registers when this feature is enabled and send the value of N it selected in these bytes of the ACR packet. CTS can come from the SUBPACK_LOW registers or the Hardware controlled CTS.

Audio frequency notes: There are several places in the HDMI and Audio registers where the audio sampling frequency is reported or set. Here is a breakdown of all such fields.

In SPDIF audio encoding, one bit of each audio sample is part of the "channel status" information. The bits from all 192 audio samples combine to form the 192 bit channel status packet. For consumer applications, only the first 40 bits have defined values. These bits are included in the encoded HDMI audio packet. Four of these bits contain the audio sampling frequency as reported by the audio source. See the IEC60958-3 spec for more information.

SPDIF_CHN_STATUS1 and SPDIF_CHN_STATUS2 are read only registers that contain the 40 bits of channel status data read from the last audio block. The audio frequency the audio stream reports can be read from SPDIF_CHN_STATUS1_SFREQ. This is the sampling frequency that ACR_CTRL refers to with _PACKET.

SPDIF_CHN_STATUS1_ORIGINAL is the original sampling frequency of the audio. If the source of the audio stream changed the sampling frequency from its original frequency for any reason, the original sampling frequency is reported here.

AUDIO_CNTRL0_SAMPLING_FREQ is the sampling frequency measured by the audio block. It counts the number of dispclks periods that occur between to specific points in the audio stream. It compares this count to the thresholds in the AUDIO_FS registers to determine what the audio sampling frequency is. This is the sampling frequency that ACR_CTRL refers to as

_MEASURE. This is the sampling frequency used to determine the correct value of N when Hardware selected N is enabled (see AUDIO_N).

The CHANNEL_STATUS1 and CHANNEL_STATUS2 registers are for debug. They can be used to replace the channel status bits that were in the original SPDIF stream with user defined bits. CHANNEL_STATUS1_SFREQ can be used to report a different sampling frequency to downstream devices.

ACR_CTRL_FREQS can be written to select a specific pair of SUBPACK registers to send as your ACR packet. ACR_CTRL_FREQS_ENABLE must be set to _YES for this to have any effect.

The HDMI Audio Infoframe, AVI Infoframe, and Generic Infoframe have nearly identical priv register interfaces. The next five registers control the Audio Infoframe as described in section 8.2.2 of the HDMI spec.

HDMI_AUDIO_INFOFRAME_CTRL

This register controls the frequency and generation of audio infoframe packets. The contents of the packet should be written into the header (HDMI_AUDIO_INFOFRAME_HEADER) and subpacket (HDMI_AUDIO_INFOFRAME_SUBPACK0_LOW, HDMI_AUDIO_INFOFRAME_SUBPACK0_HIGH) registers.

ENABLE: Setting this field to _YES will initiate infoframe generation. Setting this bit to _NO will disable infoframe generation at the beginning of the next frame. The frequency of infoframe generation is controlled by OTHER and SINGLE fields.

OTHER: Setting this field to _EN while SINGLE is set to _DIS will cause infoframe to be transmitted to every other frame.

SINGLE: Setting this field to _EN while OTHER is set to _DIS will cause infoframe to be transmitted exactly once.

If OTHER and SINGLE fields are both set to _DIS, infoframe will be generated every frame. Software should never set OTHER and SINGLE both to _EN.

See chapter 8.2.2 - Audio InfoFrame, in the HDMI spec for more information

CHKSUM_HW: HW provides a way to calculate the Checksum for the infoframes.

_ENABLE will enable the HW calculation to be passed to the packet

_DISABLE :

1. Will use the register value defined in NV_PDISP_SOR_HDMI_AUDIO_INFOFRAME_SUBPACK0_LOW_PB0 for the SPDIF

2. Will use the Check Sum provided by the Azalia codec for the Azalia audio formats.

Usage: normal operation

Offset: 01eh | Read/Write: R/W | Reset: 0b10xxx0xxx0

Bit	Reset	Description
9	ENABLE	CHKSUM_HW: 0 = DISABLE 1 = ENABLE
8	0x0	SINGLE: 0 = DIS 1 = EN
4	0x0	OTHER: 0 = DIS 1 = EN
0	0x0	ENABLE: 0 = NO 1 = YES 0 = DIS 1 = EN

25.6.28 HDMI_NV_PDISP_HDMI_AUDIO_INFOFRAME_STATUS_0

HDMI_AUDIO_INFOFRAME_STATUS

The SENT bit will be set to _DONE, after the first packet is sent. After the ENABLE bit in INFOFRAME_CTRL is set to _NO, the SENT bit will be set to _WAITING after the start of the next frame to indicate that it is safe to change the contents of the packet header and subpacket registers.

Usage: normal operation

Offset: 01fh | Read/Write: RO | Reset: 0bx

Bit	Reset	Description
0	X	SENT: 1 = DONE 0 = WAITING

25.6.29 HDMI_NV_PDISP_HDMI_AUDIO_INFOFRAME_HEADER_0

HDMI_AUDIO_INFOFRAME_HEADER

This register should be written with the value of the HDMI Audio InfoFrame header. This header is described in table 8-4 of chapter 8.2.2 of the HDMI spec. HB0, HB1, and HB2 are defined fields of the header from the spec.

Offset: 020h | Read/Write: R/W | Reset: 0b000000000000000000000000

Bit	Reset	Description
23:16	0x0	HB2
15:8	0x0	HB1
7:0	0x0	HB0

25.6.30 HDMI_NV_PDISP_HDMI_AUDIO_INFOFRAME_SUBPACK0_LOW_0

HDMI_AUDIO_INFOFRAME_SUBPACK0_LOW

This register should be written with the lower 4 bytes of the HDMI Audio Infoframe. PB0, PB1, PB2, and PB3 are defined fields from the spec. See chapter 8.2.2 - Audio InfoFrame, Table 8-5, in the HDMI spec for more information

Offset: 021h | Read/Write: R/W | Reset: 0b00000000000000000000000000000000

31:24	0x0	PB3
23:16	0x0	PB2
15:8	0x0	PB1
7:0	0x0	PB0

25.6.31 HDMI_NV_PDISP_HDMI_AUDIO_INFOFRAME_SUBPACK0_HIGH_0

HDMI_AUDIO_INFOFRAME_SUBPACK0_HIGH

This register should be written with the upper 2 bytes of the HDMI Audio Infoframe. PB4 and PB5 are defined fields from the spec. See chapter 8.2.2 - Audio InfoFrame, Table 8-5, in the HDMI spec for more information

Offset: 022h | Read/Write: R/W | Reset: 0b0000000000000000

Bit	Reset	Description
15:8	0x0	PB5
7:0	0x0	PB4

25.6.32 HDMI_NV_PDISP_HDMI_AVI_INFOFRAME_CTRL_0

The following registers are used to send a fourteen-byte packet intended for sending avi infoframe packet as described in section 8.2.1 of the HDMI spec.

HDMI_AVI_INFOFRAME_CTRL

This register controls the frequency and generation of AVI infoframe packets. The fields of this register are identical to HDMI_AUDIO_INFOFRAME_CTRL. See chapter 8.2.1 - Auxiliary Video information (AVI) InfoFrame, in the HDMI spec for more information

Offset: 023h | Read/Write: R/W | Reset: 0b10xxx0xxx0

Bit	Reset	Description
9	ENABLE	CHKSUM_HW: 0 = DISABLE 1 = ENABLE
8	DIS	SINGLE: 0 = DIS 1 = EN
4	DIS	OTHER: 0 = DIS 1 = EN
0	NO	ENABLE: 0 = NO 1 = YES 0 = DIS 1 = EN

25.6.33 HDMI_NV_PDISP_HDMI_AVI_INFOFRAME_STATUS_0

HDMI_AVI_INFOFRAME_STATUS

The SENT bit will be set to _DONE, after the first packet is sent. After the ENABLE bit in INFOFRAME_CTRL is set to _NO, the SENT bit will be set to _WAITING after the start of the next frame to indicate that it is safe to change the contents of the packet header and subpacket registers.

Offset: 024h | Read/Write: RO | Reset: 0bx

25.6.34 HDMI_NV_PDISP_HDMI_AVI_INFOFRAME_HEADER_0

HDMI_AVI_INFOFRAME_HEADER

This register should be written with the value of the HDMI AVI InfoFrame header. This header is described in table 8-1 of chapter 8.2.1 of the HDMI spec. HB0, HB1, and HB2 are defined fields of the header from the spec.

Offset: 025h | Read/Write: R/W | Reset: 0b000000000000000000000000

Bit	Reset	Description
23:16	0x0	HB2
15:8	0x0	HB1
7:0	0x0	HB0

25.6.35 HDMI_NV_PDISP_HDMI_AVI_INFOFRAME_SUBPACK0_LOW_0

HDMI_AVI_INFOFRAME_SUBPACK0_LOW

This register should be written with the lower 4 bytes of the HDMI AVI Infoframe. PB0, PB1, PB2, and PB3 are defined fields from the spec. See chapter 8.2.1 - Auxiliary Video information (AVI) InfoFrame, Table 8-2, in the HDMI spec for more information.

25.6.39 HDMI_NV_PDISP_HDMI_GENERIC_CTRL_0

The following registers are used to send a 28-byte packet intended for sending any packet type. These registers will most likely be used for debug purposes.

HDMI_GENERIC_CTRL

This register controls the frequency and generation of generic infoframe packets. The fields of this register are identical to HDMI_AUDIO_INFOFRAME_CTRL except where noted below.

HBLANK: If HBLANK is set to _EN, then this packet will be sent (once) during the next horizontal blanking interval. The packet will still be sent at most once per frame. Software can poll GENERIC_STATUS_SENT to determine when the packet has been sent.

Using HBLANK is intended to mimic Audio Sample Packets and ACR Packets and therefore sending of the actual audio packets should be disabled by setting AUDIO to _DIS. This feature is used for Debug purposes only.

To mimic an audio packet:

- begin
- wait for GENERIC_STATUS_SENT=_WAITING
- write next 4 audio samples to GENERIC_HEADER/GENERIC_SUBPACK registers
- set HBLANK = _EN
- wait for GENERIC_STATUS_SENT=_SENT
- set HBLANK = _DIS
- end

AUDIO: Audio packet transmission will be stopped when set to _DIS. Normal audio packet transmission will be allowed when set to _EN. This is used during debug to disable normal audio when using HBLANK.

Offset: 02ah | Read/Write: R/W | Reset: 0b1xxx0xxx0xxx0xxx0

Bit	Reset	Description
16	EN	AUDIO: 0 = DIS 1 = EN
12	DIS	HBLANK: 0 = DIS 1 = EN
8	DIS	SINGLE: 0 = DIS

Bit	Reset	Description
		1 = EN
4	DIS	OTHER: 0 = DIS 1 = EN
0	NO	ENABLE: 0 = NO 1 = YES 0 = DIS 1 = EN

25.6.40 HDMI_NV_PDISP_HDMI_GENERIC_STATUS_0

HDMI_GENERIC_STATUS

The SENT bit will be set to _DONE, after the first packet is sent. After the ENABLE bit in INFOFRAME_CTRL is set to _NO, the SENT bit will be set to _WAITING after the start of the next frame to indicate that it is safe to change the contents of the packet header and subpacket registers.

25.6.50 HDMI_NV_PDISP_HDMI_ACR_CTRL_0

HDMI_ACR_CTRL

The Audio Clock Regeneration (ACR) packet contains the N and CTS values that the HDMI sink requires to recreate the audio clock. This mechanism is described in chapter 7.2 of the HDMI spec.

If software needs to specify N and CTS directly, this register is used to select the audio sampling frequency detection mechanism. The sampling rate is used to index one of the seven ACR_XXXX_SUBPACK_LOW/HIGH registers which must be

written with the correct value of N and CTS. N and CTS are determined by the current audio sampling frequency and the pixel clock frequency:

CTS = (PixelClock*N) / (128*AudioSamplingFrequency)

The selected sampling rate must point to a valid entry (i.e. one of the 7 listed below) and the selected ACR_XXXX_SUBPACK_HIGH_ENABLE must be set to enable sending the packet.

When software is controlling N and CTS directly, the ACR packet is sent every 27th audio frame (of 0 to 191) of the audio block. The sampling frequency read from the channel status bits is not available until the 27th audio frame.

PACKET_ENABLE: Set this to _YES to use the channel status information read from the incoming SPDIF audio stream to determine the sampling frequency.

MEASURE_ENABLE: Set this to _YES to use the sampling frequency measured in the in the audio block to determine the sampling frequency. This is the sampling frequency that is read from AUDIO_CNTRL0_SAMPLING_FREQ.

FREQS_ENABLE: Set this to _YES to use the sampling frequency written into the _FREQS field of this register.

FREQS: This is the audio sampling frequency that will be used when FREQS_ENABLE is _YES.

When Hardware is used to measure CTS, all ENABLE fields of this register should be set to _NO.

All four subpackets contain the same ACR packet.

15:8	0x0	SB5
7:0	0x0	SB6

25.6.65 HDMI_NV_PDISP_HDMI_CTRL_0

HDMI_CTRL

REKEY: REKEY is the number of clocks required for HDCP rekey, starting from when DE is deasserted. No HDMI packets can be sent during this time. Due to a two cycle delay in hardware, REKEY should be set to two less than the desired value.

AUDIO_LAYOUT: AUDIO_LAYOUT controls layout (HB1[4]) of the Audio Sample Packet Header. Two different layouts are supported in the HDMI spec. The hardware only supports layout _2CH (2 channel audio). This should not need to be programmed beyond its init value of _2CH.

See Section 5.3.4 of the HDMI specification.

AUDIO_LAYOUT_SELECT: For projects with integrated audio codec, the AUDIO_LAYOUT information is automatically detected by HW (default). We can override this capability and fall back on AUDIO_LAYOUT based selection by setting AUDIO_LAYOUT_SELECT to _SW_BASED.

If NV_CHIP_DISP_EXTENDED_AUD_FMT is not defined in the project spec, this field has no meaning, and only AUDIO_LAYOUT field will take effect.

SAMPLE_FLAT: SAMPLE_FLAT controls the values of (HB2[3:0]) of the Audio Sample Packet Header and should be _CLR. See Section 5.3.4 of the HDMI specification.

MAX_AC_PACKET: Set MAX_AC_PACKET to the maximum number of 32-pixel packets that will fit in the horizontal blanking interval. This controls the maximum number of audio packets, ACR packets, GCP packets, infoframes, etc that will be sent during the horizontal blanking period.

MAX_AC_PACKET <= Floor[((HBLANK-REKEY-18)/32)]

CT_SELECT: Diagnostic workaround bit to decide whether the value of "coding type" will be HW based or SW based. CT field is required in the construction of Audio Infoframe packet (HDMI Spec sec 8.2.2). By default CT field is constructed by SW but by setting this bit CT field in the construction of the Audio Infoframe packet comes as a sideband signal from the hdacodec. If NV_CHIP_DISP_EXTENDED_AUD_FMT is not defined in projects.spec, this field has no meaning

CC_SELECT: Diagnostic workaround bit to decide whether the value of "channel count" will be HW based or SW based. CC field is required in the construction of Audio Infoframe packet (HDMI Spec sec 8.2.2). By default CC field is constructed by SW but by setting this bit CC field in the construction of the Audio Infoframe packet comes as a sideband signal from the hdacodec. If NV_CHIP_DISP_EXTENDED_AUD_FMT is not defined in projects.spec, this field has no meaning

SF_SELECT: Diagnostic workaround bit to decide whether the value of "sampling frequency" will be HW based or SW based. SF field is required in the construction of Audio Infoframe packet (HDMI Spec sec 8.2.2). By default SF field is constructed by SW but by setting this bit SF field in the construction of the Audio Infoframe packet comes as a sideband signal from the hdacodec. If NV_CHIP_DISP_EXTENDED_AUD_FMT is not defined in projects.spec, this field has no meaning

SS_SELECT: Diagnostic workaround bit to decide whether the value of "sample size" will be HW based or SW based. SS field is required in the construction of Audio Infoframe packet (HDMI Spec sec 8.2.2). By default SS field is constructed by SW but by setting this bit SS field in the construction of the Audio Infoframe packet comes as a sideband signal from the hdacodec. If NV_CHIP_DISP_EXTENDED_AUD_FMT is not defined in projects.spec, this field has no meaning

CA_SELECT: Diagnostic workaround bit to decide whether the value of "channel allocation" will be HW based or SW based. CA field is required in the construction of Audio Infoframe packet (HDMI Spec sec 8.2.2). By default CA field is constructed by SW but by setting this bit CA field in the construction of the Audio Infoframe packet comes as a sideband signal from the hdacodec. If NV_CHIP_DISP_EXTENDED_AUD_FMT is not defined in projects.spec, this field has no meaning

ENABLE: Set to _YES to enable HDMI for this head. Set to _NO to disable HDMI for this head.

25.6.66 HDMI_NV_PDISP_HDMI_VSYNC_KEEPOUT_0

HDMI_VSYNC_KEEPOUT

Defines the start and end of the VSYNC keepout period where HDMI packets should not be sent. This is defined in chapter 2.7 the HDCP 1.1 spec.

END: Defines the end of the keepout period. This is measured in pixels after the active edge of VSYNC. This is defined in the spec and should not need to be written beyond its init value.

START: Defines the start of the keepout period. This is measured in pixels after the active edge of VSYNC. This is defined in the spec and should not need to be written beyond its init value.

ENABLE: When set to _YES, the keepout window is respected and no HDMI packets are sent in the period of time between START and END. This should be _YES. When set to _NO, the keepout window is ignored and HDMI packets may be sent regardless of the keepout window.

Offset: 045h l Read/Write: R/W l Reset: 0b1xxxxx0110011010xxxxxx1010001010

Bit	Reset	Description
31	YES	ENABLE: 0 = NO 1 = YES 0 = DIS 1 = EN
25:16	0x19a	START

25.6.67 HDMI_NV_PDISP_HDMI_VSYNC_WINDOW_0

HDMI_VSYNC_WINDOW

Defines the start and end of the window of opportunity where the HDCP EESS signaling occurs. This is defined in chapter 2.7 of the HDCP 1.1 spec.

END: Defines the end of the window of opportunity. This is measured in pixels after the active edge of VSYNC. This is defined in the spec and should not need to be written beyond its init value.

START: Defines the start of the window of opportunity. This is measured in pixels after the active edge of VSYNC. This is defined in the spec and should not need to be written beyond its init value.

ENABLE: _YES will allow EESS signaling during the window of opportunity. _NO will prevent EESS signaling.

25.6.68 HDMI_NV_PDISP_HDMI_GCP_CTRL_0

The following registers are used to send a single-byte packet intended for sending the general control packet as described in section 5.3.6 of the HDMI spec. This control packet is used to control the AVMUTE flag.

HDMI_GCP_CTRL

This register controls the frequency and generation of GCP packets. The fields of this register are identical to HDMI_AUDIO_INFOFRAME_CTRL.

All four subpackets contain the same GCP packet.

Offset: 047h l Read/Write: R/W l Reset: 0b0xxx0xxx0

Bit	Reset	Description
8	DIS	SINGLE: 0 = DIS 1 = EN
4	DIS	OTHER: 0 = DIS 1 = EN

7:0	0x1	SB0: 1 = SET_AVMUTE 16 = CLR_AVMUTE

25.6.71 HDMI_NV_PDISP_HDMI_CHANNEL_STATUS1_0

HDMI_CHANNEL_STATUS1

This register is used for debug purposes only. Normally, the channel status bits encoded in the SPDIF sample stream are passed directly into the HDMI audio packet. HDMI_CHANNEL_STATUS1/2 can be used to override these bits with user defined values.

If STATUS2_ENABLE is set to _YES, then the 40-bit contents of CHANNEL_STATUS2/1 is inserted into the Cl and Cr bits of the audio sample packets for audio frames 0-39. Cl and Cr contain the channel status bits. See chapter 5.3.4 of the HDMI spec for information on Cr and Cl.

The fields in SPDIF_CHN_STATUS1/2 correspond to the fields in CHANNEL_STATUS1/2 for all values except for the ABCDM field. The values read from SPDIF_CHN_STATUS1/2 can be passed directly into the fields for CHANNEL_STATUS1/2 without any manipulation. This could be used if the user only needs to force one of the fields to a specific value and leave the rest untouched. Information on the channel status bits can be found in Chapter 5 of the IEC60958-3 spec.

ABCDM: This is the first byte of the channel status information. These bits have several meanings. See chapter 5.2.1 of IEC60958-3 for more information.

CODE: This byte defines the Category Code of the input device. This code indicates what type of equipment is generating the input. See 5.3.1 of the IEC60958-3 spec for the values of codes.

SOURCE: Source number of the audio.

CHANNEL: Channel number of the audio. The channel number inserted into channel 2 will be STATUS1_CHANNEL + 1

SFREQ: The reported sampling frequency of the audio stream.

ACCURACY: Transmitter Clock accuracy.

-LVL1 High accuracy mode: Transmitted sampling frequency is within a tolerance of +/-50*10^-6

-LVL2 Normal accuracy mode: Transmitted sampling frequency is within a tolerance of +/-1000*10^-6

-LVL3 Variable pitch shifted clock mode: Only specially designed receivers can receive the signal in this mode

-OTHER: Interface frame rate not matched to sampling frequency: This is for all other modes that do not have an embedded sampling frequency clock.

25.6.76 HDMI_NV_PDISP_HDMI_SPARE_0

HDMI_SPARE

HW_CTS - If this is set to _ENABLE, Hardware measured CTS will be enabled. This method is more accurate than using software controlled CTS. The HDMI block will count the number of TMDS clocks that occur during the interval 1/(128 * audio sample rate) and use the value as CTS and issue the ACR Packet at each interval. When hardware measured CTS is enabled, all ENABLE fields of ACR_CTRL must be set to _NO. Also, ACR_0441_SUBPACK_HIGH_ENABLE must be set to _YES.

ACR_0441_SUBPACK_HIGH_N should be written with the value of N for the current sampling frequency.

The N value must also be written into AUDIO_N_VALUE (See the AUDIO register section for more details).

The value of N can be determined from the current audio sampling frequency, the current pixel clock rate, and tables 7-1. 7-2, and 7-3 in the HDMI spec. In most cases the value in the "Other" row can be used.

FORCE_SW_CTS: When HW_CTS is ENABLE, it uses measured CTS. However, when the audio clock / video clock ratio is known, this is undesirable. Currently, HW_CTS can't be disabled.

When FORCE_SW_CTS=ENABLE along with HW_CTS=ENABLE, the HW_CTS is used to control transmission of ACR packets, but the CTS is programmed by SW in the ACR_0441_SUBPACK_LOW registers.

SUPRESS_SP_B: Default SUPRESS_SP_B=0 is to disable B bits in audio sample packets, for non-present samples. Setting SUPRESS_SP_B=1 restores the old behavior.

CTS_RESET_VAL: When an ACR packet is sent, the CTS counter is reset to the value in this field. This should be set to the INIT value of 1

ACR_PRIORITY: This controls the priority of the ACR packet with respect to Audio Sample packets. This should be set to _HIGH.

LOW: ACR packets will have lower priority than Audio Sample packets

HIGH: ACR packets will have higher priority than Audio Sample packets

SW needs to make sure these registers are set when audio is active:

- HDMI_SPARE_HW_CTS = _HW_CTS_ENABLE
- HDMI_SPARE_CTS_RESET_VAL = 1
- HDMI_SPARE_ACR_PRIORITY = _HIGH
- ACR_CTRL_*_ENABLE = _NO
- ACR_0441_SUBPACK_HIGH_ENABLE = _YES
- ACR_0441_SUBPACK_HIGH_N = N
- AUDIO_N_VALUE = N
- ACR_0441_SUBPACK_LOW_SB1 = _USE_HW_CTS_VAL

HDMI_SPARE: 0:0 rw HW_CTS init=DISABLE

enum (DISABLE,ENABLE)

1:1 rw FORCE_SW_CTS init=DISABLE

enum (DISABLE,ENABLE)

2:2 rw SUPRESS_SP_B init=SUPRESS

enum (SUPRESS, KEEP)

25.6.77 HDMI_NV_PDISP_HDMI_SPDIF_CHN_STATUS1_0

HDMI_SPDIF_CHN_STATUS1

HDMI_SPDIF_CHN_STATUS1/2 contains the value of the channel status bits extracted from the incoming SPDIF audio data stream. See IEC60958-3 chapter 5 for more information on these fields.

USE Specifies consumer use (CONSUMER) or professional (PRO) use of the channel status block. SPDIF_CHN_STATUS1/2 assumes consumer use.

TYPE Specifies the type of data the audio word represents.

- -PCM: Audio sample word represents linear PCM samples
- -OTHER: Audio sample word is something other than liner PCM (ie. compressed audio)

COPYRIGHT Copyright status of the audio.

- -YES: Copyright is asserted
- -NO: Copyright is not asserted

D: The value of these bits have different meanings based on the value of _TYPE.

If _TYPE==_PCM, then:

- NO_PREEMPHASIS: 2 audio channels without pre-emphasis
- PREEMPHASIS: 2 audio channels with 50microseconds/15microseconds pre-emphasis

All other states are reserved for future use.

MODE Defines one of four possible channel status formats for bytes 1-23 of channel status. Currently only the value "0" is defined. This format is assumed for the SPDIF_CHN_STATUS1/2.

CODE: This byte defines the Category Code of the input device. This code indicates what type of equipment is generating the input. See 5.3.1 of the IEC60958-3 spec for the values of codes.

SOURCE: Source number of the audio. If this value is zero then no source number was reported.

CHANNEL: Channel number of the audio. This reports the channel number reported for the first subframe of audio. If this value is zero then the channel number was not reported.

SFREQ: This is the reported sampling frequency of the input audio stream. The value UNDEFINED means that the sampling frequency was not indicated by the audio stream.

ACCURACY: Transmitter Clock accuracy.

- -LVL1 High accuracy mode: Transmitted sampling frequency is within a tolerance of +/-50*10^-6
- -LVL2 Normal accuracy mode: Transmitted sampling frequency is within a tolerance of +/-1000*10^-6
- -LVL3 Variable pitch shifted clock mode: Only specially designed receivers can receive the signal in this mode

- -OTHER: Interface frame rate not matched to sampling frequency: This is for all other modes that do not have an embedded sampling frequency clock.

0	X	MAX_LENGTH

25.7 HDCPRIF REGISTERS

This is the register space for the HDCP ROM interface control registers. These register controls writing the contents of the HDCPRIF_KEY registers (56 bits) into the local key store. The keys are decoded by the CD, which outputs them on the internal key data bus. The key registers are then written by overloading the priv reg bus with the key data when a write to either key register is executed. The key data must then be input into the key store using the control commands below. As no access to key data from public busses is allowed, all these operations are performed as hardware controlled functions that are initiated by software.

Typical operation is as follows:

1. Write to the CTRL register with LOCAL_ENABLED, AUTOINC_DISABLED, WRITE5_INIT, WRITE7_INIT, WRITE1_INIT, LOAD_SELECT_ZERO, LOAD_ADDRESS_ZERO.
2. Decode the downstream KSV key data in the CD block.
3. Write NV_PDISP_HDCPRIF_KEY(0) and NV_PDISP_HDCPRIF_KEY(1) with zeroes. This operation will be overloaded with the key data from the CD block.
4. Write to the CTRL register with LOCAL_ENABLED, AUTOINC_ENABLED, WRITE5_TRIGGER, WRITE7_INIT, WRITE1_INIT, LOAD_SELECT_ZERO, LOAD_ADDRESS_ZERO. Poll for WRITE5_DONE.
5. Decode the downstream key in the CD block.
6. Write NV_PDISP_HDCPRIF_KEY(0) and NV_PDISP_HDCPRIF_KEY(1) with zeroes. This operation will be overloaded with the key data from the CD block.
7. Write to the CTRL register with LOCAL_ENABLED, AUTOINC_ENABLED, WRITE7_TRIGGER, WRITE5_INIT, WRITE1_INIT, LOAD_SELECT_ZERO, LOAD_ADDRESS_ZERO. Poll for WRITE7_DONE.
8. Repeat 5 through 7 39 more times. There are always 40 keys and one KSV value.

If upstream key authentication is required, do the following:

9. Decode the upstream KSV key data in the CD block.
10. Write NV_PDISP_HDCPRIF_KEY(0) and NV_PDISP_HDCPRIF_KEY(1) with zeroes. This operation will be overloaded with the key data from the CD block.
11. Write to the CTRL register with LOCAL_ENABLED, AUTOINC_ENABLED, WRITE5_TRIGGER, WRITE7_INIT, WRITE1_INIT, LOAD_SELECT_ZERO, LOAD_ADDRESS_ZERO. Poll for WRITE5_DONE.
12. Decode the first upstream key in the CD block.
13. Write NV_PDISP_HDCPRIF_KEY(0) and NV_PDISP_HDCPRIF_KEY(1) with zeroes. This operation will be overloaded with the key data from the CD block.
14. Write to the CTRL register with LOCAL_ENABLED, AUTOINC_ENABLED, WRITE7_TRIGGER, WRITE5_INIT, WRITE1_INIT, LOAD_SELECT_ZERO, LOAD_ADDRESS_ZERO. Poll for WRITE7_DONE.

15. Repeat 12 through 14 39 more times. There are always 40 keys and one KSV value.

This will leave the store as follows (the required format):

Byte 0 to Byte 4: downstream KSV

Byte 5 to Byte 11: 1'st downstream key

Byte 12 to Byte 18: 2'nd downstream key

...

Byte 278 to Byte 284: 40'th downstream key

Byte 285 to Byte 289: upstream KSV

Byte 290 to Byte 296: 1'st upstream key

...

Byte 563 to Byte 569: 40'th upstream key

25.7.1 HDMI_NV_PDISP_SOR_CAP_0

SOR (Serial Output Resource): The registers are defined as if all the sors are fully featured (e.g. dual link). If a feature is not supported, the register remains accessible, i.e. writes will not hang, reads will always return the default value.

Each SOR unit consists of two sub-links designated A and B. In single link operation, the A and/or B sub-link is active. In dual link modes, both links are active. SOR units consist of either one or two links operating in the following combinations:

- Sub-link A (single link mode)
- Sub-link B (single link mode)
- Sub-link AB (dual single link copy mode)
- Sub-links A+B (dual link mode)
- Sub-links A,B (dual single link mode) planned for future enhanced zaphod mode.

Driver level control of the SOR is accomplished through methods in the core channel of the display engine. However, certain aspects of SOR operation are chip, process, voltage, and pixel clock dependent. These need to be controlled via registers by the VBIOS or RM during mode configuration. In addition, the preset LVDS mode may occasionally require some tweaking (to handle certain odd panels), so registers are provided to customize the support of LVDS.

This register reports the innate capabilities of the sor. Note that depending on the actual board build configuration, these values may not be exactly the same ones reflected in the overall capabilities structure reported through the class. With the exception of the last bit, the values assumed by these fields are automatically produced by the hw. The last bit represents the state of a fuse per sor that can be blown to constrain the sor to be usable only for LVDS.

This assists the determination of security for HDCP encrypted output operation. If the fuse is blown for lvds only, then the sor module hardware will enforce this. In addition, the fuse value must be taken into account when reporting overall capabilities.

Note: THIS REGISTER DEFINITION MUST BE KEPT COHERENT WITH DSI_SOR_CAP(i) !

Usage: boot / initialization

3	X	DUAL_LVDS_24: 0 = FALSE 1 = TRUE
2	X	DUAL_LVDS_18: 0 = FALSE 1 = TRUE
1	X	SINGLE_LVDS_24: 0 = FALSE 1 = TRUE
0	X	SINGLE_LVDS_18: 0 = FALSE 1 = TRUE

25.7.2 HDMI_NV_PDISP_SOR_PWR_0

This register contains bits that control the power state of the sor. For simplicity, the sequencer will be used to perform all power control operations in the sor (even in TMDS where the sequencing is relatively simple). This unifies the approach and makes it easier for the HW and SW to deal with the sor's. At boot, the SW must load and configure the sor sequencer via the SOR_SEQ_CTL and SOR_SEQ_INST registers below. The sequencer must be properly programmed for power control to work.

NORMAL_STATE: Sets the normal operating state. There are two choices. Powered up and powered down. To change this register, SW should load in the new value and write SETTING_NEW=TRIGGER. Once the change has been successfully completed, the SETTING_NEW will indicate DONE. This is the state that SW will want to control in order to power up and down the interface.

NORMAL_START: The execution of the power up and power down sequence can be modified somewhat by choosing to use either the NORM or ALT program entry point.

SAFE_STATE: Sets the safe operating state. There are only two choices. Powered up and powered down. To change this register, SW should load in the new value and write SETTING_NEW=TRIGGER. Once the change has been successfully completed, the SETTING_NEW will indicate DONE. The execution of the power up and power down sequence can be modified somewhat by choosing to use either the standard or the alternate program entry point. This is the state that the HW will use whenever it initiates the mode switch/shutdown procedure for this pior. In general, this should be set to STATE_PD and left there always.

SAFE_START: The execution of the power up and power down sequence can be modified somewhat by choosing to use either the NORM or ALT program entry point.

HALT_DELAY: Once the sequencer gets to the instruction with the HALT=1, the program is essentially complete i.e. the attached unit is powered up or down as was requested. Some panels however, have a minimum time before their state can be changed again. If the halt instruction has a non-zero delay, this bit will be set while that time expires.

MODE: The currently active state, normal or safe. After reset, the MODE is always SAFE.

SETTING_NEW: This bit is used to trigger a new setting of power mode to take effect. The typical procedure might be something like:

1. Make sure SETTING_NEW==DONE, i.e. not already an outstanding change request. (If there is an outstanding change request, SW must wait for it to complete)

2. Update the NORMAL and SAFE power mode fields.

3. Write SETTING_NEW=TRIGGER

4. Poll for SETTING_NEW=DONE. If it doesn't happen within one frame time, then SW may opt to accelerate the change by writing SOR_SEQ_CTL SWITCH=FORCE (be careful not to disturb other settings in that register!).

Usage: boot / initialization / mode switch / normal operation / shutdown

Offset: 055h l Read/Write: R/W l Reset: 0b0xxxxxxxxxxxxx00xxxxxxxxxxxxxx00

Bit	R/W	Reset	Description
31	RW	0x0	SETTING_NEW: 0 = DONE 1 = PENDING 1 = TRIGGER
28	RO	X	MODE: 0 = NORMAL 1 = SAFE
24	RO	X	HALT_DELAY: 0 = DONE 1 = ACTIVE
17	RW	0x0	SAFE_START: 0 = NORMAL 1 = ALT
16	RW	0x0	SAFE_STATE: 0 = PD 1 = PU
1	RW	0x0	NORMAL_START: 0 = NORMAL 1 = ALT
0	RW	0x0	NORMAL_STATE: 0 = PD 1 = PU

25.7.3 HDMI_NV_PDISP_SOR_TEST_0

This register contains control bits that configure certain aspects of testing mode of the SOR.

TEST_ENABLE: To enable testing

- 0 = normal operation
- 1 = test mode

In test mode test_fastclkint and test_loadpulse signals from the core are used in place of the internally generated signals.

INVD: Invert the data. Note that combining INVD with the choice of DSRC and TPAT below permits ramp up, ramp down, walking one, walking zero, all one, all zero.

ACT_HEAD_OPMODE: Report the current OR operating mode.

ATTACHED: Report whether the OR is currently attached to a head.

DSRC: When DSRC=NORMAL, then the serializers behave normally and use the encoded RGB data. When DSRC=DEBUG, the serializers load from DEBUGA0, DEBUGA1, DEBUGB0, and DEBUGB1 bits instead of the normal data coming down the pipe. When DSRC=TGEN, the data is taken from the built in test generator.

TPAT: Selects the test generator pattern. When test generator is running, H will be high for 1 in 4 repetitions (of duration 1024 clocks), V will be high for 4 in 16 repetitions coincident with H. Only operates when test mode is enabled.

LO force all 0s

TDAT use hw fixed value

RAMP test generator output ramps

WALK test generator output is a walking one

MAXSTEP 0, 1023, ...

MINSTEP 511, 512, ...

CRC: The source of the data for crc computation (for verification) can be either before the hi-speed serializer logic, or post the hi-speed seralizer/deserializer logic.

TESTMUX[7:0]: Test MUX select - output seen on PROBE

Usage: debug

25.7.4 HDMI_NV_PDISP_SOR_PLL0_0

These registers configure the main sor pll and other frequency dependent controls. The value loaded is a function of the pixel clock frequency, and whenever pixel clock changes, these registers must be updated. In general, these registers will be updated during the second interrupt of a mode switch.

PWR: 1 = powerdown the TMDS pll

PDBG: 1 = powerdown the bandgap

VCOPD: 1 = powerdown the VCO

PDPORT: 1 = powerdown the output drivers

RESISTORSEL: Selects the internal resistor (0) or external resistor (1).

PULLDOWN: Weak pulldown enable

- 1 = 2Kohm pulldown on all outputs.
- 0 = Weak pulldown disabled.

Note: pulldown is also controlled by the sequencer. the pulldown is derived from an OR of

NV_PDISP_SOR_PLL0_PULLDOWN and the sequencer control of pulldown. This priv reg field does not read the final pulldown value. In other words if sw writes NV_PDISP_SOR_PLL0_PULLDOWN to DISABLED and sequencer pulldown is enabled, then NV_PDISP_SOR_PLL0_PULLDOWN read will return DISABLED (while pulldown might be ENABLED due to sequencer control).

VCOCAP[3:0]: Selects the VCO capacitor and adjusts ring oscillator inter-stage load.

FILTER[3:0]: Field selects the loop filter and adjusts the filter resistor value.

ICHPMP[3:0]: Specifies additions to the charge pump current in steps of 0.375uA.

TMDS_TERM: This bit is used to enable termination. Termination is only used in tmds mode of operation, and may not be needed at lower operating frequencies (in which case, disabling it saves power).

TERMADJ[3:0]: Termination resistance control.

LOADADJ[3:0]: Load pulse position adjust

AUX0-AUX7: Most of these bits currently have no assigned function, but are provided to permit control of possible future features of the macro.

- AUX0 No function
- AUX1 No function
- AUX2 No function

- AUX3 rotate grn channel by 1 bit to reduce tmds EMI
- AUX4 No function
- AUX5 No function
- AUX6 No function
- AUX7 No function

TMDS_ANALOG_X4_HP_B revision:

BG_V17_S[3:0]: Bandgap 1.7V output voltage control

TX_REG_LOAD[1:0]: TX regulator default loading

- 00 -> 0.5mA (default)
- 01 -> 1.0mA
- 10 -> 1.5mA
- 11 -> 2.0mA

PE_EN: Pre-emphasis enable. PE_EN active only at 1080p, but turn off at 720p

- 0 -> disable
- 1 -> enable

HALF_FULL_PE: Pre-emphasis half bit time or full bit time (Note 2)

- 0 -> half bit time (default)
- 1 -> full bit time (for long trace)

S_D_PIN_PE: Pre-emphasis on one single pin or on differential pins (D+ and D-) (Note 2)

- 0 -> Single pin (default)
- 1 -> differential pins

See also the NV_PDISP_PE_CURRENT register below.

25.7.7 HDMI_NV_PDISP_SOR_CSTM_0

The class permits the driver to select a number of operating modes for the sor. Some of these modes (TMDS modes) are well defined and stable. Some modes may require customization by SW before they will work. These registers are used for that customization. The fields available for customization are:

- PD_TXDA[3:0]: Bitwise control to power down the data pins of link A. Set to DISABLE to powerdown the pin.
- PD_TXDB[3:0]: Bitwise control to power down the data pins of link B. Set to DISABLE to powerdown the pin.
- PD_TXCA: Power down the clock pin of link A. Set to DISABLE to power down the pin.
- PD_TXCB: Power down the clock pin of link B. Set to DISABLE to power down the pin.

UPPER: Designates whether LVDS bank A is the upper, odd, or first pixel. Bank B is always set to !UPPER. The serial output from UPPER=1 will be Clock and A0-A3. The serial output from UPPER=0 (and DUALMODE) will be Clock and A4-A7. Default is bank A has UPPER=1, bank B has UPPER=0.

MODE[1:0]: Controls the digital output encoding applied to the data stream in custom mode and is only used for data muxing at the input of the SOR. This field does not control the TMDS macro.

- 0 = LVDS
- 1 = TMDS
- 2 = reserved
- 3 = reserved

LINKACTA

LINKACTB Enables (1) or disables (0) the digital logic of links A and B

LVDS_EN: Output driver configuration for controlling the encoding of the data and the output common mode control. This does not control the internal clock dividers of the TMDS macro.

- 0 = TMDS
- 1 = LVDS

DUP_SYNC: This field only has an effect when in LVDS mode. When asserted in LVDS mode, it forces the link to use DE, HSYNC, and VSYNC for the encoding and to never use RES, CNTLE, and CNTLF. RES becomes DE. CNTLE becomes HSYNC. CNTLF becomes VSYNC.

NEW_MODE: For backwards compatibility, set register to 0 so the old mode is used. In old mode, for the second link in dual link mode, all the control bits are zeroed out except for vsync. When new mode is used none of the control bits of the second link for dual-link mode are zeroed out.

BALANCED: For MODE = LVDS, this enables balanced encoding Balanced mode will selectively invert sets of bits in the serial stream in an attempt to keep the average DC value near zero. Default is unbalanced. Has no effect in other modes.

PLLDIV: Controls the internal clock dividers of the TMDS_MACRO by setting the feedback divider for the high-speed PLL.

- 0 = divide by 7 (LVDS)

- 1 = divide by 10 (TMDS)

ROTCLK[3:0]: Skews the TXC clock to come out earlier. By changing this register value, you can configure the skew between output data (TX data) and output clock (TXC). This field specifies the number of sclk cycles which the output clock should come out earlier than its normal phase. For TMDS, sclk is 10x pixel clock so ROTVAL should be between 0-9. For LVDS, sclk is 7x pixel clock so ROTVAL should be between 0-7.

ROTDAT[2:0]: Before encoding the 8 bits of each color channel, the 8 bits within each color channel can be right rotated. All color channels are rotate by the same amount. For example, if ROTDAT = 6, then input channel data (r7,r6,r5,r4,r3,r2,r1,r0} would become {r5,r4,r3,r2,r1,r1,r7,r6}.

ROTDAT should be between 0 and 7.

TMDS modes of operation are standard and stable. The table below summarizes the fixed values the HW uses for the above fields for TMDS operating modes.

	SINGLE TMDS_A	SINGLE TMDS_B	SINGLE TMDS_AB	SINGLE TMDS	Dual TMDS
PD_TXDA[2:0]	0	7	0	0	0
PD_TXDA[3]	1	1	1	1	1
PD_TXDB[2:0]	7	0	0	0	0
PD_TXDB[3]	1	1	1	1	1
PD_TXCA	0	1	0	0	0
PD_TXCB	1	0	0	0	1
UPPER	1	1	1	1	1
MODE[1:0]	1	1	1	1	1
LINKACTA	1	0	1	1	1
LINKACTB	0	1	1	1	1
LVDS_EN	0	0	0	0	0
DUP_SYNC	0	0	0	0	0
NEW_MODE	0?	1	1	1	0?
BALANCED	0	0	0	0	0
PLLDIV	1	1	1	1	1
ROTCLK[3:0]	0	0	0	0	0
ROTDAT[2:0]	0	0	0	0	0

The first register defines the total custom mode. This is useful for defining possible new modes of operation as well as for test and characterization in the lab. Which is to say, this is a diagnostic workaround register set. SW should never need to use it. Also, note that if LVDS_ONLY=TRUE, then this register cannot be used as the HW will only permit Protocol=LVDS to be enabled. This register is intended to have the same format as the second register.

Usage: boot / initialization / mode switch

25.7.9 HDMI_NV_PDISP_SOR_CRCA_0

The following registers are used to fetch crc's when running VGA mode tests. Three registers are used. Once contains the valid bit, one contains the actual computed crc, the third contains the error (overrun bit). Proper use of these registers is as follows:

1) poll SOR_CRCA for VALID == TRUE.

2) reset SOR_CRCA by writing RESET to it.

3) read SOR_CRCB to get the crc

Usage: verif

Offset: 05ch l Read/Write: R/W l Reset: 0b0

Bit	Reset	Description
0	0x0	VALID: 0 = FALSE 1 = TRUE 1 = RESETV

25.7.10 HDMI_NV_PDISP_SOR_CRCB_0

Usage: verif

Offset: 05dh l Read/Write: RO l Reset: 0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx

Bit	Reset	Description
31:0	X	CRC

25.7.11 HDMI_NV_PDISP_SOR_BLANK_0

This register can be used to override the SOR output resource pixels with blank data.

OVERRIDE: Setting this field to true will override the pixel bus from the rg and output black pixels instead.

TRANSITION: This field controls the timing of the output resource blank override. The choices are IMMEDIATE The output resource will be blanked or restored to its previous output data immediately.

NEXT_VSYNC The output resource will be blanked or restored to its previous output data at the next vsync.

STATUS This read-only field returns BLANKED when the output resource is sending blank pixels forced by the OVERRIDE bit, otherwise it returns NOT_BLANKED.

Usage: boot / initialization / mode switch / normal operation

Offset: 05eh l Read/Write: R/W l Reset: 0bx00

Bit	R/W	Reset	Description
2	RO	X	STATUS: 0 = NOT_BLANKED 1 = BLANKED
1	RW	0x0	TRANSITION: 0 = IMMEDIATE 1 = NEXT_VSYNC
0	RW	0x0	OVERRIDE: 0 = FALSE 1 = TRUE

25.7.12 HDMI_NV_PDISP_SOR_SEQ_CTL_0

Sequencer control registers for sor. Up to three pins can be assigned to an SOR for use in controlling the power to an attached LVDS flat panel. The meaning of any particular pin and whether it is actually available to this SOR is controlled in either the host or pcb manager. In addition, the sequencer can override the individual link clock and data power control pins, thereby forcing them all into disabled or tristate mode and it can override the DE signal from the RG (for TMDS mode) to force the link to become inactive.

PU_PC: The program counter for the start of the power up program sequence. Always 0.

PU_PC_ALT: The alternate entry point into the power up program sequence. Defaults to the same value as PU_PC.

PD_PC: The program counter for the start of the power down program sequence. Defaults to 8, evenly dividing the available program space.

PD_PC_ALT: The alternate entry point into the power down program sequence. Defaults to the same default value as PD_PC.

PC: The current value of the program counter (useful for status and debug).

STATUS: Indicates if the sequencer is STOPPED or RUNNING.

SWITCH: If a particular sequencer instruction is waiting for vsync to arrive, writing this bit to FORCE will cause the wait condition to be satisfied immediately.

Note: The sequencer can begin with arbitrary phase relative to the 1 uS timer that is used to advance the internal counters. Thus the actual time delay for the first event can be almost one uS less than what is requested. Subsequent instructions in a chain of events do transition on 1 uS boundaries, however. If a minimum spec of "x" uS is required, then it is best to program "x+1" uS of delay.

Usage: boot / initialization / mode switch

25.8 Test and Debug Registers

25.8.1 HDMI_NV_PDISP_SOR_VCRCA0_0

To quickly determine if the TMDS is working properly, a running CRC stamp is kept which is reset at each VSYNC. For each sub-link, there are up to 40 bits of encoded data which has been re-parallelized from the serial data going out.

These encoded bits of data are broken up into 3 16-bits chunks depending on either LVDS or TMDS encoding:

For TMDS, the encoded data is as follows:

- CRCH: {8'b00000000,TMDS_CLK_ENC[9:2]}
- CRCM: {TMDS_CLK_ENC[1:0],TMDS_TX2_ENC[9:0],TMDS_TX1_ENC[9:6]}
- CRCL: {TMDS_TX1_ENC[5:0],TMDS_TX0_ENC[9:0]}

For LVDS, the encoded data is as follows:

- CRCH: {8'b00000000,LVDS_CLK_ENC[6:4]}
- CRCM: {LVDS_CLK_ENC[3:0],,LVDS_A3_ENC[6:0],LVDS_A2_ENC[6:2]}
- CRCL: {LVDS_A2_ENC[1:0],LVDS_A1_ENC[6:0],LVDS_A0_ENC[6:0]}

For each of these chunks, a CRC16 is computed, CRCH for the upper 16-bit chunk, CRCM form the middle 16-bit chunk, and CRCL for the lower 16-bit chunk. The CRC16 takes in the 16-bits of encoded data plus the crc16 value of the previous cycle to generate the new crc16. The crc equation which is used is:

x^16 + x^11 + x^4 + 1.

At each vsync, the previous running crc16 values are captured into the vcrc registers and a previous crc value of all zeroes are fed into the CRC16 units. This means the running crc16 is reset at each vsync.

> **Note:** For power saving, the VCRC is only computed when NV_PDISP_SOR_TRIG != 0. Also, it seems these aren't latched at vsync but are free-running.

The VCRC registers for sub-link A

Usage: debug

Bit	Reset	Description
15:0	X	CRCH

25.8.5 HDMI_NV_PDISP_SOR_EDATAA0_0

EDATA has the encoded data for the serial channels TXC, TX3, TX2, TX1, and TX0. For each link, there up to 40 bits of encoded data. The encoded bits making up the data are as follows:

For TMDS, the encoded data is as follows:

```
EDATA[39:0] =
{TMDS_CLK_ENC[9:0],
TMDS_TX2_ENC[9:0],
TMDS_TX1_ENC[9:0],
TMDS_TX0_ENC[9:0]}
```

For LVDS, the encoded data is as follows:

```
EDATA[39:0] =
{5'b00000,
LVDS_CLK_ENC[6:0],
LVDS_A3_ENC[6:0],
LVDS_A2_ENC[6:0],
LVDS_A1_ENC[6:0],
LVDS_A0_ENC[6:0]}
```

The EDATA registers can be written to when any of the trigger bits for capture are set high.

The EDATA registers for sub-link A

Bit	Reset	Description
15:0	X	TX2

25.8.9 HDMI_NV_PDISP_SOR_DEBUGA0_0

The debug registers for sub-link A

The following registers control the debug data input to the serializer. These bits are only relevant when TEST_ENABLE is set.

DEBUGA0 has the data for the serial channels TXC, TX3, TX2, TX1, and TX0. For each link, there up to 40 bits of data to be encoded. The bits to be encoded which make up the data are as follows:

For TMDS, the data to be encoded are loaded as follows:

```
{TMDS_CLK_ENC[9:0], TMDS_TX2_ENC[9:0], TMDS_TX1_ENC[9:0], TMDS_TX0_ENC[9:0]}
 =
 {DEBUGA1, DEBUGA0}
```

For LVDS, the encoded data is as follows:

```
 {5'b00000, LVDS_CLK_ENC[6:0], LVDS_A3_ENC[6:0], LVDS_A2_ENC[6:0],
 LVDS_A1_ENC[6:0], LVDS_A0_ENC[6:0]}
 =
 {DEBUGA1[2:0], DEBUGA0}
```

Usage: debug

Offset: 07ah l Read/Write: R/W l Reset: 0b00000000000000000000000000000000

Bit	Reset	Description
7:0	0x0	VAL: 0 = RESETV

25.8.11 HDMI_NV_PDISP_SOR_TRIG_0

TRIG specifies the number of pixel clock cycles after the previous VSYNC was detected to capture state data into IDATA, EDATA, CNT, and CCRC. After the trigger has captured data, the trigger gets reset with the next VSYNC and waits TRIG pixel cycles to capture data again. If the TRIG value is larger than the number of cycles between consecutive VSYNC's, then the trigger is not reset while it is still pending to capture data. Once the data have been captured, the trigger is reset with the following VSYNC to capture data again. If TRIG is all zeros, then the trigger is disabled and no capturing occurs.

Usage: debug

Offset: 07ch l Read/Write: R/W l Reset: 0b000000000000000000000000

Bit	Reset	Description
23:0	0x0	VAL: 0 = RESETV

25.8.12 HDMI_NV_PDISP_SOR_MSCHECK_0

The mode switch monitor is used for hw debug only. To use, the test should set the CTL bit to CLEAR and then to RUN. At the end of the test, the register can be read. The various fields indicate the number of times the following conditions occurred:

- CRC enable went from false to true
- CRC enable went from true to false
- data enable went from false to true
- data enable went from true to false

All counts are 4 bits, so the count will clamp at 15.

Usage: debug

Offset: 07dh l Read/Write: R/W l Reset: 0b1xxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx

Bit	R/W	Reset	Description
31	RW	0x1	CTL: 0 = CLEAR 1 = RUN
15:12	RO	X	DATA_ENABLE_T2F
11:8	RO	X	DATA_ENABLE_F2T
7:4	RO	X	CRC_ENABLE_T2F
3:0	RO	X	CRC_ENABLE_F2T

25.8.13 HDMI_NV_PDISP_SOR_LANE_DRIVE_CURRENT_0

TMDS per-lane I/O current control.

Although each control is specified as 8b below, making it easy to set the value in hex, really only the 6 lsbs of each lane are used.

000000 -> 1.500 mA

000001 -> 1.875 mA

...

(each increment is an additional 0.375 mA)

...

111110 -> 24.750 mA

By default, FUSE_OVERRIDE is FALSE, meaning that the TMDS current control is driven via calibration data stored in the fuse block. Software can override these defaults by programming FUSE_OVERRIDE to TRUE, and setting each LANEn field to the appropriate value.

Offset: 07eh l Read/Write: R/W l Reset: 0b0x100000xx100000xx100000xx100000

Bit	Reset	Description
31	FALSE	FUSE_OVERRIDE: 0 = FALSE 1 = TRUE
29:24	0x20	LANE3
21:16	0x20	LANE2
13:8	0x20	LANE1
5:0	0x20	LANE0

25.9 Audio Registers

25.9.1 HDMI_NV_PDISP_AUDIO_DEBUG0_0

This is the register space for the SPDIF audio decoding block. Please refer IEC60958-1 for general and IEC60958-3 for consumer specification.

AUDIO_DEBUG0

This register is meant for debugging. It indicates various possible errors in the incoming SPDIF stream or FIFO overflows. _NO indicates that no error of this type has occurred. _YES indicates that an error of the given type occurred at least once.

This is a write-1-to-clear register, i.e., to clear the _ERROR bits, just write _RESET to the bit you want to clear.

THRESHOLD_ERROR: When THRESHOLD_LOW is bigger than THERSHOLD_HIGH, this bit will be set. This indicates the internal state machine has reached an invalid state likely due to glitches in the input or the input being disconnected/reconnected.

HA/HB_FIFO_ERROR: The data is passed from the audio to the HDMI block via an async FIFO. This bit indicates that the FIFO is full. There is one bit for each head. This is an indication of HDMI unit does not drain away the audio sample data fast enough. We should only be looking at the bit for the head currently running HDMI. The bit for the other head will always be set since that FIFO will never be drained.

FRAME_ERROR: A block should have 192 frames. When an non-192 frames' block is detected this bit will be set. Again, this indicates a problem with the incoming SPDIF stream.

BITS_ERROR: A frame should have 56 bits audio sample + 8 bits preamble. If a non 56 bits audio sample is detected in a frame, this bit will be set.

OVERFLOW_ERROR: If the spdif input stream is floating, the 10 bits pulse width counter will be overflowed, then this bit will be set. See OVERFLOW_TH for detail.

PREAMBLE_ERROR: A frame should have 56 bits audio sample + 8 bits preamble. If there is no valid preamble for a given sample, this bit will be set.

Offset: 07fh l Read/Write: R/W l Reset: 0b0xxx0xxx0xxx0xxx0xxx0xxx0xxx0

Bit	Reset	Description
24	0x0	PREAMBLE_ERROR: 0 = NO 1 = YES 1 = RESETV
20	0x0	OVERFLOW_ERROR: 0 = NO 1 = YES 1 = RESETV
16	0x0	BITS_ERROR: 0 = NO 1 = YES 1 = RESETV
12	0x0	FRAME_ERROR: 0 = NO 1 = YES 1 = RESETV
8	0x0	HB_FIFO_ERROR: 0 = NO 1 = YES 1 = RESETV
4	0x0	HA_FIFO_ERROR: 0 = NO 1 = YES 1 = RESETV
0	0x0	THRESHOLD_ERROR: 0 = NO 1 = YES 1 = RESETV

25.9.2 HDMI_NV_PDISP_AUDIO_DEBUG1_0

AUDIO_DEBUG1

OVERFLOW_TH (bit 9:0): There is a 10 bits counter running on dispclk_audio_fs and counting spdif's input pulse length. The maximum pulse length count is 305, when dispclk=416MHz and fs=32KHz. If someone unpluged the spdif input connector, this counter will count above 305 (0x131) and then overflow eventually. OVERFLOW_TH is the threshold that being used to conclude when the spdif input is being unpluged or floating. If the 10 bits counter is larger or equal to OVERFLOW_TH, then OVERFLOW_ERROR bit will be set.

SW should not need to program this register to anything but its init value. The init value is the maximum value that the 10 bit counter can reach before overflowing.

PACKET_NOISE_FILTER_ENABLE: A register delays packets long enough to determine if the packet was of a legitimate length. If a packet contains more than 56 bits, we will drop the packet and flag an error condition NV_PDISP_AUDIO_DEBUG0_PREAMBLE_ERROR = _YES. This register is included as a debug to allow disabling the packet delay and dropping functionality.

When ENABLE is _YES, bad audio packets will be dropped and preamble errors flagged

When ENABLE is _NO, bad audio frames will be sent through as is.

PREAMBLE_RECOVER_CYA: When YES, audio recover circuit accepts a new preamble and audio sample even when it arrives unexpectedly (i.e., before previous sample has completed.) NO restores legacy behavior, which is to drop the new sample. SW should not need to change this bit.

Offset: 080h l Read/Write: R/W l Reset: 0b1xxxxxxxxxxxxxx1xxxxxx1111111111

25.9.3 HDMI_NV_PDISP_AUDIO_DEBUG2_0

AUDIO_DEBUG2

There is an LFSR (linear feedback shift register) that can generate pseudo- random data to feed the output fifo rather than use the incoming SPDIF stream. This is useful for testing in emulation or bringup; a feature that SW shouldn't worry about.

LFSR_COUNT: LFSR_COUNT is the rate of filling LFSR data into the FIFO. The rate needs to be close to actual spdif data input rate, which is depended on fs (audio sampling frequency). Set LFSR_COUNT according to the following table:

For dispclk_audio_fs = 416 MHz:

- fs = 32.0KHz, LFSR_COUNT = 0x32DC
- fs = 44.1KHz, LFSR_COUNT = 0x24E8
- fs = 48.0KHz, LFSR_COUNT = 0x21E8
- fs = 88.2KHz, LFSR_COUNT = 0x1274
- fs = 96.0KHz, LFSR_COUNT = 0x10F4
- fs = 176.4KHz, LFSR_COUNT = 0x093A
- fs = 192.0KHz, LFSR_COUNT = 0x087A

For dispclk_audio_fs = 277Mhz:

- fs = 32.0KHz, LFSR_COUNT = 0x21EB
- fs = 44.1KHz, LFSR_COUNT = 0x189A
- fs = 48.0KHz, LFSR_COUNT = 0x169B
- fs = 88.2KHz, LFSR_COUNT = 0x0C4D
- fs = 96.0KHz, LFSR_COUNT = 0x0B4D
- fs = 176.4KHz, LFSR_COUNT = 0x0626
- fs = 192.0KHz, LFSR_COUNT = 0x05A6

CHANNEL_STATUS: This bit does not do anything right now, since the channel status bit is generated on HDMI side.

USER: This is the user bit that is going into FIFO when LFSR_DATA_EN is set.

VALIDITY: This is the validity bit that is going into FIFO when LFSR_DATA_EN is set.

LFSR_DATA_EN: When this bit is set, FIFO will be filled with LFSR (Linear Feedback Shift Register) data and ignore incoming spdif input stream. LFSR will generate pseudorandom data in the following pattern:

F->E->C->8->1->2->4->9->3->6->D->A->5->B->7->F->E.....

Offset: 081h l Read/Write: R/W l Reset: 0b0xxxxxx0xxx0xxx00010000111101000

Bit	Reset	Description
31	0x0	LFSR_DATA_EN: 0 = NO 1 = YES
24	0x0	VALIDITY
20	0x0	USER
16	0x0	CHANNEL_STATUS
15:0	0x21e8	LFSR_COUNT

25.9.4 HDMI_NV_PDISP_AUDIO_FS1_0

When a B preamble (A B preamble is an indicator of the start of a frame in SPDIF) is detected, a counter that is running on dispclk_audio_fs will count the number of clocks needed for the 8 HALFs (or 4 bits) B preamble length and compare against each of FSx_LOW and FSx_HIGH. (where x goes from 1->7, one entry per audio frequency)

For one the 7 cases, we will have the case that:

FSx_LOW <= 8 HALF count <= FSx_HIGH

and the hardware will report that the incoming stream is running at frequncy 'x' in the AUDIO_CNTRL0_SAMPLING_FREQ register field.

- FS1 is for fs = 32.0KHz.
- FS2 is for fs = 44.1KHz.
- FS3 is for fs = 48.0KHz.
- FS4 is for fs = 88.2KHz.
- FS5 is for fs = 96.0KHz.
- FS6 is for fs = 176.4KHz.
- FS7 is for fs = 192.0KHz.

The formula to compute 8 HALFs is following:

8 HALFs = 8 * hdmi_audio_clk / (fs * 128)

The value programmed in FSx_HIGH should be 8 HALF count + 10

The value programmed in FSx_LOW should be 8 HALF count - 10

For example: if the audio sample frequency is 32kHz and dispclk_audio_fs is 216 Mhz, then the 8 HALFs (or 4 bits) preamble length is:

8 HALFs = 8 * 216.0Mhz / (32.0 kHz * 128)

= 421 (or 422)

So, when FS1_LOW = 412 (0x19c) and FS1_HIGH = 430 (0x1ae), the 412 <= 8 HALFs <= 430 condition will be true. And AUDIO_CNTRL0_SAMPLING_FREQ will be equal to _32_0KHZ, which means 32kHz of audio sampling frequency is detected.

The init values of the registers below are based on a hdmi_audio_clk of 216 MHz, and SW should reprogram these every time that changes (which should not happen.)

AUDIO_FS1

25.9.11 HDMI_NV_PDISP_AUDIO_PULSE_WIDTH_0

AUDIO_PULSE_WIDTH

This is a status only register used for debugging.

HALF: Because S/PDIF input stream is in biphase coding, a 32 bit sub-frame is broken down to 64 states. HALF (half bit or 1 state) is the number of dispclk_audio_fs periods for a minimum pulse length that can be measured on the S/PDIF input stream at any given audio fs.

e.g. HALF = dispclk_audio_fs / (fs * 128)

THREE_HALF: THREE_HALF is the number of dispclk_audio_fs periods for the maximum pulse length in the spdif input stream. THREE_HALF should be approximately 3 times of HALF, this only happen in B, M or W preamble.

COUNT2LOCK: If LOCK is set, COUNT2LOCK is number of frames to skip before locking down the HALF and THREE_HALF values. This field has no effect if LOCK is not set.

LOCK: If LOCK is set, it locks down the HALF and THREE_HALF values. If LOCK is clear, then HALF and THREE_HALF are updated every frame (B or M preamble) Setting LOCK means that the hardware will not detect changes in speeds of the incoming audio stream.

This mode should not be used by software. It is meant as a debugging tool.

Offset: 089h l Read/Write: R/W l Reset: 0b0xx01xxxxxxxxxxxxxxxxxxxxxxx

Bit	R/W	Reset	Description
28	RW	0x0	LOCK: 0 = NO 1 = YES

25.9.12 HDMI_NV_PDISP_AUDIO_THRESHOLD_0

AUDIO_THRESHOLD

This is a status only register which is useful for debugging. It provides information about some characteristics of the SPDIF stream.

THRESHOLD_LOW: THRESHOLD_LOW is 1.5 times of HALF. If a spdif pulse is less than or equal to THRESHOLD_LOW, then a bit '1' is detected.

THRESHOLD_HIGH: THRESHOLD_HIGH is 2.5 times of HALF. If a spdif pulse is less than or equal to THRESHOLD_HIGH and bigger than THRESHOLD_LOW, then a bit '0' is detected.

Offset: 08ah l Read/Write: RO l Reset: 0bxxxxxxxxxxxxxxxxxxxxxxxx

Bit	Reset	Description
21:12	X	HIGH
9:0	X	LOW

25.9.13 HDMI_NV_PDISP_AUDIO_CNTRL0_0

AUDIO_CNTRL0

ERROR_TOLERANCE: Because the (dispclk_audio_fs / audio sampling frequency) is a non-integer in general and due to the spdif input stream's jitter, THREE_HALF is not exactly equal to 3 times of HALF. ERROR_TOLERANCE is the error count in dispclk periods allowed for 3 x HALF vs THREE_HALF. Based on simulation, the value of 4 to 7 is a good value when dispclk_audio_fs = 416Mhz. It is anticipated that SW doesn't need to change this field from its init value.

SOFT_RESET: Reset the frame_counter and wait for the next B preamble to resume the audio data transfer. This is intended to clear registers in case the HW ends up in a bad state, and should only be used for debug.

SOFT_RESET_ALL: Reset all register in audio block. This is currently a placeholder and is not implemented.

SAMPLING_FREQ: This will reports the incoming spdif audio stream sampling frequency HDMI spec only support 7 audio sample frequency (fs), anything other than those 7 fs, it will be reported as UNKNOWN.

SOURCE_SELECT: Determines whether to use the SPDIF or Azalia (HDAL) audio input. This field has no effect on chips without the HDAL input. The default is AUTO: selects SPDIF audio until the HDAL audio input is initialized by the external controller

FRAMES_PER_BLOCK: FRAMES_PER_BLOCK is number of frames per block. By spec each block has 192 (0xC0) frames.

Offset: 08bh l Read/Write: R/W l Reset: 0b11000000xxxxxxxxxx0xxx000000110

7:0	RW	0x6	ERROR_TOLERANCE

25.9.14 HDMI_NV_PDISP_AUDIO_N_0

AUDIO_N

N_VALUE: N_VALUE is the N parameter in HDMI Audio Clock Regeneration Packet. This value should be written when Hardware measured CTS is enabled. The correct N value can be read from tables 7-1, 7-2, and 7-3 in the HDMI spec.

N_RESET: N_RESET is reset for N counter, If software is controlling the value of N, every time the audio stream changes sampling freq (fs), software (RM) need to reset the N counter by writing _ASSERT to N_RESET and follow by writing a _DEASSERT to N_RESET.

If the Hardware selected N feature is enabled (N_LOOKUP = _ENABLE), Software only needs to reset the N counter when writing to the AUDIO_NVAL registers and when enabling/disabling N_LOOKUP.

1) set N_RESET = _ASSERT

2) modify N value registers

3) set N_RESET = _DEASSERT

Modifying N_VALUE can be done in step 1.

N_GENERATE: N_GENERATE controls how the audio block generates the 128*fs/N pulse, which is related to CTS. The detail of CTS can be found in HDMI 1.1 spec Chapter 7. This bit is strictly for debugging purpose only.

_NORMAL: This method increments the CTS counter a variable number of times based on the length of the SPDIF pulse.

_ALTERNATE: This method attempts to recreate the 128*fs clock and increments the CTS counter at regular intervals based on HALF.

N_LOOKUP: When set to _ENABLE, the hardware will select the appropriate value of N to use from one of the AUDIO_NVAL registers. This selection is based on the audio sampling frequency detected by the audio block. This is not the sampling frequency reported in the channel status bits. N_RESET should be toggled when this feature is enabled. When set to _DISABLE, software must program the correct N value into AUDIO_N.

20	0x0	RESETF: 1 = ASSERT 0 = DEASSERT
19:0	0x0	VALUE

25.9.15 HDMI_NV_PDISP_AUDIO_NVAL_0320_0

The following seven registers are used when Hardware N lookup is enabled (AUDIO_N_LOOKUP). These registers should be written with the correct N values for the current pixel clock frequency. These values can be found in tables 7-1, 7-2, and 7-3 of the HDMI specification. These registers are initialized to the value in the "other" row of these tables.

These registers may need to be reprogrammed when the pixel clock frequency changes. When changing the value of these registers, the N counter should be reset by toggling _RESET in AUDIO_N.

VALUE: The correct N value for 32kHz audio at the current pixel clock frequency should be written here.

25.9.22 HDMI_NV_PDISP_HDCPRIF_ROM_TIMING_0

This register controls the timing of the cryptorom interface. Any time the hdmi_clk period changes, the values here must be changed too.

The cryptorom bit period must more than 1 uS. 500 KHz is a safe target. The hdmi_clk frequency is reduced by the scale factor defined by the PRESCALE divider; the period is equal to (PRESCALE+1) hdmi_clk ticks.

BIT_PERIOD defines the timing of the SCL (serial clock) output. The SCL pin will be driven high for counts 0 .. (BIT_PERIOD >> 1), and will be driven low for counts (BIT_PERIOD >> 1)+1 .. BIT_PERIOD.

DATA_DLY defines how many scaled ticks pass before SDA (the data bit) makes a transition after the falling edge of SCL (for data writes and for ACK'ing after data reads).

START_DLY defines how many scaled ticks pass before SDA (the data bit) makes a transition after the rising edge of SCL (for START and STOP).

The defaults make sure even with an HDMI clock of 150 MHz, the bit clock will not be faster than 500 KHz.

In general, programming should be something like this. Given the hdmi_clk frequency and the target I2C bit rate, figure out the necessary prescale. The prescale must be large enough such that the BIT_PERIOD divisor fits into 8 bits, but it should otherwise be as small as possible in order to minimize the time quantization.

(PRESCALE+1)*(BIT_PERIOD+1)*(hdmi_clk period) >= (I2C bit period)

BIT_PERIOD+1 can be as large as 256. Rearranging:

PRESCALE = ceil[(I2C bit period)/(hdmi_clk period) / 256] - 1

= ceil[(hdmi_clk frequency)/(I2C frequency) / 256] - 1

This determines the time quantum of the other divisors:

- prescale_period = (hdmi_clk period) / (PRESCALE + 1)

Next, determine the bit period:

- BIT_PERIOD = ceil[(hdmi_clk frequency) / (PRESCALE+1) / (I2C frequency)] - 1

SDA (data) normally changes only while SCL is low. The Atmel datasheet says that SDA must hold for at least 10ns after SCL falls and must be set up at least 100 ns before SCL rises. Thus, DATA_DLY must be:

- DATA_DLY > floor(BIT_PERIOD/2) + 10 ns
- DATA_DLY < BIT_PERIOD - 100 ns

In most circumstances setting DATA_DLY to arrive 75% of the way through the cycle is OK.

- DATA_DLY = floor((BIT_PERIOD+1) * 3 / 4) - 1

The start and stop conditions extend the SCL high time before the next falling SCL transition. One Atmel datasheet says that SDA (data) must not change within 200 ns of the rising or falling edge of SCL. A safe calculation is to assume that we wait a tick less than half a clock period:

- START_DLY = floor(BIT_PERIOD / 2) - 2

25.9.23 HDMI_NV_PDISP_SOR_REFCLK_0

SOR_REFCLK

The HDMI clock is programmable and varies, depending on screen resolution. The NV_PDISP_SOR_SEQ_INSTn instructions (above) can wait for certain time intervals to elapse. Whenever hdmi_clk frequency is changed, this register must be reprogrammed to divide hdmi_clk to produce a 1 us time reference, otherwise the time intervals requested by NV_PDISP_SOR_SEQ_INSTn won't be accurate.

The format of DIVISOR is an unsigned 8.2 divider. Because this is a simple digital divider, not a PLL, fractional values result in a jitter of one hdmi_clk between successive "1 us" intervals, but the long term average works out to the requested divisor. This jitter is OK because the NV_PDISP_SOR_SEQ_INST wait intervals don't need to be exact. If the integer part is written as 0, it will be interpreted the same as "1".

Offset: 095h l Read/Write: R/W l Reset: 0b0001100100

Bit	Reset	Description
15:8	0x19	DIV_INT: default: 27 MHz

25.9.24 HDMI_NV_PDISP_CRC_CONTROL_0

CRC_CONTROL

The main CRC enable bit flows along the pipeline. This register controls the injection of this bit at the top of the pipeline. This register is double-buffered. The active value is updated at start of each frame from this 'arm' register.

Other registers such as SOR_STATE2.ASY_CRCMODE and SOR_*CRC* control the actual CRC logic, once enabled.

ARM_CRC_CONTROL enables or disables computation of CRC, effective at the start of next frame.

Offset: 096h l Read/Write: R/W l Reset: 0b0

Bit	Reset	Description
0	NO	ARM_CRC_ENABLE: 0 = NO 1 = YES 0 = DIS 1 = EN

25.9.25 HDMI_NV_PDISP_INPUT_CONTROL_0

INPUT_CONTROL

HDMI_SRC_SELECT selects which of the two display units to take input from. This register should be changed only when HDMI is idle.

ARM_RGB_RANGE controls whether R/G/B values of 0 and 255 are permitted (FULL), or removed by clamping to [1,254] (LIMITED).

According to EIA/CEA-861-B and HDMI specs, the 640x480 VGA mode uses FULL, and all others use LIMITED.

Note that this does not scale the video or change the black and white points (VGA is [0,255], others are [16,235]). That must be done, if necessary, in display or at the source.

See HDMI 1.2a spec section 6.6.

This register is double-buffered, and will take effect on next frame boundary.

Offset: 097h l Read/Write: R/W l Reset: 0b00

25.9.28 HDMI_NV_PDISP_KEY_CTRL_0

HDCP KEY SRAM Register Control

This is the register space for the HDCP ROM interface control register. This register controls writing the contents of the hdcp_key_data bus (56 bits) into the local key store. The keys are decoded in the Crypto block, and then the key data is presented on the bus.

LOCAL: If this bit is ENABLED the on-chip HDCP key store will be used by the HDCP encryption block. If DISABLED external Crypto-ROM will be used.

AUTOINC: If this bit is ENABLED the address written to by the WRITE16 function will autoincrement after the operation is complete. This is the normal operating mode.

WRITE16: If this bit is set to TRIGGER the HDCP keys module will write all the 16 bytes of data from the hdcp_key_data bus (sourced by the CD module) into the local key store. The bytes are written into the store at contiguous bytes pointed to by the ADDRESS field in autoincrement mode, or contiguous bytes pointed to by the LOAD_ADDRESS field otherwise. Poll this bit until it reports DONE to ensure the write is complete.

PKEY_REQUEST_RELOAD: Requests that the private key be requested again from KFUSE. Will autoclear to zero as soon as the requested transfer of the key begins, but note that only PKEY_LOADED will indicated when the key is ready for use.

PKEY_LOADED: Indicates that the private key value has been received from KFUSE and is ready for use.

LOAD_ADDRESS: For the WRITE16 function this field selects the start byte address of the contiguous locations in the local key store to be written with the hdcp_key_data. This field is ignored if the AUTOINC bit is ENABLED. Addresses start at 0.

ADDRESS: This read-only field reports the next byte address in the local key store to be written to once the TRIGGER bits are DONE. For the WRITE16 operation the address will increment by 16. Addresses start at 0.

Typical operation is as follows:

1. Write to the register with LOCAL_ENABLED, AUTOINC_DISABLED, WRITE5_INIT, WRITE7_INIT, LOAD_ADDRESS_ZERO.
2. Write the downstream KSV key data into the CD module and decrypt the key (see dev_cd.ref - HDCP_KEY_REG(i) and NV_PCIPHER_CTL1).
3. Write to the register with LOCAL_ENABLED, AUTOINC_ENABLED, WRITE5_TRIGGER, WRITE7_INIT, LOAD_ADDRESS_ZERO. Poll for WRITE5_DONE.
4. Write the first downstream key data into the CD module and decrypt the key (see dev_cd.ref - HDCP_KEY_REG(i) and NV_PCIPHER_CTL1).

5. Write to the register with LOCAL_ENABLED, AUTOINC_ENABLED, WRITE7_TRIGGER, WRITE7_INIT, LOAD_ADDRESS_ZERO. Poll for WRITE7_DONE.
6. Repeat steps 4 and 5 39 more times. There are always 40 keys and one KSV value.

If upstream key authentication is required do the following:

7. Write the upstream KSV key data into the CD module and decrypt the key.
8. Write to the register with LOCAL_ENABLED, AUTOINC_ENABLED, WRITE5_TRIGGER, WRITE7_INIT, LOAD_ADDRESS_ZERO. Poll for WRITE5_DONE.
9. Write the first upstream key data into the CD module and decrypt the key (see dev_cd.ref - HDCP_KEY_REG(i) and NV_PCIPHER_CTL1).
10. Write to the register with LOCAL_ENABLED, AUTOINC_ENABLED, WRITE7_TRIGGER, WRITE7_INIT, LOAD_ADDRESS_ZERO. Poll for WRITE7_DONE.
11. Repeat steps 9 and 10 39 more times. There are always 40 keys and one KSV value.

This will leave the store as follows (the required format):

- Byte 0 to Byte 4: downstream KSV
- Byte 5 to Byte 11: 1'st downstream key
- Byte 12 to Byte 18: 2'nd downstream key

  ...
- Byte 278 to Byte 284: 40'th downstream key
- Byte 285 to Byte 289: upstream KSV
- Byte 290 to Byte 296: 1'st upstream key

  ...
- Byte 563 to Byte 569: 40'th upstream key

25.9.1 HDMI_NV_PDISP_SOR_AUDIO_CNTRL0_0

HD Audio (aka Azalia) audio

PORT_CONNECTIVITY: This controls the behavior of the Port Connectivity field of the Azalia Configuration Defaults Verb. This can be used to disable a codec that is associated with an SOR that does not connect to a physical port.

ENABLE: Report 00 in the Port Connectivity field by default. This corresponds to "The Port Complex is connected to a jack"

DISABLE: Report 01 in the Port Connectivity field by default. This corresponds to "No physical connection for Port" See table 100 and table 101 of the High Definition Audio Specification (Revision 1.0) for more information.

AFIFO_FLUSH: When the DP and HDMI logic are not in the middle of sending an audio packet, they will flush out any entries at the head of the afifo that is not tagged as the beginning of a sample. This ensures that the next new audio packet sent will begin on the correct channel. This is a diagnostic workaround bit to disable the flushing.

ENABLE: Automatically fix the AFIFO if it gets out of alignment

DISABLE: Do not throw out any AFIFO entries.

SAMPLING_FREQ: This will reports the incoming audio stream sampling frequency in the Azalia codec. The HDMI spec only supports 7 audio sample frequency (fs). Anything other than those 7 fs will be reported as UNKNOWN. See HDMI 1.1 spec Table 7-4 (page 77)

SOURCE_SELECT: Determines whether to use the SPDIF or Azalia (HDAL) audio input. This field has no effect on chips without the HDAL input. The default is AUTO: selects SPDIF audio until the HDAL audio input is initialized by the external controller

INJECT_NULLSMPL: When the bit is enabled, if the audio format is stereo LPCM as indicated by the stream format in the corresponding output converter widget, the codec inserts null samples into the audio FIFO for each Azalia frame in which it did not receive any samples. This is done only for stereo LPCM and not for any other audio format. This bit should be disabled by default for backwards compatibility.

INPUT_MODE: This bit indicates what the audio data source is. HDA is Azaalia data, SPDIF is SPDIF data.

Offset: 0ach | Read/Write: R/W | Reset: 0bxx0xxxxxxx01xxxxxxx1xxxxxxxxxxx0

Bit	R/W	Reset	Description

Bit	Reset	Description
31:0	0x0	Reserved

25.9.4 HDMI_NV_PDISP_SOR_AUDIO_NVAL_0320_0

The following seven registers are used for HDMI N values for azalia. These registers should be written with the correct N values for the current pixel clock frequency. These values can be found in tables 7-1, 7-2, and 7-3 of the HDMI specification. These registers are initialized to the value in the "other" row of these tables.

For DisplayPort Audio, a value of 2^15 (0x8000) will always be used.

VALUE: The correct N value for 32kHz audio at the current pixel clock frequency should be written here.

25.9.17 HDMI_NV_PDISP_SOR_AUDIO_HDA_ELD_BUFWR_0

SW Programming Model

In an integrated graphics chip, which includes an Nvidia Audio Controller, with support for an Nvidia Audio Codec Driver, the following is the background and the suggested programming model (Modified from Intel DCN HDA-034-A)

The audio software for the HDMI codec will need information about the audio capabilities of an attached HDMI sink device. This information is stored in the HDMI sink device's EDID. Typically, the EDID flows through a graphics adapter to graphics software, so the graphics adapter HW will not have knowledge of the EDID contents.

To that end, a new mechanism is defined for passing the HDMI sink device's audio EDID information from the graphics software to the audio software. The data payload containing the audio information will be known as EDID-Like Data or ELD and will contain a subset of the HDMI sink devices EDID information.

The ELD information will be valid if the HDMI sink is attached and powered on and the ELD Valid bit is set. The Pin Widget that is associated with this HDMI widget will report if the device is attached and that the ELD memory is populated and valid by reporting Presence Detect of 1 and ELD Valid of 1 to a Pin Sense control command. As with the Presence Detect bit, the changes to the ELD Valid bit can also result in the generation of unsolicited responses.

Each codec implements a 96-byte ELD buffer that is written by RM and read by the audio driver. Once the ELD buffer is written by RM, the valid bit, NV_PDISP_SOR_AUDIO_HDA_PRESENSE_ELDV is set to _VALID to indicate that ELD contents have been initialized by RM. On hot unplug events, NV_PDISP_SOR_AUDIO_HDA_PRESENSE_ELDV is set to _INVALID to erase ELD programming in the audio driver.

Offset: 0bch | Read/Write: R/W | Reset: 0b0000000000000000

Bit	Reset	Description
15:8	0x0	INDEX
7:0	0x0	DATABYTE

25.9.18 HDMI_NV_PDISP_SOR_AUDIO_HDA_PRESENSE_0

Reports the HotPlug state and ELD state to the audio driver. Changes to this state can cause an unsolicited response.

ELDV: Indicates whether the data in the ELD buffer is valid and ready to read.

PD: Presense Detect. This should be set to _PRESENT by SW upon hotplug and _NOT_PRESENT on unplug.

Offset: 0bdh | Read/Write: R/W | Reset: 0b00

Bit	Reset	Description
1	INVALID	ELDV: 0 = INVALID 1 = VALID
0	NOT_PRESENT	PD: 0 = NOT_PRESENT 1 = PRESENT

25.9.19 HDMI_NV_PDISP_SOR_AUDIO_HDA_CP_0

Reports the Content Protection state requested by the Audio driver. It is at the discretion of the video driver to enable or disable Content protection. This is a read only register set by the Content Protection Control (CP_CONTROL) verb.

REQUEST_STATE

_DONT_CARE: No state change requested

_RESERVED: Unused

_PROTECTION_OFF: Audio driver requests Content Protection to be disabled.

_PROTECTION_ON : Audio driver requests Content Protection to be enabled.

Offset: 0beh | Read/Write: RO | Reset: 0bxxx

Bit	Reset	Description
2	X	REQUEST_STATE_VALID
1:0	X	REQUEST_STATE: 0 = DONT_CARE 2 = PROTECTION_OFF 3 = PTOTECTION_ON

25.9.20 HDMI_NV_PDISP_SOR_AUDIO_AVAL_0320_0

When using the Azalia codec, it is difficult to recover the 128*fs clock frequency from the incoming audio stream. Therefore, when using the Azalia codec, these registers must be programmed to emulate the N counter.

When using SPDIF, the N counter will run at 128*fs (audio sampling frequency) and count to a value determined by the HDMI spec. The Azalia counter will run at 24MHz at all times, and it needs to count for the same period of time as the N counter would have.

Refer section 7.2 of HDMI spec 1.2

AVAL values do not need to be programmed by SW. Their default values are OK. If the NVAL changes, it will change the N counter frequency. AVAL will need to be changed to match with this new NVAL. Certain resolutions may require different NVALs.

For Mobile chips, clock is 24 MHz, not 54 MHz. For 44.1, default N of 6272 gives non-integer AVAL. Choosing N of 4704 instead (nominal CTS 61875) gives N frequency of 1200 Hz.

48k: 1ms 24000 azaclk cycles (0x5DC0)

44.1k: 1ms/1.2 20000 azaclk cycles (0x4E20)

But this is academic because we hard-code CTS/N since the pixel clock / audio clock ratios are known and fixed.

At 27 MHz pixel clock			
	CTS	**N**	**AVAL**
44.1	22500	4704	20000
88.2	22500	9408	20000
176.4	22500	18816	20000
At 74.25 MHz pixel clock			
44.1	61875	4704	20000
88.2	61875	9408	20000
176.4	61875	18816	20000
At 148.5 MHz pixel clock:			
44.1	123750	4704	20000
88.2	123750	9408	20000
176.4	123750	18816	20000

[THIS PAGE INTENTIONALLY LEFT BLANK]

26.0 MIPI-CSI (CAMERA SERIAL INTERFACE)

The Camera Serial Interface (CSI) is based on MIPI CSI 2.0 standard specification and implements the CSI receiver which receives data from an external camera module with a CSI transmitter. It consists of two CSI receiver interfaces so it can receive serial transmission from two cameras:

- CSI-A interface supports 1-clock lane and up to 4 data lanes. In 3 and 4-data lane configurations, CSI-A uses CSI-B's data lanes.
- CSI-B interface supports 1 clock lane and 2-data lanes.

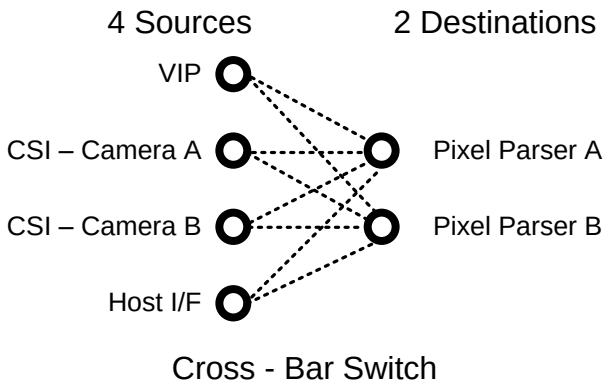
The CSI interface can also receive a digital CSI compatible byte stream from either the 8-bit Video Input (VI) port or from the host interface. The CSI stream coming from VI port is provided to accommodate the possibility of using an external CSI receiver or to take advantage of the rich CSI data formats transmission using the traditional 8-bit digital CMOS video interface. Similarly, CSI stream coming from host is provided to take advantage of the rich CSI data formats.

Only 1 data/pixel stream can be processed at any given time. The two streams can come from any one or two of the four possible sources, as shown in Figure 66. If the two streams come from a single source, then the streams are separated using a filter indexed on different virtual channel numbers or data types. In case of separation using data types, the normal data type is separated from the embedded data type. Since there are only two pixel parsers, virtual channel and embedded data capability cannot be used at the same time.

CSI supports both single-shot mode and continuous mode.

CSI is designed with error resilience.

Figure 66: Data Source/Destination Options



The MIPI CSI 2.0 standard is available from MIPI to its members at http://www.mipi.org/

26.1 Use Cases

The use cases for CSI fall into the following categories listed in Table 71:

Table 71: CSI Use Cases

Case	Description	Sources	Destinations
Normal	Standard CSI	Camera A or B	PPA or PPB
Virtual Channel	One stream goes to 2 parsers. Packet filtering based on VC	Camera A,B	PPA and PPB

Case	Description	Sources	Destinations
	number in header	VIP, or Host	
Embedded Data	One stream goes to 2 parsers. Packet filtering based on data type in header	Camera A,B VIP, or Host	PPA and PPB
Embedded Data (without filtering)	One stream goes to 1 parser. Has normal and embedded data	Camera A,B VIP, or Host	PPA or PPB
VIP	CSI payload-only or packet sources from VIP (Diagnostic Workaround mode) *	VIP	PPA or PPB
Host	Payload-only or Packet sources from Host I/F	Host I/F	PPA or PPB

* In the Tegra® 3 devices, packet mode in the CSI VIP path is not supported.

26.2 Input Data Format

The supported data formats are summarized in Table 72.

Table 72: Supported CSI Formats

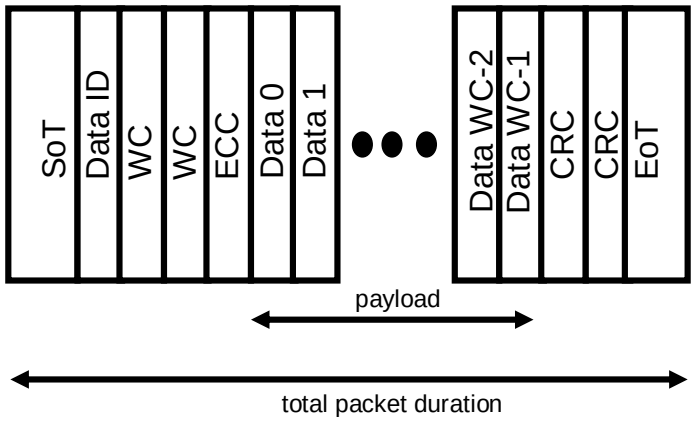
Data Format	
RGB	RGB888, RGB666, RGB565, RGB555, RGB444
YUV	YUV422-8b, YUV422-10b, YUV420-8b (legacy), YUV420-8b, YUV420-10b, YUV444-8b
RAW	RAW6, RAW7, RAW8, RAW10, RAW12, RAW14
User defined	JPEG8
Embedded	Embedded control information

The formats YUV422/420-10b are converted to YUV422/420-8b by taking the most significant bits.

26.3 CSI Packet Structure

The CSI packet structure is illustrated in Figure 67. It has a start-of-transmission sequence, SoT, which contains a 1-byte preamble sequence. The packet is composed of a 4-byte header, a body of WC bytes, and a 2-byte CRC check. The end-of-transmission, EoT, is indicated by the line state going from high speed transmission to LP11 state.

Figure 67: CSI Packet Structure



26.4 CSI Implementation

The CSI interface essentially consists of:

- MIPI D-Phy block
- Control Interface Logic (CIL) for Serial Clock Receiver
- CSI data path module which is implemented as a sub-module of VI module

In Tegra 3 implementations, two CSI bricks including csia_pad with 2x data lanes and csib_pad with 2x data lane receive serial data from cameras, deserialize them into 8b parallel data, and send them to the CSICIL block. The CSICIL block performs packet boundary detection by searching for the packet preamble. The main CSI module receives 8b packet aligned data from CSICIL, performs parity checking on the header, header decoding, CRC check, and pixel parsing. The output is sent out to VI through the 28b bus which outputs 1 pixel per VI clock.

26.5 Performance Limitations

Performance of the CSI interface is subject to several factors that must all be met. The performance factors that are directly related to the CSI interface are the serial data rate and the internal pixel rate. Maximum serial data rate is expected to be 1Gbps given the ideal system condition. This data rate may be degraded depending on system design and may also be limited by the CSI transmitter in the camera.

For each CSI data lane, the serial data stream received by the CSI PHY is internally converted to a byte stream by the CSI Control Interface Logic (CIL) before further processed by the CSI module that resides as part of the Video Input (VI) module. The CSI byte clock is used to transfer this data byte stream (1 byte per data lane) between the CIL and the CSI data paths. This CSI byte clock is derived from the received CSI serial clock by dividing the CSI serial clock by 4. So for 1Gbps serial CSI data rate, the serial clock frequency is 500 MHz and the byte clock frequency is 125 MHz.

The byte stream received by the CSI CIL logic is converted to a pixel stream at 1 pixel per clock in the CSI module. This pixel stream output is further processed by other modules (ISP or the rest of VI datapath or EPP). The maximum output pixel clock rate of CSI module is 300 MHz.

Depending on where the CSI pixel stream is processed (ISP, VI, or EPP), the maximum pixel clock frequency is limited by the pixel clock frequency of the modules that process this pixel stream.

> **Note:** VI/ISP/EPP pixel frequency may be lower than CSI output pixel clock frequency and therefore, may limit the actual pixel data rate. Please refer to ISP, VI and EPP specification.

Note that with multiple data lanes per CSI interface, the maximum serial data link speed may not be achievable due to pixel clock frequency limitations. Also, if two data streams come from the same CSI interface, since the streams are interleaved in time, the pixel clock frequency limitations may also limit the frame rate of the combined streams.

Table 73: Packet Efficiency

	Best* WC=65536	Typical* WC=1024
Payload	524us	8192ns
Overhead	356ns	356ns
Efficiency	99.9%	96%

26.6 Error Resilience

CSI is required to be designed to tolerate and/or recover stream errors at various levels.

According to the CSI 2.0 specification, CSI must be able to detect and correct one-bit header error, detect two or more bits header errors, and detect possible payload errors using 16-bit CRC.

Due to the architectural constraints in VI and EPP, CSI has to always send “valid” stream data to VI, even when the incoming stream contains errors and causes CSI to drop packets. For stream data with a format other than *embedded*, “valid” stream data means one or more full frames of data that VI exactly expects for certain frame width and frame height.

If the incoming stream data (non-embedded) contains less bytes than the word count (WC), or less number of lines than the expected frame height, CSI must be able to pad pixels to short lines, or pad lines to short frames, so that CSI always sends “valid” frame data to VI.

26.7 Other Architectural Constraints

The following specifies other architectural constraints for this design:

- Because there are only 2 pixel parsers, embedded data and virtual channel cannot be supported simultaneously.
- Embedded data in a frame can be output in the same output port as the pixel data stream; however, in some cases where image processing or data reformatting is performed in VI/ISP/EPP, this embedded data may be accidentally processed in VI/ISP/EPP. Currently, VI/ISP/EPP cannot differentiate between embedded data or pixel data.
- CSI stream from VI port is limited to VI port input clock frequency (96 MHz) at 8-bit/clock. This stream may have fully compatible CSI packets format or it may carry only CSI compatible data format without packet header/footer and short packets. If it carries only CSI compatible data format, it should be transmitted using VI video input stream format with external H/V syncs.
- CSI stream from host interface should be sent in 32-bit data through the Y-FIFO with frame/line definition compatible only. So, CSI stream coming from host should only contain CSI compatible data formats but without the CSI packet header/footer or short packets. The header information should be set using registers.
- Same stream going to different pixel parsers. This case will work as long as no stall comes from VI side. If stall comes then the current frame will be invalid. This is an exception case which will never normally occur. STM_ERR will be generated and S/W needs to take appropriate action.

26.8 CSI Datapath Module

The CSI datapath consists of four input ports and two output ports. There are two datapaths for pixel stream processing; therefore, at any time, a maximum of two input ports maybe active simultaneously.

The components of CSI datapath include:

- Four input ports from: CSI A interface, CSI B interface, 8-bit VI port, and 32-bit host interface. Each port is capable of carrying a stream with CSI compatible data format.
- Three asynchronous input buffers (FIFOs) to receive streams from VI port, CSI A interface, and CSI B interface.
- Four header parsers for searching packet header and to perform error detection and correction of CSI header.
- Two pixel parsers with corresponding output ports. Each pixel parser can convert CSI packet data stream to an output a pixel stream. Each output port consists of maximum 24-bit of data per clock. Depending on the output data format options, one or two pixels per clock may be sent.

26.8.1 Header Parser

CSI pixel stream processing mainly consists of header parser and pixel parser. There are 4 header parsers: header parser A, header parser B, header parser V, and header parser H.

Header parser A is enabled when CSI A interface is selected as input source. Similarly header parser B is enabled when CSI B interface is selected as input source.

In general the header parser is used for:

- Detecting long and short packet headers and deciding what to do with the packet. This includes performing error detection and correction on the packet header prior to making decision and dealing with uncorrectable packet header.
- Skipping extra data on longer than expected data packets.
- Skipping next packet on imminent input buffer overflow when the pixel parser is busy processing current packet.

When enabled, the header parser will interpret CSI packet header, perform error detection and correction. If the packet header is uncorrectable, then an error is flagged and interrupt generated. If good or correctable CSI packet header is found, then the header parser will check the Data Identifier (DI) byte in the packet header and check the 2-bit Virtual Channel (VC) identifier and the 6-bit Data Type (DT) within this Data Identifier byte and will also check the 2-byte Word Count (WC) value in the packet header. If the virtual channel ID does not match the expected (programmed) value for the corresponding pixel parser then the packet is discarded. If the virtual channel ID matches the expected (programmed) value for the corresponding pixel parser then the header parser must decide what to do with the packet depending on the Data Type and the Word Count value. For long packet, if the Data Type does not match the expected (programmed) value for the corresponding pixel parser then the packet is discarded. If the Data Type of the long packet matches the expected (programmed) value for the corresponding pixel parser, then the corresponding pixel parser is notified to process the remaining packet data and checksum.

When first enabled, header parser must always search for Frame Start packet which is a CSI short packet. However, when input source is VI or host, there is an option to indicate Frame Start using the incoming vertical sync signal. If vertical sync signal is used to indicate frame start then if CSI frame start packet is encountered then the header parser will discard it. When frame start packet/signal is found, the header parser will notify the corresponding pixel parser so that it can make preparation to process a new frame and output frame start code.

26.8.1.1 Data Type

There are 64 possible types based on 6 bit Data Type value.

Data Type	Description
0x00 – 0x07	Synchronization Short Packet Data Types
0x08 – 0x0F	Generic Short Packet Data Types
0x10 – 0x17	Generic Long Packet Data Types
0x18 – 0x1F	YUV Data
0x20 – 0x27	RGB Data
0x28 – 0x2F	RAW Data
0x30 – 0x37	User Defined Byte-based Data
0x38 – 0x3F	Reserved

26.8.1.2 Short Packets

There are 16 possible short packets based on Data Type value.

Data Type	Description
0x00	Frame Start Code
0x01	Frame End Code
0x02	Line Start Code (Optional)
0x03	Line End Code (Optional)
0x04 – 0x07	Reserved

26.8.1.3 Long Packets

CSI long packets are data packets which always consist of 1-line of data per packet with exception of arbitrary data packets. There are various data types defined. Please refer to Section 26.2 for a summary of CSI data formats and their corresponding CSI module internal output format.

Generic long packets need special handling. There are 3 generic long packet types defined: null packet (DT=0x10), blanking data packet (DT=0x11), and embedded data packet (DT=0x12). There are also 5 reserved generic long packet types (DT=0x13 to 0x17). The header parser should discard all null packets and all reserved generic long packets.

Blanking data packets may contain blank color or blank image information. The transmission of blanking data packet is optional in the CSI2.0 specification. Null and blanking data are defined in CSI2.0 specification mainly to accommodate a receiver which is timing sensitive and requires line start/end for every line in the frame. As a CSI receiver, this product does not have such blank timing sensitivity and it typically does not process blank data and does not store it to memory. Blanking data packet can therefore be discarded by the header parser.

However, some module may have a requirement for specific number of “blank” or extra lines at the end of vertical active area, such as the ISP module, which requires input active scan area to be about 6 lines larger than output active area. If a module that takes CSI output stream requires extra lines at the end of active image then blanking packet data can be used to generate these additional lines. In the future, there might be other reasons to process blank data. So, an option should be provided to accept and process blanking data. In the absence of better definition of blanking data format in the CSI spec, if software decides that blanking data cannot be discarded then, the pixel parser should assume that the blanking data format is the same as the programmed expected data type of the pixel stream.

The current CSI 2.0 specification specifies that embedded data packets consists of 8-bit arbitrary data. This embedded data is, typically not the same pixel color as the image data. It might be used to send headers/status for JPEG/MPEG compressed data at the beginning or end of image data or in between image data lines. It might also be used to send closed caption text information or other type of information.

The exact use of embedded data is not clear, and therefore in most cases, embedded data is probably not used, or if sent by the transmitter, the embedded data packets can simply be discarded. If for some reason, it is important to receive the embedded data, there are other options that should be supported. Since there are two pixel parsers, if there is only one video source, it is best to direct embedded data to the other pixel parser which does not process the normal image data. In this way, the embedded data can be treated the same way as 8-bit arbitrary/compressed image data and can be output as 8-bit/clock or 16-bit/clock format. If there are two video sources that occupy both the pixel parsers, then embedded data if it has to be stored to memory, needs to be output in the same channel as the image data as 8-bit/16-bit data. But this also means that the module that receives output of CSI module and does image processing must have the ability to differentiate embedded data and not do image processing on this data prior to writing it to memory.

26.8.1.4 Top or Bottom Field Tag

During frame start, a tag is passed from CSI to VI to indicate top or bottom field. The 1-bit tag is at the least significant bit of the CSI output bus. If the bit is “1”, the field is top, but bottom otherwise.

26.9 Software Requirements

26.9.1 Error Counters

To help debug, three 32-bit error counters have been implemented. SW can program each counter to increment at the event of any one of many error conditions or status change. The error conditions are:

- Header errors corrected
- Header uncorrectable errors
- CRC errors

- Packets too short, actual length less than WC
- Overflow errors due to padding packets too short
- FIFO overflow errors
- Illegal word count
- SoT single-bit error
- SoT multi-bit error, packet discarded
- EoT sequence error
- ESC-entry error
- LP-CTRL error
- The statistics that can be monitored include:
- line packets processed
- total packets processed
- ESC command processed

26.9.2 Programming Sequence

The following sequence is recommended for capturing a single frame:

1. Set up CSI registers for use case, such as number of lanes, virtual channel
2. Initialize and power up CSI interface
3. Wait for initialization time or done signal from calibration logic
4. Power up camera thru I2C interface
5. All CSI data and clock lanes are in stop state, LP11
6. Initiate frame capture thru I2C
7. Frame done, CSI goes back to stop state, LP11

26.9.3 Escape Mode Handling

In the MIPI PHY specification, an escape mode is available for low speed command and data transfer. In our implementation, the escape mode entry is detected inside CSICIL. The command byte will be deposited in a register and interrupt generated from CSI. Software reads the register and decodes. CSI supports only one escape mode command which is Ultra-Low Power Mode (ULPM).

ULPM Command

Upon receiving the ULPM, software will synchronously power down the CSI interface and the camera as follows:

1. Software put camera in sleep mode thru I2C
2. Camera sends ULPM command to CSI
3. CSI receives ULPM and raise interrupt
4. Software powers down CSI which goes to sleep in sync with camera’s CSI transmitter

26.10 DPHY Modes of Operation

The MIPI DPHY has 3 basic modes of operation. High speed mode employs differential signaling and achieves data rate of 1Gbps. Both the driver and receiver are matched to 100 ohm differential. The driver is voltage mode for lower power consumption as opposed to current mode.

Low power control mode employs single-ended CMOS signaling for handshaking between camera and host. In this mode, there is no clock and no maximum symbol time defined in the specification. In the NV implementation, the receiver samples the input using both edges of the internal pixel clock, so the timing resolution is half the clock period of the pixel clock period.

The low power escape mode employs self-clocking using both data P and N pins. The clock is generated by XOR of data P and N. The maximum transfer rate is 20Mbps for a 50ns bit time. In our implementation, the receiver samples the input using both edges of the internal pixel clock also. It is the goal to sample at least twice during the bit interval; therefore, the internal pixel clock should have a minimum frequency of 20MHz.

Table 74: MIPI DHY Mode of Operations

Modes	Description	Clock
High speed (HS)	High speed differential signaling. Upto 1 Gbps. Burst transmission for low power.	500 MHz differential
Low Power (LP) Control	Single-ended 1.2V CMOS level. Low speed signaling for handshaking. Supports ULPM sleep state.	No Clock
Low Power (LP) Escape	Same as above. Low speed signaling for data, used for escape command entry only. 20Mbps	2 stage synchronizers to VI clock

26.11 MIPI-CSI Registers

26.11.1 CSI_VI_INPUT_STREAM_CONTROL_0

VI Input Stream Control

Offset: 200h | Read/Write: R/W | Reset: 0bx

Bit	Reset	Description
7	X	VIP_SF_GEN: VIP Start Frame Generation Don't use vi2csi_vip_vsync to generate start frame (SF), or end frame (EF) markers in the pixel parser output stream. 0 = VSYNC_SF : Pulses on vi2csi_vip_vsync will be used to generate start frame (SF) and end frame (EF) markers in the pixel parser output stream. In Tegra 3 devices, only payload_only mode is supported in the VIP input stream path, and this field may always be programmed to VSYNC_SF. 1 = NO_VSYNC_SF

26.11.2 CSI_HOST_INPUT_STREAM_CONTROL_0

Host Input Stream Control

Offset: 202h | Read/Write: R/W | Reset: 0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx

Bit	R/W	Reset	Description
28:16	RW	X	HOST_FRAME_HEIGHT: Host Frame Height Specifies the height of the host frame when the host is supplying CSI format payload only data to one of the CSI pixel parsers. Programmed Value = number of lines - 1
8	RO	X	HOST_END_OF_PACKET: Writing this bit with a 1 indicates End of Packet, when CSI Host data is being received in Packet Format. In Packet Format vi2csi_host_hsync is not used to indicate beginning of packet.
7	RW	X	HOST_SF_GEN: Host Start Frame Generation Don't use CSI Host Line counter to generate start, or End, of Frame control outputs. This setting should only be used if HOST_DATA_FORMAT is set to PACKETS, and the Host data stream has frame sync packets. 0 = LINE_COUNTER : CSI Host Line counter will be used to generate Frame start and end control. To signal the start of the first frame the pixel parser will send a SF control,

Bit	R/W	Reset	Description
			and signal start of frame mark, when it is first enabled with Host as its source. This setting should be used when HOST_DATA_FORMAT is set to PAYLOAD_ONLY. 1 = SHORT_PACKETS
3:0	RW	X	HOST_DATA_FORMAT: Host Data Format Data written to Y_FIFO_WRITE port should be in CSI packet format. To indicate end of packet a 1 should be written to HOST_END_OF_PACKET. A 1 should also be written to HOST_END_OF_PACKET before writing the first word of packet data to Y_FIFO_WRITE. 0 = PAYLOAD_ONLY : Data written to Y_FIFO_WRITE port should be CSI line payload data only (no header, no footer, and no short packets). A value of 1 should not be written to HOST_END_OF_PACKET (end of packet pulse only gets generated when a 1 is written to this bit). First line will be indicated when one of the pixel parsers is first enabled with its CSI_PPA/B_STREAM_SOURCE set to "HOST". The values in the following PIXEL_STREAM_A/B_CONTROL0 fields, for the pixel parser that is receiving host data, will be ignored; CSI_PPA/B_PACKET_HEADER overridden with "NOT_SENT", CSI_PPA/B_DATA_IDENTIFIER overridden with "DISABLED", CSI_PPA/B_WORD_COUNT_SELECT overridden with "REGISTER". CSI_PPA/B_CRC_CHECK overridden with "DISABLE", CSI_PPA/B_VIRTUAL_CHANNEL_ID, CSI_PPA/B_EMBEDDED_DATA_OPTIONS, and CSI_PPA/B_HEADER_EC_ENABLE. CSI_PPA/B_DATA_TYPE should be programmed with the 6 bit data type that is to be used to interpret the stream. CSI_PPA/B_WORD_COUNT should be programmed with the number of bytes per line. 1 = PACKETS

26.11.3 CSI_INPUT_STREAM_A_CONTROL_0

CSI Input Stream A Control

Offset: 204h | Read/Write: R/W | Reset: 0b011111111xxxxxxxxxxx0xx01

Bit	Reset	Description
23:16	0xff	CSI_A_SKIP_PACKET_THRESHOLD: CSI-A Skip Packet Threshold. This value is compared against the internal FIFO that buffer the input streams. A packet will be skipped (discarded) if the pixel stream processor is busy (probably due to padding process of a short line) and the number of entries in the internal FIFO exceeds this threshold value. Note that each entry in the internal FIFO buffer is four bytes. To turn off this feature, set the value to its maximum value (all ones).
4	0x0	CSI_A_SKIP_PACKET_THRESHOLD_ENABLE: Enables skip packet threshold feature. Skip packet feature is enabled. 0 = DISABLE : Skip packet feature is disabled. 1 = ENABLE
1:0	0x1	CSI_A_DATA_LANE: CSI-A Data Lane 0= 1 data lane 1= 2 data lanes 2= 3 data lanes 3= 4 data lanes

26.11.4 CSI_PIXEL_STREAM_A_CONTROL0_0

CSI Pixel Stream A Control 0

Offset: 206h | Read/Write: R/W | Reset: 0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxx000 |

Bit	Reset	Description
29:28	X	CSI_PPA_PAD_FRAME: CSI Pixel Parser A Pad Frame This specifies how to deal with frames that are shorter (fewer lines) than expected. Short frames are usually caused by line packets being dropped because of packet errors. Expected frame height is specified in PPA_EXP_FRAME_HEIGHT. To do padding the value in CSI_PPA_WORD_COUNT needs to be set to the number of input bytes in each line's payload. Short frames will not be padded out. 0 = PAD0S : Lines of all zeros will be used to pad out frames that are shorter than expected height. PPA_EXP_FRAME_HEIGHT must be programmed to an appropriate value if this fields is set to PAD0S. 1 = PAD1S : Lines of all ones will be used to pad out frames that are shorter than expected height. PPA_EXP_FRAME_HEIGHT must be programmed to an appropriate

Bit	Reset	Description
		value if this fields is set to PAD1S. 2 = NOPAD
27	X	CSI_PPA_HEADER_EC_ENABLE: CSI Pixel Parser A Packet Header Error Correction Enable. This parameter specifies whether single bit errors in the packet header will be automatically corrected, or not. Single bit errors in the header will not be corrected. Header ECC check will still set header ECC status bits and the packet will be processed by Pixel Parser A. DISABLE should not be used when processing interleaved streams (Same stream going to both PPA and PPB). 0 = ENABLE : Single bit errors in the header will be automatically corrected. 1 = DISABLE
25:24	X	CSI_PPA_PAD_SHORT_LINE: CSI Pixel Parser A Pad Short Line This specifies how to deal with shorter than expected line (the number of bytes received is less than the specified word count) short line is not padded (will output less pixels than expected). This option is not recommended and may cause other modules that receives CSI output stream to hang up. 0 = PAD0S : short line is padded by pixel of zeros such that the expected number of output pixels is correct. Due to the time required to do the padding, subsequent line packet maybe discarded and therefore may cause a short frame (total number of lines per frame is less than expected). 1 = PAD1S : short line is padded by pixel of ones such that the expected number of output pixels is correct. Due to the time required to do the padding, subsequent line packet maybe discarded and therefore may cause a short frame (total number of lines per frame is less than expected). 2 = NOPAD
21:20	X	CSI_PPA_EMBEDDED_DATA_OPTIONS: CSI Pixel Parser A Embedded Data Options. This specifies how to deal with embedded data within the specified input stream assuming that the CSI_PPA_DATA_TYPE is not embedded data and assuming that embedded data is not already processed by other CSI pixel stream processor. Output embedded data as 8-bpp arbitrary data stream. 0 = DISCARD : discard (throw away) embedded data 1 = EMBEDDED
19:16	X	CSI_PPA_OUTPUT_FORMAT_OPTIONS: CSI Pixel Parser A Output Format Options This parameter specifies options for output data format. Output for storing RAW data to memory through ISP. Undefined LS color bits for RGB_666, RGB_565, RGB_555, and RGB_444, will be zeroed. 0 = ARBITRARY : Output as 8-bit arbitrary data stream This may be used for compressed JPEG stream 1 = PIXEL : Output the normal 1 pixel/clock. Undefined LS color bits for RGB_666, RGB_565, RGB_555, and RGB_444, will be zeroed. 2 = PIXEL_REP : Same as PIXEL except MS color bits, for RGB_666, RGB_565, RGB_555, and RGB_444, will be replicated to their undefined LS bits. 3 = STORE
15:14	X	CSI_PPA_VIRTUAL_CHANNEL_ID: CSI Pixel Parser A Virtual Channel Identifier This is CSI compatible virtual channel identifier as defined in CSI specification. If the source stream contains packet headers and CSI_PPA_DATA_IDENTIFIER is ENABLED this value will be compared to the CSI Virtual Channel Identifier value in the 2 MSB of the CSI Data Identifier (DI) byte. This value will be ignored if the source stream doesn't contain packet headers, or CSI_PPA_DATA_IDENTIFIER is DISABLED, then this value will be ignored. 0 = ONE 1 = TWO 2 = THREE 3 = FOUR
13:8	X	CSI_PPA_DATA_TYPE: CSI Pixel Parser A Data Type This is CSI compatible data type as defined in CSI specification. If the source stream contains packet headers this value can be compared to the CSI Data Type value in the 6 LSB of the CSI Data Identifier (DI) byte. If the source stream doesn't contain packet headers, or CSI_PPA_DATA_IDENTIFIER is DISABLED, this value will be used to determine how the stream will be converted to pixels. 24 = YUV420_8 25 = YUV420_10 26 = LEG_YUV420_8 28 = YUV420CSPS_8 29 = YUV420CSPS_10

Bit	Reset	Description
		30 = YUV422_8 31 = YUV422_10 32 = RGB444 33 = RGB555 34 = RGB565 35 = RGB666 36 = RGB888 40 = RAW6 41 = RAW7 42 = RAW8 43 = RAW10 44 = RAW12 45 = RAW14 48 = ARB_DT1 49 = ARB_DT2 50 = ARB_DT3 51 = ARB_DT4
7	X	CSI_PPA_CRC_CHECK: CSI Pixel Parser A Data CRC Check This parameter specifies whether the last 2 bytes of packet should be treated as CRC checksum and used to perform CRC check on the payload data. Note that in case there are 2 bytes of data CRC at the end of the packet, the packet word count does not include the CRC bytes. Data CRC Check is enabled. 0 = DISABLE : Data CRC Check is disabled regardless of whether there are CRC checksum at the end of the packet. 1 = ENABLE
6	X	CSI_PPA_WORD_COUNT_SELECT: CSI Pixel Parser A Word Count Select This parameter is effective only if packet header is sent as part of the stream. The number of bytes per line is to be extracted from Word Count field in the packet header. Note that if the serial link is not error free, programming this bit to HEADER may be dangerous because the word count information in the header may be corrupted. 0 = REGISTER : Word Count in packet header is ignored and the number of bytes per line/packet is specified by CSI_PPA_WORD_COUNT. Payload CRC check will not be valid if the word count in CSI_PPA_WORD_COUNT is different than the count in the packet header. It is recommended to always program this bit to REGISTER and always program CSI_PPA_WORD_COUNT. 1 = HEADER
5	X	CSI_PPA_DATA_IDENTIFIER: CSI Pixel Parser A Data Identifier (DI) byte processing This parameter is effective only if packet header is sent as part of the stream. Enabled - Data Identifier byte in packet header should be compared against the CSI_PPA_DATA_TYPE and the CSI_PPA_VIRTUAL_CHANNEL_ID. 0 = DISABLED : Disabled - Data Identifier byte in packet header should be ignored (not checked against CSI_PPA_DATA_TYPE and against CSI_PPA_VIRTUAL_CHANNEL_ID). In this case, CSI_PPA_DATA_TYPE specifies the stream data format. 1 = ENABLED
4	X	CSI_PPA_PACKET_HEADER: CSI Pixel Parser A Packet Header processing This specifies whether packet header is sent in the beginning of packet or not. Packet header is sent. This setting should be used if the stream source is CSI Interface A or B. 0 = NOT_SENT : Packet header is not sent. This setting should not be used if the stream source is CSI Interface A or B. Unless CSI-A, or CSI-B, is operating in a stream capture debug mode. In this case, CSI_PPA_DATA_TYPE specifies the stream data format and the number of bytes per line/packet is specified by CSI_PPA_WORD_COUNT. This implies that a packet footer is also not sent. In this case, no packet footer CRC check should be performed. 1 = SENT
2:0	0x0	CSI_PPA_STREAM_SOURCE: CSI Pixel Parser A Stream Source Host 0 = CSI_A : CSI Interface A 1 = CSI_B : CSI Interface B 6 = VI_PORT : VI port 7 = HOST

26.11.5 CSI_PIXEL_STREAM_A_CONTROL1_0

CSI Pixel Stream A Control 1

Offset: 207h | Read/Write: R/W | Reset: 0b00000000 |

Bit	Reset	Description
7:4	0x0	CSI_PPA_TOP_FIELD_FRAME_MASK: CSI Pixel Parser A Top Field Frame Mask
3:0	0x0	CSI_PPA_TOP_FIELD_FRAME: CSI Pixel Parser A Top Field Frame This parameter specifies the frame number for top field detection for interlaced input video stream. Top Field is indicated when each of the least significant four bits of the frame number that has a one in its mask bit matches the corresponding bit in this parameter. In other words, Top Field is detected when the bitwise AND of ~(CSI_PPA_TOP_FIELD_FRAME ^ <frame number>) & CSI_PPA_TOP_FIELD_FRAME_MASK is one. Frame Number is taken from the WC field of the Frame Start short packet.

26.11.6 CSI_PIXEL_STREAM_A_WORD_COUNT_0

CSI Pixel Stream A Word Count

Offset: 208h | Read/Write: R/W | Reset: 0bxxxxxxxxxxxxxxxx |

Bit	Reset	Description
15:0	X	CSI_PPA_WORD_COUNT: CSI Pixel Parser A Word Count. This parameter specifies the number of bytes per line/packet in the case where Word Count field in packet header is not used or where packet header is not sent. This count does not include the additional 2 bytes of CRC checksum if data CRC check is enabled. When the input stream comes from a CSI camera port, this parameter must be programmed when CSI_PPA_PAD_SHORT_LINE is set to either PAD0S or PAD1S, no matter whether CSI_PPA_WORD_COUNT_SELECT is set to REGISTER or HEADER. When the input stream comes from the host path or from the VIP path, and the data mode is PAYLOAD_ONLY, this count must be programmed. Given a line width of N pixels, the programming value of this parameters is as follows **Data format** — **Value** YUV420_8 — N bytes YUV420_10 — N/4*5 bytes LEG_YUV420_8 — N/2*3 bytes YUV422_8 — N*2 bytes YUV422_10 — N/2*5 bytes RGB888 — N*3 bytes RGB666 — N/4*9 bytes RGB565 — N*2 bytes RGB555 — N*2 bytes RGB444 — N*2 bytes RAW6 — N/4*3 bytes RAW7 — N/8*7 bytes RAW8 — N bytes RAW10 — N/4*5 bytes RAW12 — N/2*3 bytes RAW14 — N/4*7 bytes

26.11.7 CSI_PIXEL_STREAM_A_GAP_0

CSI Pixel Stream A Gap

Offset: 209h | Read/Write: R/W | Reset: 0b00000000000000000000000000000000

Bit	Reset	Description
31:16	0x0	PPA_FRAME_MIN_GAP: Minimum number of viclk cycles from end of frame (Video_control = EF) to start of next frame (Video_control = SF). This parameter is to ensure that minimum V-blank time requirement of VI/ISP is satisfied. This field takes effect only when the frame gap of the input stream is less than the specified value.
15:0	0x0	PPA_LINE_MIN_GAP: Minimum number of viclk cycles from end of previous line (Video_control = EL_DATA) to start of next line (Video_control = SL). This parameter is to ensure that minimum H-blank time requirement of VI/ISP is satisfied. This field takes effect only when the line gap of the input stream is less than the specified value.

26.11.8 CSI_PIXEL_STREAM_PPA_COMMAND_0

CSI Pixel Parser A Command

Offset: 20ah | Read/Write: R/W | Reset: 0bxxxxxxxxxxxxxx00

Bit	Reset	Description
15:12	X	CSI_PPA_START_MARKER_FRAME_MAX: CSI Pixel Parser A Start Marker Maximum Start Frame is indicated when Min condition above is met and the least significant four bits of the frame number are less than, or equal to, this value.
11:8	X	CSI_PPA_START_MARKER_FRAME_MIN: CSI Pixel Parser A Start Marker Minimum Start Frame is indicated when Max condition below is met and the least significant four bits of the frame number are greater than, or equal to, this value.
4	X	CSI_PPA_VSYNC_START_MARKER: CSI Pixel Parser A VSYNC Start Marker start of frame is indicated when VSYNC signal is received. When the input stream is from the VIP path and the data mode is PACKET, then this field may be programmed to VSYNC. 0 = FSPKT : Start of frame is indicated when a Frame Start short packet is received with a frame number whose least significant four bits are greater than, or equal to, CSI_PPA_START_MARKER_FRAME_MIN and less than, or equal to, CSI_PPA_START_MARKER_FRAME_MAX. When the input stream is from a CSI port, or from the host path, or from the VIP path and the data mode is PAYLOAD_ONLY, then this field may be programmed to FSPKT. 1 = VSYNC
2	X	CSI_PPA_SINGLE_SHOT: CSI Pixel Parser A Single Shot Mode SW should Clear it along with disabling the CSI_PPA_ENABLE, once a frame is captured 0 = DISABLE 1 = ENABLE
1:0	0x0	CSI_PPA_ENABLE: CSI Pixel Parser A Enable This parameter controls CSI Pixel Parser A to start or stop receiving data. Reset (disable immediately) Enabling the pixel Parser does not enable the corresponding input source to receive data. If Pixel parser is enabled later than the corresponding input source, CSI will keep on rejecting incoming stream, till it encounters a valid SF. 0 = NOP : no operation 1 = ENABLE : enable at the next frame start as specified by the CSI Start Marker 2 = DISABLE : disable after current frame end and before next frame start. 3 = RST

26.11.9 CSI_PIXEL_STREAM_A_EXPECTED_FRAME_0

CSI Pixel Stream A Expected Frame

Offset: 232h | Read/Write: R/W | Reset: 0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx

Bit	Reset	Description
28:16	X	PPA_EXP_FRAME_HEIGHT: CSI-PPA Expected Frame Height Specifies the expected height of the CSI-PPA frame output. Padding out of frames that are shorter than this expected height can be specified using CSI_PPA_PAD_FRAME. If CSI_PPA_PAD_FRAME is set to PAD0S or PAD1S, this parameter must be programmed. If CSI_PPA_PAD_FRAME is set to NOPAD, this parameter may not be programmed. Programmed Value = number of lines
15:4	X	PPA_MAX_CLOCKS: Maximum Number of viclk clock cycles between line start requests. The value in this field is in terms of 256 viclk clock cycles.
0	X	PPA_ENABLE_LINE_TIMEOUT: When set to one enables checking of the time between start line requests from the Header Parser to CSI-PPA. A fake EF will be outputted by CSI-PPA if this time between line starts exceeds the value in MAX_CLOCKS_BETWEEN_LINES. Padding lines can be inserted before the fake EF, if the number of lines outputted, when the fake EF is generated is less than the expected frame height. The type of padding is specified using CSI_PPA_PAD_FRAME.

26.11.10 CSI_INPUT_STREAM_B_CONTROL_0

CSI Input Stream B Control

Offset: 20fh | Read/Write: R/W | Reset: 0b01111111xxxxxxxxxxx0xx01

Bit	Reset	Description
23:16	0x7f	CSI_B_SKIP_PACKET_THRESHOLD: CSI-B Skip Packet Threshold This value is compared against the internal FIFO that buffer the input streams. A packet will be skipped (discarded) if the pixel stream processor is busy (probably due to padding process of a short line) and the number of entries in the internal FIFO exceeds this threshold value. Note that each entry in the internal FIFO buffer is four bytes. To turn off this feature, set the value to its maximum value (all ones).
4	0x0	CSI_B_SKIP_PACKET_THRESHOLD_ENABLE: Enables skip packet threshold feature. Skip packet feature is enabled. 0 = DISABLE : Skip packet feature is disabled. 1 = ENABLE
1:0	0x1	CSI_B_DATA_LANE: CSI-B Data Lane 0= 1 data lane 1= 2 data lanes 2= 3 data lanes (not supported on SC17 & SC25) 3= 4 data lanes (not supported on SC17 & SC25)

26.11.11 CSI_PIXEL_STREAM_B_CONTROL0_0

CSI Pixel Stream A Control 0

Offset: 211h | Read/Write: R/W | Reset: 0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxx000

Bit	Reset	Description
29:28	X	CSI_PPB_PAD_FRAME: CSI Pixel Parser B Pad Frame This specifies how to deal with frames that are shorter (fewer lines) than expected. Short frames are usually caused by line packets being dropped because of packet errors. Expected frame height is specified in PPB_EXP_FRAME_HEIGHT. To do padding the value in CSI_PPB_WORD_COUNT needs to be set to the number of input bytes in each lines payload. Short frames will not be padded out. 0 = PAD0S : Lines of all zeros will be used to pad out frames that are shorter than expected height. PPB_EXP_FRAME_HEIGHT must be programmed to an appropriate value if this fields is set to PAD0S. 1 = PAD1S : Lines of all ones will be used to pad out frames that are shorter than expected height. PPB_EXP_FRAME_HEIGHT must be programmed to an appropriate

Bit	Reset	Description
		value if this fields is set to PAD1S. 2 = NOPAD
27	X	CSI_PPB_HEADER_EC_ENABLE: CSI Pixel Parser B Packet Header Error Correction Enable This parameter specifies whether single bit errors in the packet header will be automatically corrected, or not. Single bit errors in the header will not be corrected. Header ECC check will still set header ECC status bits and the packet will be processed by Pixel Parser B. DISABLE should not be used when processing interleaved streams (Same stream going to both PPA and PPB). 0 = ENABLE : Single bit errors in the header will be automatically corrected. 1 = DISABLE
25:24	X	CSI_PPB_PAD_SHORT_LINE: CSI Pixel Parser B Pad Short Line This specifies how to deal with shorter than expected line (the number of bytes received is less than the specified word count) short line is not padded (will output less pixels than expected). This option is not recommended and may cause other modules that receives CSI output stream to hang up. 0 = PAD0S : short line is padded by pixel of zeros such that the expected number of output pixels is correct. Due to the time required to do the padding, subsequent line packet maybe discarded and therefore may cause a short frame (total number of lines per frame is less than expected). 1 = PAD1S : short line is padded by pixel of ones such that the expected number of output pixels is correct. Due to the time required to do the padding, subsequent line packet maybe discarded and therefore may cause a short frame (total number of lines per frame is less than expected). 2 = NOPAD
21:20	X	CSI_PPB_EMBEDDED_DATA_OPTIONS: CSI Pixel Parser B Embedded Data Options This specifies how to deal with embedded data within the specified input stream assuming that the CSI_PPB_DATA_TYPE is not embedded data and assuming that embedded data is not already processed by other CSI pixel stream processor. output embedded data as 8-bpp arbitrary data stream. 0 = DISCARD : discard (throw away) embedded data 1 = EMBEDDED
19:16	X	CSI_PPB_OUTPUT_FORMAT_OPTIONS: CSI Pixel Parser B Output Format Options This parameter specifies output data format. Output for storing RAW data to memory through ISP. Undefined LS color bits for RGB_666, RGB_565, RGB_555, and RGB_444, will be zeroed. 0 = ARBITRARY : Output as 8-bit arbitrary data stream This may be used for compressed JPEG stream 1 = PIXEL : Output the normal 1 pixel/clock. Undefined LS color bits for RGB_666, RGB_565, RGB_555, and RGB_444, will be zeroed. 2 = PIXEL_REP : Same as PIXEL except MS color bits, for RGB_666, RGB_565, RGB_555, and RGB_444, will be replicated to their undefined LS bits. 3 = STORE
15:14	X	CSI_PPB_VIRTUAL_CHANNEL_ID: CSI Pixel Parser B Virtual Channel Identifier This is CSI compatible virtual channel identifier as defined in CSI specification. If the source stream contains packet headers and CSI_PPB_DATA_IDENTIFIER is ENABLED this value will be compared to the CSI Virtual Channel Identifier value in the 2 MSB of the CSI Data Identifier (DI) byte. This value will be ignored if the source stream doesn't contain packet headers, or CSI_PPB_DATA_IDENTIFIER is DISABLED, then this value will be ignored. 0 = ONE 1 = TWO 2 = THREE 3 = FOUR
13:8	X	CSI_PPB_DATA_TYPE: CSI Pixel Parser B Data Type This is CSI compatible data type as defined in CSI specification. If the source stream contains packet headers this value can be compared to the CSI Data Type value in the 6 LSB of the CSI Data Identifier (DI) byte. If the source stream doesn't contain packet headers, or CSI_PPB_DATA_IDENTIFIER is DISABLED, this value will be used to determine how the stream will be converted to pixels. 24 = YUV420_8 25 = YUV420_10 26 = LEG_YUV420_8 28 = YUV420CSPS_8 29 = YUV420CSPS_10

Bit	Reset	Description
		30 = YUV422_8 31 = YUV422_10 32 = RGB444 33 = RGB555 34 = RGB565 35 = RGB666 36 = RGB888 40 = RAW6 41 = RAW7 42 = RAW8 43 = RAW10 44 = RAW12 45 = RAW14 48 = ARB_DT1 49 = ARB_DT2 50 = ARB_DT3 51 = ARB_DT4
7	X	CSI_PPB_CRC_CHECK: CSI Pixel Parser B Data CRC Check This parameter specifies whether the last 2 bytes of packet should be treated as CRC checksum and used to perform CRC check on the payload data. Note that in case there are 2 bytes of data CRC at the end of the packet, the packet word count does not include the CRC bytes. Data CRC Check is enabled. 0 = DISABLE : Data CRC Check is disabled regardless of whether there are CRC checksum at the end of the packet. 1 = ENABLE
6	X	CSI_PPB_WORD_COUNT_SELECT: CSI Pixel Parser B Word Count Select This parameter is effective only if packet header is sent as part of the stream. The number of bytes per line is to be extracted from Word Count field in the packet header. Note that if the serial link is not error free, programming this bit to HEADER may be dangerous because the word count information in the header may be corrupted. 0 = REGISTER : Word Count in packet header is ignored and the number of bytes per line/packet is specified by CSI_PPB_WORD_COUNT. Payload CRC check will not be valid if the word count in CSI_PPB_WORD_COUNT is different than the count in the packet header. It is recommended to always program this bit to REGISTER and always program CSI_PPB_WORD_COUNT. 1 = HEADER
5	X	CSI_PPB_DATA_IDENTIFIER: CSI Pixel Parser B Data Identifier (DI) byte processing This parameter is effective only if packet header is sent as part of the stream. Enabled - Data Identifier byte in packet header should be compared against the CSI_PPB_DATA_TYPE and the CSI_PPB_VIRTUAL_CHANNEL_ID. 0 = DISABLED : Disabled - Data Identifier byte in packet header should be ignored (not checked against CSI_PPB_DATA_TYPE and against CSI_PPB_VIRTUAL_CHANNEL_ID). In this case, CSI_PPB_DATA_TYPE specifies the stream data format. 1 = ENABLED
4	X	CSI_PPB_PACKET_HEADER: CSI Pixel Parser B Packet Header processing This specifies whether packet header is sent in the beginning of packet or not. Packet header is sent. This setting should be used if the stream source is CSI Interface A or B. 0 = NOT_SENT : Packet header is not sent. This setting should not be used if the stream source is CSI Interface A or B. Unless CSI-A, or CSI-B, is operating in a stream capture debug mode. In this case, CSI_PPB_DATA_TYPE specifies the stream data format and the number of bytes per line/packet is specified by CSI_PPB_WORD_COUNT. This implies that a packet footer is also not sent. In this case, no packet footer CRC check should be performed. 1 = SENT
2:0	0x0	CSI_PPB_STREAM_SOURCE: CSI Pixel Parser B Stream Source Host 0 = CSI_A : CSI Interface A 1 = CSI_B : CSI Interface B 6 = VI_PORT : VI port 7 = HOST

5	0x0	CILB_BYPASS_LP_SEQ: see CILA_BYPASS_LP_SEQ above
3:0	0x2	CILB_THS_SETTLE: settle time for data lane when moving from LP to HS (LP11->LP01->LP00), this setting determines how many csicil clock cycles (72 MHz lp clock cycles) to wait, after LP00, before starting to look at the data.

26.11.20 CSI_CSI_PIXEL_PARSER_STATUS_0

Pixel Parser Status

These status bits are cleared to zero when its bit position is written with one. For example write 0x2 to CSI_PIXEL_PARSER_STATUS will clear only PPA_ILL_WD_CNT.

Offset: 21eh | Read/Write: RO | Reset: 0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx

Bit	Reset	Description
31	X	HPH_UNC_HDR_ERR: Uncorrectable Header Error, Set when the Host port header parser parses a header with a multi bit error. This error will be detected by the headers ECC, but can't be corrected. The packet will be discarded.
30	X	HPV_UNC_HDR_ERR: Uncorrectable Header Error, Set when the VI port header parser parses a header with a multi bit error. This error will be detected by the headers ECC, but can't be corrected. The packet will be discarded.
26	X	PPB_SPARE_STATUS_1: PPB Spare Status bit. This bit will get set when Pixel Parser B has a line timeout. Line timeout needs to be enabled by setting PPB_ENABLE_LINE_TIMEOUT and programming PPB_MAX_CLOCKS for the MAX clocks between lines.
25	X	PPB_INTERFRAME_LINE: Set when CSI-PPB receives a request to output a line that is not in the active part of the frame output. That is after EF and before SF, or before start marker is found. The interframe line will not be outputted by the Pixel Parser.
24	X	PPB_EXTRA_SF: Set when CSI-PPB receives a SF when it is expecting an EF. This happens when EF of the frame gets corrupted before arriving CSI. CSI-PPB will insert a fake EF and the drop the current frame with Correct SF.
23	X	PPB_SHORT_FRAME: Set when CSI-PPB receives a short frame. This bit gets set even if CSI_PPB_PAD_FRAME specifies that short frames are to be padded to the correct line length.
22	X	PPB_STMERR: Stream Error, set when the control output of PPB doesn't follow the correct sequence. The correct sequence for CSI is: SF -> (SL_DATA or EF), SL_DATA -> (DATA or EL_DATA), DATA -> EL_DATA, EL_DATA -> (SL_DATA or EF), EF -> SF. Stream Errors can be caused by receiving a corrupted stream, or a CSI RTL bug.
21	X	PPB_FIFO_OVRF: FIFO Overflow, set when the fifo that is feeding packets to PPB overflows.
20	X	PPB_PL_CRC_ERR: PayLoad CRC Error, Set when a packet that was processed by PPB had a payload CRC error.
19	X	PPB_SL_PKT_DROPPED: Short Line Packet Dropped, set when a incoming packet gets dropped because the input FIFO level reaches CSI_B_SKIP_PACKET_THRESHOLD when padding a short line.
18	X	PPB_SL_PROCESSED: Short Line Processed, Set when a line with a payload that is shorter than its packet header word count is processed by PPB.
17	X	PPB_ILL_WD_CNT: Illegal Word Count, set when a line with a word count that doesn't generate an integer number of pixels (Unused bytes at the end of payload) is processed by PPB.
16	X	PPB_HDR_ERR_COR: Header Error Corrected, set when a packet that was processed by PPB has a single bit header error. This error will be detected by the headers ECC, and corrected by it if header error correction is enabled (CSI_B_HEADER_EC_ENABLE = 0). This flag will be set and the packet will be processed even if the error is not corrected.
15	X	HPB_UNC_HDR_ERR: Uncorrectable Header Error, Set when header parser B parses a header with a multi bit error. This error will be detected by the headers ECC, but can't be corrected. The packet will be discarded. a multi bit error. This error will be detected by the headers ECC, but can't be corrected. The packet will be discarded.
14	X	HPA_UNC_HDR_ERR: Uncorrectable Header Error, Set when header parser A parses a header with a multi bit error. This error will be detected by the headers ECC, but can't be corrected. The packet will be discarded.

Bit	Reset	Description
10	X	PPA_SPARE_STATUS_1: PPA Spare Status bit. This bit will get set when Pixel Parser A has a line timeout. Line timeout needs to be enabled by setting PPA_ENABLE_LINE_TIMEOUT and programming PPA_MAX_CLOCKS for the MAX clocks between lines.
9	X	PPA_INTERFRAME_LINE: Set when CSI-PPA receives a request to output a line that is not in the active part of the frame output. That is after EF and before SF, or before start marker is found. The interframe line will not be outputted by the Pixel Parser.
8	X	PPA_EXTRA_SF: Set when CSI-PPA receives a SF when it is expecting an EF. This happens when EF of the frame gets corrupted before arriving CSI. CSI-PPA will insert a fake EF and the drop the current frame with Correct SF.
7	X	PPA_SHORT_FRAME: Set when CSI-PPA receives a short frame. This bit gets set even if CSI_PPA_PAD_FRAME specifies that short frames are to be padded to the correct line length.
6	X	PPA_STMERR: Stream Error, set when the control output of PPA doesn't follow the correct sequence. The correct sequence for CSI is: SF -> (SL_DATA or EF), SL_DATA -> (DATA or EL_DATA), DATA -> EL_DATA, EL_DATA -> (SL_DATA or EF), EF -> SF. Stream Errors can be caused by receiving a corrupted stream, or a CSI RTL bug.
5	X	PPA_FIFO_OVRF: FIFO Overflow, set when the fifo that is feeding packets to PPA overflows.
4	X	PPA_PL_CRC_ERR: PayLoad CRC Error, Set when a packet that was processed by PPA had a payload CRC error.
3	X	PPA_SL_PKT_DROPPED: Short Line Packet Dropped, set when a incoming packet gets dropped because the input FIFO level reaches CSI_A_SKIP_PACKET_THRESHOLD when padding a short line.
2	X	PPA_SL_PROCESSED: Short Line Processed, Set when a line with a payload that is shorter than its packet header word count is processed by PPA.
1	X	PPA_ILL_WD_CNT: Illegal Word Count, set when a line with a word count that doesn't generate an integer number of pixels (Unused bytes at the end of payload) is processed by PPA.
0	X	PPA_HDR_ERR_COR: Header Error Corrected, Set when a packet that was processed by PPA has a single bit header error. This error will be detected by the headers ECC, and corrected by it if header error correction is enabled (CSI_A_HEADER_EC_ENABLE = 0). This flag will be set and the packet will be processed even if the error is not corrected.

26.11.21 CSI_CSI_CIL_STATUS_0

CSI Control and Interface Logic Status

These status bits are cleared to zero when its bit position is written with one. For example write 0x2 to CSI_CIL_STATUS will clear only CILA_SOT_MB_ERR.

Offset: 21fh | Read/Write: RO | Reset: 0bxxxxxxxxxxxxxxxxxxxxxxxx

Bit	Reset	Description
22	X	CILB_ESC_DATA_REC: Escape Mode Data Received, set when CIL-B receives an Escape Mode Data byte. The Data Byte can be read from bits 23-16 of ESCAPE_MODE_DATA. This status bit will also be cleared when CILB_ESC_CMD_REC is set.
21	X	CILB_ESC_CMD_REC: Escape Mode Command Received, set when CIL-B receives an Escape Mode Command byte. The Command Byte can be read from bits 23-16 of ESCAPE_MODE_COMMAND.
20	X	CILB_CTRL_ERR: Control Error, set when CIL-B detects LP state 01 or 10 followed by a stop state (LP11) instead of transitioning into the Escape mode or Turn Around mode (LP00)..
19	X	CILB_ESC_ENTRY_ERR: Escape Mode Entry Error, set when CIL-B detects an Escape

Bit	Reset	Description
		Mode Entry Error. The Escape mode command byte will not be received.
18	X	CILB_SYNC_ESC_ERR: Sync Escape Error, set when CIL-B detects that the wrong (non-multiple of 8) number of bits have been received for an Escape Command, or Data Byte.
17	X	CILB_SOT_MB_ERR: Start of Transmission Multi Bit Error, set when CIL-B detects a multi bit start of transmission byte error in one of the packets SOT bytes. The packet will be discarded.
16	X	CILB_SOT_SB_ERR: Start of Transmission Single Bit Error, set when CIL-B detects a single bit error in one of the packets start of transmission bytes. The packet will be sent to CSI-B for processing.
15	X	MIPI_AUTO_CAL_DONE: MIPI Auto Calibrate done, set when the auto calibrate sequence for MIPI pad bricks is done.
6	X	CILA_ESC_DATA_REC: Escape Mode Data Received, set when CIL-A receives an Escape Mode Data byte. The Data Byte can be read from bits 7-0 of ESCAPE_MODE_DATA. This status bit will also be cleared when CILA_ESC_CMD_REC is set.
5	X	CILA_ESC_CMD_REC: Escape Mode Command Received, set when CIL-A receives an Escape Mode Command byte. The Command Byte can be read from bits 7-0 of ESCAPE_MODE_COMMAND.
4	X	CILA_CTRL_ERR: Control Error, set when CIL-A detects LP state 01 or 10 followed by a stop state (LP11) instead of transitioning into the Escape mode or Turn Around mode (LP00).
3	X	CILA_ESC_ENTRY_ERR: Escape Mode Entry Error, set when CIL-A detects an escape mode entry error. The Escape mode command byte will not be received.
2	X	CILA_SYNC_ESC_ERR: Sync Escape Error, set when CIL-A detects that the wrong (non-multiple of 8) number of bits have been received for an Escape Command, or Data Byte.
1	X	CILA_SOT_MB_ERR: Start of Transmission Multi Bit Error, set when CIL-A detects a multi bit start of transmission byte error in one of the packets SOT bytes. The packet will be discarded.
0	X	CILA_SOT_SB_ERR: Start of Transmission Single Bit Error, set when CIL-A detects a single bit error in one of the packets Start of Transmission bytes. The packet will be sent to the CSI-A for processing.

26.11.22 CSI_CSI_PIXEL_PARSER_INTERRUPT_MASK_0

CSI Pixel Parser Interrupt Mask

Offset: 220h | Read/Write: R/W | Reset: 0b00xx00000000000000xx000000000000

Bit	Reset	Description

26.11.24 CSI_CSI_READONLY_STATUS_0

CSI Read Only Status

This register is used to return CSI read only status.

Offset: 222h | Read/Write: RO | Reset: 0bxx

Bit	Reset	Description
1	X	CSI_PPB_ACTIVE: One only when Pixel Parser B is capturing frame data.

Bit	Reset	Description
0	X	CSI_PPA_ACTIVE: One only when Pixel Parser A is capturing frame data.

26.11.25 CSI_ESCAPE_MODE_COMMAND_0

Escape Mode Command

This register is used to receive escape mode command bytes from CIL-A and CIL-B.

Offset: 223h | Read/Write: RO | Reset: 0bxxxxxxxxxxxxxxxxxxxxxxxx

Bit	Reset	Description
23:16	X	CILB_ESC_CMD_BYTE: CIL-B Escape Mode Command Byte, this is the 8 bit entry command that was received, by CIL-B, during the last escape Mode sequence. This command byte can only be assumed to be valid when CILB_ESC_CMD_REC status bit is set.
7:0	X	CILA_ESC_CMD_BYTE: CIL-A Escape Mode Command Byte, this is the 8 bit entry command that was received, by CIL-A, during the last escape Mode sequence. CIL-A monitors Byte Lane 0, only, for escape mode sequences. This command byte can only be assumed to be valid when CILA_ESC_CMD_REC status bit is set.

26.11.26 CSI_ESCAPE_MODE_DATA_0

Escape Mode Data

This register is used to receive escape mode data bytes from CIL-A and CIL-B.

Offset: 224h | Read/Write: RO | Reset: 0bxxxxxxxxxxxxxxxxxxxxxxxx

Bit	Reset	Description
23:16	X	CILB_ESC_DATA_BYTE: CIL-B Escape Mode Data Byte, when read this field returns the last Escape Mode Data byte that was received by CIL-B. Escape Mode Data bytes are the bytes that are received in Escape Mode after receiving the Escape Mode Command. These bytes can be used to implement MIPI's CSI Specs Low Power Data Transmission. This field is only valid when the status bit, CILB_ESC_DATA_REC, is set, and will be overwritten by the next Escape Mode data byte if not read before the next byte come in.
7:0	X	CILA_ESC_DATA_BYTE: CIL-A Escape Mode Data Byte, when read this field returns the last Escape Mode Data byte that was received by CIL-A. Escape Mode Data bytes are the bytes that are received in Escape Mode after receiving the Escape Mode Command. These bytes can be used to implement MIPI's CSI Specs Low Power Data Transmission. This field is only valid when the status bit, CILA_ESC_DATA_REC, is set, and will be overwritten by the next Escape Mode data byte if not read before the next byte come in.

26.11.30 CSI_CILB_PAD_CONFIG1_0

CIL-B Pad Configuration 4

Offset: 228h | Read/Write: R/W | Reset: 0bxxxxxxxxxxxxxxxx0000000000000000

Bit	R/W	Reset	Description
31:16	RO	X	PAD_CILB_SPARE_RO: Spare Read only bits for CILB Config
15:0	RW	0x0	PAD_CILB_SPARE: Spare bits for CILB Config PAD_CILB_SPARE[15] is being used to disable the CSI-B RTL code that blocks fifo push that are past the end of the line packet. 0: disabled, 1: push blocking enabled

26.11.31 CSI_CIL_PAD_CONFIG0_0

CIL Pad Configuration 0

Offset: 229h | Read/Write: R/W | Reset: 0b00000000x000xx10

Bit	Reset	Description
15:8	0x0	PAD_CIL_SPARE: Spare bit for CIL BIAS Config PAD_CIL_SPARE[7] is used is being used to flush VI's Y-FIFO when it is being use as a stream source for one of the Pixel Parsers. Setting PAD_CIL_SPARE[7] to 1 will hold vi2csi_host_stall low. Which will force VI's Y-FIFO to be purged. PAD_CIL_SPARE[7] must be low for the pixel parser to receive source data from VI's Y-FIFO.
6:4	0x0	PAD_CIL_VADJ: VAUXP level adjustment 00 -> no adjustment, default 01 -> 105% 10 -> 110% 11 -> 115% 100 -> no adjustment 101 -> 95% 110 -> 90% 111 -> 85%
1	0x1	PAD_CIL_PDVREG: Power down voltage regulator, 1=power down
0	0x0	PAD_CIL_VBYPASS: Bypass bang gap voltage reference

26.11.32 CSI_CILA_MIPI_CAL_CONFIG_0

Calibration Settings for CIL-A MIPI pads

Offset: 22ah | Read/Write: R/W | Reset: 0b00101010xx100000xxx00000xxx00000

Bit	R/W	Reset	Description
31	RO	0x0	MIPI_CAL_STARTCAL: Writing a one to this bit starts the Calibration State machine. This bit must be set even if both overrides set in order to latch in the over ride value
30	RW	0x0	MIPI_CAL_OVERIDEA: When 0 (normal operation), use the above registers as an offset to the Calibration State machine setting for channel A TERMADJ/HSPUADJ/HSPDADJ values to the Mipi Pads. When 1, use the register values above as the actual value going to channel A TERMADJ/HSPUADJ/HSPDADJ on the Mipi Pads.
29:26	RW	0xa	MIPI_CAL_NOISE_FLT: The DRIVRY & TERMRY signals coming from MIPI Pads are utilized by Calibration state machine for PAD Calibration. The drivry/termry comes from a noisy analog source and it could have some glitches. The filter in calibsm is sensitive to these noises. If the calibration done status does not show up, we can change the sensitivity of the filter through these bits. Ideally this has to be programmed in a range from 10 to 15. For the case when MIPI_CAL_PRESCALE = 2'b00, this needs to be programmed between 2 to 5.
25:24	RW	0x2	MIPI_CAL_PRESCALE: Auto Cal calibration step prescale: Set to 00 when calibration step should be 0.1 us Set to 01 when calibration step should be 0.5 us Set to 10 when

Bit	R/W	Reset	Description
			calibration step should be 1.0 us Set to 11 when calibration step should be 1.5 us this will keep the mipi bias cal step between 0.1-1.5 usec Default set for 1.0 us calibration step.

0	X	CILB_CLK_LANE_CTRL_ERR: Control Error, set when CIL-B detects incorrect line state sequence on clock lane

[THIS PAGE INTENTIONALLY LEFT BLANK]

27.0 VIDEO INPUT (VI)

The Video Input block is normally used to receive pixels from an external device, such as a camera, and transfer them to memory. The MIPI CSI interface connects to the VI block and transfers received data to it.

This section describes the VI registers; however, it is not intended to be a programming guide to VI, as it is expected that NVIDIA supplied drivers will always be used with it. The register interface is documented to aid with understanding those drivers.

27.1 VI Registers

Refer to “Reading Register Tables” in the Introduction section for the register table protocol as well as recommendations for accessing registers.

27.1.1 VI_CTXSW_0

Context Switch Register

Should be common to all modules. Includes the current channel/class (which is writable by software) and the next channel/class (which the hardware sets when it receives a context switch).

Context switch works like this:

Any context switch request triggers an interrupt to the host and causes the new channel/class to be stored in NEXT_CHANNEL/NEXT_CLASS. Software sees that there is a context switch interrupt and does the necessary operations to make the module ready to receive traffic from the new context. It clears the context switch interrupt and writes CURR_CHANNEL/CLASS to the same value as NEXT_CHANNEL/CLASS, which causes a context switch acknowledge packet to be sent to the host. This completes the context switch and allows the host to continue sending data to the module.

Context switches can also be preloaded. If CURR_CLASS/CHANNEL are written and updated to the next CLASS/CHANNEL before the context switch request occurs, an acknowledge will be generated by the module, and no interrupt will be triggered. This is one way for software to avoid dealing with context switch interrupts.

Another way to avoid context switch interrupts is to set the AUTO_ACK bit. This bit tells the module to automatically acknowledge any incoming context switch requests without triggering an interrupt. CURR_* and NEXT_* will be updated by the module so they will always be current.

Offset: 0x20 | Read/Write: R/W | Reset: 0xf000f800 (0bxxxxxxxxxxxxxxxx11111x0000000000)

Bit	R/W	Reset	Description
31:28	RO	X	NEXT_CHANNEL: Next requested channel
25:16	RO	X	NEXT_CLASS: Next requested class
15:12	RW	0xf	CURR_CHANNEL: Current working channel, reset to 'invalid'
11	RW	0x1	AUTO_ACK: Automatically acknowledge any incoming context switch requests 0 = MANUAL 1 = AUTOACK
9:0	RW	0x0	CURR_CLASS: Current working class

27.1.2 VI_INTSTATUS_0

Offset: 0x21 | Read/Write: RO | Reset: 0x00000000 (0b0)

Bit	Reset	Description
0	0x0	CTXSW_INT: Context switch interrupt status (clear on write)

27.1.3 VI_VI_INPUT_CONTROL_0

VI Input Control

For Parallel VIP input, limitation for vsync and hsync has to be followed to avoid ISP hang:

Software must always program parallel cameras (including the VIP pattern generator) in a way that avoids simultaneous HSYNC and VSYNC active edges.

Offset: 0x22 | Read/Write: R/W | Reset: 0x00000000 (0b00000000xxxxxxxxxx0000000000000)

Upper bits are padded with 0s. 1011=YUV422 stream from the ALT mux 0 = RGB16 1 = RGB16D 2 = RGB24 3 = YUV422POST 4 = YUV422PRE 5 = JPEG_STREAM 6 = VIP_BAYER 7 = CSI_PPA_BAYER 8 = CSI_PPB_BAYER 9 = VIP_BAYER_DIRECT 10 = YUV422ALT

27.1.7 VI_HOST_INPUT_FRAME_SIZE_0

Host Input Frame Width

Input Frame Width and Height give the total input data dimensions. The VI input stage will cull/clip pixels outside the Active Region (see register VI_HOST_H_ACTIVE and VI_HOST_V_ACTIVE). The amount of data per frame is expected to be INPUT_WIDTH * INPUT_HEIGHT * the bytes per pixel (determined from the INPUT_HOST_FORMAT). For planar, the BPP is 1 for the Y FIFO and 1/2 for U and V. For non planar, it is 2.

The Bayer data is treated as 1 byte per pixel, so if it is more, then the input width and the H_ACTIVE should be scaled accordingly, so that internally generated HSYNC and VSYNCs for ISP are correct.

For Bayer input, it is important to insert blanking data for horizontal and vertical, allowing ISP to do sideband calculations.

Offset: 0x26 | Read/Write: R/W | Reset: 0x00000000 (0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx)

Bit	Reset	Description
28:16	X	INPUT_FRAME_HEIGHT: Host Input Frame Height. Specifies in terms of lines the height of the input data coming from host.
12:0	X	INPUT_FRAME_WIDTH: Specifies in terms of pixels the width of the input data coming from host.

27.1.8 VI_HOST_H_ACTIVE_0

VI Horizontal Active

This register defines the horizontal active area of the input video source with respect to the internally generated horizontal sync. (This is for data coming in from host.)

Offset: 0x27 | Read/Write: R/W | Reset: 0x00000000 (0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx)

Bit	Reset	Description
28:16	X	HOST_H_ACTIVE_PERIOD: Horizontal Active Period. This parameter specifies the number of pixels in the horizontal active area. H_ACTIVE_START + H_ACTIVE_PERIOD should be less than 2^NV_VI_H_IN (or 8192). This parameter should be programmed with an even number (bit 16 is ignored internally).

Bit	Reset	Description
12:0	X	HOST_H_ACTIVE_START: Horizontal Active Start (offset to active). This parameter specifies the number of pixels to be discarded until the first active pixel. If programmed to 0, the first active pixel is the first pixel popped from the Host YUV FIFO.

27.1.9 VI_HOST_V_ACTIVE_0

Vertical Active

This register defines the vertical active area of the input video source with respect to the internally generated vertical sync. (This is for data coming in from the host.)

Offset: 0x28 | Read/Write: R/W | Reset: 0x00000000 (0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx)

Bit	Reset	Description
28:16	X	HOST_V_ACTIVE_PERIOD: Vertical Active Period. This parameter specifies the number of lines in the vertical active area. V_ACTIVE_START + V_ACTIVE_PERIOD should be less than 2^NV_VI_V_IN (or 8192).
12:0	X	HOST_V_ACTIVE_START: Vertical Active Start (offset to active) This parameter specifies the number of horizontal sync active edges from vertical sync active edge to the first vertical active line. If programmed to 0, the first active line starts after the first horizontal sync active edge following the vertical sync active edge.

27.1.10 VI_VIP_H_ACTIVE_0

VI Horizontal Active

This register defines the horizontal active area of the input video source with respect to horizontal sync. (This is for VIP data.)

Offset: 0x29 | Read/Write: R/W | Reset: 0x00000000 (0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx)

Bit	Reset	Description
28:16	X	VIP_H_ACTIVE_PERIOD: Horizontal Active Period. This parameter specifies the number of pixels in the horizontal active area. The value is the END of the active region, so PERIOD-START = active area This parameter should be programmed with an even number
12:0	X	VIP_H_ACTIVE_START: Horizontal Active Start (offset to active). This parameter specifies the number of clock active edges from horizontal sync active edge to the first horizontal active pixel. If programmed to 0, the first active line starts after the first active clock edge following the horizontal sync active edge.

27.1.11 VI_VIP_V_ACTIVE_0

Vertical Active

This register defines the vertical active area of the input video source with respect to vertical sync. (This is for VIP data.)

Offset: 0x2a | Read/Write: R/W | Reset: 0x00000000 (0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx)

Bit	Reset	Description
28:16	X	VIP_V_ACTIVE_PERIOD: Vertical Active Period. This parameter specifies the number of lines in the vertical active area. The value is the END of the active region, so PERIOD-START = active area
12:0	X	VIP_V_ACTIVE_START: Vertical Active Start (offset to active). This parameter specifies the number of horizontal sync active edges from vertical sync active edge to the first vertical active line. If programmed to 0, the first active line starts after the first horizontal sync active edge following the vertical sync active edge.

27.1.12 VI_VI_PEER_CONTROL_0

VI Peer to Peer Control

For all fields in this register:

- 00= Disabled
- 01= First memory
- 10= Second memory
- 11= not defined

Offset: 0x2b | Read/Write: R/W | Reset: 0x00000000 (0b00000000)

Bit	Reset	Description
7:6	0x0	DISPLAY_B_CONTROL: VI to Display B Control Bus enable. The VI will send a valid buffer signal along with Y,U,V buffer addresses and Frame Start and Frame End 0 = DISABLED 1 = FIRST 2 = SECOND
5:4	0x0	SB_CONTROL: VI to StretchBLT Control Bus enable. The VI will send a valid buffer signal along with buffer index and Frame Start and Frame End The VI to SB control bus is separate from the VI to JPEGE/MPEGE bus. This control bus is controlled by the "2nd Output to MC" write client interface. 0 = DISABLED 1 = FIRST 2 = SECOND
3:2	0x0	ENCODER_CONTROL: VI to JPEGE and MPEGE Control Bus enable. VI will send a valid buffer signal along with buffer index and Frame Start and Frame End 0 = DISABLED 1 = FIRST 2 = SECOND
1:0	0x0	DISPLAY_CONTROL: VI to Display Control Bus enable. The VI will send a valid buffer signal along with Y,U,V buffer addresses and Frame Start and Frame End 0 = DISABLED 1 = FIRST 2 = SECOND

27.1.13 VI_VI_DMA_SELECT_0

Host DMA select

Offset: 0x2c | Read/Write: R/W | Reset: 0x00000000 (0b00)

Bit	Reset	Description
1:0	0x0	DMA_REQUEST: Host DMA Request enable at end of block. Request to host DMA can be enabled every time a block of video input data is written to memory. 00= Disabled 01= Write Buffer DMA for RAW data stream 10= First memory 11= Second memory 0 = DISABLED 1 = STREAM 2 = FIRST 3 = SECOND

27.1.14 VI_HOST_DMA_WRITE_BUFFER_0

Host DMA Write Buffer Configuration Registers

Offset: 0x2d | Read/Write: R/W | Reset: 0x00000000 (0b000xxxxxxxxxxxxxxxxxxxxxxxxx)

Bit	Reset	Description
27:26	0x0	SOURCE_SEL: Data source selection 00= VIP (backward compatible) 01= CSI_PPA 10= CSI_PPB 0 = VIP 1 = CSI_PPA 2 = CSI_PPB
25	0x0	DMA_ENABLE: DMA Enable 0 = DISABLED 1 = ENABLED
24:16	X	BUFFER_NUMBER: Buffer Number
15:0	X	BUFFER_SIZE: Buffer Size

27.1.15 VI_HOST_DMA_BASE_ADDRESS_0

Host DMA Write Buffer Configuration Registers

Offset: 0x2e | Read/Write: R/W | Reset: 0x00000000 (0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx)

Bit	Reset	Description
31:0	X	DMA_BASE_ADDR: Base Address

27.1.16 VI_HOST_DMA_WRITE_BUFFER_STATUS_0

Host DMA Write Buffer Status Register

Offset: 0x2f | Read/Write: RO | Reset: 0x00000000 (0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx)

Bit	Reset	Description
26:0	X	WB_STATUS: Status of the Host DMA write buffer

27.1.17 VI_HOST_DMA_WRITE_PEND_BUFCOUNT_0

Host DMA Write Buffer Pending Buffer Count

Offset: 0x30 | Read/Write: RO | Reset: 0x00000000 (0bxxxxxxxxxx)

Bit	Reset	Description
8:0	X	PEND_BUFCOUNT: Pending buffer count of the Host DMA write buffer.

27.1.18 VI_VB0_START_ADDRESS_FIRST_0

Video Buffer O Start Address for First Output

First Output Registers

These registers are used to setup the first of two memory outputs for VI Address Y, U, V; Frame size; Count; Size (line stride and block height); and Buffer Stride

Offset: 0x31 | Read/Write: R/W | Reset: 0x00000000 (0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx)

Bit	Reset	Description
31:0	X	VB0_START_ADDRESS_1: This is the byte address of video buffer 0 if output data format is RGB or YUV non-planar. This is the byte address of video buffer 0 Y-plane if output data format is YUV planar.

27.1.19 VI_VB0_BASE_ADDRESS_FIRST_0

Video Buffer O BASE Address for First Output

BASE address is used in Tiling mode. The BASE address always points to the left_upper corner of a surface. A surface can contain multiple buffers, in circular_buffer case.

Writes to the BASE address register will cause the corresponding internal buffer index to be reset to zero.

Offset: 0x32 | Read/Write: R/W | Reset: 0x00000000 (0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx)

Bit	Reset	Description
31:0	X	VB0_BASE_ADDRESS_1: This is the first byte address of video buffer 0. This is the byte address of video buffer 0 Y-plane if output data format is planar.

27.1.20 VI_VB0_START_ADDRESS_U_0

Video Buffer O Start Address U (linked to First Output)

Offset: 0x33 | Read/Write: R/W | Reset: 0x00000000 (0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx)

Bit	Reset	Description
31:0	X	VB0_START_ADDRESS_U: This is the byte address of video buffer 0 U-plane, if output data format is YUV planar. Due to clock gating, the primary OUTPUT_TO_MEMORY must be enabled and the OUTPUT_FORMAT must be set to a planar format prior to writing this register

27.1.21 VI_VB0_BASE_ADDRESS_U_0

Video Buffer O BASE Address U (linked to First Output)

Offset: 0x34 | Read/Write: R/W | Reset: 0x00000000 (0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx)

Bit	Reset	Description
31:0	X	VB0_BASE_ADDRESS_U: This is the first byte address of video buffer 0 U-plane, if output data format is planar.

27.1.22 VI_VB0_START_ADDRESS_V_0

Video Buffer O Start Address V (linked to First Output)

Offset: 0x35 | Read/Write: R/W | Reset: 0x00000000 (0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx)

Bit	Reset	Description
31:0	X	VB0_START_ADDRESS_V: This is the byte address of video buffer 0 V-plane, if output data format is YUV planar. Due to clock gating, the primary OUTPUT_TO_MEMORY must be enabled and the OUTPUT_FORMAT must be set to a planar format prior to writing this register

27.1.23 VI_VB0_BASE_ADDRESS_V_0

Video Buffer O BASE Address V (linked to First Output)

Offset: 0x36 | Read/Write: R/W | Reset: 0x00000000 (0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx)

Bit	Reset	Description
31:0	X	VB0_BASE_ADDRESS_V: This is the byte address of video buffer 0 V-plane, if output data format is YUV planar.

27.1.24 VI_VB0_SCRATCH_ADDRESS_UV_0

Video Buffer O Scratch Address UV (linked to First Output)

Offset: 0x37 | Read/Write: R/W | Reset: 0x00000000 (0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx)

Bit	Reset	Description
31:0	X	VB0_SCRATCH_ADDRESS_UV: If OUTPUT_FORMAT is YUV420PA, this is used. This is the byte address of video buffer 0. UV intermediate data is saved here during the YUV422 to YUV420PA conversion. The size allocated needs to match the FIRST_FRAME_WIDTH register setting.

27.1.25 VI_FIRST_OUTPUT_FRAME_SIZE_0

Width and Height of First Output Frame

This is the size of the frame being written to memory. Apply decimation or averaging to calculate the output frame size. Whether or not downscaling is used specify whatever the size of the frame being written to memory.

Offset: 0x38 | Read/Write: R/W | Reset: 0x00000000 (0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx)

Bit	Reset	Description
28:16	X	FIRST_FRAME_HEIGHT: Frame height in lines which the VI needs to process
12:0	X	FIRST_FRAME_WIDTH: Frame width in pixel which the VI needs to process

27.1.26 VI_VB0_COUNT_FIRST_0

Video Buffer Set 0 Count for First Output

Offset: 0x39 | Read/Write: R/W | Reset: 0x00000000 (0bxxxxxxxx)

Bit	Reset	Description
7:0	X	VB0_COUNT_1: Video Buffer Set 0 Count. This specifies the number of buffers in video buffer set 0.

27.1.27 VI_VB0_SIZE_FIRST_0

Video Buffer Set 0 Size for First Output

Offset: 0x3a | Read/Write: R/W | Reset: 0x00000000 (0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx)

Bit	Reset	Description
28:16	X	VB0_V_SIZE_1: Video Buffer Set 0 Vertical Size. This specifies the number of lines in each buffer in video buffer set 0. This value will be divided by 2 for chroma buffers for YUV420 planar formats
12:0	X	VB0_H_SIZE_1: Video Buffer Set 0 Horizontal Size. This parameter specifies the line stride (in pixels) for lines in the video buffer set 0. For YUV non-planar format, this parameter must be programmed as multiple of 2 pixels (bit 0 is ignored). For YUV planar format, this parameter must be programmed as multiple of 8 pixels (bits 2-0 are ignored) and it specifies the luma line stride or twice the chroma line stride. This value is divided by 2 for chroma buffers for YUV422 and YUV420 planar formats

27.1.28 VI_VB0_BUFFER_STRIDE_FIRST_0

Video Buffer Set 0 Buffer Stride

Offset: 0x3b | Read/Write: R/W | Reset: 0x00000000 (0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx)

Bit	Reset	Description
31:30	X	VB0_BUFFER_STRIDE_C: Video Buffer Set 0 Chroma Buffer Stride 00= Equal to Luma Buffer Stride 01= Equal to Luma Buffer Stride divided by 2 in this case Luma Buffer Stride should be multiple of 2 bytes. 10= Equal to Luma Buffer Stride divided by 4 in this case Luma Buffer Stride should be multiple of 4 bytes. 1x= Reserved 0 = CBS1X 1 = CBS2X 2 = CBS4X
29:0	X	VB0_BUFFER_STRIDE_L: Video Buffer Set 0 Luma Buffer Stride This is luma buffer stride (in bytes)

27.1.29 VI_VB0_START_ADDRESS_SECOND_0

Video Buffer O Start Address for Second Output

Second Output Registers

These registers are used to set up the second of two memory outputs for VI Address; Frame size; Count; Size (line stride and block height); and Buffer Stride.

Offset: 0x3c | Read/Write: R/W | Reset: 0x00000000 (0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx)

Bit	Reset	Description
31:0	X	VB0_START_ADDRESS_2: This is byte address of video buffer 0 if output data format is RGB or YUV non-planar. This is byte address of video buffer 0. This output data is read by the SB function of the GR2D block.

27.1.30 VI_VB0_BASE_ADDRESS_SECOND_0

Video Buffer O Base Address for Second Output

Offset: 0x3d | Read/Write: R/W | Reset: 0x00000000 (0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx)

Bit	Reset	Description
31:0	X	VB0_BASE_ADDRESS_2: This is the byte address of video buffer 0, if output data format is RGB or non-planar. This is the first byte address of the video buffer

27.1.31 VI_SECOND_OUTPUT_FRAME_SIZE_0

Width and Height of Second Output Frame

Offset: 0x3e | Read/Write: R/W | Reset: 0x00000000 (0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx)

Bit	Reset	Description
28:16	X	SECOND_FRAME_HEIGHT: frame height in lines which the VI needs to process
12:0	X	SECOND_FRAME_WIDTH: frame width in pixel which the VI needs to process

27.1.32 VI_VB0_COUNT_SECOND_0

Video Buffer Set 0 Count for Second Output

Offset: 0x3f | Read/Write: R/W | Reset: 0x00000000 (0bxxxxxxxx)

Bit	Reset	Description
7:0	X	VB0_COUNT_2: This specifies the number of buffers in video buffer set 0.

27.1.33 VI_VB0_SIZE_SECOND_0

Video Buffer Set 0 Size for Second Output

Offset: 0x40 | Read/Write: R/W | Reset: 0x00000000 (0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx)

Bit	Reset	Description
28:16	X	VB0_V_SIZE_2: Video Buffer Set 0 Vertical Size. This specifies the number of lines in each buffer in video buffer set 0.
12:0	X	VB0_H_SIZE_2: Video Buffer Set 0 Horizontal Size. This parameter specifies the line stride (in pixels) for lines in the video buffer set 0. For YUV non-planar format, this parameter must be programmed as multiple of 2 pixels (bit 0 is ignored).

27.1.34 VI_VB0_BUFFER_STRIDE_SECOND_0

Video Buffer Set 0 Buffer Stride for Second Output

Offset: 0x41 | Read/Write: R/W | Reset: 0x00000000 (0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx)

Bit	Reset	Description
29:0	X	VB0_BUFFER_STRIDE_2: Video Buffer Set 0 Luma Buffer Stride. This is luma buffer stride (in bytes)

27.1.35 VI_H_LPF_CONTROL_0

VI Horizontal Low-Pass Filter (LPF) Control

Offset: 0x42 | Read/Write: R/W | Reset: 0x02400240 (0b0001001000000xxx0001001000000)

Bit	Reset	Description
28:16	0x240	H_LPF_C: Horizontal LPF Chrominance filter. This controls low-pass filter for U V data.
12:0	0x240	H_LPF_L: Horizontal LPF Luminance filter. This controls low-pass filter for Y data.

27.1.36 VI_H_DOWNSCALE_CONTROL_0

VI Horizontal Downscaling Control

Horizontal pixel processing starts with horizontal low-pass filtering.

Following horizontal low-pass filtering, horizontal downscaling (decimation) can then be performed with or without horizontal averaging.

If horizontal down-scaling (decimation) is performed without horizontal averaging, the down-scaling factor is specified by input active period and output frame size. Because the VI has two input methods (VIP and HOST) and two memory outputs, there are mux selects to indicate which registers to use in calculating the input and output frame sizes.

If horizontal downscaling is performed with horizontal averaging, the down-scaling factors are limited to few factors determined by H_AVG_CONTROL. When enabling averaging PLEASE be careful that the input and output ratios match the formula for the averaging decimation ratio exactly to the pixel/line.

The formulae for each of the Averaging Decimation Ratio are as follows:

- x = input size
- y(x) = output size
- 2-pixel averaging and 1/2 downscaling: y(x) = Floor(x/2)
- 4-pixel averaging and 1/3 downscaling: y(x) = Floor((x-1)/3)
- 4-pixel averaging and 1/4 downscaling: y(x) = Floor(x/4)
- 8-pixel averaging and 1/7 downscaling: y(x) = Floor((x-1)/7)
- 8-pixel averaging and 1/8 downscaling: y(x) = Floor(x/8)

Horizontal Decimation Algorithm

The Horizontal Decimator decides which pixels to drop by using a simple DDA algorithm. The accumulator will continue to add the value of the output width (numerator) for each pixel until the sum is equal to or greater than the input width (denominator). When the sum is greater than or equal to the input width (denominator), the hardware will flag that pixel as a pixel to be written out to memory. At the same time, the input width (denominator) will be subtracted from the sum, and the difference will be loaded back into the accumulator for the next line. By default the accumulator is initialized with 0's upon reset. However, the user can set the H_DEC_INIT_VAL to initialize the accumulator with a certain value from 0 to the input width (denominator). Any H_DEC_INIT_VAL that is greater or equal to the difference of the input width (denominator) and the output width (numerator) will cause the first pixel to be written out to memory. This register shifts the phase of the decimation pattern.

Offset: 0x43 | Read/Write: R/W | Reset: 0x00000000 (0b0000000000000xxxxxxxxxxxx00xx)

Bit	Reset	Description
28:16	0x0	H_DEC_INIT_VAL: Horizontal Decimation Accumulator Initial Value. The user may initialize the H-Dec accumulator with a value between 0-(H_ACTIVE_PERIOD) to change the phase of the decimation pattern. This will allow the user to decide which is the first pixel to keep.
10:8	X	H_AVG_CONTROL: Horizontal Averaging Control. This specifies the number of pixels to average and to decimate horizontally. 000= 2-pixel averaging and 1/2 downscaling 001= 4-pixel averaging and 1/3 downscaling 010= 4-pixel averaging and 1/4 downscaling 011= 8-pixel averaging and 1/7 downscaling 100= 8-pixel averaging and 1/8 downscaling other= reserved 0 = A2D2 1 = A4D3 2 = A4D4 3 = A8D7 4 = A8D8

Bit	Reset	Description
3:2	0x0	INPUT_H_SIZE_SEL_EXT: Selects input horizontal size into scalers (extension field) 00= Horizontal size selected with INPUT_H_SIZE_SEL field (backward compatible) 01= Horizontal size of CSI_PPA is provided by CSI_PPA_H_ACTIVE register 10= Horizontal size of CSI_PPB is provided by CSI_PPB_H_ACTIVE register 11= Horizontal size of ISP is provided by ISP_H_ACTIVE register 0 = USE_INPUT_H_SIZE_SEL 1 = CSI_PPA 2 = CSI_PPB 3 = ISP
1	X	OUTPUT_H_SIZE_SEL: Output Horizontal Size Select. Selects between the first and second memory output frame widths for the numerator in the downscaling ratio. Uses FIRST_FRAME_WIDTH or SECOND_FRAME_WIDTH. This is effective only when H_AVERAGING is DISABLED and H_DOWNSCALING is ENABLED. 0 = FIRST 1 = SECOND
0	X	INPUT_H_SIZE_SEL: Input Horizontal Size Select. Selects between the VIP and HOST input active area widths for the denominator in the downscaling ratio. Uses VIP_H_ACTIVE_PERIOD or HOST_H_ACTIVE_PERIOD, which is the width of the data after cropping. This is effective only when H_AVERAGING is DISABLED and H_DOWNSCALING is ENABLED. 0 = VIP 1 = HOST

27.1.37 VI_V_DOWNSCALE_CONTROL_0

VI Vertical Down-scaling Control

Vertical processing consists of optional vertical downscaling (decimation) which can be performed with or without vertical averaging.

If vertical downscaling (decimation) is performed without vertical averaging, the down-scaling factor is specified by input active period and output frame size. Because the VI has two input methods (VIP and HOST) and two memory outputs, there are mux selects to indicate which registers to use in calculating the input and output frame sizes.

If horizontal down-scaling is performed with vertical averaging, the downscaling factors are limited to few factors determined by V_AVG_CONTROL. When enabling averaging, you must ensure that the input and output ratios match the formula for the averaging decimation ratio exactly to the pixel/line.

The formulae for each of the Averaging Decimation Ratio are as follows:

- x = input size
- y(x) = output size
- 2-pixel averaging and 1/2 downscaling: y(x) = Floor(x/2)
- 4-pixel averaging and 1/3 downscaling: y(x) = Floor((x-1)/3)
- 4-pixel averaging and 1/4 downscaling: y(x) = Floor(x/4)
- 8-pixel averaging and 1/7 downscaling: y(x) = Floor((x-1)/7)
- 8-pixel averaging and 1/8 downscaling: y(x) = Floor(x/8)

Vertical Decimation Algorithm (same as the Horizontal Decimation Algorithm)

The Vertical Decimator decides which pixels to drop by using a simple DDA algorithm. The accumulator will continue to add the value of the output height (numerator) for each line until the sum is equal to or greater than the input height (denominator). When the sum is greater than or equal to the input height (denominator), the hardware will flag that line as a line to be written out to memory. At the same time, the input height (denominator) will be subtracted from the sum, and the difference will be loaded back into the accumulator for the next line. By default the accumulator is initialized with 0's upon reset. However, the user can set the V_DEC_INIT_VAL to initialize the accumulator with a certain value from 0 to the input height (denominator).

Any V_DEC_INIT_VAL that is greater or equal to the difference of the input height (denominator), and the output height (numerator) will cause the first line to be written out to memory. This register shifts the phase of the decimation pattern.

Offset: 0x44 | Read/Write: R/W | Reset: 0x00000000 (0b0000000000000xxxxxxxxxxxx00xx)

Bit	Reset	Description
28	X	IGNORE_FIELD: Specifies whether odd/even field affects vertical decimation. 0 = disabled - odd/even field affects the vertical downscaling 1 = enabled - field is ignored in vertical downscaling 0 = DISABLED 1 = ENABLED
28:16	0x0	V_DEC_INIT_VAL: Vertical Decimation Accumulator Initial Value The user may initialize the V-Dec accumulator with a value between 0-(V_ACTIVE_PERIOD) to change the phase of the decimation pattern. This will allow the user to decide which is the first line to keep.
13	X	MULTI_TAP_V_AVG_FILTER: Multi-Tap Vertical Averaging Filter 0 = disabled 1 = enabled. This will enable the Multi-Tap filtering when the Vertical Averaging is enabled. The filter settings will depend on the V_AVG_CONTROL value. 000 - 3 Taps (1,2,1)/4 001 - 5 Taps (1,2,2,2,1)/8 010 - 6 Taps (1,1,2,2,1,1)/8 011 - 11 Taps (1,1,1,2,2,2,2,2,1,1,1)/16 100 - 12 Taps (1,1,1,1,2,2,2,2,1,1,1,1)/16 0 = DISABLED 1 = ENABLED
12	X	FLEXIBLE_VSCALE: Flexible Vertical Scaling 0 = disabled, V_AVG_CONTROL specifies both vertical averaging and downscaling factor. 1 = enabled, fixed 2-line averaging with vertical downscaling controlled by V_DOWN_N and V_DOWN_D. 0 = DISABLED 1 = ENABLED
10:8	X	V_AVG_CONTROL: Vertical Averaging Control. This specifies the number of lines to average and to decimate vertically. 000= 2-line averaging and 1/2 downscaling 001= 4-line averaging and 1/3 downscaling 010= 4-line averaging and 1/4 downscaling 011= 8-line averaging and 1/7 downscaling 100= 8-line averaging and 1/8 downscaling other= reserved 0 = A2D2 1 = A4D3 2 = A4D4 3 = A8D7 4 = A8D8
3:2	0x0	INPUT_V_SIZE_SEL_EXT: Selects input vertical size into scalers (extension field) 00= Vert. size selected with INPUT_V_SIZE_SEL field (backward compatible) 01= Vert. size of CSI_PPA is provided by CSI_PPA_V_ACTIVE register 10= Vert. size of CSI_PPB is provided by CSI_PPB_V_ACTIVE register 11= Vert. size of ISP is provided by ISP_V_ACTIVE register 0 = USE_INPUT_V_SIZE_SEL 1 = CSI_PPA 2 = CSI_PPB 3 = ISP
1	X	OUTPUT_V_SIZE_SEL: Output Vertical Size Select. Selects between the first and second memory output frame heights for the numerator in the downscaling ratio. Uses FIRST_FRAME_HEIGHT or SECOND_FRAME_HEIGHT. This is effective only when V_AVERAGING is DISABLED and V_DOWNSCALING is ENABLED. 0 = FIRST 1 = SECOND

Bit	Reset	Description
0	X	INPUT_V_SIZE_SEL: Input Vertical Size Select Selects between the VIP and HOST input active area heights for the denominator in the downscaling ratio. Uses VIP_V_ACTIVE_PERIOD or HOST_V_ACTIVE_PERIOD, which is the height of the data after cropping. This is effective only when V_AVERAGING is DISABLED and V_DOWNSCALING is ENABLED. 0 = VIP 1 = HOST

27.1.38 VI_CSC_Y_0

CSC Y Offset and Gain

Color Space Conversion coefficients.

The CSC can be used for YUV to RGB conversion with brightness and hue/saturation control.

For Y color, the Y offset is applied first and saturation (clipping) is performed immediately after the Y offset is applied.

R = sat(KYRGB * sat(Y + YOF) + KUR * U + KVR * V)

G = sat(KYRGB * sat(Y + YOF) + KUG * U + KVG * V)

B = sat(KYRGB * sat(Y + YOF) + KUB * U + KVB * V)

Saturation and rounding is performed in the range of 0 to 255 for the above equations.

Typical values are:

YOF = -16.000, KYRGB = 1.1644

KUR = 0.0000, KVR = -1.5960

KUG = -0.3918, KVG = -0.8130

KUB = 2.0172, KVB = 0.0000

KUR and KVB are typically 0.0000 but they may be programmed non-zero for hue rotation.

The CSC can also take RGB input, in which case YOF, KVB, KUG, KUR should be programmed to 0, and KYRGB will be forced to 0 by the hardware for generating R and B. KYRGB will not be forced to 0 for generating G. KVR, KYRGB, and KUB can be programmed to 1.0 or used as gain control for R, G, B correspondingly.

Note that color value ranges from 0 to 255 for Y, R, G, B and -128 to 127 for U and V.

Offset: 0x45 | Read/Write: R/W | Reset: 0x00000000 (0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx)

Bit	Reset	Description
25:16	X	KYRGB: Y Gain for R, G, B colors in 2.8 format
7:0	X	YOF: Y Offset in s.7.0 format

27.1.39 VI_CSC_UV_R_0

CSC U & V coefficient for R

Offset: 0x46 | Read/Write: R/W | Reset: 0x00000000 (0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx)

Bit	Reset	Description
26:16	X	KVR: V coefficients for R in s.2.8 format
10:0	X	KUR: U coefficients for R in s.2.8 format

27.1.40 VI_CSC_UV_G_0

CSC U & V coefficient for G

Offset: 0x47 | Read/Write: R/W | Reset: 0x00000000 (0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx)

Bit	Reset	Description
25:16	X	KVG: V coefficients for G in s.1.8 format
9:0	X	KUG: U coefficients for G in s.1.8 format

27.1.41 VI_CSC_UV_B_0

CSC U & V coefficient for B

Offset: 0x48 | Read/Write: R/W | Reset: 0x00000000 (0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx)

Bit	Reset	Description
26:16	X	KVB: V coefficients for B in s.2.8 format
10:0	X	KUB: U coefficients for B in s.2.8 format

27.1.42 VI_CSC_ALPHA_0

RGB Color Space Converter Alpha value

Offset: 0x49 | Read/Write: R/W | Reset: 0x00000000 (0b00000000)

Bit	Reset	Description
7:0	0x0	RGB888_ALPHA: When output format to memory is selected for RGB888, the pixel data is 32-bit aligned. The value programmed here will be appended to the RGB888 data as the 8 MSBs and can be used as an alpha value.

27.1.43 VI_HOST_VSYNC_0

Valid when INPUT_SOURCE is HOST

Offset: 0x4a | Read/Write: RO | Reset: 0x00000000 (0bx)

Bit	Reset	Description
0	X	HOST_VSYNC_TRIGGER: This triggers VI's internal VSYNC generation. Always write once to this register with '1' before writing the Frame's data to Y_FIFO_DATA

27.1.44 VI_COMMAND_0

VI Command

This register is used initialize VI module when INPUT_SOURCE is HOST.

This register has a dual use purpose. Host input VSYNC is created by writing to this register.

Offset: 0x4b | Read/Write: R/W | Reset: 0x00000000 (0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx0)

Bit	Reset	Description
28:16	X	V_COUNTER_THRESHOLD: Vertical Counter Threshold. This specifies a threshold which, when exceeded, would generate the vertical counter interrupt if the interrupt is enabled. This is used to detect the case when the host is sending too many input data than expected by VI module.
11:8	X	Y_FIFO_THRESHOLD: Y-FIFO Threshold. This specifies maximum number of filled locations in Y-FIFO for the Y-FIFO Threshold Status bit.

Bit	Reset	Description
0	0x0	PROCESS_FIELD: Process Odd/Even field (effective when INPUT_SOURCE is HOST). Writing to this bit will initialize VI to receive one field of video. 0= odd field 1= even field 0 = ODD 1 = EVEN

27.1.45 VI_HOST_FIFO_STATUS_0

Host FIFO status

This is not needed if host input video goes through command buffer interface.

Offset: 0x4c | Read/Write: RO | Reset: 0x00000000 (0bxxxxxxxxxxxxxxxx)

Bit	Reset	Description
14:12	X	V_FIFO_STATUS: This indicates the number of filled locations in V-FIFO. If the returned value is 3'h0, the FIFO is empty and if the returned value is 3'h7 then the FIFO is full.
10:8	X	U_FIFO_STATUS: This indicates the number of filled locations in U-FIFO. If the returned value is 3'h0, the FIFO is empty and if the returned value is 3'h7 then the FIFO is full.
3:0	X	Y_FIFO_STATUS: This indicates the number of filled locations in Y-FIFO. If the returned value is 4'h0, the FIFO is empty and if the returned value is 4'hF then the FIFO is full.

27.1.46 VI_INTERRUPT_MASK_0

Interrupt Mask

Offset: 0x4d | Read/Write: R/W | Reset: 0x00000000 (0b00000000x00000000000000000000)

Bit	Reset	Description
28	0x0	SECOND_OUTPUT_DROP_MC_DATA_INT_MASK: This bit controls interrupt when VI drops data to the MC. 0 = DISABLED 1 = ENABLED
27	0x0	FIRST_OUTPUT_DROP_MC_DATA_INT_MASK: This bit controls interrupt when VI drops data to the MC. 0 = DISABLED 1 = ENABLED
26	0x0	TS_OTHER_PROTOCOL_ERROR_INT_MASK: This bit controls interrupt when the ISDB-T input get a packet which means FEC+BODY in total size but FEC and BODY do not match FEC_SIZE and BODY_SIZE 0 = DISABLED 1 = ENABLED
25	0x0	TS_OVERRUN_ERROR_INT_MASK: This bit controls interrupt when the ISDB-T input get an overrun error 0 = DISABLED 1 = ENABLED
24	0x0	TS_UNDERRUN_ERROR_INT_MASK: This bit controls interrupt when the ISDB-T input get an underrun error 0 = DISABLED 1 = ENABLED
23	0x0	TS_UPSTREAM_ERROR_INT_MASK: This bit controls interrupt when the ISDB-T vi input gets an upstream error. 0 = DISABLED 1 = ENABLED
22	0x0	RAISE_STREAM_2_INT_MASK: Stream 2 raise. This bit controls interrupt when the the Stream 2 Raise is enabled and returned 0 = DISABLED 1 = ENABLED

Bit	Reset	Description
21	0x0	RAISE_STREAM_1_INT_MASK: Stream 1 raise. This bit controls interrupt when the the Stream 1 Raise is enabled and returned 0 = DISABLED 1 = ENABLED
19	0x0	DMA_STALL_INT_MASK: Write Buffer DMA to VI. Stalls VI and causes an error This bit controls interrupt when the VI drops raw 8-bit stream data because the Write Buffer DMA is stalling. 0 = DISABLED 1 = ENABLED
18	0x0	SECOND_OUTPUT_PEER_STALL_INT_MASK: VI to Peer stall - Second Memory Output This bit controls interrupt when the VI drops peer bus packet(s) because the peer is stalling the second output peer bus and data is coming from the pins 0 = DISABLED 1 = ENABLED
17	0x0	FIRST_OUTPUT_PEER_STALL_INT_MASK: VI to Peer stall - First Memory Output. This bit controls interrupt when the VI drops peer bus packet(s) because the peer is stalling the first output peer bus and data is coming from the pins 0 = DISABLED 1 = ENABLED
16	0x0	YUV420PA_ERROR_INT_MASK: YUV420PA Error Interrupt Mask. This bit controls interrupt when the VI does not average data because the line buffer data is not ready from the memory controller. The VI will write unaveraged data and will write the U,V data from the even line in such cases. 0 = DISABLED 1 = ENABLED
15	0x0	EPP_ERROR_INT_MASK: VI to EPP Error Interrupt Mask. This bit controls interrupt when the VI drops data to the EPP because the EPP is stalling the vi2epp bus and data is coming from the pins 0 = DISABLED 1 = ENABLED
14	0x0	FRAME_SECOND_OUTPUT_INT_MASK: Buffer Done Second Output Interrupt Mask. This bit controls interrupt when the Second Output to memory has written a frame to memory. 0 = DISABLED 1 = ENABLED
13	0x0	BUFFER_SECOND_OUTPUT_INT_MASK: Buffer Done Second Output Interrupt Mask This bit controls interrupt when the Second Output to memory has written a buffer to memory. 0 = DISABLED 1 = ENABLED
12	0x0	FRAME_FIRST_OUTPUT_INT_MASK: Frame Done First Output Interrupt Mask This bit controls interrupt when the First Output to memory has written a frame to memory. 0 = DISABLED 1 = ENABLED
11	0x0	BUFFER_FIRST_OUTPUT_INT_MASK: Buffer Done First Output Interrupt Mask This bit controls interrupt when the First Output to memory has written a buffer to memory. 0 = DISABLED 1 = ENABLED
10	0x0	Y_THRESHOLD_INT_MASK: Y-FIFO Threshold Interrupt Mask This bit controls interrupt when the number of filled locations in Y-FIFO is equal or greater than the Y_FIFO_THRESHOLD value. This bit should be set to 1 only when INPUT_SOURCE is HOST. 0 = DISABLED 1 = ENABLED
9	0x0	V_COUNTER_INT_MASK: Vertical Counter Interrupt Mask (effective when VIDEO_SOURCE is HOST) This bit controls interrupt when the vertical counter threshold is reached. 0 = DISABLED 1 = ENABLED
8	0x0	VVS_INT_MASK: VVS pin Interrupt Mask This bit controls interrupt when VVS rising/falling edge is detected. 0 = DISABLED 1 = ENABLED

Bit	Reset	Description
7	0x0	VHS_INT_MASK: VHS pin Interrupt Mask This bit controls interrupt when VHS rising/falling edge is detected. 0 = DISABLED 1 = ENABLED
6	0x0	VGP6_INT_MASK: VGP6 pin Interrupt Mask This bit controls interrupt when VGP6 rising/falling edge is detected. 0 = DISABLED 1 = ENABLED
5	0x0	VGP5_INT_MASK: VGP5 pin Interrupt Mask This bit controls interrupt when VGP5 rising/falling edge is detected. 0 = DISABLED 1 = ENABLED
4	0x0	VGP4_INT_MASK: VGP4 pin Interrupt Mask. This bit controls interrupt when VGP4 rising/falling edge is detected. 0 = DISABLED 1 = ENABLED
3	0x0	VD11_INT_MASK: VD11 pin Interrupt Mask. This bit controls interrupt when VD11 rising/falling edge is detected. 0 = DISABLED 1 = ENABLED
2	0x0	VD10_INT_MASK: VD10 pin Interrupt Mask. This bit controls interrupt when VD10 rising/falling edge is detected. 0 = DISABLED 1 = ENABLED
1	0x0	VD9_INT_MASK: VD9 pin Interrupt Mask. This bit controls interrupt when VD9 rising/falling edge is detected. 0 = DISABLED 1 = ENABLED
0	0x0	VD8_INT_MASK: VD8 pin Interrupt Mask. This bit controls interrupt when VD8 rising/falling edge is detected. 0 = DISABLED 1 = ENABLED

27.1.47 VI_INTERRUPT_TYPE_SELECT_0

Interrupt Type Select

Offset: 0x4e | Read/Write: R/W | Reset: 0x00000000 (0b000000000)

Bit	Reset	Description
8	0x0	VVS_INT_TYPE: VVS pin Interrupt Type. This bit controls interrupt VVS 0 = EDGE 1 = LEVEL
7	0x0	VHS_INT_TYPE: VHS pin Interrupt Type. This bit controls interrupt VHS 0 = EDGE 1 = LEVEL
6	0x0	VGP6_INT_TYPE: VGP6 pin Interrupt Type. This bit controls interrupt VGP6 0 = EDGE 1 = LEVEL
5	0x0	VGP5_INT_TYPE: VGP5 pin Interrupt Type. This bit controls interrupt VGP5 0 = EDGE 1 = LEVEL
4	0x0	VGP4_INT_TYPE: VGP4 pin Interrupt Type. This bit controls interrupt VGP4 0 = EDGE 1 = LEVEL

Bit	Reset	Description
3	0x0	VD11_INT_TYPE: VD11 pin Interrupt Type. This bit controls interrupt VD11 0 = EDGE 1 = LEVEL
2	0x0	VD10_INT_TYPE: VD10 pin Interrupt Type. This bit controls interrupt VD10 0 = EDGE 1 = LEVEL
1	0x0	VD9_INT_TYPE: VD9 pin Interrupt Type. This bit controls interrupt VD9 0 = EDGE 1 = LEVEL
0	0x0	VD8_INT_TYPE: VD8 pin Interrupt Type. This bit controls interrupt VD8 if edge or level type 0 = EDGE 1 = LEVEL

27.1.48 VI_INTERRUPT_POLARITY_SELECT_0

Interrupt Polarity Select

Offset: 0x4f | Read/Write: R/W | Reset: 0x00000000 (0b000000000)

Bit	Reset	Description
8	0x0	VVS_INT_POLARITY: VVS pin Interrupt Type. This bit controls interrupt VVS 0= falling edge or low level 1= rising edge or high level 0 = LOW 1 = HIGH
7	0x0	VHS_INT_POLARITY: VHS pin Interrupt Type. This bit controls interrupt VHS 0= falling edge or low level 1= rising edge or high level 0 = LOW 1 = HIGH
6	0x0	VGP6_INT_POLARITY: VGP6 pin Interrupt Type. This bit controls interrupt VGP6 0= falling edge or low level 1= rising edge or high level 0 = LOW 1 = HIGH
5	0x0	VGP5_INT_POLARITY: VGP5 pin Interrupt Type. This bit controls interrupt VGP5 0= falling edge or low level 1= rising edge or high level 0 = LOW 1 = HIGH
4	0x0	VGP4_INT_POLARITY: VGP4 pin Interrupt Type. This bit controls interrupt VGP4 0= falling edge or low level 1= rising edge or high level 0 = LOW 1 = HIGH
3	0x0	VD11_INT_POLARITY: VD11 pin Interrupt Type. This bit controls interrupt VD11 0= falling edge or low level 1= rising edge or high level 0 = LOW 1 = HIGH
2	0x0	VD10_INT_POLARITY: VD10 pin Interrupt Type. This bit controls interrupt VD10 0= falling edge or low level 1= rising edge or high level 0 = LOW 1 = HIGH
1	0x0	VD9_INT_POLARITY: VD9 pin Interrupt Type. This bit controls interrupt VD9 0= falling edge or low level 1= rising edge or high level

Bit	Reset	Description
		0 = LOW 1 = HIGH
0	0x0	VD8_INT_POLARITY: VD8 pin Interrupt Type. This bit controls interrupt VD8 if edge or level type. 0= falling edge or low level 1= rising edge or high level 0 = LOW 1 = HIGH

27.1.49 VI_INTERRUPT_STATUS_0

Interrupt Enable

This register returns interrupt status when read. Except for bits 15-14, when this register is written, the interrupt status corresponding to the bits written with 1 will be reset.

Interrupt status corresponding to the bits written with 0 will be left unchanged.

Note that interrupt status bits can be set even when their corresponding interrupt enable bits, in VI10R, are cleared. When these bits are set and their corresponding interrupt enable bits are set, an interrupt is generated. The interrupt can be cleared, or left unchanged, by writing 1 or 0, respectively, to the corresponding bits in this register.

Clearing the interrupt status bits does not affect the interrupt enable bits.

Offset: 0x50 | Read/Write: RO | Reset: 0x00000000 (0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx)

Bit	Reset	Description
28	X	SECOND_OUTPUT_DROP_MC_DATA_INT_STATUS: If SECOND_OUTPUT is dropping data to MC, INTR will be set. 0 = NOINTR 1 = INTR
27	X	FIRST_OUTPUT_DROP_MC_DATA_INT_STATUS: If FIRST_OUTPUT is dropping data to MC, INTR will be set. 0 = NOINTR 1 = INTR
26	X	TS_OTHER_PROTOCOL_ERROR_INT_STATUS: This bit shows the status of the condition when the ISDB-T input an other protocol error (ex: total packet received is FEC_SIZE+BODY_SIZE but the individual FEC portion != FEC_SIZE and the individual BODY portion != BODY_SIZE 0= Interrupt not detected 1= Interrupt detected 0 = NOINTR 1 = INTR
25	X	TS_OVERRUN_ERROR_INT_STATUS: This bit shows the status of the condition when the ISDB-T input get an overrun error (more bytes in packet than specified 0= Interrupt not detected 1= Interrupt detected 0 = NOINTR 1 = INTR
24	X	TS_UNDERRUN_ERROR_INT_STATUS: This bit shows the status of the condition when the ISDB-T input get an underrun error (START condition detected prior to receiving a full packet) 0= Interrupt not detected 1= Interrupt detected 0 = NOINTR 1 = INTR
23	X	TS_UPSTREAM_ERROR_INT_STATUS: This bit shows the status of the condition when the ISDB-T vi input gets an upstream error (error from the tuner) 0= Interrupt not detected 1= Interrupt detected 0 = NOINTR 1 = INTR

Bit	Reset	Description
22	X	RAISE_STREAM_2_INT_STATUS: This bit shows the status of the condition when the Raise Stream 2 returns to the Host 0= Interrupt not detected 1= Interrupt detected 0 = NOINTR 1 = INTR
21	X	RAISE_STREAM_1_INT_STATUS: This bit shows the status of the condition when the Raise Stream 1 returns to the Host 0= Interrupt not detected 1= Interrupt detected 0 = NOINTR 1 = INTR
20	X	FIELD_STATUS: Top or Bottom Field Status This bit specifies whether the last received video data field is top field or bottom field as defined by FIELD_TYPE bit. This bit is forced to 0 if FIELD_DETECT is DISABLED when VIDEO_SOURCE is VIP. This bit cannot be reset by software by writing a 1. 0= Bottom field received 1= Top field received 0 = BOTTOM 1 = TOP
19	X	DMA_STALL_INT_STATUS: This bit shows the status of the condition when the VI drops data to the Write Buffer DMA 0= Interrupt not detected 1= Interrupt detected 0 = NOINTR 1 = INTR
18	X	SECOND_OUTPUT_PEER_STALL_INT_STATUS: This bit shows the status of if the VI dropped a buffer packet to the peer communicating with the second memory output 0= Interrupt not detected 1= Interrupt detected 0 = NOINTR 1 = INTR
17	X	FIRST_OUTPUT_PEER_STALL_INT_STATUS: This bit shows the status of if the VI dropped a buffer packet to the peer communicating with the first memory output 0= Interrupt not detected 1= Interrupt detected 0 = NOINTR 1 = INTR
16	X	YUV420PA_ERROR_INT_STATUS: YUV420PA Error Interrupt Enable This bit shows the status of if the VI does not average data because the line buffer data is not ready from the memory controller. The VI will write unaveraged data and will write the U,V data from the even line in such cases. 0= Interrupt not detected 1= Interrupt detected 0 = NOINTR 1 = INTR
15	X	EPP_ERROR_INT_STATUS: VI to EPP Error Interrupt Enable This bit controls interrupt when the VI drops data to the EPP because the EPP is stalling the vi2epp bus and data is coming from the pins 0= Interrupt not detected 1= Interrupt detected 0 = NOINTR 1 = INTR
14	X	FRAME_SECOND_OUTPUT_INT_STATUS: Frame Done Second Output Interrupt Status This bit is set when a frame has been written to memory by the second output. 0= Interrupt not detected 1= Interrupt detected 0 = NOINTR 1 = INTR

Bit	Reset	Description
13	X	BUFFER_SECOND_OUTPUT_INT_STATUS: Buffer Done Second Output Interrupt Status This bit is set when a buffer has been written to memory by the second output. 0= Interrupt not detected 1= Interrupt detected 0 = NOINTR 1 = INTR
12	X	FRAME_FIRST_OUTPUT_INT_STATUS: Frame Done First Output Interrupt Status This bit is set when a frame has been written to memory by the first output. 0= Interrupt not detected 1= Interrupt detected 0 = NOINTR 1 = INTR
11	X	BUFFER_FIRST_OUTPUT_INT_STATUS: Buffer Done First Output Interrupt Status This bit is set when a buffer has been written to memory by the first output. 0= Interrupt not detected 1= Interrupt detected 0 = NOINTR 1 = INTR
10	X	Y_THRESHOLD_INT_STATUS: Y-FIFO Threshold Interrupt Enable This bit controls interrupt when the number of filled locations in Y-FIFO is equal or greater than the Y_FIFO_THRESHOLD value. 0= Interrupt not detected 1= Interrupt detected 0 = NOINTR 1 = INTR
9	X	V_COUNTER_INT_STATUS: Vertical Counter Interrupt Status (effective when VIDEO_SOURCE is HOST). This bit controls interrupt when the vertical counter threshold is reached. 0 = NOINTR 1 = INTR
8	X	VVS_INT_STATUS: VVS pin Interrupt Status. This bit controls interrupt when VVS rising/falling edge is detected. 0= Interrupt not detected 1= Interrupt detected 0 = NOINTR 1 = INTR
7	X	VHS_INT_STATUS: VHS pin Interrupt Status. This bit controls interrupt when VHS rising/falling edge is detected. 0= Interrupt not detected 1= Interrupt detected 0 = NOINTR 1 = INTR
6	X	VGP6_INT_STATUS: VGP6 pin Interrupt Status. This bit controls interrupt when VGP6 rising/falling edge is detected. 0= Interrupt not detected 1= Interrupt detected 0 = NOINTR 1 = INTR
5	X	VGP5_INT_STATUS: VGP5 pin Interrupt Status This bit controls interrupt when VGP5 rising/falling edge is detected. 0= Interrupt not detected 1= Interrupt detected 0 = NOINTR 1 = INTR
4	X	VGP4_INT_STATUS: VGP4 pin Interrupt Status. This bit controls interrupt when VGP4 rising/falling edge is detected. 0= Interrupt not detected 1= Interrupt detected 0 = NOINTR 1 = INTR

Bit	Reset	Description
3	X	VD11_INT_STATUS: VD11 pin Interrupt Status. This bit controls interrupt when VD11 rising/falling edge is detected. 0= Interrupt not detected 1= Interrupt detected 0 = NOINTR 1 = INTR
2	X	VD10_INT_STATUS: VD10 pin Interrupt Status. This bit controls interrupt when VD10 rising/falling edge is detected. 0= Interrupt not detected 1= Interrupt detected 0 = NOINTR 1 = INTR
1	X	VD9_INT_STATUS: VD9 pin Interrupt Status. This bit controls interrupt when VD9 rising/falling edge is detected. 0= Interrupt not detected 1= Interrupt detected 0 = NOINTR 1 = INTR
0	X	VD8_INT_STATUS: VD8 pin Interrupt Status. This bit controls interrupt when VD8 rising/falling edge is detected. 0= Interrupt not detected 1= Interrupt detected 0 = NOINTR 1 = INTR

27.1.50 VI_VIP_INPUT_STATUS_0

Video Input Port status

Offset: 0x51 | Read/Write: RO | Reset: 0x00000000 (0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx)

Bit	Reset	Description
31:16	X	FRAME_COUNT: The number of frames received (VSYNCs). Any write to this register clears this.
15:0	X	LINE_COUNT: The number of lines received (HSYNCs)

27.1.51 VI_VIDEO_BUFFER_STATUS_0

Interrupt Enable

Offset: 0x52 | Read/Write: RO | Reset: 0x00000000 (0bxxxxxxxxxxxxxxxxxxxx)

Bit	Reset	Description
19:16	X	RAW_STREAM_WRITE_COUNT: Write count of the Raw Stream Write FIFO. This is the FIFO used to synchronize the data coming from pads into the VI clock domain.
15:8	X	SECOND_VIDEO_BUFFER_STATUS: Buffer status. This specifies the buffer number of the last video data field written to memory
7:0	X	FIRST_VIDEO_BUFFER_STATUS: Buffer status. This specifies the buffer number of the last video data field written to memory

27.1.52 VI_SYNC_OUTPUT_0

VI H and V Sync Output control

This register controls VHS and VVS output when H/V syncs are generated internally in the VI module (VIDEO_SOURCE is VIP and SYNC_FORMAT is INTHVS).

The generated VHS and VVS signal can be sent to external video source device and used to synchronize the video data transfer from the video source to the VI module. VHS and VVS pin should be configured in output mode to output the internally generated H/V syncs.

Also in this case, the internally generate H/V syncs can be used by the VI module as horizontal and vertical reference signals for the incoming video data.

Offset: 0x53 | Read/Write: R/W | Reset: 0x00000000 (0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx)

Bit	Reset	Description
31:19	X	VVS_OUTPUT_PERIOD: This specifies VVS output pulse period in term of number of VHS cycles. Programmed value is actual value - 1 so valid value ranges from 2 to 4096.
18:16	X	VVS_OUTPUT_WIDTH: This specifies VVS output pulse width in term of number of VHS cycles. Programmed value is actual value - 1 so valid value ranges from 1 to 8.
15:3	X	VHS_OUTPUT_PERIOD: This specifies VHS output pulse period in term of number of VI clock cycles. Programmed value is actual value - 1 so valid value ranges from 32 to 8192.
2:0	X	VHS_OUTPUT_WIDTH: This specifies VHS output pulse width in term of number of VI clock cycles. Programmed value is actual value - 1 so valid value ranges from 1 to 8.

27.1.53 VI_VVS_OUTPUT_DELAY_0

VI V Sync Output Delay

Offset: 0x54 | Read/Write: R/W | Reset: 0x00000000 (0bxxxx)

Bit	Reset	Description
3:0	X	VVS_OUTPUT_DELAY: This specifies the number of VI clock cycles from leading edge of VHS to leading edge of VVS. Programmed value is actual value + 2 so valid value ranges from -2 to 13.

27.1.54 VI_PWM_CONTROL_0

VI Pulse Width Modulation Control

VI Pulse Width Modulation signal generation

PWM signal generation logic can generate up to 128 pulses per line internally and the PWM pulse select registers determines which of the 128 pulses will be output. Any of the 128 internally generated pulse can be independently selected as output if they occur within one line time.

PWM signal can be output on the VGP6 pin if VGP6 output is enabled and the output select is set to PWM.

The PWM will be triggered by the first vsync after the PWM_ENABLE bit has been set.

Offset: 0x55 | Read/Write: R/W | Reset: 0x00000000 (0b00000000xx00xxxx00000000xxx0xxx0)

Bit	Reset	Description
31:24	0x0	PWM_COUNTER: PWM Counter 8-bit value used when PWM_MODE is set to COUNTER to determine how many times the PWM will cycle through the 128 cycles before stopping.
21:20	0x0	PWM_MODE: PWM Mode Continuous - after PWM is turned on, continue through the PWM's 128 cycles repeatedly until the PWM is turned off. Single - after PWM is turned on, cycle once through the 128 cycles and stop. Counter - after PWM is turned on, cycle through the 128 cycles PWM_COUNTER number of times then stop. 0 = CONTINUOUS 1 = SINGLE 2 = COUNTER
15:12	0x0	PWM_LOW_PULSE: PWM Low Pulse (1 to 16)
11:8	0x0	PWM_HIGH_PULSE: PWM High Pulse (1 to 16)

Bit	Reset	Description
4	0x0	PWM_DIRECTION: PWM Direction 0= Incrementing 1= Decrementing 0 = INCR 1 = DECR
0	0x0	PWM_ENABLE: PWM Enable 0 = DISABLED 1 = ENABLED

27.1.55 VI_PWM_SELECT_PULSE_A_0

PWM Pulse Select A

The next 4 registers select which of the internal 128 pulses to be output. Each bit in the four registers corresponds to one internal pulse.

Offset: 0x56 | Read/Write: R/W | Reset: 0x00000000 (0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx)

Bit	Reset	Description
31:0	X	PWM_SELECT_A: PWM Select bits 31 to 0

27.1.56 VI_PWM_SELECT_PULSE_B_0

PWM Pulse Select B

27.1.64 VI_PIN_OUTPUT_DATA_0

VI pins Output Data

This register contains output data when the video camera interface pins are used as general-purpose output pins. When a bit in this register is written, the data bits can be output on the corresponding pin if the corresponding pin output buffer is enabled, and the pin output control select bits are programmed to output the bit in this register.

The output signal at the pin IS affected by the corresponding pin output inversion bit.

Offset: 0x5f | Read/Write: R/W | Reset: 0x00000000 (0bxxxxxxxxxxxxxxxxxxxxxxxx)

27.1.65 VI_PIN_OUTPUT_SELECT_0

VI pins Output Select

This is the mux select used at the Pad Macro. For VCLK, VHSYNC, VVSYNC. Selects between the register programmed GPIO outputs (set to 0) and the internally generated VICLK, HSYNC, VSYNC (set to 1). For VGP1-VGP2, selects between the I2C outputs (set to 0) and the VI register programmed GPIO outputs (set to 1). For VD0-VD11, reserved for future use data pins output will be driven by GPIO outputs if enabled.

27.1.66 VI_RAISE_VIP_BUFFER_FIRST_OUTPUT_0

Raise vector at buffer end

Raise vectors are received from host. If host is the input source, the host will send a raise vector at the end of a line, and the VI returns it when that has been written to memory.

A raise written when decimation or averaging is selected in the VI is not supported.

If the Video Input Port is the input source, the host should program raise vectors to either raise at buffer end or at frame end.

Since there are 2 memory outputs for VI, there are two separate raise vectors for buffer/frame.

27.1.80 VI_VI_MCCIF_FIFOCTRL_0

Memory Client Interface FIFO Control Register

> **Note:** The FIFO timing aspects of this register are not supported but are retained for software compatibility.

The clock enable fields of this register control the 2nd-level clock gating for the MC side of the MCCIF.

A '1' written to the override field will result in that clock reverting to the legacy mode of operation (where the msc*clk is on whenever the client clock is enabled.

Offset: 0x6f | Read/Write: R/W | Reset: 0x00000000 (0b00xxxxxxxxxxxx0000)

4:0	X	CSI_PPB_RAISE_FRAME_START_VECTOR: Raise returned by VI when CSI PPB issues a frame start to the consumer.

27.1.90 VI_CSI_PPB_RAISE_FRAME_END_0

CSI Pixel Parser B Raise

Offset: 0x79 | Read/Write: R/W | Reset: 0x00000000 (0bxxxxxxxxxxxxxxxxxxxx)

Bit	Reset	Description
19:16	X	CSI_PPB_RAISE_FRAME_END_CHANNEL: Raise return channel
15:8	X	CSI_PPB_RAISE_FRAME_END_COUNT: Number of frame ends since the last raise >= count for raise to be returned
4:0	X	CSI_PPB_RAISE_FRAME_END_VECTOR: Raise returned by VI when CSI PPB issues a frame end to the consumer.

27.1.91 VI_CSI_PPA_H_ACTIVE_0

VI Horizontal Active

This register defines the horizontal captured (active) area of the input video source with respect to horizontal sync. (This is for CSI data.)

Offset: 0x7a | Read/Write: R/W | Reset: 0x00000000 (0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx)

Bit	Reset	Description
28:16	X	CSI_PPA_H_ACTIVE_PERIOD: Horizontal Active Period. This parameter specifies the number of pixels in the horizontal active area. H_ACTIVE_START + H_ACTIVE_PERIOD should be less than 2^NV_VI_H_IN (or 8192). This parameter should be programmed with an even number (bit 16 is ignored internally).
12:0	X	CSI_PPA_H_ACTIVE_START: Horizontal Active Start (offset to active). This parameter specifies the number of clock active edges from horizontal sync active edge to the first horizontal active pixel. If programmed to 0, the first active line starts after the first active clock edge following the horizontal sync active edge.

27.1.92 VI_CSI_PPA_V_ACTIVE_0

Vertical Active

This register defines the vertical captured (active) area of the input video source with respect to vertical sync. (This is for CSI data.)

Offset: 0x7b | Read/Write: R/W | Reset: 0x00000000 (0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx)

Bit	Reset	Description
28:16	X	CSI_PPA_V_ACTIVE_PERIOD: Vertical Active Period. This parameter specifies the number of lines in the vertical active area. V_ACTIVE_START + V_ACTIVE_PERIOD should be less than 2^NV_VI_V_IN (or 8192).
12:0	X	CSI_PPA_V_ACTIVE_START: Vertical Active Start (offset to active). This parameter specifies the number of horizontal sync active edges from vertical sync active edge to the first vertical active line. If programmed to 0, the first active line starts after the first horizontal sync active edge following the vertical sync active edge.

27.1.93 VI_CSI_PPB_H_ACTIVE_0

VI Horizontal Active

This register defines the horizontal captured (active) area of the input video source with respect to horizontal sync. (This is for CSI data.)

Offset: 0x7c | Read/Write: R/W | Reset: 0x00000000 (0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx)

Bit	Reset	Description
28:16	X	CSI_PPB_H_ACTIVE_PERIOD: Horizontal Active Period. This parameter specifies the number of pixels in the horizontal active area. H_ACTIVE_START + H_ACTIVE_PERIOD should be less than 2^NV_VI_H_IN (or 8192). This parameter should be programmed with an even number (bit 16 is ignored internally).
12:0	X	CSI_PPB_H_ACTIVE_START: Horizontal Active Start (offset to active). This parameter specifies the number of clock active edges from horizontal sync active edge to the first horizontal active pixel. If programmed to 0, the first active line starts after the first active clock edge following the horizontal sync active edge.

27.1.94 VI_CSI_PPB_V_ACTIVE_0

Vertical Active

This register defines the vertical captured (active) area of the input video source with respect to vertical sync. (This is for CSI data.)

Offset: 0x7d | Read/Write: R/W | Reset: 0x00000000 (0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx)

Bit	Reset	Description
28:16	X	CSI_PPB_V_ACTIVE_PERIOD: Vertical Active Period. This parameter specifies the number of lines in the vertical active area. V_ACTIVE_START + V_ACTIVE_PERIOD should be less than 2^NV_VI_V_IN (or 8192).
12:0	X	CSI_PPB_V_ACTIVE_START: Vertical Active Start (offset to active). This parameter specifies the number of horizontal sync active edges from vertical sync active edge to the first vertical active line. If programmed to 0, the first active line starts after the first horizontal sync active edge following the vertical sync active edge.

27.1.95 VI_ISP_H_ACTIVE_0

Used when an image comes from ISP

Used only with input from ISP: defines input image horizontal size in pixels

Offset: 0x7e | Read/Write: R/W | Reset: 0x00000000 (0bxxxxxxxxxxxxxx)

Bit	Reset	Description
12:0	X	ISP_H_ACTIVE_PERIOD: Horizontal image size in pixels coming out of the ISP. Must be an even number (bit 0 is ignored).

27.1.96 VI_ISP_V_ACTIVE_0

Used when an image comes from ISP

Used only with input from ISP: defines input image vertical size in lines

Offset: 0x7f | Read/Write: R/W | Reset: 0x00000000 (0bxxxxxxxxxxxxxx)

Bit	Reset	Description
12:0	X	ISP_V_ACTIVE_PERIOD: Vertical image size in lines coming out of the ISP. Must be an even number (bit 0 is ignored).

27.1.97 VI_STREAM_1_RESOURCE_DEFINE_0

This register defines resources used by stream 1.

The field definitions are:

- 0 = resource not used
- 1 = resource used.

Stream raises ("safe to reprogram VI" raises)

The I/O resources used by a data stream going through VI are indicated in STREAM_?_RESOURCE_DEFINE register.

Once resources are set in this register, and after the start of the following picture when ALL the stream's resources are done and idle processing that picture, a raise is generated. It is then safe to reprogram VI's functional units involved in processing that stream.

Two simultaneous data streams are supported, and they do not have to be mutually exclusive.

When no resources are indicated for a stream, no raise is generated.

Offset: 0x80 | Read/Write: R/W | Reset: 0x00000000 (0b000000000000)

Bit	Reset	Description

27.1.101 VI_TS_MODE_0

ISDB-T Mode Selection Register

ISDB-T tuner mode register settuner/demodulator mode.

Offset: 0x84 | Read/Write: R/W | Reset: 0x00000000 (0bxxxxxx)

Bit	Reset	Description
5:4	X	FLOW_CONTROL_MODE: This field selects the buffer flow control for the Write DMA RDMA: The RDMA engine will release the buffers back to the WDMA as the buffers are consumed NONE: The VI will automatically release the buffer back to the WMDA after each buffer ready is generated. CPU: Software needs to write the TS_CPU_FLOW_CTL register to release each buffer to the WDMA 0 = RDMA 1 = NONE 2 = CPU 3 = RESERVED
3:2	X	PROTOCOL_SELECT: This field selected the pin configuration used for VD[1] NONE: TS_ERROR is tied to 0 TS_PSYNC is tied to 0 TS_ERROR: TS_ERROR is on VD[1] TS_PSYNC is tied to 0 TS_PSYNC: TS_ERROR is tied to 0. TS_PSYNC is on VD[1] 0 = NONE 1 = TS_ERROR 2 = TS_PSYNC 3 = RESERVED
1	X	INPUT_MODE: This field determines if input data is in serial or parallel format 0 = PARALLEL 1 = SERIAL
0	X	ENABLE: This field indicates the global enable for ISDB-T protocol handling 0 = DISABLED 1 = ENABLED

27.1.102 VI_TS_CONTROL_0

ISDB-T Mode Control Register

Offset: 0x85 | Read/Write: R/W | Reset: 0x00000008 (0bxxxxxxxxxxxxxxxxxxxxxxxxxxxx1xxx)

Bit	Reset	Description
30:24	X	FEC_SIZE: This field stores the number of FEC bytes to capture (after the BODY has been captured)
23:16	X	BODY_SIZE: This field stores the number of BODY bytes to capture (including PSYNC)
7	X	STORE_UPSTREAM_ERROR_PKTS: This field determines if VI should store packets to memory that have been flagged as UPSTREAM_ERROR packets. DISCARD: Do not store packets in memory STORE: Store UPSTREAM_ERROR packets in memory 0 = DISCARD 1 = STORE
6	X	BODY_VALID_SELECT: This field determines if VALID is used during BODY packet capture IGNORE: the VALID signal is ignored during the capture GATE: the VALID signal gates the capture of BODY data. 0 = IGNORE 1 = GATE
5:4	X	START_SELECT: This field defines how the START of packet condition is determined PSYNC: PSYNC assertion rising edge VALID: VALID assertion rising edge BOTH: PSYNC && VALID asserted rising edge 0 = RESERVED 1 = PSYNC 2 = VALID 3 = BOTH
3	LOW	CLK_POLARITY: 0 = HIGH 1 = LOW
2	X	ERROR_POLARITY: 0 = HIGH 1 = LOW
1	X	PSYNC_POLARITY: 0 = HIGH 1 = LOW
0	X	VALID_POLARITY: This field indicates the polarity of TS_VALID. Only has affect when TS_MODE.ENABLE == ENABLED LOW indicates that the polarity of TS_VALID is active low. HIGH indicates that the polarity of TS_VALID is active high. 0 = HIGH 1 = LOW

27.1.103 VI_TS_PACKET_COUNT_0

ISDB-T Packet Count Register

Offset: 0x86 | Read/Write: RO | Reset: 0x00000000 (0bxxxxxxxxxxxxxxxxx)

Bit	Reset	Description
16	X	TS_PACKET_COUNT_VALUE_OVERFLOW: This field is set to OVERFLOW when the value passes from 0xFFFF to 0x0000. It stays high until the CPU writes a zero to this bit to reset it. 0 = NONE 1 = OVERFLOW
15:0	X	TS_PACKET_COUNT_VALUE: This field holds the current value of the received packet counter. This counter increments in the presence of a new packet, regardless of whether it is flagged as an error. The counter can be cleared by writing this register with 0's and can also be preloaded to any value by writing the preload value to the register.

27.1.104 VI_TS_ERROR_COUNT_0

ISDB-T Error Count Register

Offset: 0x87 | Read/Write: RO | Reset: 0x00000000 (0bxxxxxxxxxxxxxxxxx)

Bit	Reset	Description
16	X	TS_ERROR_COUNT_VALUE_OVERFLOW: This field is set to OVERFLOW when the value passes from 0xFFFF to 0x0000. It stays high until the CPU writes a zero to this bit to reset it. 0 = NONE 1 = OVERFLOW
15:0	X	TS_ERROR_COUNT_VALUE: This field holds the current value of the error packet counter. This counter increments in the presence of a packet flagged as error (see TS_ERROR) 0000 or a detected protocol violation. The counter can be cleared by writing this register with 0's and can also be preloaded to any value by writing the preload value to the register.

27.1.105 VI_TS_CPU_FLOW_CTL_0

ISDB-T CPU Flow Control Register

Offset: 0x88 | Read/Write: RO | Reset: 0x00000000 (0bx)

Bit	Reset	Description
0	X	BUFFER_RELEASE: Used only when the FLOW_CONTROL_MODE register is set to CPU. Software must write this register to release each buffer back to WDMA. Failure to write this register when buffers are consumed will result in the WDMA stalling when it consumes all allocated/free buffers.

27.1.106 VI_VB0_CHROMA_BUFFER_STRIDE_FIRST_0

Video Buffer Set 0 Chroma Buffer Stride

This feature represents an alternative value to using VB0_BUFFER_STRIDE_C.

HOST_DMA_WRITE_BUFFER.BUFFER_SIZE (bytes) is used to hold the number of bytes in a buffer for ISDB-T mode.

Offset: 0x89 | Read/Write: R/W | Reset: 0x00000000 (0b0xxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx)

Bit	Reset	Description
31	0x0	VB0_CHROMA_BUFFER_STRIDE_SELECT: select type of Chroma buffer stride: 0 = Use VB0_BUFFER_STRIDE_C, deriving chroma buffer stride from luma buffer stride (default). 1 = Use VB0_CHROMA_BUFFER_STRIDE. 0 = RATIO 1 = VALUE
29:0	X	VB0_CHROMA_BUFFER_STRIDE: Chroma buffer stride in bytes

27.1.107 VI_VB0_CHROMA_LINE_STRIDE_FIRST_0

Video Buffer Set 0 Chroma Line Stride for First Output of Planar YUV formats

Offset: 0x8a | Read/Write: R/W | Reset: 0x00000000 (0b0xxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx)

Bit	Reset	Description
31	0x0	VB0_CHROMA_LINE_STRIDE_SELECT: select type of Chroma line stride: 0 = Use VB0_H_SIZE_1, deriving chroma line stride from luma line stride (default). 1 = Use VB0_CHROMA_H_SIZE_1. 0 = RATIO 1 = VALUE
12:0	X	VB0_CHROMA_H_SIZE_1: Video Buffer Set 0 chroma horizontal size This parameter specifies the chroma line stride (in pixels) for lines in the video buffer set 0. This parameter must be programmed as a multiple of 4 pixels (bits 1-0 are ignored).

27.1.108 VI_EPP_LINES_PER_BUFFER_0

Number of buffers per output frame in EPP

This register is used for VI2EPP syncpt only.

The VI will based on num_lines = frame_height/EPP_NUM_OF_BUFFER_PER_FRAME, send vi2epp_trigger for every num_lines

Offset: 0x8b | Read/Write: R/W | Reset: 0x00000000 (0bxxxxxxxxxxxxx)

Bit	Reset	Description
12:0	X	LINES_PER_BUFFER: Maximum 256 buffers per frame. linesPerBuffer = FLOOR(eppLineCount/eppBufferCount) linesPerBuffer must be > 2 eppLineCount must take into account any cropping in the EPP.

27.1.109 VI_BUFFER_RELEASE_OUTPUT1_0

Writes to this register will decrease BUFFER_COUNTER by 1.

Offset: 0x8c | Read/Write: R/W | Reset: 0x00000000 (0bx)

Bit	Reset	Description
0	X	BUFFER_RELEASE_OUTPUT1

27.1.110 VI_BUFFER_RELEASE_OUTPUT2_0

Offset: 0x8d | Read/Write: R/W | Reset: 0x00000000 (0bx)

Bit	Reset	Description
0	X	BUFFER_RELEASE_OUTPUT2

27.1.111 VI_DEBUG_FLOW_CONTROL_COUNTER_OUTPUT1_0

Debug register

Offset: 0x8e | Read/Write: RO | Reset: 0x00000000 (0bxxxxxxxx)

Bit	Reset	Description
7:0	X	BUFFER_COUNT_OUTPUT1

27.1.112 VI_DEBUG_FLOW_CONTROL_COUNTER_OUTPUT2_0

Offset: 0x8f | Read/Write: RO | Reset: 0x00000000 (0bxxxxxxxx)

Bit	Reset	Description
7:0	X	BUFFER_COUNT_OUTPUT2

27.1.113 VI_TERMINATE_BW_FIRST_0

Writes to this register will terminate MC on BW operation in the FIRST output.

Offset: 0x90 | Read/Write: R/W | Reset: 0x00000000 (0bx)

Bit	Reset	Description
0	X	TERMINATE_FIRST_BW

27.1.114 VI_TERMINATE_BW_SECOND_0

Writes to this register will terminate MC on BW operation in the SECOND output.

Offset: 0x91 | Read/Write: R/W | Reset: 0x00000000 (0bx)

Bit	Reset	Description
0	X	TERMINATE_SECOND_BW

27.1.115 VI_VB0_FIRST_BUFFER_ADDR_MODE_0

Memory Controller Tiling definitions

Offset: 0x92 | Read/Write: R/W | Reset: 0x00000000 (0b0xxxxxxx0)

Bit	Reset	Description
8	0x0	UV1_TILE_MODE: 0 = LINEAR 1 = TILED
0	0x0	Y1_TILE_MODE: 0 = LINEAR 1 = TILED

27.1.116 VI_VB0_SECOND_BUFFER_ADDR_MODE_0

Offset: 0x93 | Read/Write: R/W | Reset: 0x00000000 (0b0)

Bit	Reset	Description
0	0x0	Y2_TILE_MODE: 0 = LINEAR 1 = TILED

27.1.117 VI_RESERVE_0_0

Reserved register

Bits [13:0] are reserved for the VIP Pattern Generator (Pattern Width).

VIP Pattern Generator

The VIP Pattern Generator, when enabled, overrides the inputs from the attached camera with internally generated pattern data, HSYNCs, and VSYNCs. The purpose of the pattern generator is to facilitate regression testing of the VI driver and hardware without constraining the board level design.

The pattern generator logic runs on the pd2vi_clock domain. See the CLK_RST_CONTROLLER_CLK_SOURCE_VI_0 register for how to enable a loopback from the vi_sensor clock to the pd2vi_clock.

The user must program the pattern width, pattern height, and Bayer select registers prior to enabling the pattern generator. It is illegal to change the values of those registers without first disabling the pattern generator.

The pattern generator has no concept of blanking time. The width and the height of the pattern should correspond to the full hblank+hactive and vblank+vactive.

Offset: 0x94 | Read/Write: R/W | Reset: 0x00000000 (0bxxxxxxxxxxxxxxxx)

Bit	Reset	Description
15:12	X	nc_RESERVE_0_3
11:8	X	nc_RESERVE_0_2: there are 2 clocks per pixel for YUV422)

Bit	Reset	Description
7:4	X	nc_RESERVE_0_1: pattern width in clocks.
3:0	X	nc_RESERVE_0_0: Program to *one less* than the desired value

27.1.118 VI_RESERVE_1_0

Reserved register

Bits [13:0] are reserved for the VIP Pattern Generator (Pattern Height)

Offset: 0x95 | Read/Write: R/W | Reset: 0x00000000 (0bxxxxxxxxxxxxxxxx)

Bit	Reset	Description
15:12	X	nc_RESERVE_1_3
11:8	X	nc_RESERVE_1_2
7:4	X	nc_RESERVE_1_1: Pattern height in lines
3:0	X	nc_RESERVE_1_0: Program to one less than the desired value

27.1.119 VI_RESERVE_2_0

Reserved register

Bit 0 is reserved for VIP Pattern Gen Enable. Bit 1 is reserved for VIP Pattern Generator Bayer Select.

Offset: 0x96 | Read/Write: R/W | Reset: 0x00000000 (0bxxxxxxxxxxxx0000)

Bit	Reset	Description
15:12	X	nc_RESERVE_2_3
11:8	X	nc_RESERVE_2_2
7:4	X	nc_RESERVE_2_1
3:0	0x0	nc_RESERVE_2_0: 1: BAYER pattern 0: YUV pattern

27.1.120 VI_RESERVE_3_0

Reserved register

Offset: 0x97 | Read/Write: R/W | Reset: 0x00000000 (0bxxxxxxxxxxxxxxxx)

Bit	Reset	Description

Memory Client Interface Hysteresis Registers

27.1.122 VI_MCCIF_VIRUV_HYST_0

Memory Client Interface FIFO Control Register

> **Note:** The FIFO timing aspects of this register are not supported but are retained for software compatibility.

The clock enable fields of this register control the second-level clock gating for the MC side of the MCCIF.

A '1' written to the override field will result in that clock reverting to the legacy mode of operation (where the msc*clk is on whenever the client clock is enabled.

Memory Client Hysteresis Control Register

> **Note:** Hysteresis is not supported by the MCCIF clients.
> Registers are retained for backwards compatibility but are not used by the hardware.

Offset: 0x99 | Read/Write: R/W | Reset: 0xcf04ff06 (0b11001111000001001111111100000110)

Bit	Reset	Description
31	ENABLE	CBR_ VIRUV2MC_HYST_EN: 1 = ENABLE 0 = DISABLE
30:28	0x4	CBR_ VIRUV2MC_HYST_REQ_TH
27:24	0xf	CBR_VIRUV2MC_HYST_TM
23:16	0x4	CBR_VIRUV2MC_DHYST_TH
15:8	0xff	CBR_VIRUV2MC_DHYST_TM
7:0	0x6	CBR_VIRUV2MC_HYST_REQ_TM

27.1.123 VI_MCCIF_VIWSB_HYST_0

Memory Client Hysteresis Control Register

> **Note:** Hysteresis is not supported by the MCCIF clients.
> Registers are retained for backwards compatibility but are not used by the hardware.

Offset: 0x9a | Read/Write: R/W | Reset: 0xc00001ff (0b1100xxxxxxxxxxxxxxx000111111111)

Bit	Reset	Description
31	ENABLE	CBW_VIWSB2MC_HYST_EN: 1 = ENABLE 0 = DISABLE
30:28	0x4	CBW_VIWSB2MC_HYST_REQ_TH
11:0	0x1ff	CBW_VIWSB2MC_HYST_REQ_TM

27.1.124 VI_MCCIF_VIWU_HYST_0

Memory Client Hysteresis Control Register

> **Note:** Hysteresis is not supported by the MCCIF clients.
> Registers are retained for backwards compatibility but are not used by the hardware.

Offset: 0x9b | Read/Write: R/W | Reset: 0xc00001ff (0b1100xxxxxxxxxxxxxxx000111111111)

Bit	Reset	Description
31	ENABLE	CBW_VIWU2MC_HYST_EN: 1 = ENABLE 0 = DISABLE
30:28	0x4	CBW_VIWU2MC_HYST_REQ_TH
11:0	0x1ff	CBW_VIWU2MC_HYST_REQ_TM

27.1.125 VI_MCCIF_VIWV_HYST_0

Memory Client Hysteresis Control Register

> **Note:** Hysteresis is not supported by the MCCIF clients.
> Registers are retained for backwards compatibility but are not used by the hardware.

Offset: 0x9c | Read/Write: R/W | Reset: 0xc00001ff (0b1100xxxxxxxxxxxxxxx000111111111)

Bit	Reset	Description

11:0	0x1ff	CBW_VIWV2MC_HYST_REQ_TM

27.1.126 VI_MCCIF_VIWY_HYST_0

Memory Client Hysteresis Control Register

> **Note:** Hysteresis is not supported by the MCCIF clients.
> Registers are retained for backwards compatibility but are not used by the hardware.

Offset: 0x9d | Read/Write: R/W | Reset: 0xc00001ff (0b1100xxxxxxxxxxxxxxxx000111111111)

Bit	Reset	Description
31	ENABLE	CBW_VIWY2MC_HYST_EN: 1 = ENABLE 0 = DISABLE
30:28	0x4	CBW_VIWY2MC_HYST_REQ_TH
11:0	0x1ff	CBW_VIWY2MC_HYST_REQ_TM

27.1.127 VI_FIELD_STATUS_SHADOW1_0

This register contains a copy of the field status and frame counter registers at the end of the previous frame. The register is updated when the OP_DONE syncpt fires at the end of the frame. So the value should be "safe" to read for the entire "next" frame. There are 2 registers, each of which is tied to one of the 2 output channels

Offset: 0x9e | Read/Write: RO | Reset: 0x00000000 (0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx)

Bit	Reset	Description
31:16	X	FRAME_COUNT_SHADOW1: Shadow copy of the number of frames received (VSYNCs)
0	X	FIELD_STATUS_SHADOW1: Shadow copy of the field count register - synced to channel 1

27.1.128 VI_FIELD_STATUS_SHADOW2_0

Offset: 0x9f | Read/Write: RO | Reset: 0x00000000 (0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx)

Bit	Reset	Description
31:16	X	FRAME_COUNT_SHADOW2: Shadow copy of the number of frames received (VSYNCs)
0	X	FIELD_STATUS_SHADOW2: Shadow copy of the field count register - synced to channel 2

27.1.129 VI_COREMUX_CROP_H_ACTIVE_0

VI Horizontal Active

This register defines the horizontal captured (active) area of the input video source with respect to horizontal sync.

Offset: 0xa0 | Read/Write: R/W | Reset: 0x00000000 (0b0xxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx)

Bit	Reset	Description
31	0x0	COREMUX_CROP_ENABLE: enable cropping after core-mux 0 = DISABLED 1 = ENABLED
28:16	X	COREMUX_CROP_H_ACTIVE_PERIOD: Horizontal Active Period. This parameter specifies the number of pixels in the horizontal active area. H_ACTIVE_START + H_ACTIVE_PERIOD should be less than 2^NV_VI_H_IN (or 8192). This parameter should be programmed with an even number (bit 16 is ignored internally).
12:0	X	COREMUX_CROP_H_ACTIVE_START: Horizontal Active Start (offset to active). This parameter specifies the number of clock active edges from horizontal sync active edge to the first horizontal active pixel. If programmed to 0, the first active line starts after the first active clock edge following the horizontal sync active edge.

27.1.130 VI_COREMUX_CROP_V_ACTIVE_0

Vertical Active

This register defines the vertical captured (active) area of the input video source with respect to vertical sync.

Offset: 0xa1 | Read/Write: R/W | Reset: 0x00000000 (0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx)

Bit	Reset	Description
28:16	X	COREMUX_CROP_V_ACTIVE_PERIOD: Vertical Active Period. This parameter specifies the number of lines in the vertical active area. V_ACTIVE_START + V_ACTIVE_PERIOD should be less than 2^NV_VI_V_IN (or 8192).
12:0	X	COREMUX_CROP_V_ACTIVE_START: Vertical Active Start (offset to active). This parameter specifies the number of horizontal sync active edges from vertical sync active edge to the first vertical active line. If programmed to 0, the first active line starts after the first horizontal sync active edge following the vertical sync active edge.

27.1.131 VI_ALTMUX_CROP_H_ACTIVE_0

VI Horizontal Active

This register defines the horizontal captured (active) area of the input video source with respect to horizontal sync.

Offset: 0xa2 | Read/Write: R/W | Reset: 0x00000000 (0b0xxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx)

Bit	Reset	Description
31	0x0	ALTMUX_CROP_ENABLE: enable cropping after core-mux 0 = DISABLED 1 = ENABLED
28:16	X	ALTMUX_CROP_H_ACTIVE_PERIOD: Horizontal Active Period. This parameter specifies the number of pixels in the horizontal active area. H_ACTIVE_START + H_ACTIVE_PERIOD should be less than 2^NV_VI_H_IN (or 8192). This parameter should be programmed with an even number (bit 16 is ignored internally).
12:0	X	ALTMUX_CROP_H_ACTIVE_START: Horizontal Active Start (offset to active). This parameter specifies the number of clock active edges from horizontal sync active edge to the first horizontal active pixel. If programmed to 0, the first active line starts after the first active clock edge following the horizontal sync active edge.

27.1.132 VI_ALTMUX_CROP_V_ACTIVE_0

Vertical Active

This register defines the vertical captured (active) area of the input video source with respect to vertical sync.

Offset: 0xa3 | Read/Write: R/W | Reset: 0x00000000 (0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx)

Bit	Reset	Description
28:16	X	ALTMUX_CROP_V_ACTIVE_PERIOD: Vertical Active Period. This parameter specifies the number of lines in the vertical active area. V_ACTIVE_START + V_ACTIVE_PERIOD should be less than 2^NV_VI_V_IN (or 8192).
12:0	X	ALTMUX_CROP_V_ACTIVE_START: Vertical Active Start (offset to active). This parameter specifies the number of horizontal sync active edges from vertical sync active edge to the first vertical active line. If programmed to 0, the first active line starts after the first horizontal sync active edge following the vertical sync active edge.

27.1.133 VI_VI_STEREO_CONTROL_0

This register controls the aspects of stereo capture.

Offset: 0xa4 | Read/Write: R/W | Reset: 0x00000000 (0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx0)

Bit	Reset	Description
31:24	X	HBLANK_WIDTH: Number of blank pixels inserted at the end of the super line.
21:16	X	SEAM_WIDTH: Number of blank pixels inserted between lines
8	X	STEREO_BUFFER_1_SRC: Source for stereo buffer 1 0 = CSIA 1 = CSIB
4	X	STEREO_BUFFER_0_SRC: Source for stereo buffer 0 0 = CSIA 1 = CSIB
0	DISABLED	ENABLE_STEREO: Enable stereo capture. Lines from two sources will be concatenated and sent to ISP 0 = DISABLED 1 = ENABLED

27.1.134 VI_VI_CSIA_PATTERN_GEN_SIZE_0

Control register for CSI-A pattern generator

Offset: 0xa5 | Read/Write: R/W | Reset: 0x00000000 (0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx)

Bit	Reset	Description
29:16	X	CSIA_PG_V_COUNT_MAX: Maximum Y of pattern (program to 1 less than pattern height)
13:0	X	CSIA_PG_H_COUNT_MAX: Maximum X of pattern (program to 1 less than pattern width)

27.1.135 VI_VI_CSIA_PATTERN_GEN_CONTROL_0

Offset: 0xa6 | Read/Write: R/W | Reset: 0x00000002 (0b00xxxx0010)

Bit	Reset	Description
9:8	0x0	CSIA_PG_UPDATE_CYCLES: "dead" cycles between updates of pattern generator, i.e., 0 = update every cycle, 1 = update every other cycle
3	0x0	CSIA_PG_ZERO_V_COUNT: hold V count to zero when generating pattern data
2	0x0	CSIA_PG_ZERO_H_COUNT: hold H count to zero when generating pattern data
1	BAYER	CSIA_PG_BAYER: enable pattern generator 0 = YUV 1 = BAYER
0	DISABLED	CSIA_PG_ENABLE: enable pattern generator 0 = DISABLED 1 = ENABLED

27.1.136 VI_VI_CSIB_PATTERN_GEN_SIZE_0

Control Register for CSI-B pattern generator

Offset: 0xa7 | Read/Write: R/W | Reset: 0x00000000 (0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx)

Bit	Reset	Description
29:16	X	CSIB_PG_V_COUNT_MAX: Maximum Y of pattern (program to 1 less than pattern height)
13:0	X	CSIB_PG_H_COUNT_MAX: Maximum X of pattern (program to 1 less than pattern width)

27.1.137 VI_VI_CSIB_PATTERN_GEN_CONTROL_0

Offset: 0xa8 | Read/Write: R/W | Reset: 0x00000002 (0b00xxxx0010)

Bit	Reset	Description
9:8	0x0	CSIB_PG_UPDATE_CYCLES: "dead" cycles between updates of pattern generator, i.e., 0 = update every cycle, 1 = update every other cycle
3	0x0	CSIB_PG_ZERO_V_COUNT: hold V count to zero when generating pattern data
2	0x0	CSIB_PG_ZERO_H_COUNT: hold H count to zero when generating pattern data
1	BAYER	CSIB_PG_BAYER: enable pattern generator 0 = YUV 1 = BAYER
0	DISABLED	CSIB_PG_ENABLE: enable pattern generator 0 = DISABLED 1 = ENABLED

27.2 MIPI-CSI Registers

Refer to the CSI section in this document for descriptions of these registers.

[THIS PAGE INTENTIONALLY LEFT BLANK]

28.0 SD/MMC CONTROLLER

The SD/MMC Controller can interface with SD, SDIO, and eMMC devices. Tegra® 3 contains four instances of this controller:

Controller	UHS-I Signaling Supported	8-bit eMMC Supported	Signaling Voltages
SDMMC1	Yes	1 & 4-bit only	1.8, 2.8-3.3 V
SDMMC2	No	Yes	1.2, 1.8, 2.8-3.3 V
SDMMC3	Yes	Yes	1.8, 2.8-3.3 V
SDMMC4	No	Yes	1.2, 1.8, 2.8-3.3 V

28.1 Standards Supported

- "SD Specifications Part E1 SDIO Specification", Technical Committee SD Card Association, Version 2.00, 30-January 2007.
- "SD Specifications Part 1 Physical Layer Specification", Technical Committee SD Card Association, Version 3.01, 18-February 2010.
- "SD Specifications Part A2 SD Host Controller Standard Specification", Technical Committee SD Association, Version 3.00, 18-February 2010.
- JEDEC eMMC Electrical Interface Specification, Version 4.41, JEDEC SOLID STATE TECHNOLOGY ASSOCIATION, March 2010.

28.2 Speeds Supported

The following SD 3.0 data transfer modes are supported over the 4-bit interface:

- Default Speed mode: 3.3V signaling, Frequency up to 25 MHz, up to 12.5 MB/sec
- High Speed mode: 3.3V signaling, Frequency up to 50 MHz, up to 25 MB/sec
- SDR12: 1.8V signaling, Frequency up to 25 MHz, up to 12.5 MB/sec
- SDR25: 1.8V signaling, Frequency up to 50 MHz, up to 25 MB/sec
- SDR50: 1.8V signaling, Frequency up to 100 MHz, up to 50 MB/sec
- SDR104: 1.8V signaling, Frequency up to 208 MHz, up to 104 MB/sec
- DDR50: 1.8V signaling, Frequency up to 50 MHz, sampled on both clock edges, up to 50 MB/sec

28.3 Operation

28.3.1 Hardware / Software Partitioning

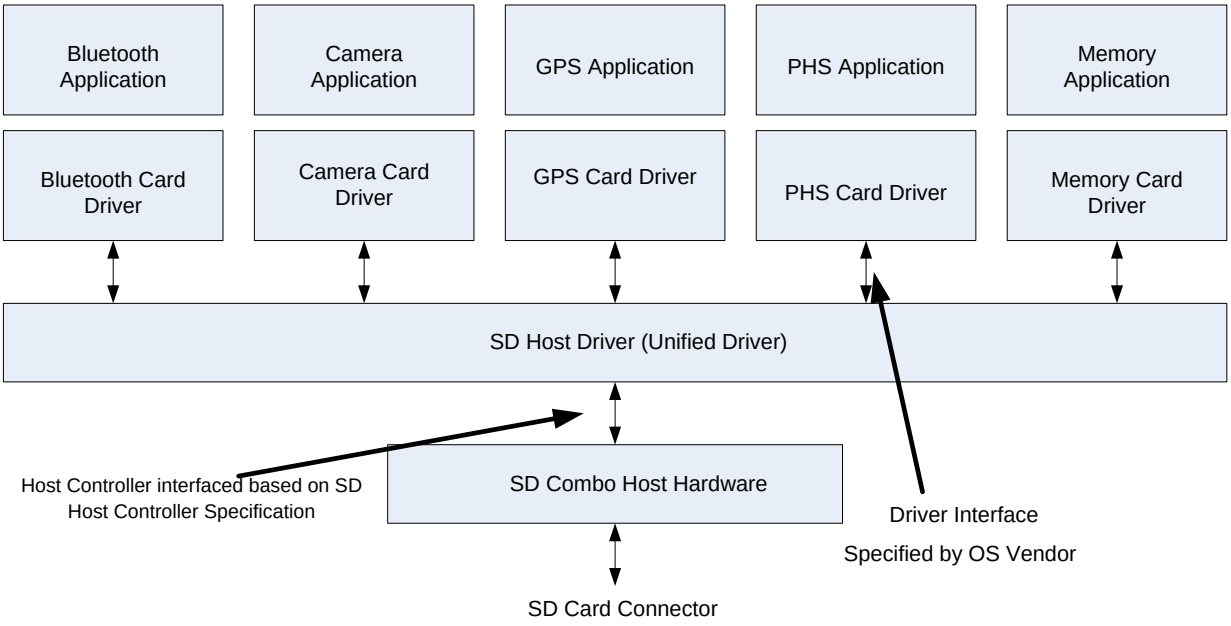
Hardware

Sends out the programmed command, stores the response, and makes it visible to software. It updates the status registers and generates interrupts when attention is required. Software may also configure it for DMA operation.

Software

Determines which type of card is inserted in the slot by sending the initialization commands and observing the responses received from the card. After identifying the card that is inserted, it should only program the corresponding set of commands that are applicable. It can enable interrupts for which notification is desired.

Figure 68. Host Hardware and Driver Architecture



28.4 Performance

Table 75 Performance Maximums

Interface Standard	Maximum Performance
SD & SDIO	Up to 104 MB/s in UHS-I SDR104 mode
eMMC	Up to 104 MB/s in 8-bit DDR mode

28.5 Caveats and Assumptions

- A single SDMMC controller handles only one device at a time.
- The software should configure SDMMC_VENDOR_CLOCK_CNTRL_x_SDMMC_CLK to _DISABLE before turning off the SDMMC clock (and configure back to _ENABLE after turning on the SDMMC clock). This is required in order to support asynchronous card interrupts when no clock is supplied to the card.
- In non-DMA mode of operation, the maximum block length supported is 512 bytes. Refer to the Programming Guidelines section for additional information.
- Tegra 3 PMC can be configured to wake Tegra 3 from the LP0 power state based on either:
  - Card Detection GPIO state
  - Asynchronous interrupt on the DAT1 line
- The SD Host Controller standard registers for reporting Card Detect and Write Protect state are tied off. Instead, software should check the Card Detect and Write Protect state through system-specific GPIOs.
- Off-card ECC, described in the MMC specification, is not supported.

28.6 Programming Guidelines

This section assumes a SD Host driver complying with the SD Specifications' Part A2, SD Host Control Standard Specification, is already available. The following subsections detail the necessary changes required for fully-featured SD (and eMMC boot mode) operation on Tegra 3 devices.

28.6.1 Initialization

The following register writes should be done before the SD host driver is loaded. These register writes can be done in any order, and writes to different register fields within the same register should ideally be combined into a single write for efficiency:

28.6.1.1 General

These settings apply to all SDMMC controllers in use:

- Enable SD3.0 support by setting SDMMC_VENDOR_MISC_CNTRL_x_SDMMC_SPARE0[4].
- Enable SDR50 support by setting SDMMC_VENDOR_MISC_CNTRL_x_SDMMC_SPARE0[3].
- Enable tuning in SDR50 by setting SDMMC_VENDOR_CLOCK_CNTRL_x_SDR50_TUNING_OVERRIDE.
- Enable SDR104 support by setting SDMMC_VENDOR_MISC_CNTRL_x_SDMMC_SPARE0[2].
- Clamp clocks during resets by setting these two values:
  - SDMMC_VENDOR_CLOCK_CNTRL_x_PADPIPE_CLKEN_OVERRIDE_NORMAL
  - SDMMC_VENDOR_CLOCK_CNTRL_x_SPI_MODE_CLKEN_OVERRIDE_NORMAL

28.6.1.2 SDMMC1

These settings are specific to the SDMMC1 controller:

- If using the SDMMC1 interface, set the pads' drive strengths:
  - APB_MISC_GP_SDIO1CFGPADCTRL_0_CFG2TMC_SDIO1CFG_CAL_DRVDN = 6'h2A
  - APB_MISC_GP_SDIO1CFGPADCTRL_0_CFG2TMC_SDIO1CFG_CAL_DRVUP = 6'h2E
  - APB_MISC_GP_SDIO1CFGPADCTRL_0_CFG2TMC_SDIO1CFG_CAL_DRVDN_SLWR = 2'h1
  - APB_MISC_GP_SDIO1CFGPADCTRL_0_CFG2TMC_SDIO1CFG_CAL_DRVUP_SLWF = 2'h1
  - SDMMC_SDMEMCOMPPADCTRL_0_SDMMC2TMC_CFG_SDMEMCOMP_VREF_SEL = 4'h7
  - SDMMC_AUTO_CAL_CONFIG_0_AUTO_CAL_ENABLE_ENABLED
  - SDMMC_AUTO_CAL_CONFIG_0_AUTO_CAL_PD_OFFSET = 8'h70
  - SDMMC_AUTO_CAL_CONFIG_0_AUTO_CAL_PU_OFFSET = 8'h62
- If using the SDMMC1 interface, correctly enable the integrated pullup/down resistors there:
  - PINMUX_AUX_SDMMC1_CLK_0_PULL_UP_NORMAL
  - If using eMMC (a stronger external 4.7 kOHm pullup is used on the CMD line):
    - PINMUX_AUX_SDMMC1_CMD_0_PULL_UP_NORMAL
  - If using SD or SDIO:
    - PINMUX_AUX_SDMMC1_CMD_0_PULL_UP_PULL_UP
  - PINMUX_AUX_SDMMC1_DAT3_0_PULL_UP_PULL_UP
  - PINMUX_AUX_SDMMC1_DAT2_0_PULL_UP_PULL_UP
  - PINMUX_AUX_SDMMC1_DAT1_0_PULL_UP_PULL_UP
  - PINMUX_AUX_SDMMC1_DAT0_0_PULL_UP_PULL_UP

28.6.1.3 SDMMC2

These settings are specific to the SDMMC2 controller:

- If using the SDMMC2 controller's external interface shared with the VI pins, correctly enable the integrated pullup/down resistors there:
  - PINMUX_AUX_VI_PCLK_0_PULL_UP_NORMAL
  - If using eMMC (a stronger external 4.7 kOHm pullup is used on the CMD line):
    - PINMUX_AUX_VI_D1_0_PULL_UP_NORMAL
  - If using SD or SDIO:
    - PINMUX_AUX_VI_D1_0_PULL_UP_PULL_UP
  - PINMUX_AUX_VI_D2_0_PULL_UP_PULL_UP
  - PINMUX_AUX_VI_D3_0_PULL_UP_PULL_UP
  - PINMUX_AUX_VI_D4_0_PULL_UP_PULL_UP
  - PINMUX_AUX_VI_D5_0_PULL_UP_PULL_UP
  - PINMUX_AUX_VI_D6_0_PULL_UP_PULL_UP
  - PINMUX_AUX_VI_D7_0_PULL_UP_PULL_UP
  - PINMUX_AUX_VI_D8_0_PULL_UP_PULL_UP
  - PINMUX_AUX_VI_D9_0_PULL_UP_PULL_UP
- If using the SDMMC2 controller's external interface shared with the KBC pins, correctly enable the integrated pullup/down resistors there:
  - PINMUX_AUX_KB_ROW10_0_PULL_UP_NORMAL
  - If using eMMC (a stronger external 4.7 kOHm pullup is used on the CMD line):
    - PINMUX_AUX_KB_ROW11_0_PULL_UP_NORMAL
  - If using SD or SDIO:
    - PINMUX_AUX_KB_ROW11_0_PULL_UP_PULL_UP
  - PINMUX_AUX_KB_ROW6_0_PULL_UP_PULL_UP
  - PINMUX_AUX_KB_ROW7_0_PULL_UP_PULL_UP
  - PINMUX_AUX_KB_ROW8_0_PULL_UP_PULL_UP
  - PINMUX_AUX_KB_ROW9_0_PULL_UP_PULL_UP
  - PINMUX_AUX_KB_ROW12_0_PULL_UP_PULL_UP
  - PINMUX_AUX_KB_ROW13_0_PULL_UP_PULL_UP
  - PINMUX_AUX_KB_ROW14_0_PULL_UP_PULL_UP
  - PINMUX_AUX_KB_ROW15_0_PULL_UP_PULL_UP
- If using the SDMMC2 controller's external interface shared with the DAP pins, correctly enable the integrated pullup/down resistors there:
  - PINMUX_AUX_DAP1_SCLK_0_PULL_UP_NORMAL
  - If using eMMC (a stronger external 4.7 kOHm pullup is used on the CMD line):
    - PINMUX_AUX_DAP1_FS_0_PULL_UP_NORMAL
  - If using SD or SDIO:
    - PINMUX_AUX_DAP1_FS_0_PULL_UP_PULL_UP
  - PINMUX_AUX_DAP1_DIN_0_PULL_UP_PULL_UP
  - PINMUX_AUX_DAP1_DOUT_0_PULL_UP_PULL_UP

- PINMUX_AUX_SPDIF_OUT_0_PULL_UP_PULL_UP
- PINMUX_AUX_SPDIF_IN_0_PULL_UP_PULL_UP

28.6.1.4 SDMMC3

These settings are specific to the SDMMC3 controller:

- If using the SDMMC3 interface, set the pads' drive strengths:
  - APB_MISC_GP_SDIO2CFGPADCTRL_0_CFG2TMC_SDIO2CFG_CAL_DRVDN = 6'h2A
  - APB_MISC_GP_SDIO2CFGPADCTRL_0_CFG2TMC_SDIO2CFG_CAL_DRVUP = 6'h2E
  - APB_MISC_GP_SDIO2CFGPADCTRL_0_CFG2TMC_SDIO2CFG_CAL_DRVDN_SLWR = 2'h1
  - APB_MISC_GP_SDIO2CFGPADCTRL_0_CFG2TMC_SDIO2CFG_CAL_DRVUP_SLWF = 2'h1
  - APB_MISC_GP_SDIO2CFGPADCTRL_0_CFG2TMC_SDIO3CFG_CAL_DRVDN = 6'h2A
  - APB_MISC_GP_SDIO2CFGPADCTRL_0_CFG2TMC_SDIO3CFG_CAL_DRVUP = 6'h2E
  - APB_MISC_GP_SDIO2CFGPADCTRL_0_CFG2TMC_SDIO3CFG_CAL_DRVDN_SLWR = 2'h1
  - APB_MISC_GP_SDIO2CFGPADCTRL_0_CFG2TMC_SDIO3CFG_CAL_DRVUP_SLWF = 2'h1
  - SDMMC_SDMEMCOMPPADCTRL_2_SDMMC2TMC_CFG_SDMEMCOMP_VREF_SEL = 4'h7
- If using SDMMC3 interface for SD or SDIO (instead of eMMC), additionally calibrate the pads by setting:
  - SDMMC_AUTO_CAL_CONFIG_2_AUTO_CAL_ENABLE_ENABLED
  - SDMMC_AUTO_CAL_CONFIG_2_AUTO_CAL_PD_OFFSET = 8'h70
  - SDMMC_AUTO_CAL_CONFIG_2_AUTO_CAL_PU_OFFSET = 8'h62
- If using the SDMMC3 interface, correctly enable the integrated pullup/down resistors there:
  - PINMUX_AUX_SDMMC3_CLK_0_PULL_UP_NORMAL
  - If using eMMC (a stronger external 4.7 kOHm pullup is used on the CMD line):
    - PINMUX_AUX_SDMMC3_CMD_0_PULL_UP_NORMAL
  - If using SD or SDIO:
    - PINMUX_AUX_SDMMC3_CMD_0_PULL_UP_PULL_UP
  - PINMUX_AUX_SDMMC3_DAT3_0_PULL_UP_PULL_UP
  - PINMUX_AUX_SDMMC3_DAT2_0_PULL_UP_PULL_UP
  - PINMUX_AUX_SDMMC3_DAT1_0_PULL_UP_PULL_UP
  - PINMUX_AUX_SDMMC3_DAT0_0_PULL_UP_PULL_UP

28.6.1.5 SDMMC4

These settings are specific to the SDMMC4 controller:

- If using the SDMMC4 controller's external interface shared with the GMI pins, correctly enable the integrated pullup/down resistors there:
  - PINMUX_AUX_SDMMC4_CLK_0_PULL_UP_NORMAL
  - If using eMMC (a stronger external 4.7 kOHm pullup is used on the CMD line):
    - PINMUX_AUX_SDMMC4_CMD_0_PULL_UP_NORMAL
  - If using SD or SDIO:
    - PINMUX_AUX_SDMMC4_CMD_0_PULL_UP_PULL_UP
  - PINMUX_AUX_SDMMC4_DAT7_0_PULL_UP_PULL_UP
  - PINMUX_AUX_SDMMC4_DAT6_0_PULL_UP_PULL_UP

- PINMUX_AUX_SDMMC4_DAT5_0_PULL_UP_PULL_UP
- PINMUX_AUX_SDMMC4_DAT4_0_PULL_UP_PULL_UP
- PINMUX_AUX_SDMMC4_DAT3_0_PULL_UP_PULL_UP
- PINMUX_AUX_SDMMC4_DAT2_0_PULL_UP_PULL_UP
- PINMUX_AUX_SDMMC4_DAT1_0_PULL_UP_PULL_UP
- PINMUX_AUX_SDMMC4_DAT0_0_PULL_UP_PULL_UP
- PINMUX_AUX_SDMMC4_RST_N_0_PULL_UP_PULL_DOWN

- If using the SDMMC4 controller's external interface shared with the CAM pins, correctly enable the integrated pullup/down resistors there:
  - PINMUX_AUX_CAM_MCLK_0_PULL_UP_NORMAL
  - If using eMMC (a stronger external 4.7 kOHm pullup is used on the CMD line):
    - PINMUX_AUX_GPIO_PCC1_0_PULL_UP_NORMAL
  - If using SD or SDIO:
    - PINMUX_AUX_GPIO_PCC1_0_PULL_UP_PULL_UP
  - PINMUX_AUX_GPIO_PBB0_0_PULL_UP_PULL_UP
  - PINMUX_AUX_CAM_I2C_SCL_0_PULL_UP_PULL_UP
  - PINMUX_AUX_CAM_I2C_SDA_0_PULL_UP_PULL_UP
  - PINMUX_AUX_GPIO_PBB3_0_PULL_UP_PULL_UP
  - PINMUX_AUX_GPIO_PBB4_0_PULL_UP_PULL_UP
  - PINMUX_AUX_GPIO_PBB5_0_PULL_UP_PULL_UP
  - PINMUX_AUX_GPIO_PBB6_0_PULL_UP_PULL_UP
  - PINMUX_AUX_GPIO_PBB7_0_PULL_UP_PULL_UP
  - PINMUX_AUX_GPIO_PCC2_0_PULL_UP_PULL_DOWN

28.6.2 eMMC Boot Modes

Note:	Only two of the four SD/MMC controllers can be a boot device: either SDMMC3 or SDMMC4.

28.6.3 Boot Option1

1. The clock to the card needs to be configured to 20 MHz.
2. Program the number of blocks. Configuring block length has no effect; it is always fixed to 512 bytes.
3. Configuring the data transfer direction has no impact, since it taken as CARD to HOST for boot mode.
4. Select either SDMA or PIO mode. (Tegra 3 devices do not support ADMA modes during boot option 1.)
5. Configure **SDMMC_VENDOR_BOOT_ACK_TIMEOUT_0** – The max timeout value that needs to be programmed is 50ms.The value programmed should exclude the 74 cycles that are required to enter boot mode.
6. Configure **SDMMC_VENDOR_BOOT_DAT_TIMEOUT_0** – The max timeout value that needs to be programmed is 1 sec. The value programmed should exclude the 74 cycles that are required to enter boot mode.
7. Configure **SDMMC_VENDOR_BOOT_CNTRL_0**[1] to 1 to ask the engine to look for boot_ack.
8. Configure **SDMMC_VENDOR_BOOT_CNTRL_0**[0] to trigger the engine.
9. If **SDMMC_INTERRUPT_STATUS_0**[31] = 1,the BOOT_ACK is not equal to 00101.The engine just informs the software and continues to fetch data from the card

10. If **SDMMC_INTERRUPT_STATUS_0**[30] = 1, the BOOT_ACK timeout has occurred. The engine just informs the software and continues to fetch data from the card.
11. The software should look for transfer complete interrupt. If data_time_out error has occurred, then the data transfer is not successful.
12. After successful data transfer from card, the software should look for sdma_engine_busy bit of **SDMMC_OBS_BUS[4].** Software shouldn't program commands until this bit is zero.

28.6.4 Boot Option2

Boot option2 is treated like any normal read command. The BOOT_ACK should be enabled if the card supports boot acknowledgment. **SDMMC_VENDOR_BOOT_ACK_TIMEOUT_0, SDMMC_VENDOR_BOOT_DAT_TIMEOUT_0** should be programmed based on the frequency of operation.

28.6.5 Card Detect and Write Protect

The standard SD Host SDCD# and CDWP# registers act as if those two pins are connected to zero. So, the SD driver must get the SDCD# and CDWP# interrupts and status via platform-specific GPIOs.

Additionally, an abort command should be issued if a card is removed during an SD transfer.

28.6.6 Improving Non-DMA (PIO) performance

When transferring more than a single 512 byte block size, PIO performance is reduced because the standard process waits for the buffer ready interrupt before beginning to move the next block of data.

Next block data movement can instead be pipelined on a four-byte word basis. To do this, software should waiting for SDMMC_PRESENT_STATE_x's BUFFER_READ_EN or BUFFER_WRITE_EN fields to assert instead of the buffer ready interrupt. These status fields signify that the next four-byte word can be read from or written to the internal 512 byte buffer.

28.6.7 SD3.0 Signal Voltage Switching

Note: This section is applicable only to the UHS-I SDMMC1 and SDMMC3 controllers. The SDMMC2 and SDMMC4 controllers do not require these settings.

After setting 1.8V Signal Enable in the *Host Control 2* register, the SD host driver communicates with the hardware platform to change the SDMMC1 or SDMMC3 I/O voltage from 3.3 to 1.8V. This is typically via I2C control of an external "PMIC" (Power Management IC), but varies from platform to platform.

Similarly, when resetting the controller (e.g., when an SD3.0 card in 1.8V mode has been removed), the SD host driver again communicates with the system software/platform to increase the SD IO voltage back to 3.3V.

28.6.8 Tuning

Because Tegra 3 SDMMC controllers do not automatically vary the RX clock trim each time Execute Tuning is set to 1, the SD Host driver must do this manually.

SD 3.0 cards can operate at frequencies up to 208 MHz. On Tegra 3 devices, for the card to operate at high frequencies, the correct tap value must be programmed. The tap value in the vendor clock control register controls the track delay so that the input data is sampled correctly. The appropriate tap delay for the given platform is found using frequency tuning. The passing tap value range can be found by incrementing the tap value after each iteration and running frequency tuning.

In frequency tuning, CMD19 is issued to the card and wait for the Buffer Read Ready interrupt. Once the interrupt is generated, in HOST_CONTROL_2 register (offset 03Eh), check whether EXECUTE_TUNING bit is cleared and the SAMPLING_CLOCK_SELECT bit is set. If both the conditions are met, treat tuning as successful and consider the tap value as working. After finding the passing tap range, the ideal tap value is calculated, which is 75% between the highest passing

tap and the lowest passing tap. Set this tap value and run frequency tuning again to confirm that the tap value works. If the passing tap range falls in between 0 and 10, discount it and try to find a higher passing tap range.

During testing, the tap range between 0 and 10 was found to be insufficient for operating frequencies up to 208MHz.

28.7 SDMMC Registers

28.7.1 Standard Registers

Note: For standard registers' usage, refer to the SD Host Controller Specification version 3.00.

There are a few vendor-specific register fields within the standard register offset range (0x00 through 0xff). (Future products will move these vendor-specific register fields out of the standard-defined register offset range.) These fields are described below:

28.7.1.1 Present State Register

Offset: 024h | Read/Write: R

Bit	Reset	Description
28:25	X	DAT_7_4_LINE_LEVEL: This status reflects the DAT[7:4] lines' state for debug.

28.7.1.2 Interrupt Status Register

Offset: 030h | Read/Write: R/W

Bit	Reset	Description
31:30	0	VEND_SPEC_ERROR Bit 1: BOOT_ACK_ERR: Occurs When Boot Ack Status is not equal to '010' Bit 0: BOOT_ACK_TIMEOUT_ERR: Occurs When Boot Ack is not received within the programmed number of cycles.

28.7.1.3 Interrupt Status Enable Register

Offset: 034h | Read/Write: R/W

Bit	Reset	Description
31:30	0	VEND_SPEC_ERROR 0 = Enable neither BOOT_ACK_ERR nor BOOT_ACK_TIMEOUT_ERR statuses. 1 = Enable only BOOT_ACK_TIMEOUT_ERR status. 2 = Enable only BOOT_ACK_ERR status. 3 = Enable both BOOT_ACK_ERR and BOOT_ACK_TIMEOUT_ERR statuses.

28.7.1.4 Interrupt Signal Enable Register

Offset: 038h | Read/Write: R/W

Bit	Reset	Description
31:30	0	VEND_SPEC_ERROR 0 = Enable neither BOOT_ACK_ERR nor BOOT_ACK_TIMEOUT_ERR interrupts to CPU. 1 = Enable only BOOT_ACK_TIMEOUT_ERR interrupt to CPU. 2 = Enable only BOOT_ACK_ERR interrupt to CPU. 3 = Enable both BOOT_ACK_ERR and BOOT_ACK_TIMEOUT_ERR interrupts to CPU.

28.7.1.5 Force Event Register

Offset: 050h | Read/Write: R/W

Bit	Reset	Description
31:30	0	VEND_SPEC_ERROR 0 = no effect 1 = Force a BOOT_ACK_TIMEOUT_ERR event 2 = Force a BOOT_ACK_ERR event. 3 = Force both BOOT_ACK_ERR and BOOT_ACK_TIMEOUT_ERR events.

28.7.2 Vendor-Specific Registers

The following Registers are Vendor Specific Registers and are mapped to the Vendor Specific Address Space (offsets 0x100 - 0x1FF).

28.7.2.1 SDMMC_VENDOR_CLOCK_CNTRL_0

TAP_VAL - Tap Value for the input data path trimmer. This determines the tap value needed to sample the input data correctly. Delay per each tap can range from 100ps to 250ps. Following values are recommended on different SDMMC interfaces for all modes up to SDR50.

- SDMMC1 - 5
- SDMMC2_DAP - 5
- SDMMC2_KBC - 5
- SDMMC2_VI - 6
- SDMMC3 - 5
- SDMMC4_PLANAR - 5
- SDMMC4_POP - 5

For SDR104 (only supported for SDMMC1 and SDMMC3), the tap value is determined by the tuning procedure.

BASE_CLK_FREQ -- Software should program the actual clock frequency programmed in CAR registers CLK_RST_CONTROLLER_CLK_SOURCE_SDMMC*_0 for each SDMMC controller. This should be done after every time SDMMC is reset and after every soft reset.

This is important as all SDMMC controllers follow the same register map, but could be programmed with different frequencies depending on the use case.

SPI_MODE_CLKEN_OVERRIDE - Software should always program this to 0 (NORMAL).

PADPIPE_CLKEN_OVERRIDE - Software should always program this to 0 (NORMAL).

Vendor Clock Control Register

Offset: 100h | Read/Write: R/W | Reset: 0b00000000001011101000 0xx001101

Bit	Reset	Description
28:24	0x0	TRIM_VAL: Reserved. Software should not change these bits.
23:16	0x5	TAP_VAL: Tap value for input data path trimmer.
15:8	0xd0	BASE_CLK_FREQ: System software programs the base SD/MMC clock frequency into this register before loading the SD/MMC driver. This value is readable in the standard, but not writeable, SDMMC_CAPABILITIES_0_BASE_CLOCK_FREQUENCY register field
5	0x0	SDR50_TUNING_OVERRIDE: override the SDR50_TUNING capabilities bit. Software should only set this bit if it is required to use Tuning for SDR50. (only supported for

Bit	Reset	Description
		SDMMC1 and SDMMC3) 0 = NORMAL : 0 -> No Tuning support advertised for SDR50 mode. 1 = OVERRIDE : 1 -> Tuning support is enabled for SDR50 mode
4	0x0	HW_RSTN_OVERRIDE: Hardware reset override for SDMMC4 instance This is a sticky 1 bit, will be reset using PMC2CAR_RSTN reset. This bit is valid only for SDMMC4 Instance 0 = NORMAL : 0 -> No override. 1 = OVERRIDE : 1 -> Override enabled.
3	0x1	PADPIPE_CLKEN_OVERRIDE: Override for padmacro and pipemacro clken. 1 -> CLKEN is kept asserted to padmacro and pipemacro when internal CLKEN is de-asserted. 0 -> CLKEN is to padmacro and pipemacro can be de-asserted along with internal CLKEN
2	0x1	SPI_MODE_CLKEN_OVERRIDE: Override for CLKEN during SPI_MODE during sw_reset. 1 -> CLKEN is kept asserted while doing sw_reset. 0 -> CLKEN is de-asserted while doing sw_reset
1	0x0	INPUT_IO_CLK: Feedback clock is selected by default. Software should not change this. Disabling Feedback clock will select Internal Clock that requires TAP Value Programming. 0 = FEEDBACK 1 = INTERNAL
0	0x1	SDMMC_CLK: This is set when sdmmc_clk is supplied by the CAR module prior to sdmmc_clk switch OFF. This bit should be written '0'. Prior to sdmmc_clk switch OFF. This bit should be written '0'. By writing zero, the asynchronous card interrupt is routed to the Interrupt controller. 0 = DISABLE 1 = ENABLE

28.7.2.2 SDMMC_VENDOR_SPI_CNTRL_0

Vendor SPI Control Register

Offset: 104h | Read/Write: R/W | Reset: 0b0

Bit	Reset	Description
0	0x0	SPI_MODE: SPI mode is not supported. 0 = DISABLE : 0 -> SPI mode is not enabled. 1 = Reserved.

28.7.2.3 SDMMC_VENDOR_SPI_INTR_STATUS_0

The fields are valid when a SPI error has occurred.

SPI Interrupt Status Register

Offset: 108h | Read/Write: RO | Reset: 0bxxxxxxxxx

Bit	Reset	Description
8:5	X	DAT_ERR_TOKEN: Data Error Token, while read from card
4:0	X	DAT_RESPONSE: Data Response while write to card 5 = DATA_ACCEPTED 11 = CRC_ERR 13 = WRITE_ERR

28.7.2.4 SDMMC_VENDOR_BOOT_CNTRL_0

This register is used to configure Boot Mode to support MMC v4.3 cards.

Vendor Boot Control Register

Offset: 110h | Read/Write: R/W | Reset: 0b00

Bit	Reset	Description
1	0x0	BOOT_ACK: This bit is used to support Boot Option in MMC 4.3 version cards. If set Boot acknowledgment is given by card else not given by card 0 = DISABLE 1 = ENABLE
0	0x0	BOOT: This bit enables/disable BootOption1.If set BootOption1 is enable, HW auto clears it when boot data is done. Writing 0 terminates the BootOption1 0 = DISABLE 1 = ENABLE

28.7.2.5 SDMMC_VENDOR_BOOT_ACK_TIMEOUT_0

Vendor Boot Acknowledgment Timeout Register

Offset: 114h | Read/Write: R/W | Reset: 0b00000000000000000000

Bit	Reset	Description
19:0	0x0	VALUE: If Boot Acknowledgment is not received within the programmed number of cycles. Boot Acknowledgement Timeout error occurs(VENDOR_SPECIFIC_ERR[0])

28.7.2.6 SDMMC_VENDOR_BOOT_DAT_TIMEOUT_0

Boot Data Timeout Register

Offset: 118h | Read/Write: R/W | Reset: 0b00000000000000000000000000

Bit	Reset	Description
24:0	0x0	VALUE: If Boot Data is not received within the programmed number of cycles. Then Data Timeout error occurs.

28.7.2.7 SDMMC_VENDOR_DEBOUNCE_COUNT_0

The Debounce Counter runs on 32 KHz clock.

Keeping the default value to 100ms = (100 * 32cycles/1ms) = 3200 cycles for 100ms = 0xC80

Debounce Counter Value Register

Offset: 11ch | Read/Write: R/W | Reset: 0b00000000000000110010000000

Bit	Reset	Description
23:0	0xc80	VALUE: The number of 32KHz clock cycles is programmed to meet Debounce period of the card slot.

28.7.2.8 SDMMC_VENDOR_MISC_CNTRL_0

- SDMMC_SPARE0: Spare register bits with reset value of 0
  - SDMMC_SPARE0[0] : SW_RESET_CLKEN_OVERRIDE, override the sdmmc_clken when doing SW_RESET if set to 1.
  - SDMMC_SPARE0[1] : When set, allows SD clock to be stopped in the middle of a read data block while in SDR104 mode.

    Unsafe for at least some SD cards, but may improve SDR104 DMA read performance in some cases.
  - SDMMC_SPARE0[2] : When set, SDR104 support is advertised in SDMMC_CAPABILITIES_HIGHER_0_SDR104
  - SDMMC_SPARE0[3] : When set, SDR50 support is advertised in SDMMC_CAPABILITIES_HIGHER_0_SDR50
  - SDMMC_SPARE0[4] : When set, SD3.0 support is advertised in SDMMC_SLOT_INTERRUPT_STATUS_0_SPECIFICATION_VERSION_NUMBER Otherwise, only SD2.0 support is advertised
  - SDMMC_SPARE0[5] : When 0, masks the pad macro's "high speed" enable to 0, causing the pad macro to always launch data on the falling edge of the clock. This prevents the SD Host driver's setting of SDMMC_POWER_CONTROL_HOST_x_HIGH_SPEED_EN from undesirably affecting the output timing.
- SDMMC_SPARE1: Spare register bits with reset value of 1
  - SDMMC_SPARE1[0] : CMD_CONFLICT_DISABLE, disable command line conflict if set to 1.

Misc Vendor Cntrl Register

Offset: 120h | Read/Write: R/W | Reset: 0b11111111111111110000000000000000

Bit	Reset	Description
31:16	0xffff	SDMMC_SPARE1: Spare register bits with reset value of 1
15:1	0x0	SDMMC_SPARE0: Spare register bits with reset value of 0
0	0x0	ERASE_TIMEOUT_LIMIT: Erase timeout value 0= Finite, It is limited to the programmed value in the DATA_TIMEOUT_VALUE 1= Infinite, Controller would be monitoring until the card is busy.

28.7.2.9 SDMMC_SDMEMCOMPPADCTRL_0

If AUTO_CAL_ENABLE is disabled (0), the values in this register is used to drive the DRVUP/DRVDN controls to the SDMMC pads.

SDMEMCOMP Pad control register

Offset: 1e0h | Read/Write: R/W | Reset: 0b1111111x1111111xxxxxxxx1000

Bit	Reset	Description
26:20	0x7f	CFG_SDMEMCOMP_DRVUP: used if AUTOCAL is disabled
18:12	0x7f	CFG_SDMEMCOMP_DRVDN: used if AUTOCAL is disabled
3:0	0x8	SDMMC2TMC_CFG_SDMEMCOMP_VREF_SEL

28.7.2.10 SDMMC_AUTO_CAL_CONFIG_0

SDMEMCOMP pad auto-calibration settings - Valid for SDMMC1/SDMMC3 Instances

AUTO_CAL_SLW_OVERRIDE

- 0 (Normal operation) pad DRVDN/UP_SLWR/F tied to AUTO_CAL output
  DRDVDN/UP_SLWR/F[1:0] = AUTO_CAL_PULLDOWN/UP[4:3]
- 1 (override) use CFG2TMC_SDIO[1|3]*_DRVDN/UP_SLWR/F pins to control pad slew inputs

AUTO_CAL_OVERRIDE

- 0 (normal operation): use AUTO_CAL_PU/PD_OFFSET as an offset to the calibration state machine setting
- 1 (override) : use AUTO_CAL_PU/PD_OFFSET register values directly

Offset: 1e4h | Read/Write: R/W | Reset: 0b0000xxxxxxxxx001x0000000x0000000

Bit	R/W	Reset	Description
31	RO	0x0	AUTO_CAL_START: Writing a one to this bit starts the calibration state machine. This bit must be set even if the override is set in order to latch in the override value.
30	RW	0x0	AUTO_CAL_OVERRIDE: 0 (normal operation): use AUTO_CAL_PU/PD_OFFSET as an offset to the calibration state machine setting 1 (override) : use AUTO_CAL_PU/PD_OFFSET register values directly
29	RW	DISABLED	AUTO_CAL_ENABLE: 1 (normal operation): use SDMMC generated pullup/dn (override or autocal) 0 (disabled): use sdmmc2tmc_cfg* register settings for pullup/dn 0 = DISABLED 1 = ENABLED
28	RW	0x0	AUTO_CAL_SLW_OVERRIDE: AUTOCAL slew rate override 0 (Normal operation) pad DRVDN/UP_SLWR/F tied to AUTO_CAL output DRDVDN/UP_SLWR/F[1:0] = AUTO_CAL_PULLDOWN/UP[4:3] 1 (override) use CFG2TMC_SDIO[1|3]*_DRVDN/UP_SLWR/F pins to control pad slew inputs
18:16	RW	0x1	AUTO_CAL_STEP: calibration step interval (in microseconds)
14:8	RW	0x0	AUTO_CAL_PD_OFFSET: 2's complement offset for pull-down value
6:0	RW	0x0	AUTO_CAL_PU_OFFSET: 2's complement offset for pull-up value

28.7.2.11 SDMMC_AUTO_CAL_INTERVAL_0

SDMEMCOMP pad calibration interval - Valid for SDMMC1/SDMMC3 Instances

Offset: 1e8h | Read/Write: R/W | Reset: 0b00000000000000000000000000000000

Bit	Reset	Description
31:0	0x0	AUTO_CAL_INTERVAL: 0: do calibration once Otherwise, auto-calibration occurs at intervals equivalent to the programmed number of microseconds.

28.7.2.12 SDMMC_AUTO_CAL_STATUS_0

SDMEMCOMP pad calibration status - Valid for SDMMC1/SDMMC3 Instances

Offset: 1ech | Read/Write: RO | Reset: 0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx

Bit	Reset	Description
31:0	X	AUTO_CAL_ACTIVE: One when auto calibrate is active - valid only after auto calibrate

Bit	Reset	Description
		sequence has completed (AUTO_CAL_ACTIVE == 0)
30:24	X	AUTO_CAL_PULLDOWN_ADJ: Pulldown code sent to pads
22:16	X	AUTO_CAL_PULLUP_ADJ: Pullup code sent to pads
14:8	X	AUTO_CAL_PULLDOWN: Pulldown code generated by auto-calibration
6:0	X	AUTO_CAL_PULLUP: Pullup code generated by auto-calibration

29.0 NAND FLASH CONTROLLER

The NAND flash interface controller allows Tegra® 3 devices to access NAND flash memories for mass storage. The controller supports both asynchronous (legacy) interfaces and ONFI 2.2 standard with error protection scheme required for data integrity in SLC and MLC devices. Tegra 3 devices support 24-bit BCH ECC correction. Up to 8 chip selects are supported natively, with more possible through GPIOs. The NAND Flash controller is an AHB master and can initiate high speed data transfers between external DRAM and NAND Flash memory through hardware buffering. NAND controller registers are connected on the APB interface as a slave, for register read/write access.

29.1 Features

The NAND Flash controller supports both PIO and DMA modes of operations for NAND Flash access. Interrupts are generated upon a COMMAND sequence completion, as programmed in the NAND_COMMAND register. Supported operations include individual cycles of command, address, read data and write data; or a combined sequence for program, erase and read operations. When hardware ECC is enabled, data transfer cycles are extended to update the flash spare area to store the parity data information.

In PIO transfer modes, data written into the RESP register is transmitted out, and similarly read data is captured in the RESP register. Typically, READ ID or READ STATUS sequences should make use of PIO mode of operation. PIO mode is not recommended for large transfers or when performance is a criterion.

Note:	PIO mode is not recommended for large transfers or when performance is a criterion.

In DMA mode, write data from DRAM is transmitted out, while for read transfers, data received from flash is transferred to DRAM as programmed in the DMA configuration registers. For each of the data pipelines, a separate FIFO is used to throttle the Read/Write transfers.

The NAND controller supports HW_ERROR_CORRECTION without using large buffers for page size data storage in the ECC decoder/encoder. It supports Error correction without using large buffers for page size data storage in ECC decoder/Encoder. Entire pages are not stored. Only sectors (512b/1kb chunks) are stored, thus reducing RAM area and increasing throughput.

The automatic RBSY status mode of operation reduces the software overhead by checking RBSY line status for CMB_RBSY application.

The NAND Controller supports Command queue mode of operation targeted to reduce the software overhead in managing the IO transfers on page basis. A number of Flash operations can be queued in this mode of operation with NAND DMA interface that will bring in these commands and execute them in sequence.

29.1.1 Feature Summary

- Supports asynchronous interface requirements of various NAND Flash memory vendors
- Programmable cycles to support multiple commands/operations in single sequence
- Programmable timing interface
- 8/16-bit data interface support
- Optional BCH coding based ECC for main/spare area data – 512 byte/1 kbyte codeword
- Programmable error correction capability of t=4,8,14, 16 and 24 bit error for each 512/1k bytes of data for BCH selection of main and spare area
- Programmable page size ranging from 512 bytes, 1k, 2k, 4k and 8k bytes
- EDO mode of read access for maximum read throughput
- Automated hardware status check

- Command queue mode of operation to queue up a number of flash operations
- Interface support up to 8 different devices
- Single DMA based programming interface for multi-page read/write transfer
- Scatter gather DMA structure that enables software to program fragmentation up front. The hardware automatically pre-fetches this information, and gathers fragments, thus eliminating the need for software to join the memory for non-contiguous memory targets
- Software control to interleave operations on multiple cards for optimum performance
- Extended decode status information to support software wear leveling and bad block management

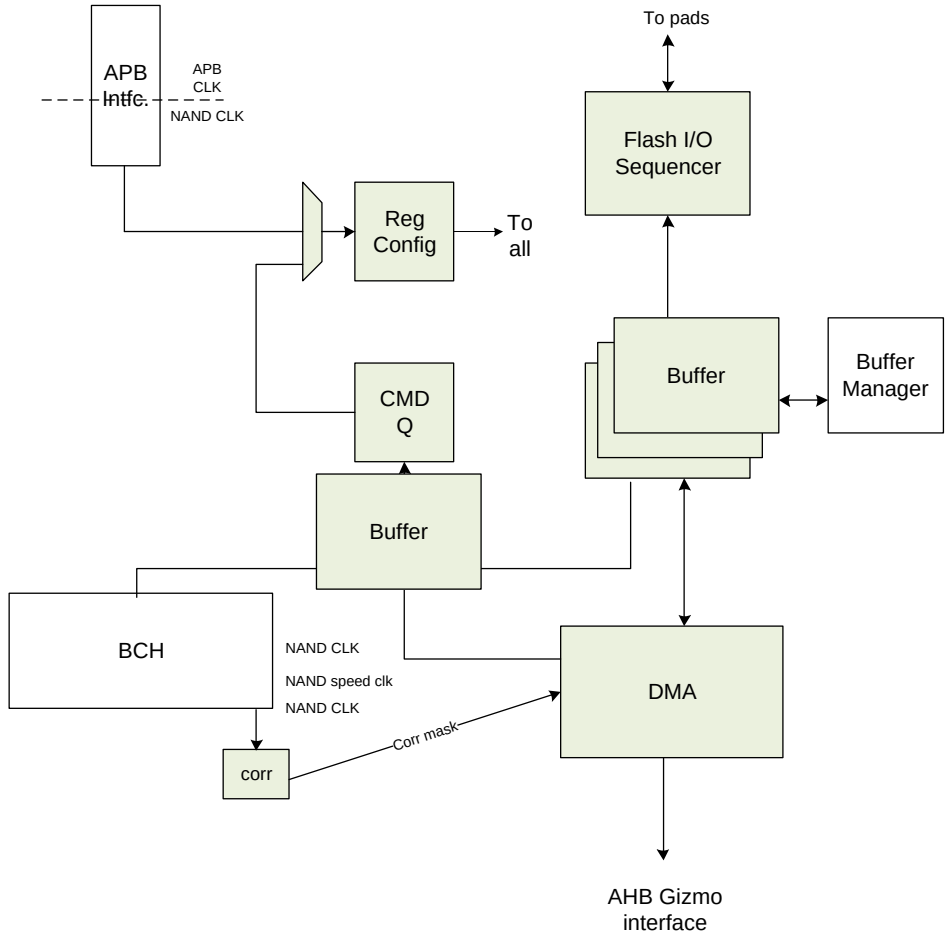
29.1.2 Software Features

The following Flash commands are supported:

- Flash Program (write)
- Flash Read
- Single plane Cache Write
- Double plane Cache Write
- Flash Cache Read
- Block Erase
- Read Status
- Read Status Multi-plane
- Reset
- Random Data Input/Output

29.2 Functional Description

Figure 69. NAND Controller Block Diagram



29.2.1 BCH Error Detection/Correction for Main and Spare Block Data

The following table summarizes the parity size lengths requirements for different Tag sizes.

Table 76 BCH ECC for Main and Spare

ECC (per 512 bytes)	Page Size (bytes)	Parity Size (bytes)
t=4	2k	28 bytes
t=8	2k	52 bytes
t=14	2k	92 bytes
t=16	2k	104 bytes
t=24	2k	104 bytes
t=4	4k	56 bytes
t=8	4k	104 bytes
t=14	4k	184 bytes

29.2.2 Hardware Error Correction

The NAND controller consists of quad buffers of 1k sector size to support hardware error correction. When ECC is enabled during data read from the NAND controller, data written to memory is already corrected (if it is correctable). Data read from the Flash interface is stored in the buffer and supplied to ECC logic to locate error location and apply correction on-the-fly with bit masks at the error bit locations while writing to memory.

29.2.3 Extended Decode Status Information

This section provides detailed information of error pattern development to enable software evaluation of wear-leaving and early detection of bad blocks. Once DMA completes a programmed number of pages of read, information is available of error pattern on a page basis. Without this mechanism, there is no way for software to figure out error pattern development in media, since hardware error correction is deployed. Once the errors approach the maximum correctable number, software can relocate these blocks to a new location.

Decode status buffer is stored with information of sub-page indication of correctable errors and un-correctable errors. For every page with correctable/uncorrectable error, an entry is made to this buffer. Upon DMA completion, software can read these buffer contents through APB register interface for error pattern analysis. Detailed description of related registers:

- CORRFAIL_ERR flag in NAND_ISR register indicates that DMA transfer of specified pages results in correctable OR un-correctable errors. If there are no correctable/un-correctable errors in any of the pages of DMA transfer, this bit is not SET.
- Register NAND_DEC_RESULT indicates the count of pages that result in correctable/un-correctable errors. Software reads these entries from decode status buffer.
- Register NAND_DEC_STAT_BUF. Reading this register fetches an entry from decode status buffer. Each entry of this buffer relates to page which results in either correctable/un-correctable error.

For both 8k page selection and 8k page selection with Tag only transfer enabled, there are 2 entries per page.

When page decode results in more number of errors than the threshold programmed OR uncorrectable errors, an entry is made into decode status buffer and an interrupt is raised. There are a couple of options available for software in this context depending on the use case:

- Service the interrupt read status buffer contents and Initiate abort.
- Service the interrupt read status buffer and continue the Read operation. Save the decode result statistics.

Do not enable/service the interrupt and let the DMA complete. Maximum number of page decode statistics are limited to 32 entries. This translates to 16 pages of DMA for 8k bytes page selection and 32 pages of DMA for all page sizes less than 8 kbytes.

Example

If 4 pages result in correctable errors and 2 pages in uncorrectable errors out of a total DMA transfer of 64 pages, PAGE_COUNT in NAND_DEC_RESULT will indicate as ‘PAGE_COUNT=6’. Software should read these 6 entries reading NAND_DEC_STAT_BUF register by CPU access and process it for further action.

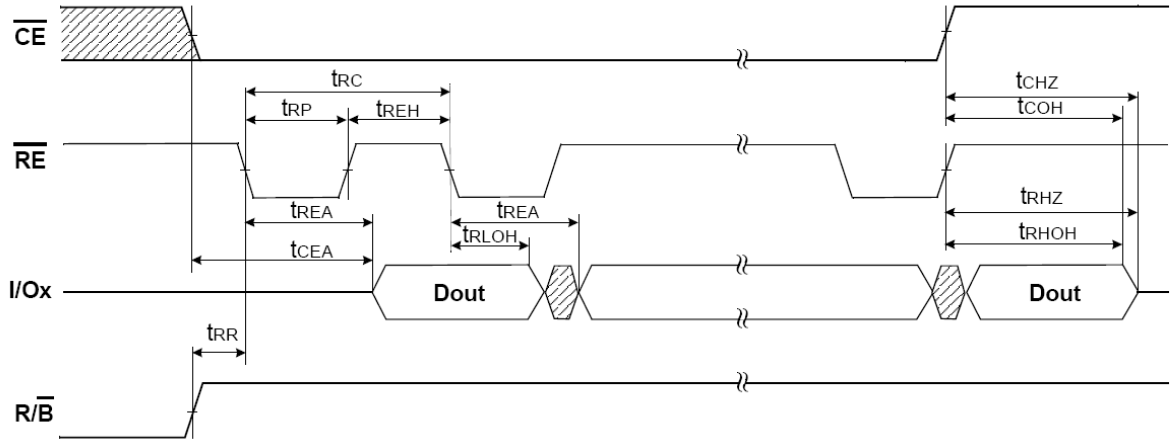
29.2.3.1 EDO Mode of READ Access

The latest generations of Flash support EDO (Extended Data Output) mode of operation. In this mode, Flash drives the data for an extended amount of time even after Read cycle hold time is completed. This enables the Host system to sample the data even on completion of READ pulse.

Since the typical read cycle of operation consists of asynchronous mode of operation (Host drives the READ pulse, and flash device drives the data), path/pad delays of read pulse extend the read pulse width so that correct data is sampled on the positive edge of READ pulse. Data availability at the following negative edge enables the Host system application to run without extending these pulse width timings, and thus improve performance.

EDO mode of read operation is controlled through the configuration bit EDO_MODE. Otherwise default Read data is sampled on pos-edge of READ pulse. The following diagram shows the extended data output timings.

Figure 70 EDO Mode Read Access

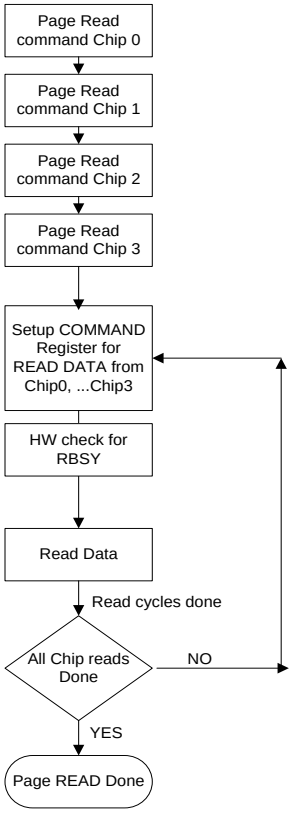


29.2.3.2 Automatic RBSY Status

The aim is to avoid software overhead checking the RBSY line status for CMB_RBSY application with single RBSY line. Read status command register NAND_HWSTATUS_CMD [7000:0050] is used for READ STATUS command issued by HW, configurable for the flash type used.

So when actual page read commands are issued, software can avoid the polling check for RBSY lines. When CMB_RBSY is enabled for read data transfer, hardware issues Read Status command using command byte in NAND_HWSTATUS_CMD register, and iterates till the flash is ready and moves to data read phase and completes the data transfer.

Figure 71 Interleaved READ Access for Combined RBSY Application with Auto RBSY



29.2.3.3 Skip Spare Bytes

In previous implementations of NAND Controllers with HW encoder, Tag data is written to flash in sequential order in spare area of flash. If main page ECC encode is not enabled, Tag data starts at location '0' in the spare area. Typically, with HW Encoder enabled, spare area write starts with parity bytes of main data. Flash vendors generally provide bad block information at these locations (there is no standard as to how much). These bytes need to be preserved for file system maintenance.

Skip spare feature allows achieving this functionality of skipping first few bytes of spare area as selected with SKIP_SPARE_SEL. Refer to NAND_CONFIG register for different options provided. Bit [23] of NAND_CONFIG, SKIP_SPARE_EN – turns on this new mode of operation. Ability to skip 4/8/12/16 bytes is supported with this enhancement.

29.2.3.4 Command Queue Processor

Command queue scheme is targeted to reduce the software overhead in managing the I/O transfers on a page basis. Each IO transfer typically consists of a page size of transfer for read/write/copy back or block erase. Considering 64k block of data transfer, current approach requires setup, initiation and track of 32 I/O CMD transfers for 2k page size selection. DMA is initialized once followed by multiple commands of I/O, sometimes repeatedly by just issuing the new command changing the address registers.

In command queue implementation, parameters required for each of the command (I/O transaction) are put together in the form of a packet. Software keeps on posting these packets, reducing the overhead to handle page transfer interrupts etc. NAND I/O and state control are now fed with the configuration of the current command in progress. After the completion of current command new packet is fetched from the command queue to proceed for the new I/O transfer without software intervention.

The following parameters are identified, which could vary from packet to packet depending on the flash sequences to be carried out. Each command packet consists few or all of the following parameters and each parameter is a 32-bit configuration register in the existing hardware implementation.

Table 77 Command Queue Registers

Command Queue Data set
NAND_COMMAND
NAND_CMD_REG1
NAND_CMD_REG2
NAND_ADDR_REG1
NAND_ADDR_REG2
NAND_DMA_MST_CTRL
NAND_DMA_CFG.A
NAND_DMA_CFG.B
NAND_DATA_BLOCK_PTR
NAND_TAG_PTR
NAND_ECC_PTR
NAND_HWSTATUS_CMD
NAND_HWSTATUS_MASK
NAND_CONFIG

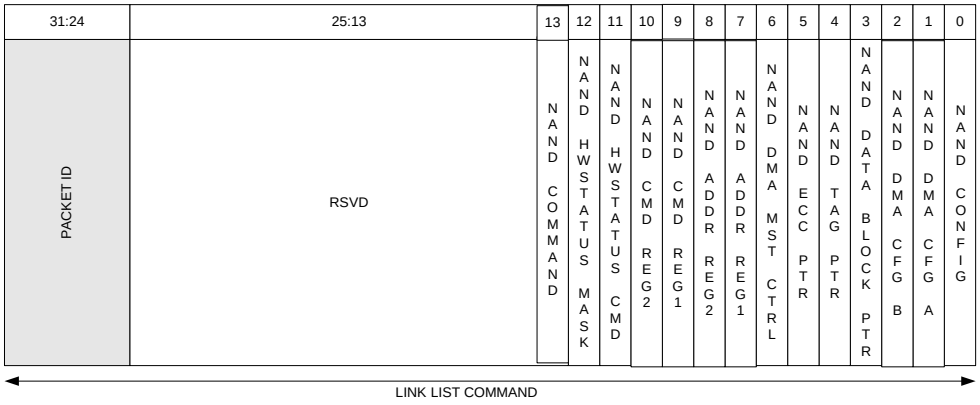
Note: Registers not listed above are not part of command queue configuration, and static during the duration of Command queue execution. These should be properly configured as described in programming guide lines and register spec.

Command Queue Definition

Terminology:

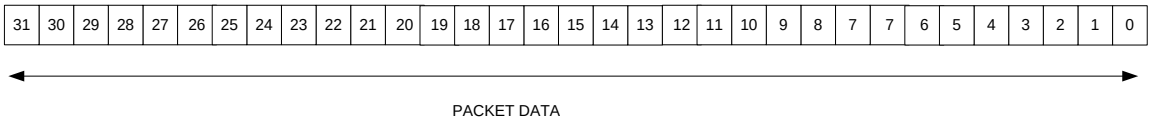
- Command Queue Command: command queue command register to define the register set programming.
- Command Queue Packet: one set of command and respective command data/registers.
- Command Queue Data: command packet parameter/register set value to be configured.
- Command Queue: set of command packets.

Figure 72 Command Queue Command Format



Within the ***command*** register, bit [13:0] is used to identify which register(s) need to be programmed with ***command queue data(s)*** that follows. A '1' within bit [13:0] indicates the corresponding register requires programming with ***command queue data***; a '0' indicates there's no programming needed for the corresponding register. The command queue command parser will always scan the ***command queue command*** starting from bit [0] to bit [13].

Figure 73 Command Queue Data Format



Following the ***command queue command***, one or more ***command queue data(s)*** follow. The 1st ***command queue data*** following the ***command queue command*** corresponds to the right most '1' bit within bit [13:0] of the ***command queue command***. Similarly, the 2nd command queue data following the command queue command corresponds to the 2nd right most '1' bit within bit [13:0] of the ***command queue command***.

Figure 74 Command Queue Packet Format

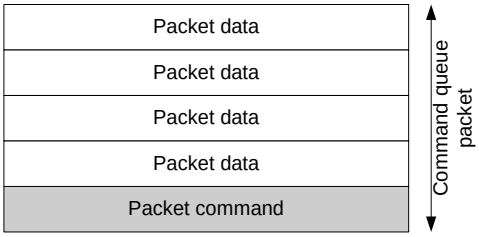


Figure 75 Command Queue Format

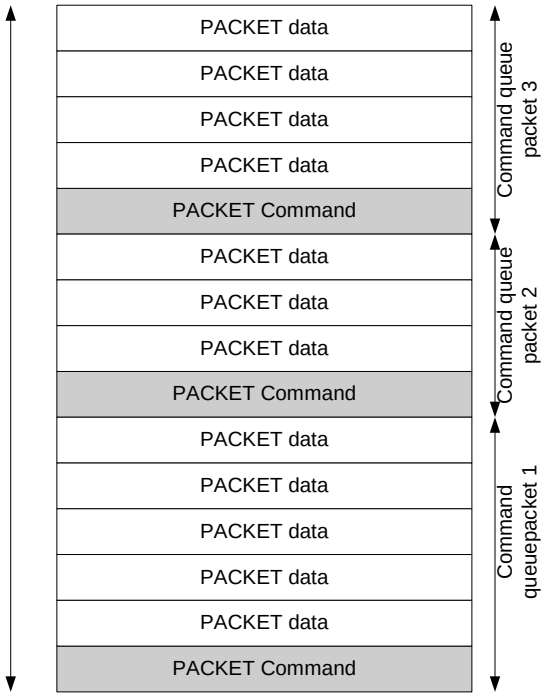
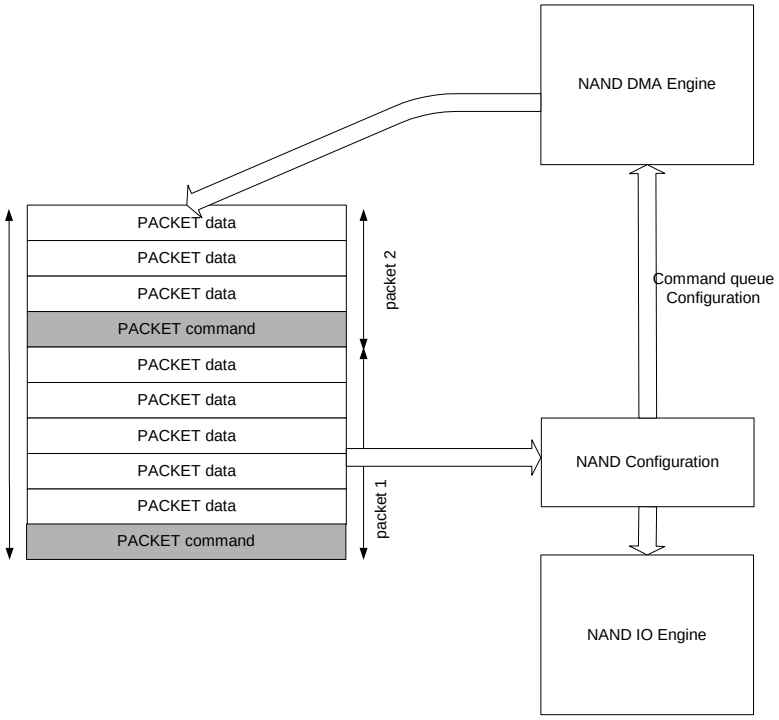


Command Queue Parser

Command queue parser fetches one command, followed by as many respective packet data fetches from this internal buffer as bit fields set in PACKET command register. When all the PACKET command data are fetched, corresponding sequence of register settings will configure the NAND Controller engine for specific sequence of IO operation. As soon as one command packet is completed, new command packet is processed.

Figure 76. Command Queue Parser



29.2.3.5 Memory Lock

The hardware provides a programmable address range on the flash controller, and a write once unchangeable bit for each range (unless the HW is reset) to implement this feature for software.

- NAND_LOCK_CONTROL: software configures which range check is applicable now.
- NAND_LOCK_STATUS: HW indicates which of the range is matched caused this interrupt.
- NAND_LOCK_APERTURE_START0 – NAND_LOCK_APERTURE_END0: If Block erase command address matches this range (inclusive of start, ends), actual flash erase is skipped and LOCK_ERROR interrupt is generated.

29.3 Programming Guidelines

29.3.1 Clocking

For Async or legacy single data rate mode:

- Configure CLK_SOURCE_NDFLASH register with desired clock source selection and DIVISOR settings like any peripheral clock programming requirements. NAND Controller clocks should be enabled with CLK_ENABLE_NDFLASH=1 it field in CLK_OUT_ENABLE_L register
- Configure CLK_SOURCE_NDFLASH register bit field NDFLASH_DIV2_SEL =0.

For DDR rate mode of interface:

- Configure CLK_SOURCE_NDFLASH (0x60006160) register with desired clock source selection and DIVISOR settings like any peripheral clock programming requirements. Frequency selection should be such that achieved clock frequency is twice the desired DDR interface frequency of operation.
- Configure CLK_SOURCE_NDFLASH register bit field NDFLASH_DIV2_SEL=1. This will make internal logic to operate on interface frequency and portion of logic on twice the interface frequency.

> **Note:** In Tegra 3 NAND, separate clocking branch has been added for clocking search algorithm in error correction logic. This is to speed up error location search during decode operation. Clock source options similar to CLK_SOURCE_NDFLASH exist for this clock branch.

- NAND speed clock should be enabled with CLK_ENABLE_NAND_SPEED=1 field in CLK_OUT_ENABLE_U register.
- Configure CLK_SOURCE_NAND_SPEED register with desired clock source selection and DIVISOR settings.
- NAND speed clock achieved frequency should be greater than or equal to NAND_CLK as programmed through CLK_SOURCE_NDFLASH register. For BootRom purpose, this may be programmed same as NAND_CLK where the decode latency is not a major concern.

29.3.2 Pin Muxing

Tegra 3 NAND has 2 pin multiplexing options, one on GMI pins and the other on KBC pins. The set of MISC registers to be programmed for both these selections are listed below.

29.3.2.1 GMI Option

1) With 8 Chip selects and 1 RBSY line.

PINMUX_AUX_GMI_IORDY_0 = 0x21
PINMUX_AUX_GMI_ADV_N_0 = 0x21
PINMUX_AUX_GMI_CS4_N_0 = 0x21
PINMUX_AUX_GMI_CS3_N_0 = 0x21
PINMUX_AUX_GMI_AD1_0 = 0x21
PINMUX_AUX_GMI_AD3_0 = 0x21
PINMUX_AUX_GMI_AD5_0 = 0x21
PINMUX_AUX_GMI_AD7_0 = 0x21
PINMUX_AUX_GMI_AD9_0 = 0x21
PINMUX_AUX_GMI_AD11_0 = 0x21
PINMUX_AUX_GMI_AD13_0 = 0x21
PINMUX_AUX_GMI_AD15_0 = 0x21
PINMUX_AUX_GMI_OE_N_0 = 0x21
PINMUX_AUX_GMI_WP_N_0 = 0x21
PINMUX_AUX_GMI_CS1_N_0 = 0x21
PINMUX_AUX_GMI_CS7_N_0 = 0x21
PINMUX_AUX_GMI_WAIT_0 = 0x21
PINMUX_AUX_GMI_CLK_0 = 0x21
PINMUX_AUX_GMI_CS2_N_0 = 0x21
PINMUX_AUX_GMI_AD0_0 = 0x21
PINMUX_AUX_GMI_AD2_0 = 0x21
PINMUX_AUX_GMI_AD4_0 = 0x21
PINMUX_AUX_GMI_AD6_0 = 0x21
PINMUX_AUX_GMI_AD8_0 = 0x21
PINMUX_AUX_GMI_AD10_0 = 0x21
PINMUX_AUX_GMI_AD12_0 = 0x21
PINMUX_AUX_GMI_AD14_0 = 0x21
PINMUX_AUX_GMI_WR_N_0 = 0x21
PINMUX_AUX_GMI_DQS_0 = 0x21
PINMUX_AUX_GMI_CS0_N_0 = 0x21
PINMUX_AUX_GMI_CS6_N_0 = 0x21
PINMUX_AUX_GMI_RST_N_0 = 0x21

2) With 4 Chip selects and 4 RBSY lines.

PINMUX_AUX_GMI_IORDY_0 = 0x21
PINMUX_AUX_GMI_ADV_N_0 = 0x21
PINMUX_AUX_GMI_CS4_N_0 = 0x21
PINMUX_AUX_GMI_CS3_N_0 = 0x21
PINMUX_AUX_GMI_AD1_0 = 0x21
PINMUX_AUX_GMI_AD3_0 = 0x21
PINMUX_AUX_GMI_AD5_0 = 0x21
PINMUX_AUX_GMI_AD7_0 = 0x21
PINMUX_AUX_GMI_AD9_0 = 0x21
PINMUX_AUX_GMI_WAIT_0 = 0x21
PINMUX_AUX_GMI_CLK_0 = 0x21
PINMUX_AUX_GMI_CS2_N_0 = 0x21
PINMUX_AUX_GMI_AD0_0 = 0x21
PINMUX_AUX_GMI_AD2_0 = 0x21
PINMUX_AUX_GMI_AD4_0 = 0x21
PINMUX_AUX_GMI_AD6_0 = 0x21
PINMUX_AUX_GMI_AD8_0 = 0x21
PINMUX_AUX_GMI_AD10_0 = 0x21

PINMUX_AUX_GMI_AD11_0 = 0x21
PINMUX_AUX_GMI_AD12_0 = 0x21
PINMUX_AUX_GMI_AD13_0 = 0x21
PINMUX_AUX_GMI_AD14_0 = 0x21
PINMUX_AUX_GMI_AD15_0 = 0x21
PINMUX_AUX_GMI_WR_N_0 = 0x21
PINMUX_AUX_GMI_OE_N_0 = 0x21
PINMUX_AUX_GMI_DQS_0 = 0x21
PINMUX_AUX_GMI_WP_N_0 = 0x21
PINMUX_AUX_GMI_CS0_N_0 = 0x21
PINMUX_AUX_GMI_CS1_N_0 = 0x21
PINMUX_AUX_GMI_CS6_N_0 = 0x20
PINMUX_AUX_GMI_CS7_N_0 = 0x20
PINMUX_AUX_GMI_RST_N_0 = 0x20

Also, NAND_FBIO_CFG [7000:811C] register should be programmed for either of these CS/RBSY selection.

- CFG_RETIME_STAGES=0x0

29.3.2.2 KBC Option

1) With 2 Chip selects and 1 RBSY line

PINMUX_AUX_KB_ROW0_0 = 0x21
PINMUX_AUX_KB_ROW1_0 = 0x21
PINMUX_AUX_KB_ROW2_0 = 0x21
PINMUX_AUX_KB_ROW3_0 = 0x21
PINMUX_AUX_KB_ROW4_0 = 0x21
PINMUX_AUX_KB_ROW5_0 = 0x21
PINMUX_AUX_KB_ROW6_0 = 0x21
PINMUX_AUX_KB_ROW7_0 = 0x21
PINMUX_AUX_KB_ROW8_0 = 0x21
PINMUX_AUX_KB_ROW9_0 = 0x21
PINMUX_AUX_KB_ROW10_0 = 0x21
PINMUX_AUX_KB_ROW11_0 = 0x21
PINMUX_AUX_KB_ROW12_0 = 0x21
PINMUX_AUX_KB_ROW13_0 = 0x21
PINMUX_AUX_KB_ROW14_0 = 0x21
PINMUX_AUX_KB_ROW15_0 = 0x21
PINMUX_AUX_KB_COL0_0 = 0x21
PINMUX_AUX_KB_COL1_0 = 0x21
PINMUX_AUX_KB_COL2_0 = 0x21
PINMUX_AUX_KB_COL3_0 = 0x21
PINMUX_AUX_KB_COL4_0 = 0x21
PINMUX_AUX_KB_COL5_0 = 0x21
PINMUX_AUX_KB_COL6_0 = 0x21
PINMUX_AUX_KB_COL7_0 = 0x21

NAND_FBIO_CFG [7000:811C] register should also be programmed

- CFG_RETIME_STAGES=0x1

29.3.3 Interrupts

For write transfers,

- DMA done interrupt, IS.DMA_DONE in NAND_DMA_MST_CTRL is set and it happens before the Command completion for a single page DMA transfer size.
- Command done interrupt, IS.CMD_DONE as in NAND_ISR indicates the I/O transaction completion as per NAND_COMMAND register configuration.
- If spare access with B_VALID or HW_ECC is enabled, CMD_DONE interrupt guarantees that all of these operations are completed.

For read transfers,

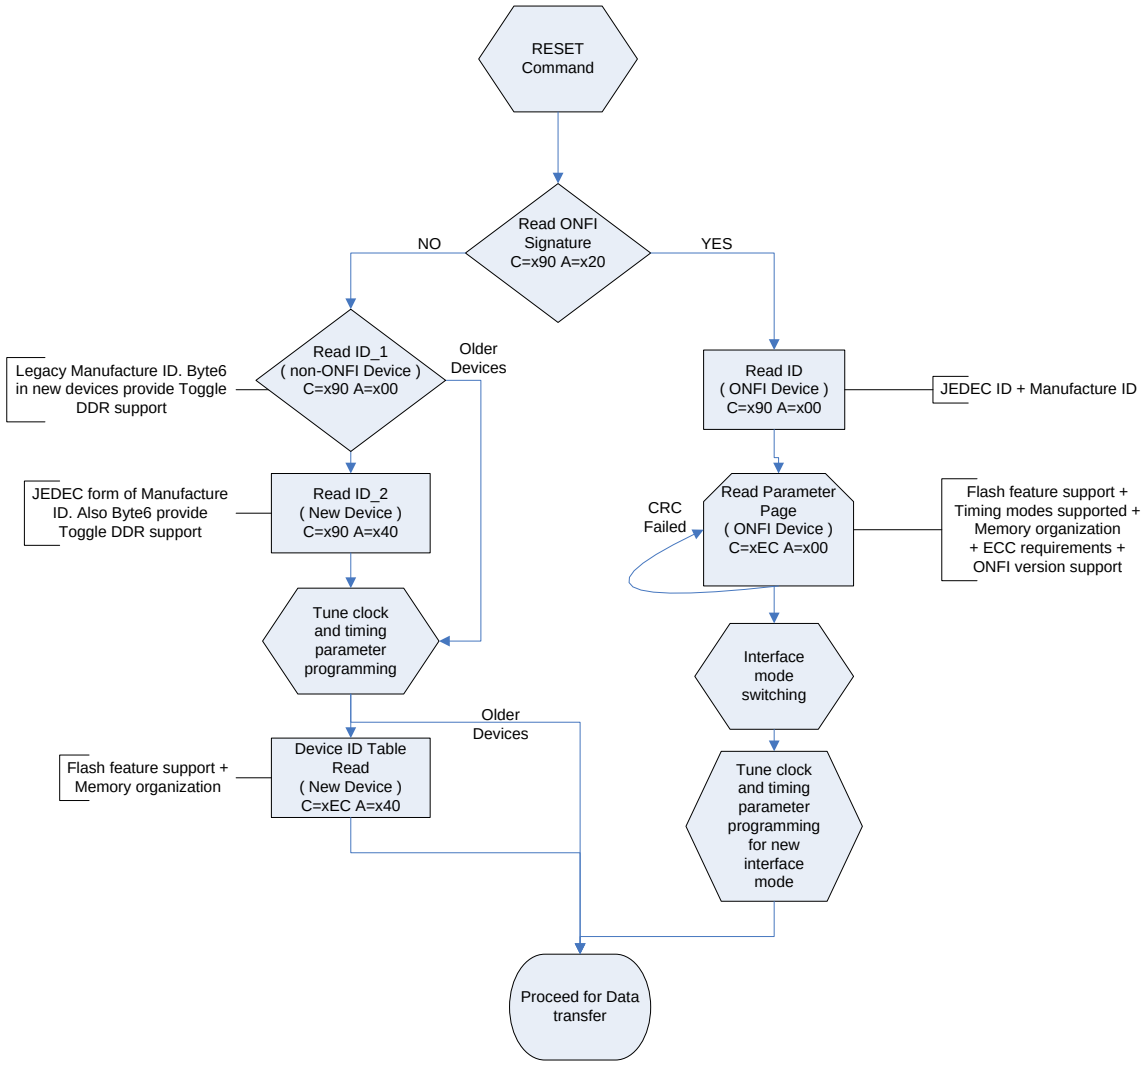
- Command done interrupt, IS.CMD_DONE as in NAND_ISR indicates the I/O transaction completion as per NAND_COMMAND register configuration.
- DMA done interrupt, IS.DMA_DONE in NAND_DMA_MST_CTRL is set which happens after the Command completion for a single page DMA transfer size. In addition it is guaranteed that actual data are transferred to XMB destinations as programmed which is inclusive of TAG information if it is enabled.

29.3.4 Device Initialization Sequence

The flow chart below details the sequence required during initialization to support variety of devices, i.e. starting from legacy NAND devices with asynchronous mode support, asynchronous devices with toggle DDR support, to all flavors of ONFI standards up to ONFI 2.2 specification.

- Once it is detected that the device is not ONFI compliant, from device maker code and device code, software has to figure out whether read ID information of 6 byte is valid or not. The latest generation devices from most vendors have 6th byte for interface mode capabilities. Bit fields in 6th byte indicate support of toggle DDR mode.
- For older legacy devices, device ID table read command may not be supported.
- For ONFI devices, Read Parameter Page structure provides information of interface mode support and other device capabilities.

Figure 77. Device Initialization Sequence



29.3.5 Interface Modes and Switching Modes

The latest generations of Flash devices support different interface modes of operation. Considering the power and performance requirements, software can operate in any of the interface modes supported by the device. Tegra 3 NAND Controller supports different interface modes as offered by the device manufacturers. The sections that follow outline the

interface modes and required guidelines for switching modes within that category. Programming of timing registers is covered in subsequent section. In general, timing register changes or NAND clock frequency changes should be done when the controller is idle and no operations are in progress to Flash.

29.3.5.1 Legacy Asynchronous Interface Devices

These are devices with legacy asynchronous interface, and are not ONFI compliant. Mode switching is not allowed for such devices. However, minimum timing requirements must be met as per NAND Controller clock frequency and timing register programming.

- Tegra 3 NAND Controller supports 2 sets of timing registers. With NAND_TIMING, NAND_TIMING2 registers timing programming is backward compatible to Tegra 2 etc.
- New set of timing registers are selected with TIMING_SEL=1 bit field in NAND_CONFIG2 register.
- Relevant timing registers: NAND_ASYNC_TIMING0, NAND_ASYNC_TIMING1, NAND_ASYNC_TIMING2, NAND_ASYNC_TIMING3

29.3.5.2 Toggle DDR Interface Devices

In these devices, there is no interface mode switching as in ONFI devices.

- On power on, device comes up in toggle interface.
- Different interface mode speeds are achieved with NAND clock frequency selection. Timing parameters have to be worked out as per timing equations along with clock frequency selection.
- Enable toggle DDR interface mode of operation with TOGGLE_DDR=1 setting in NAND_CONFIG2 register
- Relevant timing registers: NAND_ASYNC_TIMING_0, NAND_ASYNC_TIMING_1, NAND_ASYNC_TIMING_2, NAND_ASYNC_TIMING_3, NAND_TDDR_TIMING_0, NAND_TDDR_TIMING_1

29.3.5.3 ONFI Devices (Including DDR Capable Devices)

Devices conforming to ONFI standards fall in this category. Devices compliant to ONFI standards can range from asynchronous mode of transfer to DDR mode of transfer. Interface mode switching is allowed in such devices as per guidelines indicated in the standard.

Summary

- On power on, device comes up in asynchronous mode 0
- Program timing registers to work for ONFI async mode 0 timing requirements
- Perform Device initialization routine as described in section 3.4.2 of ONFI 2.2 spec
- Issue Read Parameter Page command to identify device capabilities and interface modes supported
- Issue Set Features command to switch to async modes of higher speed or source synchronous (DDR) modes
- Configure clocking changes for NAND Controller to operate at new frequency as required. In case of switching from async mode to DDR mode, additional clock source selection changes are required as described in clocking section.
- Update NAND Controller timing registers as per new interface mode. For switching to async modes, update of respective register fields is required. Switching to DDR mode requires additional timing register configuration.
- Enable toggle DDR interface mode of operation with SYNC_DDR=1 setting in NAND_CONFIG2 register. For asynchronous interface mode only, SYNC_DDR=0 configuration is required.
- Relevant timing registers for asynchronous modes: NAND_ASYNC_TIMING_0, NAND_ASYNC_TIMING_1, NAND_ASYNC_TIMING_2, and NAND_ASYNC_TIMING_3.
- Relevant timing registers for source synchronous modes: NAND_ASYNC_TIMING_0, NAND_ASYNC_TIMING_1, NAND_ASYNC_TIMING_2, NAND_SDDR_TIMING_0, NAND_SDDR_TIMING_1

29.3.6 Programming of Command, Address and Data Transfer Sequences

NAND Flash Controller register interface allows for a flexible programming sequence that is fully under firmware control. Firmware can issue command, address and data transfers individually or combine them to form Read/Write/Status read sequences that the NAND flashes require.

For all the programming sequences described below, it is assumed that,

- NAND_TIMING register has already been programmed with the correct value for the NAND device in use. More details on programming the NAND timing register are given below.
- BUS_WIDTH field is set or cleared based on the flash card data width requirement.

29.3.6.1 Command Transfer

- Write to the NAND_CMD_REG1 with the command byte.
- Write to NAND_COMMAND register with CLE bit set, CE bit field set to the desired Chip Enable and the GO bit set. The CLE bit being set indicates that a command needs to be issued. The GO bit being set initiates the CLE transfer on the interface.
- Firmware can now check the status of the operation by polling the GO status. GO bit is cleared by the hardware on completion of the operation. Alternately, software can enable operation completion interrupt and handle the interrupt

29.3.6.2 Address Transfer

- Write to the NAND_ADDR_REG1/NAND_ADDR_REG2 with address bytes to be transferred. Software needs to form the address bytes in the format and sequence expected by the NAND device being used. Order of the address transfer by hardware is: NAND_ADDR_REG1 [7:0], NAND_ADDR_REG1 [15:8], NAND_ADDR_REG1 [23:16], NAND_ADDR_REG1 [31:24], NAND_ADDR_REG2 [7:0], NAND_ADDR_REG2 [15:8], NAND_ADDR_REG2 [23:16], NAND_ADDR_REG2 [31:24]. Actual number of address bytes transferred depends on the ALE_SIZE field. A maximum of 8 address bytes can be issued.
- Write to NAND_COMMAND register with ALE bit set, CE bit field set to the desired Chip Enable and the GO bit set. The ALE bit being set indicates that address cycles are present in the current sequence. The GO bit being set initiates the ALE transfer on the interface.
- Wait for completion of the operation through GO bit polling or CMD_DONE interrupt.

29.3.6.3 Write Data Transfer

This is used for writing data to the NAND Flash.

- Configure the PAGE_SIZE_SEL.A, BUS_WDITH fields in the NAND_CONFIG register as required by the Page size requirement of the Flash.
- Configure the DMA_BLOCK_SIZE.A field in the NAND_DMA_CFG.A register with the number of bytes to be transferred. This is the total number of bytes to be transferred and can be up to 64KBytes.
- Configure the NAND_DATA_BLOCK_PTR register with the data block address to be written to the flash.
- The above configuration initiates data transfers to flash. However, transfers to the device start as soon as the data is available in FIFO. Data transfers are throttled based on the internal buffer status.
- Program the NAND_DMA_MST_CTRL register DIR, BURST SIZE fields for transmit and enable the DMA_GO bit.
- Write to NAND_COMMAND register with the TX bit set, the CE bit field set of the desired chip and the GO bit set.
- This operation starts the write transfers on the NAND interface with command values from registers and data from buffers. Individual data transfer of byte or half-word wide is based on BUS_WIDTH parameter programmed. Transfers continue until a programmed size of data is written.

29.3.6.4 Read Data Transfers

This is used for reading data from the NAND Flash.

- Configure the DMA_BLOCK_SIZE.A and PAGE_SIZE_SEL.A fields in the NAND_DMA_CFG.A register with the number of bytes to be transferred. This is the total number of bytes to be transferred and can be up to 64KB.
- Configure the NAND_DATA_BLOCK_PTR register with the data block address to be written to the flash.
- The above configuration's initiates data reads from the device to internal buffer. Data reads on the NAND interface are throttled based on the buffer status.
- Program the NAND_DMA_MST_CTRL register DIR, BURST SIZE fields for receive and enable the DMA_GO bit. The above configuration prepares the transfer from buffers to AHB. But the actual data transfer starts only after valid entries available in buffers
- Write to NAND_COMMAND register with the RX bit set, the CE bit field set of the desired chip and the GO bit set.
- This Read operation continues until the transfer size worth of data is read and placed into the buffer as per transaction size selected. DMA Read operation continues until the buffer read is transferred to DMA destination of the programmed DMA length.
- Polling or interrupt can be used by firmware to determine the completion of each operation.

29.3.7 Programming of Flash Operations

All sequences described below are optimized for the performance of common NAND sequences by enabling multiple control bits when issuing NAND_COMMAND. Software has the flexibility of issuing these transfer operations individually and achieving the same results, albeit with lower performance.

Note:	In the following description, "operation" is used to indicate the command issued to the NAND Flash Controller; "sequence" refers to the sequence of events on the NAND Flash Interface.

29.3.7.1 Reset Sequence

In order to reset the NAND Flash, a reset command needs to be issued.

- Write to NAND_CMD_REG1 with LSB byte as "0xFF"
- Write to NAND_COMMAND register with CLE bit set, and GO bit set. Clear all the other control bits.
- Reset command is issued on the NAND interface
- NAND Controller operation completion is reflected in the status bit (GO bit is cleared). Additionally, command done interrupt is generated if it has been enabled.

29.3.7.2 Status Read Sequence

This sequence is used to read the status from the NAND Flash. By definition, this requires issuing a command "0x70" followed by reading a byte of data. This can be achieved in a single operation as follows:

- Write to NAND_CMD_REG1 with LSB byte as "0x70"
- Write to NAND_COMMAND register with the following
- CLE bit set
- PIO bit set, RX bit set
- TRANS_SIZE set to 1 byte
- Clear bits TX, SEC_CMD, AFT_DAT, A_VALID, B_VALID
- Set the GO bit
- The GO bit being set initiates the Controller "operation" to issue a sequence on the NAND interface.

- NAND controller sends out the CLE with command “0x70” and follows this with a response read of one byte from the NAND device. The Controller handles all the timing requirements of the NAND device based on the parameters programmed in NAND_TIMING register. The read byte is placed into the NAND_RESP register in little-endian format
- When the read is complete, NAND Controller operation is complete. This is reflected in the status bits, and command done interrupt is also generated when enabled. If polling is used, firmware can poll the GO bit. This is set by firmware to initiate the transfer and when the operation is done, hardware will clear this bit.

29.3.7.3 Read ID Sequence

Read ID requires issuing a READ ID command (0x90), followed by an address cycle and then reading 4 bytes of ID information. This is achieved as follows:

- Write to NAND_CMD_REG1 with LSB byte as “0x90”
- Write to NAND_ADDR_REG1 with the address byte.
- Write to NAND_COMMAND register with the following
  - CLE bit set
  - ALE bit set, ALE_SIZE field is set to the appropriate number of bytes required.
  - PIO, RX bits are set
  - TX bits is cleared
  - TRANS_SIZE field is set to 4 bytes (maximum of 4 bytes is only possible)
  - SEC_CMD, AFT_DAT bits are cleared
  - Clear A_VALID, B_VALID bit
  - Set CE bit field for desired chip select.
  - Set GO bit starts interface command sequence.
- When the GO bit is set, CLE (0x90) -> ALE -> DATA READ sequence is initiated on the interface:
- Write to NAND_CONFIG register with the following
  - Set EDO_MODE field if flash memory supports. Note that tRP/tRP_RESP timing values should be adjusted to reduce the round trip delay factor, hence improving the performance.
  - Set BUS_WIDTH field for 16-bit data interface selection
- The data read from flash is written into the NAND_RESP register (since PIO bit is set)
- When entire sequence is completed, the operation done is indicated by the command done interrupt as well as hardware clear of ‘GO’ bit.

29.3.7.4 Block Erase Sequence

Block erase requires block erase setup command to be issued (0x60), followed by Address for the block (row only), and finally the block erase command. This is achieved as follows:

- Write to NAND_CMD_REG1 with LSB byte as “0x60”
- Write to NAND_CMD_REG2 with LSB byte as “0xD0”
- Write to NAND_ADDR_REG1/NAND_ADDR_REG2 with the block address.
- Write to NAND_COMMAND register with the following
  - CLE bit set
  - ALE bit set, ALE_SIZE field is set to the appropriate number of bytes required.
  - PIO, TX, RX bits are cleared
  - Set the SEC_CMD bit (for issuing the second command “0xD0”)
  - AFT_DAT bit is cleared (0), since the second command needs to be after address stage

- Clear A_VALID, B_VALID bits
- Set CE bit field for desired chip select.
- Set GO bit starts interface command sequence.

- When the GO bit is set , CLE (0x60) -> ALE –> CLE (0xD0) sequence is initiated on the interface
- When entire sequence is completed, the operation done is indicated by the command done interrupt as well as hardware clear of `GO' bit

29.3.7.5 Page Program Sequence

This sequence is used to write a page of data to the NAND Flash without ECC and without spare region access. First a write command “0x80” should be issued, followed by the destination address. Then, all the page data is written to the device. After writing the page data, programming is initiated by issuing the program command “0x10”. This sequence is achieved as follows:

- Write to NAND_CMD_REG1 with LSB byte as “0x80”
- Write to NAND_CMD_REG2 with LSB as “0x10”
- Write to NAND_ADDR_REG1/NAND_ADDR_REG2 with the correct address bytes to be transferred.
- Configure NAND_TIMING, NAND_TIMING2 registers as described later in this document
- Write to NAND_CONFIG register with the following
  - Configure the PAGE_SIZE_SEL to select the page transfer size based on flash memory organization
  - If PROG_OFFSET_EN feature is disable, set SKIP_SPARE field so that controller can skip writing to factory bad block information at the start of spare region.
  - Set BUS_WIDTH field for 16-bit data interface selection
  - Set COM_RBSY field for wired-AND connection of flash RBSY lines to RBSY0 line.
- For COM_RBSY selection, configure NAND_HWSTATUS_CMD and NAND_HWSTATUS_MASK register appropriately. NAND controller uses this to complete the flash sequence by issuing read status commands to figure out the previous flash operation status.
- Configure NAND_DATA_BLOCK_PTR register with system buffer location to be programmed in main area
- Configure NAND_TAG_PTR register with system buffer location to be programmed in flash spare
- Configure the DMA_BLOCK_SIZE.A register with proper DMA transfer size required for a page transfer. However, for multi-page transfer this could be as much as the total DMA transfer size required.
- Configure NAND_DMA_CFG.B register with the total number of TAG bytes to be transferred from the spare region for all the 4 pages along with the TAG_BYTE_SIZE for a page. If the tag information is 8 bytes, then program this to (4 * 12 bytes/page) = 48 byte transfer.
- Configure NAND_IER and NAND_DMA_MST_CTRL registers as per the software requirements of interrupt indication on flash interface sequence or DMA sequence completion
- Write to NAND_COMMAND register with the following
  - CLE bit set
  - ALE bit set, ALE_SIZE field is set to the appropriate number of bytes required
  - TRANS_SIZE set to page size.
  - TX bit is set and PIO bit is cleared (indicates that this is a data should be fetched from FIFO)
  - Set the SEC_CMD bit (for issuing the second command “0x10”)
  - Set AFT_DAT bit since second command needs to be issued after the data stage.
  - Set A_VALID bit since only the data is being written. Note that spare region can also be written to by setting A_VALID and providing the appropriate address and data size information.
  - Set CE bit field for desired chip select

- Enable the DMA controller for transferring data to the NAND flash FIFO under flow control with the following in NAND_DMA_MST_CTRL register:
  - Set DMA_EN_A = 1
  - Set DMA_DIR=1 for Flash write operation
  - Select proper BURST_SIZE field per use case requirement.
  - Set DMA_GO field which starts DMA operation
- Start IO transfer by setting GO bit in NAND_COMMAND register, When the GO operation is initiated the NAND Controller issues the following sequence on the interface: CLE (0x80) -> ALE -> DATA -> CLE (0x10). The DATA stage is throttled based on the availability of data in the FIFO.
- When entire sequence is completed, the operation done is indicated by the command done interrupt as well as hardware clear of `GO' bit. DMA completion is indicated by hardware clear of `DMA_GO' bit.

29.3.7.6 Page Read Sequence

This sequence is used to read a page of data from the NAND Flash without ECC and without spare region access. First a read command “0x00” should be issued, followed by the destination address. Then, read is issued through command “0x30”. When the data becomes ready in the NAND Flash, the entire page is then read out. This sequence is achieved as follows:

- Write to NAND_CMD_REG1 with LSB byte as “0x00”
- Write to NAND_CMD_REG2 with LSB byte as “0x30”
- Write to NAND_ADDR_REG1/NAND_ADDR_REG2 with the correct address bytes to be read.
- Configure the DMA_BLOCK_SIZE.A register with proper DMA read transfer size required for a PAGE transfer. However, for multi-page transfer this could be as much as the total DMA transfer size required.
- Configure the data block source address of read data in NAND_DATA_BLOCK_PTR register.
- Configure NAND_IER register as per the software requirements of interrupt indication on NAND IO sequence or DMA sequence completion
- Configure NAND_TIMING, NAND_TIMING2 registers as described later section in this document
- Write to NAND_CONFIG register with the following
  - Configure the PAGE_SIZE_SEL to select the page transfer size based on flash memory organization
  - If PROG_OFFSET_EN is disabled, set SKIP_SPARE field so that controller can skip writing to factory bad block information at the start of spare region.
  - Set EDO_MODE field if flash memory supports. Note that tRP/tRP_RESP timing values should be adjusted to reduce the round trip delay factor, hence improving the performance.
  - Set BUS_WIDTH field for 16-bit data interface selection
  - Set COM_RBSY field for wired-AND connection of flash RBSY lines to RBSY0 line.
  - Reading with ECC is covered in later sections with multiple pages
- For COM_RBSY selection, configure NAND_HWSTATUS_CMD and NAND_HWSTATUS_MASK register appropriately. NAND controller uses this to complete the flash sequence by issuing read status commands to figure out the previous operation status.
- Write to NAND_COMMAND register with the following
  - CLE bit set
  - ALE bit set, ALE_SIZE field is set to the appropriate number of bytes required
  - TRANS_SIZE set to page size selection with MSB set
  - RX bit is set and PIO bit cleared (indicates that this is a read data should be placed FIFO)
  - Set the SEC_CMD bit (for issuing the second command “0x30”)

  - AFT_DAT bit needs to be cleared since second command needs to be issued before the data stage.
  - Set A_VALID bit since only data is being read. Spare region can also be read by issuing multiple A_VALID commands with the appropriate address and size. .
- Set CE bit field for desired chip select
- Enable the DMA controller for transferring data to the NAND flash FIFO under flow control with the following in NAND_DMA_MST_CTRL register:
  - Set DMA_EN_A = 1
  - Set DMA_DIR=0 for Flash read operation
  - Select proper BURST_SIZE field per use case requirement.
  - Set DMA_GO field which starts DMA operation
- Start I/O transfer by setting GO bit in NAND_COMMAND register. When the GO operation is initiated the NAND Controller issues the following sequence on the interface: CLE (0x00) -> ALE -> CLE (0x30) -> DATA read. The DATA stage is throttled based on the availability of empty slots in the FIFO. Before entering the data stage the controller will ensure the NAND Flash is ready.
- When entire sequence is completed, the operation done is indicated by the command done interrupt as well as hardware clear of `GO' bit

29.3.7.7 Tag Only Write Sequence

This programming sequence describes the case of spare only region writes with and without ECC. The illustration is for a 4 page transfer. First a write command "0x80" should be issued, followed by the destination address. Then, all the spare data is written to the device. After writing the spare data, programming is initiated by issuing the program command "0x10". This sequence is achieved as follows:

- Write to NAND_CMD_REG1 with LSB byte as "0x80"
- Write to NAND_CMD_REG2 with LSB byte as "0x10"
- Write to NAND_ADDR_REG1/NAND_ADDR_REG2 with the correct row & column address byte location where the transfer starts.
- Write to NAND_CONFIG register with the following
  - Set BUS_WIDTH field for 16-bit data interface selection
  - Set COM_RBSY field for wired-AND connection of flash RBSY lines to RBSY0 line.
  - SKIP_SPARE feature bits do not have any significance.
  - Configure TAG_BYTE_SIZE inclusive of ECC parity bytes (fixed 4 bytes of parity for Tag information) if ECC option is selected. Note that (n-1) values should be programmed in TAG_BYTE_SIZE field for `n' bytes transfer
- Program NAND_DMA_CFG.B register with the total number of TAG bytes to be transferred to the spare region for all the 4 pages along with the TAG_BYTE_SIZE for a page. If the tag information is 8 bytes, then program this to (4 * 8bytes/page) = 32bytes transfer. Enabling ECC for write operation doesn't alter DMA length programming, since these are calculated and appended by hardware automatically. Note that (n-1) values should be programmed in DMA size field for `n' words/bytes transfer respectively.
- Configure NAND_TAG_PTR register with system buffer location to be programmed in flash
- Configure NAND_IER register as per the software requirements of interrupt handling.
- Configure NAND_TIMING, NAND_TIMING2 registers as described later section in this document
- For COM_RBSY selection or RBSY_CHK/RD_STATUS_CHK sequences, configure NAND_HWSTATUS_CMD and NAND_HWSTATUS_MASK registers appropriately. NAND controller uses these registers to complete the flash sequence by issuing read status commands automatically to figure out the previous operation status or flash is ready for the next operation, etc.

- Write to NAND_COMMAND register with the following:
  - CLE bit set
  - ALE bit set, ALE_SIZE field is set to the appropriate number of bytes required
  - TRANS_SIZE set to page size selection with MSB bit set.
  - TX bit is set (indicates that this is a data write)
  - Set the SEC_CMD bit (for issuing the second command “0x10”)
  - Set AFT_DAT bit since second command needs to be issued after the data stage
  - Set B_VALID=1 and A_VALID=0 to indicate that spare access is only required
- Set CE bit field for desired chip select
- For ECC case configure NAND_BCH_CONFIG register:
  - Set BCH_TAG_TVALUE field for error correction strength selection
  - Set BCH_ECC field to enable error correction
- Enable the DMA controller for transferring data to the device under flow control with the following in NAND_DMA_MST_CTRL register:
  - Set DMA_EN_B = 1
  - Set DMA_DIR=1 for Flash write operation
  - Select proper BURST_SIZE field per use case requirement.
  - Set DMA_GO field which starts DMA operation
- Start I/O transfer by setting GO bit in NAND_COMMAND register. When the GO operation is initiated the NAND Controller issues the following sequence on the interface: CLE (0x80) -> ALE -> WR Tag bytes -> WR Tag ECC bytes (if ECC is enabled) -> CLE (0x10). When entire sequence is completed, operation done is indicated by the command done interrupt as well as Hardware clear of `GO’ bit.
- Since the DMA transfer size was programmed for 4 pages, the DMA is constantly filling the FIFO with the next page data (and similarly the tag information). Therefore, the next page data is readily available in the FIFO at the end of the prior sequence.
- Repeat next page write operation by programming the GO bit in NAND_COMMAND register as described above. For this entire transfer of 4 pages spare data transfer, one DMA setup is required, followed by 4 commands being issued by writing to the NAND_COMMAND register for every page.
- DMA completion is indicated by hardware clear of `DMA_GO’ bit. When IO completes actual transfer to device GO bit in NAND_COMMAND register is cleared.

In Tegra 3 devices, hardware also allows positioning of parity bytes and tag information bytes in spare area. The additional programming requirement for this mode of operation is as follows:

- Mode is determined by setting PROG_OFFSET_EN =1 field in NAND_CONFIG2 register.
- NAND_ADDR1, NAND_ADDR2 registers be programmed to indicate row/page location in flash.
- Configure NAND_TAG_OFFSET and NAND_TAG_ECC_OFFSET registers to specify the respective locations in spare area. Hardware computes final column address based on above configuration plus PAGE_SIZE selection.
- Configure BCH_TAG_TVAL selection in NAND_BCH_CONFIG2 register since tag can have different error correction capability independent of main data selection.
- Configure NAND_RANDOM_WR register with Random Data Input command code appropriate to that device. Default value of 0x85 should work for wide variety of devices.

29.3.7.8 Tag Only Read Sequence

This programming sequence describes the case of spare only region reads with and without ECC. The illustration is for a 4 page transfer. First a read command “0x00” should be issued, followed by the destination address. Then, read is issued through command “0x30”. Tag only access with ECC is defined as programmable offset feature turned off with spare only access. This sequence is achieved as follows:

- Write to NAND_CMD_REG1 with LSB byte as “0x00”
- Write to NAND_CMD_REG2 with LSB byte as “0x30”
- Write to NAND_ADDR_REG1/NAND_ADDR_REG2 with the correct row & column address byte location where the transfer starts.
- Write to NAND_CONFIG register with the following
  - Set BUS_WIDTH field for 16-bit data interface selection
  - Set COM_RBSY field for wired-AND connection of flash RBSY lines to RBSY0 line.
  - Set EDO_MODE field if flash memory supports. Note that tRP/tRP_RESP timing values should be adjusted to reduce the round trip delay factor, hence improving the performance.
  - SKIP_SPARE feature bits do not have any significance.
  - Configure TAG_BYTE_SIZE inclusive of ECC parity bytes (fixed 4 bytes of parity for Tag information) if ECC option is selected. Note that (n-1) values should be programmed in TAG_BYTE_SIZE field for `n’ bytes transfer
- For ECC case configure NAND_BCH_CONFIG register,
  - Set BCH_TAG_TVALUE field for error correction strength selection
  - Set BCH_ECC field to enable error correction
- Program NAND_DMA_CFG.B register with the total number of TAG bytes to be transferred from the spare region for all the 4 pages along with the TAG_BYTE_SIZE for a page. If the tag information is 8 bytes, then program this to (4 * 12 bytes/page) = 48 byte transfer. When ECC is enabled, Tag size for DMA configuration should consider the parity data size bytes, since these read by hardware automatically. Note that (n-1) values should be programmed in DMA size field for `n’ words/bytes transfer respectively.
- Configure NAND_TAG_PTR register with system buffer location to be programmed in flash
- Configure NAND_IER register as per the software requirements of interrupt handling.
- Configure NAND_TIMING, NAND_TIMING2 registers as described later section in this document
- For COM_RBSY selection or RBSY_CHK/RD_STATUS_CHK sequences, configure NAND_HWSTATUS_CMD and NAND_HWSTATUS_MASK registers appropriately. NAND controller uses these registers to complete the flash sequence by issuing read status commands automatically to figure out the previous operation status or flash is ready for next operation, etc.
- Write to NAND_COMMAND register with the following
  - CLE bit set
  - ALE bit set, ALE_SIZE field is set to the appropriate number of bytes required
  - TRANS_SIZE set to page size selection with MSB bit set.
  - RX bit is set (indicates that this is a data write)
  - Set the SEC_CMD bit (for issuing the second command “0x10”)
  - Set AFT_DAT=0 since second command needs to be issued to initiate flash data read
  - Set B_VALID =1 and A_VALID=0 to indicate that spare access is only required.
  - Set CE bit field for desired chip select
- Enable the DMA controller for transferring data from NAND controller internal buffer to DMA destination with the following in NAND_DMA_MST_CTRL register:

- Set DMA_DIR=0 for Flash read operation
- Set DMA_EN_B = 1
- Select proper BURST_SIZE field per use case requirement.
- Set DMA_GO field which starts DMA operation

- Start I/O transfer by setting GO bit in NAND_COMMAND register. When the GO operation is initiated the NAND Controller issues the following sequence on the interface: CLE (0x00) -> ALE -> CLE (0x30) > RD Tag bytes -> RD Tag Parity bytes.(with ecc enabled). When entire sequence is completed, it is indicated by the command done interrupt as well as hardware clear of `GO' bit.
- Since the DMA transfer size was programmed for 4 pages, the DMA is constantly waiting to pullout from buffers
- Software repeats next page read operation by programming the GO bit in NAND_COMMAND register as described above. For this entire transfer of 4 pages spare data transfer, one DMA setup is required, followed by 4 commands being issued by writing to the NAND_COMMAND register for every page.
- Since the DMA transfer waits for IO transfer, DMA_GO completes the total transfer

In Tegra 3 devices, hardware allows reading of parity bytes and tag information bytes in spare area. The additional programming requirements for this mode are as follows:

- Mode is determined by setting PROG_OFFSET_EN =1 field in NAND_CONFIG2 register.
- NAND_ADDR1, NAND_ADDR2 registers be programmed to indicate row/page location in flash.
- Configure NAND_TAG_OFFSET and NAND_TAG_ECC_OFFSET registers to specify the respective locations in spare area. Hardware computes final column address based on above configuration plus PAGE_SIZE selection.
- Configure BCH_TAG_TVAL selection in NAND_BCH_CONFIG2 register since tag can have different error correction capability independent of main data selection.
- Configure NAND_RANDOM_RD register with Random Data Output command codes appropriate to that device. Default value of 0x05, 0xEO should work for wide variety of devices.

29.3.7.9 Multiple Page Write with ECC for Data and Tag

This sequence describes the case where multiple pages of data are to be transferred to the NAND device, along with Tag information into the spare region with error protection. Block A refers to the data payload (usually a page size), and Block B refers to the TAG information of spare for description below. Tag bytes of spare region are treated as extended sector of main page data. Parity byte computation of last sector of page includes the tag bytes. Following sequence shows the required programming for transferring 4 pages of data, along with the associated tag.

- Write to NAND_CMD_REG1 with LSB byte as “0x80”
- Write to NAND_CMD_REG2 with LSB byte as “0x10”
- Write to NAND_ADDR_REG1/NAND_ADDR_REG2 with the correct address bytes to be transferred.
- Configure NAND_TIMING, NAND_TIMING2 registers as described later section in this document.
- Write to NAND_CONFIG register with the following
  - Configure the PAGE_SIZE_SEL to select the page transfer size based on flash memory organization
  - Set SKIP_SPARE field so that controller can skip starting few bytes in spare region along with SKIP_SPARE_SEL setting. If SKIP_SPARE=0, controller starts writing the parity bytes at the column “0” of spare region.
  - Set BUS_WIDTH field for 16-bit data interface selection
  - Set COM_RBSY field for wired-AND connection of flash RBSY lines to RBSY0 line.
  - Configure TAG_BYTE_SIZE (n-1) value for `n' bytes transfer
  - Set EDO_MODE field if flash memory supports. Note that tRP/tRP_RESP timing values should be adjusted to reduce the round trip delay factor, hence improving the performance.

- For COM_RBSY selection, configure NAND_HWSTATUS_CMD and NAND_HWSTATUS_MASK register appropriately. NAND controller uses this to complete the flash sequence by issuing read status commands to figure out the previous operation status.
- Configure the Data block source address in NAND_DATA_BLOCK_PTR register.
- Configure the Tag data source address in NAND_TAG_PTR register.
- Program NAND_DMA_CFG.A register with proper DMA_BLOCK_SIZE.A (4*page_size) as per PAGE_SIZE_SEL fields.
- Program NAND_DMA_CFG.B register with the total number of TAG bytes to be transferred to the spare region for all the 4 pages along with the TAG_BYTE_SIZE for a page. If the tag information is 8 bytes, then program this to (4 * 8bytes/page) = 32bytes transfer. Please note that DMA size programming register actually works on (n-1) words programming for n word transfer.
- Enable ECC mechanism by setting BCH_ECC in NAND_BCH_CONFIG register. BCH_TVALUE field selects the ECC correction capability for Data and tag.
- Clear PROG_OFFSET_EN bit field in NAND_CONFIG2 register. This is the default selection on reset.
- Configure NAND_IER and NAND_DMA_MST_CTRL registers as per the software requirements of interrupt indication on flash interface sequence or DMA sequence completion
- Write to NAND_COMMAND register with the following
  - CLE bit set
  - ALE bit set, ALE_SIZE field is set to the appropriate number of bytes required
  - TRANS_SIZE set to page size selection with MSB bit set.
  - TX bit is set (indicates that this is a data write)
  - Set the SEC_CMD bit (for issuing the second command “0x10”)
  - Set AFT_DAT bit since second command needs to be issued after the data stage.
  - Set A_VALID, B_VALID. A_VALID being set indicates that this operation requires data payload transfer, B_VALID being set indicates that spare access required for Tag information.
  - Set CE bit field for desired chip select
- Enable the DMA controller for transferring data to the internal buffer under flow control with the following in NAND_DMA_MST_CTRL register:
  - Set DMA_DIR=1 for Flash write operation
  - Set DMA_EN_A = 1
  - Set DMA_EN_B = 1
  - Select proper BURST_SIZE field per use case requirement.
  - Set DMA_GO field which starts DMA operation
- Start I/O transfer by setting GO bit in NAND_COMMAND register.
- When entire sequence is completed, the operation done is indicated by the command done interrupt as well as Hardware clear of `GO’ bit.
- Since the DMA transfer size was programmed for 4 pages, the DMA is constantly filling the internal buffer with the next page data (and similarly the tag information). Therefore, the next page data is readily available as the current sequence is above to finish on flash interface.
- Repeat next page write operation by programming the NAND_COMMAND register. This process is repeated for the remaining pages. For this entire transfer of 4 pages, one DMA setup is required, followed by 4 commands being issued by writing to the NAND_COMMAND register for every page.

In Tegra 3 devices, hardware allows positioning of parity bytes and tag information bytes in spare area as per offset registers. The additional programming requirements for this mode of operation are as follows:

- Mode is determined by setting PROG_OFFSET_EN =1 field in NAND_CONFIG2 register.
- NAND_ADDR1, NAND_ADDR2 registers determine the starting address of the page
- Configure NAND_MAIN_ECC_OFFSET, NAND_TAG_OFFSET and NAND_TAG_ECC_OFFSET registers to specify the respective locations in spare area.
- Configure BCH_TAG_TVAL selection in NAND_BCH_CONFIG2 register since tag can have different error correction capability independent of main data selection.
- Configure NAND_RANDOM_WR register with Random Data Input command code appropriate to that device. Default value of 0x85 should work for wide variety of devices.

29.3.7.10 Multiple Page Read with ECC for Data and Tag

This sequence describes the case where multiple pages of data along with Tag information are to be read from the NAND device with error protection. Block A refers to the data payload (usually a page size), and Block B refers to the Tag information of Spare region contents for description. Tag bytes of spare region are treated as extended sector of main page data. Syndrome data computation of last sector of page includes the tag bytes. Following sequence shows the required programming for transferring 4 pages of data, along with the associated tag.

- Write to NAND_CMD_REG1 with LSB byte as “0x00”
- Write to NAND_CMD_REG2 with LSB byte as “0x30”
- Write to NAND_ADDR_REG1/NAND_ADDR_REG2 with the correct address bytes to be read.
- Configure NAND_IER and NAND_DMA_MST_CTRL registers as per the software requirements of interrupt indication on flash interface sequence or DMA sequence completion
- Configure NAND_TIMING, NAND_TIMING2 registers as described later section in this document
- Write to NAND_CONFIG register with the following
  - Configure the PAGE_SIZE_SEL to select the page transfer size based on flash memory organization
  - Set SKIP_SPARE field so that controller can skip starting few bytes in spare region along with SKIP_SPARE_SEL setting. SKIP_SPARE programming is only required if spare access/ECC scheme is enabled
  - Set EDO_MODE field if flash memory supports. Note that tRP/tRP_RESP timing programming can be adjusted to reduce the round trip delay factor, hence improving the performance.
  - Set BUS_WIDTH field for 16-bit data interface selection
  - Set COM_RBSY field for wired-AND connection of flash RBSY lines to RBSY0 line.
  - Configure TAG_BYTE_SIZE (n-1) value for `n’ bytes transfer
- For COM_RBSY selection, configure NAND_HWSTATUS_CMD and NAND_HWSTATUS_MASK register appropriately. NAND controller uses this to complete the flash sequence by issuing read status commands to figure out the previous operation status.
- Clear PROG_OFFSET_EN bit field in NAND_CONFIG2 register. This is the default selection on reset.
- Enable ECC mechanism by setting BCH_ECC in NAND_BCH_CONFIG register. BCH_TVALUE field selects the ECC correction capability for Data and tag.
- Configure the Data block source address in NAND_DATA_BLOCK_PTR register.
- Configure the Tag data source address in NAND_TAG_PTR register.
- Program NAND_DMA_CFG.A register with proper DMA_BLOCK_SIZE.A (4*page_size) and PAGE_SIZE_SEL fields. Configure the Data block destination address in NAND_DATA_BLOCK_PTR register.
- Program NAND_DMA_CFG.B register with proper DMA_BLOCK_SIZE.B (4*TAG_BYTE_SIZE). Configure the Data block destination address in NAND_DATA_BLOCK_PTR register.
- Write to NAND_COMMAND register with the following
  - CLE bit set

- ALE bit set, ALE_SIZE field is set to the appropriate number of bytes required
- TRANS_SIZE set to page size.
- RX bit is set (indicates that this is a read)
- Set the SEC_CMD bit (for issuing the second command “0x30”)
- AFT_DAT bit needs to be cleared since second command needs to be issued before the data stage.
- Set A_VALID and B_VALID. A_VALID being set indicates that this operation requires data payload transfer and B_VALID indicates the Tag information to be transferred.
- CE bit field set to the desired chip.

- Enable the DMA controller for transferring data to the NAND flash FIFO under flow control with the following in NAND_DMA_MST_CTRL register:
  - Set DMA_DIR=0 for Flash read operation
  - Set DMA_EN_A = 1
  - Set DMA_EN_B = 1
  - Select proper BURST_SIZE field per use case requirement.
  - Set DMA_GO field which starts DMA operation
- Start IO transfer by setting GO bit in NAND_COMMAND register. When the GO operation is initiated the NAND Controller issues the following sequence on the interface: CLE (0x00) -> ALE -> CLE (0x30) ->RD DATA -> RD ECC Parity Bytes -> RD Tag Info. The DATA/Tag stage is throttled based on the availability of space in the respective FIFO’s.
- When entire sequence is completed, the operation done is indicated by the command done interrupt as well as Hardware clear of `GO’ bit.
- ECC correctable error or uncorrectable error as discovered in decode process are pushed in to decode status buffer on page basis. Once the entire DMA sequence is completed software can read this decode status buffer for error statistics
- Initiate next page read operation by setting the GO bit in the NAND_COMMAND register. This process is repeated for the remaining pages. For this entire transfer of 4 pages, one DMA setup is required, followed by 4 commands being issued by writing to the NAND_COMMAND register after every page.

In Tegra 3, hardware allows reading of parity bytes and tag information bytes in spare area as specified in offset registers. The additional programming requirements for this mode of operation are as follows:

- Mode is determined by setting PROG_OFFSET_EN =1 field in NAND_CONFIG2 register.
- NAND_ADDR1, NAND_ADDR2 registers determine the starting address of the page
- Configure NAND_MAIN_ECC_OFFSET, NAND_TAG_OFFSET and NAND_TAG_ECC_OFFSET registers to specify the respective locations in spare area.
- Configure BCH_TAG_TVAL selection in NAND_BCH_CONFIG2 register since tag can have different error correction capability independent of main data selection.
- Configure NAND_RANDOM_RD register with Random Data Output command codes appropriate to that device. Default value of 0x05, 0xEO should work for wide variety of devices.

29.3.7.11 PIO Write data transfers

This describes the case of write transfers for page program in PIO mode of operation. The following sequence on the interface is required in the interface to achieve this program sequence: CLE (0x80) -> ALE -> DATA -> CLE (0x10). This sequence can be viewed as multiple GO sequences in PIO mode such as,

- **Step 1:** Single GO command sequence for combined CLE, ALE transfers for initialization
- **Step 2:** Multiple GO commands to transfer data in PIO mode

- **Step 3:** Final program command

The programming sequence illustration assumes a page size of 512bytes without spare area access. For spare area access data sequence as in Step 2 should be repeated for required transfer length.

- **Step1:** Write to NAND_CMD_REG1 with LSB byte as “0x80”
- **Step1:** Write to NAND_ADDR_REG1/NAND_ADDR_REG2 with the correct address bytes to be transferred.
- **Step1:** Write to NAND_COMMAND register with the following
  - CLE bit set
  - ALE bit set, ALE_SIZE field is set to the appropriate number of bytes required
  - CE bit field set to the desired chip.
  - GO bit is set, which initiates the IO transfer and gets cleared on transfer completion.
- Write to NAND_RESP register with appropriate data bytes to be transferred. LSB byte in this register is the first one to be transmitted out. NAND_RESP registers is a shared register used for PIO write data/PIO read data. Note that NAND_RESP write data is not readable by software
- **Step2:** Write to NAND_COMMAND register with the following
  - Clear any other bit fields which are SET earlier
  - TRANS_SIZE set to select the small transaction sizes and configure the TRANS_SIZE to be 0x3 for 4 byte transfer. In PIO mode only 4 bytes can be transferred with the single GO command
  - TX bit is set and PIO bit is set which indicates that this is a data should be fetched from NAND_RESP register
  - Set A_VALID bit since only the data is being written. Note that spare region can also be written to by setting A_VALID and provide the appropriate address and data size information
  - CE bit field set to the desired chip
  - GO bit is set, which initiates the IO transfer and gets cleared on transfer completion
- **Step3:** Repeat the data transfer sequence multiple times(128 times for total 512 byte transfer) setting the GO bit to complete the total page transfer.
- **Step3:** Write to NAND_CMD_REG1 with LSB as “0x10”
- **Step3:** Write to NAND_COMMAND register with the following
  - Clear any other bit fields which are SET earlier
  - CLE bit set
  - CE bit field set to the desired chip.
  - GO bit is set, which initiates the I/O transfer and gets cleared on transfer completion.

29.3.7.12 PIO Read data transfers

This describes the case of read transfers for page read in PIO mode of operation. Following sequence on the interface is required in the interface to achieve this sequence: CLE (0x00) -> ALE -> CLE (0x30) -> DATA. This sequence can be viewed as multiple GO sequences in PIO mode such as,

- **Step1:** Single GO command sequence for combined CLE (0x00), ALE and CLE (0x30) transfers for initialization
- **Step2:** Wait for RBSY from flash
- **Step 2:** Multiple GO commands to transfer data in PIO mode.

Following programming sequence illustration assumes a page size of 512bytes without spare area access. For spare area access data sequence as in Step 2 should be repeated for required transfer length.

- Write to NAND_CMD_REG1 with LSB byte as “0x00” and NAND_CMD_REG2 with LSB byte as “0x30”
- Write to NAND_ADDR_REG1/NAND_ADDR_REG2 with the correct address bytes to be transferred.

- **Step1:** Write to NAND_COMMAND register with the following
  - CLE bit set
  - ALE bit set, ALE_SIZE field is set to the appropriate number of bytes required
  - Set the SEC_CMD bit (for issuing the second command “0x30”)
  - AFT_DAT bit needs to be set cleared since second command needs to be issued before data cycles
  - CE bit field set to the desired chip.
  - GO bit is set, which initiates the IO transfer and gets cleared on transfer completion.
- **Step2:** Wait for RBSY=1 status from flash. RDY status from flash indicates that data is copied from internal cells to page register. Host controller can pulse read cycles to read data now
- **Step3:** Write to NAND_CONFIG register with the following
  - Set BUS_WIDTH field for 16-bit data interface selection
  - Set COM_RBSY field for wired-AND connection of flash RBSY lines to RBSY0 line.
  - Set EDO_MODE field if flash memory supports. Note that tRP/tRP_RESP timing values should be adjusted to reduce the round trip delay factor, hence improving the performance.
- For COM_RBSY selection, configure NAND_HWSTATUS_CMD and NAND_HWSTATUS_MASK register appropriately. NAND controller uses this to complete the flash sequence by issuing read status commands to figure out the previous operation status.
- **Step3:** Write to NAND_COMMAND register with the following
  - Clear any other bit fields which are SET earlier
  - TRANS_SIZE set to select the small transaction sizes and configure the TRANS_SIZE to be 0x3 for 4 byte transfer. In PIO mode only 4 bytes can be transferred with the single GO command
  - RX bit is set and PIO bit is set which indicates that this is a data should be fetched from NAND_RESP register.
  - CE bit field set to the desired chip.
  - GO bit is set, which initiates the IO transfer and gets cleared on transfer completion
- Read data is available in NAND_RESP register after the GO command completion.
- Repeat the data transfer sequence multiple times(128 times for total 512 byte transfer) setting the GO bit to complete the total page transfer.

29.3.8 RBSY_CHK and RD_STATUS_CHK programming

RBSY_CHK and RD_STATUS_CHK have been introduced in NAND Controller to facilitate command queue mode, but these features can also be handy in normal mode and reduces good amount of interrupt handling overhead.

If RBSY_CHK is enabled in NAND_COMMAND register for a flash sequence:

NAND controller waits for the RBSY status of selected flash to start command/Address/data cycles. If COM_RBSY=0, RBSY lines are readily available to figure the flash ready status. If COM_RBSY=1, controller issues Read Status Command using the command code set in HWSTATUS_CMD register to figure out the same. On the received data, it applies the RBSY_MASK and compares the data with expected value. RBSY_EXP_VAL should be programmed as per the flash specification, including the polarity. If response data masked with RBSY_MASK_VAL matches, then it proceeds for actual Command/Address/Data cycle transfer. Otherwise it keeps on repeating the same procedure after pre-defined time. If RD_STATUS_CHK is also enabled, controller proceeds to RD_STATUS_CHK phase.

If RD_STATUS_CHK is enabled in NAND_COMMAND register for flash sequence:

NAND controller issues Read Status Command using the command code set in HWSTATUS_CMD register. On the received response data, it applies RD_STATUS_MASK and compares the data with expected value. If it doesn’t match with RDSTATUS_EXP_VAL it raises error interrupt ISR.LL_ERROR. RDSTATUS_EXP_VAL should be

programmed as per the flash specification. If response data masked with RDSTATUS_MASK_VAL matches, then it proceeds for actual Command/Address/Data cycle transfer.

29.3.9 ECC Performance/ power knobs

In Tegra 3 devices, a system of monitoring the pipeline bottleneck is supported. A part of the BCH pipeline which is usually the bottleneck, is the polynomial root search engine. This logic can be potentially clocked at a higher rate than the rest of the BCH engine and NAND module. The rest of the logic operates at 100/200 MHz (nand_clk) while the search engine can operate at any frequency

Nand_clk <= nand_speed_clk <- 400 MHz.

Software has the option of dynamically setting the nand_speed_clk.

There are a few hardware register to help Software make this decision. Both these registers are relevant only for Read with ECC decode enabled operation.

The Buf_stall_accumulated registers aggregates the number of cycles that the I/O engine has stalled due to all the buffers being full. The corr_fifo_accumulated register counts the stalls due to the search engine. Software can look at the Buf_stall register to find out whether the NAND module is back pressuring the I/O interface during an ECC read, and compare the corr_fifo register to check whether the search engine is the culprit. If the number of stalls is high enough, and corr_fifo stalls are comparable, then that scenario is a good candidate to increase the nand_speed_clk frequency.

Now the duration for accumulation is left entirely to software. It is the software's task to manage and reset these registers appropriately. This is done purposely so software can decide over what granularity it wants to make the perf/watt decision. After software has read out this value and has no more use for it, it should write 32'h0 into the two register to reset their value, for the next accumulation as required. But it can choose accumulate the statistics over several DMA transfers until the max value of 32'hffffffff has reached. Hardware guarantees that the accumulation of stall cycles will not overflow.

29.3.10 SGDMA Mode of Operation

In Tegra 3 devices, the NAND controller supports an indirect scheme of addressing memory on the AHB bus. Software sets up descriptors in address length pairs to describe each fragment of memory, the set of which constitutes the data that needs to be written to/read from the flash device.

This section describes the DMA Mechanism from a software viewpoint (It concentrates on the SG-DMA mode only):

29.3.10.1 SG-DMA Mode Registers

Registers	Relevant Fields	Notes
NAND_DMA_MST_C TRL_0	DMA_GO, DIR, BURST_SIZE, DMA_EN_A, DMA_EN_B	Most of the sense of these fields is similar in SG-DMA mode as in normal mode.
NAND_DMA_CFG_A_0	DMA_BLOCK_SIZE_A	In the normal this describes DATA size in bytes. In SGDMA mode, this denotes no. of address length pairs in the DATA descriptor table. . In both modes, n-1 value is adhered to maintain compatibility.
NAND_DMA_CFG_B_0	DMA_BLOCK_SIZE_B	In the normal this describes TAG size in bytes. In SGDMA mode, this denotes no. of address length pairs in the TAG descriptor table. In both modes, n-1 value is adhered to maintain compatibility.
NAND_DATA_BLOCK_PTR_0		In the normal mode this points to start of DMA data block. In SGDMA mode, this points to start address of DATA descriptor table.
NAND_TAG_BLOCK_PTR_0		In the normal mode this points to start of DMA data block. In SGDMA mode, this points to start address of TAG descriptor table.
NAND_CONFIG2_0	SGDMA_EN	Single bit selector that tells hardware to operate in SGDMA mode.

Example

Suppose software needs to transfer 64kB of memory to the flash. (Flash write operation).

The OS may have this data in several data fragments in system memory. As opposed to forming the contiguous memory set in chips before Tegra 2, software now needs to set up the descriptor table, with the start address and length (bytes) of each fragment. The DMA engine will automatically fetch all the data, align all the fetches.

The following example shows a descriptor table. (Main)

At the starting address pointed by NAND_DATA_BLOCK_PTR_0 with following offsets.

OFFSET 0x00	Address 1 [31:0]
0x04	Length1 [15:0] padded with 16 0-msbs
0x08	Address2[31:0]
0x0c	Length2 [15:0] padded with 16 0-msbs
-----	---------
0x30	Address7 [31:0]
0x34	Length7 [15:0] padded with 16 0-msbs

For this table, the register programming would be:

- NAND_DMA_MST_C TRL_0 — Fields have same meaning as in normal dma case
- NAND_DMA_CFG_A_0 — 6 (7 -1)
- NAND_DMA_CFG_B_0 — NA
- NAND_DATA_BLOCK_PTR_0 — <start addr>
- NAND_TAG_BLOCK_PTR_0 — NA
- NAND_CONFIG2_0 — SGDMA_EN=1

29.3.10.2 Programming Notes

- Descriptors have complete flexibility to describe anything from 1 byte to an entire transfer.
- Descriptor lengths need not be word or half word aligned i.e. byte granular lengths are permitted. It follows that descriptor addresses can also be byte aligned.
- Descriptor need not align to sector boundaries.
- *Descriptors need not align to page boundaries. The DMA automatically context switches at a page boundary, saves the current fetch context and restores it at the next main/tag page.
- The data burst size is same as the programmed data burst. However, depending on the alignment of descriptors, the controller reduces the burst in cases when there is a need to align to page boundaries, descriptor boundaries and start addresses of the fetch. The burst size, however, is guaranteed to be equal to or less than the programmed size.
- Descriptor entry fetch is always done in single word bursts.
- Main and Tag areas have separate descriptor tables each, each describing the respective data areas.
- The sum of lengths of the descriptor entries is the intended data transfer length. This is NOT explicitly programmed in SG-DMA mode. Only the table and the number of addr-length pairs in the table (table size) are programmed. Each address and length is 32-bit fields (length is actually 16 bit but we align it to a word boundary).

29.3.10.3 Hardware prefetch/ performance Notes

Hardware does not sequentially fetch descriptor and respective data. The tables are prefetched ahead of time, and also dynamically filled (dependent on data arbitration and bubbles in the data fetching) so that the next data fetch address is

(almost) always ready on the completion of a descriptor data fragment. Hence we always fetch descriptor in single burst to avoid descriptor to clog the fetch. Main and Tag descriptors are filled based on the occupancy levels of the respective buffers. This mechanism will prevent a performance drop when the data is very fragmented i.e. size of descriptor lengths is small, and no. of descriptors is large.

29.3.11 Abort Operation

Tegra 3 NAND supports an alternative to module reset for a prospective clean exit when software decides to abort an operation. Functionally, an abort is supported at any time after a valid transaction has been started, but typically would only abort on the following cases. Each of the below cases represents an unexpected error case, and causes an interrupt, upon which software would typically abort the transaction.

29.3.11.1 Triggers to an Abort Condition

- Lock Error
- Decode fatal error
- Rd status error (cmdQ error)

29.3.11.2 Abort Programming Sequence

On receiving any of the above triggers (or otherwise), software can set the abort bit in CONFIG2 register (bit 31) to initiate an abort. The Controller then goes through a series of operations depending on when and in what operation the abort was received, and sets the abort_done bit in the ISR after a few clock cycles and generates an interrupt with the abort_done bit set in the ISR. At that point, software is expected to reprogram all state and config registers in the next transaction like a brand new transaction. In Tegra 3, a “resume” is NOT supported.

It is essential while aborting a non-ecc use case i.e. when config bch_ecc bit = 0, that the nand_speed_clk is shut off. This should be the case to save power anyway, but software must sure to turn off nand_speed_clk.

29.3.12 NAND Timing Registers

Hardware implementation of timings in NAND controller follows the simple implementation of running timing counter for no. of clocks for programmed. Timing equations representing the timing parameter implementation are described below. For different Flash timings or for different NAND Clock frequency options timing parameters be calculated and programmed in respective timing registers. Following equation cites an example of such calculation:

Consider AC timing parameter tWP from flash requirement is 20ns. Governing equation for this timing parameter is,

tWP (in ns) = (TWP count programmed + 1) X NAND_CLK_PERIOD

So required bit field programming value of TWP_CNT = tWP(ns)/NAND_CLK_PERIOD -1

Considering NAND Clock source is selected for 100MHz frequency, resulting timing count to be programmed is,

TWP_CNT = 20ns/10ns (clock period) -1 = 1

Table 78 ASYNC Mode Timing Equations with TIMING_SEL=0 (NAND_TIMING, NAND_TIMING2)

TIMING_VALUE	Guideline	Timing equation
TWP_CNT	Refer to tWP timing from flash datasheet	tWP = [TWP_CNT +1] * NAND_CLK_PERIOD
TWH_CNT	Refer to tWH timing from flash datasheet	tWH = [TWH_CNT +1] * NAND_CLK_PERIOD
TRP_CNT	Non-EDO mode: Max(tRP, tREA) timings from flash datasheet + 6ns (round trip delay) EDO mode: tRP timing from flash datasheet	Max(tRP,tREA) + Round_Trip_Delay = [TRP_CNT +1] * NAND_CLK_PERIOD tRP = [TRP_CNT +1] * NAND_CLK_PERIOD

TIMING_VALUE	Guideline	Timing equation
TRH_CNT	Refer to tRH/tREH timing from flash datasheet	tRH = [TRH_CNT +1] * NAND_CLK_PERIOD
TCS_CNT	Program for Max(tCS, tCH, tALS, tALH, tCLS, TCLH) timings from flash datasheet	Max(tCS, tCH, tALS, tALH, tCLS, TCLH) = [TCS_CNT + TWP_CNT +2] * NAND_CLK_PERIOD
TCR_TAR_TRR_CNT	Program Max(tCR, tAR, tRR) timings from flash data sheet	Max(tCR, tAR, tRR) = (TCR_TAR_TRR_CNT+4) * NAND_CLK_PERIOD
TWHR_CNT	Program Max(tWHR,tWHR2) timing from flash data sheet	Max(tWHR,tWHR2) = (TWHR_CNT+1) * NAND_CLK_PERIOD
TWB_CNT	Refer to tWB timing from flash datasheet	tWB = (TWB _CNT+ TWH_CNT + TCS_CNT - 6) * NAND_CLK_PERIOD
TADL_CNT	Refer to tADL timing from flash datasheet	tADL = (TADL_CNT + TWH_CNT + TWP_CNT + 6) * NAND_CLK_PERIOD

Table 79 ASYNC Mode Timing Equations with TIMING_SEL=1(NAND_ASYNC_TIMING_0-3)

TIMING_VALUE	Guideline	Timing equation
TWP_CNT	Refer to tWP timing from flash datasheet	tWP = [TWP_CNT +1] * NAND_CLK_PERIOD
TWH_CNT	Refer to tWH timing from flash datasheet	tWH = [TWH_CNT +1] * NAND_CLK_PERIOD
TRP_CNT	Non-EDO mode: Max(tRP, tREA) timings from flash datasheet + 6ns (round trip delay) EDO mode: tRP timing from flash datasheet	Generated timing for ASYNC modes, Max(tRP,tREA) + 6ns = [TRP_CNT +1] * NAND_CLK_PERIOD tRP = [TRP_CNT +1] * NAND_CLK_PERIOD Fixed generated timing in DDR modes, tRP = (NAND_CLK_PERIOD/2) ns. Do not impact with TRP_CNT programmed value for all DDR modes.
TREA_CNT	Non-EDO mode: Max(tRP, tREA) timings from flash datasheet + 6ns (round trip delay) EDO mode: tRP timing from flash datasheet	Max(tRP,tREA) + 6ns = [TREA_CNT +1] * NAND_CLK_PERIOD tRP = [TREA_CNT +1] * NAND_CLK_PERIOD Not required for to program TREA_CNT for DDR all modes.
TRH_CNT	Refer to tRH/tREH timing from flash datasheet	tRH = [TRH_CNT +1] * NAND_CLK_PERIOD. Fixed generated timing in toggle DDR mode, tREH = (NAND_CLK_PERIOD/2)ns Fixed generated timing in DDR modes, tRP = (NAND_CLK_PERIOD/2) ns. Do not impact with TRH_CNT programmed value for all DDR modes.
TCLH_CNT	Max(tCH,tCLH) timings from flash datasheet	Generated timing for all ASYNC and toggle DDR, tCLH = (TCLH_CNT + TWH_CNT + 3) * NAND_CLK_PERIOD ns Fixed generated timing for ONFI DDR, tCLH = NAND_CLK_PERIOD/2 ns. Do not impact with TCLH_CNT programmed value for ONFI DDR mode. For new Samsung devices with tCWAW timing requirement, tCLH = (TCWAW_CNT + TWH_CNT + TALS_CNT + TWP_CNT + 5) * NAND_CLK_PERIOD
TCH_CNT	Reserved bit field. Hardware implementation of tCLH timing and other timing parameter guarantees this timing requirement.	
TALH_CNT	Refer to tALH timing from flash datasheet	Generated timing for all ASYNC and toggle DDR, tALH = (TALH_CNT + TWH_CNT + 3) * NAND_CLK_PERIOD

TIMING_VALUE	Guideline	Timing equation
		Fixed generated timing for ONFI DDR, tALH = NAND_CLK_PERIOD/2 ns. Do not impact with TALH_CNT programmed value for ONFI DDR mode.
TCLS_CNT	Refer to tCLS timing from flash datasheet	Generated timing for all ASYNC and toggle DDR, tCLS = (TCLS_CNT + TWP_CNT + 2) * NAND_CLK_PERIOD Fixed generated timing for ONFI DDR, tCLS = NAND_CLK_PERIOD/2 ns. Do not impact with TCLS_CNT programmed value for ONFI DDR mode.
TALS_CNT	Refer to tALS timing from flash datasheet	Generated timing for all ASYNC and toggle DDR, tALS = (TALS_CNT + TWP_CNT + 2) * NAND_CLK_PERIOD Fixed generated timing for ONFI DDR, tALS = NAND_CLK_PERIOD/2 ns. Do not impact with TALS_CNT programmed value for ONFI DDR mode.
TCS_CNT	Refer to tCS timing from flash datasheet	Generated timing for all ASYNC and toggle DDR, tCS = (TCS_CNT + TCLS_CNT + TWP_CNT + 4) * NAND_CLK_PERIOD ns Generated timing for ONFI DDR, tCS = (TCS_CNT + 1) * NAND_CLK_PERIOD ns If Flash is not ready busy and controller waiting for RBSY_CHK condition, that time will add up.
TCR_CNT	Reserved bit field. Programming proper TRR_CNT meets this timing	
TAR_CNT	Refer to tAR, tWHR timings from flash datasheet	Address cycle ALE low to data output time Covered by tRR timing during Data read operation. Generated timing during Read ID, Max(tAR, tWHR) = (TAR_CNT+1) * NAND_CLK_PERIOD ns This timing parameter is not relevant for ONFI DDR mode. Do not impact with TAR_CNT programmed value for ONFI DDR mode.
TRR_CNT	Refer to tRR timing from flash datasheet	tRR = (TRR_CNT + 4) * NAND_CLK_PERIOD
TWHR_CNT	Refer to tWHR timing from flash datasheet	Generated timing for async and Toggle DDR modes, tWHR = (TWH_CNT + TCLH_CNT + TWHR_CNT + TRR_CNT + 5) * NAND_CLK_PERIOD ns. Generated timing for ONFI DDR modes, tWHR = (TCAD_CNT + TWHR_CNT + 4) * NAND_CLK_PERIOD ns.
TWHR2_CNT	Refer to tWHR2 timing from flash datasheet	Relevant for Samsung new devices only, Generated timing, tWHR2 = (TCLH_CNT + TWH_CNT + TWHR2_CNT + 6) * NAND_CLK_PERIOD ns This timing parameter is not relevant for ONFI DDR mode. Do not impact with TWHR2_CNT programmed value for ONFI DDR mode.
TWB_CNT	Refer to tWB timing from flash datasheet	Generated timing for all async and toggle DDR modes, tWB = (TWH_CNT + TCLH_CNT + TWB_CNT - 6) * NAND_CLK_PERIOD ns. Generated timing for ONFI DDR, tWB = (TCAD_CNT + TWB_CNT - 6) * NAND_CLK_PERIOD ns.
TADL_CNT	Refer to tADL timing from flash datasheet	Generated timing for ASYNC and toggle DDR, tADL = (TWH_CNT + TALH_CNT + TADL_CNT + 4) * NAND_CLK_PERIOD ns Generated timing for ONFI DDR, tADL = (TCAD_CNT + TADL_CNT + 4) *

TIMING_VALUE	Guideline	Timing equation
		NAND_CLK_PERIOD ns
TRHW_CNT	Refer to tRHW timing from flash datasheet	Generated timing for all async and toggle DDR modes, tRHW = (TRHW_CNT + TREH_CNT + TCLS_CNT + 4) * NAND_CLK_PERIOD ns. For ONFI DDR modes, tRHW = (TRHW_CNT + 1) * NAND_CLK_PERIOD ns.
TCWAW_CNT	Refer to tCWAW timing from flash datasheet	Relevant for Samsung new devices only. Generated timing for async and toggle DDR modes, tCWAW = (TCWAW_CNT + TWH_CNT + TALS_CNT + TWP_CNT + 5) * NAND_CLK_PERIOD ns This timing parameter is not relevant for ONFI DDR mode. Do not impact with TCWAW_CNT programmed value for ONFI DDR mode.

Table 80 NAND Toggle DDR Timing equations (NAND_TDDR_TIMING0-1)

TIMING_VALUE	Guideline	Timing equation
TRPSTH_CNT	Refer to tRPSTH timing from flash datasheet	tRPSTH = [TRPSTH_CNT +1] * NAND_CLK_PERIOD
TRPST_CNT	Refer to tRPST timing from flash datasheet	tRPST = [TRPST_CNT +2] * NAND_CLK_PERIOD
TRPRE_CNT	Refer to tRPRE timing from flash datasheet	tRPRE = [TRPRE_CNT +1] * NAND_CLK_PERIOD
TCDQSH_CNT	Refer to tCDQSH timing from flash datasheet	tCDQSH = (TWH_CNT + TCLH_CNT +TCDQSH_CNT +5) * NAND_CLK_PERIOD
TCDQSS_CNT	Refer to tCDQSS timing from flash datasheet	tCDQSS = TCDQSS_CNT * NAND_CLK_PERIOD
TWPSTH_CNT	Refer to tWPSTH timing from flash datasheet	tWPSTH = (TWPSTH_CNT + 1) * NAND_CLK_PERIOD
TWPST_CNT	Refer to tWPST timing from flash datasheet	tWPST = (TWPST_CNT + 4) * NAND_CLK_PERIOD
TWPRE_CNT	Refer to tWPRE timing from flash datasheet	tWPRE = (TCDQSS_CNT + TADL_CNT + TWPRE_CNT + 2) * NAND_CLK_PERIOD

Table 81 NAND SDDR timing equations (NAND_SDDR_TIMING_0-1)

TIMING_VALUE	Guideline	Timing equation
TCKWR_CNT	Refer to tCKWR timing from flash	Generated timing, tCKWR = (TCKWR_CNT +1) * NAND_CLK_PERIOD ns
TCAD_CNT	Refer to tCAD timing from flash	Command, Address, Data delay Generated timing, tCAD = (TCAD_CNT+1) * NAND_CLK_PERIOD ns.
TWRCK_CNT	Refer to tWRCK timing from flash	Generated timing tWRCK = (TWRCK_CNT +1) * NAND_CLK_PERIOD ns.
TWPST_CNT	Refer to tWPST timing from flash	Generated timing, tWPST = 3 * NAND_CLK Required programmed values for all clock frequencies or devices TWPST_CNT = 0.
TWPRE_CNT	Refer to tWPRE timing from flash	Generated timing tDQSS = 1 * NAND_CLK Generated timing tWRPRE = 3 * NAND_CLK. Generated timing tDQSS = 1 * NAND_CLK. Required programmed values for all clock frequencies or devices TWPRE_CNT = 0.
TCCS_CNT	Refer to tCCS timing from flash	Generated timing tCCS = (TCCS_CNT + TCAD_CNT + 4) * NAND_CLK_PERIOD ns.

29.3.13 Round Trip Delay Calculation for tRP Timing

Standard asynchronous interface for read operation require timing adjustment so that NAND controller properly samples the read data coming in from flash. This is because NAND controller samples the read data coming from flash with the same synchronous clock (NAND_CLK) used for read enable (REN_) signal generation at the end of Read pulse timing. Because of this implementation approach, delay incurred in REN signal going, and delay incurred in DATA coming including on board should be accounted for. tRP timing calculation. Hence Read Pulse width timing has to be extended by tDLY timing to account for round trip delay.

Total delay tDLY = REN out delay + REN out delay on board + DATA out delay from flash to chip input + DATA INPUT pad delay + setup time of flop

Essentially above equation is simplified to,

tDLY = REN out PAD delay + Round trip delay on board + Max(DATA INPUT pad delay) + setup time of flop

Where Round trip delay on board = Max (REN out delay on board + DATA out delay from flash to chip input) based on board design.

Based on Tegra 3 silicon timing data, the above equation reduces to:

tDLY = 3.3 ns + Round trip delay on board + 2ns

= 5.3 ns + Round trip delay on board (<500ps typically)

29.3.14 Read/Write Cycle Time Programming

It is common that from flash timing requirements, total cycle time of read/write access is slightly more than pulse width time (tRP/tWP) plus hold time (tREH/tWH). tRP, tREH achieved timings shall make sure that tRC timing requirement is also met with whatever NAND clock selection. For example, for one of the Samsung flash timing requirement are such as:

tRP=12, tREH=10 but tRC = 25ns (tRP + tREH < tRC)

From achieved timing requirements point of view, all these 3 should be satisfied not just tRP/tREH alone. In NAND controller tRP/tRP_RESP, tREH, tWP, tWH timings are programmable. By virtue of generated timings of these individual timing parameters, tRC, tWC timings can be met.

Achieved Read cycle time (tRC) is nothing but,

Read pulse width time + Read Hold time => tRP/TRP_RESP timing + tREH timing

Achieved Write cycle time (tWC) is nothing but,

Write pulse width time + Write hold time ==> tWP timing + tWH timing

For the same illustration described above, adjustment of 3ns to satisfy read/write cycle timing can be achieved:

Option1: tRP = 15ns, tREH=10ns

Option2: tRP = 12ns, tREH=13ns

Option2 is preferable, because with NAND_CLK_PERIOD=12.5ns all these timing requirements are met closely with slight margin. Also to achieve option1 timings, NAND_CLK resolution of 5ns period is required which is costly from power front. So when choosing tRP, tREH timing requirements, total cycle timing requirements have to be taken into account.

29.3.15 tRP Programming for EDO Mode of Operation

In EDO mode of operation NAND controller samples read data on completion of Read Cycle timing. With this effect for tRP calculation tDLY adjustment as described in earlier section is not required provided, tDLY < tRC condition is met. If tDLY is more than tRC, the delay adjustment required for EDO mode will be,

tDLY_EDO = (tDLY + Round trip board delay) – tRC time

Also the requirement for tRP timing of, Max (tRP, tREA) will also be gone since tREA is also less than tRC practically for any flash. So tRP timing considering the total Read Cycle timing requirement as described in Read/Write cycles programming section will suffice, and there is no need to extend tRP pulse width. One can observe 30% better performance improvement using EDO mode compared to non-EDO mode of operation.

29.3.16 QUSE/DQS Delay Programming for DDR Modes

Proper QUSE/DQS programming is required to sample incoming read data in DDR modes. Following guideline should be maintained along with characterization to reliably work with all DDR variants of devices.

The programming guide line for following registers ignoring the PVT variation and based on Silicon validation platform is given below.

FBIO_CFG.CFG_QUSE_LATE, FBIO_QUSE_DLY and CFG_DQSIB_DLY

- QUSE coarse delay setting based on NAND_CLK,

ONFI/Toggle DDR modes

Frequency	QUSE_LATE setting
0 < Freq < 24MHz	FBIO_CFG.CFG_QUSE_LATE [3:0] = 4'b0
24 <= Freq < 66MHz	FBIO_CFG.CFG_QUSE_LATE [1] =1
66 <= Freq < 100MHz	FBIO_CFG.CFG_QUSE_LATE [2] =1

- QUSE fine tune delay from delay line programming, FBIO_QUSE_DLY. CFG_QUSE_DLY_BYTE_0 = 0x00
- DQS fine tune delay from delay line programming such as,

  NAND_FBIO_DQSIB_DLY_0 = ((1.25 * (1000/NAND_CLK frequency))>=63)? 63: (1.25 * (TIMESCALE/NAND_CLK frequency));

29.3.17 Safe Timing Values and Trimmer Settings for Boot ROM

Purpose of this section is to provide guidance on safe value settings for timing parameters as well as QUSE/DQS delay values during boot. Since ONFI compliant DDR devices can boot up in regular ASYNC mode, it's not recommend to operate to turn on DDR modes during boot for such flashes. Any required trimmer/timing register settings can be programmed through BCT to support switching to DDR mode follow-on to boot. Initialization and command sequences of ONFI standard mode should be adopted in bootrom driver like in async mode of operation.

During boot, as the clocking runs on at crystal frequency of 24MHz and hardware ensures by design that it's possible to come up with safe settings of various timing register and programmable trimmer values for reliable working of various type of flash devices for Async interface and Toggle Interface. Since Toggle devices data transfer is DDR only requires the boot support and hence Safe value programming.

Below references of register settings for timing and trimmer settings cover legacy Async interface/ONFI Async interface and Toggle DDR interface. In summary -

- Legacy Async interface or Samsung devices including toggle DDR flash.
  - ASYNC only flashes controller is remains in default ASYNC mode of operation.
  - After Toggle flash identification, controller switched to toggle DDR mode of operation.
- ONFI devices including DDR devices only in ASYNC mode.
  - After device initialization and identification sequences remains in default ASYNC mode of operation.

Safe Timing register values are,

Timing Register	Required register setting
NAND_ASYNC_TIMING0	0x0A00_0A0A
NAND_ASYNC_TIMING1	0x050A_010A
NAND_ASYNC_TIMING2	0x0A00_0000
NAND_ASYNC_TIMING3	0x0001_1111
NAND_TDDR_TIMING0	0x0000_0111
NAND_TDDR_TIMING1	0x0004_0110

Safe QUSE/DQS delay settings for toggle DDR support are,

Register	Required field	Value
FBIO_CFG	CFG_QUSE_LATE	0x0
FBIO_QUSE_DLY	CFG_QUSE_DLY_BYTE_0	0x0
FBIO_DQSIB_DLY	CFG_DQSIB_DLY_BYTE_0	0x3F

29.3.17.1 Command Queue Abort/Stall Conditions

When there is failure in any previous command sequence operation, Command queue execution will be aborted triggering interrupt to processor, if RD_STATUS_CHK is enabled. It is possible that,

- Current Register status will not reflect the register configured which caused the failure.
- SW has to figure out what is the last command sequence to the flash which caused this failure.
- Re arranges the list as per application, and configures the Command queue configuration registers to re-start new sequence of operations.

If RD_STATUS_CHK fails for any of the command packet execution is stopped right away, i.e. at this time the command packet which needs the RD_STAUS_CHK is read from the buffer and executed up to the RD_STATUS_CHK only. Associated read/write/command transaction to flash as programmed NAND_COMMAND register is abandoned further and software has to come back from this packet for recovery procedure.

Also software can halt the command queue execution at any point of time by clearing the LL_START bit of NAND_LL_CONFIG register. Removing LL_START is allowed at any time during command queue execution and is interpreted as a way of disabling the command queue execution. By this time recognizing the LL_START clear, NAND controller should have extracted next packet command and accordingly NAND_LL_STATUS registers will reflect the status as in Abort condition.

Word counter status registers in NAND_LL_STATUS register will be useful for calculating the next start address for both cases. However, in case of Halt, please note that enabling the LL_START will not resume execution and will repeat the execution from start. Software should configure NAND_LL_PTR register for necessary correction and can continue execution enabling LL_START.

Next start address after Abort/Halt should be calculated as:

> *NAND_LL_PTR + (LL_LENGTH_DONE – LL_LENGHT_LAST_PACKET) * 4 = Byte Address of the command packet where the command queue execution stopped either because of the COMMAND QUEUE Error [RD_STATUS_CHK error] or COMMAND QUEUE Stall.

29.4 NAND Controller Registers

29.4.1 NAND_COMMAND_0

Configuration of this register determines the flash sequence to be initiated by NAND controller.

NAND Command Register

Offset: 000h | Read/Write: R/W | Reset: 0b00000000100000000000000000000100

Bit	Reset	Description
31	0x0	GO: 0 = HW clears when programmed nand IO operation is completed. 0 = DISABLE 1 = ENABLE
30	0x0	CLE: CLE enable 1 = Flash sequence has Command Cycle(CLE) enabled 0 = Flash sequence has Command Cycle(CLE) disabled 0 = DISABLE 1 = ENABLE
29	0x0	ALE: ALE enable 1 = Flash sequence has Address Cycle(CLE) enabled 0 = Flash sequence has Address Cycle(CLE) disabled 0 = DISABLE 1 = ENABLE
28	0x0	PIOPIO mode of operation enable 1 = Dataout is from NAND_RESP register and Datain is to NAND_RESP register 0 = Dataout is from FIFO buffer and Datain to FIFO buffer 0 = DISABLE 1 = ENABLE
27	0x0	TX: write data transfer enable - required for FLASH program 1 = Write data transfers to flash is enabled 0 = Write data transfers to flash is disabled. 0 = DISABLE 1 = ENABLE
26	0x0	RX: read data transfer enabled - required for FLASH read 1 = Read data transfers from flash is enabled 0 = Read data transfers from flash is disabled. 0 = DISABLE 1 = ENABLE
25	0x0	SEC_CMD: CMD2 sequence to flash enable 1 = NAND command sequence have a second command(CLE) cycle 0 = NAND command sequence doesn't have second CLE cycle 0 = DISABLE 1 = ENABLE
24	0x0	AFT_DAT: CMD2 placement control 1 - CMD2 CLE cycle is issued after data transfer cycles. this is the typical usage during FLASH program 0 - CMD2 CLE cycle is issued right after Address transfer cycles, typical usage during FLASH read 0 = DISABLE 1 = ENABLE
23:20	0x8	TRANS_SIZE: Transfer size of bytes depends on PAGE_SIZE_SEL field of NAND_CONFIG register 0 = BYTES1 1 = BYTES2 2 = BYTES3 3 = BYTES4 4 = BYTES5 5 = BYTES6 6 = BYTES7 7 = BYTES8 8 = BYTES_PAGE_SIZE_SEL

Bit	Reset	Description
19	0x0	A_VALID: Main data region transfer enable 1 = Involves Main area data transfer in flash sequence 0 = Doesn't involve Main area data transfer 0 = DISABLE 1 = ENABLE
18	0x0	B_VALID: Spare region (aka TAG) transfer enable 1 = Involves spare area data transfer in flash sequence 0 = Doesn't involve spare area data transfer 0 = DISABLE 1 = ENABLE
17	0x0	RD_STATUS_CHK: Hardware assisted read status check enable 1 = Indicates to controller that current IO sequence need RD STATUS check condition to be qualified. 0 = auto read status check is disabled notes: please refer to NAND_HWSTATUS_CMD register for qualifier condition 0 = DISABLE 1 = ENABLE
16	0x0	RBSY_CHK: Hardware assisted rbsy check enable 1 = Indicates to controller that current IO sequence need RBSY check condition to be qualified. 0 = auto RBSY check is disabled notes: please refer to NAND_HWSTATUS_CMD register for qualifier condition 0 = DISABLE 1 = ENABLE
15	0x0	CE7: Chip select enable for Flash Card 7 0 = DISABLE 1 = ENABLE
14	0x0	CE6: Chip select enable for Flash Card 6 0 = DISABLE 1 = ENABLE
13	0x0	CE5: Chip select enable for Flash Card 5 0 = DISABLE 1 = ENABLE
12	0x0	CE4: Chip select enable for Flash Card 4 0 = DISABLE 1 = ENABLE
11	0x0	CE3: Chip select enable for Flash Card 3 0 = DISABLE 1 = ENABLE

7	0x0	RD_STATUS_END: Do page read status command sequence after data read 0 = DISABLE 1 = ENABLE
6	0x0	WAIT_RBSY_LOW: Wait for RBSY low before deactivating the chip select to complete the flash sequence 0 = DISABLE 1 = ENABLE

Bit	Reset	Description
5:4	0x0	CLE_BYTE_SIZE: Command cycle byte count 0 = CLE_BYTES1 1 = CLE_BYTES2 2 = CLE_BYTES3 3 = CLE_BYTES4
3:0	0x4	ALE_BYTE_SIZE: Address cycle byte count 0 = ALE_BYTES1 1 = ALE_BYTES2 2 = ALE_BYTES3 3 = ALE_BYTES4 4 = ALE_BYTES5 5 = ALE_BYTES6 6 = ALE_BYTES7 7 = ALE_BYTES8 8 = ALE_BYTES9 : Reserved 9 = ALE_BYTES10 : Reserved 10 = ALE_BYTES11 : Reserved 11 = ALE_BYTES12 : Reserved 12 = ALE_BYTES13 : Reserved 13 = ALE_BYTES14 : Reserved 14 = ALE_BYTES15 : Reserved 15 = ALE_BYTES16

29.4.2 NAND_STATUS_0

Collection of NAND flash RBSY line status and other internal operations status.

NAND Status Register

Offset: 004h | Read/Write: RO | Reset: 0bxxxxxxxx00xxxxxx1

Bit	Reset	Description
15	X	RBSY7: 1 = Indicates flash7 is RDY
14	X	RBSY6: 1 = Indicates flash6 is RDY
13	X	RBSY5: 1 = Indicates flash5 is RDY
12	X	RBSY4: 1 = Indicates flash4 is RDY
11	X	RBSY3: 1 = Indicates flash3 is RDY
10	X	RBSY2: 1 = Indicates flash2 is RDY
9	X	RBSY1: 1 = Indicates flash1 is RDY
8	X	RBSY0: 1 = Indicates flash0 is RDY
7	0	WR_ACT: 1 = Indicates write cycles to flash are in progress
6	0	RD_ACT: 1 = Indicates read cycles to flash are in progress
0	1	ISEMPTY: 1 = Indicates NAND controller is in IDLE state of operation, and there are no flash/DMA transactions pending.

29.4.3 NAND_ISR_0

Interrupt status hardware behavior: All interrupt status bits are SET, respective event occurs and writes 1 to clear.

NAND Interrupt Status Register

Offset: 008h | Read/Write: R/W | Reset: 0b0xxxxxxxxxxxxxxx00000000000000

Bit	R/W	Reset	Description
31	RW	0x0	ABORT_DONE: 1 = This interrupt is generated after an abort was initiated by software by setting CONFIG2_ABORT bit, and hardware has finished abort sequence and returned to Idle ready for next flash operation. Note that it is required of software to reprogram all state/registers/pointers like a new transaction. (Hardware will typically hold data registers as is. and reset control registers after an abort)
24	RO	X	CORRFAIL_ERR: 1 = Correctable OR Un-correctable errors occurred in the DMA transfer without regard to HW_ERR_CORRECTION feature is enabled or not. Use extended decode results in NAND_DEC_RESULT and NAND_DEC_STATUS_EXT to figure out further action for block replacement/wear leveling during file system management for software. Covers all ECC selection: RS/Hamming/BCH modes
15	RW	0x0	IS_RBSY7: 1 = Flash7 is Ready interrupt occurred. This bit is set only when not running in COMMAND QUEUE MODE
14	RW	0x0	IS_RBSY6: 1 = Flash6 is Ready interrupt occurred. This bit is set only when not running in COMMAND QUEUE MODE
13	RW	0x0	IS_RBSY5: 1 = Flash5 is Ready interrupt occurred. This bit is set only when not running in COMMAND QUEUE MODE
12	RW	0x0	IS_RBSY4: 1 = Flash4 is Ready interrupt occurred. This bit is set only when not running in COMMAND QUEUE MODE
11	RW	0x0	IS_RBSY3: 1 = Flash3 is Ready interrupt occurred. This bit is set only when not running in COMMAND QUEUE MODE
10	RW	0x0	IS_RBSY2: 1 = Flash2 is Ready interrupt occurred. This bit is set only when not running in COMMAND QUEUE MODE
9	RW	0x0	IS_RBSY1: 1 = Flash1 is Ready interrupt occurred. This bit is set only when not running in COMMAND QUEUE MODE
8	RW	0x0	IS_RBSY0: 1 = Flash0 is Ready interrupt occurred. This bit is set only when not running in COMMAND QUEUE MODE
7	RW	0x0	IS_UND: 1 = FIFO under run interrupt occurred this should not happen in general usage, if it happens there is a potential hardware issue.
6	RW	0x0	IS_OVR: 1 = FIFO is Overrun this should not happen in general usage, if it happens there is potential hardware issue.
5	RW	0x0	IS_CMD_DONE: 1 = Command operations are completed as per NAND command register settings. This is set ONLY when not running in COMMAND QUEUE MODE
4	RW	0x0	IS_ECC_ERR: 1 = ECC error generated for following reasons. ->ecc decode resulted in uncorrectable errors in one of sector(sub-page) ->ecc decode resulted in correctable errors more than trigger level as defined in TRIG_LVL in NAND_CONFIG register. Bit is set for legacy mode of ECC selection with HW_ECC & ECC_TAG_EN only i.e. for RS/Hamming selection. This bit is not set for BCH selection
3	RW	0x0	IS_LL_DONE: 1 = Command queue execution completed
2	RW	0x0	IS_LL_ERR: 1 = One of the Command queue packet execution returned error because of Read Status Check failure

29.4.4 NAND_IER_0

NAND Interrupt Enable Register

Offset: 00ch | Read/Write: R/W | Reset: 0b0xxxxxxxxxxx00000000000000000x0

Bit	Reset	Description
31	0x0	ABORT_DONE: 1 = This interrupt is generated after an abort was initiated by software by setting CONFIG2_ABORT bit, and hardware has finished abort sequence and returned to Idle ready for next flash operation. Note that it is required of software to reprogram all state/registers/pointers like a new transaction. (Hardware will typically hold data registers as is. and reset control registers after an abort)
19:16	0x0	ERR_TRIG_VAL: Trigger for correctable error Interrupts by main ECC RS decoder, if HW_ERR_CORRECTION feature is enabled. Mechanism for software to get an idea on error pattern development over a period of usage. NAND controller will trigger interrupt if the current main page read transfer resulted in correctable errors reached this trigger value for Reed-Solomon selection. For example, of ECC_ERROR interrupt for t=4, with ERR_TRIG_VAL=3 could imply only one of the following. a) If DEC_FAIL = 1, one of the sub-page decode returned failure because no. of symbol errors are more than 4. b) If DEC_FAIL = 0, one of the sub-page decode returned 3 correctable errors. 0 = CORR_ERRS_0 : Reports for every single error, equivalent to ECC_ERROR interrupt without HW_ERR_CORRECTION feature. 1 = CORR_ERRS_1 2 = CORR_ERRS_2 3 = CORR_ERRS_3 4 = CORR_ERRS_4 5 = CORR_ERRS_5 6 = CORR_ERRS_6 7 = CORR_ERRS_7 8 = CORR_ERRS_8 9 = CORR_ERRS_9 10 = CORR_ERRS_10 11 = CORR_ERRS_11 12 = CORR_ERRS_12 13 = CORR_ERRS_13 14 = CORR_ERRS_14 15 = CORR_ERRS_15
15	0x0	IE_RBSY7: Flash7 RBSY line High interrupt enable 0 = DISABLE 1 = ENABLE
14	0x0	IE_RBSY6: Flash6 RBSY line High interrupt enable 0 = DISABLE 1 = ENABLE
13	0x0	IE_RBSY5: Flash5 RBSY line High interrupt enable 0 = DISABLE 1 = ENABLE
12	0x0	IE_RBSY4: Flash4 RBSY line High interrupt enable 0 = DISABLE 1 = ENABLE
11	0x0	IE_RBSY3: Flash3 RBSY line High interrupt enable 0 = DISABLE 1 = ENABLE
10	0x0	IE_RBSY2: Flash2 RBSY line High interrupt enable 0 = DISABLE 1 = ENABLE
9	0x0	IE_RBSY1: Flash1 RBSY line High interrupt enable 0 = DISABLE 1 = ENABLE

Bit	Reset	Description
8	0x0	IE_RBSY0: Flash0 RBSY line High interrupt enable 0 = DISABLE 1 = ENABLE
7	0x0	IE_UND: FIFO underrun interrupt enable 0 = DISABLE 1 = ENABLE
6	0x0	IE_OVR: IFO overrun interrupt enable 0 = DISABLE 1 = ENABLE
5	0x0	IE_CMD_DONE: Command operations done interrupt enable 0 = DISABLE 1 = ENABLE
4	0x0	IE_ECC_ERR: ECC error interrupt enable. Please refer to IS_ECC_ERR above for interrupt event details 0 = DISABLE 1 = ENABLE
3	0x0	IE_LL_DONE: Command queue execution completion interrupt enable 0 = DISABLE 1 = ENABLE
2	0x0	IE_LL_ERR: Flash errors in Command queue execution error interrupt enable 0 = DISABLE 1 = ENABLE
0	0x0	GIE: 0 = Global Interrupt mask enable. Masks all of the interrupts, and interrupt to signal to CPU is disabled. 0 = DISABLE 1 = ENABLE

29.4.5 NAND_CONFIG_0

Combination of NAND_COMMAND register determines the sequence of operations to be carried on. ECC selection and strength etc are selectable from this register.

NAND Configuration Register

Offset: 010h | Read/Write: R/W | Reset: 0b00010x00000000110000000000000000

Bit	Reset	Description
31	0x0	HW_ECC: Hardware Error detection enable for Main page read data 0 = DISABLE 1 = ENABLE
30	0x0	ECC_SEL: Hardware Error detection/correction algorithm selection 0 = HAMMING 1 = RS
29	0x0	HW_ERR_CORRECTION: Enable Auto hardware error correction. Emulates software behavior of reading the error vectors from system buffer as pointed in the error vector address register, applies correction and updates the memory word with corrected data. This is done on page basis as soon as the decode information is available as the flash read is placed in memory. 0 = DISABLE 1 = ENABLE

Bit	Reset	Description
28	0x1	PIPELINE_EN: Pipelines of decode operation enable. Enable next page flash READ data transfer even before current page ECC Decode is completed. If disabled, new page READ is started only after the previous page flash read, ECC decode(detection) are completed. 0 = DISABLE 1 = ENABLE
27	0x0	ECC_EN_TAG: Hardware Error detection enable for Spare read data 0 = DISABLE 1 = ENABLE
25:24	0x0	TVALUE: Hardware Error correction algorithm strength selection for RS ECC selection. 0 = TVAL4 : (t=4) 4 bit error correction per each 512 bytes of data 1 = TVAL6 : (t=6) 6 bit error correction per each 512 bytes of data 2 = TVAL8 : (t=8) 8 bit error correction per each 512 bytes of data 3 = TVAL_RSVD
23	0x0	SKIP_SPARE: Skip spare feature enable. SKIP_SPAE_SEL below indicates how many bytes in spare area of flash to be skipped over either for reading/writing. 0 = DISABLE 1 = ENABLE
22	0x0	COM_BSY: Combined RBSY selection enabled. 0 = DISABLE: RBSY0 is from Flash card 0 1 = ENABLE: RBSY0 seen by hardware is wired AND of all flash cards connected
21	0x0	BUS_WIDTH: Flash read/write data bus width 0 = BUS_WIDTH_8 : selection Data bus width 8-bit 1 = BUS_WIDTH_16 : selection Data bus width 16-bit
20	0x0	LPDDR1_MODE: LPDDR1 mode of pin ordering enable. Pin ordering to be package friendly with LPDDR1 0 = DISABLE : Standard mode of pin ordering 1 = ENABLE : Pin ordering compatible with LP-DDR1 multi chip package
19	0x0	EDO_MODE: EDO mode of flash read enable. 0 = DISABLE : Data sampled on positive edge of REN 1 = ENABLE : Data sampled on completion of read cycle time
18:16	0x3	PAGE_SIZE_SEL: Page size selection - depends on Flash memory organization used. 0 = PAGE_SIZE_256 : 256 bytes size is not supported - RSVD 1 = PAGE_SIZE_512 2 = PAGE_SIZE_1024 3 = PAGE_SIZE_2048 4 = PAGE_SIZE_4096 5 = PAGE_SIZE_8192 6 = PAGE_SIZE_RSVD2 7 = PAGE_SIZE_RSVD3
15:14	0x0	SKIP_SPARE_SEL: Size in granularity of 4 bytes to skipped for spare access 0 = SKIP_SPARE_SIZE_4 1 = SKIP_SPARE_SIZE_8 2 = SKIP_SPARE_SIZE_12 3 = SKIP_SPARE_SIZE_16
13	0x0	DEBUG_MODE: Debug mode selection for hardware debug
12:9	0x0	DEBUG_SEL: Debug selection for hardware debug
8:0	0x0	TAG_BYTE_SIZE: Block Size in bytes for TAG data from spare area of flash. This is used for specifying the size of the TAG Block data bytes to be move/from to spare area. Used when B_VALID is true. Specified in bytes (n-1 encoding)

29.4.6 NAND_TIMING_0

Control the flash interface signals for asynchronous timings

where n - value programmed in the respective field of timing register.

NAND Timing Register

Offset: 014h | Read/Write: R/W | Reset: 0b00000000000000000000000xx000000

Bit	Reset	Description
31:28	0x0	TRP_RESP_CNT: Read pulse width(RE Low time)timing for status read cycles Generated timing = (n+1) * NAND_CLK_PERIOD ns GUIDELINE: for tRP_RESP/tRP timing non-EDO mode: Max(tRP, tREA) timing + 6ns (round trip delay) EDO mode: tRP timing from flash datasheet Notes: (1)"round trip delay" to account for - REN out PAD delay + REN out board delay + DATA driven OUT from flash to chip input + DATA INPUT pad delay. (2)For EDO modes - since controller latches data without regard to `nRE' (REN) posedge tREA, round trip delay factors need not be considered.
27:24	0x0	TWB_CNT: WE High to RBSY low asserted (by flash) timing Generated timing = (n+1) * NAND_CLK_PERIOD ns. GUIDELINE: Refer to tWB timing from flash datasheet
23:20	0x0	TCR_TAR_TRR_CNT: RBSY High to RE low timing Generated timing = (n+3) * NAND_CLK_PERIOD ns. GUIDELINE: Program Max(tCR, tAR, tRR) timings from flash data sheet
19:16	0x0	TWHR_CNT: WE High to RE Low timing - Status Read Cycles Generated timing = (n+1) * NAND_CLK_PERIOD ns. GUIDELINE: Refer to tWHR timing from flash data sheet
15:14	0x0	TCS_CNT: CLE/ALE Setup/Hold time. Generated timing = (n+2) * NAND_CLK_PERIOD ns. GUIDELINE: Program Max(tCS, tCH, tALS, tALH) timings from flash datasheet This timing is met timing requirements. 1. from CE Low -> WE posedge of CLE/ALE. 2. from WE posedge of CLE to-> WE posedge of ALE. Please note that this amounts to, 1(above case): (n+2)*NAND_CLK_PERIOD + tWP(of following CLE/ALE cycle) 2(above case): tWH(hold time of current CLE cycle) + (n+2).NAND_CLK_PERIOD of CLE cycle (n+2)*NAND_CLK_PERIOD of ALE cycle + tWP(pusle width of ALE cycle).
13:12	0x0	TWH_CNT: Write pulse HOLD time Generated timing = (n+1) * NAND_CLK_PERIOD ns. GUIDELINE: Refer to tWH timing from flash datasheet

Bit	Reset	Description
11:8	0x0	TWP_CNT: Write pulse width time Generated timing = (n+1) * NAND_CLK_PERIOD ns. GUIDELINE: Refer to tWP timing from flash datasheet
5:4	0x0	TRH_CNT: Read pulse HOLD time Generated timing = (n+1) * NAND_CLK_PERIOD ns. GUIDELINE: Refer to tRH timing from flash datasheet
3:0	0x0	TRP_CNT: Read pulse width(RE Low time)timing for Data read cycles Generated timing = (n+1) * NAND_CLKS, where n - value programmed in the tRP_RESP_CNT field of timing register. GUIDELINE: tRP_RESP/tRP timing register programming non-EDO mode: Max(tRP, tREA) timing + 6ns (round trip delay) EDO mode: tRP timing Notes: (1) "round trip delay" to account for - REN out PAD delay + REN out board delay + DATA driven OUT from flash to chip input + DATA INPUT pad delay. (2) For EDO modes - since controller latches data without regard to `nRE' (REN) posedge tREA, round trip delay factors need not be considered.

29.4.7 NAND_RESP_0

Staging register meant for PIO mode of transfer Contents should be written by CPU access to this register for write transfer. Contents are readable by CPU access to this register after read transfer.

NAND Response Register

Offset: 018h | Read/Write: R/W | Reset: 0b00000000000000000000000000000000

Bit	Reset	Description
31:24	0x0	BYTE3: Write/Response data byte 3 (MSB)
23:16	0x0	BYTE2: Write/Response data byte 2
15:8	0x0	BYTE1: Write/Response data byte 1
7:0	0x0	BYTE0: Write/Response data byte 0 (LSB)

29.4.8 NAND_TIMING2_0

Controls the flash interface signals asynchronous timings.

NAND Timing2 Register

Offset: 01ch | Read/Write: R/W | Reset: 0b0000

Bit	Reset	Description
3:0	0x0	TADL_CNT: WE posedge of address cycle to WE posedge of data cycle GUIDELINE: Refer to tADL timing from flash datasheet Please note that timing generated from controller is for the duration from ALE low to WP low. Generated timing = (TWH+TADL+TWP+6) * NAND_CLK_PERIOD ns

29.4.9 NAND_CMD_REG1_0

Command cycle generation use these during COMMAND1 time:

- CLE cycle1 command value setting

NAND Command1 Register

Offset: 020h | Read/Write: R/W | Reset: 0b00000000000000000000000000000000

Bit	Reset	Description
31:24	0x0	CMD_BYTE3: Command byte 3(MSB)
23:16	0x0	CMD_BYTE2: Command byte 2
15:8	0x0	CMD_BYTE1: Command byte 1
7:0	0x0	CMD_BYTE0: Command byte 0(LSB)

29.4.10 NAND_CMD_REG2_0

Command cycle generation use these during COMMAND2 time:

- CLE cycle2 command value setting

NAND Command2 Register

Offset: 024h | Read/Write: R/W | Reset: 0b00000000000000000000000000000000

Bit	Reset	Description
31:24	0x0	CMD_BYTE3: Command byte 3(MSB)
23:16	0x0	CMD_BYTE2: Command byte 2
15:8	0x0	CMD_BYTE1: Command byte 1
7:0	0x0	CMD_BYTE0: Command byte 0(LSB)

29.4.11 NAND_ADDR_REG1_0

Address cycle generation uses these bytes:

- ALE cycle value setting

NAND Address1 Register

Offset: 028h | Read/Write: R/W | Reset: 0b00000000000000000000000000000000

Bit	Reset	Description
31:24	0x0	ADDR_BYTE3: Address byte 3
23:16	0x0	ADDR_BYTE2: Address byte 2
15:8	0x0	ADDR_BYTE1: Address byte 1
7:0	0x0	ADDR_BYTE0: Address byte 0 (LSB)

29.4.12 NAND_ADDR_REG2_0

Address cycle generation uses these bytes:

- ALE cycle value setting

NAND Addr2 Register

Offset: 02ch | Read/Write: R/W | Reset: 0b00000000000000000000000000000000

Bit	Reset	Description
31:24	0x0	ADDR_BYTE7: Address byte 3
23:16	0x0	ADDR_BYTE6: Address byte 2
15:8	0x0	ADDR_BYTE5: Address byte 1
7:0	0x0	ADDR_BYTE4: Address byte 0 (LSB)

29.4.13 NAND_DMA_MST_CTRL_0

NAND controller DMA interface is configured with this register. Number of page transfers DMA can be initiated only ONCE.

Maximum number of pages transferrable directly depends on the maximum DMA length of 64K bytes.

NAND DMA Master Control Register

Offset: 030h | Read/Write: R/W | Reset: 0b00100100xxx0xxxxxxxxxxxxxxxxxx00

Bit	Reset	Description
31	0x0	DMA_GO: NAND DMA interface enable for data transfers. Hardware clears when programmed length of data transfer is completed. 0 = DISABLE 1 = ENABLE
30	0x0	DIR: DMA data transfer direction. 0 = DMA_RD : 1 = DMA_WR : Read from system and write to flash

Bit	Reset	Description
29	0x1	DMA_PERF_EN: DMA performance feature enable. As soon as the Error vectors equal to BURST SIZE programmed received DMA suspends current data transfers and moves to Error vector transfer and waits till that page decode is completed. Potentially if Error vectors are received around each 512 sub-page boundary this could cause stall of next page READ data transfers causing performance degradation. To take advantage of PIPELINE_EN ECC decoder pipeline capability this should be enabled. 0 = DISABLE : 1 = ENABLE
28	0x0	IE_DMA_DONE: DMA transfer completion interrupt enable 0 = DISABLE 1 = ENABLE
27	0x0	REUSE_BUFFER: Reuse buffer for storing error vectors. 0 = DISABLE, increments the Error Vector destination address continuously till the total DMA transfer size is done 1 = ENABLE, same buffer is used for storing the error vectors for every page decoded
26:24	0x4	BURST_SIZE: DMA burst size selection 0 = BURST_RSVD1 1 = BURST_RSVD2 2 = BURST_1WORDS 3 = BURST_4WORDS 4 = BURST_8WORDS 5 = BURST_16WORDS 6 = BURST_RSVD3 7 = BURST_RSVD4
20	0x0	IS_DMA_DONE: 1 = DMA transfer completed interrupt status. This is set ONLY when not running in COMMAND QUEUE MODE
2	0x0	DMA_EN_A: Enable DMA transfer for Data (A) 0 = DISABLE 1 = ENABLE
1	0x0	DMA_EN_B: Enable DMA transfer for TAG/Spare (B) 0 = DISABLE 1 = ENABLE

29.4.14 NAND_DMA_CFG_A_0

DMA transfer length meant for main area in flash.

NAND DMA Configuration Register for main area

Offset: 034h | Read/Write: R/W | Reset: 0b0000000000000000

Bit	Reset	Description
15:0	0x0	DMA_BLOCK_SIZE_A: Normal mode: DMA Data Block size in Bytes(N-1) value Sgdma mode : no. of entries in the main descriptor table (N-1)

29.4.15 NAND_DMA_CFG_B_0

DMA transfer length meant for spare area in flash.

NAND DMA Configuration Register for spare area

Offset: 038h | Read/Write: R/W | Reset: 0b0000000000000000

Bit	Reset	Description
15:0	0x0	DMA_BLOCK_SIZE_B: DMA TAG Block size in Bytes(N-1) value

29.4.16 NAND_FIFO_CTRL_0

Indicates FIFO status useful for debug. Also each of these FIFO buffers can be flushed out to come out of abnormal conditions (e.g., controller hang).

NAND FIFO Control/Status Register

Offset: 03ch | Read/Write: R/W | Reset: 0bxxxxxxxxxxxx0000

Bit	R/W	Reset	Description
15	RO	X	LL_BUF_EMPTY: 1 = Indicates Command queue FIFO Empty
14	RO	X	LL_BUF_FULL: 1 = Indicates Command queue FIFO Full
13	RO	X	FIFO_A_EMPTY: 1 = Indicates Data FIFO Empty
12	RO	X	FIFO_A_FULL: 1 = Indicates Data FIFO Full
11	RO	X	FIFO_B_EMPTY: 1 = Indicates TAG FIFO Empty
10	RO	X	FIFO_B_FULL: 1 = Indicates TAG FIFO Full
9	RO	X	FIFO_C_EMPTY: 1 = Indicates ECC FIFO Empty
8	RO	X	FIFO_C_FULL: 1 = Indicates ECC FIFO Full
3	RW	0x0	LL_BUF_CLR: field set to "CLEAR_ALL_FIFO" flushes all the buffers(i.e.,LL_BUF,FIFO_A,FIFO_B,FIFO_C) 0 = CLEAR_NO_FIFO 1 = CLEAR_ALL_FIFO
2	RW	0x0	FIFO_A_CLR: Flush the DATA FIFO contents
1	RW	0x0	FIFO_B_CLR: Flush the TAG FIFO contents
0	RW	0x0	FIFO_C_CLR: Flush the ECC FIFO contents

29.4.17 NAND_DATA_BLOCK_PTR_0

NAND Data Block Address Register

Offset: 040h | Read/Write: R/W | Reset: 0b00000000000000000000000000000000

Bit	Reset	Description
31:0	0x0	DMA_DATA_BLOCK_PTR: DMA data block source/destination address pointer Buffer format in descriptor mode SGDMA_EN=1 Addr0(Byte aligned, 32-bit memory address | Length0(Byte granularity) | Addr1(Byte aligned, 32-bit memory address | Length1(Byte granularity) |.... | Buffer format in regular mode SGDMA_EN=0 Data word0(4bytes) Data word1(4bytes) Data word2(4bytes) ....

29.4.18 NAND_TAG_PTR_0

NAND TAG Block Address Register

Offset: 044h | Read/Write: R/W | Reset: 0b00000000000000000000000000000000

Bit	Reset	Description
31:0	0x0	DMA_TAG_PTR: DMA TAG block source/destination address pointer Buffer format in descriptor mode SGDMA_EN=1 Addr0(Byte aligned, 32-bit memory address | Length0(Byte granularity) | Addr1(Byte aligned, 32-bit memory address | Length1(Byte granularity) |.... | Buffer format in regular mode SGDMA_EN=0 Tag word0(4bytes) Tag word1(4bytes) Tag word2(4bytes) ....

29.4.19 NAND_ECC_PTR_0

NAND ECC Block Address Register

Offset: 048h | Read/Write: R/W | Reset: 0b00000000000000000000000000000000

Bit	Reset	Description
31:2	0x0	DMA_ECC_PTR: DMA Error vector destination address pointer

29.4.20 NAND_DEC_STATUS_0

NAND Decode Status Register

Offset: 04ch | Read/Write: RO | Reset: 0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx

Bit	Reset	Description
31:24	X	ERR_PAGE_NUMBER: Indicates the reference to the PAGE for Error Correction to be applied. Valid when IS_ECC_ERROR is generated
23:16	X	ERR_COUNT: No. of Errors occurred in main block READ data plus TAG read data when corresponding features are enabled.

Bit	Reset	Description
15:8	X	SUB_PAGE_FAIL: Indicates sub-page decode failure within a page size. When decode failure is observed software can use to figure out which sub-page (512 byte) decode failure. for ex: of 2K page size selection, bit 0 - first sub-page bit 1 - second sub-page bit 2 - third sub-page bit 3 - fourth sub-page and so on as applicable
1	X	A_ECC_FAIL: 0 = Main block data decode without decode fail
0	X	B_ECC_FAIL: 0 = Tag block data decode without decode fail

29.4.21 NAND_HWSTATUS_CMD_0

NAND Hardware Status Command Register

Offset: 050h | Read/Write: R/W | Reset: 0b00000000

Bit	Reset	Description
7:0	0x0	HWSTATUS_CMD: Command byte value used for READ STATUS commands when automatic hardware RBSY_CHK or RD_STATUS_CHK are enabled.

29.4.22 NAND_HWSTATUS_MASK_0

NAND Read Status Mask Register

Offset: 054h | Read/Write: R/W | Reset: 0b11111111111000000100000001000000

Bit	Reset	Description
31:24	0xff	RDSTATUS_MASK: 8 bit Mask value to extract the correct bit fields from READ STATUS information for RD_STATUS_CHK
23:16	0xe0	RDSTATUS_EXP_VAL: 8 bit expected RD STATUS VALUE for RD_STATUS_CHK
15:8	0x40	RBSY_MASK: 8 bit Mask value to extract the correct bit fields from READ STATUS information for RBSY_CHK
7:0	0x40	RBSY_EXP_VAL: 8 bit expected RD STATUS VALUE for RBSY_CHK

29.4.23 NAND_LL_CONFIG_0

NAND Command Queue Configuration Register

Offset: 058h | Read/Write: R/W | Reset: 0b0xxxxxxxxxxx1100xxxx000000000000

Bit	Reset	Description
31	0x0	LL_START: Command Queue feature enable. Hardware clears when command queue data and flash operations are completed. 0 = DISABLE 1 = ENABLE
19	0x1	WORD_CNT_STATUS_EN: Enable word count status update in LL_STATUS register 0 = DISABLE 1 = ENABLE

Bit	Reset	Description
18:16	0x4	BURST_SIZE: DMA burst size selection for Command Queue data requests 0 = BURST_RSVD1 1 = BURST_RSVD2 2 = BURST_1WORDS 3 = BURST_4WORDS 4 = BURST_8WORDS 5 = BURST_16WORDS 6 = BURST_RSVD3 7 = BURST_RSVD4
11:0	0x0	LL_LENGTH: Command queue up word length programmed is parsed and `START is done when the execution is complete. However, when errors are detected for any case of the flash operation failure command queue execution is aborted immediately before this length.

29.4.24 NAND_LL_PTR_0

NAND Command Queue Address Register

Offset: 05ch | Read/Write: R/W | Reset: 0b00000000000000000000000000000000

Bit	Reset	Description
31:2	0x0	LL_PTR: Command queue data pointer Register

29.4.25 NAND_LL_STATUS_0

NAND Command Queue Status Register

Offset: 060h | Read/Write: RO | Reset: 0bxxxxxxxx00xxxxxxxxxxxxxxxxxxxxxx

Bit	Reset	Description
31:24	X	LL_PKT_ID: Command queue PACKET ID completed at this time. Software has write access to this bit field position so that any time software can clear this field. Also NAND controller reset will reset this status.
23	0x0	IS_LL_DONE: Interrupt status of LL_DONE {Read Only}
22	X	IS_LL_ERR: Interrupt status of LL_ERR {Read Only}
19:16	X	LL_LENGTH_LAST_PKT: Command queue Word length of last packet executed in the queue. Please note that WORD_CNT_STATUS_EN in LL_CONFIG should be enabled for this status update
11:0	X	LL_LENGTH_DONE: Command queue Word length(32-bit) completed till this time. Please note that WORD_CNT_STATUS_EN in LL_CONFIG should be enabled for this status update

29.4.26 NAND_LOCK_CONTROL_0

Flash erase operation for selected [7:0] apertures are discarded.

NAND Memory Lock Control Register

Offset: 064h | Read/Write: R/W | Reset: 0b000000000

Bit	Reset	Description
8	0x0	IE_LOCK_ERR: Interrupt enable on memory range match. 0 = DISABLE 1 = ENABLE
7	0x0	LOCK_APER_EN7: Enable lock feature for selected apertures 7 Can be set only once register field, hardware reset OR controller reset ONLY can disable this feature. LOCK_APER_START7, LOCK_APER_END7, LOCK_APER_CHIPID7 can't be programmed once this SET 0 = DISABLE 1 = ENABLE
6	0x0	LOCK_APER_EN6: Enable lock feature for selected apertures 6 Can be set only once register field, hardware reset OR controller reset ONLY can disable this feature. LOCK_APER_START6, LOCK_APER_END6, LOCK_APER_CHIPID6 can't be programmed once this SET 0 = DISABLE 1 = ENABLE
5	0x0	LOCK_APER_EN5: Enable lock feature for selected apertures 5 Can be set only once register field, hardware reset OR controller reset ONLY can disable this feature. LOCK_APER_START5, LOCK_APER_END5, LOCK_APER_CHIPID5 can't be programmed once this SET 0 = DISABLE 1 = ENABLE
4	0x0	LOCK_APER_EN4: Enable lock feature for selected apertures 4 Can be set only once register field, hardware reset OR controller reset ONLY can disable this feature. LOCK_APER_START4, LOCK_APER_END4, LOCK_APER_CHIPID4 can't be programmed once this SET 0 = DISABLE 1 = ENABLE
3	0x0	LOCK_APER_EN3: Enable lock feature for selected apertures 3 Can be set only once register field, hardware reset OR controller reset ONLY can disable this feature. LOCK_APER_START3, LOCK_APER_END3, LOCK_APER_CHIPID3 can't be programmed once this SET 0 = DISABLE 1 = ENABLE
2	0x0	LOCK_APER_EN2: Enable lock feature for selected apertures 2 Can be set only once register field, hardware reset OR controller reset ONLY can disable this feature. LOCK_APER_START2, LOCK_APER_END2, LOCK_APER_CHIPID2 can't be programmed once this SET 0 = DISABLE 1 = ENABLE
1	0x0	LOCK_APER_EN1: Enable lock feature for selected apertures 1 Can be set only once register field, hardware reset OR controller reset ONLY can disable this feature. LOCK_APER_START1, LOCK_APER_END1, LOCK_APER_CHIPID1 can't be programmed once this SET 0 = DISABLE 1 = ENABLE

Bit	Reset	Description
0	0x0	LOCK_APER_EN0: Enable lock feature for selected apertures 0 Can be set only once register field, hardware reset OR controller reset ONLY can disable this feature. LOCK_APER_START0, LOCK_APER_END0, LOCK_APER_CHIPID0 can't be programmed once this SET 0 = DISABLE 1 = ENABLE

29.4.27 NAND_LOCK_STATUS_0

Status indicating which aperture matched.

Offset: 068h | Read/Write: R/W | Reset: 0b000000000

Bit	R/W	Reset	Description
8	RW	0x0	IS_LOCK_ERR: 1 = Memory protection error detected check LOCK_STATUS register to identify which aperture matched.
7	RO	0x0	LOCK_APER_STATUS7: Respective bit is set by hardware on protection range detection. Write 1 to clear IS.LOCK_ERR will clear this status information
6	RO	0x0	LOCK_APER_STATUS6: Respective bit is set by hardware on protection range detection. Write 1 to clear IS.LOCK_ERR will clear this status information
5	RO	0x0	LOCK_APER_STATUS5: Respective bit is set by hardware on protection range detection. Write 1 to clear IS.LOCK_ERR will clear this status information
4	RO	0x0	LOCK_APER_STATUS4: Respective bit is set by hardware on protection range detection. Write 1 to clear IS.LOCK_ERR will clear this status information
3	RO	0x0	LOCK_APER_STATUS3: Respective bit is set by hardware on protection range detection. Write 1 to clear IS.LOCK_ERR will clear this status information
2	RO	0x0	LOCK_APER_STATUS2: Respective bit is set by hardware on protection range detection. Write 1 to clear IS.LOCK_ERR will clear this status information
1	RO	0x0	LOCK_APER_STATUS1: Respective bit is set by hardware on protection range detection. Write 1 to clear IS.LOCK_ERR will clear this status information
0	RO	0x0	LOCK_APER_STATUS0: Respective bit is set by hardware on protection range detection. Write 1 to clear IS.LOCK_ERR will clear this status information

29.4.28 NAND_LOCK_APER_START0_0

Program this in the format of "Row Address" NAND flash memory for protection.

NAND Memory Lock Aperture0 Start Address Register

Offset: 06ch | Read/Write: R/W | Reset: 0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx

Bit	Reset	Description
31:0	X	ADDR

29.4.29 NAND_LOCK_APER_START1_0

Program this in the format of "Row Address" NAND flash memory for protection.

NAND Memory Lock Aperture1 Start Address Register

Offset: 070h | Read/Write: R/W | Reset: 0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx

Bit	Reset	Description
31:0	X	ADDR

29.4.30 NAND_LOCK_APER_START2_0

Program this in the format of "Row Address" NAND flash memory for protection.

NAND Memory Lock Aperture2 Start Address Register

Offset: 074h | Read/Write: R/W | Reset: 0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx

Bit	Reset	Description
31:0	X	ADDR

29.4.31 NAND_LOCK_APER_START3_0

Program this in the format of "Row Address" NAND flash memory for protection.

NAND Memory Lock Aperture3 Start Address Register

Offset: 078h | Read/Write: R/W | Reset: 0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx

Bit	Reset	Description
31:0	X	ADDR

29.4.32 NAND_LOCK_APER_START4_0

Program this in the format of "Row Address" NAND flash memory for protection.

NAND Memory Lock Aperture4 Start Address Register

Offset: 07ch | Read/Write: R/W | Reset: 0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx

Bit	Reset	Description
31:0	X	ADDR

29.4.33 NAND_LOCK_APER_START5_0

Program this in the format of "Row Address" NAND flash memory for protection.

NAND Memory Lock Aperture5 Start Address Register

Offset: 080h | Read/Write: R/W | Reset: 0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx

Bit	Reset	Description
31:0	X	ADDR

29.4.34 NAND_LOCK_APER_START6_0

Program this in the format of "Row Address" NAND flash memory for protection.

NAND Memory Lock Aperture6 Start Address Register

Offset: 084h | Read/Write: R/W | Reset: 0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx

Bit	Reset	Description
31:0	X	ADDR

29.4.35 NAND_LOCK_APER_START7_0

Program this in the format of "Row Address" NAND flash memory for protection.

NAND Memory Lock Aperture7 Start Address Register

Offset: 088h | Read/Write: R/W | Reset: 0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx

Bit	Reset	Description
31:0	X	ADDR

29.4.36 NAND_LOCK_APER_END0_0

Program this in the format of "Row Address" NAND flash memory for protection.

NAND Memory Lock Aperture0-7 End Address Register

Offset: 08ch | Read/Write: R/W | Reset: 0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx

Bit	Reset	Description
31:0	X	ADDR

29.4.37 NAND_LOCK_APER_END1_0

Program this in the format of "Row Address" NAND flash memory for protection.

NAND Memory Lock Aperture0-7 End Address Register

Offset: 090h | Read/Write: R/W | Reset: 0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx

Bit	Reset	Description
31:0	X	ADDR

29.4.38 NAND_LOCK_APER_END2_0

Program this in the format of "Row Address" NAND flash memory for protection.

NAND Memory Lock Aperture0-7 End Address Register

Offset: 094h | Read/Write: R/W | Reset: 0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx

Bit	Reset	Description
31:0	X	ADDR

29.4.39 NAND_LOCK_APER_END3_0

Program this in the format of "Row Address" NAND flash memory for protection.

NAND Memory Lock Aperture0-7 End Address Register

Offset: 098h | Read/Write: R/W | Reset: 0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx

Bit	Reset	Description
31:0	X	ADDR

29.4.40 NAND_LOCK_APER_END4_0

Program this in the format of "Row Address" NAND flash memory for protection.

NAND Memory Lock Aperture0-7 End Address Register

Offset: 09ch | Read/Write: R/W | Reset: 0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx

Bit	Reset	Description
31:0	X	ADDR

29.4.41 NAND_LOCK_APER_END5_0

Program this in the format of "Row Address" NAND flash memory for protection.

NAND Memory Lock Aperture0-7 End Address Register

Offset: 0a0h | Read/Write: R/W | Reset: 0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx

Bit	Reset	Description
31:0	X	ADDR

29.4.42 NAND_LOCK_APER_END6_0

Program this in the format of "Row Address" NAND flash memory for protection.

NAND Memory Lock Aperture0-7 End Address Register

Offset: 0a4h | Read/Write: R/W | Reset: 0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx

Bit	Reset	Description
31:0	X	ADDR

29.4.43 NAND_LOCK_APER_END7_0

Program this in the format of "Row Address" NAND flash memory for protection.

NAND Memory Lock Aperture0-7 End Address Register

Offset: 0a8h | Read/Write: R/W | Reset: 0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx

Bit	Reset	Description
31:0	X	ADDR

29.4.44 NAND_LOCK_APER_CHIPID0_0

NAND Memory Lock Aperture0-7 Chip Select Register

Offset: 0ach | Read/Write: R/W | Reset: 0bxxxxxxxx

Bit	Reset	Description
7	X	CS7: Memory Protection of aperture[0-7] valid for Chip select7 0 = DISABLE : Memory Protection of aperture[0-7] not valid for Chip select7 1 = ENABLE
6	X	CS6: Memory Protection of aperture[0-7] valid for Chip select6 0 = DISABLE : Memory Protection of aperture[0-7] not valid for Chip select6 1 = ENABLE

Bit	Reset	Description
10:8	0x0	BCH_TAG_TVALUE: BCH error correction strength selection for Tag 24 single bit random errors per codeword 0 = BCH_TVAL4 : 4 single bit random errors per codeword 1 = BCH_TVAL8 : 8 single bit random errors per codeword 2 = BCH_TVAL14 : 14 single bit random errors per codeword 3 = BCH_TVAL16 : 16 single bit random errors per codeword 4 = BCH_TVAL24
6:4	0x0	BCH_TVALUE: BCH error correction strength selection 24 single bit random errors per codeword 0 = BCH_TVAL4 : 4 single bit random errors per codeword 1 = BCH_TVAL8 : 8 single bit random errors per codeword 2 = BCH_TVAL14 : 14 single bit random errors per codeword 3 = BCH_TVAL16 : 16 single bit random errors per codeword 4 = BCH_TVAL24
0	0x0	BCH_ECC: BCH encoder & decoder is enabled 0 = DISABLE : BCH encoder & decoder is not enabled 1 = ENABLE

29.4.53 NAND_BCH_DEC_RESULT_0

NAND BCH/RS/Hamming extended decode status information

- CORRFAIL_ERR flag is added to NAND_ISR register to indicate that out of total DMA transfers of specified pages there are correctable OR un-correctable errors. Please check the description field below. If there are no correctable/un-correctable errors this bit will not be SET.
- New register NAND_DEC_RESULT indicates the count of pages resulted in correctable/un-correctable errors.
- New register NAND_DEC_STAT_BUF. Reading this register will fetch out an entry from decode status buffer. Each entry of this buffer relate to page which resulted in either correctable/un-correctable error. Please check the description of this entry described as NAND_DEC_STAT_EXT below. It is up to software how this can be used; hopefully this serves for all purposes.

Example

If there are 4 pages resulted in correctable errors and 2 pages of uncorrectable errors out of total DMA transfer of 64 pages, PAGE_COUNT in NAND_DEC_RESULT will indicate as PAGE_COUNT=6. Software should read these 6 entries reading NAND_DEC_STAT_BUF register by CPU access and process it for further action.

Offset: 0d0h | Read/Write: RO | Reset: 0bxxxxxxxxx

Bit	Reset	Description
8	X	CORRFAIL_ERR: 1 = Correctable OR Un-correctable errors occurred in the DMA transfer without regard to HW_ERR_CORRECTION feature is enabled or not. Use extended decode results in NAND_DEC_RESULT and NAND_DEC_STATUS_EXT to figure out further action for block replacement/wear leveling during file system management for software.
7:0	X	PAGE_COUNT: No. of pages resulted either in un-correctable or correctable errors

29.4.54 NAND_BCH_DEC_STATUS_BUF_0

For page sizes upto 4k one entry per page exists in the Decode status buffer

For page size 8k, two entries exists in Decode status buffer.

Upon DMA complete software can read this buffer mapped to this register address to gather error statistics.

ECC Decode status Register

Offset: 0d4h | Read/Write: RO | Reset: 0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx

Bit	Reset	Description
31:24	X	FAIL_SEC_FLAG: Sector wise un-correctable error indicator Bit 31 = 1, sector 7 has un-correctable errors Bit 31 = 0, sector 7 has no un-correctable errors ... Bit 24 = 1, sector 0 has un-correctable errors Bit 24 = 0, sector 0 has no un-correctable errors
23:16	X	CORR_SEC_FLAG: Sector wise correctable error indicator Bit 23 = 1, sector 7 has correctable errors Bit 23 = 0, sector 7 has no correctable errors ... Bit 16 = 1, sector 0 has correctable errors Bit 16 = 0, sector 0 has no correctable errors
14	X	FAIL_TAG: Spare area error decode resulted in un-correctable errors in case of RS/Hamming ECC selection. For BCH this field is not applicable.
13	X	CORR_TAG: Spare area error decode resulted in correctable errors in case of RS/Hamming ECC selection. For BCH this field is not applicable.
12:8	X	MAX_CORR_CNT: Maximum no. of correctable errors occurred out of all sectors. For example of 2K page, if sector 0 has 2 correctable errors and sector3 has 4 errors MAX_ERR_CNT will reflect as 4
7:0	X	PAGE_NUMBER: Page number which resulted in either correctable/un-correctable errors 0 to 63 indication for 64 pages of DMA transfer.

29.4.55 NAND_CONFIG2_0

Field interpretation of 2nd word in 8k page

New Control register for features added in Tegra 3

Offset: 0d8h l Read/Write: R/W l Reset: 0b00xxxxxxxxxxxx0000000000000x000

Bit	Reset	Description
31	0x0	ABORT: 0 = HW clears when abort is completed and controller has gone back to idle and ready for next transfer. 1 = Written by software, set triggers abort.
30	0x0	FORCE_ABORT: intended to be used only in specific cases. Typically software would like this set to 0.
16	0x0	CODEWORD_SEL: Codeword selection for ECC computation as well as minimum unit for partial page read. No of sectors read during partial page read is determined by this selection. 14 bit polynomial, minimum ECC unit is 1k bytes 0 = BCH_512 : 13 bit polynomial, minimum ECC unit is 512 bytes This is default selection i.e. backward compatible to Tegra 2. 1 = BCH_1024
15:12	0x0	SECTOR_START: Reserved
11:8	0x0	SECTOR_CNT: Reserved
7	0x0	TIMING_SEL: Implement timing as per proposed new timing registers. 0 = DISABLE : Implement timings as per NAND_TIMING, NAND_TIMING2 registers 1 = ENABLE

Bit	Reset	Description
6	0x0	CLK_OFF: power saving enable by turning off clock in DDR interface Clock will be turned during unused time of Write operation Feature applicable for SYNC_DDR mode of Interface selection 0 = DISABLE : Clock will be continuous during the entire period of write operation 1 = ENABLE
5	0x0	SYNC_DDR: DDR mode of operation, as defined by ONFI standard DQS toggles but there is clock in interface. During Command/Address phase SDR mode of transfer is done. I.e One Address/Command byte per clock During Data transfer phase data is transferred on every edge of clock/DQS 0 = DISABLE : 1 = ENABLE
4	0x0	TOGGLE_DDR: Synchronous DDR mode of operation, as defined by Samsung. During Command/Address phase ASYNC mode of transfer is done. During Data transfer phase data is transferred on every edge of DQS 0 = DISABLE : 1 = ENABLE
2	0x0	PARTIAL_PAGE: Reserved 0 = DISABLE 1 = ENABLE
1	0x0	SGDMA_EN: Scatter Gather DMA feature is enabled. NAND_DATA_BLOCK_PTR, NAND_TAG_PTR indicates buffer address of respective descriptor buffers. Descriptor buffer consists of, Addr0(Byte aligned, 32-bit memory address | Length0(Byte granularity) | Addr1(Byte aligned, 32-bit memory address | Length1(Byte granularity) |.... | A single descriptor buffer fetch should result in completing the total DMA length as programmed in DMA_CNFGA DMA_CNFGB registers. 0 = DISABLE : Scatter Gather DMA feature is turned off. NAND_DATA_BLOCK_PTR, NAND_TAG_PTR indicates source/destination buffer address which are word aligned 1 = ENABLE
0	0x0	PROG_OFFSET_EN: Enable software control for Tegra 3. Features position bytes in spare region (1) Offset locations programmed in MAIN_ECC_OFFSET, TAG_OFFSET, TAG_ECC_OFFSET will be used to position the bytes in spare region for read/write/ (2) Tag ECC is done separately. Tag bytes, and parity bytes will be positioned in spare as programmed in OFFSET registers Without BCH_ECC, tag only transfers are also possible. ECC strength of Tag is determined by the BCH_TAG_TVALUE setting Tag transfer size is determined by the TAG_BYTE_SIZE and B_valid bit fields in NAND_CONFIG, NAND_COMMAND registers respectively. Main only transfers are possible clearing B_VALID bit field just like in Tegra 2 devices. 0 = DISABLE : hardware controller behavior as in Tegra 2 devices. (1) I.e. Based on the skip spare selection following order is followed. Skip bytes -> Tag Bytes -> ECC bytes of Main and Tag together (2) Tag ECC computation is done along with Main last unit of data 1 = ENABLE

29.4.56 NAND_MAIN_ECC_OFFSET_0

Programmable offset for Main data ecc bytes in spare. Offset location is w.r.t start of column address of spare region.

Example: from 4th byte location in spare required settings of START_ADDR = 0x4

Offset: 0dch l Read/Write: R/W l Reset: 0b000000000000

Bit	Reset	Description
11:0	0x0	START_ADDR: Total size of ECC bytes granularity is in terms byte for 8-bit device and 2-byte for 16 bit device. Since this is dictated by flash access width

29.4.57 NAND_TAG_OFFSET_0

Programmable offset for Tag bytes in spare. Offset location is w.r.t start of column address of spare region.

Offset: 0e0h l Read/Write: R/W l Reset: 0b000000000000

Bit	Reset	Description
11:0	0x0	START_ADDR: Total size of Tag bytes granularity is in terms byte for 8-bit device and 2-byte for 16 bit device. Since this is dictated by flash access width |

29.4.58 NAND_TAG_ECC_OFFSET_0

Programmable offset for Tag ecc bytes in spare. Offset location is w.r.t start of column address of spare region.

Offset: 0e4h l Read/Write: R/W l Reset: 0b000000000000

Bit	Reset	Description
11:0	0x0	START_ADDR: Total size of Tag ecc bytes granularity is in terms byte for 8-bit device and 2-byte for 16 bit device. Since this is dictated by flash access width

29.4.59 NAND_RESP2_0

Staging register meant for PIO mode of transfer. Contents should be written by CPU access to this register for write transfer. Contents are readable by CPU access to this register after read transfer.

NAND Response2 Register

Offset: 0e8h l Read/Write: R/W l Reset: 0b00000000000000000000000000000000

Bit	Reset	Description
31:24	0x0	BYTE3: Write/Response data byte 3 (MSB)
23:16	0x0	BYTE2: Write/Response data byte 2
15:8	0x0	BYTE1: Write/Response data byte 1
7:0	0x0	BYTE0: Write/Response data byte 0 (LSB)

29.4.60 NAND_RANDOM_RD_0

Defining register for Random Data input/output command sequences required to seek to respective column address location for sector wise read/write operation.

Register for Random Data Output command values

Offset: 0ech l Read/Write: R/W l Reset: 0b0000010111100000

Bit	Reset	Description
15:8	0x5	CMD1_CODE
7:0	0xe0	CMD2_CODE

29.4.61 NAND_RANDOM_WR_0

Register for Random Data Input command value

Offset: 0f0h l Read/Write: R/W l Reset: 0b10000101

Bit	Reset	Description
7:0	0x85	CMD1_CODE

29.4.62 NAND_ASYNC_TIMING_0_0

Required for Asynchronous or all DDR modes.

ASYNC Timing register0

Offset: 0f4h l Read/Write: R/W l Reset: 0b00000000000000000000000000000000

Bit	Reset	Description
27:24	0x0	TAR: Address cycle ALE low to data output time Covered by tRR timing during Data read operation Generated timing during Read ID, Max(tAR, tWHR) = (TAR_CNT+1) * NAND_CLK_PERIOD ns This timing parameter is not relavant for ONFI DDR mode, where in recommended programming value, TAR_CNT=0.
23:20	0x0	TCR: RSVD: Command cycle CE/CLE low to data output time Recommended programming value, TAR_CNT=0. Below equations indicate implemented timings for tCR/tCLR timings, which are not dependent on TCR value programmed. If tRR, tWHR, tWHR2 timings are met tCR/tCLR timings will be met Automatically. Generated timing, tCR = (TRR_CNT + 4) * NAND_CLK_PERIOD ns Generated timing during status read, tCLR = (TWHR_CNT + TRR_CNT +3) * NAND_CLK_PERIOD ns Generated timing during random read, tCLR = (TWHR2_CNT + 4) * NAND_CLK_PERIOD ns
19:16	0x0	TRR: Flash Ready to data output time Program this to meet timing requirement much as Max(tAR,tRR) from datasheet. Generated timing for all modes, tRR = (TRR_CNT + 4) * NAND_CLK_PERIOD ns
15:8	0x0	TWHR: WE High to data output time Generated timing for async and Toggle DDR modes, tWHR = (TWH_CNT + TCLH_CNT + TWHR_CNT + TRR_CNT + 5) * NAND_CLK_PERIOD ns. Generated timing for ONFI DDR modes, tWHR = (TCAD_CNT + TWHR_CNT + 4) * NAND_CLK_PERIOD ns.
7:0	0x0	TWB: WE High to RBSY low time Generated timing for all async and toggle DDR modes, tWB = (TWH_CNT + TCLH_CNT + TWB_CNT - 6) * NAND_CLK_PERIOD ns. Generated timing for ONFI DDR, tWB = (TCAD_CNT + TWB_CNT - 6) * NAND_CLK_PERIOD ns.

29.4.63 NAND_ASYNC_TIMING_1_0

Required for Asynchronous or all DDR modes.

ASYNC Timing register1

Offset: 0f8h l Read/Write: R/W l Reset: 0b00000000000000000000000000000000

Bit	Reset	Description
31:24	0x0	TRHW: Data output to command, address, or data input time ONFI device specific. Generated timing for all async and toggle DDR modes, tRHW = (TRHW_CNT + TREH_CNT + TCLS_CNT + 4) * NAND_CLK_PERIOD ns. For ONFI DDR modes, tRHW = (TRHW_CNT + 1) * NAND_CLK_PERIOD ns.

Bit	Reset	Description
23:16	0x0	TWHR2: WE High to data output time for Random data out Relevant for Samsung new devices only, Generated timing, tWHR2 = (TCLH_CNT + TWH_CNT + TWHR2_CNT + 6) * NAND_CLK_PERIOD ns For ONFI DDR, recommended programming value TWHR2_CNT = 0.
15:8	0x0	TCS: Chip select setup time Generated timing for all ASYNC and toggle DDR, tCS = (TCS_CNT + TCLS_CNT + TWP_CNT + 4) * NAND_CLK_PERIOD ns Generated timing for ONFI DDR, tCS = (TCS_CNT + 1) * NAND_CLK_PERIOD ns If Flash is not ready busy and controller waiting for RBSY_CHK condition, that time will add up.
7:0	0x0	TADL: Address to data loading time Generated timing for ASYNC and toggle DDR, tADL = (TWH_CNT + TALH_CNT + TADL_CNT + 4) * NAND_CLK_PERIOD ns Generated timing for ONFI DDR, tADL = (TCAD_CNT + TADL_CNT + 4) * NAND_CLK_PERIOD ns

29.4.64 NAND_ASYNC_TIMING_2_0

Required for Asynchronous or all DDR modes.

ASYNC Timing register2

Offset: 0fch l Read/Write: R/W l Reset: 0b000000000000xxxx0000000000000000

Bit	Reset	Description
31:24	0x0	TCWAW: Command Write cycle to Address cycle time for Random data input Relevant for Samsung new devices only, Generated timing for async and toggle DDR modes, tCWAW = (TCWAW_CNT + TWH_CNT + TALS_CNT + TWP_CNT + 5) * NAND_CLK_PERIOD ns For ONFI DDR, recommended programming value TCWAW_CNT = 0.
23:20	0x0	TCH: RSVD Hardware implementation guarantees timing requirement. Generated timing for all ASYNC and toggle DDR, tCH = (TCLH_CNT + TWH_CNT + 3) * NAND_CLK_PERIOD ns Fixed generated timing for ONFI DDR, tCH = NAND_CLK_PERIOD/2 ns.
15:12	0x0	TCLH: CLE/CH hold time Generated timing for all ASYNC and toggle DDR, tCLH = (TCLH_CNT + TWH_CNT + 3) * NAND_CLK_PERIOD ns Fixed generated timing for ONFI DDR, tCLH = NAND_CLK_PERIOD/2 ns. Hence required programming value TCLH_CNT = 0
11:8	0x0	TCLS: CLE setup time Generated timing for all ASYNC and toggle DDR, tCLS = (TCLS_CNT + TWP_CNT + 2) * NAND_CLK_PERIOD ns Fixed generated timing for ONFI DDR, tCLS = NAND_CLK_PERIOD/2 ns. Hence required programming value TCLS_CNT = 0
7:4	0x0	TALH: ALE hold time Generated timing for all ASYNC modes, tALH = (TALH + TWH_CNT + 3) * NAND_CLK_PERIOD ns Generated timing for toggle DDR, tALH = (TCDQSS + TWH_CNT + 3) * NAND_CLK_PERIOD ns Fixed generated timing for ONFI DDR, tALH = NAND_CLK_PERIOD/2 ns. Hence required programming value TALH_CNT = 0
3:0	0x0	TALS: ALE setup time Generated timing for all ASYNC modes, tALS = (TALS_CNT + TWP_CNT + 2) * NAND_CLK_PERIOD ns Fixed generated timing for ONFI DDR, tALS = NAND_CLK_PERIOD/2 ns. Hence required programming value TALS_CNT = 0

29.4.65 NAND_ASYNC_TIMING_3_0

Required for Asynchronous or Toggle DDR modes.

ASYNC Timing register3

Offset: 100h l Read/Write: R/W l Reset: 0b00000000000000000000

Bit	Reset	Description
19:16	0x0	TREA: RE access time. RE low to valid dataout from device For Status read cycles, instead of TRP timing, TREA timing will be used. Generated timing for non-EDO mode, Max(tRP, tREA) = (TREA_CNT +1) * NAND_CLK_PERIOD ns Generated timing for EDO mode, tREA = (TREA_CNT +1) * NAND_CLK_PERIOD ns
15:12	0x0	TWH: Write cycle Hold time Generated timing, tWH = (TWH_CNT +1) * NAND_CLK_PERIOD ns.
11:8	0x0	TWP: Write cycle Pulse(low) time Generated timing, tWP = (TWP_CNT +1) * NAND_CLK_PERIOD ns.
7:4	0x0	TREH: Read cycle Hold time Generated timing, tREH = (TREH_CNT +1) * NAND_CLK_PERIOD ns. Fixed generated timing in toggle DDR mode, tREH = (NAND_CLK_PERIOD/2)ns
3:0	0x0	TRP: Read cycle Pulse(low) time Generated timing for non-EDO mode, Max(tRP, tREA) = (TRP_CNT +1) * NAND_CLK_PERIOD ns Generated timing for EDO mode, tRP = (TRP_CNT +1) * NAND_CLK_PERIOD ns. Fixed generated timing in toggle DDR mode, tRP = (NAND_CLK_PERIOD/2)ns

29.4.66 NAND_TDDR_TIMING_0_0

Required for Toggle DDR mode. Note that all ASYNC timing registers (ASYNC_TIMING_0-3) to be programmed along with DDR specific timing registers.

Toggle DDR Timing register0

Offset: 104h l Read/Write: R/W l Reset: 0b000000000000

Bit	Reset	Description
11:8	0x0	TRPSTH: Data Read Postamble Hold time Generated timing, tRPSTH = (TRPSTH_CNT +1) * NAND_CLK_PERIOD ns.
7:4	0x0	TRPST: Data Read Postamble time Generated timing, tRPST = (TRPST_CNT +2) * NAND_CLK_PERIOD ns. Right now round trip delay extends this a bit more.
3:0	0x0	TRPRE: Data Read Preamble time Generated timing, tRPRE = (TRPRE_CNT +1) * NAND_CLK_PERIOD ns.

29.4.67 NAND_TDDR_TIMING_1_0

Required for Toggle DDR mode. Note that all ASYNC timing registers (ASYNC_TIMING_0-3) to be programmed along with DDR specific timing registers.

Toggle DDR Timing register1

Offset: 108h l Read/Write: R/W l Reset: 0b0000000000000000xxxx000000000000

Bit	Reset	Description
31:24	0x0	TCDQSH: DQS hold time for data input finish Generated timing tCDQSH = (TWH_CNT + TCLH_CNT + TCDQSH_CNT +5) * NAND_CLK_PERIOD ns.
23:16	0x0	TCDQSS: DQS setup time for data input start Generated timing tCDQSS = TCDQSS_CNT * NAND_CLK_PERIOD ns.
11:8	0x0	TWPSTH: Data write Postamble Hold time Generated timing, tWPSTH = (TWPSTH_CNT + 1) * NAND_CLK_PERIOD ns.
7:4	0x0	TWPST: Data write Postamble time Generated timing, tWPST = (TWPST_CNT+ 4) * NAND_CLK_PERIOD ns.
3:0	0x0	TWPRE: Data Write Preamble time Generated timing tWPRE = (TCDQSS_CNT + TADL_CNT + TWPRE_CNT + 2) * NAND_CLK_PERIOD ns.

29.4.68 NAND_SDDR_TIMING_0_0

Required for SYNC_DDR mode. Note that ASYNC_TIMING0, ASYNC_TIMING1, ASYNC_TIMING2 registers to be programmed for sync DDR interface selection.

Synchronous DDR (standard DDR, ONFI DDR with clock) Timing register0

Offset: 10ch l Read/Write: R/W l Reset: 0b000000000000xxxx000000000000

Bit	Reset	Description
27:24	0x0	TCKWR: Data output end to W/R High time Generated timing, tCKWR = (TCKWR_CNT +1) * NAND_CLK_PERIOD ns.
23:16	0x0	TCAD: Command, Address, Data delay Command -> Command Address -> Address Command -> Address Address -> Command Command/Address -> start of data Generated timing tCAD = (TCAD_CNT+1) * NAND_CLK_PERIOD ns.
11:8	0x0	TWRCK: W/R low to data output cycle time Generated timing tWRCK = (TWRCK_CNT +1) * NAND_CLK_PERIOD ns.
7:4	0x0	TWPST: DQS write Postamble time Generated timing tWPST = 3 * NAND_CLK Required programmed values for all clock frequencies or devices TWPST_CNT = 0.
3:0	0x0	TWPRE: DQS Write Preamble time controls the timing parameters, tWRPRE, tDQSS Generated timing tDQSS = 1 * NAND_CLK. Generated timing tWRPRE = 3 * NAND_CLK. Required programmed values for all clock frequencies or devices TWPRE_CNT = 0.

29.4.69 NAND_SDDR_TIMING_1_0

Required for SYNC_DDR mode. Note that ASYNC_TIMING0, ASYNC_TIMING1, ASYNC_TIMING2 registers to be programmed for sync DDR interface selection.

Synchronous DDR (standard DDR, ONFI DDR with clock) Timing register1

Offset: 110h l Read/Write: R/W l Reset: 0b00000000

Bit	Reset	Description
7:0	0x0	TCCS: Change column setup time Address cycle to data cycle for Random data commands Generated timing tCCS = (TCCS_CNT + TCAD_CNT + 4) * NAND_CLK_PERIOD ns.

29.4.70 NAND_FBIO_DQSIB_DLY_0

The FBIO_DQSIB_DELAY register sets the trimmers for inbound dqs delay on each of the inbound byte lanes.

FBIO configuration register

Offset: 114h l Read/Write: R/W l Reset: 0b00000000

Bit	Reset	Description
7:0	0x0	CFG_DQSIB_DLY_BYTE_0: 47 = MAX

29.4.71 NAND_FBIO_QUSE_DLY_0

QUSE_LATE and QUSE_DLY determine how much added delay fbio should add to the QUSE path. QUSE needs to align (approximately) with the incoming DQS (DDR1) in order to qualify it, since the incoming DQS/feedback clock is not always valid.

DRAMC can position QUSE with m2clk granularity (2 bit times). For DDR1 only, QUSE_LATE provides finer granularity of 1/2 an m4clk cycle (1/2 bit time). The amount of delay we add will be primarily a function of the round trip wire delay to/from the DRAM. Other portions of the delay (driver and receiver delay) are compensated for by delay through a non-bonded QUSE pad cell.

QUSE_DLY controls trimmers in each byte lane. This also allows for variation in the propagation delay from the "common" pad macro where the QUSE logic lives out to each of the 4 byte lanes.

QUSE delay register

Offset: 118h l Read/Write: R/W l Reset: 0b00110100

Bit	Reset	Description
7:0	0x34	CFG_QUSE_DLY_BYTE_0: 47 = MAX

29.4.72 NAND_FBIO_CFG_0

FBIO configuration register

Offset: 11ch l Read/Write: R/W l Reset: 0b01000000

Bit	Reset	Description
7:6	0x1	CFG_RETIME_STAGES
5	0x0	CFG_DEN_EARLY: 0 = DISABLE 1 = ENABLE
4	0x0	CFG_BYPASS_DQS_DLY: 0 = DISABLE 1 = ENABLE
3:0	0x0	CFG_QUSE_LATE

29.4.73 NAND_FBIO_SPARE_0

The FBIO_SPARE register provides extra bits for future needs. They are connected to FBIO at the "common" pad macro, which is near the center of each fbio partition.

FBIO spare register

Offset: 120h l Read/Write: R/W l Reset: 0b00000000000000000000000000000000

Bit	Reset	Description
31:0	0x0	CFG_FBIO_SPARE

29.4.74 NAND_FC_KNOBS_0

Feature Control register for feature control and perf options enable=1; disable=0 for all features //

Offset: 124h l Read/Write: R/W l Reset: 0b000000000

Bit	Reset	Description
8	0x0	ENABLE_IO_FORCE_FLUSH: Enabling this forces IO state to IDLE immediately in the abort io sequence, Recommended leave default 0 unless used only in conjunction with force abort. 0 = DISABLE 1 = ENABLE
7	0x0	DMA_CLK_GATE_OVERRIDE: Disable 2nd level clock gating for DMA engine. Recommended leave default 0. 0 = DISABLE 1 = ENABLE
6	0x0	ECC_CLK_GATE_OVERRIDE: Disable 2nd level clock gating for ECC engine. Recommended leave default 0. 0 = DISABLE 1 = ENABLE
5	0x0	USE_DOUBLE_BUFFERS_FOR_512B_SECTORS: enabling this turns ON the optimization to use double buffers to fully use all the buffer space when sector size is 512. By default, buffers are 1k sized, so each buffer is used for two 512 sectors. Not supported in Tegra 3. Recommended: leave default 0. 0 = DISABLE 1 = ENABLE

Bit	Reset	Description
4	0x0	DISABLE_CONSECUTIVE_REQS: Enabling this disables data requests on consecutive cycles. Recommended setting is 0. 0 = DISABLE 1 = ENABLE
3	0x0	GATE_ABORT_TO_GIZMO: due some possible AHB issue, we may want to gate the abort to the gizmo fifos. Recommended setting 1. 0 = DISABLE 1 = ENABLE
2	0x0	DISABLE_CONTEXT_SWITCH: enabling this turns off the addr/length saves during a main/tag context switch. If this is disabled then main/tag descriptors need to align to page boundaries. i.e. descriptor may not span pages. However, for main_only or tag_only transfers this bit has no effect. Recommended setting is 0. 0 = DISABLE 1 = ENABLE
1	0x0	WORD_ALIGNED_XFER: enabling this makes the DMA bypass the byte reform logic that is needed for byte aligned transfers. Diagnostic workaround for forcing word-aligned transfers. Recommended setting is 0. 0 = DISABLE 1 = ENABLE
0	0x0	PERF_WORD_ALIGNED_XFER: enable this bit when all data transfers (whether in SGDMA mode or not) are guaranteed to be word-aligned. This bit enables an optimization in the request/data queuing which is valid for word-aligned transfers. Recommended setting is 0. 0 = DISABLE 1 = ENABLE

30.0 GMI CONTROLLER

The Generic Memory Interface (GMI) is a controller that supports a number of memory types, including synchronous NOR, asynchronous NOR, and other flash memories with similar interfaces, such as MuxOneNAND.

The GMI Controller is also known as the Sync-NOR (SNOR) Controller, and enables:

- Data transfer between internal and external memory.
- Interface with Synchronous/Asynchronous Flash Memories.
- Ability to boot from MuxOneNAND.

The GMI/SNOR Controller is on the AHB bus, it provides a way to access external NOR-Flash through Master as well as Slave modes. The SNOR controller supports DMA transfer between Flash Memory and System Memory to save on processor cycles. In order to reduce the number of I/O pins, the NOR interface and NAND interface share pins.

SNOR controller can operate in 2 modes:

- Programmed IO (PIO) mode – In this case the CPU/COP operates as master and issues the read/write commands, and the SNOR controller operates as the slave. The SNOR controller handles the transfer of data between the flash memory and CPU registers or COP
- DMA mode – In this case the SNOR controller operates as the master; the SNOR controller handles the transfer of data between the flash memory and system memory or IRAM

30.1 Functional Description

The GMI/SNOR Controller supports the following operation:

- Synchronous and Asynchronous Flash Memories support
- MuxOneNAND support.
- AHB Master and Slave mode support.
- Booting Option.
- Address-Data Mux / Non-Mux Configuration.
- Fast Access Modes – Burst (Reads/Writes) and Page Mode (Reads).
- Programmable WAIT states for Asynchronous access.
- Programmable Data RDY Configuration (same cycle or next cycle).
- Support 16/32 bits wide Data Bus.
- Support for 8 chip selects: Any combination of 8-SNOR chip selects.

30.1.1 GMI Functional Waveforms

Table 82 GMI (SNOR) Signal Descriptions

Pin Function	Description	Type
Non-Muxed		
GMI_A[27:0]	Address bus: Up to 28 bits of address, depending on type/size of device	Out
GMI_D[31:28] GMI_AD[27:0]	Data bus: 32- or 16-bit data bus	Bidir
Muxed AD		
GMI_D[31:28] GMI_AD[27:0]	Multiplexed Address/Data bus: For 16-bit, muxed A/D memory, the lower 16 bits of address are muxed with the data bus. The upper address lines, GMI_AD[27:16], are non-multiplexed.	Bidir
GMI_A[27:16]	Upper Address bus	Out
General		
GMI_CLK	Clock: Used to synchronize the Tegra® 3 and GMI devices during Synchronous operations. Rising Edge active.	Out
GMI_ADV_N	Address Valid: Programmable polarity output. For synchronous read operations, the address is typically latched either on the inactive edge of ADV_N or on the first rising edge of CLK after ADV_N goes active (slower devices <= 108MHz) or on the last rising edge of CLK after ADV_N goes active (faster devices >= 108MHz) For Asynchronous reads, the address is latched on the inactive of ADV_N. For writes, ADV_N is held active and the address is valid throughout the cycle for non-muxed operation. In the non-muxed case the address will be valid for the duration of the entire access. Only in the muxed mode is it valid during the ADV_N (ADV_WIDTH) + MUXED_WIDTH (the minimum in this case is 1 + 1 = 2 cycles)	Out
GMI_CE[7:0]_N	Chip Enable: Programmable polarity output. When active, CEx_N selects the device and when inactive, de-selects the device which is typically put in low power mode.	Out
GMI_OE_N	Output Enable: Programmable polarity output. When active, OE_N enables the output drivers of the selected (CEx_N active) devices. When inactive, OE_N disables the output drivers of selected devices (CEx_N active) and places them in High-Z.	Out
GMI_WR_N	Write Enable: Programmable polarity output. When active, WR_N enables write operations for the enabled (CEx_N active) devices. The address and write data is latched by the enabled devices on the inactive (trailing) edge of WR_N.	Out
GMI_RST_N	Reset: Active low output. When low, RST_N resets the connected devices and inhibits writes. When high, RST_N enables normal operation.	Out
GMI_WAIT	Wait (or Ready): Level configurable input. When asserted, WAIT (RDY) indicates the read data is invalid (Wait) or Valid (Ready). WAIT (RDY) is driven by the devices when CEx_N and OE_N are low and High-Z when when CEx_N or OE_N are high.	In
GMI_WP_N	Write Protect: Active low output. When low, WP_N enables the device lock down mechanism, or inhibits write cycles.	Out
GMI_DPD	Deep Power Down: Active high output. When high, Device will enter Deep Power Down mode. When low, device will be in or return to normal operating mode.	Out

30.2 Programming Guidelines

During power-on reset the GMI/SNOR Controller has the Slave Interface active. This means any processor can send a request to the GMI Controller/Device. The default setting for the controller as well as external device is in 16-bit MUX mode. Depending on the internal fuses burned, the boot ROM can configure the GMI interface to match that of the external nonvolatile memory, either multiplexed or non-multiplexed. SNOR DMA can be programmed in Burst, Page and Asynchronous modes for NON-MUX devices whereas only Burst and Asynchronous modes are present in case of MUX devices. The GMI Controller supports Burst Writes/Reads, Asynchronous Writes/Reads and Page Reads (only for NON-MUX Devices).

SNOR Register Base address is 0x7000_9000.

SNOR Clock Source Register address is 0x6000_61D0.

The following should be considered while accessing the GMI:

- Using the Slave Interface Asynchronous Writes/Reads are permitted.
- To work in Master Mode, program the “MST_ENB” bit of the Configuration Register.
- Provide the DMA starting NOR Address (0xD000_0000) as well as AHB Address (iRAM 0x4000_0000 or DRAM 0x0000_0000) first, before enabling the “GO_NOR” and “DMA_GO” bits.
- Use the device configuration command cycles to enable the different features of the device including Burst Mode.
- Enable the “GO_NOR” bit followed by “DMA_GO” bit for DMA operation.
- DMA status can be seen by polling the DMA Status Busy Signal or using the transfer done interrupt.
- SNOR timing registers should be programmed per the device specifications.
- In Interrupt polling mode, DMA operation is completed when DMA_GO/GO_NOR are deasserted (disabled).

30.3 GMI Registers

30.3.1 SNOR_CONFIG_0

SNOR Configuration Register

Offset: 000h | Read/Write: R/W | Reset: 0b00010000010000xxx00xxx00000000000

Bit	Reset	Description
31	0x0	GO_NOR: When set a NOR operation commences. 0 = DISABLE 1 = ENABLE
30	0x0	WORDWIDE_GMI: NOR Device DataBus width Configuration Bit. 0 = NOR16BIT 1 = NOR32BIT
29	0x0	NOR_DEVICE_TYPE: External NOR Memory Type. 0 = SNOR 1 = MUXONENAND (simulation purpose)
28	0x1	MUXMODE_GMI: NOR Device Address-Data Configuration Bit. 0 = AD_NONMUX 1 = AD_MUX
27:26	0x0	BURST_LENGTH: Burst Length Types 00=Continuous Burst, 01=8 Words, 10=16 Words, 11=32 Words. 0 = CNTBRST 1 = BL8WORD 2 = BL16WORD 3 = BL32WORD
25	0x0	Reserved
24	0x0	RDY_ACTIVE: Device RDY Active Status 0=With Data, 1=One Cycle Before Data. 0 = WITHDATA 1 = BEFOREDATA
23	0x1	RDY_POLARITY: Ready signal polarity 0=Active low, 1=Active high. 0 = RESV 1 = HIGH
22	0x0	ADV_POLARITY: ADV pulse polarity 0=Active low, 1=Active high. 0 = LOW 1 = RESV
21	0x0	OE_WE_POLARITY: OE/WE polarity 0=Active low, 1=Active high. 0 = LOW 1 = RESV
20	0x0	CS_POLARITY: Chip Select polarity 0=Active low, 1=Active high. 0 = LOW 1 = RESV
19	0x0	NOR_DPD: Indicates the Power Down Mode enable bit. 0 = DISABLE 1 = ENABLE
15	0x0	NOR_WP: Sets the NOR Write protect enable bit. 0 = DISABLE 1 = ENABLE
14	0x0	NMUX_ASYNC_IO: Sets the non-mux async IO mode . 0 = DISABLE 1 = ENABLE

Bit	Reset	Description
10:8	0x0	PAGE_SIZE: Sets the number of words in a page if page mode is selected. 0 = BRST 1 = PG4WORD 2 = PG8WORD 3 = PG16WORD 4 = RESV4 5 = RESV5 6 = RESV6 7 = RESV7
7	0x0	MST_ENB: Selection bit between Master DMA and Slave Interface. 0 = DISABLE 1 = ENABLE
6:4	0x0	SNOR_SEL: SNOR 8 chip selects combinations. 0 = CS0 1 = CS1 2 = CS2 3 = CS3 4 = CS4 5 = CS5 6 = CS6 7 = CS7
3	0x0	CE_LAST: Indicates if the ADV gets asserted before CE. 0 = DISABLE 1 = RESV
2	0x0	CE_FIRST: Indicates if the CE gets asserted before ADV. 0 = DISABLE 1 = RESV
1:0	0x0	DEVICE_MODE: This field specifies the Mode of Operation for SYNC Memories. 0 = ASYNC 1 = PAGE 2 = BURST 3 = RESV

30.3.2 SNOR_STA_0

This status register has bits that provide the controller status, along with the external interrupts from the SNOR devices. The FIFO status is also provided along with the status on the count of the words transferred through DMA

SNOR Status Register

Offset: 004h | Read/Write: R/W | Reset: 0bx0x00000xxxxxxxxxxxxxxxxxxxxxxxx

Bit	R/W	Reset	Description
31	RO	X	DEVICE_BSY: Indicates that the device status.
30	RW	0x0	SLAVE_DONE: Indicates that the slave access is completed
28	RW	0x0	CONT_OVERFLOW: Overflow during continuous mode
27	RW	0x0	DEVICE_INTR_2: Device Interrupt-2 from MuxOneNand Memory.
26	RW	0x0	DEVICE_INTR_1: Device Interrupt-1 from MuxOneNand Memory.
25	RW	0x0	DEVICE_INTR_2_ENB: Device Interrupt-2 Enable Bit.

Bit	R/W	Reset	Description
24	RW	0x0	DEVICE_INTR_1_ENB: Device Interrupt-1 Enable Bit.
23	RO	X	SLV_FIFO_FULL: SLV FIFO full status.
22	RO	X	SLV_FIFO_EMPTY: SLV FIFO empty status.
21	RO	X	MST_FIFO_FULL: MST FIFO full status.
20	RO	X	MST_FIFO_EMPTY: MST FIFO empty status.
15:0	RO	X	DMA_DATA_CNT: Indicates the number of Data to be transferred; current dma_data_count.

30.3.3 SNOR_NOR_ADDR_PTR_0

Contains the starting address of the NOR access.

SNOR Address Register

Offset: 008h | Read/Write: R/W | Reset: 0b00000000000000000000000000000000

Bit	Reset	Description
31:0	0x0	SNOR_NOR_ADDR_PTR: Indicates that the NOR controller Address.

30.3.4 SNOR_AHB_ADDR_PTR_0

Contains the starting address of the AHB access.

SNOR AHB Address Register

Offset: 00ch | Read/Write: R/W | Reset: 0b00000000000000000000000000000000

Bit	Reset	Description
31:0	0x0	SNOR_AHB_ADDR_PTR: Indicates that the AHB side Address.

30.3.5 SNOR_TIMING0_0

This register contains the timing parameters used for the page access, along with the timing parameters for the widths of ADV pulse, CE hold, etc.

SNOR Timing0 Register

Offset: 010h | Read/Write: R/W | Reset: 0b0011xxxx0001xxxx0001000100010100

Bit	Reset	Description
31:28	0x3	PAGE_RDY_WIDTH: This represents the number of wait clock cycles from address to 1st data ready.
23:20	0x1	PAGE_SEQ_WIDTH: Page Sequential width indicates the delay cycle between the intra page Read access.
15:12	0x1	MUXED_WIDTH: Indicates in number of cycles MUX address/data asserted on the bus.

Bit	Reset	Description
11:8	0x1	HOLD_WIDTH: Indicates in number of cycles CE stays asserted after the de-assertion of WR_N (in case of SLAVE/MASTER Request) or OE_N (in case of MASTER Request).
7:4	0x1	ADV_WIDTH: Indicates the number of cycles during which ADV stays asserted.
3:0	0x4	CE_WIDTH: Indicates the number of cycles before CE is asserted.

30.3.6 SNOR_TIMING1_0

This register contains the timing parameters of the WE and OE widths along with the WAIT width.

SNOR Timing1 Register.

Offset: 014h | Read/Write: R/W | Reset: 0b000000x00000000100000001000000011

Bit	Reset	Description
31:26	0x0	SNOR_TAP_DELAY: Tap delay
24	0x0	SNOR_CE: Clock Override
23:16	0x1	WE_WIDTH: Write access time
15:8	0x1	OE_WIDTH: Read access time.
7:0	0x3	WAIT_WIDTH: Indicates in cycles the number of wait states before when READY is issued.

30.3.7 SNOR_MIO_CFG_0

This register contains the MIO configuration bits such as the width of the words, the polarity of the ready along with the three bits to select the 8 different chip selects for MIO.

MIO Configuration Register

Offset: 018h | Read/Write: R/W | Reset: 0b01xxxxx111

Bit	Reset	Description
29	0x0	MIO_WORDWIDE: Indicates the data bus size of MIO Memory. 0 = MIO16BIT 1 = MIO32BIT
28	0x1	MIO_RDY_POL: Specifies the polarity of MIO RDY. 0 = RESV 1 = HIGH
22:20	0x7	MIO_SEL: MIO 8 chip selects combinations. 0 = MIO0 1 = MIO1 2 = MIO2 3 = MIO3 4 = MIO4 5 = MIO5 6 = MIO6 7 = MIO7

30.3.8 SNOR_MIO_TIMING0_0

This register contains the timing parameters for the MIO accesses MIO Timing - 0 Register

Offset: 01ch | Read/Write: R/W | Reset: 0b000001xx000010xx000001xx000010

Bit	Reset	Description
29:24	0x1	MIO_A_DED_WR: Minimum number of MIO bus clock cycles between the end of a write access and the start of the following access (write or read) for MIO.
21:16	0x2	MIO_A_WR_TIME: Minimum number of MIO bus clock cycles during a write access that the MIO_RD signal is set low for MIO.
13:8	0x1	MIO_A_DED_RD: Minimum number of MIO bus clock cycles between the end of a read access and the start of the following access (write or read) for MIO.
5:0	0x2	MIO_A_RD_TIME: Minimum number of MIO bus clock cycles during a read access that the MIO_RD signal is set low for MIO.

30.3.9 SNOR_DMA_CFG_0

SNOR DMA Configuration Register

Offset: 020h | Read/Write: R/W | Reset: 0b00000100xxxxxxxx00000000000000

Bit	Reset	Description
31	0x0	DMA_GO: This represents the number of DMA is enabled. 0 = DISABLE 1 = ENABLE
30	0x0	BSY: Indicates the status of DMA.
29	0x0	DIR: This represents the direction of DMA data transfer. 0 = NOR2AHB 1 = AHB2NOR
28	0x0	IE_DMA_DONE: Interrupt Enable on DMA transfer completion. 0 = DISABLE 1 = ENABLE
27	0x0	IS_DMA_DONE: Interrupt Status (Write 1 to clear). 0 = DISABLE 1 = ENABLE
26:24	0x4	BURST_SIZE: DMA burst size. 0 = RESV0 1 = RESV1 2 = RESV2 3 = RESV3 4 = BS1WORD 5 = BS4WORD 6 = BS8WORD 7 = RESV7
23	0x0	CONTINUOUS: 0 = Once DMA transfer, 1 = continuous DMA transfer. 0 = DISABLE 1 = ENABLE
15:2	0x0	WORD_COUNT: Specifies the number of words that need to be transferred.

30.3.10 SNOR_CS_MUX_CFG_0

SNOR CHIP Select MUX Configuration Register

Offset: 024h | Read/Write: R/W | Reset: 0b111x110x101x100x011x010x001x000

Bit	Reset	Description
30:28	0x7	CS7_MUX: This represents which chip selects goes to which memory. Chip selection between SNOR and MIO Memories.
26:24	0x6	CS6_MUX: This represents which chip selects goes to which memory. Chip selection between SNOR and MIO Memories.
22:20	0x5	CS5_MUX: This represents which chip selects goes to which memory. Chip selection between SNOR and MIO Memories.
18:16	0x4	CS4_MUX: This represents which chip selects goes to which memory. Chip selection between SNOR and MIO Memories.
14:12	0x3	CS3_MUX: This represents which chip selects goes to which memory. Chip selection between SNOR and MIO Memories.
10:8	0x2	CS2_MUX: This represents which chip selects goes to which memory. Chip selection between SNOR and MIO Memories.
6:4	0x1	CS1_MUX: This represents which chip selects goes to which memory. Chip selection between SNOR and MIO Memories.
2:0	0x0	CS0_MUX: This represents which chip selects goes to which memory. Chip selection between SNOR and MIO Memories.

31.0 SATA CONTROLLER

31.1 Overview

The Serial Advance Technology Attachment (SATA) controller enables a control path from a Tegra® 3 device to an external SATA device. An SSD/HDD/ODD/e-SATA drive can be connected. This is a one port configuration.

31.2 Device ID

The device ID for the SATA controller in Tegra 3 devices is 0x0E1E. The AHCI driver needs to make sure class code is set to 0x0106 and program interface code set to 0x01 before it starts operating the controller in AHCI mode.

31.3 Power Gating Sequence

This section describes all the steps needed to achieve power gating.

31.3.1 Goals

The power gating POR is:

- Wake events from the drives are supported
- Wake events can only happen in non LP0 mode
- No wake support in LP0 state
- The entire partition including the FPCI wrapper is power gated
- If there can be no wake event, the pads can be put in IDDQ mode. This is decided on the type of drive connected
- The wakeup of the partition (SAX) that hosts the SATA controller and the IPFS shall be initiated by software

31.3.2 Power Gating Overview

Power gating and ungating can be initiated by software. Power gating should be done when the SATA link is in slumber mode, with no outstanding commands. The software should keep a backup of a set of registers in system memory as they lose value once the power is removed. This involves all the configuration space, extended configuration space registers and the MMIO space registers. Since the SW is expected to know the state of registers inside the controller, it need not read the registers every time a power gating sequence is performed.

If HW wake up is to be supported (for e.g., hot plug detection), the pads should be left in slumber. If HW wake up is not needed, then the pads should be placed in the IDDQ mode. This is the preferred mode of operation. The bits pad_iddq_override_en and pad_iddq_override_value could be used to control the state of the pads.

31.3.3 Hardware Initiated Wake up

For a hardware initiated wake up, the pads detect activity on the SATA link. Once the OOB sequence is detected, the bit oob_wake_detected unit is written. Note that the controller itself is not involved in this signal as it is power gated.

The signal from the pads that is of concern here is the rx_stat_idle. This signal must be monitored for any activity. This is an active low signal. There should be two bits that the SW would need to read for the interrupt.

1. To log the status and send an interrupt to SW (SW controlled PG) or signal to the PMC (HW controlled PG). There are three bits associated with this.
    a. A status bit SATA_L0_RX_STAT_IDLE in the register SATA_AUX_RX_STAT_INT_0. This bit shows the current status of rx_stat_idle. It is set to 1 whenever there is activity on the RX path, else it is set to 0.

b. A sticky interrupt status bit SATA_RX_STAT_INT_STATUS in the register SATA_AUX_RX_STAT_INT_0. This is set whenever rx_stat_idle is set to 1 and will stay 1 until the interrupt is cleared by SW.

c. There are bits to set/clear the bits above. Writing a 1 to SATA_RX_STAT_INT_SET bit in SATA_AUX_RX_STAT_SET_0 register will set the status. Writing a 1 to SATA_RX_STAT_INT_CLR will clear this status.

2. To have a mask to enable / disable interrupts. This is done via central interrupt controller with the interrupt SATA_RX_STAT in PRI_ICTLR_* registers. Follow the same guidelines as any other units to enable/disable the SATA_RX_STAT interrupt.

The SW clears the interrupt and the mask during normal operation.

31.3.4 Bits Required in Power Gating Sequences

The following bits are required in power gating sequences. Some of them are needed in both HW and SW sequencing methods. Some of them are required only in one of the modes of power gating. The bits could be named differently. The bits are –

- Oob_wake_en – this bit is to be placed in a non power gated region. Its role is to enable wake events from the drive. This is enabled by writing a 1 to SATA_RX_STAT in PRI_ICTLR_* registers
- Oob_wake_detected – this bit shall be written when “oob_wake_en” is asserted and a wake is detected on the SATA link. The “rx_stat_idle” toggling shall assert this bit. In SW mode of power gating, an interrupt needs to be sent to the SATA driver. This is the SATA_RX_STAT_INT_STATUS bit in register SATA_AUX_RX_STAT_INT_0.
- Pmc2sata_pg_info – this bit shall drive the signal pmc2sata_pg_info.

31.3.5 SW Initiated Power Gating / un-Gating Sequence

Steps involved in Power Gating

#	Description	Register Programming	Comments
1.	Driver decides to enter power gating, based on the fact that links are in slumber state and no commands are outstanding.		
2.	Driver programs a register in the PMC to indicate to SATA that it is entering power gating. This shall drive the pmc2sata_pg_info signal.	APBDEV_PMC_SATA_PWRGT_0.PG_INFO = 1	If driver detects a HW wake from the drive before setting PG_INFO bit, it should bail out and should not begin the PG sequence.
3.	Driver would read out the registers in the SATA controller and save it in system memory.	Register list is in appendix.	The time taken for this would depend on the time taken for the SW to read a register. Ideally this should be done only once.
4.	Driver needs to read and set the rx_idle_t registers in apbmisc so idle threshold can be continuously driven while SAX is power-gated	Read SATA_AUX_MISC_CNTL_1_0 register L0_RX_IDLE_T_SAX field and write that value into same register L0_RX_IDLE_T_NPG field. And write ‘1’ to L0_RX_IDLE_T_MUX field.	
5.	Driver should read the error and interrupt registers before entering power gating.	Read PxSERR and PxIS, and IS registers. Also read PxCI register to make sure that there are no outstanding commands. If (PxCI !=0) or any unexpected error, driver should bail out of PG sequence by setting APBDEV_PMC_SATA_PWRGT_0.PG_INFO = 0 Sets the bit rx_stat_idle_bypass to enable detection of a comwake.	If there is something unexpected or an error is detected or if HW wake is detected from the drive, then the SW should bail out of PG sequence (clear PMC bit) Once PG_INFO=1 and/or rx_stat_idle bypass is enabled, HW wake could be detected via rx_stat_idle interrupt only. In that case, driver needs to wait until HBA is in active state (PxSSTS.DET=0x3 and PxSSTS.IPM=0x1) before issuing any new commands.

#	Description	Register Programming	Comments
6.	Driver should gate SATA Clocks and assert reset to SATA.	CLK_RST_CONTROLLER_CLK_OUT_ENB_V_0 .SATA_CLKEN= '0' CLK_RST_CONTROLLER_RST_DEVICES_V_0. SATA_RESET=1 CLK_RST_CONTROLLER_RST_DEVICES_W_0 .SATACOLD_RST=1	
7.	*If HW wake up (example hot-plug or async notification) is needed:* Driver shall write a bit in Intr Ctlr in non-power gated region to enable the rx_stat interrupt generation on detection of rx_stat(OOB) wake.	Clear sata_rx_stat interrupt status and enable sata_rx_stat interrupt to start detecting rx_stat_idle changes from sata pad when detecting oob wake sequence : Write apb_misc sata_aux register RX_STAT_CLR bit[0] "SATA_RX_STAT_INT_CLR" field to '1' Write interrupt controller register **PRI_ICTLR_CPU_IER_SET_0 bit[13] "**SATA_RX_STAT" field to '1' The mapped status bit for sata_rx_stat interrupt in interrupt controller is at register **PRI_ICTLR_ISR_0 bit[13] "SATA_RX_STAT"**	At this point, sideband(phy logic + intr ctlr) takes over interrupt generation.
8.	*If HW wake up (example hot-plug or async notification) is needed:* Driver/RM shall place the SATA PADPLL in reset. *If Hw wake up is not needed:* Driver/RM shall place the SATA PHY and SATA PADPLL in IDDQ.	a) SATA_PADPLL_RESET_SWCTL =1 SATA_PADPLL_RESET_OVERRIDE_VALUE=1 b) SATA_PADPLL_RESET_SWCTL =1 SATA_PADPLL_RESET_OVERRIDE_VALUE=1 SATA_PADPHY_IDDQ_SWCTL=1 SATA_PADPHY_IDDQ_OVERRIDE_VALUE=1 Wait for time specified in SATA_LANE_IDDQ2_PADPLL_IDDQ SATA_PADPLL_IDDQ_SWCTL=1 SATA_PADPLL_IDDQ_OVERRIDE_VALUE=1	Whether this is done by driver or RM depends on whether we implement HW low power sequencing. Guideline: if SATA PLL is to be controlled by SW at run time (no HW low power sequencing), then it should be done by driver, not RM. Conversely, if it is to be controlled by SW only during power gating, then it can be in RM.
9.	Driver reports to the RM that SATA is being powered down. If PCIe® is not being used, RM can set the PLLE to either reset or IDDQ. *If HW wake up is needed and exit latency cannot be met with PLLE IDDQ mode, then* PLLE can be set to reset. *If HW wake up is not needed or PLLE IDDQ mode exit latency is sufficient:* PLLE can be set to IDDQ.	a) PLLE_ENABLE_SWCTL=1 CLK_RST_CONTROLLER_PLLE_BASE_0.PLLE _ENABLE=0 b) PLLE_ENABLE_SWCTL=1 CLK_RST_CONTROLLER_PLLE_BASE_0.PLLE _ENABLE=0 PLLE_IDDQ_SWCTL=1 PLLE_IDDQ_OVERRIDE_VALUE=1	RM takes over from this point of time. Wait Time= 1us?
10.	RM now shall power gate the controller. This shall also involve the setting of the clamps, and assertion of the resets.	APBDEV_PMC_PWRGATE_TOGGLE_0.SAX=1 << reset overrides exist in the CAR block >>	The clamp value of the HW is such that it shall place the SATA PAD PLL in IDDQ mode but it is overridden by sw value as swctl on iddq/reset is enabled above.
11.	RM indicates to the AHCI SW, that power gating is complete.		This is more of an implicit step; returning of the RM PG API function is considered RM telling module driver that PG is done.

Steps involved in Power Ungating

#	Description	Register Programming	Comments
1	If HW wake up is allowed and an OOB sequence is detected, an rx_stat interrupt will be sent by the interrupt ctlr Or, driver decides to wake up the controller.	When sata_rx_stat interrupt is detected and serviced, interrupt routine should disable this interrupt and clear the status by doing : Write interrupt controller register PRI_ICTLR_CPU_IER_CLR_0 bit[13] "SATA_RX_STAT" field to '1' Write apb_misc sata_aux register RX_STAT_CLR	

#	Description	Register Programming	Comments
		bit[0] “SATA_RX_STAT_INT_CLR” field to ‘1’	
2	If SATA PHY and SATA PADPLL is in IDDQ mode, driver/RM brings it out of IDDQ mode.	Get SATA PHY and PLL out of IDDQ as below: SATA_PADPLL_IDDQ_OVERRIDE_VALUE=0 Wait for programmable delay of SATA_PADPLL_IDDQ2LANE_SLUMBER_DLY. Suggested value of this delay is 3 microseconds. SATAPAD_IDDQ_OVERRIDE_VALUE=0	
3	RM checks if PLLE is already turned on or not. Part (a) : If PLLE is already turned on, it waits for TBD microseconds before moving on to next step. Part (b): If PLLE is off, it brings it up.	If PCIe is running, PLLE could be already running. Check that it is running by checking its PLLE_ENABLE and PLLE_LOCK bit. Part (a): If they both are set, then PLLE is already turned on. Wait for TBD microseconds. Part (b) If they both aren’t set, then do PLLE training and init sequence. If using spread spectrum, set the following bits: CLK_RST_CONTROLLER_PLLE_SS_CNTL_0.PLLE_SSCBYP=1 CLK_RST_CONTROLLER_PLLE_SS_CNTL_0.PLLE_BYPASS_SS=1 CLK_RST_CONTROLLER_PLLE_SS_CNTL_0.PLLE_INTERP_RESET=1 Set PLLE_LOCK_ENABLE bit in CLK_RST_CONTROLLER_PLLE_MISC register to DISABLE (0). Set the PLLE_ENABLE and PLLE_ENABLE_CML bits to DISABLE (0) in CLK_RST_CONTROLLER_PLLE_BASE register. Also set PLLE_SETUP=0 and PLLE_EXT_SETUP_17_16=0 in CLK_RST_CONTROLLER_PLLE_MISC register. Check that PLLE_IDDQ_SWCTL=1 and PLLE_IDDQ_OVERRIDE_VALUE=1. If they are not set to 1, set them to 1. Then set PLLE_IDDQ_OVERRIDE_VALUE=0 to begin the training sequence. Wait for PLLE training sequence to finish by waiting until PLLE_PLL_READY bit is set to 1 in CLK_RST_CONTROLLER_PLLE_MISC register program PLLE parameters (most are the default POR values) – set the following values: CLK_RST_CONTROLLER_PLLE_BASE register: PLLE_PLDIV_CML = 0xd PLLE_PLDIV = 0x18 PLLE_MDIV = 0x1 PLLE_NDIV = 0xc8 I*. These settings are for Tegra 3: PLLE_PLDIV_CML = 0xb PLLE_PLDIV = 0x12 PLLE_MDIV = 0x1 PLLE_NDIV = 0x96 CLK_RST_CONTROLLER_PLLE_MISC register PLLE_SETUP = 0x7 (This isn’t default) PLLE_LOCK_ENABLE = ENABLE (1) (This isn’t default) If using spread spectrum, set the following bits:	

#	Description	Register Programming	Comments
		CLK_RST_CONTROLLER_PLLE_SS_CNTL_0.PLLE_SSCBYP=1 CLK_RST_CONTROLLER_PLLE_SS_CNTL_0.PLLE_BYPASS_SS=1 CLK_RST_CONTROLLER_PLLE_SS_CNTL_0.PLLE_INTERP_RESET=1 Enable the PLLE now by setting PLLE_ENABLE and PLLE_ENABLE_CML to ENABLE (1) in CLK_RST_CONTROLLER_PLLE_BASE register. Wait for PLLE to lock by waiting until PLLE_LOCK bit is set to 1 in CLK_RST_CONTROLLER_PLLE_MISC register. After PLLE_LOCK is detected, wait for an additional programmable delay of PLLE_LOCK_DLY. This will help in case the PLLE_LOCK gets asserted earlier. The suggested value of this additional delay is 25 microseconds. Do the following steps if you intend to use spread spectrum: program spread spectrum coefficients- CLK_RST_CONTROLLER_PLLE_SS_CNTL_0.PLLE_SSCMAX = 0x29, CLK_RST_CONTROLLER_PLLE_SS_CNTL_0.PLLE_SSCINCINTRV = 0x1d, CLK_RST_CONTROLLER_PLLE_SS_CNTL_0.PLLE_SSCINC = 0x1. 11*) These settings are for Tegra 3: CLK_RST_CONTROLLER_PLLE_SS_CNTL_0.PLLE_SSCMAX = 0x24, CLK_RST_CONTROLLER_PLLE_SS_CNTL_0.PLLE_SSCINCINTRV = 0x18, CLK_RST_CONTROLLER_PLLE_SS_CNTL_0.PLLE_SSCINC = 0x1. CLK_RST_CONTROLLER_PLLE_SS_CNTL_0.PLLE_BYPASS_SS=0 CLK_RST_CONTROLLER_PLLE_SS_CNTL_0.PLLE_SSCBYP=0 CLK_RST_CONTROLLER_PLLE_SS_CNTL_0.PLLE_INTERP_RESET=0 Enable CML clock for SATA by setting PLLE_CML1_OEN bit to 1 in CLK_RST_CONTROLLER_PLLE_AUX_0 register. If PLLE is already turned on, check that the SATA CML clock output is turned on. Otherwise, turn it on by setting PLLE_CML1_OEN bit to 1 in CLK_RST_CONTROLLER_PLLE_AUX_0 register.	
4	RM deasserts reset to SATA PADPLL and waits until it locks.	SATA_PADPLL_RESET_OVERRIDE_VALUE=0 Wait for Satapll_lockdet =’1’	Expected maximum time for SATA PADPLL to lock = 15 microseconds.
5	RM toggles the powergate sax bit in PMC to power-ungate SAX partition.	Toggle the SAX partition register bits in PMC APBDEV_PMC_PWRGATE_TOGGLE_0.SAX=0 APBDEV_PMC_REMOVE_CLAMPING_CMD_0.SAX=1	
6	RM returns the status to the driver that the power un-gating is complete.		This is an implicit step. No action here.
7	Driver turns on the clocks to SATA and deasserts resets.	SW to Ungate txclk and all SATA clks, reset CLK_RST_CONTROLLER_CLK_OUT_ENB_V_0.SATA_CLKEN= ‘1’ ,	

#	Description	Register Programming	Comments
		CLK_RST_CONTROLLER_RST_DEVICES_W_0 .SATACOLD_RST= ‘0’ , CLK_RST_CONTROLLER_RST_DEVICES_V_0. SATA_RESET =0	
8	Driver restores the registers of the controller.	Driver should restore the registers in the following order: IPFS, CFG, Ext CFG, BAR5. Make sure that any registers that change values based on customer design are restored to their proper values. During the restoration of the registers, the driver would now need to restore the register T_SATA0_CFG_POWER_GATE_SSTS_RESTORED after the ssts_det, ssts_spd are restored. This register is used to tell the controller whether a drive existed earlier or not and move the PHY state machines into either HR_slumber or not.	Expected to take ~10 us.
9	Driver needs to switch the rx_idle_t driven source back to from SATA controller after SAX is power-ungated	Write SATA_AUX_MISC_CNTL_1_0 register L0_RX_IDLE_T_MUX field to ‘0’.	
10	Driver can start to use main SATA interrupt instead of the rx_stat_t interrupt.	After SATA logic power-ungated we can start to use main interrupt from sata controller and interrupt status mapped to interrupt controller register PRI_ICTLR_ISR_0 bit[23] “SATA_CTL”	
11	Set the bits in the CAR to allow HW based low power sequencing.	SATAPAD_PLL_PLLE_IDDQ_RESET_SWCTL =0	
12	Driver indicates to controller that power un-gating process is complete.	Clear bit in PMC . APBDEV_PMC_SATA_PWRGT_0.Pmc2sata_pg_info = 0 Clears the bit rx_stat_idle_bypass to enable detection of a comwake.	

Note: Wakeup behavior when CPU is off

Wake up might include waking the CPU itself

If the CPU is powered down, the rx_stat interrupt causes flow controller/PMC to power up CPU, CPU goes to reset vector handler code in OS kernel patch which will restore CPU state, reinit CPU, un-powergate SATA, restore SATA state, gives control to AHCI SW.

If the CPU is powered up, the rx_stat interrupt signal generates a CPU interrupt, interrupt handler in driver shall un-powergate SATA, restore SATA state.

31.3.6 Software Changes

In SW initiated power gating and ungating, the entry and exit of the power gating the controller is controlled by the software. In the HW initiated wake up mode, the software would need to read the bit oob_wake_detected to determine if the controller needs to be power ungated. The software would need to keep a backup of all the registers in system memory and would need to reprogram them once in the power un-gating process. The software would need to program the registers in the correct sequence as mentioned above.

There is a bug in the hardware, where the PxCMD.CR does not have the right value after register restoration following power-ungating. The Software should not read that bit.

A software workaround is needed when SW is initiating power-gating. To prevent an accidental COMRESET from being sent on the SATA link, software will need to set override for HW to not look at SATA PLL lockdet when shutting down SATA PLL.

This can be done by writing SATA ext. config space register T_SATA0_CFG_MISC(0x550), need to write bit[10] to ‘1’ and bit[8] to ‘0’ (field T_SATA0_CFG__PHY_RESET_USAGE_MODE).

31.3.7 Registers to Save and Restore

This list of registers that require save and restore across power gating sequence is included below. Apart from this the software is expected to save and restore the configuration space registers.

Save and restore

T_AHCI_HBA_SPARE_0
T_AHCI_HBA_GHC
T_AHCI_HBA_EM_LOC
T_AHCI_PORT_PXCLB
T_AHCI_PORT_PXFB
T_AHCI_PORT_PXIE
T_AHCI_HBA_SHUTDOWN_TIMER
T_AHCI_PORT_PXSCTL
T_AHCI_PORT_MP
T_AHCI_HBA_CCC_PORTS
T_AHCI_HBA_CCC_CTL - OP (optional)
T_AHCI_HBA_EM_CTL - OP
T_AHCI_PORT_PXCLBU
T_AHCI_PORT_PXFBU
T_AHCI_PORT_PXCMD
T_AHCI_HBA_PLL_CTRL
T_AHCI_PORT_PXFBS

Save and restore via bkdr writes

T_AHCI_HBA_CAP
T_AHCI_HBA_CAP2
NV_PROJ__SATA0_CHX_AHCI_PORT_PXSIG
T_AHCI_PORT_BKDR
T_AHCI_HBA_PI
NV_PROJ__SATA0_CHX_AHCI_PORT_PXTFD
NV_PROJ__SATA0_CHX_AHCI_PORT_PXSSTS

Registers to read only, not needed to restore

T_AHCI_HBA_BOHC
T_AHCI_PORT_INTR
T_AHCI_PORT_PXSERR

31.4 Address Translation

The bar spaces and PCI™ Config space from the PCI bus environment are mapped as is to an address space carved out of ARM (ordering of the registers is not changed). Tegra 3 devices do not follow the PCI specifications. They do not have any concept of the PCI configuration space, BAR space, and the extended configuration space. The system addressing is of 32 bits, unlike 40 bits in the PCI bus environment. The address can map up to 4 GB.

There is an address translation mechanism in the IPFS. With this address translation, a certain address range is mapped to the configuration space registers, and likewise for the BAR 5 and the extended configuration space registers.

The address mapping that is being done is explained in the table in the Appendix. Even though, BAR 0 to Bar 4 are not applicable to Tegra 3 devices, they too have been allocated address ranges.

31.4.1 Address Translation Table

The next table shows how all of the SATA register spaces and SATA-IPFS registers are mapped to Tegra 3 memory map. In Tegra 3, 64KB APB space is allocated for all these registers and 512B APB space allocated for SATA iobist registers.

Register Section		DFPCI address [39:0]	APB adr[31:0] for DFPCI mapping	PRI address [31:0]	APB adr[31:0] for PRI mapping

31.6 Registers Used in Power Gating/Un-gating Sequence

31.6.1 APBDEV_PMC_SATA_PWRGT_0

This register is also a part of the PMC section of this document.

IDDQ override Regs (bits 5:0)

Offset: 1ach | Read/Write: R/W | Reset: 0b00111111

Bit	Reset	Description
7	0x0	SW_PLL_EDPD: sata pll put in dpd state when bit is set, independently of powergating - kept only until drivers are fixed 0 = OFF 1 = ON
6	0x0	PG_INFO: sm2sata_pg_info
5	0x1	PLLE_IDDQ_OVERRIDE_VALUE: 0 The plle is powered up 1 Sw can put the plle in iddq

Bit	Reset	Description
		by setting this bit and PLLE_IDDQ_SWCTL -- default 0 = OFF 1 = ON
4	0x1	PLLE_IDDQ_SWCTL: 0 The PLLE is put in IDDQ mode by HW (SATA +AFI+CAR) signals. 1 The PLLE is put in IDDQ by SW -- default 0 = OFF 1 = ON
3	0x1	PADPHY_IDDQ_OVERRIDE_VALUE: 0 The PHY is powered up 1 Sw can put the PHY in IDDQ by setting this bit and SATA_PADPHY_IDDQ_SWCT - default 0 = OFF 1 = ON
2	0x1	PADPHY_IDDQ_SWCTL: 0 The SATA PHY is put in IDDQ mode by HW (SATA +AFI+CAR) signals. 1 The Sataphy is put in IDDQ by SW - default 0 = OFF 1 = ON
1	0x1	PADPLL_IDDQ_OVERRIDE_VALUE: 0 The pad PLL is powered up 1 SW can put the pad PLL in IDDQ by setting this bit and SATA_PADPLL_IDDQ_SWCTL- default 0 = OFF 1 = ON
0	0x1	PADPLL_IDDQ_SWCTL: 0 The Sata padpll is put in IDDQ mode by HW (SATA +AFI+CAR) signals.1 The SATA padpll is put in IDDQ by SW. - default 0 = OFF 1 = ON

31.6.2 CLK_RST_CONTROLLER_SATA_PLL_CFG0_0

This register is also a part of the CAR section of this document.

SATA power sequencer input SW control program guide

SW control input can be used for test coverage or driving power sequencer SM via software.

SATA power sequencer is driven by three primary reset and powerdown input signals: reset, lane_pd, padpll_pd.

Normal power up sequence is to deassert in the order of padpll_pd->lane_pd->reset.

Normal power down sequence is to assert in the order of reset->lane_pd->padpll_pd.

It is acceptable to assert all three at the same time.

It is acceptable for reset or lane_pd to return to power-up state in the middle of a power-down sequence.

SATA PLL Reset Override Register (bit 1:0)

Offset: 490h | Read/Write: R/W | Reset: 0bxx10xxxxxxxxxxxxxxx0000x011

Bit	R/W	Reset	Description
27:26	RO	X	SATA_SEQ_STATE: SATA power sequencer state 0 = SEQ_OFF 1 = SEQ_ON 2 = SEQ_BUSY
25	RW	SEQ_ON	SATA_SEQ_START_STATE: SATA power sequencer start state 0 = SEQ_OFF 1 = SEQ_ON
24	RW	DISABLE	SATA_SEQ_ENABLE: SATA power sequencer enable. Start state is loaded on first cycle after set. 0 = DISABLE 1 = ENABLE

Bit	R/W	Reset	Description
7	RW	0x0	SATA_SEQ_PADPLL_PD_INPUT_VALUE: 0=pad PLL is power up, 1=SW control padpll PD by setting this and SATA_SEQ_IN_SWCTL bit
6	RW	0x0	SATA_SEQ_LANE_PD_INPUT_VALUE: 0=IOPHY is power up, 1=SW control IOPHY PD by setting this and SATA_SEQ_IN_SWCTL bit
5	RW	0x0	SATA_SEQ_RESET_INPUT_VALUE: 0=SATA reset deasserted, 1=SW control reset by setting this and SATA_SEQ_IN_SWCTL bit
4	RW	0x0	SATA_SEQ_IN_SWCTL: 0=seq input by HW, 1=seq input by SW
2	RW	0x0	SATA_PADPLL_USE_LOCKDET: 0=Use programmable delay, 1=use lockdet signals from PLL
1	RW	0x1	SATA_PADPLL_RESET_OVERRIDE_VALUE: 0=pad PLL is power up, 1=SW control reset by setting this and SATA_PADPLL_RESET_SWCTL bit
0	RW	0x1	SATA_PADPLL_RESET_SWCTL: 0=reset by HW, 1=reset by SW

31.6.3 CLK_RST_CONTROLLER_PLLE_AUX_0

This register is also a part of the CAR section of this document.

Note that Range value is the recommended range. All counters supports 0-255 step range.

Offset: 48ch | Read/Write: R/W | Reset: 0b0xxxxx10000001000100000001110000

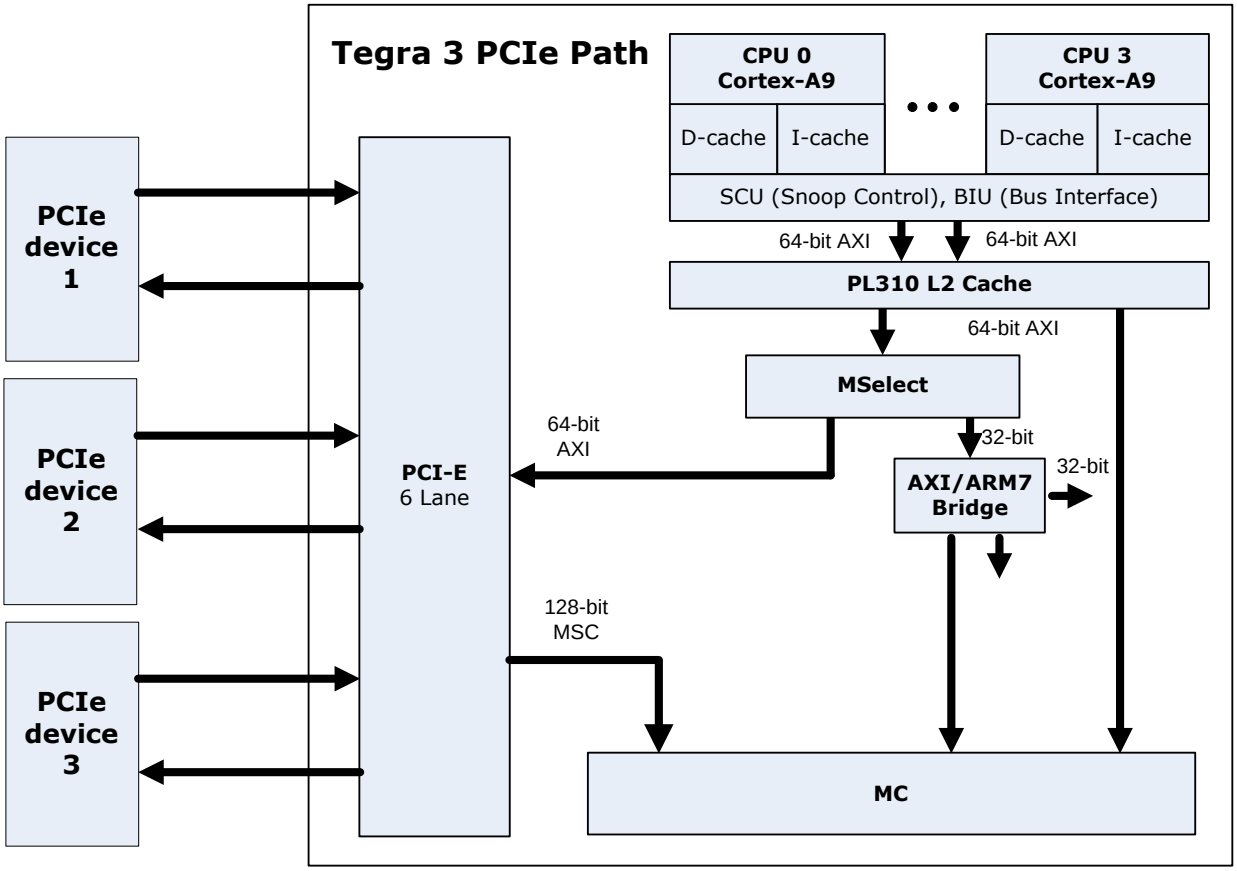
Bit	R/W	Reset	Description
31	RW	SKIP	PLLE_SS_SEQ_INCLUDE: 0=skip, 1=include. PLLE spread spectrum power sequencer include. 0 = SKIP 1 = INCLUDE
27:26	RO	X	PLLE_SEQ_STATE: PLLE power sequencer state 0 = SEQ_OFF 1 = SEQ_ON 2 = SEQ_BUSY
25	RW	SEQ_ON	PLLE_SEQ_START_STATE: PLLE power sequencer start state 0 = SEQ_OFF 1 = SEQ_ON
24	RW	DISABLE	PLLE_SEQ_ENABLE: PLLE power sequencer enable. Start state is loaded on first cycle after set. 0 = DISABLE 1 = ENABLE
23:16	RW	0x4	PLLE_SS_DLY: PT6: Delay between spread spectrum ON<->OFF transitions in SS power toggle sequence: ON->OFF->ON. Range 0-255ms in 1ms steps.
15:8	RW	0x40	PLLE_LOCK_DLY: PT5: Delay from PLLE ENABLE to lock. Range 0-128us in 1us steps
7	RW	0x0	TEST_FAST_PT: 0=normal timer steps. 1=fast timer steps. Fast programmable timer steps size for testing. Normal is per us or ms, fast is per osc clock. Applies to all programmable timer counters in SATA, PCIe and PLLE seq.
6	RW	0x1	PLLE_SS_SWCTL: 0=PLLE spread spectrum config setup by HW, 1=setup by SW during training
5	RW	0x1	PLLE_CONFIG_SWCTL: 0=PLLE config setup by HW, 1=PLLE setup by SW during training. Affects resetable bits when PLL is off. SETUP and EXT_SETUP bits. All other config bit are left untouched as initialized. ex. M/N/P, SS coeff.
4	RW	0x1	PLLE_ENABLE_SWCTL: 0=PLLE enable by HW, 1=PLLE enable by SW
3	RW	0x0	PLLE_USE_LOCKDET: 0=Use programmable delay, 1=use lockdet signals from PLLE

Bit	R/W	Reset	Description
2	RW	OSC_DIV	PLLE_REF_SRC: PLLE input reference clock source select. 0=OSC_DIV (options: mux (plls, ext_osc), /2, /4), 1=PLLP_OUT0 (use pre-divM=18 for 12MHz reference) 0 = OSC_DIV 1 = PLLP_OUT0
1	RW	DISABLE	PLLE_CML1_OEN: PLLE CML1 clock out enable. Used for SATA. 0 = DISABLE 1 = ENABLE

32.0 PCI EXPRESS (PCIe) ARCHITECTURE

The Tegra® 3 devices incorporate a 6-lane PCI Express® (PCIe®) bridge with support for both upstream and downstream FPCI interfaces that serves as the control path from Tegra 3 device to the external PCIe device. The PCIe bridge enables a connection to one, two, or three PCIe endpoints.

Figure 82 PCIe Bridge



32.1 Supported Configurations

Tegra 3 devices support the following lane/controller (number of lanes by number of controllers) configurations:

- 4×1, 1×2
- 4×1, 2×1
- 2×3

32.1.1 Device Recommendations

NVIDIA recommends that all PCIe devices used with Tegra 3 devices should support message signaled interrupt (MSI) signaling, and should be used in that mode. Correct operation of interrupts is ensured in this mode.

32.2 Registers

The PCI Express registers are located as follows:

Name	Location	Description
NV_PCIE_AXI_RP_T0C0	NV_ADDRESS_MAP_PCIE_BASE	Start of PCIe extended config space for controller 0
NV_PCIE_AXI_RP_T0C1	(NV_PCIE_AXI_RP_T0C0) + 4096	Start of PCIe extended config space for controller 1
NV_PCIE_AXI_PCA_UFPCI_T0C0	(NV_PCIE_AXI_RP_T0C1) + 4096	Start of PCIe pca0 space
NV_PCIE_AXI_PCA_XCLK_T0C0	(NV_PCIE_AXI_PCA_UFPCI_T0C0) + 256)	Start of PCIe pca1 space
NV_PCIE_AXI_PADS	(NV_PCIE_AXI_RP_T0C1) + 8192	Start of PCIe pads space
NV_PCIE_AXI_RP_T0C2	(NV_PCIE_AXI_PADS) + 4096	Start of PCIe extended config space for controller 2

32.2.1 PCI Compatible Configuration Registers

32.2.1.1 T_PCIE2_RP_DEV_ID (x000h)

This register implements the Device ID and Vendor ID registers as defined by the PCI™ 2.0 Specification.

Device ID and Vendor ID Register

Offset: 000h | Read/Write: RO

Bit	Reset	Description
31:16	None	**T_PCIE2_RP_DEV_ID_DEVICE_ID**: The DEVICE_ID bits identify the particular device. This identifier is allocated by the vendor. NVIDIA uses unique Device IDs for Root Complexes with different Maximum Link Widths. E1Ch **DEVICE_ID_TMS0_CTLR0_W4** E1Dh **DEVICE_ID_TMS0_CTLR1_W2 |** E1Dh **DEVICE_ID_TMS0_CTLR2_W2**
15:0	10DEh	**T_PCIE2_RP_DEV_ID_VENDOR_ID**: The VENDOR_ID bits identify the manufacturer of the device. Valid vendor identifiers are allocated by the PCI SIG to ensure uniqueness. 10DEh **VENDOR_ID_NVIDIA** (default)

32.2.1.2 T_PCIE2_RP_DEV_CTRL (x0004h)

Command and Status Register

Offset: 004h | Read/Write: R/W

Bit	R/W	Reset	Description
31	RW1C	0h	**T_PCIE2_RP_DEV_CTRL_DETECTED_PERR**: This bit is set by the Primary side device whenever it receives a Poisoned TLP, regardless of the state the Parity Error Response bit in the Command register. 0h **DETECTED_PERR_NOT_ACTIVE** (default) 1h **DETECTED_PERR_ACTIVE** 1h **DETECTED_PERR_SET**

Bit	R/W	Reset	Description
30	RW1C	0h	**T_PCIE2_RP_DEV_CTRL_SIGNALED_SERR**: This bit is set when the Primary side device sends an ERR_FATAL or ERR_NONFATAL message, and the SERR Enable bit is set. 0h **SIGNALED_SERR_NOT_ACTIVE** (default) 1h **SIGNALED_SERR_ACTIVE** 1h **SIGNALED_SERR_SET**
29	RW1C	0h	**T_PCIE2_RP_DEV_CTRL_RECEIVED_MASTER**: This bit is set when the Primary side Requestor receives a Completion with Unsupported Request Completion Status. 0h **RECEIVED_MASTER_NO_ABORT** (default) 1h **RECEIVED_MASTER_ABORT** 1h **RECEIVED_MASTER_SET**
28	RW1C	0h	**T_PCIE2_RP_DEV_CTRL_RECEIVED_TARGET**: This bit is set when the Primary side Requestor receives a Completion with Completer Abort Completion Status. 0h **RECEIVED_TARGET_NO_ABORT** (default) 1h **RECEIVED_TARGET_ABORT** 1h **RECEIVED_TARGET_SET**
27	RW1C	0h	**T_PCIE2_RP_DEV_CTRL_SIGNALED_TARGET**: This bit is set when the Primary side device completes a Request using Completer Abort Completion Status. 0h **SIGNALED_TARGET_NO_ABORT** (default) 1h **SIGNALED_TARGET_ABORT** 1h **SIGNALED_TARGET_SET**
26:25	R	0h	**T_PCIE2_RP_DEV_CTRL_DEVSEL_TIMING**: Does not apply to PCI Express. Hardwired to 0. 0h **DEVSEL_TIMING_FAST** (default) 1h **DEVSEL_TIMING_MEDIUM** 2h **DEVSEL_TIMING_SLOW**
24	RW1C	0h	**T_PCIE2_RP_DEV_CTRL_MASTER_DATA_PERR**: Master Data Parity Error bit. This bit is set by the Primary side Requestor if the Parity Error Response bit in the Command register is 1b and either of the following two conditions occurs: * Requestor receives a Completion marked poisoned * Requestor poisons a write Request If the Parity Error Response bit is 0b, this bit is never set. 0h **MASTER_DATA_PERR_NOT_ACTIVE** (default) 1h **MASTER_DATA_PERR_ACTIVE** 1h **MASTER_DATA_PERR_SET**
23	R	0h	**T_PCIE2_RP_DEV_CTRL_FAST_BACK2BACK**: Does not apply to PCI Express. Hardwired to 0. 0h **FAST_BACK2BACK_INCAPABLE** (default) 1h **FAST_BACK2BACK_CAPABLE**
22	R	0	Reserved
21	R	0h	**T_PCIE2_RP_DEV_CTRL_66MHZ**: Does not apply to PCI Express. Hardwired to 0. 0h **66MHZ_INCAPABLE** (default) 1h **66MHZ_CAPABLE**
20	R	1h	**T_PCIE2_RP_DEV_CTRL_CAPLIST**: The CAPLIST bit indicates that the device configuration space includes a capabilities list. Hardwired to 1. 1h **CAPLIST_PRESENT** (default) 0h **CAPLIST_NOT_PRESENT**
fs19	R	0h	**T_PCIE2_RP_DEV_CTRL_INTR_STATUS**: The INTR_STATUS bit indicates that an INTx interrupt message is pending internally to the device. 0h **INTR_STATUS_NOT_ACTIVE** (default) 1h **INTR_STATUS_ACTIVE**

Bit	R/W	Reset	Description
18:11	R	0	Reserved
10	R/W	0h	**T_PCIE2_RP_DEV_CTRL_INTR_DISABLE**: The INTR-DISABLE bit controls the ability of the device to generate INTx interrupt messages. When set, devices are prevented from generating INTx interrupt messages. 0h **INTR_DISABLE_INIT** (default) 1h **INTR_DISABLE_YES** 0h **INTR_DISABLE_NO**
9	R	0h	**T_PCIE2_RP_DEV_CTRL_BACK2BACK**: Does not apply to PCI Express. Hardwired to 0. 0h **BACK2BACK_DISABLED** (default) 1h **BACK2BACK_ENABLED**
8	R/W	0h	**T_PCIE2_RP_DEV_CTRL_SERR**: SERR Enable bit. This bit, when set, enables reporting of Non-fatal and Fatal errors detected by the Root Complex. In addition, this bit, when set, enables transmission by the primary interface of ERR_NONFATAL and ERR_FATAL error messages forwarded from the secondary interface. This bit does not affect the transmission of forwarded ERR_COR messages. 0h **SERR_DISABLED** (default) 1h **SERR_ENABLED**
7	R	0h	**T_PCIE2_RP_DEV_CTRL_STEP**: Does not apply to PCI Express. Hardwired to 0. 0h **STEP_DISABLED** (default) 1h **STEP_ENABLED**
6	R/W	0h	**T_PCIE2_RP_DEV_CTRL_PERR**: Parity Error Response bit. This bit, when set, controls the reporting of parity errors detected by the root complex (see Master Data Parity Error bit in the Status register). 0h **PERR_DISABLED** (default) 1h **PERR_ENABLED**
5	R	0h	**T_PCIE2_RP_DEV_CTRL_PALETTE_SNOOP**: Does not apply to PCI Express. Hardwired to 0. 0h **PALETTE_SNOOP_DISABLED** (default) 1h **PALETTE_SNOOP_ENABLED**
4	R	0h	**T_PCIE2_RP_DEV_CTRL_WRITE_AND_INVAL**: Does not apply to PCI Express. Hardwired to 0. 0h **WRITE_AND_INVAL_DISABLED** (default) 1h **WRITE_AND_INVAL_ENABLED**
3	R	0h	**T_PCIE2_RP_DEV_CTRL_SPECIAL_CYCLE**: Does not apply to PCI Express. Hardwired to 0. 0h **SPECIAL_CYCLE_DISABLED** (default) 1h **SPECIAL_CYCLE_ENABLED**
2	R/W	0h	**T_PCIE2_RP_DEV_CTRL_BUS_MASTER**: The BUS_MASTER bit controls the ability of the root complex to issue memory and I/O read/write requests. It controls forwarding of memory or I/O requests from the secondary interface to the primary interface. 0h **BUS_MASTER_DISABLED** (default) 1h **BUS_MASTER_ENABLED**
1	R/W	0h	**T_PCIE2_RP_DEV_CTRL_MEMORY_SPACE**: The MEMORY_SPACE bit indicates that the device will respond to memory space accesses on the primary interface. A value of 0 disables the device response on the primary interface. A value of 1 allows the device to forward memory transactions from the primary interface to the secondary interface. 0h **MEMORY_SPACE_DISABLED** (default) 1h **MEMORY_SPACE_ENABLED**

Bit	R/W	Reset	Description
0	R/W	0h	**T_PCIE2_RP_DEV_CTRL_IO_SPACE**: The IO_SPACE bit indicates that the device will respond to I/O space accesses on the primary interface. A value of 0 disables the device response on the primary interface. A value of 1 allows forwarding of I/O accesses from the primary interface to the secondary interface. 0h **IO_SPACE_DISABLED** (default) 1h **IO_SPACE_ENABLED**

32.2.1.3 T_PCIE2_RP_REV_CC (x0008h)

This register implements the Revision ID and Class Code registers as defined by the PCI 2.0 Specification.

Revision ID and Class Code Registers

Offset: 008h | Read/Write: RO

Bit	Reset	Description
31:8	6040XXh	**T_PCIE2_RP_REV_CC_CLASS_CODE**: The CLASS_CODE bits identify the generic function of the device and (in some cases) a specific register-level programming interface. The register is broken into three byte-size fields. The upper byte (bits 31:24) is a base class code which broadly classifies the type of function the device performs. The middle-byte (bits 23:16) is a sub-class code which identifies more specifically the function of the device. The lower byte (bits 15:8) identifies a specific register-level programming interface, if any, so that device independent software can interact with the device. 60400h **CLASS_CODE_HOST** (default) 60400h **CLASS_CODE_P2P**
7:0	None	**T_PCIE2_RP_REV_CC_REVISION_ID**: The REVISION_ID bits specify a device specific revision identifier. The top nibble is the Major Revision and the bottom nibble is the Minor Revision. The Major Revision is changed every time there is an all layer change to the Controller (A, B, C ...). The Minor Revision is updated through metal edits each time there is a metal revision changing the functionality of this block. A1h **REVISION_ID_VAL**

32.2.1.4 T_PCIE2_RP_MISC_1 (x000Ch)

This register implements the Cache Line Size, Latency Timer, Header Type, and BIST registers as defined by the PCI 2.0 Specification.

Cache Line Size, Latency Timer, Header Type, and BIST Registers

Offset: 00ch | Read/Write: R/W

Bit	R/W	Reset	Description
31:24	R	0h	**T_PCIE2_RP_MISC_1_BIST**: The BIST register field is optional and not used. Hardwired to 0. 0h **BIST_ZERO** (default)
23	R	0h	**T_PCIE2_RP_MISC_1_HEADER_TYPE1**: The HEADER_TYPE bits identify the layout of the bytes 10h through 3FH in configuration space and also whether or not the device contains multiple functions. Bit 23 in this register is used to identify a multi-function device. If the bit is 0, then the device is single function. If the bit is 1, then the device has multiple functions. 0h **HEADER_TYPE1_SINGLEFUNC** (default) 1h **HEADER_TYPE1_MULTIFUNC**

Bit	R/W	Reset	Description
22:16	R	1h	**T_PCIE2_RP_MISC_1_HEADER_TYPE0**: The HEADER_TYPE bits identify the layout of the bytes 10h through 3FH in configuration space and also whether or not the device contains multiple functions. Bits 22:16 in this register specify the layout of bytes 10h through 3Fh. PCI-Express Root Port Devices always employ Type 1 headers, hence this register is hard-wired to 1h. 0h **HEADER_TYPE0_NON_BRIDGE** 1h **HEADER_TYPE0_P2P_BRIDGE** (default)
15:11	R	0h	**T_PCIE2_RP_MISC_1_PLATENCY_TIMER**: The primary/master latency timer does not apply to PCI Express. Hardwired to 0. 0h **PLATENCY_TIMER_0_CLOCKS** (default)
10:8	R	0	Reserved
7:0	R/W	0h	**T_PCIE2_RP_MISC_1_CACHE_LINE_SIZE**: The cache line size register is set by the system firmware and the operating system to system cache line size. However, note that legacy PCI software may not always be able to program this field correctly especially in case of Hot-Plug devices. This field is implemented by PCI Express devices as a read-write field for legacy compatibility purposes but has no impact on any PCI Express device functionality. 0h **CACHE_LINE_SIZE_0_BYTES** (default)

32.2.1.5 T_PCIE2_RP_BAR_0 (x0010h)

This register implements the Base Address Register 0 as defined by the PCI-to-PCI Bridge Architecture Specification, Revision 1.2. It is unused and hard-wired to 0.

Base Address Register 0

Offset: 010h | Read/Write: RO

Bit	Reset	Description
31:0	0h	**T_PCIE2_RP_BAR_0_RESERVED**: This register is unused and hard-wired to 0. 0h **RESERVED_0** (default)

32.2.1.6 T_PCIE2_RP_BAR_1 (x0014h)

This register implements the Base Address Register 1 as defined by the PCI-to-PCI Bridge Architecture Specification, Revision 1.2. It is unused and hard-wired to 0.

Base Address Register 1

Offset: 014h | Read/Write: RO

Bit	Reset	Description
31:0	0h	**T_PCIE2_RP_BAR_1_RESERVED**: This register is unused and hard-wired to 0. 0h **RESERVED_0** (default)

32.2.1.7 T_PCIE2_RP_BN_LT (x0018h)

This register implements the Primary Bus Number, Secondary Bus Number, Subordinate Bus Number, and Secondary Latency Timer registers as defined by the PCI-to-PCI Bridge Architecture Specification, Revision 1.2.

Primary Bus, Secondary Bus, Subordinate Bus Numbers, and Secondary Latency Timer Registers

Offset: 018h | Read/Write: R/W

Bit	R/W	Reset	Description
31:27	R	0h	**T_PCIE2_RP_BN_LT_SLATENCY_TIMER**: This register does not apply to PCI Express. Hardwired to 0. 0h **SLATENCY_TIMER_0_CLOCKS** (default)
26:24	R	0	Reserved
23:16	R/W	0h	**T_PCIE2_RP_BN_LT_SUB_BUS_NUMBER**: Subordinate Bus Number register is used to record the bus number of the highest numbered PCI bus segment which is behind the bridge Configuration software programs the value in this register. The bridge uses this register in conjunction with the Secondary Bus Number register to determine when to respond to a Type 1 configuration transaction on the primary interface. 0h **SUB_BUS_NUMBER_0** (default) 1h **SUB_BUS_NUMBER_1** 2h **SUB_BUS_NUMBER_2** FFh **SUB_BUS_NUMBER_255**
15:8	R/W	0h	**T_PCIE2_RP_BN_LT_SEC_BUS_NUMBER**: The Secondary Bus Number register is used to record the bus number of the PCI bus segment to which the secondary interface of the bridge is connected. Configuration software programs the value in this register. The bridge uses this register to decode Type 1 configuration transactions on the primary interface and convert them to Type 0 accesses on the secondary interface. 0h **SEC_BUS_NUMBER_0** (default) 1h **SEC_BUS_NUMBER_1** 2h **SEC_BUS_NUMBER_2** FFh **SEC_BUS_NUMBER_255**
7:0	R/W	0h	**T_PCIE2_RP_BN_LT_PRI_BUS_NUMBER**: The Primary Bus Number register is used to record the bus number of the PCI bus segment to which the primary interface of the bridge is connected. Configuration software programs the value in this register. The bridge uses this register to decode Type 1 configuration transactions on the secondary interface that must be converted to Special Cycle transactions on the primary interface. 0h **PRI_BUS_NUMBER_0** (default)

32.2.1.8 T_PCIE2_RP_IO_BL_SS (x001Ch)

This register implements the I/O Base, I/O Limit, and Secondary Status registers as defined by the PCI-to-PCI Bridge Architecture Specification, Revision 1.2.

The I/O Base and I/O Limit registers define an address range that is used by the bridge to determine when to forward I/O transactions from one interface to the other.

The Secondary Status register is similar in function and bit definition to the Status register defined above; however, its bits reflect status conditions of the secondary interface (the Status register reflects the status conditions of the primary interface)

I/O Base, I/O Limit and Secondary Status Registers

Offset: 01ch | Read/Write: R/W

Bit	R/W	Reset	Description
31	RW1C	0h	**T_PCIE2_RP_IO_BL_SS_DETECTED_PERR**: This bit is set when the Secondary side device receives a Poisoned TLP, regardless of the state the Parity Error Response bit in the Bridge Control register. 0h **DETECTED_PERR_NOT_ACTIVE** (default) 1h **DETECTED_PERR_ACTIVE** 1h **DETECTED_PERR_SET**

Bit	R/W	Reset	Description
30	RW1C	0h	**T_PCIE2_RP_IO_BL_SS_RECEIVED_SERR**: This bit is set when the Secondary side device receives an ERR_FATAL or ERR_NONFATAL message. 0h **RECEIVED_SERR_NOT_ACTIVE** (default) 1h **RECEIVED_SERR_ACTIVE** 1h **RECEIVED_SERR_SET**
29	RW1C	0h	**T_PCIE2_RP_IO_BL_SS_RECEIVED_MASTER**: This bit is set when the Secondary side device receives a Completion with Unsupported Request Completion Status. 0h **RECEIVED_MASTER_NO_ABORT** (default) 1h **RECEIVED_MASTER_ABORT** 1h **RECEIVED_MASTER_SET**
28	RW1C	0h	**T_PCIE2_RP_IO_BL_SS_RECEIVED_TARGET**: This bit is set when the Secondary side device receives a Completion with Completer Abort Completion Status. 0h **RECEIVED_TARGET_NO_ABORT** (default) 1h **RECEIVED_TARGET_ABORT** 1h **RECEIVED_TARGET_SET**
27	RW1C	0h	**T_PCIE2_RP_IO_BL_SS_SIGNALED_TARGET**: This bit is set when the Secondary side device completes a Request using Completer Abort Completion Status. 0h **SIGNALED_TARGET_NO_ABORT** (default) 1h **SIGNALED_TARGET_ABORT** 1h **SIGNALED_TARGET_SET**
26:25	R	0h	**T_PCIE2_RP_IO_BL_SS_DEVSEL_TIMING**: Does not apply to PCI Express. Hardwired to 0. 0h **DEVSEL_TIMING_FAST** (default) 1h **DEVSEL_TIMING_MEDIUM** 2h **DEVSEL_TIMING_SLOW**
24	RW1C	0h	**T_PCIE2_RP_IO_BL_SS_MASTER_DATA_PERR**: Master Data Parity Error bit. This bit is set by the Secondary side Requestor if the Parity Error Response Enable bit in the Bridge Control register is 1b and either of the following two conditions occurs: * Requestor receives a Completion marked poisoned * Requestor poisons a write Request If the Parity Error Response bit is 0b, this bit is never set. 0h **MASTER_DATA_PERR_NOT_ACTIVE** (default) 1h **MASTER_DATA_PERR_ACTIVE** 1h **MASTER_DATA_PERR_SET**
23	R	0h	**T_PCIE2_RP_IO_BL_SS_FAST_BACK2BACK**: Does not apply to PCI Express. Hardwired to 0. 0h **FAST_BACK2BACK_INCAPABLE** (default) 1h **FAST_BACK2BACK_CAPABLE**
22	R	0	Reserved
21	R	0h	**T_PCIE2_RP_IO_BL_SS_66MHZ**: Does not apply to PCI Express. Hardwired to 0. 0h **66MHZ_INCAPABLE** (default) 1h **66MHZ_CAPABLE**
20:16	R	0	Reserved

Bit	R/W	Reset	Description
15:12	R/W	0h	**T_PCIE2_RP_IO_BL_SS_IO_LIMIT**: This register corresponds to address bits AD[15:12] of the I/O limit. For the purpose of address decoding, the bridge assumes that the lower 12 address bits of the I/O limit are 0xFFF. The I/O Limit register can be programmed to a smaller value than the I/O Base register if there are no I/O addresses on the secondary side of the bridge. 0h **IO_LIMIT_ADDRESS_0** (default) 1h **IO_LIMIT_ADDRESS_256** 2h **IO_LIMIT_ADDRESS_512** Fh **IO_LIMIT_ADDRESS_64K**
11:8	R	1h	**T_PCIE2_RP_IO_BL_SS_IO_LIMIT_SUPPORT**: Identifies the I/O addressing support. When 0h, the device supports only 16-bit addressing. When 1h, it supports 32-bit addressing, in which case the I/O Limit Upper 16 Bits register is used to extend the I/O limit to 32 bits. Hard-wired to 1h. 0h **IO_LIMIT_SUPPORT_16** 1h **IO_LIMIT_SUPPORT_32** (default)
7:4	R/W	0h	**T_PCIE2_RP_IO_BL_SS_IO_BASE**: This register corresponds to address bits AD[15:12] of the I/O base address. For the purpose of address decoding, the bridge assumes that the lower 12 address bits, AD[11:0], of the I/O base address are zero. 0h **IO_BASE_ADDRESS_0** (default) 1h **IO_BASE_ADDRESS_256** 2h **IO_BASE_ADDRESS_512** Fh **IO_BASE_ADDRESS_64K**
3:0	R	1h	**T_PCIE2_RP_IO_BL_SS_IO_BASE_SUPPORT**: Identifies the I/O addressing support. When 0h, the device only supports 16-bit addressing. When 1h, it supports 32-bit addressing, in which case the I/O Base Upper 16 Bits register is used to extend the I/O base address to 32 bits. Hard-wired to 1h. 0h **IO_BASE_SUPPORT_16** 1h **IO_BASE_SUPPORT_32** (default)

32.2.1.9 T_PCIE2_RP_MEM_BL (x0020h)

This register implements the Memory Base and Memory Limit registers as defined by the PCI-to-PCI Bridge Architecture Specification, Revision 1.2.

The Memory Base and Memory Limit registers define an address range that is used by the bridge to determine when to forward memory-mapped I/O transactions from one interface to the other.

Memory Base and Memory Limit Registers

Offset: 020h | Read/Write: R/W

Bit	R/W	Reset	Description
31:20	R/W	0h	**T_PCIE2_RP_MEM_BL_MEM_LIMIT**: This register corresponds to address bits AD[31:20] of the memory-mapped I/O limit. For the purpose of address decoding, the bridge assumes that the lower 20 address bits, AD[19:0], of the memory-mapped I/O limit are 0xFFFFF. The Memory Limit register must be programmed to a smaller value than the Memory Base register if there are no memory-mapped I/O addresses on the secondary side of the bridge. 0h **MEM_LIMIT_ADDRESS_0** (default) 1h **MEM_LIMIT_ADDRESS_1MEG** 2h **MEM_LIMIT_ADDRESS_2MEG** FFFh **MEM_LIMIT_ADDRESS_4GIG**
19:16	R	0	Reserved

Bit	R/W	Reset	Description
15:4	R/W	1h	**T_PCIE2_RP_MEM_BL_MEM_BASE**: This register corresponds to address bits AD[31:20] of the memory-mapped I/O base address. For the purpose of address decoding, the bridge assumes that the lower 20 address bits, AD[19:0], of the memory-mapped I/O base address are zero. 0h **MEM_BASE_ADDRESS_0** 1h **MEM_BASE_ADDRESS_1MEG** (default) 2h **MEM_BASE_ADDRESS_2MEG** FFFh **MEM_BASE_ADDRESS_4GIG**
3:0	R	0	Reserved

32.2.1.10 T_PCIE2_RP_PRE_BL (x0024h)

This register implements the Prefetchable Memory Base and Prefetchable Memory Limit registers as defined by the PCI-to-PCI Bridge Architecture Specification, Revision 1.2.

The Prefetchable Memory Base and Prefetchable Memory Limit registers define an address range that is used by the bridge to determine when to forward prefetchable memory transactions from one interface to the other.

Prefetchable Memory Base and Prefetchable Memory Limit Registers

Offset: 024h | Read/Write: R/W

Bit	R/W	Reset	Description
31:20	R/W	0h	**T_PCIE2_RP_PRE_BL_PREFETCH_MEM_LIMIT**: This register corresponds to address bits AD[31:20] of the prefetchable memory limit. For the purpose of address decoding, the bridge assumes that the lower 20 address bits, AD[19:0], of the prefetchable memory limit are 0xFFFFF. The Prefetchable Memory Limit register must be programmed to a smaller value than the Prefetchable Memory Base register if there is no prefetchable memory on the secondary side of the bridge. 0h **PREFETCH_MEM_LIMIT_ADDRESS_0** (default) 1h **PREFETCH_MEM_LIMIT_ADDRESS_1MEG** 2h **PREFETCH_MEM_LIMIT_ADDRESS_2MEG** FFFh **PREFETCH_MEM_LIMIT_ADDRESS_4GIG**
19:16	R	1h	**T_PCIE2_RP_PRE_BL_L64BIT**: Identifies the prefetchable memory addressing support. When 0h, the device supports only 32-bit addressing. When 1h, it supports 64-bit addressing, in which case the Prefetchable Limit Upper 32 Bits register is used to extend the prefetchable memory limit to 64 bits. Hard-wired to 1h. 1h **L64BIT_YES** (default)
15:4	R/W	1h	**T_PCIE2_RP_PRE_BL_PREFETCH_MEM_BASE**: This register corresponds to address bits AD[31:20] of the prefetchable memory base address. For the purpose of address decoding, the bridge assumes that the lower 20 address bits, AD[19:0], of the Prefetchable memory base address are zero. 0h **PREFETCH_MEM_BASE_ADDRESS_0** 1h **PREFETCH_MEM_BASE_ADDRESS_1MEG** (default) 2h **PREFETCH_MEM_BASE_ADDRESS_2MEG** FFFh **PREFETCH_MEM_BASE_ADDRESS_4GIG**
3:0	R	1h	**T_PCIE2_RP_PRE_BL_B64BIT**: Identifies the prefetchable memory addressing support. When 0h, the device supports only 32-bit addressing. When 1h, it supports 64-bit addressing, in which case the Prefetchable Base Upper 32 Bits register is used to extend the prefetchable memory base address to 64 bits. Hard-wired to 1h. 1h **B64BIT_YES** (default)

32.2.1.11 T_PCIE2_RP_PRE_BU32 (x0028h)

This register implements the Prefetchable Memory Base Upper 32 Bits register as defined by the PCI-to-PCI Bridge Architecture Specification, Revision 1.2.

Prefetchable Memory Base Upper 32 Bits Register

Offset: 028h | Read/Write: R/W

Bit	Reset	Description
31:0	0h	**T_PCIE2_RP_PRE_BU32_BASE_UPPER_BITS**: This register specifies the upper 32 bits, corresponding to AD[63::32], of the 64-bit prefetchable memory base address. 0h **BASE_UPPER_BITS_0** (default)

32.2.1.12 T_PCIE2_RP_PRE_LU32 (x002Ch)

This register implements the Prefetchable Memory Limit Upper 32 Bits register as defined by the PCI-to-PCI Bridge Architecture Specification, Revision 1.2.

Prefetchable Memory Limit Upper 32 Bits Register

Offset: 02ch | Read/Write: R/W

Bit	Reset	Description
31:0	0h	**T_PCIE2_RP_PRE_LU32_LIMIT_UPPER_BITS**: This register specifies the upper 32 bits, corresponding to AD[63::32], of the 64-bit prefetchable memory limit. 0h **LIMIT_UPPER_BITS_0** (default)

32.2.1.13 T_PCIE2_RP_IO_BL_U16 (x0030h)

This register implements the I/O Base Upper 16 Bits and I/O Limit Upper 16 Bits registers as defined by the PCI-to-PCI Bridge Architecture Specification, Revision 1.2.

I/O Base Upper 16 Bits and I/O Limit Upper 16 Bits Registers

Offset: 030h | Read/Write: R/W

Bit	Reset	Description
31:16	0h	**T_PCIE2_RP_IO_BL_U16_LIMIT_UPPER_BITS**: This register specifies the upper 16 bits, corresponding to AD[31::16], of the 32-bit I/O limit. 0h **LIMIT_UPPER_BITS_0** (default)
15:0	0h	**T_PCIE2_RP_IO_BL_U16_BASE_UPPER_BITS**: This register specifies the upper 16 bits, corresponding to AD[31::16], of the 32-bit I/O base address. 0h **BASE_UPPER_BITS_0** (default)

32.2.1.14 T_PCIE2_RP_CAP_PTR (x0034h)

This register implements the Capabilities Pointer register as defined by the PCI 2.0 Specification.

Capabilities Pointer

Offset: 034h | Read/Write: RO

Bit	Reset	Description
31:8	0	Reserved
7:0	40h	**T_PCIE2_RP_CAP_PTR_CAP_PTR**: The CAP_PTR bits indicate the offset into configuration space where the capabilities list begins. 40h **CAP_PTR_PM** (default)

32.2.1.15 T_PCIE2_RP_ROM_BA (x0038h)

This register implements the optional Expansion ROM Base Address register as defined by the PCI-to-PCI Bridge Architecture Specification, Revision 1.2. It is unused and hard-wired to 0.

Expansion ROM Base Address Register

Offset: 038h | Read/Write: RO

Bit	Reset	Description
31:0	0h	**T_PCIE2_RP_ROM_BA_RESERVED**: This register is unused and hard-wired to 0. 0h **RESERVED_0** (default)

32.2.1.16 T_PCIE2_RP_INTR_BCR (x003Ch)

This register implements the Interrupt Line, Interrupt Pin, and Bridge Control registers as defined by the PCI 2.0 Specification and PCI-to-PCI Bridge Architecture Specification, Revision 1.2.

Interrupt Line, Interrupt Pin, and Bridge Control Registers

Offset: 03ch | Read/Write: R/W

Bit	R/W	Reset	Description
31:28	R	0	Reserved
27	R	0h	**T_PCIE2_RP_INTR_BCR_DIS_TIMER_SERR**: Does not apply to PCI Express. Hard-wired to 0. 0h **DIS_TIMER_SERR_DISABLED** (default) 1h **DIS_TIMER_SERR_ENABLED**
26	R	0h	**T_PCIE2_RP_INTR_BCR_DIS_TIMER_STATUS**: Does not apply to PCI Express. Hard-wired to 0. 0h **DIS_TIMER_STATUS_NOT_ACTIVE** (default) 1h **DIS_TIMER_STATUS_ACTIVE**
25	R	0h	**T_PCIE2_RP_INTR_BCR_SECONDARY_DIS_TIMER**: Does not apply to PCI Express. Hard-wired to 0. 0h **SECONDARY_DIS_TIMER_LONG** (default) 1h **SECONDARY_DIS_TIMER_SHORT**

Bit	R/W	Reset	Description
24	R	0h	**T_PCIE2_RP_INTR_BCR_PRIMARY_DIS_TIMER**: Does not apply to PCI Express. Hard-wired to 0. 0h **PRIMARY_DIS_TIMER_LONG** (default) 1h **PRIMARY_DIS_TIMER_SHORT**
23	R	0h	**T_PCIE2_RP_INTR_BCR_FAST_B2B**: Does not apply to PCI Express. Hard-wired to 0. 0h **FAST_B2B_DISABLED** (default) 1h **FAST_B2B_ENABLED**
22	R/W	0h	**T_PCIE2_RP_INTR_BCR_SB_RESET**: Setting this bit triggers a hot reset on the corresponding PCI Express Port. 0h **SB_RESET_DISABLED** (default) 1h **SB_RESET_ENABLED**
21	R	0h	**T_PCIE2_RP_INTR_BCR_MABORT**: Does not apply to PCI Express. Hard-wired to 0. 0h **MABORT_DISABLED** (default) 1h **MABORT_ENABLED**
20	R/W	0h	**T_PCIE2_RP_INTR_BCR_VGA_16BITIO**: When Enabled, allows full 16-bit decode of IO address range for VGA. 0h **VGA_16BITIO_DISABLED** (default) 1h **VGA_16BITIO_ENABLED**
19	R/W	0h	**T_PCIE2_RP_INTR_BCR_VGA_ADDRESS**: When enabled the P2P bridge will claim all of the legacy VGA addresses. Memory address range: 000A_0000 - 000B_FFFF IO address ranges: 3B0-3BB, 3C0-3DF (including all aliases if VGA_16BITIO is not set). 0h **VGA_ADDRESS_DISABLED** (default) 1h **VGA_ADDRESS_ENABLED**
18	R/W	0h	**T_PCIE2_RP_INTR_BCR_ISA_ADDRESS**: Modifies the response by the bridge to ISA I/O addresses. This applies only to I/O addresses that are enabled by the I/O Base and I/O Limit registers and are in the first 64 KB of PCI I/O address space (0000 0000h to 0000 FFFFh). If this bit is set, the bridge will block any forwarding from primary to secondary of I/O transactions addressing the last 768 bytes in each 1-KB block. 0h **ISA_ADDRESS_DISABLED** (default) 1h **ISA_ADDRESS_ENABLED**
17	R/W	0h	**T_PCIE2_RP_INTR_BCR_SERR_FORWARD**: This bit controls forwarding of ERR_COR, ERR_NONFATAL and ERR_FATAL from secondary to primary. 0h **SERR_FORWARD_DISABLED** (default) 1h **SERR_FORWARD_ENABLED**
16	R/W	0h	**T_PCIE2_RP_INTR_BCR_PERR_RESP**: This bit controls the response to Poisoned TLPs. 0h **PERR_RESP_DISABLED** (default) 1h **PERR_RESP_ENABLED**
15:8	R	1h	**T_PCIE2_RP_INTR_BCR_INTR_PIN**: This register contains the interrupt pin the device (or device function) uses. A value of 1 corresponds to INTA#. A value of 2 corresponds to INTB#. A value of 3 corresponds to INTC#. A value of 4 corresponds to INTD#. Devices (or device functions) that do not use an interrupt pin must put a 0 in this register. This register is read-only. 0h **INTR_PIN_NONE** 1h **INTR_PIN_INTA** (default) 2h **INTR_PIN_INTB** 3h **INTR_PIN_INTC** 4h **INTR_PIN_INTD**

Bit	R/W	Reset	Description
7:0	R/W	0h	**T_PCIE2_RP_INTR_BCR_INTR_LINE**: This register contains the interrupt routing information. The register is read/write and must be implemented by any device (or device function) that uses an interrupt pin. POST software will write the routing information into this register as it initializes and configures the system. The value in this register tells which input of the system interrupt controller(s) the device's interrupt pin is connected to. Device drivers and operating systems can use this information to determine priority and vector information. INTR_LINE is written to 0xff (no connection) by software if the bridge does not use an interrupt pin. Some PCI BIOSes cannot handle aliased INTR_LINEs. Some PCI BIOSes cannot handle INTR_LINE initialized to 0xff. 0h **INTR_LINE_IRQ0** (default) 1h **INTR_LINE_IRQ1** Fh **INTR_LINE_IRQ15** FFh **INTR_LINE_UNKNOWN**

32.2.2 PCI Subsystem ID and Subsystem Vendor ID Capability Registers

32.2.2.1 T_PCIE2_RP_SS_0 (x0040h)

This register implements the first register of the Subsystem ID and Subsystem Vendor ID Capability list item, as defined by the PCI-to-PCI Bridge Architecture Specification, Revision 1.2.

Subsystem ID and Subsystem Vendor ID Capability Register 0

Offset: 040h | Read/Write: RO

Bit	Reset	Description
31:16	0	Reserved
15:8	48h	**T_PCIE2_RP_SS_0_NEXT_PTR**: This read-only field points to the next capabilities list item. 48h **NEXT_PTR_PM** (default)
7:0	Dh	**T_PCIE2_RP_SS_0_CAP_ID**: This read-only field is used to detect the presence of the SSID/SSVID registers in a PCI-to-PCI bridge. Hard-wired to 0Dh. Dh **CAP_ID_SS** (default)

32.2.2.2 T_PCIE2_RP_SS_1 (x0044h)

This register implements the second register of the .Subsystem ID and Subsystem Vendor ID Capability list item, as defined by the PCI-to-PCI Bridge Architecture Specification, Revision 1.2.

Subsystem ID and Subsystem Vendor ID Capability Register 1

Offset: 044h | Read/Write: RO

Bit	Reset	Description
31:16	0h	**T_PCIE2_RP_SS_1_SSID**: The SSID identifies the particular add-in card or subsystem and is assigned by the vendor. 0h **SSID_INIT** (default)
15:0	10DEh	**T_PCIE2_RP_SS_1_SSVID:** The SSVID identifies the manufacturer of the add-in card or subsystem. The SSVID is assigned by PCI-SIG to insure uniqueness (the Vendor ID is used as the SSVID also). 10DEh SSVID_INIT (default)

32.2.3 PCI Power Management Capability Structure Registers

32.2.3.1 T_PCIE2_RP_PM_0 (x0048h)

This register implements the Power Management Capabilities register as defined in Section 7.6 of PCI Express Specifications.

Power Management Capabilities Register

Offset: 048h | Read/Write: RO

Bit	Reset	Description
31:27	1Fh	**T_PCIE2_RP_PM_0_PME_SUPPORT:** This 5-bit field indicates the power states in which the function may assert PME#. A value of 0b for any bit indicates that the function is not capable of asserting the PME# signal while in that power state. bit(11) XXXX1b = PME# can be asserted from D0 bit(12) XXX1Xb = PME# can be asserted from D1 bit(13) XX1XXb = PME# can be asserted from D2 bit(14) X1XXXb = PME# can be asserted from D3hot bit(15) 1XXXXb = PME# can be asserted from D3cold Bits 31, 30, and 27 must be set to 1b for PCI-PCI Bridge structures representing Ports on Root Complexes/Switches to indicate that the Bridge will forward PME Messages. 1Fh PME_SUPPORT_YES (default) 0h PME_SUPPORT_NO
26	0h	**T_PCIE2_RP_PM_0_D2_SUPPORT**: If this bit is a "1", this function supports the D2 Power Management State. 1h **D2_SUPPORT_YES** 0h **D2_SUPPORT_NO** (default)
25	0h	**T_PCIE2_RP_PM_0_D1_SUPPORT**: If this bit is a "1", this function supports the D1 Power Management State. 1h **D1_SUPPORT_YES** 0h **D1_SUPPORT_NO** (default)
24:22	0h	**T_PCIE2_RP_PM_0_AUX_CURRENT:** This 3 bit field reports the 3.3Vaux auxiliary current requirements for the PCI function. Bit 3.3Vaux 8 7 6 Max. Current Required 1 1 1 375 mA 1 1 0 320 mA 1 0 1 270 mA 1 0 0 220 mA 0 1 1 160 mA 0 1 0 100 mA 0 0 1 55 mA 0 0 0 0 (self powered) 0h AUX_CURRENT_0 (default)
21	0h	**T_PCIE2_RP_PM_0_DEV_SPEC_INIT**: The Device Specific Initialization bit indicates whether special initialization of this function is required (beyond the standard PCI configuration header) before the generic class device driver is able to use it. Note that this bit is not used by some operating systems. Microsoft Windows and Windows NT, for instance, do not use this bit to determine whether to use D3. Instead, they use the driver's capabilities to determine this. A "1" indicates that the function requires a device specific initialization sequence following transition to the D0 uninitialized state. 0h **DEV_SPEC_INIT_NOT_NEEDED** (default) 1h **DEV_SPEC_INIT_NEEDED**
20	0	Reserved

Bit	Reset	Description
19	0h	**T_PCIE2_RP_PM_0_PME_CLOCK**: Does not apply to PCI Express. Must be hardwired to 0. 0h **PME_CLOCK_NOT_NEEDED** (default) 1h **PME_CLOCK_NEEDED**
18:16	3h	**T_PCIE2_RP_PM_0_PCIPM_REV**: A value of 010b indicates that this function complies with Revision 1.1 of the PCI Power Management Interface Specification. 3h **PCIPM_REV_12** (default) 2h **PCIPM_REV_11**
15:8	50h	**T_PCIE2_RP_PM_0_NEXT_PTR**: This read-only field points to the next capabilities list item. 50h **NEXT_PTR_MSI** (default)
7:0	1h	**T_PCIE2_RP_PM_0_CAP_ID**: This read-only field is used to detect the presence of the Power Management Capability registers in a PCI-to-PCI bridge. Hard-wired to 01h. 1h **CAP_ID_PM** (default)

32.2.3.2 T_PCIE2_RP_PM_1 (x004Ch)

This register implements the Power Management Status/Control register as defined in Section 7.6 of PCI Express Specification.

Power Management Status/Control Register

Offset: 04ch | Read/Write: R/W

Bit	R/W	Reset	Description
31:24	R	0h	**T_PCIE2_RP_PM_1_PME_DATA**: The PME Data register is not implemented. Hard-wired to 0. 0h **PME_DATA_UNS** (default)
23	R	0h	**T_PCIE2_RP_PM_1_PME_BPCC:** The bus power/clock control mechanism is not used. Hard-wired to 0. 0h **PME_BPCC_UNS** (default)
22	R	0h	**T_PCIE2_RP_PM_1_PME_B2B3:** The bus power/clock control mechanism is not used. Therefore the B2/B3 support bit is hard-wired to 0. 0h **PME_B2B3_UNS** (default)
21:16	R	0	Reserved
15	RW1C	0h	**T_PCIE2_RP_PM_1_PME_STATUS**: This bit is set when the function would normally assert the PME# signal independent of the state of the PME_En bit. Writing a "1" to this bit will clear it and cause the function to stop asserting a PME# (if enabled). Writing a "0" has no effect. This bit is sticky and must be explicitly cleared by the operating system each time the operating system is initially loaded. NOTE: This field is reset by Cold Reset 0h **PME_STATUS_NOT_ACTIVE** (default) 1h **PME_STATUS_ACTIVE** 1h **PME_STATUS_SET**
14:13	R	0h	**T_PCIE2_RP_PM_1_PME_DATA_SCALE:** The PME Data register is not implemented. Hard-wired to 0. 0h **PME_DATA_SCALE_UNS** (default)

Bit	R/W	Reset	Description
12:9	R	0h	**T_PCIE2_RP_PM_1_PME_DATA_SEL**: The PME Data register is not implemented. Hard-wired to 0. 0h **PME_DATA_SEL_UNS** (default)
8	R/W	0h	**T_PCIE2_RP_PM_1_PME:** A "1" enables the function to assert PME#. When "0", PME# assertion is disabled. This bit is sticky and must be explicitly cleared by the operating system each time it is initially loaded. NOTE: This field is reset by Cold Reset 0h PME_DISABLE (default) 1h PME_ENABLE
7:2	R	0	Reserved
1:0	R/W	0h	**T_PCIE2_RP_PM_1_PWR_STATE:** This 2-bit field is used both to determine the current power state of a function and to set the function into a new power state. The definition of the field values is given below. 00b - D0 01b - D1 10b - D2 11b - D3hot If software attempts to write an unsupported, optional state to this field, the write operation must complete normally on the bus; however, the data is discarded and no state change occurs. 0h **PWR_STATE_D0** (default) 1h **PWR_STATE_D1** 2h **PWR_STATE_D2** 3h **PWR_STATE_D3HOT**

32.2.4 PCI MSI Capability Structure Registers

32.2.4.1 T_PCIE2_RP_MSI_CTRL (x0050h)

The MSI capability structure is required for all PCI Express devices that are capable of generating interrupts.

MSI enables a device to request service by writing a system-specified message to a system-specified address. The transaction address specifies the message destination and the transaction data specifies the message. System software initializes the message destination and message during device configuration.

MSI Control and Capability Registers

Offset: 050h | Read/Write: R/W

Bit	R/W	Reset	Description
31:24	R	0h	**T_PCIE2_RP_MSI_CTRL_RSVD:** The RSVD field is reserved by the specification. 0h **RSVD_0** (default)
23	R	1h	**T_PCIE2_RP_MSI_CTRL_64BIT_CAP:** The 64BIT_CAP field indicates if the function is capable of generating a 64-bit message address. If 1, the function is capable. 1h **64BIT_CAP_TRUE** (default)
22:20	R/W	0h	**T_PCIE2_RP_MSI_CTRL_MULT_EN:** The MULT_EN field indicates the number of allocated messages. It is always aligned to a power of 2. 0h **MULT_EN_CODE0** (default) 1h **MULT_EN_CODE2** 2h **MULT_EN_CODE4** 3h **MULT_EN_CODE8**
19:17	R	1h	**T_PCIE2_RP_MSI_CTRL_MULT_CAP**: The MULT_CAP field determines the number of requested messages. It should always be a power of 2.

Bit	R/W	Reset	Description
			1h **MULT_CAP_CODE2** (default)
16	R/W	0h	**T_PCIE2_RP_MSI_CTRL_MSI:** The MSI bit controls if the function is permitted to use message signaled interrupt to request service. If 1, the function is permitted to use MSI and prohibits the use of INTx messages. 0h **MSI_DISABLE** (default) 1h **MSI_ENABLE**
15:8	R	None	**T_PCIE2_RP_MSI_CTRL_NEXT_PTR:** The NEXT_PTR field points to the next item in the capabilities list. 60h **NEXT_PTR_MSIMAP** 80h **NEXT_PTR_PCIEXP**
7:0	R	5h	**T_PCIE2_RP_MSI_CTRL_CAP_ID:** This read-only field is used to detect the presence of the Message Signaled Interrupt Capability registers in a PCI-to-PCI bridge. Hard-wired to 05h. 5h **CAP_ID_MSI** (default)

32.2.4.2 T_PCIE2_RP_MSI_LOW_ADDR (x0054h)

The contents of this register specify the lower 32 bits of the dword aligned address for the MSI memory write transaction.

MSI Message Lower Address Register

Offset: 054h | Read/Write: R/W

Bit	R/W	Reset	Description
31:2	R/W	0h	**T_PCIE2_RP_MSI_LOW_ADDR_DWORD**: Bits 31:2 of the address. 0h **DWORD_0** (default)
1:0	R	0h	**T_PCIE2_RP_MSI_LOW_ADDR_RSVD**: The address is always DWORD aligned, hence bits 1:0 of this register are hard-wired to 0. 0h **RSVD_0** (default)

32.2.4.3 T_PCIE2_RP_MSI_UPPER_ADDR (x0058h)

The contents of this register specify the upper 32 bits of the 64-bit MSI message address.

MSI Message Upper Address Register

Offset: 058h | Read/Write: R/W

Bit	Reset	Description
31:0	0h	**T_PCIE2_RP_MSI_UPPER_ADDR_DWORD**: Bits 63:32 of the address. 0h **DWORD_0** (default)

32.2.4.4 T_PCIE2_RP_MSI_DATA (x005Ch)

The contents of this register specify the data that is written to the MSI message address.

MSI Message Data Register

Offset: 05ch | Read/Write: R/W

Bit	R/W	Reset	Description
31:16	R	0h	**T_PCIE2_RP_MSI_DATA_RSVD**: 0h **RSVD_0** (default)
15:0	R/W	0h	**T_PCIE2_RP_MSI_DATA_DATA**: The MSI message data. 0h **DATA_0** (default)

32.2.5 PCI Express Capability Structure Registers

32.2.5.1 T_PCIE2_RP_PCI_EXPRESS_CAPABILITY (x0080h)

The PCI Express Capability List register enumerates the PCI Express Capability Structure in PCI 2.3 configuration space capability list. It also identifies PCI Express device type and associated capabilities.

PCI Express Capability List Register

Offset: 080h | Read/Write: RO

Bit	Reset	Description
31:30	0	Reserved
29:25	0h	**T_PCIE2_RP_PCI_EXPRESS_CAPABILITY_INTERRUPT_MESSAGE_NUMBER**: If this function is allocated more than one MSI interrupt number, this register is required to contain the offset between the base Message Data and the MSI Message that is generated when any of the status bits in either the Slot Status register or the Root Port Status register of this capability structure are set. Hardware is required to update this field so that it is correct if the number of the MSI Messages assigned to the device changes. 0h **INTERRUPT_MESSAGE_NUMBER_ZERO** (default)
24	1h	**T_PCIE2_RP_PCI_EXPRESS_CAPABILITY_SLOT_IMPLEMENTED**: This bit when set indicates that the PCI Express Link associated with this port is connected to a slot (as compared to being connected to an integrated component or being disabled). This field is valid for the following PCI Express device/Port Types: * Root Port of PCI Express Root Complex. * Downstream Port of PCI Express Switch. 1h **SLOT_IMPLEMENTED_INIT** (default)
23:20	4h	**T_PCIE2_RP_PCI_EXPRESS_CAPABILITY_DEVICE_PORT_TYPE:** Indicates the type of PCI Express logical device. Defined encodings are: 0000b = PCI Express Endpoint device. 0001b = Legacy PCI Express Endpoint device. 0100b = Root Port of PCI Express Root Complex. 0101b = Upstream Port of PCI Express Switch. 0110b = Downstream Port of PCI Express Switch. 0111b = PCI Express-to-PCI/PCI-X Bridge. 1000b = PCI/PCI-X to PCI Express Bridge **4h DEVICE_PORT_TYPE_INIT (default)**

Bit	Reset	Description
19:16	2h	**T_PCIE2_RP_PCI_EXPRESS_CAPABILITY_VERSION**: Indicates PCI_SIG defined PCI Express capability structure version number. Must be 1h for versions 1.0a and 1.1 of the PCI-Express Specification. Must be 2h for devices compliant to the Express Capabilities Register Expansion ECN. 2h **VERSION_INIT** (default) 1h **VERSION_1** 2h **VERSION_2**
15:8	0h	**T_PCIE2_RP_PCI_EXPRESS_CAPABILITY_LIST_NEXT_CAPABILITY_PTR**: The offset to the next PCI capability structure or 0h if no other items exist in the linked list of capabilities. 0h **LIST_NEXT_CAPABILITY_PTR_INIT** (default)
7:0	10h	**T_PCIE2_RP_PCI_EXPRESS_CAPABILITY_LIST_CAPABILITY_ID**: Indicates PCI Express Capability Structure. This field must return a Capability ID of 10h indicating that this is a PCI Express Capability Structure. 10h **LIST_CAPABILITY_ID_INIT** (default)

32.2.5.2 T_PCIE2_RP_DEVICE_CAPABILITY (x0084h)

The Device Capabilities register identifies PCI Express device specific capabilities.

Device Capabilities Register

Offset: 084h | Read/Write: RO

Bit	Reset	Description
31:28	0	Reserved
27:26	0h	**T_PCIE2_RP_DEVICE_CAPABILITY_CAPTURED_SLOT_POWER_LIMIT_SCALE**: Specifies the scale used for the Slot Power Limit Value. Range of Values: 00b = 1.0x 01b = 0.1x 11b = 0.01x 11b = 0.001x This value is set by the Set_Slot_Power_Limit message or hardwired to 00b. The default value is all 00b. 0h **CAPTURED_SLOT_POWER_LIMIT_SCALE_INIT** (default)
25:18	0h	**T_PCIE2_RP_DEVICE_CAPABILITY_CAPTURED_SLOT_POWER_LIMIT_VALUE**: In combination with the Slot Power Limit Scale value, specifies the upper limit on power supplied by slot. Power limit (in Watts) is calculated by multiplying the value in this field by the value in the Slot Power Limit Scale field. This value is set by the Set_Slot_Power_Limit message or hardwired to 0000_0000b. The default value is 0000_0000b. 0h **CAPTURED_SLOT_POWER_LIMIT_VALUE_INIT** (default)
17:16	0	Reserved
15	1h	**T_PCIE2_RP_DEVICE_CAPABILITY_ROLE_BASED_ERR_REPORTING**: This bit, when set, indicates that the device implements the functionality originally defined in the Error Reporting ECN for PCI Express Base Spec 1.0a and later incorporated into PCI Express Base Spec 1.1. 1h **ROLE_BASED_ERR_REPORTING_INIT** (default)
14	0h	**T_PCIE2_RP_DEVICE_CAPABILITY_POWER_INDICATOR_PRESENT**: This bit, when set, indicates that a Power Indicator is implemented on the card or module. 0h **POWER_INDICATOR_PRESENT_INIT** (default)
13	0h	**T_PCIE2_RP_DEVICE_CAPABILITY_ATTENTION_INDICATOR_PRESENT**: This bit, when set, indicates that an Attention Indicator is implemented on the card or module. 0h **ATTENTION_INDICATOR_PRESENT_INIT** (default)

Bit	Reset	Description
12	0h	**T_PCIE2_RP_DEVICE_CAPABILITY_ATTENTION_BUTTON_PRESENT**: This bit when set indicates that an Attention Button is implemented on the card or module. 0h **ATTENTION_BUTTON_PRESENT_INIT** (default)
11:9	0h	**T_PCIE2_RP_DEVICE_CAPABILITY_ENDPOINT_L1_ACCEPTABLE_LATENCY:** This field indicates acceptable latency that an Endpoint can withstand due to the transition from L1 state to the L0 state. It is essentially an indirect measure of the Endpoint's internal buffering. • 000b -- Less than 1 us. • 001b -- 1 us to less than 2 us. • 010b -- 2 us to less than 4 us. • 011b -- 4 us to less than 8 us. • 100b -- 8 us to less than 16 us. • 101b -- 16 us to less than 32 us. • 110b -- 32 us-64 us. • 111b -- More than 64 us. 0h **ENDPOINT_L1_ACCEPTABLE_LATENCY_INIT** (default)
8:6	0h	**T_PCIE2_RP_DEVICE_CAPABILITY_ENDPOINT_L0S_ACCEPTABLE_LATENCY**: This field indicates the acceptable total latency that an Endpoint can withstand due to the transition from L0s state to the L0 state. It is essentially an indirect measure of the Endpoint's internal buffering. • 000b -- Less than 64 ns. • 001b -- 64 ns to less than 128 ns. • 010b -- 128 ns to less than 256 ns. • 011b -- 256 ns to less than 512 ns. • 100b -- 512 ns to less than 1 us. • 101b -- 1 us to less than 2 us. • 110b -- 2 us-4us. • 111b -- More than 4 us. 0h **ENDPOINT_L0S_ACCEPTABLE_LATENCY_INIT** (default)
5	None	**T_PCIE2_RP_DEVICE_CAPABILITY_EXTENDED_TAG_FIELD_SIZE**: This field indicates the maximum supported size of the Tag field. Defined encodings are: 0b = 5-bit Tag field supported. 1b = 8-bit Tag field supported.
4:3	0h	**T_PCIE2_RP_DEVICE_CAPABILITY_PHANTOM_FUNCTIONS_SUPPORTED:** This field indicates the support for use of unclaimed function numbers to extend the number of outstanding transactions allowed by logically combining unclaimed function numbers (called Phantom Functions) with the Tag identifier. This field indicates the number of most significant bits of the function number portion of Requester ID that are logically combined with the Tag identifier. Defined encodings are: • 00b -- No function number bits used for Phantom Functions; device may implement all function numbers. • 01b -- First most significant bit of the function number in Requester ID used for Phantom Functions; device may implement functions 0-3. Functions 0, 1, 2 and 3 may claim functions 4, 5, 6, and 7 as Phantom Functions respectively. • 10b -- First two most significant bits of the function number in Requestor ID used for Phantom Functions; device may implement functions 0-1. Function 0 may claim functions 2, 4 and 6 as Phantom Functions, function 1 may claim functions 3, 5 and 7 as Phantom Functions. • 11b -- All three bits of function number in Requester ID used for Phantom Functions; device must be a single function 0 device that may claim all other functions as Phantom Functions. **Note:** The Phantom Function support for the device must be enabled by the corresponding control field in the Device Control Register. 0h PHANTOM_FUNCTIONS_SUPPORTED_INIT (default)

Bit	Reset	Description
2:0	0h	**T_PCIE2_RP_DEVICE_CAPABILITY_MAX_PAYLOAD_SIZE:** This field indicates the maximum payload size that the device can support for TLP's. • 000b --128B max payload size • 001b -- 256B max payload size • 010b -- 512B max payload size • 011b -- 1024B max payload size • 100b -- 2048B max payload size • 101b -- 4096B max payload size • 110b -- Reserved • 111b -- Reserved 0h MAX_PAYLOAD_SIZE_INIT (default)

32.2.5.3 T_PCIE2_RP_DEVICE_CONTROL_STATUS (x0088h)

The Device Control register controls PCI Express device specific parameters. It also provides information about PCI Express device specific parameters.

Device Control and Device Status Registers

Offset: 088h | Read/Write: R/W

Bit	R/W	Reset	Description
31:22	R	0	Reserved
21	R	0h	**T_PCIE2_RP_DEVICE_CONTROL_STATUS_TRANSACTIONS_PENDING:** This bit when set indicates that a device has issued Non Posted requests which have not been completed. A device reports this bit cleared only when all Completions for any outstanding Non-Posted Requests have been received. 0h TRANSACTIONS_PENDING_INIT (default)
20	R	0h	**T_PCIE2_RP_DEVICE_CONTROL_STATUS_AUX_POWER_DETECTED:** Devices that require AUX power report this bit as set if AUX power is detected by the device. 0h **AUX_POWER_DETECTED_INIT** (default)
19	RW1C	0h	**T_PCIE2_RP_DEVICE_CONTROL_STATUS_UNSUPP_REQUEST_DETECTED:** This bit indicates that the device received an Unsupported Request. Errors are logged in this register regardless of whether error reporting is enabled or not in the Device Control Register. NOTE: This field is reset by Cold Reset 0h **UNSUPP_REQUEST_DETECTED_INIT (default)** **1h UNSUPP_REQUEST_DETECTED_SET**
18	RW1C	0h	**T_PCIE2_RP_DEVICE_CONTROL_STATUS_FATAL_ERROR_DETECTED:** This bit indicates status of fatal errors detected. Errors are logged in this register regardless of whether error reporting is enabled or not in the Device Control register. For devices supporting Advanced Error Handling, errors are logged in this register regardless of the settings of the correctable error mask register. 0h **FATAL_ERROR_DETECTED_INIT** (default) 1h **FATAL_ERROR_DETECTED_SET**
17	RW1C	0h	**T_PCIE2_RP_DEVICE_CONTROL_STATUS_NON_FATAL_ERROR_DETECTED:** This bit indicates status of non-fatal errors detected. Errors are logged in this register regardless of whether error reporting is enabled or not in the Device Control register. For devices supporting Advanced Error Handling, errors are logged in this register regardless of the settings of the correctable error mask register. NOTE: This field is reset by Cold Reset 0h **NON_FATAL_ERROR_DETECTED_INIT** (default) 1h **NON_FATAL_ERROR_DETECTED_SET**

Bit	R/W	Reset	Description
16	RW1C	0h	**T_PCIE2_RP_DEVICE_CONTROL_STATUS_CORR_ERROR_DETECTED:** This bit indicates status of correctable errors detected. Errors are logged in this register regardless of whether error reporting is enabled or not in the Device Control register. For devices supporting Advanced Error Handling, errors are logged in this register regardless of the settings of the correctable error mask register. Default value of this field is 0. NOTE: This field is reset by Cold Reset 0h **CORR_ERROR_DETECTED_INIT** (default) 1h **CORR_ERROR_DETECTED_SET**
15	R	0	Reserved
14:12	R/W	2h	**T_PCIE2_RP_DEVICE_CONTROL_STATUS_MAX_READ_REQUEST_SIZE:** This field sets the maximum Read Request size for the Device as a Requester. The Device must not generate read requests with size exceeding the set value. Defined encodings for this field are: • 000b -- 128B max payload size • 001b -- 256B max payload size • 010b -- 512B max payload size • 011b -- 1024B max payload size • 100b -- 2048B max payload size • 101b -- 4096B max payload size • 110b -- Reserved • 111b – Reserved Devices that do not generate Read Requests larger than 128 bytes are permitted to implement this field as Read Only (RO) with a value of 000b. 2h **MAX_READ_REQUEST_SIZE_INIT** (default)
11	R/W	1h	**T_PCIE2_RP_DEVICE_CONTROL_STATUS_ENABLE_NO_SNOOP:** If this bit is set to 1, the device is permitted to set the No Snoop Bit in the Requester Attributes of transactions it initiates that do not require hardware enforced cache coherency. Even when this bit is set to 1, a device may only set the No Snoop attribute on a transaction when it can guarantee that the address of the transaction is not stored in any cache in the system. This bit may be hardwired to 0 if a device never sets the No Snoop attribute in transactions it initiates. 1h **ENABLE_NO_SNOOP_INIT (default)**
10	R/W	0h	**T_PCIE2_RP_DEVICE_CONTROL_STATUS_AUXILLARY_POWER_PM_ENABLE:** This bit when set enables a device to draw AUX power independent of PME AUX power. AUX power is allocated as requested in the AUX_Current field of the Power Management Capabilities Register (PMC), independent of the PME_En bit in the Power Management Control/Status Register (PMCSR). For multi-function devices, a component is allowed to draw AUX power if at least one of the functions has this bit set. Devices that do not implement this capability hardwire this bit to 0. NOTE: This field is reset by Cold Reset 0h **AUXILLARY_POWER_PM_ENABLE_INIT** (default)
9	R	0h	**T_PCIE2_RP_DEVICE_CONTROL_STATUS_PHANTOM_FUNCTIONS_ENABLE:** When set, this bit enables a device to use unclaimed functions as Phantom Functions to extend the number of outstanding transaction identifiers. If the bit is cleared, the device is not allowed to use Phantom Functions. Devices that do not implement this capability hardwire this bit to 0. 0h **PHANTOM_FUNCTIONS_ENABLE_INIT** (default)
8	R/W	0h	**T_PCIE2_RP_DEVICE_CONTROL_STATUS_EXTENDED_TAG_FIELD_ENABLE:** When set, this bit enables a device to use an 8-bit Tag field as a requester. If the bit is cleared, the device is restricted to a 5-bit Tag field. Devices that do not implement this capability hardwire this bit to 0. 0h **EXTENDED_TAG_FIELD_ENABLE_INIT** (default)

Bit	R/W	Reset	Description
7:5	R/W	0h	**T_PCIE2_RP_DEVICE_CONTROL_STATUS_MAX_PAYLOAD_SIZE:** This field sets the maximum TLP payload size for the device. As a receiver, the device must handle TLP's as large as the set value; as transmitter, the device must not generate TLPs exceeding the set value. Permissible values that can be programmed are indicated by the Max_Payload_Size supported in the Device Capabilities register. Defined encodings for this field are: • 000b -- 128B max payload size • 001b -- 256B max payload size • 010b -- 512B max payload size • 011b -- 1024B max payload size • 100b -- 2048B max payload size • 101b -- 4096B max payload size • 110b -- Reserved • 111b -- Reserved 0h **MAX_PAYLOAD_SIZE_INIT** (default)
4	R/W	1h	**T_PCIE2_RP_DEVICE_CONTROL_STATUS_ENABLE_RELAXED_ORDERING:** If this bit is set, the device is permitted to set the Relaxed Ordering bit in the Attributes field of transactions it initiates that do not require strong write ordering. This bit may be hardwired to 0 if a device never sets the Relaxed Ordering Attribute in transactions it initiates as a requester. 1h **ENABLE_RELAXED_ORDERING_INIT** (default)
3	R/W	0h	**T_PCIE2_RP_DEVICE_CONTROL_STATUS_UNSUPP_REQ_REPORTING_ENABLE**: This bit enables reporting of Unsupported Requests when set. For a multi-function device, this bit controls error reporting for each function from point-of-view of the respective function. Note: The reporting of error messages (ERR_COR, ERR_NONFATAl, ERR_FATAL) received by Root Port is controlled exclusively by Root Control Register. 0h **UNSUPP_REQ_REPORTING_ENABLE_INIT** (default)
2	R/W	0h	**T_PCIE2_RP_DEVICE_CONTROL_STATUS_FATAL_ERROR_REPORTING_ENABLE**: This bit controls reporting of fatal errors. For a multi-function device, this bit controls error reporting for each function from point-of-view of the respective function. 0h **FATAL_ERROR_REPORTING_ENABLE_INIT** (default)
1	R/W	0h	**T_PCIE2_RP_DEVICE_CONTROL_STATUS_NON_FATAL_ERROR_REPORTING_ENABLE:** This bit controls reporting of non-fatal errors. For a multi-function device, this bit controls error reporting for each function from point-of-view of the respective function. 0h **NON_FATAL_ERROR_REPORTING_ENABLE_INIT** (default)
0	R/W	0h	**T_PCIE2_RP_DEVICE_CONTROL_STATUS_CORR_ERROR_REPORTING_ENABLE**: This bit controls reporting of correctable errors. For a multi-function device, this bit controls error reporting for each function from point-of-view of the respective function. 0h **CORR_ERROR_REPORTING_ENABLE_INIT** (default)

32.2.5.4 T_PCIE2_RP_LINK_CAPABILITIES (x008Ch)

The Link Capabilities Register identifies PCI Express Link specific capabilities.

Link Capabilities Register

Offset: 08ch | Read/Write: RO

Bit	Reset	Description
31:24	None	**T_PCIE2_RP_LINK_CAPABILITIES_PORT_NUMBER**: This field indicates the PCI Express port number for the given PCI Express Link.
23:22	None	**T_PCIE2_RP_LINK_CAPABILITIES_RESERVED**: Reserved.
21	0h	**T_PCIE2_RP_LINK_BW_NOTIFY**: 0h **INIT** (default)

Bit	Reset	Description
20	1h	**T_PCIE2_RP_LINK_CAPABILITIES_LINKACTV_REPORTING:** For a Downstream Port, this bit must be set to 1b if the component supports the optional capability of reporting the DL_Active state of the Data Link Control and Management State Machine. For a hot-plug capable Downstream Port (as indicated by the Hot-Plug Capable field of the Slot Capabilities register), this bit must be set to 1b. 1h LINKACTV_REPORTING_INIT (default)
19	0h	**T_PCIE2_RP_LINK_CAPABILITIES_SURPRISE_DOWN_ERPT_CAP:** For a Downstream Port, this bit must be set to 1b if the component supports the optional capability of detecting and reporting a Surprise Down error condition. 0h SURPRISE_DOWN_ERPT_CAP_INIT (default)
18	0h	**T_PCIE2_RP_LINK_CAPABILITIES_CLOCK_PM**: A value of 1b in this bit indicates that the component tolerates the removal of any reference clock(s) via the "clock request" (CLKREQ#) mechanism when the link is in the L1 and L2/3 Ready link states. A value of 0b indicates the component does not have this capability and that reference clock(s) must not be removed in these link states. This capability is applicable only in form factors that support "clock request" (CLKREQ#) capability. 0h **CLOCK_PM_INIT** (default)
17:15	2h	**T_PCIE2_RP_LINK_CAPABILITIES_L1_EXIT_LATENCY:** This field indicates the L1 exit latency for the given PCI Express Link. The value reported indicates the lenght of time this Port requires to complete transition from L1 to L0. Defined encodings are: • 000b -- Less than 1 us. • 001b -- 1 us to less than 2 us. • 010b -- 2 us to less than 4 us. • 011b -- 4 us to less than 8 us. • 100b -- 8 us to less than 16 us. • 101b -- 16 us to less than 32 us. • 110b -- 32 us-64 us. • 111b -- More than 64 us. 2h L1_EXIT_LATENCY_INIT (default)
14:12	3h	**T_PCIE2_RP_LINK_CAPABILITIES_L0S_EXIT_LATENCY:** This field indicates the L0s exit latency for the given PCI Express Link. The value reported indicates the length of time this Port requires to complete transition from L0s state to L0. Defined encodings are: • 000b -- Less than 64 ns. • 001b -- 64 ns to less than 128 ns. • 010b -- 128 ns to less than 256 ns. • 011b -- 256 ns to less than 512 ns. • 100b -- 512 ns to less than 1 us. • 101b -- 1 us to less than 2 us. • 110b -- 2 us-4us. • 111b -- Reserved. 3h L0S_EXIT_LATENCY_INIT (default)
11:10	11h	**T_PCIE2_RP_LINK_CAPABILITIES_ACTIVE_STATE_LINK_PM_SUPPORT**: This field indicates the level of active state power management supported on the given PCI Express Link. Defined encodings are: • 00b -- Reserved • 01b -- L0s Entry Supported • 10b -- Reserved • 11b -- L0s and L1 Supported 11h ACTIVE_STATE_LINK_PM_SUPPORT_INIT (default)

Bit	Reset	Description
9:4	None	**T_PCIE2_RP_LINK_CAPABILITIES_MAX_LINK_WIDTH:** This field indicates the maximum width of the given PCI Express Link. Defined encodings are: • 000000b -- Reserved • 000001b -- x1 • 000010b -- x2 • 000100b -- x4 • 001000b -- x8 • 001100b -- x12 • 010000b -- x16 • 100000b -- x32
3:0	1h	**T_PCIE2_RP_LINK_CAPABILITIES_MAX_LINK_SPEED:** This field indicates the maximum Link speed of the given PCI Express Link. Defined encodings are: 0001b = 2.5 Gb/s Link All other encodings are reserved. 1h MAX_LINK_SPEED_INIT (default)

32.2.5.5 T_PCIE2_RP_LINK_CONTROL_STATUS (x0090h)

The Link Control register controls PCI Express Link specific parameters. It also provides information about PCI Express Link specific parameters.

Link Control and Link Status Registers

Offset: 090h | Read/Write: R/W

Bit	R/W	Reset	Description
31	RW1C	0h	**T_PCIE2_RP_LINK_CONTROL_STATUS_AUTO_BANDWIDTH:** NOTE: this field is reset by Cold Reset 0h **AUTO_BANDWIDTH_TRUE** (default) 1h **AUTO_BANDWIDTH_FALSE** 1h **AUTO_BANDWIDTH_SET**
30	RW1C	0h	**T_PCIE2_RP_LINK_CONTROL_STATUS_BW_MANAGEMENT:** NOTE: this field is reset by Cold Reset 0h **BW_MANAGEMENT_TRUE** (default) 1h **BW_MANAGEMENT_FALSE** 1h **BW_MANAGEMENT_SET**
29	R	None	**T_PCIE2_RP_LINK_CONTROL_STATUS_DL_LINK_ACTIVE:** This bit indicates the status of the Data Link Control and Management State Machine. It returns a 1b to indicate the DL_Active state, 0b otherwise. This bit must be implemented if the corresponding Data Link Layer Active Capability bit is implemented. Otherwise, this bit must be hardwired to 0b.
28	R	None	**T_PCIE2_RP_LINK_CONTROL_STATUS_SLOT_CLOCK_CONFIG:** This bit indicates that the component uses the same physical reference clock that the platform provides on the connector. If the device uses an independent clock irrespective of the presence of a reference on the connector, this bit must be clear.
27	R	None	**T_PCIE2_RP_LINK_CONTROL_STATUS_LINK_TRAINING:** This read-only bit indicates that Link training is in progress; hardware clears this bit once training is complete. Note: This field is not applicable and reserved for endpoint devices and Upstream Ports of Switches.
26	R	None	**T_PCIE2_RP_LINK_CONTROL_STATUS_UNDEFINED:** The value read from this bit is undefined. In previous versions of this specification, this bit was used to indicate a Link Training Error. System software must ignore the value read from this bit. System software is permitted to write any value to this bit.

Bit	R/W	Reset	Description
25:20	R	None	**T_PCIE2_RP_LINK_CONTROL_STATUS_NEG_LINK_WIDTH:** This field indicates the negotiated width of the given PCI Express Link. Defined encodings are: • 000001b -- x1 • 000010b -- x2 • 000100b -- x4 • 001000b -- x8 • 001100b -- x12 • 010000b -- x16 • 100000b -- x32
19:16	R	1h	**T_PCIE2_RP_LINK_CONTROL_STATUS_LINK_SPEED:** This field indicates the negotiated Link Speed of the given PCI Express Link. Defined encodings are: 0001b = 2.5 Gb/s PCI Express Link 0010b = 5.0 Gb/s PCI Express Link All other encodings are reserved. 1h LINK_SPEED_GEN1 (default) 2h LINK_SPEED_GEN2 (default)
15:12	R	0	Reserved
11	R/W	0h	**T_PCIE2_RP_LINK_CONTROL_STATUS_AUTO_BANDWIDTH_INT_EN:** 0h **AUTO_BANDWIDTH_INT_EN_INIT** (default)
10	R/W	0h	**T_PCIE2_RP_LINK_CONTROL_STATUS_BW_MANAGEMENT_INT_EN:** 0h **BW_MANAGEMENT_INT_EN_INIT** (default)
9	R/W	0h	**T_PCIE2_RP_LINK_CONTROL_STATUS_HW_AUTO_WIDTH_DISABLE:** 0h **HW_AUTO_WIDTH_DISABLE_DEFAULT** (default)
8	R	0h	**T_PCIE2_RP_LINK_CONTROL_STATUS_CLOCK_PM:** **0h CLOCK_PM_DEFAULT (default)**
7	R/W	0h	**T_PCIE2_RP_LINK_CONTROL_STATUS_EXTENDED_SYNCH:** This bit when set forces extended transmission of FTS ordered sets in FTS and extra TS2 at exit from L1 prior to entering L0. This mode provides external devices monitoring the link time to achieve bit and symbol lock before the link enters L0 state and resumes communication. Default value for this bit is 0. 0h EXTENDED_SYNCH_INIT (default)
6	R/W	0h	**T_PCIE2_RP_LINK_CONTROL_STATUS_COMMON_CLOCK_CONFIGURATION:** This bit when set indicates that this component and the component at the opposite end of this Link are operating with a distributed common reference clock. A value of 0 indicates that this component and the component at the opposite end of this Link are operating with asynchronous reference clock. Components utilize this common clock configuration information to report the correct L0s and L1 Exit Latencies. 0h COMMON_CLOCK_CONFIGURATION_INIT (default)
5	R	0h	**T_PCIE2_RP_LINK_CONTROL_STATUS_RETRAIN_LINK:** This bit initiates Link retraining when set. This field is not applicable and reserved for endpoint devices and Upstream Ports of a Switch. This bit always returns 0 when read. 0h RETRAIN_LINK_INIT (default)
4	R/W	0h	**T_PCIE2_RP_LINK_CONTROL_STATUS_LINK_DISABLE:** This bit disables the Link when set to 1b. This field is not applicable and reserved for endpoint devices and Upstream Ports of a Switch. Writes to this bit are immediately reflected in the value read from the bit, regardless of the actual Link State. 0h LINK_DISABLE_INIT (default)
3	R	0h	**T_PCIE2_RP_LINK_CONTROL_STATUS_READ_COMPLETION_BOUNDARY:** Encodings are: 0b = 64 byte 1b = 128 byte This field is hardwired for a Root Port and returns its RCB support capabilities. Devices that do not implement this feature must hardwire the field to 0b. This field is R/W for devices other than Root Ports. 0h READ_COMPLETION_BOUNDARY_INIT (default)

Bit	R/W	Reset	Description
2	R	0	Reserved
1:0	R/W	0h	**T_PCIE2_RP_LINK_CONTROL_STATUS_ACTIVE_STATE_LINK_PM_CONTROL:** This field controls the level of active state PM supported on the given PCI Expres Link. Defined encodings are: • 00b -- Reserved • 01b -- L0s Entry Supported • 10b -- Reserved • 11b -- L0s and L1 Supported 0h ACTIVE_STATE_LINK_PM_CONTROL_INIT (default)

32.2.5.6 T_PCIE2_RP_SLOT_CAPABILITIES (x0094h)

The Slot Capabilities register identifies PCI Express slot specific capabilities.

Slot Capabilities Register

Offset: 094h | Read/Write: RO

Bit	Reset	Description
31:19	None	**T_PCIE2_RP_SLOT_CAPABILITIES_PHYSICAL_SLOT_NUMBER:** This hardware initialized field indicates the physical slot number attached to this Port. This field must be hardware initialized to a value that assigns a slot number that is globally unique within the chassis. These registers should be initialized to 0 for ports connected to devices that are either integrated on the system board or integrated within the same silicon as the Switch device or Root Port.
18	0h	**T_PCIE2_RP_SLOT_CAPABILITIES_NO_CMD_COMPLETED_SUPPORT:** When set to 1, this bit indicates that this slot does not generate software notification when an issued command is completed by the Hot Plug Controller. 0h NO_CMD_COMPLETED_SUPPORT_INIT (default)
17	0h	**T_PCIE2_RP_SLOT_CAPABILITIES_ELECTROMECHANICAL_INTERLOCK_PRESENT:** Indicates that the ElectroMechanical Interlock mechanism is implemented. 0h ELECTROMECHANICAL_INTERLOCK_PRESENT_NO (default)
16:15	None	**T_PCIE2_RP_SLOT_CAPABILITIES_SLOT_POWER_LIMIT_SCALE:** This field Specifies the scale used for the Slot Power Limit Value. Range of values: 00b = 1.0x 01b = 0.1x 10b = 0.01x 11b = 0.001x This register must be implemented if the Slot Implemented bit is set. The default value prior to hardware/firmware initialization is 00b.
14:7	None	**T_PCIE2_RP_SLOT_CAPABILITIES_SLOT_POWER_LIMIT_VALUE:** In combination with the Slot Power Limit Scale value, this field specifies the upper limit on power supplied by slot. Power limit (in Watts) is calculated by multiplying the value in this field by the value in the Slot Power Limit Scale field. This register must be implemented if the Slot Implemented bit is set. The default value prior to hardware/firmware initialization is 0000_0000b.
6	0h	**T_PCIE2_RP_SLOT_CAPABILITIES_HOT_PLUG_CAPABLE:** This bit when set indicates that this slot is capable of supporting Hot-plug operations. 0h HOT_PLUG_CAPABLE_NO (default)
5	0h	**T_PCIE2_RP_SLOT_CAPABILITIES_HOT_PLUG_SURPRISE:** This bit when set indicates that a device present in this slot might be removed from the system without any prior notification. 0h HOT_PLUG_SURPRISE_NO (default)
4	0h	**T_PCIE2_RP_SLOT_CAPABILITIES_POWER_INDICATOR_PRESENT:** This bit when set indicates that a Power Indicator is implemented on the chassis for this slot. 0h POWER_INDICATOR_PRESENT_NO (default)
3	0h	**T_PCIE2_RP_SLOT_CAPABILITIES_ATTENTION_INDICATOR_PRESENT:**

Bit	Reset	Description
		This bit when set indicates that an Attention Indicator is implemented on the chassis for this slot. 0h ATTENTION_INDICATOR_PRESENT_NO (default)
2	0h	**T_PCIE2_RP_SLOT_CAPABILITIES_MRL_SENSOR_PRESENT:** This bit when set indicates that an Attention Indicator is implemented on the chassis for this slot. 0h MRL_SENSOR_PRESENT_NO (default)
1	0h	**T_PCIE2_RP_SLOT_CAPABILITIES_POWER_CONTROLLER_PRESENT:** This bit when set indicates that a Power Controller is implemented for this slot. 0h POWER_CONTROLLER_PRESENT_NO (default)
0	0h	**T_PCIE2_RP_SLOT_CAPABILITIES_ATTENTION_BUTTON_PRESENT:** This bit when set indicates that an Attention Button is implemented on the chassis for this slot. 0h ATTENTION_BUTTON_PRESENT_NO (default)

32.2.5.7 T_PCIE2_RP_SLOT_CONTROL_STATUS (x0098h)

The Slot Control Register controls PCI Express Slot specific parameters. It also provides information about PCI Express Slot specific parameters.

Slot Control and Slot Status Registers

Offset: 098h | Read/Write: R/W

Bit	R/W	Reset	Description
31:25	R	0	Reserved
24	RW1C	0h	**T_PCIE2_RP_SLOT_CONTROL_STATUS_DL_LAYER_STATE_CHANGED:** When set to 1, this field enables software notification when Data Link Layer Active field is changed 0h DL_LAYER_STATE_CHANGED_INIT (default) 1h DL_LAYER_STATE_CHANGED_SET
23	R	None	**T_PCIE2_RP_SLOT_CONTROL_STATUS_ELECTROMECHANICAL_INTERLOCK_STATE:** This bit when set physically locks the add-in card which the user is trying to remove, till software releases it by resetting the bit. Indicates the current state of the interlock, ie whether the card is electro-mechanically engaged or disengaged 0b : disengaged 1b : engaged Software reads this bit to determine what state the card is in 1h ELECTROMECHANICAL_INTERLOCK_STATE_YES
22	R	None	**T_PCIE2_RP_SLOT_CONTROL_STATUS_PRESENCE_DETECT_STATE:** This bit indicates the presence of a card in the slot. The bit reflects the Presence Detect status determined via an in-band mechanism or via the Present Detect pins as defined in the PCI Express Card Electromechanical Specification. Defined encodings are: 0b = Slot Empty. 1b = Card Present in slot. This register is required to be implemented on all Switch devices and Root Ports. The presence detect field for Switch devices or Root Ports not connected to slots should be hardwired to 1. This register is required if a slot is implemented. 1h PRESENCE_DETECT_STATE_YES
21	R	0h	**T_PCIE2_RP_SLOT_CONTROL_STATUS_MRL_SENSOR_STATE:** This register reports the status of the MRL sensor if it is implemented. Defined encodings are: 0b = MRL Closed. 1b = MRL Open. 0h MRL_SENSOR_STATE_INIT (default)
20	RW1C	0h	**T_PCIE2_RP_SLOT_CONTROL_STATUS_COMMAND_COMPLETED:** This bit is set when the hot plug controller completes an issued command. 0h COMMAND_COMPLETED_INIT (default) 1h COMMAND_COMPLETED_SET
19	RW1C	0h	**T_PCIE2_RP_SLOT_CONTROL_STATUS_PRESENCE_DETECT_CHANGED:** This bit is set when a Presence Detect change is detected. 0h PRESENCE_DETECT_CHANGED_INIT (default) 1h PRESENCE_DETECT_CHANGED_SET

Bit	R/W	Reset	Description
18	RW1C	0h	**T_PCIE2_RP_SLOT_CONTROL_STATUS_MRL_SENSOR_CHANGED:** This bit is set when a MRL Sensor state change is detected. 0h MRL_SENSOR_CHANGED_INIT (default) 1h MRL_SENSOR_CHANGED_SET
17	RW1C	0h	**T_PCIE2_RP_SLOT_CONTROL_STATUS_POWER_FAULT_DETECTED:** This bit is set when the Power Controller detects a power fault at this slot. 0h POWER_FAULT_DETECTED_INIT (default) 1h POWER_FAULT_DETECTED_SET
16	RW1C	0h	**T_PCIE2_RP_SLOT_CONTROL_STATUS_ATTN_BUTTON_PRESSED:** This bit is set when the attention button is pressed. 0h ATTN_BUTTON_PRESSED_INIT (default) 1h ATTN_BUTTON_PRESSED_SET
15:13	R	0	Reserved
12	R/W	0h	**T_PCIE2_RP_SLOT_CONTROL_STATUS_DL_LAYER_STATE_CHANGED_ENABLE:** This bit is set when the value reported in the Data Link Layer Link Active field of the Link Status register is changed 0h DL_LAYER_STATE_CHANGED_ENABLE_INIT (default)
11	R	0h	**T_PCIE2_RP_SLOT_CONTROL_STATUS_ELECTROMECHANICAL_INTERLOCK_CONTROL:** indicates that the slot supports electromechanical interlock mechanism 0h ELECTROMECHANICAL_INTERLOCK_CONTROL_INIT (default)
10	R/W	0h	**T_PCIE2_RP_SLOT_CONTROL_STATUS_POWER_CONTROLLER_CONTROL:** When read this register returns the current state of the Power applied to the slot; when written sets the power state of the slot per the defined encodings. 0b = Power On. 1b = Power Off. 0h POWER_CONTROLLER_CONTROL_INIT (default)
9:8	R/W	1h	**T_PCIE2_RP_SLOT_CONTROL_STATUS_POWER_INDICATOR_CONTROL:** Reads to this register return the current state of the Power Indicator; writes to this register set the Power Indicator. 00b = Reserved 01b = On 10b = Blink 11b = Off Writes to this register also cause the Port to send the appropriate POWER_INDICATOR_* messages. 1h POWER_INDICATOR_CONTROL_INIT (default)
7:6	R/W	3h	**T_PCIE2_RP_SLOT_CONTROL_STATUS_ATTN_INDICATOR_CONTROL:** Reads to this register return the current state of the Attention Indicator; writes to this register set the Attention Indicator. Defined encodings are: 00b = Reserved 01b = On 10b = Blink 11b = Off Writes to this register also cause the Port to send the appropriate ATTENTION_INDICATOR_* messages. 3h ATTN_INDICATOR_CONTROL_INIT (default)
5	R/W	0h	**T_PCIE2_RP_SLOT_CONTROL_STATUS_HOT_PLUG_INTERRUPT_ENABLE:** This bit when set enables generation of hot plug interrupt on enabled hot plug events. 0h HOT_PLUG_INTERRUPT_ENABLE_INIT (default)
4	R/W	0h	**T_PCIE2_RP_SLOT_CONTROL_STATUS_COMMAND_COMPLETED_INTERRUPT_ENABLE:** This bit when set enables the generation of hot plug interrupt when a command is completed by the Hot plug controller. 0h COMMAND_COMPLETED_INTERRUPT_ENABLE_INIT (default)
3	R/W	0h	**T_PCIE2_RP_SLOT_CONTROL_STATUS_PRESENCE_DETECT_CHANGED_ENABLE:** This bit when set enables the generation of hot plug interrupt or wake message on a presence detect changed event. 0h PRESENCE_DETECT_CHANGED_ENABLE_INIT (default)
2	R/W	0h	**T_PCIE2_RP_SLOT_CONTROL_STATUS_MRL_SENSOR_CHANGED_ENABLE:** This bit when set enables the generation of hot plug interrupt or wake message on a MRL sensor

Bit	R/W	Reset	Description
			changed event. 0h MRL_SENSOR_CHANGED_ENABLE_INIT (default)
1	R/W	0h	**T_PCIE2_RP_SLOT_CONTROL_STATUS_POWER_FAULT_DETECTED_ENABLE:** This bit when set enables the generation of hot plug interrupt or wake message on a power fault event. 0h POWER_FAULT_DETECTED_ENABLE_INIT (default)
0	R/W	0h	**T_PCIE2_RP_SLOT_CONTROL_STATUS_ATTN_BUTTON_PRESSED_ENABLE:** This bit when set enables the generation of hot plug interrupt or wake message on an attention button pressed event. 0h ATTN_BUTTON_PRESSED_ENABLE_INIT (default)

32.2.5.8 T_PCIE2_RP_RCR (x009Ch)

The Root Control Register controls PCI Express Root Complex specific parameters. Bit positions 31:4 of this address are reserved.

Root Control Register

Offset: 09ch | Read/Write: R/W

Bit	R/W	Reset	Description
31:4	R	0	Reserved
3	R/W	0h	**T_PCIE2_RP_RCR_PME_INT**: The PME_INT bit is enable bit for generating interrupt upon receipt of a PME message as reflected in the PMESTAT bit of Root Status Register. 0h **PME_INT_DIS** (default)
2	R/W	0h	**T_PCIE2_RP_RCR_SERR_FAT**: The SERR_FAT bit is enable bit for generating System Error if a fatal error (ERR_FATAL) is reported by any of the devices in the hierarchy associated with this Root Port, or by the Root Port itself. 0h **SERR_FAT_DIS** (default)
1	R/W	0h	**T_PCIE2_RP_RCR_SERR_NONFAT**: The SERR_NONFAT bit is enable bit for generating System Error if a non-fatal error (ERR_NONFATAL) is reported by any of the devices in the hierarchy associated with this Root Port, or by the Root Port itself. 0h **SERR_NONFAT_DIS** (default)
0	R/W	0h	**T_PCIE2_RP_RCR_SERR_COR**: The SERR_COR bit is enable bit for generating System Error if a correctable error (ERR_COR) is reported by any of the devices in the hierarchy associated with this Root Port, or by the Root Port itself. 0h **SERR_COR_DIS** (default)

32.2.5.9 T_PCIE2_RP_RSR (x00A0h)

The Root Status Register provides information about PCI Express device specific parameters. Bit positions 31:18 are reserved.

Root Status Register

Offset: 0A0h | Read/Write: R/W

Bit	R/W	Reset	Description
31:18	R	0	Reserved

Bit	R/W	Reset	Description
17	R	None	**T_PCIE2_RP_RSR_PMEPEND**: The PMEPEND bit indicates that another PME is pending when the PMESTAT bit is set. When the PMESTAT bit is cleared by software, the PME is delivered by hardware by setting the PMESTAT bit again and updating the REQID appropriately. The PMEPEND bit is cleared by hardware if no more PMEs are pending.
16	RW1C	0h	**T_PCIE2_RP_RSR_PMESTAT**: The PMESTAT bit indicates that PME was asserted by the requester ID indicated in the PME Requester ID field. Subsequent PMEs are kept pending untill the status register is cleared by software by writing a 1. 0h **PMESTAT_NOT_ACTIVE** (default) 1h **PMESTAT_ACTIVE** 1h **PMESTAT_SET**
15:0	R	None	**T_PCIE2_RP_RSR_REQID**: The REQID field indicates the PCI requester ID of the last PME requestor.

32.2.5.10 T_PCIE2_RP_DEVICE_CAPABILITIES_2 (x00A4h)

Offset: 0A4h | Read/Write: RO

Bit	Reset	Description
31:5	0h	**T_PCIE2_RP_DEVICE_CAPABILITIES_2_RESERVED**: Unused bits in this register. 0h **RESERVED_0** (default)
4	1h	**T_PCIE2_RP_DEVICE_CAPABILITIES_2_CPL_TO_DIS_SUP**: Support disabling the completion timeout mechanism. 1h **CPL_TO_DIS_SUP_0** (default)
3:0	3h	**T_PCIE2_RP_DEVICE_CAPABILITIES_2_CPL_TO_RANGES_SUP**: Completion timeout ranges supported by the rootport. Ranges A and B are currently supported by the PCIe 2.0 design. 3h **CPL_TO_RANGES_SUP_0** (default)

32.2.5.11 T_PCIE2_RP_DEVICE_CONTROL_STATUS_2 (x00A8h)

This register is primarily used for Rootport Completion Timeout values. Bits 31:5 are reserved.

Offset: 0A8h | Read/Write: R/W

Bit	Reset	Description
31:5	0h	**T_PCIE2_RP_DEVICE_CONTROL_STATUS_2_RESERVED:** Unused bits in this register. **0h RESERVED_0 (default)**
4	0h	**T_PCIE2_RP_DEVICE_CONTROL_STATUS_2_CPL_TO_DISABLE:** Disables completion timeout, making the rootport always wait endlessly for a completion to a request. **0h CPL_TO_DISABLE_DEFAULT (default)**

Bit	Reset	Description
3:0	0h	**T_PCIE2_RP_DEVICE_CONTROL_STATUS_2_CPL_TO_VALUE:** This field determines the Range and hence the timeout values for Completions expected from the endpoint. Range A 50 Us to 100 ms (80 Us in design) 1 ms to 10 ms (5 ms in design) Range B 16 ms to 55 ms (40 ms in design) 65 ms to 210 ms (140 ms in design) Default 50 Us to 50 ms (10 ms in design) 1h **CPL_TO_VALUE_RANGE_A_LO** 2h **CPL_TO_VALUE_RANGE_A_HI** 5h **CPL_TO_VALUE_RANGE_B_LO** 6h **CPL_TO_VALUE_RANGE_B_HI** 0h **CPL_TO_VALUE_DEFAULT** (default)

32.2.5.12 T_PCIE2_RP_LINK_CAPABILITIES_2 (x00ACh)

This is a placeholder register and is hardwired to 0. There are no capabilities that require this register.

Offset: 0Ach | Read/Write: RO

Bit	Reset	Description
31:0	0h	**T_PCIE2_RP_LINK_CAPABILITIES_2_BITS**: 0h **BITS_0**

32.2.5.13 T_PCIE2_RP_LINK_CONTROL_STATUS_2 (x00B0h)

Offset: 0B0h | Read/Write: R/W

Bit	R/W	Reset	Description
31:17	R	0h	**T_PCIE2_RP_LINK_CONTROL_STATUS_2_RESERVED_STATUS**: 0h **RESERVED_STATUS_DEFAULT** (default)
16	R	None	**T_PCIE2_RP_LINK_CONTROL_STATUS_2_CURRENT_DEEMPHASIS_LEVEL**: 1h **CURRENT_DEEMPHASIS_LEVEL_3P5** 0h **CURRENT_DEEMPHASIS_LEVEL_6**
15:13	R	0h	**T_PCIE2_RP_LINK_CONTROL_STATUS_2_RESERVED_CONTROL**: 0h **RESERVED_CONTROL_DEFAULT** (default)
12	R/W	0h	**T_PCIE2_RP_LINK_CONTROL_STATUS_2_COMPLIANCE_DEEMPHASIS**: NOTE: This field is reset by Cold Reset. 0h **COMPLIANCE_DEEMPHASIS_INIT** (default)
11	R/W	0h	**T_PCIE2_RP_LINK_CONTROL_STATUS_2_COMPLIANCE_SOS**: NOTE: This field is reset by Cold Reset. 0h **COMPLIANCE_SOS_INIT** (default)
10	R/W	0h	**T_PCIE2_RP_LINK_CONTROL_STATUS_2_ENTER_MODIFIED_COMPLIANCE**: When this bit is set to 1, the device transmits the modified compliance pattern if the LTSSM enters Polling. Compliance state. Default value is 0b. NOTE: This field is reset by Cold Reset. 0h **ENTER_MODIFIED_COMPLIANCE_INIT** (default)

Bit	R/W	Reset	Description
9:7	R/W	0h	**T_PCIE2_RP_LINK_CONTROL_STATUS_2_TRANSMIT_MARGIN**: This field controls the value of the non-deemphasized voltage level at the transmitter pins. Encodings: 000b: 800-1200mV for full swing and 400-600mV for half-swing 001b-010b: Values must be monotonic with a non-zero slope 011b: 200-400mV for full-swing and 100-200mV for half-swing 100b-111b: reserved Default value is 0b. NOTE: This field is reset by Cold Reset. 0h **TRANSMIT_MARGIN_INIT** (default)
6	R	None	**T_PCIE2_RP_LINK_CONTROL_STATUS_2_SELECTABLE_DEEMPHASIS**: When link is operating at 5GT/s speed, selects the level of de-emphasis. This value is initialized by hardware and/or BIOS. Encodings: 1b: -3.5dB 0b: -6dB Default value is 1b.
5	R	0h	**T_PCIE2_RP_LINK_CONTROL_STATUS_2_HW_AUTO_SPEED_DISABLE**: Link speed change is disabled if set to 1b. Default value is 0b. 0h **HW_AUTO_SPEED_DISABLE_INIT**
4	R/W	0h	**T_PCIE2_RP_LINK_CONTROL_STATUS_2_ENTER_COMPLIANCE**: If set to 1b forces link to enter compliance mode at the speed indicated by Target Link Speed field. Default value is 0b. NOTE: This field is reset by Cold Reset. 0h **ENTER_COMPLIANCE_INIT** (default)
3:0	R/W	2h	**T_PCIE2_RP_LINK_CONTROL_STATUS_2_TARGET_LINK_SPEED**: This field sets an upper limit on the link operational speed by restricting the values advertised in training sequences. Defined encodings: 0001b 2.5Gb/s (Gen1) 0010b 5Gb/s (Gen2) Other encodings are reserved. Default value is 0. NOTE: This field is reset by Cold Reset. 0h **TARGET_LINK_SPEED_GEN2_DIS** 1h **TARGET_LINK_SPEED_2P5** 2h **TARGET_LINK_SPEED_5P0** (default)

32.2.5.14 T_PCIE2_RP_SLOT_CAPABILITIES_2 (x00B4h)

This is a placeholder register and is hardwired to 0. There are no capabilities that require this register.

Offset: 0B4h | Read/Write: RO

Bit	Reset	Description
31:0	0h	**T_PCIE2_RP_SLOT_CAPABILITIES_2_BITS**: 0h **BITS_0**

32.2.5.15 T_PCIE2_RP_SLOT_CONTROL_STATUS_2 (x00B8h)

This is a placeholder register and is hardwired to 0. There are no capabilities that require this register.

Offset: 0B8h | Read/Write: RO

Bit	Reset	Description
31:0	0h	**T_PCIE2_RP_SLOT_CONTROL_STATUS_2_BITS**: 0h **BITS_0**

32.2.6 Error Reporting Capability Registers

32.2.6.1 T_PCIE2_RP_ERPTCAP (0x100h)

This is the Advanced Error Reporting Enhanced Capability Header register.

Offset: 100h | Read/Write: RO

Bit	R/W	Reset	Description
31:20	R	0h	**T_PCIE2_RP_ERPTCAP_ID:** 0h **ID_NONE** (default) 1h **ID_AER**
19:16	R	0h	**T_PCIE2_RP_ERPTCAP_VERSION:** 0h **VERSION_0** (default) 1h **VERSION_1**
15:0	R	0h	**T_PCIE2_RP_ERPTCAP_NEXT_PTR:** 0h **NEXT_PTR_NONE** (default)

32.2.6.2 T_PCIE2_RP_ERPTCAP_UCERR (0x104h)

This is the Uncorrectable Error Status register.

Offset: 104h | Read/Write: R/W

Bit	R/W	Reset	Description
31:21	R	0	Reserved
20	RW1C	0h	**T_PCIE2_RP_ERPTCAP_UCERR_UNSUP_REQ_ERR**: Unsupported Request Error Status NOTE: this field is reset by Cold Reset 0h **UNSUP_REQ_ERR_FALSE** (default) 1h **UNSUP_REQ_ERR_TRUE** 1h **UNSUP_REQ_ERR_CLEAR**
19	RW1C	0h	**T_PCIE2_RP_ERPTCAP_UCERR_ECRC_ERR**: ECRC Error Status NOTE: this field is reset by Cold Reset 0h **ECRC_ERR_FALSE** (default) 1h **ECRC_ERR_TRUE** 1h **ECRC_ERR_CLEAR**
18	RW1C	0h	**T_PCIE2_RP_ERPTCAP_UCERR_MF_TLP**: Malformed TLP Status NOTE: this field is reset by Cold Reset 0h **MF_TLP_FALSE** (default) 1h **MF_TLP_TRUE** 1h **MF_TLP_CLEAR**

Bit	R/W	Reset	Description
17	RW1C	0h	**T_PCIE2_RP_ERPTCAP_UCERR_RCV_OVFL**: Receiver Overflow Status NOTE: this field is reset by Cold Reset 0h **RCV_OVFL_FALSE** (default) 1h **RCV_OVFL_TRUE** 1h **RCV_OVFL_CLEAR**
16	RW1C	0h	**T_PCIE2_RP_ERPTCAP_UCERR_UNEXP_COMP**: Unexpected Completion Status NOTE: this field is reset by Cold Reset 0h **UNEXP_COMP_FALSE** (default) 1h **UNEXP_COMP_TRUE** 1h **UNEXP_COMP_CLEAR**
15	RW1C	0h	**T_PCIE2_RP_ERPTCAP_UCERR_COMP_ABORT**: Completion Abort Status NOTE: this field is reset by Cold Reset 0h **COMP_ABORT_FALSE** (default) 1h **COMP_ABORT_TRUE** 1h **COMP_ABORT_CLEAR**
14	RW1C	0h	**T_PCIE2_RP_ERPTCAP_UCERR_COMP_TO**: Completion Timeout Status NOTE: this field is reset by Cold Reset 0h **COMP_TO_FALSE** (default) 1h **COMP_TO_TRUE** 1h **COMP_TO_CLEAR**
13	RW1C	0h	**T_PCIE2_RP_ERPTCAP_UCERR_FC_PROTO_ERR**: Flow Control Protocol Error Status NOTE: this field is reset by Cold Reset 0h **FC_PROTO_ERR_DEFAULT** (default) 1h **FC_PROTO_ERR_TRUE** 1h **FC_PROTO_ERR_CLEAR**
12	RW1C	0h	**T_PCIE2_RP_ERPTCAP_UCERR_POS_TLP**: Poisoned TLP Status NOTE: this field is reset by Cold Reset 0h **POS_TLP_FALSE** (default) 1h **POS_TLP_TRUE** 1h **POS_TLP_CLEAR**
11:5	R	0	Reserved
4	RW1C	0h	**T_PCIE2_RP_ERPTCAP_UCERR_DLINK_PROTO_ERR**: Data Link Protocol Error Status NOTE: this field is reset by Cold Reset 0h **DLINK_PROTO_ERR_FALSE** (default) 1h **DLINK_PROTO_ERR_TRUE** 1h **DLINK_PROTO_ERR_CLEAR**
3:1	R	0	Reserved
0	R	0h	**T_PCIE2_RP_ERPTCAP_UCERR_TRAINING_ERR**: Training Error Status 0h **TRAINING_ERR_DEFAULT** (default)

32.2.6.3 T_PCIE2_RP_ERPTCAP_UCERR_MK (0x108h)

This is the Uncorrectable Error Mask register.

Offset: 108h | Read/Write: R/W

Bit	R/W	Reset	Description
31:21	R	0	Reserved
20	R/W	0h	**T_PCIE2_RP_ERPTCAP_UCERR_MK_UNSUP_REQ_ERR**: NOTE: this field is reset by Cold Reset 0h **UNSUP_REQ_ERR_NOT_MASKED** (default) 1h **UNSUP_REQ_ERR_MASKED**
19	R/W	0h	**T_PCIE2_RP_ERPTCAP_UCERR_MK_ECRC_ERR**: NOTE: this field is reset by Cold Reset 0h **ECRC_ERR_NOT_MASKED** (default) 1h **ECRC_ERR_MASKED**
18	R/W	0h	**T_PCIE2_RP_ERPTCAP_UCERR_MK_MF_TLP**: NOTE: this field is reset by Cold Reset 0h **MF_TLP_NOT_MASKED** (default) 1h **MF_TLP_MASKED**
17	R/W	0h	**T_PCIE2_RP_ERPTCAP_UCERR_MK_RCV_OVFL**: NOTE: this field is reset by Cold Reset 0h **RCV_OVFL_NOT_MASKED** (default) 1h **RCV_OVFL_MASKED**
16	R/W	0h	**T_PCIE2_RP_ERPTCAP_UCERR_MK_UNEXP_COMP**: NOTE: this field is reset by Cold Reset 0h **UNEXP_COMP_NOT_MASKED** (default) 1h **UNEXP_COMP_MASKED**
15	R/W	0h	**T_PCIE2_RP_ERPTCAP_UCERR_MK_COMP_ABORT**: NOTE: this field is reset by Cold Reset 0h **COMP_ABORT_NOT_MASKED** (default) 1h **COMP_ABORT_MASKED**

32.2.6.8 T_PCIE2_RP_ERPTCAP_HDR_LOG_DW0 (0x11Ch)

This register is 16 bytes. The header is captured such that the fields of the header read by software in the same way the headers are presented in the spec, when the register is read using dword accesses. Therefore, byte 0 of the header is located in byte 3 of the Header Log register, byte 1 of the header is in the byte 2 of the header Log register and so forth.

Offset: 11Ch | Read/Write: R

Bit	R/W	Reset	Description
31:0	R	None	**T_PCIE2_RP_ERPTCAP_HDR_LOG_DW0_0**:

32.2.6.9 T_PCIE2_RP_ERPTCAP_HDR_LOG_DW1 (0x120h)

Offset: 120h | Read/Write: R

Bit	R/W	Reset	Description
31:0	R	None	**T_PCIE2_RP_ERPTCAP_HDR_LOG_DW0_1**:

32.2.6.10 T_PCIE2_RP_ERPTCAP_HDR_LOG_DW2 (0x124h)

Offset: 124h | Read/Write: R

Bit	R/W	Reset	Description
31:0	R	None	**T_PCIE2_RP_ERPTCAP_HDR_LOG_DW0_2**:

32.2.6.11 T_PCIE2_RP_ERPTCAP_HDR_LOG_DW3 (0x128h)

Offset: 128h | Read/Write: R

Bit	R/W	Reset	Description
31:0	R	None	**T_PCIE2_RP_ERPTCAP_HDR_LOG_DW0_3**:

32.2.6.12 T_PCIE2_RP_ERPTCAP_ERR_CMD (0x12Ch)

This is the Root Error Command register.

Offset: 12Ch | Read/Write: R/W

Bit	R/W	Reset	Description
31:3	R	0	Reserved
2	R/W	0h	**T_PCIE2_RP_ERPTCAP_ERR_CMD_FATAL_ERR_RPT_EN**: 0h **FATAL_ERR_RPT_EN_FALSE** (default) 1h **FATAL_ERR_RPT_EN_TRUE**

0	R/W	0h	**T_PCIE2_RP_ERPTCAP_ERR_CMD_COR_ERR_RPT_EN**: 0h **COR_ERR_RPT_EN_FALSE** (default) 1h **COR_ERR_RPT_EN_TRUE**

32.2.6.13 T_PCIE2_RP_ERPTCAP_ERR_STS (0x130h)

This is the Root Error Status register.

Offset: 130h | Read/Write: R/W

Bit	R/W	Reset	Description
31:27	R	None	**T_PCIE2_RP_ERPTCAP_ERR_STS_ADV_ERR_INTR_MSG_NUM**: If this function is allocated more than one MSI interrupt number, this register is required to contain the offset between the base message data and the MSI message that is generated when any of the status bits of this capacbility are set. HW is required to update this field so that it is correct if the number of MSI messages assigned to the device changes. 1h **ADV_ERR_INTR_MSG_NUM_ONE**
26:7	R/W	0	Reserved
6	RW1C	0h	**T_PCIE2_RP_ERPTCAP_ERR_STS_FATAL_RCVD**: Set when one or more fatal uncorrectable error messages have been received. NOTE: this field is reset by Cold Reset 0h **FATAL_RCVD_FALSE** (default) 1h **FATAL_RCVD_TRUE** 1h **FATAL_RCVD_CLEAR**

Bit	R/W	Reset	Description
5	RW1C	0h	**T_PCIE2_RP_ERPTCAP_ERR_STS_NONFATAL_RCVD**: Set when one or more non-fatal uncorrectable error messages have been received. NOTE: this field is reset by Cold Reset 0h **NONFATAL_RCVD_FALSE** (default) 1h **NONFATAL_RCVD_TRUE** 1h **NONFATAL_RCVD_CLEAR**
4	RW1C		**T_PCIE2_RP_ERPTCAP_ERR_STS_FIRST_FATAL_RCVD**: Set when the first uncorrectable error message received is for a fatal error. NOTE: this field is reset by Cold Reset 0h **FIRST_FATAL_RCVD_FALSE** (default) 1h **FIRST_FATAL_RCVD_TRUE** 1h **FIRST_FATAL_RCVD_CLEAR**
3	RW1C		**T_PCIE2_RP_ERPTCAP_ERR_STS_MULT_UNCOR_RCVD**: Set when either a fatal or a non-fatal error is received and UNCOR_RCVD is already set. NOTE: this field is reset by Cold Reset 0h **MULT_UNCOR_RCVD_FALSE** (default) 1h **MULT_UNCOR_RCVD_TRUE** 1h **MULT_UNCOR_RCVD_CLEAR**
2	RW1C		**T_PCIE2_RP_ERPTCAP_ERR_STS_UNCOR_RCVD**: Set when either a fatal or a non-fatal error message is received and this bit is not already set. NOTE: this field is reset by Cold Reset 0h **UNCOR_RCVD_FALSE** (default) 1h **UNCOR_RCVD_TRUE** 1h **UNCOR_RCVD_CLEAR**
1	RW1C		**T_PCIE2_RP_ERPTCAP_ERR_STS_MULT_COR_RCVD**: Set when a correctable error message is received and COR_RCVD is already set. NOTE: this field is reset by Cold Reset 0h **MULT_COR_RCVD_FALSE** (default) 1h **MULT_COR_RCVD_TRUE** 1h **MULT_COR_RCVD_CLEAR**
0	RW1C		**T_PCIE2_RP_ERPTCAP_ERR_STS_COR_RCVD**: Set when a correctable error message is received and this bit is not already set NOTE: this field is reset by Cold Reset 0h **COR_RCVD_FALSE** (default) 1h **COR_RCVD_TRUE** 1h **COR_RCVD_CLEAR**

32.2.6.14 T_PCIE2_RP_ERPTCAP_ERR_ID (0x134h)

This is the Error Source Identification register. This register identifies the source (Requestor ID) of first correctable and uncorrectable (non-fatal/fatal) errors reported in the Root Error Status register.

Offset: 134h | Read/Write: R

Bit	R/W	Reset	Description
31:16	R	None	**T_PCIE2_RP_ERPTCAP_ERR_ID_ERR_COR**: 0h **ERR_COR_DEFAULT** (default)
15:0	R	None	**T_PCIE2_RP_ERPTCAP_ERR_ID_ERR_UNCOR**: 0h **ERR_UNCOR_DEFAULT** (default)

32.2.6.15 T_PCIE2_RP_PRIV_XP_DL_0 (0x494h)

The T_PCIE2_RP_PRIV_XP_DL_0 register controls various configurable registers in the Data Link layer.

Offset: 494h | Read/Write: R/W

Bit	R/W	Reset	Description
31:30	R	0	Reserved
29:19	R/W	0h	**T_PCIE2_RP_PRIV_XP_DL_0_GEN2_REPLAY_TIMER_LIMIT**: Setting this register to a non-zero value will cause the DL to use the programmed value as the replay timer limit instead of the default value which is based on the negotiated width as described in section 3.5.2.1 of the PCI Express Base Specification, Rev 1.0a. The replay timer limit corresponds to the Unadjusted Replay Transmission Latency Limit listed in table 3-4 of the spec, except that it should include the Rx_L0s_Adjustment. This register takes effect in 5.0GT/s speed of operation when T_PCIE2_RP_PRIV_XP_DL_1_GEN2_DL_TIMERS_DISABLE is programmed to 0. It has no effect when T_PCIE2_RP_PRIV_XP_DL_1_GEN2_DL_TIMERS_DISABLE is programmed to 1. 0h **GEN2_REPLAY_TIMER_LIMIT_INIT** (default)
18.10	R/W	0h	**T_PCIE2_RP_PRIV_XP_DL_0_GEN2_ACK_TIMER_LIMIT**: Setting this register to a non-zero value will cause the DL to use the programmed value as the ack timer limit instead of the default value which is based on the negotiated width as described in section 3.5.3.1 of the PCI Express Base Specification, Rev 1.0a. The ack timer limit corresponds to the Unadjusted Ack Transmission Latency Limit listed in table 3-5 of the spec,except that it should include the Tx_L0s_Adjustment, and should *not* include the Internal Delay. This register takes effect in 5.0GT/s speed of operation when T_PCIE2_RP_PRIV_XP_DL_1_GEN2_DL_TIMERS_DISABLE is programmed to 0. It has no effect when T_PCIE2_RP_PRIV_XP_DL_1_GEN2_DL_TIMERS_DISABLE is programmed to 1. 0h **GEN2_ACK_TIMER_LIMIT_INIT** (default)
9:1	R/W	0h	**T_PCIE2_RP_PRIV_XP_DL_0_GEN2_UPDATE_FC_THRESHOLD**: Setting this register to a non-zero value will cause the DL to use the programmed value as the update fc frequency instead of the default value which is based on the negotiated width as described in section 2.6.1.2 of the PCI Express Base Specification, Rev 2.0. This register takes effect in 5.0GT/s speed of operation when T_PCIE2_RP_PRIV_XP_DL_1_GEN2_DL_TIMERS_DISABLE is programmed to 0. It has no effect when T_PCIE2_RP_PRIV_XP_DL_1_GEN2_DL_TIMERS_DISABLE is programmed to 1. 0h **GEN2_UPDATE_FC_THRESHOLD_INIT** (default)
0	R/W	0	**T_PCIE2_RP_PRIV_XP_DL_0_GEN2_DL_TIMERS_DISABLE**: Setting this register enables the Gen2 DL timer settings to take effect in 5.0GT/s speed of operation. 0h **GEN2_DL_TIMERS_DISABLE_INIT** (default)

32.2.6.16 T_PCIE2_RP_PIPE_CTL (0xD5Ch)

This register controls (enabling /disabling) the pipelines added to meet timing on various interfaces. A value of 0 disable the extra pipeline.

Offset: D5Ch | Read/Write: R/W

Bit	R/W	Reset	Description
31:9	R	0	Reserved
8	R/W	1h	**T_PCIE2_RP_PIPE_CTL_UFA2WRR_PWTOP**: 1h **UFA2WRR_PWTOP_INIT** (default)
7	R/W	1h	**T_PCIE2_RP_PIPE_CTL_UBFI2DFI_P2P**: 1h **UBFI2DFI_P2P_INIT** (default)
6	R/W	1h	**T_PCIE2_RP_PIPE_CTL_TXBA2DFI_WR**: 1h **TXBA2DFI_WR_INIT** (default)

Bit	R/W	Reset	Description
5	R/W	1h	**T_PCIE2_RP_PIPE_CTL_CMDQ2UFARB**: 1h **CMDQ2UFARB_INIT** (default)
4	R/W	1h	**T_PCIE2_RP_PIPE_CTL_UBFI2DFI_NTT**: 1h **UBFI2DFI_NTT_INIT** (default)
3	R/W	1h	**T_PCIE2_RP_PIPE_CTL_PCA**: 1h **PCA_INIT** (default)
2	R/W	1h	**T_PCIE2_RP_PIPE_CTL_DFIREQ**: 1h **DFIREQ_INIT** (default)
1	R/W	1h	**T_PCIE2_RP_PIPE_CTL_DFIRSP**: 1h **DFIRSP_INIT** (default)
0	R/W	1h	**T_PCIE2_RP_PIPE_CTL_DFI2UBFI**: 1h **DFI2UBFI_INIT** (default)

32.2.7 Vendor-Defined Registers

32.2.7.1 T_PCIE2_RP_RX_HDR_LIMIT (0xE00h)

These register defines the upstream header logical partition sizes. These buffers reside in UBFI. RXL provides the write interface. The buffers constitute asynchronous boundary of xclk -> ufpci_clk.

Offset: E00h | Read/Write: R/W

Bit	R/W	Reset	Description
31:24	R	0	Reserved
23:16	R/W	0h	**T_PCIE2_RP_RX_HDR_LIMIT_CPL**: Programs the size of the Completion Header Buffer. This field must be programmed with an even value. 0h **CPL_INIT** (default)
15:8	R/W	0h	**T_PCIE2_RP_RX_HDR_LIMIT_PW**: Programs the size of the Posted Write Header Buffer. When ISO PWs are enabled, this register must be halved, and programmed before both ufpci_reset_ and xreset_. This field must be programmed with an even value. 0h **PW_INIT** (default)
7:0	R/W	0h	**T_PCIE2_RP_RX_HDR_LIMIT_NP**: Programs the size of the Non-Posted (Read and Write) Header Buffer. When ISO NPs are enabled, this register must be halved, and programmed before both ufpci_reset_ and xreset_. This field must be programmed with an even value. 0h **NP_INIT** (default)

32.2.7.2 T_PCIE2_RP_RX_DATA_LIMIT (0xE04h)

These buffers reside in UBFI. RXL provides the write interface. The buffers constitute asynchronous boundary of xclk -> ufpci_clk.

Offset: E04h | Read/Write: R/W

Bit	R/W	Reset	Description
31:28	R	0	Reserved

Bit	R/W	Reset	Description
27:20	R/W	0h	**T_PCIE2_RP_RX_DATA_LIMIT_CPL**: Programs the size of the Completions Data Buffer. This field must be programmed with an even value. 0h **CPL_INIT** (default)
19:8	R/W	0h	**T_PCIE2_RP_RX_DATA_LIMIT_PW**: Programs the size of the Posted Writes Data Buffer. When ISO PWs are enabled, this register must be halved, and programmed before both ufpci_reset_ and xreset_. This field must be programmed with an even value. 0h **PW_INIT** (default)
7:0	R/W	0h	**T_PCIE2_RP_RX_DATA_LIMIT_NP**: Programs the size of the Non-Posted Write Header Buffer. This field must be programmed with an even value. 0h **NP_INIT** (default)

32.2.7.3 T_PCIE2_RP_TX_HDR_LIMIT (0xE08h)

These buffers reside in TXBA. DFI provides the write interface. These buffers constitute an asynchronous boundary of dfpci_clk -> xclk.

Offset: E08h | Read/Write: R/W

Bit	R/W	Reset	Description
31:24	R	0	Reserved
23:16	R/W	0h	**T_PCIE2_RP_TX_HDR_LIMIT_NP**: Programs the size of the downstream Non Posted Header Buffer. This should be programmed with same value as TX_DATA_LIMIT_NP. 0h **NP_INIT** (default)
15:8	R/W	0h	**T_PCIE2_RP_TX_HDR_LIMIT_PW**: Programs the size of the downstream Posted Writes Header Buffer. 0h **PW_INIT** (default
7:0	R/W	0h	**T_PCIE2_RP_TX_HDR_LIMIT_NP**: Programs the size of the downstream Non Posted Header Buffer. This should be programmed with same value as TX_DATA_LIMIT_NP. 0h **NP_INIT** (default)

32.2.7.4 T_PCIE2_RP_TX_DATA_LIMIT (0xE0Ch)

These buffers reside in TXBA. DFI provides the write interface. These buffers constitute an asynchronous boundary of dfpci_clk -> xclk.

Offset: E0Ch | Read/Write: R/W

Bit	R/W	Reset	Description
31:16	R	0	Reserved
15:8	R/W	0h	**T_PCIE2_RP_TX_DATA_LIMIT_PW**: Programs the size of the downstream Posted Writes Data Buffer. 0h **PW_INIT** (default)
7:0	R/W	0h	**T_PCIE2_RP_TX_DATA_LIMIT_NP**: Programs the size of the downstream Non Posted Data Buffer. This should be programmed with same value as TX_HDR_LIMIT_NP. 0h **NP_INIT** (default)

32.2.7.5 T_PCIE2_RP_UFPCI (0xE10h)

This register controls upstream FPCI control and arbitration in UBFI and performance fields.

Offset: E10h | Read/Write: R/W

Bit	R/W	Reset	Description
31:28	R	0	Reserved
27:23	R/W	0h	**T_PCIE2_RP_UFPCI_ISO_WEIGHT**: 0h **ISO_WEIGHT_INIT** (default)
22	R/W	0h	**T_PCIE2_RP_UFPCI_ISO_CONTROL_ENABLE**: 0h **ISO_CONTROL_ENABLE_INIT** (default)
21	R/W	0h	**T_PCIE2_RP_UFPCI_ISOPW2HPISO**: If set, converts posted writes with TC >= tc2isomap to HP_ISO writes instead of ISO writes. 0h **ISOPW2HPISO_INIT** (default)
20	R/W	0h	**T_PCIE2_RP_UFPCI_ISONP2HPISO**: If set, converts nonposted reads with TC >= tc2isomap to HP_ISO reads instead of ISO reads. 0h **ISONP2HPISO_INIT** (default)
19:12	R/W	0h	**T_PCIE2_RP_UFPCI_REQ_PEND_PERIOD**: The following timers are reset when they hit the value in REQ_PEND_PERIOD 1. noniso_timer - feeds into tms*2sm_iso_pending if system_stutter is supported 2. iso_timer - feeds into tms*2sm_noniso_pending if system_stutter is supported 3. coh_timer - feeds into tms*2sm_coh_request_pend 4. noncoh_timer - feeds into tms*2sm_noncoh_request_pend 0h **REQ_PEND_PERIOD_INIT** (default)
11:10	R/W	1h	**T_PCIE2_RP_UFPCI_WRR_GRANT_BURST**: This field controls the length of time for which a particular controller gets arbitration within a TMS. It relates to time multiplexed inter-TMS arbitration for controllers within a TMS. 1h **WRR_GRANT_BURST_INIT** (default)
9:5	R/W	0h	**T_PCIE2_RP_UFPCI_PW_PRI_OVR_COUNT**: If a PW has received this number of grants when the priority was swapped to PW, it's priority will be reset. 0h **PW_PRI_OVR_COUNT_INIT** (default)
4:0	R/W	0h	**T_PCIE2_RP_UFPCI_PW_STARV_COUNT**: If an NP has received this number of grants over PW while there are PW pending, then swap the priority to PW. 0h **PW_STARV_COUNT_INIT** (default)

32.2.7.6 T_PCIE2_RP_MISC0 (0xE14h)

This register controls miscellaneous fields.

Offset: E14h | Read/Write: R/W

Bit	R/W	Reset	Description
31	R/W	0h	**T_PCIE2_RP_MISC0_SHORT_RXL_TIMER**: This bit is used for simulations only, to test the completion timeout feature in RXL. It shortens the wait period for a completion to 1 Us. 0h **SHORT_RXL_TIMER_INIT** (default)
30	R/W	0h	**T_PCIE2_RP_MISC0_P2P_SMALL_ISA_HOLE**: When set, this bit controls the peer2peer settings on address ranges 64'hA_0000 to 64'hF_FFFF. It is used to omit address ranges A, B, C, D, E and F from being peer2peer. 0h **P2P_SMALL_ISA_HOLE_INIT** (default)

Bit	R/W	Reset	Description
29	R/W	0h	**T_PCIE2_RP_MISC0_P2P_F**: If 0 and P2P_SMALL_ISA_HOLE=1, all transactions falling within ranges 64'hF_0000 and 64'hF_FFFF will have the fpci2ufa_cmd_peer2peer bit equal to 0. Else the fpci2ufa_cmd_peer2peer bit will be set according to TOM1 and TOM2 registers. 0h **P2P_F_INIT** (default)
28	R/W	0h	**T_PCIE2_RP_MISC0_P2P_E**: If 0 and P2P_SMALL_ISA_HOLE=1, all transactions falling within ranges 64'hE_0000 and 64'hE_FFFF will have the fpci2ufa_cmd_peer2peer bit equal to 0. Else the fpci2ufa_cmd_peer2peer bit will be set according to TOM1 and TOM2 registers. 0h **P2P_E_INIT** (default)
27	R/W	0h	**T_PCIE2_RP_MISC0_P2P_D**: If 0 and P2P_SMALL_ISA_HOLE=1, all transactions falling within ranges 64'hD_0000 and 64'hD_FFFF will have the fpci2ufa_cmd_peer2peer bit equal to 0. Else the fpci2ufa_cmd_peer2peer bit will be set according to TOM1 and TOM2 registers. 0h **P2P_D_INIT** (default)
26	R/W	0h	**T_PCIE2_RP_MISC0_P2P_C**: If 0 and P2P_SMALL_ISA_HOLE=1, all transactions falling within ranges 64'hC_0000 and 64'hC_FFFF will have the fpci2ufa_cmd_peer2peer bit equal to 0. Else the fpci2ufa_cmd_peer2peer bit will be set according to TOM1 and TOM2 registers. 0h **P2P_C_INIT** (default)
25	R/W	0h	**T_PCIE2_RP_MISC0_P2P_B**: If 0 and P2P_SMALL_ISA_HOLE=1, all transactions falling within ranges 64'hB_0000 and 64'hB_FFFF will have the fpci2ufa_cmd_peer2peer bit equal to 0. Else the fpci2ufa_cmd_peer2peer bit will be set according to TOM1 and TOM2 registers. 0h **P2P_B_INIT** (default)
24	R/W	0h	**T_PCIE2_RP_MISC0_P2P_A**: If 0 and P2P_SMALL_ISA_HOLE=1, all transactions falling within ranges 64'hA_0000 and 64'hA_FFFF will have the fpci2ufa_cmd_peer2peer bit equal to 0. Else the fpci2ufa_cmd_peer2peer bit will be set according to TOM1 and TOM2 registers. 0h **P2P_A_INIT** (default)
23	R/W	0h	**T_PCIE2_RP_MISC0_NISONC2HPISO**: When set, all upstream Noniso, Non-coherent, Non-peer2peer reads will be upgraded to HPISO Reads. This upgrade is available for all controllers in a TMS if any one of the controllers has iso buffers. 0h **NISONC2HPISO_INIT** (default)
22	R	0	Reserved
21	R/W	1h	**T_PCIE2_RP_MISC0_AUTO_XCLK_FREQ_EN**: When set, the xclk for a TMS will switch dynamically (by HW itself) between 250 and 500. 250 if all root-ports in that TMS are in Gen1. 500 If any root-port in that TMS is in Gen2. This bit is valid only for Root Port 0 of that TMS, and dont care for others. 1h **AUTO_XCLK_FREQ_EN_INIT** (default)
20	R/W	0h	**T_PCIE2_RP_MISC0_RXL_CLEAR_DROP**: Clears the DROP ALL status of the receiver. DROP ALL occurs on fatal errors such as Receiver Overflow and Malformed TLPs. Once set, RXL will not allow any other transactions upstream. 0h **RXL_CLEAR_DROP_INIT** (default)
19:4	R/W	FFh	**T_PCIE2_RP_MISC0_P2P_BURST_SIZE**: Unused/unconnected. FFh **P2P_BURST_SIZE_INIT** (default)
3	R/W	0h	**T_PCIE2_RP_MISC0_ISO_PW_ENABLE**: Enables ISO PW transactions for packets with TC >= TC2ISOMAP, on controllers that have iso buffers. 0h **ISO_PW_ENABLE_INIT** (default)

Bit	R/W	Reset	Description
2	R/W	1h	**T_PCIE2_RP_MISC0_ISO_NP_ENABLE**: Enables ISO NP transactions for packets with TC >= TC2ISOMAP, on controllers that have iso buffers. 0h **ISO_NP_ENABLE_INIT** (default)
1	R/W	0h	**T_PCIE2_RP_MISC0_NATIVE_P2P_ENABLE**: Enables native peer2peer transactions on controllers that support it. Posted Write peer2peer transactions will use a shortcut through the design to enable high performance peer2peer accesses. 0h **NATIVE_P2P_ENABLE_INIT** (default)
0	R/W	0h	**T_PCIE2_RP_MISC0_ENABLE_CLUMPING**: When set, enables unitid clumping on controllers that support it. Controllers that support unitid clumping will resort to using it's unitid+1 and an additional 32 sourcetags when it has exhausted it's allotted use of first 32 sourcetags. 0h **ENABLE_CLUMPING_INIT** (default)

32.2.7.7 T_PCIE2_RP_TXBA0 (0xE18h)

This register is specific to the TXBA sub-unit in PCIe 2.0 and controls: 1. Replay buffer limits 2. Completion merging limits 3. Replay timer control fields

Offset: E18h | Read/Write: R/W

Bit	R/W	Reset	Description
31:16	R/W	0h	**T_PCIE2_RP_TXBA0_REPLAY_TIMER_EXPIRY**: When TXBA0_USE_REPLAY_TIMER_OFFSET is 1, the value programmed into TXBA0_REPLAY_TIMER_EXPIRY is added to the replay timer that HW calculates. When this bit is 0, the value in TXBA0_REPLAY_TIMER_EXPIRY is selected (if its non-zero) instead of HW value. 0h **REPLAY_TIMER_EXPIRY_INIT** (default)
15:13	R	0	Reserved
12	R/W	0h	**T_PCIE2_RP_TXBA0_USE_REPLAY_TIMER_OFFSET**: 0h **USE_REPLAY_TIMER_OFFSET_INIT** (default)
11	R/W	0h	**T_PCIE2_RP_TXBA0_CMPL_MERGE_UPTO_64DW**: Similar to above field, but the upper limit is 64 DW. When neither 32DW/64DW is set, nor completion merging is enabled, maximum merging supported is 128DW. 0h **CMPL_MERGE_UPTO_64DW_INIT** (default)
10	R/W	0h	**T_PCIE2_RP_TXBA0_CMPL_MERGE_UPTO_32DW**: When set, split completions that have payloads upto 32DW will be merged. Completions that belong to the same read request, but have payloads greater than 32DW will have one fragment merged upto 32DW, in addition to one or more packets containing the rest of the payload (which will also be merged using the same rule). 0h **CMPL_MERGE_UPTO_32DW_INIT** (default)
9	R/W	1h	**T_PCIE2_RP_TXBA0_CMPL_MERGE_DISABLE**: Disables completion merging. By default, completion merging is disabled. 1h **CMPL_MERGE_DISABLE_INIT** (default)
8:0	R/W	0h	**T_PCIE2_RP_TXBA0_REPLAY_BUF_LIMIT**: This register exists per controller. It decides how much of the replay buffer (which is shared among all the controller in a tms) is used for the controller. Range of values can be anything from 0 (when controller is disabled) to full depth of the replay buffer size (when there are no other controllers). 0h **REPLAY_BUF_LIMIT_INIT** (default)

32.2.7.8 T_PCIE2_RP_TXBA1 (0xE1Ch)

This register is specific to the TXBA sub-unit in PCIe 2.0 and controls: 1. Replay buffer limits 2. Completion merging limits 3. Replay timer control fields

Offset: E1Ch | Read/Write: R/W

Bit	R/W	Reset	Description
31:16	R	0	Reserved
15:8	R/W	0	**T_PCIE2_RP_TXBA1_CMPL_MERGE_THRESHOLD**: Completion merging is enabled only if the number of valid completions exceeds this programmed register. This is used to control the bandwidth vs. latency consideration. The maximum meaningful value of this field is the maximum number of outstanding completions (which is also size of header buffer allocated to the controller). 0h **CMPL_MERGE_THRESHOLD_INIT** (default)
7:4	R/W	0h	**T_PCIE2_RP_TXBA1_CM_OVER_PW_BURST**: These fields are inputs into the downstream arbiter. If there are bunch of downstream PW and downstream CM, txba arbiter runs PW_OVER_CM_BURST many PW before switching to CM. Once it starts running completions, it runs CM_OVER_PW_BURST completions before switching back to PW. 0h **CM_OVER_PW_BURST_INIT** (default)
3:0	R	0	Reserved

32.2.7.9 T_PCIE2_RP_FORCEFC (0xE20h)

This register updates FC priority flip threshold. Updated FCs become high priority (equivalent priority to UpdateFC timer expiring) if the number of outstanding credits to return for each type exceeds the set threshold.

If the threshold is set to 0, this feature is disabled.

Offset: E20h | Read/Write: R/W

Bit	R/W	Reset	Description
31:24	R/W	0h	**T_PCIE2_RP_FORCEFC_NPD_UNRET_THRESH**: 0h **NPD_UNRET_THRESH_INIT** (default)
23:16	R/W	0h	**T_PCIE2_RP_FORCEFC_NPH_UNRET_THRESH**: 0h **NPH_UNRET_THRESH_INIT** (default)
15:8	R/W	0h	**T_PCIE2_RP_FORCEFC_PWD_UNRET_THRESH**: 0h **PWD_UNRET_THRESH_INIT** (default)
7:0	R/W	0h	**T_PCIE2_RP_FORCEFC_PWH_UNRET_THRESH**: 0h **PWH_UNRET_THRESH_INIT** (default)

32.2.7.10 T_PCIE2_RP_TIMEOUT0 (0xE24h)

This is the LINK LTSSM Timeout 0 register.

Offset: E24h | Read/Write: R/W

Bit	R/W	Reset	Description
31:24	R/W	Dh	**T_PCIE2_RP_TIMEOUT0_PAD_SPDCHNG_GEN2**: Amount of time to wait for pads to change speed from Gen1 to Gen2. Measured in units of 1us. Dh **PAD_SPDCHNG_GEN2_INIT** (default)

Bit	R/W	Reset	Description
23:8	R/W	1F4	**T_PCIE2_RP_TIMEOUT0_PAD_PWRUP_CM**: Amount of time to wait for pads to power up (e.g. L1 wake) if common-mode voltage was not maintained during power down (i.e. L1P). Measured in units of 40ns. 1F4h **PAD_PWRUP_CM_INIT** (default)
7:0	R/W	Dh	**T_PCIE2_RP_TIMEOUT0_PAD_PWRUP**: Amount of time to wait for pads to power up (e.g. L1 wake) if common-mode voltage was maintained during power down (i.e. L1). Measured in units of 40ns. Dh **PAD_PWRUP_INIT** (default)

32.2.7.11 T_PCIE2_RP_TIMEOUT1 (0xE28h)

This is the LINK LTSSM Timeout 1 register.

Offset: E28h | Read/Write: R/W

Bit	R/W	Reset	Description
31:24	R/W	96h	**T_PCIE2_RP_TIMEOUT1_RCVRY_SPD_UNSUCCESS_EIDLE**: Amount of time to wait in E-Idle after unsuccessful speed change. Measured in units of 40ns. 96h **RCVRY_SPD_UNSUCCESS_EIDLE_INIT** (default)
23:16	R/W	14h	**T_PCIE2_RP_TIMEOUT1_RCVRY_SPD_SUCCESS_EIDLE**: Amount of time to wait in E-Idle after successful speed change. Measured in units of 40ns. 14h **RCVRY_SPD_SUCCESS_EIDLE_INIT** (default)
15:0	R/W	2E8h	**T_PCIE2_RP_TIMEOUT1_PAD_SPDCHNG_GEN1**: Amount of time to wait for pads to change speed from Gen2 to Gen1. Measured in units of 1us. 2E8h **PAD_SPDCHNG_GEN1_INIT** (default)

32.2.7.12 T_PCIE2_RP_PRBS (0xE34h)

This is the PRBS Results register.

Offset: E34h | Read/Write: R

Bit	R/W	Reset	Description
31:16	R	None	**T_PCIE2_RP_PRBS_LOCKED**: Each bit indicates that particular lane has locked onto the incoming PRBS pattern and is beginning to count bit errors. For example, if LOCKED[n] is set, lane n has successfully locked onto the incoming PRBS pattern.
15:0	R	None	**T_PCIE2_RP_PRBS_ERR_COUNT_OVERFLOW**: Each bit indicates number of bit mismatches during PRBS run exceeded 65K for that particular lane. For example, if ERR_COUNT_OVERFLOW[n] is set, lane n registers > 65K bit mismatches.

32.2.7.13 T_PCIE2_RP_PRBS_ERR_COUNT (0xE38h)

This is the PRBS Results register.

Offset: E38h | Read/Write: R/W

Bit	R/W	Reset	Description
31:16	R	0h	**T_PCIE2_RP_LANE_PRBS_ERR_COUNT**: Number of bit errors detected in the incoming PRBS stream after achieving PRBS lock for the selected lane programmed in ERR_SELECT register.
15:4	R	0	Reserved

Bit	R/W	Reset	Description
3:0	R/W	0h	**T_PCIE2_RP_LANE_PRBS_ERR_SELECT**: Selects which lane number's Error Count shows up in the ERR_COUNT register 0h **SELECT_INIT** (default)

32.2.7.14 T_PCIE2_RP_EIDLE_INFER_TO_0 (0xE3Ch)

This is an EIDLE inference timeout register.

Offset: E3Ch | Read/Write: R/W

Bit	R/W	Reset	Description
31:16	R/W	500h	**T_PCIE2_RP_EIDLE_INFER_TO_0_RCVRCFG_SUC_SPEED**: Infer E-Idle after this amount of time while in Recovery.RcvrCfg or Recovery. Speed and successful_speed_negotiation = 1. Measured in units of UI (rx symbol times). 500h **RCVRCFG_SUC_SPEED_INIT** (default)
15:0	R/W	80h	**T_PCIE2_RP_EIDLE_INFER_TO_0_L0_LPBK**: Infer E-Idle after this amount of time while in L0 or Loopback. Active Slave. Measured in units of µs. 80h **L0_LPBK_INIT** (default)

32.2.7.15 T_PCIE2_RP_EIDLE_INFER_TO_1 (0xE40h)

This is an EIDLE inference timeout register.

Offset: E40h | Read/Write: R/W

Bit	R/W	Reset	Description
31:16	R/W	3E80h	**T_PCIE2_RP_EIDLE_INFER_TO_1_UNSUC_SPEED_GEN2**: Infer E-Idle after this amount of time while in Recovery. Speed and successful_speed_negotiation = 0 and operating in Gen2 Speed. Measured in units of UI (rx symbol times). 3E80h **UNSUC_SPEED_GEN2_INIT** (default)
15:0	R/W	7D0h	**T_PCIE2_RP_EIDLE_INFER_TO_1_UNSUC_SPEED_GEN1**: Infer E-Idle after this amount of time while in Recovery. Speed and successful_speed_negotiation = 0 and operating in Gen1 Speed. Measured in units of UI (rx symbol times). 7D0h **UNSUC_SPEED_GEN1_INIT** (default)

32.2.7.16 T_PCIE2_RP_LTSSM_DBGREG (0xE44h)

This is the LTSSM debug register.

Offset: E44h | Read/Write: R/W

Bit	R/W	Reset	Description
31	RW1C	0h	**T_PCIE2_RP_LTSSM_DBGREG_LINKFSM31**: 0h **LINKFSM31_INIT** (default) 1h **LINKFSM31_CLEAR**
30	RW1C	0h	**T_PCIE2_RP_LTSSM_DBGREG_LINKFSM30**: 0h **LINKFSM30_INIT** (default) 1h **LINKFSM30_CLEAR**
29	RW1C	0h	**T_PCIE2_RP_LTSSM_DBGREG_LINKFSM29**: 0h **LINKFSM29_INIT** (default) 1h **LINKFSM29_CLEAR**

Bit	R/W	Reset	Description
28	RW1C	0h	**T_PCIE2_RP_LTSSM_DBGREG_LINKFSM28**: 0h **LINKFSM28_INIT** (default) 1h **LINKFSM28_CLEAR**
27	RW1C	0h	**T_PCIE2_RP_LTSSM_DBGREG_LINKFSM27**: 0h **LINKFSM27_INIT** (default) 1h **LINKFSM27_CLEAR**
26	RW1C	0h	**T_PCIE2_RP_LTSSM_DBGREG_LINKFSM26**: 0h **LINKFSM26_INIT** (default) 1h **LINKFSM26_CLEAR**
25	RW1C	0h	**T_PCIE2_RP_LTSSM_DBGREG_LINKFSM25**: 0h **LINKFSM25_INIT** (default) 1h **LINKFSM25_CLEAR**
24	RW1C	0h	**T_PCIE2_RP_LTSSM_DBGREG_LINKFSM24**: 0h **LINKFSM24_INIT** (default) 1h **LINKFSM24_CLEAR**
23	RW1C	0h	**T_PCIE2_RP_LTSSM_DBGREG_LINKFSM23**: 0h **LINKFSM23_INIT** (default) 1h **LINKFSM23_CLEAR**
22	RW1C	0h	**T_PCIE2_RP_LTSSM_DBGREG_LINKFSM22**: 0h **LINKFSM22_INIT** (default) 1h **LINKFSM22_CLEAR**
21	RW1C	0h	**T_PCIE2_RP_LTSSM_DBGREG_LINKFSM21**: 0h **LINKFSM21_INIT** (default) 1h **LINKFSM21_CLEAR**
20	RW1C	0h	**T_PCIE2_RP_LTSSM_DBGREG_LINKFSM20**: 0h **LINKFSM20_INIT** (default) 1h **LINKFSM20_CLEAR**
19	RW1C	0h	**T_PCIE2_RP_LTSSM_DBGREG_LINKFSM19**: 0h **LINKFSM19_INIT** (default) 1h **LINKFSM19_CLEAR**
18	RW1C	0h	**T_PCIE2_RP_LTSSM_DBGREG_LINKFSM18**: 0h **LINKFSM18_INIT** (default) 1h **LINKFSM18_CLEAR**
17	RW1C	0h	**T_PCIE2_RP_LTSSM_DBGREG_LINKFSM17**: 0h **LINKFSM17_INIT** (default) 1h **LINKFSM17_CLEAR**
16	RW1C	0h	**T_PCIE2_RP_LTSSM_DBGREG_LINKFSM16**: 0h **LINKFSM16_INIT** (default) 1h **LINKFSM16_CLEAR**
15	RW1C	0h	**T_PCIE2_RP_LTSSM_DBGREG_LINKFSM15**: 0h **LINKFSM15_INIT** (default) 1h **LINKFSM15_CLEAR**
14	RW1C	0h	**T_PCIE2_RP_LTSSM_DBGREG_LINKFSM14**: 0h **LINKFSM14_INIT** (default) 1h **LINKFSM14_CLEAR**
13	RW1C	0h	**T_PCIE2_RP_LTSSM_DBGREG_LINKFSM13**: 0h **LINKFSM13_INIT** (default) 1h **LINKFSM13_CLEAR**

Bit	R/W	Reset	Description
12	RW1C	0h	**T_PCIE2_RP_LTSSM_DBGREG_LINKFSM12**: 0h **LINKFSM12_INIT** (default) 1h **LINKFSM12_CLEAR**
11	RW1C	0h	**T_PCIE2_RP_LTSSM_DBGREG_LINKFSM11**: 0h **LINKFSM11_INIT** (default) 1h **LINKFSM11_CLEAR**
10	RW1C	0h	**T_PCIE2_RP_LTSSM_DBGREG_LINKFSM10**: 0h **LINKFSM10_INIT** (default) 1h **LINKFSM10_CLEAR**
9	RW1C	0h	**T_PCIE2_RP_LTSSM_DBGREG_LINKFSM9**: 0h **LINKFSM9_INIT** (default) 1h **LINKFSM9_CLEAR**
8	RW1C	0h	**T_PCIE2_RP_LTSSM_DBGREG_LINKFSM8**: 0h **LINKFSM8_INIT** (default) 1h **LINKFSM8_CLEAR**

32.2.7.19 T_PCIE2_RP_LTSSM_TRACE_CONTROL (0xE50h)

This is the LTSSM Trace Control register. Ltssm state changes are stored in a RAM. This register controls storing of this change in the ram.

Offset: E50h | Read/Write: R/W

Bit	R/W	Reset	Description
31:14	R	0	Reserved
13:11	R/W	0h	**T_PCIE2_RP_LTSSM_TRACE_CONTROL_TRIG_PRX_LTSSM_MINOR**: 0h **TRIG_PRX_LTSSM_MINOR_INIT** (default)
10:8	R/W	0h	**T_PCIE2_RP_LTSSM_TRACE_CONTROL_TRIG_PTX_LTSSM_MINOR**: 0h **TRIG_PTX_LTSSM_MINOR_INIT** (default)

Bit	R/W	Reset	Description
7:4	R/W	0h	**T_PCIE2_RP_LTSSM_TRACE_CONTROL_TRIG_LTSSM_MAJOR**: 0h **TRIG_LTSSM_MAJOR_INIT** (default)
3	R/W	0h	**T_PCIE2_RP_LTSSM_TRACE_CONTROL_TRIG_ON_EVENT**: when this bit is set, ltssm changes will start storing only after its state has reached the state specified in T_PCIE2_RP_LTSSM_TRACE_CONTROL_TRIG_LTSSM_MAJOR, T_PCIE2_RP_LTSSM_TRACE_CONTROL_TRIG_PTX_LTSSM_MINOR and T_PCIE2_RP_LTSSM_TRACE_CONTROL_TRIG_PRX_LTSSM_MINOR state. T_PCIE2_RP_LTSSM_ 0h **TRIG_ON_EVENT_INIT** (default)
2	R/W	0h	**T_PCIE2_RP_LTSSM_TRACE_CONTROL_CLEAR_RAM**: When written with 1, will clear all entries in ram. 0h **CLEAR_RAM_INIT** (default)
1	R/W	0h	**T_PCIE2_RP_LTSSM_TRACE_CONTROL_WRAP_EN**: When this bit is set ram is updated every time ltssm state change happens irrespective of whether write pointer has wrapped around. When this bit is clear ram update is stopped when ram is full. Ram need to be cleared by writing to T_PCIE2_RP_LTSSM_TRACE_CONTROL_CLEAR_RAM before it can start storing new trace. 0h **WRAP_EN_INIT** (default) 0h **WRAP_EN_CLEAR** 1h **WRAP_EN_SET**
0	R/W	1h	**T_PCIE2_RP_LTSSM_TRACE_CONTROL_STORE_EN**: This bit controls whether RAM need to be updated whenever ltssm_state change happens. 1h **STORE_EN_INIT** (default) 0h **STORE_EN_CLEAR** 1h **STORE_EN_SET**

32.2.7.20 T_PCIE2_RP_LTSSM_TRACE_STATUS (0xE54h)

This register helps to check the LTSSM trace which has been stored in RAM.

Offset: E54h | Read/Write: R/W

Bit	R/W	Reset	Description
31:22	R	0	Reserved
21:19	R	None	**T_PCIE2_RP_LTSSM_TRACE_STATUS_PRX_LTSSM_MINOR**: This register returns the data prx_ltssm_minor in ltssm_trace RAM point by T_PCIE2_RP_LTSSM_TRACE_STATUS_READ_ADDR
18:16	R	None	**T_PCIE2_RP_LTSSM_TRACE_STATUS_PTX_LTSSM_MINOR**: This register returns the data ptx_ltssm_minor in ltssm_trace RAM point by T_PCIE2_RP_LTSSM_TRACE_STATUS_READ_ADDR
15:12	R	None	**T_PCIE2_RP_LTSSM_TRACE_STATUS_LTSSM_MAJOR**: This register returns the data ltssm_major in ltssm_trace RAM point by T_PCIE2_RP_LTSSM_TRACE_STATUS_READ_ADDR
11	R	None	**T_PCIE2_RP_LTSSM_TRACE_STATUS_READ_DATA_VALID**: This register returns the data_valid in ltssm_trace RAM point by T_PCIE2_RP_LTSSM_TRACE_STATUS_READ_ADDR. Data valid bit is set an entry is written to that location of ram.
10:6	R/W	0h	**T_PCIE2_RP_LTSSM_TRACE_STATUS_READ_ADDR**: This is read address to ltssm trace ram 0h **READ_ADDR_INIT** (default)
5:1	R	None	**T_PCIE2_RP_LTSSM_TRACE_STATUS_WRITE_PTR**: This field indicates the current location of write pointer. This is especially useful when writing to this RAM is enabled even when ram is full and write pointer is allowed to wrap around.

Bit	R/W	Reset	Description
0	R	None	**T_PCIE2_RP_LTSSM_TRACE_STATUS_RAM_FULL**: This field indicates whether all entries in RAM have been written. This is especially useful when writing to this RAM is enabled even when RAM is full and write pointer is allowed to wrap around.

32.2.7.21 T_PCIE2_RP_PG (0xE58h)

This register helps power gate the PCIe TMS in NVIDIA-specific ways.

Offset: E58h | Read/Write: R/W

Bit	R/W	Reset	Description
31:3	R	0	Reserved
2	R/W	0h	**T_PCIE2_RP_PG_RCVD_PME_TO_ACK_INTR_EN**: This field enables generation of interrupt on reception of PME TO ACK TLP. 1h **RCVD_PME_TO_ACK_INTR_EN_ENABLED** 0h **RCVD_PME_TO_ACK_INTR_EN_DISABLED** (default)
1	R/W	0h	**T_PCIE2_RP_PG_RCVD_PME_TO_ACK**: When the root port receives a PME TO ACK TLP, it sets this field. SW can write 1 to this field to clear it to 0. NOTE: this field is reset by Cold Reset 0h **RCVD_PME_TO_ACK_INIT** (default) 1h **RCVD_PME_TO_ACK_CLEAR**
0	R/W	0h	**T_PCIE2_RP_PG_SEND_PME_TO_MSG**: Writing 1 to this field when from previous value of 0 causes the root port to send a PME TO message downstream. When the PME TO message is sent to lower stages of the root port (txtf), this field is automatically cleared to 0 by the root port. 0h **SEND_PME_TO_MSG_INIT** (default) 1h **SEND_PME_TO_MSG_SEND_NOW**

32.2.7.22 T_PCIE2_RP_VAR_RANGE0 (0xE5Ch)

The PCIe Legacy I/O Decode Range Control Registers allow a programmable I/O address range below 4K to be redirected to a PCIe bus downstream from a RP. This is normally not possible due to the definition of the standard I/O Base/Limit registers in the P2P register set. The purpose is to allow legacy devices on PCIe endpoints to operate at their PC legacy default address ranges.

The range is controlled by a pair of generic 12-bit base/limit address register. The ranges can be mapped anywhere in the lower 4K I/O address space. I/O addresses above 4K can be allocated via standard PCI PnP mechanisms.

Offset: E5Ch | Read/Write: R/W

Bit	R/W	Reset	Description
31:18	R/W	0h	**T_PCIE2_RP_VAR_RANGE0_LIMIT**: Top address for the variable range positive decode addresses. This will be set to the highest address in the range that the PCIE RP is to decode. Both this range and the base must be set properly for any cycles to be decoded. LIMIT[1:0] always 11'b 0h **LIMIT_DEFAULT** (default)
17:16	R	0h	**T_PCIE2_RP_VAR_RANGE0_RSVD1**: 0h **RSVD1_ZER0** (default)

Bit	R/W	Reset	Description
15:2	R/W	0h	**T_PCIE2_RP_VAR_RANGE0_BASE**: Base address for the variable range positive decode addresses. This will be set to the lowest address in the range that the PCIE RP is to decode. Both the base and the limit must be set properly for any cycles to be decoded. BASE must be DWORD aligned 0h **BASE_DEFAULT** (default)
1	R	0h	**T_PCIE2_RP_VAR_RANGE0_RSVD0**: 0h **RSVD0_ZER0** (default)
0	R/W	0h	**T_PCIE2_RP_VAR_RANGE0_ENABLE**: If set then positively decode the variable I/O address range defined in T_PCIE2_VAR_RANGE0. 1h **ENABLE_YES** 0h **ENABLE_NO** (default)

32.2.7.23 T_PCIE2_RP_VAR_RANGE1 (0xE60h)

The PCIe Legacy I/O Decode Range Control Registers allow a programmable I/O address range below 4K to be redirected to a PCIe bus downstream from a RP. This is normally not possible due to the definition of the standard I/O Base/Limit registers in the P2P register set. The purpose is to allow legacy devices on PCIe endpoints to operate at their PC legacy default address ranges.

The range is controlled by a pair of generic 12-bit base/limit address register. The ranges can be mapped anywhere in the lower 4K I/O address space. I/O addresses above 4K can be allocated via standard PCI PnP mechanisms.

Offset: E60h | Read/Write: R/W

Bit	R/W	Reset	Description
31:18	R/W	0h	**T_PCIE2_RP_VAR_RANGE1_LIMIT**: Top address for the variable range positive decode addresses. This will be set to the highest address in the range that the PCIe RP is to decode. Both this range and the base must be set properly for any cycles to be decoded. LIMIT[1:0] always 11'b 0h **LIMIT_DEFAULT** (default)
17:16	R	0h	**T_PCIE2_RP_VAR_RANGE1_RSVD1**: 0h **RSVD1_ZER0** (default)
15:2	R/W	0h	**T_PCIE2_RP_VAR_RANGE1_BASE**: Base address for the variable range positive decode addresses. This will be set to the lowest address in the range that the PCIe RP is to decode. Both the base and the limit must be set properly for any cycles to be decoded. BASE must be DWORD aligned 0h **BASE_DEFAULT** (default)
1	R	0h	**T_PCIE2_RP_VAR_RANGE1_RSVD0**: 0h **RSVD0_ZER0** (default)
0	R/W	0h	**T_PCIE2_RP_VAR_RANGE1_ENABLE**: If set then positively decode the variable I/O address range defined in T_PCIE2_RP_VAR_RANGE1. 1h **ENABLE_YES** 0h **ENABLE_NO** (default)

32.2.7.24 T_PCIE2_RP_VEND_XP (0xF00h)

This register contains fields unique to NVIDIA's implementation of PCI Express devices.

Offset: F00h | Read/Write: R/W

Bit	R/W	Reset	Description
31	R/W	0h	**T_PCIE2_RP_VEND_XP_FORCE_COMPLIANCE**: 0h **FORCE_COMPLIANCE_INIT** (default)
30	R	None	**T_PCIE2_RP_VEND_XP_DL_UP**: This read-only bit tells status of Data Link Layer in XP. This bit was added before the DL Link Active Reporting feature was introduced in the official PCI-Express Specification. It asserts when the DL enters the InitFC2 phase of training. This means that DL_UP will assert before the DL_LINK_ACTIVE bit asserts.
29	R/W	0h	**T_PCIE2_RP_VEND_XP_INTERLEAVE_DLLPS**: Setting this bit will cause the DL to schedule Ack and UpdateFC packets earlier or later than their respective timer expiration times in order to decrease the likelihood of losing efficiency by sending two DLLPs consecutively. 0h **INTERLEAVE_DLLPS_INIT** (default)
28	R/W	0h	**T_PCIE2_RP_VEND_XP_OPPORTUNISTIC_UPDATEFC**: If this bit is set, the DL will send any pending UpdateFC packet whenever it has nothing else to send, instead of waiting for the UpdateFC timer to expire. 0h **OPPORTUNISTIC_UPDATEFC_INIT** (default)
27	R/W	0h	**T_PCIE2_RP_VEND_XP_OPPORTUNISTIC_ACK**: If this bit is set, the DL will send pending Acks whenever it has nothing else to send, instead of waiting for the Ack Timer to expire. 0h **OPPORTUNISTIC_ACK_INIT** (default)
26	R/W	0h	**T_PCIE2_RP_VEND_XP_TRAIN_ERR_ENABLE**: Enables reporting of training errors. 0h **TRAIN_ERR_ENABLE_INIT** (default)
25:18	R/W	0h	**T_PCIE2_RP_VEND_XP_UPDATE_FC_THRESHOLD**: This field specifies an override for the UpdateFC frequency. Setting this field to a non-zero value will cause the TL to use the programmed value MULTIPLIED BY TWO as the UpdateFC timer limit instead of the default value which is based on the negotiated width as described in section 2.6.1.2 of the PCI Express Base Specification, Rev 1.0a. The UpdateFC timer limit corresponds to the UpdateFC Transmission Latency Limit listed in table 2-28 of the specification, except that it should *not* include the InternalDelay. 0h **UPDATE_FC_THRESHOLD_INIT** (default)
17:2	R	None	**T_PCIE2_RP_VEND_XP_PRBS_STAT**: This field returns the results of loopback mode testing. Each bit represents the status of one lane (1 == PASS).
1	R/W	0h	**T_PCIE2_RP_VEND_XP_PRBS_EN**: Enables the root port as loopback master using PRBS-23 as the test pattern. 0h **PRBS_EN_DISABLED** (default) 1h **PRBS_EN_ENABLED**
0	R/W	0h	**T_PCIE2_RP_VEND_XP_EMULATION**: Enables emulation mode operation. 0h **EMULATION_OFF** (default) 1h **EMULATION_ON**

32.2.7.25 T_PCIE2_RP_VEND_XP1 (0xF04h)

This register contains fields unique to NVIDIA's implementation of PCI Express devices.

Offset: F04h | Read/Write: R/W

Bit	R/W	Reset	Description
31:29	R/W	2h	**T_PCIE2_RP_VEND_XP1_L1_EXIT_LATENCY**: This field indicates the L1 exit latency for the given PCI Express Link. The value reported indicates the lenght of time this Port requires to complete transition from L1 to L0. The value is reflected in the LINK_CAPABILITIES register. Defined encodings are: • 000b Less than 1 µs. • 001b 1 us to less than 2 µs. • 010b 2 us to less than 4 µs. • 011b 4 us to less than 8 µs. • 100b 8 us to less than 16 µs. • 101b 16 us to less than 32 µs. • 110b 32 us-64 µs. • 111b More than 64 µs. 2h **L1_EXIT_LATENCY_INIT** (default) 0h **L1_EXIT_LATENCY_LT_1** 1h **L1_EXIT_LATENCY_LT_2** 2h **L1_EXIT_LATENCY_LT_4** 3h **L1_EXIT_LATENCY_LT_8** 7h **L1_EXIT_LATENCY_GT_64**
28	R/W	0h	**T_PCIE2_RP_VEND_XP1_FORCE_DOWNSTREAM_NO_SNOOP**: When this bit is set and ENABLE_NO_SNOOP bit is also set, NO_SNOOP bit is set on all downstream TLPs (except for IO and cfg, for which NO_SNOOP is never set) 1h **FORCE_DOWNSTREAM_NO_SNOOP_YES** 0h **FORCE_DOWNSTREAM_NO_SNOOP_NO** (default)
27	R/W	0h	**T_PCIE2_RP_VEND_XP1_FORCE_UPSTREAM_NONCOH**: When set this bit causes all upstream memory traffic (except MSI) to be non-coherent. 0h **FORCE_UPSTREAM_NONCOH_INIT** (default) 1h **FORCE_UPSTREAM_NONCOH_ENABLED** 0h **FORCE_UPSTREAM_NONCOH_DISABLED**
26:19	R/W	0h	**T_PCIE2_RP_VEND_XP1_LINK_PVT_CTL**: bit[0] : ACK_L1_NO_WAIT Enable behavior described in the proposed errata to 5.3.2.1 of 1.0a specification. If this bit is set to 1 on an upstream component, that component will not wait to accumulate the minimum number of credits required to send the largest possible packet for any FC type before sending PM_Request_Ack DLLPs downstream. After receiving a PM_Enter_L1 DLLP, it will begin sending PM_Request_Ack DLLPs as soon as it has received acknowledgement for the last TLP that has been sent. bit[1] : L23_READY_NO_D3 Enable entry into the L2/3 Ready state when the component is not in the D3 PMCSR state. If this bit is set to 0, the component will not allow the link to enter the L2/3 Ready state if it is not in D3. If the bit is set to 1, the link will enter L2/3 Ready after the component receives a PME_Turn_Off message, regardless of the PMCSR state. bit[2] : L1_ASPM_SUPPORT This bit determines the reported value of L1 ASPM support in the link capability register (ACTIVE_STATE_LINK_PM_SUPPORT, bit 11). bit[3] : DONT_MERGE_PMASNAK With the default setting for this bit (0), a group of PM_Active_State_Request_L1 DLLPs from the endpoint will cause a single PM_ASPM_Nak TLP to be sent. If this bit is set to 1, multiple PM_ASPM_Nak TLP messages will be sent, possibly as many as one PM_ASPM_Nak TLP for each PM_Active_State_Request_L1 DLLP. bit[4] : IGNORE_L0S This bit overrides the L0s setting for the Active Sate PM Control register. If bit[4] == 0 (do not override), then bit 0 of the T_PCIE2_RP_LINK_CONTROL_STATUS register is used to determine if our Tx side drivers should enter L0s or not. If bit[4] == 1 (override), then we ignore bit 0 of T_PCIE2_RP_LINK_CONTROL_STATUS, and never enter Tx.L0s. bit[7] : NP_REQ_TIMEOUT If set, disable downstream NP request timeout. This is for debug purposes when we want to hang instead of timeout. 0h **LINK_PVT_CTL_INIT** (default)

Bit	R/W	Reset	Description
18:10	R/W	0h	**T_PCIE2_RP_VEND_XP1_ACK_TIMER_LIMIT**: This field overrides the Ack Timer Limit for this root port. Setting this field to a non-zero value will cause the DL to use the programmed value for the Ack Timer Limit instead of the default value, which is based on the negotiated width as described in section 3.5.3.1 of the PCI Express Base Specification, Rev 1.0a. The Ack Timer Limit corresponds to the Unadjusted Ack Transmission Latency Limit listed in table 3-5 of the specification, except that it should include the Tx_L0s_Adjustment, and should *not* include the InternalDelay. 0h **ACK_TIMER_LIMIT_INIT** (default)
9	R	0	Reserved
8	R/W	1h	**T_PCIE2_RP_VEND_XP1_RNCTRL_GEN2_WAIT_FOR_FIRST_EIES**: When this bit is programmed to 1, in the Config.LinkWidth.Start state, the inactive lanes that are activated will wait for the next EIEOS transmission before sending the first packet. If programmed to 0, it will not wait for the next EIEOS transmission before sending the first packet. 1h **RNCTRL_GEN2_WAIT_FOR_FIRST_EIES_INIT** (default)
7	R	0h	**T_PCIE2_RP_VEND_XP1_RNCTRL_EN**: When this bit is programmed to a 1, it triggers the dynamic link width re-negotiation procedure in XP. This bit is a constant and always returns a value of 0 on a read. 0h **RNCTRL_EN_ZERO** (default)
6	R/W	1h	**T_PCIE2_RP_VEND_XP1_RNCTRL_GEN2_LINK_UPGRADE**: When this bit is programmed to 1, it selects the 2.0-compliant link width upgrade protocol. If programmed to 0, it selects the NV-proprietary link width upgrade protocol. 1h **RNCTRL_GEN2_LINK_UPGRADE_INIT** (default)
5:0	R/W	10h	**T_PCIE2_RP_VEND_XP1_RNCTRL_MAXWIDTH**: This field inidcates the maximum link width required at the end of dynamic link width re-negotiation process. The default value is 16. 10h **RNCTRL_MAXWIDTH_INIT** (default)

32.2.7.26 T_PCIE2_RP_VEND_XP2 (0xF08h)

This register contains fields unique to NVIDIA's implementation of PCI Express devices.

Offset: F08h | Read/Write: R/W

Bit	R/W	Reset	Description
31:24	R/W	0h	**T_PCIE2_RP_VEND_XP2_L0S_UPDATE_WAKE**: Setting this field to a non-zero value will cause the DL to wake the PL out of L0s in advance of sending it an UpdateFC packet. When the DL sees that there are fewer cycles left in the UpdateFC timer than the value in the L0S_UPDATE_WAKE register, it will tell the PL to wake out of L0s. 0h **L0S_UPDATE_WAKE_INIT** (default)
23:18	R	0	Reserved
17:8	R/W	3FFh	**T_PCIE2_RP_VEND_XP2_L0S_THRESHOLD**: This field controls the idle time required for TxL0s entry from L0, in symbol times (250 MHz clocks). Once the XP detects that it has no more DLLPs/TLPs to send, it will insert precisely (L0S_THRESHOLD + 1) logical idles between the END symbol of the last DLLP/TLP and the COM of the IDL Ordered Set. If L0S_THRESHOLD == 0x3FF, the L0s entry latency is instead (endpoint N_FTS)*4 symbol times, where (endpoint N_FTS) is the N_FTS value advertised by the endpoint during training. Therefore, the threshold can be set to anywhere from 1 to 1023 symbol times (4ns to 4092ns). 3FFh **L0S_THRESHOLD_INIT** (default) 3FFh **L0S_THRESHOLD_REMOTE_NFTS**
7:0	R/W	0h	**T_PCIE2_RP_VEND_XP2_L0S_ACK_WAKE**: Setting this field to a non-zero value will cause the DL to wake the PL out of L0s in advance of sending it an Ack packet. When the DL sees that there are fewer cycles left in the Ack timer than the value in the L0S_ACK_WAKE register, it will tell the PL to wake out of L0s. 0h **L0S_ACK_WAKE_INIT** (default)

32.2.7.27 T_PCIE2_RP_VEND_XV_TIMEOUT (0xF0Ch)

This register contains fields unique to NVIDIA's implementation of PCI Express devices.

Offset: F0Ch | Read/Write: R/W

Bit	R/W	Reset	Description
31:24	R/W	0300 00FAh	Reserved

32.2.7.28 T_PCIE2_RP_VEND_SLOT_STRAP (0xF20h)

This register contains fields unique to NVIDIA's implementation of PCI Express devices.

This is a back-door register used to set various bits in the Slot Capabilities Register, which is part of the PCI-Express Capability Structure, as defined by the PCI-Express Specification. The bits listed here map 1:1 with the bits in the Slot Capabilities Register.

NOTE: Bits marked "Reserved" may actually be writable in some chips. Therefore writes to this register must not change the default POR values for the bits marked "Reserved".

Offset: F20h | Read/Write: R/W

Bit	R/W	Reset	Description
31:19	R/W	0h	**T_PCIE2_RP_VEND_SLOT_STRAP_PHYSICAL_SLOT_NUMBER**: The physical numbering of the slots is left up to the board designer. The board designer must communicate the physical slot numbers to the SBIOS developer as well. 0h **PHYSICAL_SLOT_NUMBER_INIT** (default)
18:17	R	0	Reserved
16:15	R/W	0h	**T_PCIE2_RP_VEND_SLOT_STRAP_SLOT_POWER_LIMIT_SCALE**: This field must be programmed according to the unique power-rail capabilities of each board design. Board designers are responsible for communicating the power limits of each slot to the SBIOS developers. 0h **SLOT_POWER_LIMIT_SCALE_INIT** (default)
14:7	R/W	0h	**T_PCIE2_RP_VEND_SLOT_STRAP_SLOT_POWER_LIMIT_VALUE**: This field must be programmed according to the unique power-rail capabilities of each board design. Board designers are responsible for communicating the power limits of each slot to the SBIOS developers. 0h **SLOT_POWER_LIMIT_VALUE_INIT** (default)
6:0	R	0	Reserved

32.2.7.29 T_PCIE2_RP_VEND_CTL1 (0xF48h)

This register contains fields unique to NVIDIA's implementation of PCI Express devices. This is a control register for general feature and function control.

Offset: F48h | Read/Write: R/W

Bit	R/W	Reset	Description
31:22	R	0	Reserved
21	R/W	1h	**T_PCIE2_RP_VEND_CTL1_POLLING_RESET_FIX_EN**: 1h **POLLING_RESET_FIX_EN_INIT** (default) 1h **POLLING_RESET_FIX_EN_ENABLE** 0h **POLLING_RESET_FIX_EN_DISABLE**

Bit	R/W	Reset	Description
20	R/W	1h	**T_PCIE2_RP_VEND_CTL1_HOTPLUG_IN_TRAFFIC_EN**: 1h **HOTPLUG_IN_TRAFFIC_EN_INIT** (default) 1h **HOTPLUG_IN_TRAFFIC_EN_ENABLE** 0h **HOTPLUG_IN_TRAFFIC_EN_DISABLE**
19	R/W	0h	**T_PCIE2_RP_VEND_CTL1_NISO2ISO**: When set to 1, all upstream non-iso-pw and non-iso-np will be upgraded to ISO. 0h **NISO2ISO_INIT** (default) 1h **NISO2ISO_ENABLE** 0h **NISO2ISO_DISABLE**
18	R/W	0h	**T_PCIE2_RP_VEND_CTL1_ALLOW_UPSTREAM_CMPL_OVERTAKE_PW**: When set to 1, UBFI allows cpl bypass pw regardless of RO bit 0h **ALLOW_UPSTREAM_CMPL_OVERTAKE_PW_DIS** (default) 1h **ALLOW_UPSTREAM_CMPL_OVERTAKE_PW_EN**
17	R/W	0h	**T_PCIE2_RP_VEND_CTL1_SPLIT_ARB_BLOCK_COH**: When set to 0, take the single ufpci2fpci_arb_block_coherent as input. When set to 1, take the separate inputs of ufa2fpci_arb_block_coherent_pw and ufa2fpci_arb_block_coherent_np. 0h **SPLIT_ARB_BLOCK_COH_INIT** (default) 0h **SPLIT_ARB_BLOCK_COH_DIS** 1h **SPLIT_ARB_BLOCK_COH_EN**
16	R/W	0h	**T_PCIE2_RP_VEND_CTL1_HIDE_MSIMAP**: 0h **HIDE_MSIMAP_DIS** (default) 1h **HIDE_MSIMAP_EN**
15	R/W	1h	**T_PCIE2_RP_VEND_CTL1_LINKACTV_REPORTING**: This is a backdoor bit for setting the Data Link Layer Link Active Reporting Capable bit (bit 20 of the Link Capabilities Register). This bit *MUST* be set whenever hot-plug is enabled. Otherwise, it can be set as desired. 1h **LINKACTV_REPORTING_CAPABLE** (default) 0h **LINKACTV_REPORTING_NOT_CAPABLE**
14	R/W	1h	**T_PCIE2_RP_VEND_CTL1_P2P_ISO2NISO**: If set, forces upstream peer-to-peer ISO requests to be peer-to-peer NONISO. 1h **P2P_ISO2NISO_EN** (default) 0h **P2P_ISO2NISO_DIS**
13	R/W	0h	**T_PCIE2_RP_VEND_CTL1_ERPT**: This bit, when 0, hides the entire AER Capability structure from the capabilities list. It causes the "next pointer" of the previous capability to point to NULL. Normally, AER is the last capability in the list. 1h **ERPT_EN** 0h **ERPT_DIS** (default)
12	R/W	0h	**T_PCIE2_RP_VEND_CTL1_HIDE_MSI_CAP**: This bit, when 1, hides the entire MSI Capability structure from the capabilities list. It causes the "next pointer" of the previous capability to point to the capability that comes after MSI. 0h **HIDE_MSI_CAP_DIS** (default) 1h **HIDE_MSI_CAP_EN**
11:5	R	0	Reserved
4	R/W	0h	**T_PCIE2_RP_VEND_CTL1_ACCEPT_MSGD1**: When set, allows acceptance of NVIDIA specific vendor type message with data. 0h **ACCEPT_MSGD1_DIS** (default) 1h **ACCEPT_MSGD1_EN**

Bit	R/W	Reset	Description
3:1	R/W	7h	**T_PCIE2_RP_VEND_CTL1_TC2ISO_MAP**: This field specifies TC2ISO_MAP[2:0]. Upstream traffic with TC[2:0] >= TC2ISO_MAP[2:0] are sent as ISO requests on UFPCI Since TC[2:0] == 0 can never be sent to ISO channel, TC2ISO_MAP[2:0] == 0 is used to force ALL traffic to NONISO 7h **TC2ISO_MAP_7** (default)
0	R/W	0h	**T_PCIE2_RP_VEND_CTL1_P2P_BLOCK_P2P_ONLY**: When set, ignores ufa2fpci_arb_block_coherent for upstream peer2peer requests. 1h **P2P_BLOCK_P2P_ONLY_EN** 0h **P2P_BLOCK_P2P_ONLY_DIS** (default)

32.2.7.30 T_PCIE2_RP_VEND_XP_BIST (0xF4Ch)

This register contains fields unique to NVIDIA's implementation of PCI Express devices.

IOBIST and characterization control register.

Offset: F4Ch | Read/Write: R/W

Bit	R/W	Reset	Description
31	R	0	Reserved
30	R/W	0h	**T_PCIE2_RP_VEND_XP_BIST_GOTO_DETECT_ON_SURPRISE_EIDLE**: 0h **GOTO_DETECT_ON_SURPRISE_EIDLE_INIT** (default)
29	R/W	0h	**T_PCIE2_RP_VEND_XP_BIST_ENABLE_SERR_REPORTING**: 0h **ENABLE_SERR_REPORTING_INIT** (default)
28	R/W	0h	**T_PCIE2_RP_VEND_XP_BIST_GOTO_L1_L2_AFTER_DLLP_DONE**: 0h **GOTO_L1_L2_AFTER_DLLP_DONE_INIT** (default)
27	R/W	0h	**T_PCIE2_RP_VEND_XP_BIST_CTRL_IGNORE_LPBK_EXIT**: 0h **CTRL_IGNORE_LPBK_EXIT_INIT** (default)
26	R/W	0h	**T_PCIE2_RP_VEND_XP_BIST_CTRL_RELAX_LPBK_ENTRY**: 0h **CTRL_RELAX_LPBK_ENTRY_INIT** (default)
25	R/W	0h	**T_PCIE2_RP_VEND_XP_XP_BIST_CTRL_FORCE_PRBS_RST**: 0h **INIT** (default)
24	R/W	0h	**T_PCIE2_RP_VEND_XP_FORCE_DEEMPHASIS_ADVERTISED_EN**: 0h **INIT** (default)
23	R	0h	Reserved
22	R/W	0h	**T_PCIE2_RP_VEND_XP_FORCE_RECEIVER_COMPLIANCE_EN**: 0h **INIT** (default)
21	R/W	0h	**T_PCIE2_RP_VEND_XP_FORCE_COMPLIANCE_GEN2_SPEED_EN**: 0h **INIT** (default)
20	R/W	0h	**T_PCIE2_RP_VEND_XP_BIST_FORCE_COMPLIANCE_AND_ADVERTISE_MODE**: 0h **FORCE_COMPLIANCE_AND_ADVERTISE_MODE_INIT** (default)
19:0	R	0	Reserved

32.2.7.31 T_PCIE2_RP_VEND_XP_FTS (0xF54h)

This register contains fields unique to NVIDIA's implementation of PCI Express devices.

Offset: F54h | Read/Write: R/W

Bit	R/W	Reset	Description
31:24	R/W	80h	**T_PCIE2_RP_VEND_XP_FTS_TS_DETECT_START**: 80h **TS_DETECT_START_INIT** (default)
23:16	R/W	40h	**T_PCIE2_RP_VEND_XP_FTS_FTS_DETECT_START**: This field represents the number of symbol times we wait before the root port begins looking at FTS ordered sets when exiting L0s -- the incoming data is essentially ignored during this time. 40h **FTS_DETECT_START_INIT** (default)
15:8	R	None	**T_PCIE2_RP_VEND_XP_FTS_N_FTS_REMOTE**: NV_XVE_PRIV_XP_N_FTS_REMOTE represents the N_FTS value advertised by the remote device as recorded from the N_FTS symbol of the received TS ordered sets.
7:0	R/W	1Fh	**T_PCIE2_RP_VEND_XP_FTS_N_FTS**: This field represents the N_FTS value that we advertise to the device on the other side of the link. NOTE: If this field is modified from its default (POR) value, the Replay Timer Limit in T_PCIE2_RP_VEND_XP1 must be adjusted accordingly. 1Fh **N_FTS_INIT** (default)

32.2.7.32 T_PCIE2_RP_VEND_XP_STATS0 (0xF58h)

This register contains fields unique to NVIDIA's implementation of PCI Express devices.

Offset: F58h | Read/Write: R/W

Bit	R/W	Reset	Description
31:29	R	0	Reserved
28	R/W	0h	**T_PCIE2_RP_VEND_XP_STATS0_FAILED_L0S_EXITS_INF**: When set to 1, the failed L0s exits counter accumulates indefinitely (i.e. the one millisecond timer is ignored). 0h **FAILED_L0S_EXITS_INF_INIT** (default)
27:25	R	0	Reserved
24	R	0h	**T_PCIE2_RP_VEND_XP_STATS0_FAILED_L0S_EXITS_LC**: Loads the current value from the failed L0s exits counter into the VEND_XP_STATS1 register, and then clears the failed L0s exits counter. The counter begins counting again immediately after it is cleared. Write a 1 to this field to trigger the load-and-clear operation. 0h **FAILED_L0S_EXITS_LC_INIT** (default)
23:21	R	0	Reserved
20	r/w	0h	**T_PCIE2_RP_VEND_XP_STATS0_NAKS_RCVD_INF**: When set to 1, the NAKs received counter accumulates indefinitely (i.e. the 64 microsecond timer is ignored). 0h **NAKS_RCVD_INF_INIT** (default)
19:17	R	0	Reserved
16	R	0h	Loads the current value from the NAKs received counter into the VEND_XP_STATS1 register, and then clears the NAKs received counter. The counter begins counting again immediately after it is cleared. Write a 1 to this field to trigger the load-and-clear operation. 0h **NAKS_RCVD_LC_INIT** (default)
15:13	R	0	Reserved
12	R/W	0h	**T_PCIE2_RP_VEND_XP_STATS0_CRC_ERRORS_INF**: When set to 1, the CRC error counter accumulates indefinitely (i.e. the 64 microsecond timer is ignored). 0h **CRC_ERRORS_INF_INIT** (default

Bit	R/W	Reset	Description
11:9	R	0	Reserved
8	R	0h	**T_PCIE2_RP_VEND_XP_STATS0_CRC_ERRORS_LC**: Loads the current value from the CRC error counter into the VEND_XP_STATS1 register, and then clears the CRC error counter. The counter begins counting again immediately after it is cleared. Write a 1 to this field to trigger the load-and-clear operation. 0h **CRC_ERRORS_LC_INIT** (default)
7:5	R	0	Reserved
4	R/W	0h	**T_PCIE2_RP_VEND_XP_STATS0_8B10B_ERRORS_INF**: When set to 1, the 8b/10b error counter accumulates indefinitely (i.e. the one microsecond timer is ignored). 0h **8B10B_ERRORS_INF_INIT** (default)
3:1	R	0	Reserved
0	R	0h	**T_PCIE2_RP_VEND_XP_STATS0_8B10B_ERRORS_LC**: Loads the current value from the 8b/10b error counter into the VEND_XP_STATS1 register, and then clears the 8b/10b error counter. The counter begins counting again immediately after it is cleared. Write a 1 to this field to trigger the load-and-clear operation. 0h **8B10B_ERRORS_LC_INIT** (default)

32.2.7.33 T_PCIE2_RP_VEND_XP_STATS1 (0xF5Ch)

This register contains fields unique to NVIDIA's implementation of PCI Express devices.

Offset: F5Ch | Read/Write: R

Bit	R/W	Reset	Description
31:24	R	None	**T_PCIE2_RP_VEND_XP_STATS1_8B10B_ERRORS**: Counts the number of 8b/10b errors detected in one microsecond. Saturates at 255 (counter does not roll over to 0).
23:16	R	None	**T_PCIE2_RP_VEND_XP_STATS1_CRC_ERRORS**: Counts the number of CRC errors detected in 64 microseconds. Saturates at 255 (counter does not roll over to 0).
15:8	R	None	**T_PCIE2_RP_VEND_XP_STATS1_NAKS_RCVD**: Counts the number of NAKs received from the endpoint in 64 microseconds. Saturates at 255 (counter does not roll over to 0).
7:0	R	None	**T_PCIE2_RP_VEND_XP_STATS1_FAILED_L0S_EXITS**: Counts the number of times the RX side of the XP went into Recovery in one millisecond, due to a failed attempt to exit L0s. Saturates at 255 (counter does not roll over to 0).

32.2.7.34 T_PCIE2_RP_VEND_ERROR_COUNT (0xF60h)

This register contains 8-bit saturating counters for some of RXL and TXBA reported errors.

Offset: F60h | Read/Write: R

Bit	R/W	Reset	Description
31:24	R	0	Reserved
23:16	R	None	**T_PCIE2_RP_VEND_ERROR_COUNT_REPLAY**: Counts number of times TXBA replays. Saturates at 8'hFF. Can be cleared by writing 1 to PRIV_ERRSTS_REPLAY_STARTED_ERR.

Bit	R/W	Reset	Description
15:8	R	None	**T_PCIE2_RP_VEND_ERROR_COUNT_BAD_TLP**: Counts bad tlps reported by RXL (sum of lcrcl_err and bad_seq). Saturates at 8'hFF. Can be cleared by writing 1 to ERPTCAP_CERR_BAD_TLP
7:0	R	None	**T_PCIE2_RP_VEND_ERROR_COUNT_LCRC_ERR**: Counts LCRCL Errors reported by RXL. Saturates at 8'hFF. Can be cleared by writing 1 to PRIV_ERRSTS_LCRC_ERR.

32.2.7.35 T_PCIE2_RP_CFG_MISC (0xF64h)

This register contains fields unique to NVIDIA's implementation of PCI Express devices.

Offset: F64h | Read/Write: R/W

Bit	R/W	Reset	Description
31:8	R	0	Reserved
7:0	R/W	0h	**T_PCIE2_RP_CFG_MISC_MUTE_IDLE**: MUTE mode is a power management feature in which we can gate cpu_clk and m2clk, if all the units are idle. A particular unit is idle when it has no outstanding transactions to be sent out. The MUTE_IDLE field is used to delay the idle assertion from xvr to clk. It should be programmed to cover the synchronization delay from cpuclk to m2clk. 0h **MUTE_IDLE_MIN** (default) FFh **MUTE_IDLE_MAX**

32.2.7.36 T_PCIE2_RP_PRIV_XP_INIT_RECOVERY (0xF68h)

Each new time frame, the number of 8b10b errors is counted. As soon as the number of 8b10b errors is equal to the threshold, the link is sent into recovery. If at the end of the time frame, the number of 8b10b errors is smaller than the threshold, a new time frame is started in which the 8b10b errors are counted.

Offset: F68h | Read/Write: R/W

Bit	R/W	Reset	Description
31	R/W	0h	**T_PCIE2_RP_PRIV_XP_INIT_RECOVERY_8B10B_ERROR_ENABLE**: This bit enables the feature T_PCIE2_RP_ERRORRATE_8B10B_ENABLE_OFF disables the feature T_PCIE2_RP_ERRORRATE_8B10B_ENABLE_ON enables the feature 0h **8B10B_ERROR_ENABLE_INIT** (default)
30:20	R/W	64h	**T_PCIE2_RP_PRIV_XP_INIT_RECOVERY_8B10B_ERROR_WINDOW**: Programs the timeframe in multiples of 1 microsecond. 31 23 22 1 0 T_PCIE2_RP_PRIV_XP_INIT_RECOVERY_8B10B 64h **8B10B_ERROR_WINDOW_100US** (default)
19:0	R/W	9C4h	**T_PCIE2_RP_PRIV_XP_INIT_RECOVERY_8B10B_ERROR_THRESHOLD**: Bit [21:1] programs the 8b10b error threshold. If the number of errors in the programmed timeframe is equal to the threshold, the link is sent into recovery. 9C4h **8B10B_ERROR_THRESHOLD_2500** (default)

32.2.7.37 T_PCIE2_RP_PRIV_XP_LCTRL_2 (0xF6Ch)

Offset: F6Ch | Read/Write: R/W

Bit	R/W	Reset	Description
31	R	None	**T_PCIE2_RP_PRIV_XP_LCTRL_2_UPCONFIGURE_CAPABLE**: Gen2 link width up-configure capability of remote device as recorded from data rate id of received TS ordered sets.
30	R/W	0h	**T_PCIE2_RP_PRIV_XP_LCTRL_2_REV2P0_COMPLIANCE_DIS**: To disable advertising rev2.0 support and link width up-configure capability. 0h **REV2P0_COMPLIANCE_DIS_INIT** (default)
29	R/W	1h	**T_PCIE2_RP_PRIV_XP_LCTRL_2_EIDLE_INFERENCE_EN**: To disable electrical idle inference. It is enabled by default. 1h **EIDLE_INFERENCE_EN_INIT** (default)
28	R/W	1h	**T_PCIE2_RP_PRIV_XP_LCTRL_2_SURPRISE_IDLE_USE_STAT_IDLE**: When set, use idle status signals from the pad to detect surprise electrical idle entry when running in Gen1 speed. 1h **SURPRISE_IDLE_USE_STAT_IDLE_INIT** (default)
27	R/W	1h	**T_PCIE2_RP_PRIV_XP_LCTRL_2_ALLOW_SPEED_CHANGE_FROM_L1**: When set to 1, allow speed change to be initiated from the L1 or Rx_L0s link states. 1h **ALLOW_SPEED_CHANGE_FROM_L1_INIT** (default)
26:24	R/W	0h	**T_PCIE2_RP_PRIV_XP_LCTRL_2_RECOVERY_SPEED_TIMEOUT_ADJ**: To adjust the minimum length of time the transmitter stays in electrical idle in the Recover.Sped state. The value denotes the time in microseconds added. 0h **RECOVERY_SPEED_TIMEOUT_ADJ_INIT** (default)
23:20	R/W	6h	**T_PCIE2_RP_PRIV_XP_LCTRL_2_N_EIE_SYMBOLS**: This represents the number of K28.7 symbols transmitted prior to transmitting the first FTS ordered set in the Tx.L0s.FTS state when running in Gen2 speed. 6h **N_EIE_SYMBOLS_INIT** (default)
19	R/W	0h	**T_PCIE2_RP_PRIV_XP_LCTRL_2_DEEMPHASIS_STRAP**: This is the backdoor register for BIOS to write an initial value to the HWInit register PCIE2_RP_LINK_CONTROL_STATUS_2_SELECTABLE_DEEMPHASIS. 0 = -6db 1 = -3.5db 0h **DEEMPHASIS_STRAP_INIT** (default)
18	R/W	0h	**T_PCIE2_RP_PRIV_XP_LCTRL_2_ENFORCE_DEEMPHASIS**: Forces root port to use de-emphasis value specific in Link Control 2 Selectable De-emphasis field instead of the value requested by the endpoint (advertised in TSs). This bit is reserved for endpoint. Default value is 0b. Functionality of this bit is no longer needed since TX_PEAK_R2_SEL1/SEL0 registers provide complete control over AMP/PEAK/PEAK_PRE settings in gen2. NOTE: this field is reset by Cold Reset 0h **ENFORCE_DEEMPHASIS_INIT** (default)
17	R/W	0h	**T_PCIE2_RP_PRIV_XP_LCTRL_2_POLLING_PREDETERMINED_LANES**: When set to 1, only lane 0 or 15 needs to detect an exit from electrical idle before moving from Polling.Active to Polling.Config. This bit is not yet implemented. 0h **POLLING_PREDETERMINED_LANES_DISABLE** (default)
16	R/W	0h	**T_PCIE2_RP_PRIV_XP_LCTRL_2_AUTONOMOUS_CHANGE**: When set to 1, it indicates that the Upstream port-initiated link width/speed change is not caused by a link reliability issue. 0h **AUTONOMOUS_CHANGE_INIT** (default)

Bit	R/W	Reset	Description
15:12	R	1h	**T_PCIE2_RP_PRIV_XP_LCTRL_2_DATA_RATE_SUPPORTED_REMOTE**: Gen2 data rate supported by other side as recorded from data rate identifier of received TS ordered sets. 1h **DATA_RATE_SUPPORTED_REMOTE_2P5** (default) 2h **DATA_RATE_SUPPORTED_REMOTE_5P0_2P5**
11:8	R/W	2h	**T_PCIE2_RP_PRIV_XP_LCTRL_2_DATA_RATE_SUPPORTED**: When set to 4'b01, the supported link speed reported in the Link Capabilities Register is 2.5Gb/s. When set to 4'b10, the supported link speeds reported in the Link Capabilities Register are 5.0Gb/s and 2.5Gb/s. 1h **DATA_RATE_SUPPORTED_2P5** 2h **DATA_RATE_SUPPORTED_5P0_2P5** (default)
7:4	R/W	2h	**T_PCIE2_RP_PRIV_XP_LCTRL_2_TARGET_LINK_SPEED**: Specifies the link rate to change to. This is reflected in the data rate advertised in the data rate identifier field of TS ordered sets. 1h **TARGET_LINK_SPEED_2P5** 2h **TARGET_LINK_SPEED_5P0** (default)
3	R/W	0h	**T_PCIE2_RP_PRIV_XP_LCTRL_2_CTL_TX_MARGIN_OVERRIDE**: 0h **CTL_TX_MARGIN_OVERRIDE_DISABLED** (default) 1h **CTL_TX_MARGIN_OVERRIDE_ENABLED**
2	R	0	Reserved
1	R/W	0h	**T_PCIE2_RP_PRIV_XP_LCTRL_2_ADVERTISED_RATE_CHANGE**: A write of 1 to this bit triggers the LTSSM to enter Recovery state, without setting the speed change bit, to change the advertised rate. This bit returns a value of 0 on a read. 0h **ADVERTISED_RATE_CHANGE_ZERO** (default)
0	R/W	0h	**T_PCIE2_RP_PRIV_XP_LCTRL_2_SPEED_CHANGE**: A write of 1 to this bit triggers the link speed negotiation procedure. This bit returns a value of 0 on a read. 0h **SPEED_CHANGE_ZERO** (default)

32.2.7.38 T_PCIE2_RP_PRIV_XP_PAD_PWRUP (0xF74h)

Offset: F74h | Read/Write: R/W

Bit	R/W	Reset	Description
31:24	R	0	Reserved
23:16	R/W	0h	**T_PCIE2_RP_PRIV_XP_PAD_PWRUP_PMRX_PWRUP_THRESHOLD**: It is the time to hold CDR at reset in Recovery.RcvrLock while waiting for power rails to be stable 0h **PMRX_PWRUP_THRESHOLD_INIT** (default)
15:0	R	0	Reserved

32.2.7.39 T_PCIE2_RP_PRIV_XP_RECOVERY_REASONS (0xF84h)

This register records the reasons we went into recovery. Each bit represents a different reason. Search for "recovery_reason" in the linkfsm to see what each bit means, as it's bound to change project to project. Writing a 0 clears the register and puts us into "record ALL recoveries encountered" mode. Writing a 1 clears the register and puts us into "record NEXT recovery encountered" mode. Default mode is "record ALL".

Offset: F84h | Read/Write: R/W

Bit	R/W	Reset	Description
31:0	R/W	0h	**T_PCIE2_RP_PRIV_XP_RECOVERY_REASONS_VALUE**: 0h **VALUE_INIT** (default) 0h **VALUE_REC_ALL** 1h **VALUE_REC_NEXT**

32.2.7.40 T_PCIE2_RP_PRIV_XP_RECOVERY_COUNT (0xF88h)

This register reflects the number of RECOVERY STATE entries in XP by the XVR. It is reset whenever it is read. If the count saturates before it is read then it remains saturated till it is read.

Offset: F88h | Read/Write: R

Bit	R/W	Reset	Description
31:0	R	0h	**T_PCIE2_RP_PRIV_XP_RECOVERY_COUNT_VALUE**: 0h **VALUE_INIT** (default)

32.2.7.41 T_PCIE2_RP_PRIV_XP_RX_L0S_ENTRY_COUNT (0xF8Ch)

This register reflects the number of entries from L0 to L0s at ltssm RX side. It is reset whenever it is read. If the count saturates before it is read then it remains saturated till it is read.

Offset: F8Ch | Read/Write: R

Bit	R/W	Reset	Description
31:0	R	0h	**T_PCIE2_RP_PRIV_XP_RX_L0S_ENTRY_COUNT_VALUE**: 0h **VALUE_INIT** (default)

32.2.7.42 T_PCIE2_RP_PRIV_XP_TX_L0S_ENTRY_COUNT (0xF90h)

This register reflects the number of entries from L0 to L0s at ltssm TX side. It is reset whenever it is read. If the count saturates before it is read then it remains saturated till it is read.

Offset: F90h | Read/Write: R

Bit	R/W	Reset	Description
31:0	R	0h	**T_PCIE2_RP_PRIV_XP_TX_L0S_ENTRY_COUNT_VALUE**: 0h **VALUE_INIT** (default)

32.2.7.43 T_PCIE2_RP_PRIV_XP_L1_ENTRY_COUNT (0xF94h)

This register reflects the number of entries from L0 to L1 It is reset whenever it is read. If the count saturates before it is read then it remains saturated till it is read

Offset: F94h | Read/Write: R

Bit	R/W	Reset	Description
31:0	R	0h	**T_PCIE2_RP_PRIV_XP_L1_ENTRY_COUNT_VALUE**: 0h **VALUE_INIT** (default)

32.2.7.44 T_PCIE2_RP_PRIV_XP_L1_TO_RECOVERY_COUNT (0xF98h)

This register reflects the number of entries from L1 to Recovery. It is reset whenever it is read. If the count saturates before it is read then it remains saturated till it is read.

Offset: F98h | Read/Write: R

Bit	R/W	Reset	Description
31:0	R	0h	**T_PCIE2_RP_PRIV_XP_L1_TO_RECOVERY_COUNT_VALUE**: 0h **VALUE_INIT** (default)

32.2.7.45 T_PCIE2_RP_PRIV_XP_L0_TO_RECOVERY_COUNT (0xF9Ch)

This register reflects the number of entries from L0 to Recovery. It is reset whenever it is read. If the count saturates before it is read then it remains saturated till it is read.

Offset: F9Ch | Read/Write: R/W

Bit	R/W	Reset	Description
31:9	R	0	Reserved
8	R/W	0h	**T_PCIE2_RP_PRIV_XP_L0_TO_RECOVERY_COUNT_REASON**: 0h **REASON_INIT** (default) 0h **REASON_ALL** 1h **REASON_ERR**
7:0	R	0h	**T_PCIE2_RP_PRIV_XP_L0_TO_RECOVERY_COUNT_VALUE**: 0h **VALUE_INIT** (default)

32.2.7.46 T_PCIE2_RP_PRIV_XP_L1P_ENTRY_COUNT (0xFA0h)

This register reflects the number of entries from L0 to Deep L1. It is reset whenever it is read. If the count saturates before it is read then it remains saturated till it is read.

Offset: FA0h | Read/Write: R

Bit	R/W	Reset	Description
31:0	R	0h	**T_PCIE2_RP_PRIV_XP_L1P_ENTRY_COUNT_VALUE**: 0h **VALUE_INIT** (default)

32.2.7.47 T_PCIE2_RP_PRIV_XP_ASLM_COUNT (0xFA4h)

This register reflects the number of switching between x1 and x16 for Gen2 Only. It is reset whenever it is read. If the count saturates before it is read then it remains saturated till it is read.

Offset: FA4h | Read/Write: R

Bit	R/W	Reset	Description
31:0	R	0h	**T_PCIE2_RP_PRIV_XP_ASLM_COUNT_VALUE**: 0h **VALUE_INIT** (default)

32.2.7.48 T_PCIE2_RP_RP_VEND_CTL2 (0xFA8h)

This register contains miscellaneous control fields.

Offset: FA8h | Read/Write: R/W

Bit	R/W	Reset	Description
31:25	R	0h	Reserved
24	R/W	0h	**T_PCIE2_RP_VEND_CTL2_COMPLIANCE_X8_DELAY**: CTL for compliance delay pattern If set to 0, delay pattern will wrap as soon as the pattern hits lane n - 1 where n is the max width of the controller for the current xbar configuration. This ensures that there is always at least one lane sending a delay pattern during compliance. If set to 1, delay pattern will wrap when the pattern hits lane 8 or 16 (mod 8) even if it's max width is narrower than x8. This means there will be stretches when no lane is sending a delay pattern during compliance. 0h **COMPLIANCE_X8_DELAY_INIT** (default)
23	R/W	1h	**T_PCIE2_RP_VEND_CTL2_IGNORE_ATTENTION_BUTTON_MSG**: When this bit is set, DUT will ignore upstream Attention button pressed message which has been send by endpoint. PCIe spec 1.1 specifies that we should ignore this message. 0h **IGNORE_ATTENTION_BUTTON_MSG_FALSE** 1h **IGNORE_ATTENTION_BUTTON_MSG_TRUE** (default)
22	R/W	0h	**T_PCIE2_RP_VEND_CTL2_UNBLOCK_UP_TRANSACTIONS**: When an upstream error has occured which causes all further upstream transaaction to be blocked, writing one to this bit will clean blocking of all upstream transacton. 0h **UNBLOCK_UP_TRANSACTIONS_FALSE** (default) 1h **UNBLOCK_UP_TRANSACTIONS_TRUE**
21	R/W	0h	**T_PCIE2_RP_VEND_CTL2_BLOCK_UP_TRANSACTIONS_ON_ERR**: To block all upstream transaction after an Error has been detected and forwarding of packet after the error can cause data corruption or break programming paradigm. 0h **BLOCK_UP_TRANSACTIONS_ON_ERR_EN** (default) 1h **BLOCK_UP_TRANSACTIONS_ON_ERR_DIS**
20	R/W	0h	**T_PCIE2_RP_VEND_CTL2_HW_AUTO_WIDTH_DISABLE_DIS**: To hide the LINK_CONTROL_STATUS_HW_AUTO_WIDTH_DISABLE register. 1h **HW_AUTO_WIDTH_DISABLE_DIS_TRUE** 0h **HW_AUTO_WIDTH_DISABLE_DIS_FALSE** (default)

32.2.7.58 T_PCIE2_RP_TIMEOUT2 (0xFDCh)

Offset: FDCh | Read/Write: R/W

Bit	R/W	Reset	Description
31:5	R	0	Reserved
4:0	R/W	Ah	**T_PCIE2_RP_TIMEOUT2_MIN_L1_L2_IDLE_TIME**: Sets minimum amount of time we stay in L1/L2. Holds off exit-condition detection for this amount of time (to prevent accidental wake from data before E-Idle (e.g. 2nd EIOS in Gen2) Measured in units of 4ns scaled with XCLK frequency Ah **MIN_L1_L2_IDLE_TIME_INIT** (default)

32.2.7.59 T_PCIE2_RP_PRIV_MISC (0xFE0h)

Offset: FE0h | Read/Write: R/W

Bit	R/W	Reset	Description
31	R/W	0h	**T_PCIE2_RP_PRIV_MISC_TMS_CLK_CLAMP_ENABLE**: Enables per-TMS XCLK/XTXCLK clamping using value from T_PCIE2_RP_PRIV_MISC_CLK_CLAMP_THRESHOLD to determine when to clamp. This will clamp all the logic inside a TMS shared between controllers. Note: This enable is per TMS. Use this TMS's controller 0's register to set this. 0h **TMS_CLK_CLAMP_ENABLE_INIT** (default)
30:24	R/W	3h	**T_PCIE2_RP_PRIV_MISC_TMS_CLK_CLAMP_THRESHOLD**: Number of contiguous nbref_clks (25MHz) after clamping requirements are met (L1, lanes powered down if necessary, tx FIFO empty, no eidle exit, etc) before actually clamping xclk/xtxclk. Choose a value large enough to allow all upstream transactions to clear the XP (make it into the fpci clk domain) and for the sleep signals coming from the ltssm to make it to the pads. If the value is too small, upstream transactions will get stuck in the XP and/or the sleep signals will not assert properly. The value must also be large enough so that config transactions have time to propogate from pri domain to xclk domain. Note: This enable is per TMS. Use this TMS's controller 0's register to set this. 3h **TMS_CLK_CLAMP_THRESHOLD_INIT** (default)
23	R/W	0h	**T_PCIE2_RP_PRIV_MISC_CTLR_CLK_CLAMP_ENABLE**: Enables per-controller XCLK/XTXCLK clamping using value from T_PCIE2_RP_PRIV_MISC_CTLR CLK_CLAMP_THRESHOLD to determine when to clamp. 0h **CTLR_CLK_CLAMP_ENABLE_INIT** (default)
22:16	R/W	1h	**T_PCIE2_RP_PRIV_MISC_CTLR_CLK_CLAMP_THRESHOLD**: Number of contiguous nbref_clks (25MHz) after clamping requirements are met (L1, lanes powered down if necessary, tx FIFO empty, no eidle exit, etc) before actually clamping xclk/xtxclk. Choose a value large enough to for the sleep signals coming from the ltssm to make it to the pads. If the value is too small,the sleep signals will not assert properly. 1h **CTLR_CLK_CLAMP_THRESHOLD_INIT** (default)
15:4	R	0	Reserved
3:0	R/W	Fh	**T_PCIE2_RP_PRIV_MISC_PRSNT_MAP**: Fh **PRSNT_MAP_INIT** (default)

32.2.7.60 T_PCIE2_RP_VEND_XP3 (0xFE8h)

This register is the Symbol Alignment Error Handling register.

Offset: FE8h | Read/Write: R/W

Bit	R/W	Reset	Description
31:8	R	0	Reserved

Bit	R/W	Reset	Description
7:0	R/W	3h	**T_PCIE2_RP_VEND_XP3_SA_ERROR_LIMIT**: Specifies number of misaligned COM symbols we need to see before declaring loss of Symbol Alignment. When Symbol Alignment is lost, the error bit for all subsequent symbols is asserted until 1 good COM symbol is seen. Then the error bit is deasserted and the counter tracking misaligned COM symbols is reset. Set to 0 to disable this feature. Note: Since 8b10b and symbol alignment errors are indistinguishable, symbol alignment errors (when error limit is hit) will contribute to all 8b10b error counts including the Goto Recovery on 8b10b errors feature. This is useful to speed up link retraining after losing symbol alignment. 3h **SA_ERROR_LIMIT_INIT** (default)

32.2.7.61 T_PCIE2_RP_XP_CTL_1 (0xFECh)

This register contains control registers used in XP.

Offset: FECh | Read/Write: R/W

Bit	R/W	Reset	Description
31	R	1h	Reserved
30:28	R/W	1h	**T_PCIE2_RP_XP_CTL_1_SPARE**: 1h **SPARE_INIT** (default)
27	R/W	1h	**T_PCIE2_RP_XP_CTL_1_EXIT_L1_AT_CLKREQ_ASSERTION**: When set, ltssm will exit L1 when clkreq assertion happens. NOTE : This feature only applies to downstream port 0h **EXIT_L1_AT_CLKREQ_ASSERTION_DISABLED** 1h **EXIT_L1_AT_CLKREQ_ASSERTION_ENABLED** (default)
26	R/W	1h	**T_PCIE2_RP_XP_CTL_1_NEW_IOBIST_CTRL**: This bit when set will enable control signals from iobist to take effect. Some of the control signal will be are enabling/disabling scrambling, enabling and disabling cheking for SKP symbols. 0h **NEW_IOBIST_CTRL_DISABLED** 1h **NEW_IOBIST_CTRL_ENABLED** (default)
25	R/W	0h	**T_PCIE2_RP_XP_CTL_1_OLD_IOBIST_EN**: This bit when set will enable old iobist, else it will enable new iobist. 0h **OLD_IOBIST_EN_INIT** (default)
24:19	R/W	0h	**T_PCIE2_RP_XP_CTL_1_EIOS_DEBOUNCE_TIMER**: This is number of xclk for which rx_data_en signals need to be de-asserted before asserting it again. 0h **EIOS_DEBOUNCE_TIMER_INIT** (default)
18	R/W	0h	**T_PCIE2_RP_XP_CTL_1_DISABLE_RX_LANE_AFTER_EIOS**: Disable rx_lane_en after EIOS is seen in any of the enabled lane during recovery.Rlock and Recovery.Config in order to avoid coupling. 0h **DISABLE_RX_LANE_AFTER_EIOS_INIT** (default)
17	R/W	0h	**T_PCIE2_RP_XP_CTL_1_ENABLE_DESKEW_FOR_SPDCH_NEGOTIATION**: When set to 0, forces LTSSM to disable deskew in Recovery.RcvrCfg state if the transition from Recovery.RcvrLock to RcvrCfg state is due to LTSSM detecting eight consecutive training set on any of the lanes but not all of the lanes, and speed change bit is set to 1. When set to 1, LTSSM will always enable deskew in Recovery.RcvrCfg state. 0h **ENABLE_DESKEW_FOR_SPDCH_NEGOTIATION_INIT** (default)
16	R/W	0h	**T_PCIE2_RP_XP_CTL_1_BYPASS_CONFIG_PWRUP**: When set to 0, forces LTSSM to go from Recovery.RcvrLock to Config.Pwrup if LTSSM sees training set on some but not all the active lanes. This bit only takes effect when link is operating in dynamically reduced link width and spec-defined link width resize is enabled. When set to 1, LTSSM will go from Recovery.RcvrLock to Config.LinkStart directly, bypassing Config.Pwrup, when LTSSM sees training set on some but not all the active lanes. 0h **BYPASS_CONFIG_PWRUP_INIT** (default)

Bit	R/W	Reset	Description
15	R/W	0h	**T_PCIE2_RP_XP_CTL_1_RESET_TS_CTRL_ON_ERROR**: When set to 1, in Config.LinkStart state, LTSSM will reset the internal TS_CTRL0 register if 8b10b error is present on any symbol of the training set. When set to 0, in Config.LinkStart state, LTSSM will reset the internal TS_CTRL0 register if 8b10b error is present on symbols 0, 4 or 5 only. 0h **RESET_TS_CTRL_ON_ERROR_INIT** (default)
14	R/W	0h	**T_PCIE2_RP_XP_CTL_1_RX_EIDLE_EXIT_TIMER_IN_CONFIG**: When set to 1, T_PCIE2_RP_XP_IDLE_TIMER_1_RX_EIDLE_EXIT will be applied in Config.LinkStart only. When set to 0, T_PCIE2_RP_XP_IDLE_TIMER_1_RX_EIDLE_EXIT will be applied in Config.LinkStart, Recovery and Polling. 0h **RX_EIDLE_EXIT_TIMER_IN_CONFIG_INIT** (default)
13	R/W	1h	**T_PCIE2_RP_XP_CTL_1_FORCE_RESET_IN_CONFIG**: When set to 1, LTSSM will force receiver logic to be reset when enabling lanes in Config.LinkStart state for PCIe 2.0 spec-defined link width upconfiguration. 1h **FORCE_RESET_IN_CONFIG_INIT** (default)
12	R/W	1h	**T_PCIE2_RP_XP_CTL_1_LINK_RESIZE_PWRDN_CTL**: 1h **LINK_RESIZE_PWRDN_CTL_INIT** (default)
11	R/W	1h	**T_PCIE2_RP_XP_CTL_1_ALLOW_SPEED_CHANGE_FROM_L0S**: When set to 1, LTSSM will initiate link speed/width/advertised rate change while RX side is in L0s link state. The default value of this register is 1. 1h **ALLOW_SPEED_CHANGE_FROM_L0S_INIT** (default)
10	R/W	0h	**T_PCIE2_RP_XP_CTL_1_PRESERVE_TX_PACKET_ON_DL_RETRAIN**: When set to 1, LTSSM will wait for framer to be idle before entering Recovery for DL initiated link retrain. Note: Setting this bit to 1 could prevent LTSSM to enter Recovery on a replay rollover event if the retry buffer is very full. 0h **PRESERVE_TX_PACKET_ON_DL_RETRAIN_INIT** (default)
9	R/W	0h	**T_PCIE2_RP_XP_CTL_1_PRESERVE_TX_PACKET_ON_RECOVERY**: Note: Setting this bit to 1 does not work if L1 ASPM is enabled as it will cause hang during L1 negotiation if Rootport initiate entry to Recovery. Note: During DL init sequence, if link is retrained, setting this bit to 1 would hang the chip. 0h **PRESERVE_TX_PACKET_ON_RECOVERY_INIT** (default)
8	R/W	1h	**T_PCIE2_RP_XP_CTL_1_PRESERVE_TX_PACKET_ON_WIDTH_CHANGE**: When set to 1, LTSSM will wait for framer to be idle before entering Recovery for link width change. 1h **PRESERVE_TX_PACKET_ON_WIDTH_CHANGE_INIT** (default)
7	R/W	1h	**T_PCIE2_RP_XP_CTL_1_PRESERVE_TX_PACKET_ON_SPEED_CHANGE**: When set to 1, LTSSM will wait for framer to be idle before entering Recovery for link speed change or advertised rate change. 1h **PRESERVE_TX_PACKET_ON_SPEED_CHANGE_INIT** (default)
6	R/W	0h	**T_PCIE2_RP_XP_CTL_1_RESET_LANE_ENABLE_ORIG_IN_DETECT**: This fields will allow lane_enable_original to be reset in Detect state. 0h **RESET_LANE_ENABLE_ORIG_IN_DETECT_INIT** (default)
5:2	R/W	0h	**T_PCIE2_RP_XP_CTL_1_IDLE_TO_L0_DELAY**: This fields set the number of clocks that the LTSSM will delay the transition from Recovery.Idle to L0.Normal link state or Config.Idle to L0.Normal link state. 0h **IDLE_TO_L0_DELAY_INIT** (default)

Bit	R/W	Reset	Description
1	R/W	0h	**T_PCIE2_RP_XP_CTL_1_LWLO_HUNT_ON_BAD_TS1**: When set to 1, the LWLOFSM hunt timer does not reset when any lane receives an error on the TS1 ordered set in the Config.LinkStart, Config.LinkAccept, Config.LaneWait, and Config.LaneAccept states. When set to 0, the LWLOFSM hunt timer will reset when any lane receives the first error on the TS1 ordered set after any lanes has locked and hunt timer has started counting in the Config.LinkStart, Config.LinkAccept, Config.LaneWait, and Config.LaneAccept states. 0h **LWLO_HUNT_ON_BAD_TS1_INIT** (default)
0	R/W	0h	**T_PCIE2_RP_XP_CTL_1_FORCE_SA_IN_CONFIG**: When set to 1, enables symbol alignment in Config.LinkAccept, Config.LaneWait, Config.LaneAccept, and Config.Complete states. 0h **FORCE_SA_IN_CONFIG_INIT** (default)

32.2.7.62 T_PCIE2_RP_PRIV_XP_L1BEACON (0xFF0h)

Offset: FF0h | Read/Write: R/W

Bit	R/W	Reset	Description
31:10	R	0	Reserved
9:2	R/W	0h	**T_PCIE2_RP_PRIV_XP_L1BEACON_N_EIE_SYMBOLS**: It is number of EIE symbols sent in L1 Beacon Entry/Exist state 40h **N_EIE_SYMBOLS_INIT** (default)
1	R/W	0h	**T_PCIE2_RP_PRIV_XP_L1BEACON_TX_BYP_CTRL**: 0h **TX_BYP_CTRL_DEFAULT** (default) 0h **TX_BYP_CTRL_ONLYL0** 1h **TX_BYP_CTRL_ALLLANES**
0	R/W	0h	**T_PCIE2_RP_PRIV_XP_L1BEACON_EN**: 0h **EN_DEFAULT** (default)

32.2.7.63 T_PCIE2_RP_TIMEOUT3 (0xFF4h)

Offset: FF4h | Read/Write: R/W

Bit	R/W	Reset	Description
31:24	R/W	Ch	**T_PCIE2_RP_TIMEOUT3_RX_L0S_IDLE_TIME_GEN2**: This register controls the amount of time LTSSM delays the detection of electrical idle exit in the RX_L0s state at gen2 speed of operation. Ch **RX_L0S_IDLE_TIME_GEN2_INIT** (default)
23:16	R/W	4h	**T_PCIE2_RP_TIMEOUT3_RX_L0S_IDLE_TIME_GEN1**: This register controls the amount of time LTSSM delays the detection of electrical idle exit in the RX_L0s state at gen1 speed of operation. 4h **RX_L0S_IDLE_TIME_GEN1_INIT** (default)
15:8	R/W	FFh	**T_PCIE2_RP_TIMEOUT3_TX_L0S_IDLE_TIME**: This register controls the minimum amount of time LTSSM stays in TX_L0S_IDLE state Measured in units of 40ns scaled with XCLK frequency. A setting of 8'hFF disables the delay. FFh **TX_L0S_IDLE_TIME_INIT** (default)
7:4	R/W	0h	**T_PCIE2_RP_TIMEOUT3_RX_EIDLE_EXIT_DELAY**: This register controls the amount of time the LTSSM delays the detection of TS ordered set when exiting out of electrical idle state. Each increment represents 2^X microseconds. A setting of 0 disables the delay. 0h **RX_EIDLE_EXIT_DELAY_INIT** (default)

Bit	R/W	Reset	Description
3:0	R/W	0h	**T_PCIE2_RP_TIMEOUT3_TX_EIDLE_EXIT_DELAY**: This register controls the amount of time the LTSSM delays the transmission of TS ordered sets when exiting out of electrical idle state. Unit is in microseconds. Each increment represents 2^X microseconds. A setting of 0 disables the delay. 0h **TX_EIDLE_EXIT_DELAY_INIT** (default)

32.2.7.64 T_PCIE2_RP_XP_CTL_2 (0xFF8h)

This register contains controls bits used in XP.

LOOPBACK_EXIT_THRESHOLD: This register programs the maximum amount of time spent in Loopback.Exit state as loopback slave. Unit is in xclk. The setting of 0 disables the timer in Loopback.Exit state such that loopback slave relies on detection of electrical idle data to exit from Loopback.

Default is 64 xclks.

CONFIG_LINKSTART_REQUIRE_PAD_LANE_NUM: This register forces LTSSM training set detector to require PAD in the lane number symbol of training set in Config.LinkStart state.

Offset: FF8 | Read/Write: R/W

Bit	R/W	Reset	Description
31:9	R	0	Reserved
8	R/W	0h	**T_PCIE2_RP_XP_CTL_2_CONFIG_LINKSTART_REQUIRE_PAD_LANE_NUM**: 0h **INIT** (default)
7:0	R/W	40h	**T_PCIE2_RP_XP_CTL_2_LOOPBACK_EXIT_THRESHOLD**: 40h **INIT** (default)

32.2.7.65 T_PCIE2_RP_VEND_XP_STATS2 (0xFFCh)

This register contains fields unique to NVIDIA's implementation of PCI Express devices.

Offset: FFC | Read/Write: R/W

Bit	R/W	Reset	Description
31:16	R	0	Reserved
15:0	R/W	0h	**T_PCIE2_RP_VEND_XP_STATS2_8B10B_ERR_LANEMASK**: Each individual bit represent the corresponding logical lane. When set to 1, the 8b10b error from that specific lane will be masked out from the counter in T_PCIE2_RP_VEND_XP_STATS1_8B10B_ERRORS 0h **8B10B_ERR_LANEMASK_INIT** (default) FFFEh **8B10B_ERR_LANEMASK_LN0** FFFDh **8B10B_ERR_LANEMASK_LN1** FFFBh **8B10B_ERR_LANEMASK_LN2** FFF7h **8B10B_ERR_LANEMASK_LN3** FFEFh **8B10B_ERR_LANEMASK_LN4** FFDFh **8B10B_ERR_LANEMASK_LN5** FFBFh **8B10B_ERR_LANEMASK_LN6** FF7Fh **8B10B_ERR_LANEMASK_LN7**

32.3 PCIE Root Port Interface Registers

The registers mentioned here are registers internal to AXI to FPCI wrapper target. These registers will control both AXI initiator and target block behavior.

Register Name	Description
BARi mapping, i in [0,8]	Defines the size of BARi and where BARi is mapped in AXI and FPCI address space
MSI BAR	Defines the BAR used to detect MSI accesses from upstream FPCI
Configuration	Depends on production mode
Interrupt mask	Selectively drive interrupt to MPCORE
Interrupt type	Which interrupt has occurred
Interrupt signature	Identifies the last interrupt detected by AFI
AXI field overrides	Overrides for AXI initiator fields ACACHE/AUSER/APROT
PCIe 2.0 Config/Status I/O	Static configuration inputs to PCIe 2.0 and output status signals

32.3.1.1 AXI BARi Mapping

In the register name, i ranges from 0 to 8.

Field	Bits	R/W	Reset	Description
Size	19:0	R/W	See Note 1	The size of the address range associated with BARi is in 4KB increments. Value of 0 signifies BARi is not used.

Note 1: The reset values for each BAR Size as given here:
BAR0: Size = (NV_ADDRESS_MAP_REMAP_PCIE_SIZE >> 12)
BAR1-8: 0 (disabled)

Field	R/W	R/W	Reset	Description
Start	31:12	R/W	See Note 2	The start of AXI address space for BARi. The AXI target address is compared to start/size for each BAR to determine if the access is to that BAR

Note 2: The reset values depend on the system address mapping after reset and are specific for each BAR as follows:
BAR0: (NV_ADDRESS_MAP_REMAP_PCIE_BASE >> 12)
BAR1-8: Start = 0

32.3.1.2 FPCI BARi Mapping

In the register name, i ranges from 0 to 8.

Field	Bits	R/W	Reset	Description
Start	31:4	R/W	See Note 3	The start of the FPCI address space mapped into the BARi range of PCI memory space. Bits 31:4 correspond to FPCI address bits 39:12.

Field	Bits	R/W	Reset	Description
Memory Mapped Access	0	R/W	1	Indicates if the address region is memory mapped to configuration or IO space. 1 **Memory Mapped Access** (PW only) 0 **IO/Config Access** (NWP only)

Note 3: The reset values depend on the system address mapping after reset and are specific for each BAR as follows:
BAR0: Size = (NV_ADDRESS_MAP_REMAP_PCIE_SIZE >> 12)
BAR1-8: Start = 0

32.3.1.3 MSI Bar Size

Field	Bits	R/W	Reset	Description
Size	19:0	R/W	0	The size of the address range associated with MSI BAR is in 4KB increments. Value of 0 signifies BAR is not used.

32.3.1.4 MSI FPCI BAR Start

Field	Bits	R/W	Reset	Description
Start	31:4	R/W	See Note 4	The start of upstream FPCI address space for MSI BAR. The upstream FPCI address is compared to start/4KB range for MSI BAR to determine if the access is MSI. Bits 31:4 of MSI BAR start correspond to upstream FPCI address bits 39:12.

Note 4: The reset values for MSI BAR FPCI Start = (NV_PROJ__PCIE2_RP_MSI_FPCI_BAR)

32.3.1.5 MSI AXI BAR Start

Field	Bits	R/W	Reset	Description
Start	31:12	R/W	See Note 5	The start of upstream AXI address space for MSI BAR. The upstream FPCI address is compared to start/4KB range for MSI BAR to determine if the access is MSI. Bits 31:12 of MSI BAR start correspond to upstream AXI address bits 39:12.

Note 5: The reset values for MSI BAR AXI Start = (NV_ADDRESS_MAP_EMEM_BASE >> 12)

32.3.1.6 MSI VECTORi

In the register name, i ranges from 0 to 7.

Field	Bits	R/W	Reset	Description
VECTORi	31:0	R/W	0	Each vector register corresponds to 32 of the possible 256 MSI vectors. VECTOR0 corresponds to MSI vectors 31-0. Vector7 corresponds to MSI vectors 255-223. When an upstream MSI is sent, the bit corresponding to the MSI vector is set to 1 by hardware if the corresponding enable bit is 1. The bit is set to 0 if a 1 is written to its location.

32.3.1.7 MSI ENABLE VECTORi

In the register name, i ranges from 0 to 7.

Field	Bits	R/W	Reset	Description
ENABLE VECTORi	31:0	R/W	0	Each vector register corresponds to the enable bit for 32 of the possible 256 MSI vectors. ENABLE VECTOR0 corresponds to enable bits for MSI vectors 31-0. Vector7 corresponds to enable bits for MSI vectors 255-223. When an upstream MSI is sent, the bit corresponding to the MSI vector is set to 1 by hardware if the corresponding enable bit is 1.

32.3.1.8 Configuration

Bits	R/W	Reset	Description
16	R	0	PE2 PRESENT. PCIe slot 1 present pin, when 0 indicates a PCIe card is present in the slot
15:14	R/W	10b	Reserved
13	R	0	PE1 PRESENT. PCIe slot 1 present pin, when 0 indicates a PCIe card is present in the slot
12	R	0	PE0 PRESENT. PCIe slot 0 present pin, when 0 indicates a PCIe card is present in the slot
11	R	1	Target Read Idle. This read-only bit provides status reads to AFI target. A value of 1b indicates there are no outstanding reads to downstream FPCI.
10	R	1	Target Write Idle. This read-only bit provides status writes to AFI target. A value of 1b indicates there are no outstanding writes to downstream FPCI.
9	R	1	MSI Vector Empty . This read-only bit provides status on whether MSI vector registers have any active bits.
6:1	R/W	0	Reserved
0	R/W	0	Enable FPCI When the PCI device block is disabled, it is completely invisible on the PCI bus, i.e. it doesn't even process PCI configuration accesses. Note: This bit qualifies device_disable_t0c0, device_disable_t0c1 and device_disable_t0c2 of PCIe 2.0.

32.3.1.9 CLKGATE HYSTERESIS

Bit	R/W	Reset	Description
7:0	R/W	20	CLK_DISABLE_CNT. Number of AFI clock cycles to wait after clock gating criteria is met to disable AFI/FPCI clocks

32.3.1.10 PLLE

Bit	R/W	Reset	Description
9	R/W	0	**Bypass PADS2PLLE Control.** Overrides PCIe PADS CLKREQ control of PLLE.
8	R/W	0	**Bypass PCIE2PLLE Control.** Overrides PCIe 2.0 CLOCK CLAMP control of PLLE.
7:2	R	0	Reserved

Bit	R/W	Reset	Description
1	R/W	0	**Enable PADS2PLLE Control**. When active all CLKREQ going inactive signal disable to PLLE. When SATA, PCIe 2.0 and PADS all signal DISABLE to PLLE then PLLE will disable.
0	R/W	0	**Enable PCIE2PLLE Control**. When active PCIe 2.0 CLOCK CLAMP going active signal disable to PLLE. When SATA, PCIe 2.0 and PADS all signal DISABLE to PLLE then PLLE will disable.

32.3.1.11 FPCI Error Masks

Bit	R/W	Reset	Description
2	R/W	0	**Master Abort Mask.** This bit allows FPCI error to be forwarded to AXI response when FPCI error response indicates Master Abort. 1 = forward error, 0 = return AXI OKAY response (2'b0)
1	R/W	0	**Data Error Mask.** This bit allows FPCI error to be forwarded to AXI response when FPCI error response indicates Data Error. 1 = forward error, 0 = return AXI OKAY response (2'b0)
0	R/W	0	**Target Abort Mask**. This bit allows FPCI error to be forwarded to AXI response when FPCI error response indicates Target Abort or if FPCI does not respond with devsel to the target access. 1 = forward error, 0 = return AXI OKAY response (2'b0)

32.3.1.12 Interrupt Masks

Bit	R/W	Reset	Description
8	R/W	0	**MSI Mask.** MSI to MPCORE gated by mask
7:1	R	0	Reserved
0	R/W	0	**AFI Interrupt Mask.** AFI Interrupt to MPCORE gated by mask.

32.3.1.13 Interrupt Control

Detected errors are logged in an error signature register as specified here. There is one error signature register that always store the first error that occurred after enabling the error capture. The interrupt code register logs the interrupt ID shown in the ID column of the table below. This register will store the ID for the associated interrupt when current ID in the register is zero. Software must write zero to the register to re-enable it to store subsequent interrupts. For ID=6, the capture information is the sideband message bits. There is an associated interrupt generated to the CPU. Since FPCI address is 40 bits, a separate capture register is used for the upper 8 bits of the address.

Bit	R/W	Reset	Description
3:0	R/W	0	**Interrupt Code.** Six interrupts codes at this time, see the error and message table below. If the code is 0, logging of the next interrupt is enabled.

Error/Message	ID	Capture Information
AXI Slave error	1	Bits[31:2] of Initiator AXI address, direction of transaction
AXI Decode error	2	
AXI Slave error – PCIe target abort or data error	3	Bits[39:2] of Target FPCI address, direction of transaction
AXI Decode error – PCIe master abort	4	
AXI Decode error – write to NPW address region > 4B	5	Bits[39:2] of Target AXI address, direction of transaction

Error/Message	ID	Capture Information
PCIe 2.0 Sideband message	6	Sideband UnitID, Bits[4:0] of sideband message
FPCI Decode error – not in PCIe 2.0 memory space	7	Bits[39:2] of Target FPCI address, direction of transaction
AXI Decode error – not in AFI BAR or register space	8	Bits[31:2] of Target AXI address, direction of transaction
FPCI Timeout	9	None
Slot Present Pin Change	10	Bits[2:0] capture status of slots 2-0 present pin
Slot Clock Request Change	11	Bits[2:0] capture status of slots 2-0 clock request
TMS Clock Clamp Change	12	Bit[0] captures level of clock clamp
TMS Ready for power down	13	None – all 3 controllers are ready for power down
Peer-to-peer error	14	Error response from endpoint device (tms02ufa_cmd_error), Bits[39:2] of Target FPCI address, direction of transaction

32.3.1.14 Interrupt Signature

Bit	R/W	Reset	Description
31:2	R/W	0	**Interrupt Information.** If signature type is 1 – 5, information bits indicate address bits [31:2], either in FPCI memory space or AXI space. If interrupt code is 6, interrupt signature bits[x:0] contain sideband information {sideband unitid, 3'b0, tms02sm_msg[4:0]}.
1	R	0	Reserved
0	R/W	0	**Direction.** Indicate direction of the AXI transaction. 1 = read 0 = write

32.3.1.15 Interrupt Upper FPCI Address

Bit	R/W	Reset	Description
17:16	R/W	0	**Interrupt Address.** These 2 bits are for the captured endpoint device error response (tms02ufa_cmd_error) when interrupt code is 14.
15:8	R	0	Reserved
7:0	R/W	0	**P2P Error Response.** These 8 bits are the upper byte of captured FPCI address (bits[39:32]) when interrupt code is 3, 4 or 7.

32.3.1.16 Sideband Message Interrupt Enable

The PCI Express block has a sideband interface to transmit System Management and Interrupt messages. The message interface is simple, a message request along with message type and message data are presented to the AXI to FPCI wrapper. The AFI will capture the message in the signature register and assert an interrupt to MPCORE if the associated enable bit of the message enable register is active.

The message is encoded in bits of the request message signal (tms02sm_msg[4:0]). A table of the meaning of the bits is listed below.

The Tegra 3 devices merge PCI Express merge multiple PCI Express Root Ports into one module. To allow the external logic to distinguish which Root Port is the source of the event, the UnitID of the Root Port will be also sent with the message

(tms02sm_unitid[4:0]). Having knowledge of which Root Port is the source of the event is required for system level error handling and interrupt isolation in virtualized systems.

Bit	R/W	Reset	Description
14:0	R/W	0	**Enable Message.** Each of the bits in this register correspond to enabling the associated message shown below

[1:0]	[3:2]	[4]	Enable bit	MSG_TYPE	Description
00	00	1	0	Interrupt	INTA Assertion.
	01		1		INTB Assertion.
	10		2		INTC Assertion.
	11		3		INTD Assertion.
	00	0	4		INTA Deassertion
	01		5		INTB Deassertion
	10		6		INTC Deassertion
	11		7		INTD Deassertion
01	00	0	8	Error	Correctable Error
	01		9		Un-Correctable Non-Fatal Error
	10		10		Un-Correctable Fatal Error
10	00	0	11	PME	PME assertion.
10	01	0	12	Hotplug	Hotplug SCI assertion
11	00	1	13	Interrupt	Root Port Interrupt Assertion
11	00	0	14		Root Port Interrupt Deassertion

32.3.1.17 AFI Interrupt Enable

Bit	R/W	Reset	Description
12	R/W	0	**EN_P2P_ERR.** Enable bit for interrupt code 14 in the Errors and Messages table.
11	R/W	0	**EN_RDY4PD_SENSE.** Enable bit for interrupt code 13 in the Errors and Messages table.
10	R/W	0	**EN_CLKCLAMP_SENSE.** Enable bit for interrupt code 12 in the Errors and Messages table.
9	R/W	0	**EN_PE_CLKREQ_SENSE.** Enable bit for interrupt code 11 in the Errors and Messages table.
8	R/W	0	**EN_PE_PRSNT_SENSE.** Enable bit for interrupt code 10 in the Errors and Messages table.
7	R/W	0	**EN_FPCI_TIMEOUT.** Enable bit for interrupt code 9 in the Errors and Messages table.
6	R/W	0	**EN_AXI_DECERR.** Enable bit for interrupt code 8 in the Errors and Messages table.
5	R/W	0	**EN_DFPCI_DECERR.** Enable bit for interrupt code 7 in the Errors and Messages table.
4	R/W	0	**EN_TGT_WRERR.** Enable bit for interrupt code 5 in the Errors and Messages table.
3	R/W	0	**EN_TGT_DECERR.** Enable bit for interrupt code 4 in the Errors and Messages table.
2	R/W	0	**EN_TGT_SLVERR.** Enable bit for interrupt code 3 in the Errors and Messages table.
1	R/W	0	**EN_INI_DECERR.** Enable bit for interrupt code 2 in the Errors and Messages table.
0	R/W	0	**EN_INI_SLVERR.** Enable bit for interrupt code 1 in the Errors and Messages table.

32.4 PCIe Root Port Control Registers

The registers mentioned here are registers are used to drive static configuration signals to PCIe root port controller.

32.4.1.1 FPCI Timeout

Bit	R/W	Reset	Description
31	R/W	0	**Timeout Threshold.** SM (system management) threshold specifying how long to wait for response from FPCI before declaring it timeout
30:20	R	0	Reserved
19:0	R/W	0	**Timeout Enable.** SM (system management) timeout enable

32.4.1.2 PCIe Throttle

Bit	R/W	Reset	Description
31	R/W	0	**Throttle Enable.** SM (system management) to PCIe throttle enable. When enabled, the throttle period and duty cycle are used in place of those in the vendor defined thermal management config register.
30:16	R	0	Reserved
15:4	R/W	0	**Throttle Period.** SM (system management) to PCIe override to root port vendor defined thermal management period register.
3	R	0	Reserved
2:0	R/W	0	**Throttle Duty Cycle.** SM (system management) to PCIe override to root port vendor defined thermal management duty cycle register.

32.4.1.3 PME

Bit	R/W	Reset	Description
19	R	0	**C2 Presence State.** PCIe Controller 2 Link Presence State
18	R	0	**C2 PME Ack.** PCIe Controller 2 Endpoint PME Ack
17	R	0	**C2 PME.** PCIe Controller 2 Endpoint PME message
16	R/W	0	**C2 PME Turn Off.** SM (system management) to PCIe Controller 2 PME Turn Off. This field should remain low for Tegra 3 devices.
15:12	R	0	Reserved
11	R	0	**C1 Presence State.** PCIe Controller 1 Link Presence State
10	R	0	**C1 PME Ack.** PCIe Controller 1 Endpoint PME Ack
9	R	0	**C1 PME.** PCIe Controller 0 Link Presence State
7	R	0	Reserved
8	R/W	0	**C1 PME Turn Off.** SM (system management) to PCIe Controller 1 PME Turn Off. This field should remain low for Tegra 3 devices.
6	R	0	**C0 Presence State.** PCIe Controller 0 Link Presence State
5	R	0	**C0 PME Ack.** PCIe Controller 0 Endpoint PME Ack

Bit	R/W	Reset	Description
4	R	0	**C0 PME.** PCIe Controller 0 Endpoint PME message
3:1	R	0	Reserved
0	R/W	0	**C0 PME Turn Off.** SM (system management) to PCIe Controller 0 PME Turn Off. This field should remain low for Tegra 3 devices.

32.4.1.4 Request Pending

Bit	R/W	Reset	Description
11	R	0	**C2 Non-ISO Request Pending.** SM (system management) status that Non-ISO request pending from PCIe Controller 2 to FPCI when in low power mode.
10	R	0	**C2 ISO Request Pending.** SM (system management) status that ISO request pending from PCIe Controller 2 to FPCI when in low power mode.
9	R	0	**C2 Non-Coherent Request Pending.** SM (system management) status that Non-coherent request pending from PCIe Controller 2 to FPCI when in low power mode.
8	R	0	**C2 Coherent Request Pending.** SM (system management) status that coherent request pending from PCIe Controller 2 to FPCI when in low power mode.
7	R	0	**C1 Non-ISO Request Pending.** SM (system management) status that Non-ISO request pending from PCIe Controller 1 to FPCI when in low power mode.
6	R	0	**C1 ISO Request Pending.** SM (system management) status that ISO request pending from PCIe Controller 1 to FPCI when in low power mode.
5	R	0	**C1 Non-Coherent Request Pending.** SM (system management) status that Non-coherent request pending from PCIe Controller 1 to FPCI when in low power mode.
4	R	0	**C1 Coherent Request Pending.** SM (system management) status that coherent request pending from PCIe Controller 1 to FPCI when in low power mode.
3	R	0	**C0 Non-ISO Request Pending.** SM (system management) status that Non-ISO request pending from PCIe Controller 0 to FPCI when in low power mode.
2	R	0	**C0 ISO Request Pending.** SM (system management) status that ISO request pending from PCIe Controller 0 to FPCI when in low power mode.
1	R	0	**C0 Non-Coherent Request Pending.** SM (system management) status that Non-coherent request pending from PCIe Controller 0 to FPCI when in low power mode.
0	R	0	**C0 Coherent Request Pending.** SM (system management) status that coherent request pending from PCIe Controller 0 to FPCI when in low power mode.

32.4.1.5 PCIe CONFIG

Bit	R/W	Reset	Description
28:24	R/W	1	**T0C2 Unit ID.** PCIe Controller 2 Unit ID. Upstream FPCI request unit ID from controller 2.
23:20	R/W	4	**XBAR Config**. SM (system management) configuration of PCIe crossbar. This input determines how PCIe root port connects to PCIe endpoints. Valid configurations for Tegra 3 are : • 1x4,1x2 • 1x4,2x1 • 3x2
16:12	R/W	3	**T0C1 Unit ID.** PCIe Controller 1 Unit ID. Upstream FPCI request unit ID from controller 1.

Bit	R/W	Reset	Description
8:4	R/W	2	**T0C0 Unit ID.** PCIe Controller 0 Unit ID. Upstream FPCI request unit ID from controller 0.
3	R/W	1	**Disable Device T0C2.** Disable PCIe controller C2. This bit is qualified with Enable FPCI to generate PCIe 2.0 signal ***device_disable_t0c2***.
2	R/W	1	**Disable Device T0C1.** Disable PCIe controller C1. This bit is qualified with Enable FPCI to generate PCIe 2.0 signal ***device_disable_t0c1***.
1	R/W	0	**Disable Device T0C0.** Disable PCIe controller C0. This bit is qualified with Enable FPCI to generate PCIe 2.0 signal ***device_disable_t0c0***.
0	R	1	Reserved

32.4.1.6 REV ID

Bit	R/W	Reset	Description
28:24	R/W	0	**REVID Write Enable.** Write Enable for PCI backdoor rev ID override value.
23:20	R/W	0	**REVID Override.** Override for PCI config revision id read-only register. This allows backdoor changes to rev ID for metal spins.

32.4.1.7 Top-of-Memory (TOM)

Bit	R/W	Reset	Description
29:16	R/W	3F3Fh	Top of Memory Limit 2. Determines peer-to-peer range as: {TOM2:: 26'b0} to 0xFC_FFFF_FFFF
5:0	R/W	3Fh	Top of Memory Limit 1. Determines peer-to-peer range as: {TOM1 :: 26'b0} to 0xFFFF_FFFF (except MSI region)

32.4.1.8 P2PBOM CTRL

Bit	R/W	Reset	Description
19:0	R/W	0	**P2P_BASE.** Peer-to-peer Bottom of Memory drives bits 39:20 of p2p_base_63_to_20 with top bits tied to 0.

32.4.1.9 P2PTOM CTRL

Bit	R/W	Reset	Description
19:0	R/W	003FFh	**P2P_LIMIT.** Peer-to-peer Bottom of Memory drives bits 39:20 of p2p_limit_63_to_20 with top bits tied to 0.

32.4.1.10 FUSE

Bit	R/W	Reset	Description
14:12	R/W	3	**PCIe Width T0C2.** Configure PCIe controller 1 as x1, x2, x4, x8, or x16. This should remain 3'b011 for Tegra 3 single endpoint or 3'b010 for multiple endpoints.
11	R		Reserved
10:8		3	**PCIe Width T0C1.** Configure PCIe controller 1 as x1, x2, x4, x8, or x16. This should remain 3'b011 for Tegra 3 single endpoint or 3'b010 for multiple endpoints.

Bit	R/W	Reset	Description
7	R		Reserved
6:4		3	**PCIe Width T0C0.** Configure PCIe controller 0 as x1, x2, x4, x8, or x16. This should remain 3'b011 for Tegra 3 single endpoint or 3'b010 for multiple endpoints. The widths are enumerated below. • X1_MODE – 3'b001 • X2_MODE – 3'b010 • X4_MODE – 3'b011 • X8_MODE – 3'b100 • X16_MODE – 3'b101
3	R		Reserved
2		1	**PCIe Gen2 Disable.** Disable Gen 2 capability of PCIe. This should remain on for Tegra 3.
1		1	**PCIe SLI Disable.** Disable SLI capability for GPU. This bit controls peer-to-peer transactions. For single controller configuration, this should remain on. For dual controller configuration, this should be disabled when enabling peer-to-peer transactions.
0	R		Reserved

32.4.1.11 C0-C1 PMU

Bit	R/W	Reset	Description
24	R	0	**C1 PMU Toggle.** PCIe Controller 1 PMU toggle response from PCIe
23:20	R	0	**C1 PMU Status.** PCIe Controller 1 PMU Status
19:17	R		Reserved
16	R	0	**C0 PMU Toggle.** PCIe Controller 0 PMU toggle response from PCIe
15:12	R	0	**C0 PMU Status.** PCIe Controller 0 PMU Status
11:8	R/W	0	**C1 Load Indicator Scale.** PCIe Controller 1 PMU Load Indicator Scale
7:4	R/W	0	**C0 Load Indicator Scale.** PCIe Controller 0 PMU Load Indicator Scale
3:1	R		Reserved
0	R/W	0	**Update Fast Toggle.** PMU Load Indicator Enable.

32.4.1.12 C2 PMU

Bit	R/W	Reset	Description
16	R	0	**C2 PMU Toggle.** PCIe Controller 2 PMU toggle response from PCIe
15:13	R		Reserved
11:8	R	0	**C2 PMU Status.** PCIe Controller 2 PMU Status
7:4	R/W	0	**C2 Load Indicator Scale.** PCIe Controller 2 PMU Load Indicator Scale
3:0	R		Reserved

32.4.1.13 PCIe Clock Config/Status

Bit	R/W	Reset	Description
27:24	R	0	**C2 Pad Macro CLK Select.** Clock select to pad macro from PCIe Controller 2. For Tegra 3 devices, this should remain 0.
23:20	R	0	**C1 Pad Macro CLK Select.** Clock select to pad macro from PCIe Controller 1. For Tegra 3 devices, this should remain 0.
19:16	R	0	**C0 Pad Macro CLK Select.** Clock select to pad macro from PCIe Controller 0. For Tegra 3 devices, this should remain 0.
15	R	0	**C2 Select XTXCLK1X Gen2.** Request to select Gen2 speed clock (500 MHz) for PCIe Controller1 XTXCLK1X. This is generated when register settings for PCIe 2.0 specify Gen2 speed clocks. This should remain low for Tegra 3 devices.
14	R	0	**C2 Disable XTXCLK1X.** Request to gate PCIe Controller 2 XTXCLK1X when in low power mode.
13	R	0	**C1 Disable XTXCLK1X.** Request to gate PCIe Controller 1 XTXCLK1X when in low power mode.
12	R	0	**C0 Disable XTXCLK1X.** Request to gate PCIe Controller 0 XTXCLK1X when in low power mode.
11	R	0	**Clamp CLK.** Request to gate TMS/FPCI clocks when in low power mode.
10	R	0	**C1 Select XTXCLK1X Gen2.** Request to select Gen2 speed clock (500 MHz) for PCIe Controller1 XTXCLK1X. This is generated when register settings for PCIe 2.0 specify Gen2 speed clocks. This should remain low for Tegra 3 devices.
9	R	0	**C0 Select XTXCLK1X Gen2.** Request to select Gen2 speed clock (500 MHz) for PCIe Controller0 XTXCLK1X. This is generated when register settings for PCIe 2.0 specify Gen2 speed clocks. This should remain low for Tegra 3 devices.
8	R	0	**Select XCLK Gen2.** Request to select Gen2 speed clock (500 MHz) for XCLK. This is generated when register settings for PCIe 2.0 specify Gen2 speed clocks. This should remain low for Tegra 3.
6	R/W	0	**C2 Off XTXCLK1X.** Controller 2 Acknowledge to Disable XTXCLK1X request. Used for clock gating.
5	R/W	0	**C2 Ready XTXCLK1X Gen2.** Controller 2 Acknowledge to Select XTXCLK1X Gen2 request. This should remain low for Tegra 3.
4	R/W	0	**C1 Off XTXCLK1X.** Controller 1 Acknowledge to Disable XTXCLK1X request. Used for clock gating.
3	R/W	0	**C1 Ready XTXCLK1X Gen2.** Controller 1 Acknowledge to Select XTXCLK1X Gen2 request. This should remain low for Tegra 3.
2	R/W	0	**C0 Off XTXCLK1X.** Controller 0 Acknowledge to Disable XTXCLK1X request. Used for clock gating.
1	R/W	0	**C0 Ready XTXCLK1X Gen2.** Controller 0 Acknowledge to Select XTXCLK1X Gen2 request. This should remain low for Tegra 3.
0	R/W	0	**Ready XCLK Gen2.** Acknowledge to Select XCLK Gen2 request. This should remain low for Tegra 3.

32.4.1.14 Bus Trace

Bit	R/W	Reset	Description
21	R	0	**Bus Trace Trigger.** Bus trigger from bus trace module in PCIe 2.0
20	R/W	0	**Trace External Start.** Start signal to bus trace module in PCIe 2.0
19:18	R		Reserved
17:16	R/W	0	**Bus Trace Mux Sel.** Mux select to bus trace module in PCIe 2.0
15:0	R/W	0	**Chip ID.** Chip ID to bus trace module in PCIe 2.0

32.5 PCIe Slot Registers

The registers mentioned here are registers are used to control clock and reset to each of the PCIe slots.

32.5.1.1 PEX0 CTRL

Bit	R/W	Reset	Description
3	R/W	0	**PEX0_REFCLK_EN.** Clock Enable to PCIe slot 0
2	R		Reserved
1	R/W	0	**PEX0_CLKREQ_EN.** Enable to allow CLKREQ0 to control PCIe slot 0 clock
0	R/W	0	**PEX0_RST_L**. Reset to PCIe slot 0

32.5.1.2 PEX0 STATUS

Bit	R/W	Reset	Description
0	R	0	**PEX0_CLKREQ_L**. Clock request status for PCIe slot 0

32.5.1.3 PEX1 CTRL

Bit	R/W	Reset	Description
3	R/W	0	**PEX1_REFCLK_EN.** Clock Enable to PCIe slot 1
2	R		Reserved
1	R/W	0	**PEX1_CLKREQ_EN.** Enable to allow CLKREQ1 to control PCIe slot 1 clock
0	R/W	0	**PEX1_RST_L**. Reset to PCIe slot 1

32.5.1.4 PEX1 STATUS

Bit	R/W	Reset	Description
0	R	0	**PEX1_CLKREQ_L**. Clock request status for PCIe slot 1

32.5.1.5 PEX2 CTRL

Bit	R/W	Reset	Description
3	R/W	0	**PEX2_REFCLK_EN.** Clock Enable to PCIe slot 2
2	R		Reserved
1	R/W	0	**PEX2_CLKREQ_EN.** Enable to allow CLKREQ1 to control PCIe slot 2 clock
0	R/W	0	**PEX2_RST_L**. Reset to PCIe slot 2

32.5.1.6 PEX2 STATUS

Bit	R/W	Reset	Description
0	R	0	**PEX2_CLKREQ_L**. Clock request status for PCIe slot 2

32.5.1.7 PEXBIAS CTRL

Bit	R/W	Reset	Description
0	R/W	1	**PEX_BIAS_PWRD**. Power down to PCIe slot clock bias pad

[THIS PAGE INTENTIONALLY LEFT BLANK]

33.0 I2C CONTROLLER

The I^2C controller (I2C) implements an I^2C 2.1 specification-compliant I2C master and a slave controller. I2C supports multiple masters and slaves. It also supports fast mode (400 KHz operation) and high speed mode (3.4 MHz operation). Tegra® 3 devices have five instances of this controller. All five instances present identical I2C master functionality.

I2C supports DMA over APB bus in addition to single byte transfers. I2C also supports packet mode transfers where the data to be transferred is encapsulated in a predefined packet format as payload and sent to I2C over APB bus via DMA. The header of the packet specifies the type of operation to be performed, the size and other parameters (described in detail in subsequent sections).

Features

- Supports standard and fast mode of operation (0-400 KHz) as well as high speed mode (up to 2.577 MHz).
- Independent Master Controller and Slave Controller with separate register-based host interface
- Master supports clock stretching by the slave
- Supports one to eight-byte burst data transfers
- Supports 4 kilobytes of transfer in packet mode. Can be extended beyond 4Kbytes by breaking up transfers into multiple packets (in both DMA and non-DMA modes)
- Both master and slave support transactions with 7-bit or 10-bit addressing
- Master is capable of data transfers to/from two or more slaves consecutively with a repeated-start condition
- Fully programmable 7-bit or 10-bit address for the slave
- Supports general call addressing
- Supports Recognition and Transfer of data to peripherals that do not send an acknowledge
- Slave can also be configured not to acknowledge
- Master supports packet based DMA

Clocking

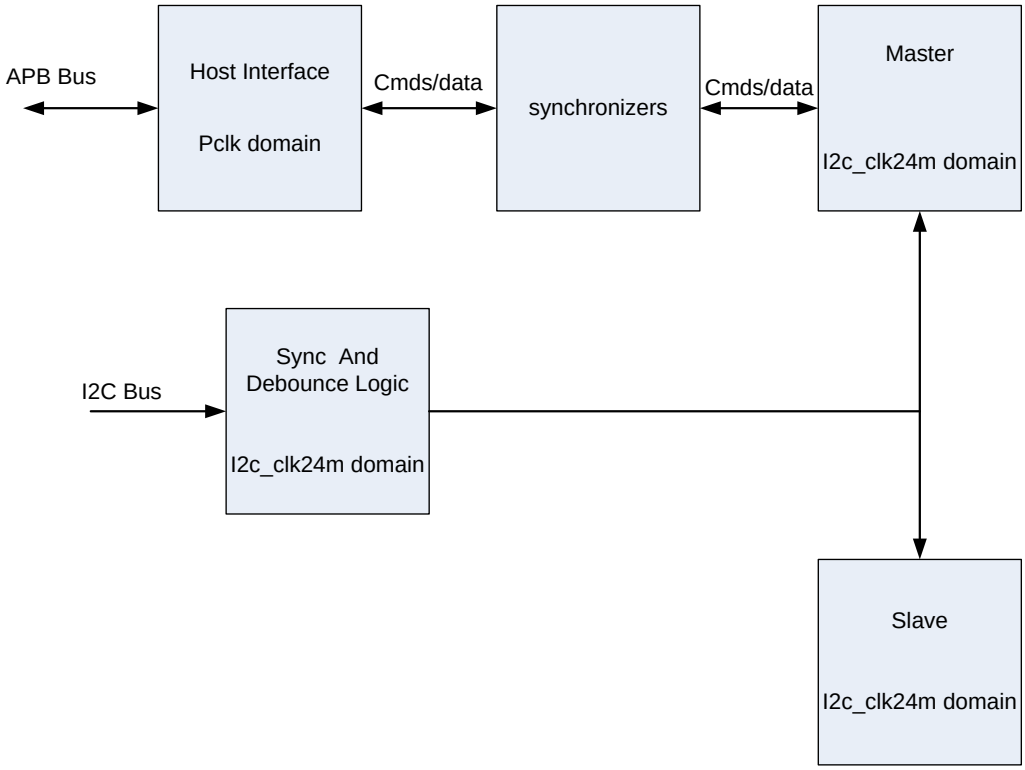
I2C has two clock domains:

- Host interface runs on APB clock. APB clock is derived from sys_clk and can be 1.0, ½, 1/3 or ¼ times the sys_clk.
- I2C interface controller runs on a fixed frequency clock running at 72 MHz. The 72 MHz clock is derived from PLLP. Even though we can mux between PLLP, PLLC, PLLM, and OSC clocks, PLLP is always selected and used.

33.1 Functionality

The I^2C controller can work as both a Master and a Slave. The Master can address the internal slave (for basic testing) or an external 7-bit or 10-bit addressed Slave device. The Master can be programmed for either a single slave transaction or a two-slave transaction. The two-slave transaction is generally useful in a random read from an external device. When reading from an external device, the random read address needs to be set with an initial dummy-write to the device, followed by a repeated-start and a read transaction to the same device. The internal Slave address can be programmed to be either a 7-bit or a 10-bit address. Figure 83 below shows the I2C controller in both the master and slave modes.

Figure 83 I2C Controller Block Diagram



33.2 Interfaces

A typical peripheral controller might require the following set of steps to communicate or control an external peripheral:

1. Set up the registers
2. Program the ‘go’ bit to start the interaction with external peripheral
3. Peripheral controller collects the response from peripheral and interrupts software
4. Software reads the response

33.2.1 Packet Flow

The flow is a transport path that can be uniquely identified in the system. It is a virtual path or channel that carries a particular type of packets from a source to a destination. A flow carries logical information and is not dependent on the physical implementation.

Information exchange between hardware peripheral controller and software as described in section 33.2 can be classified into:

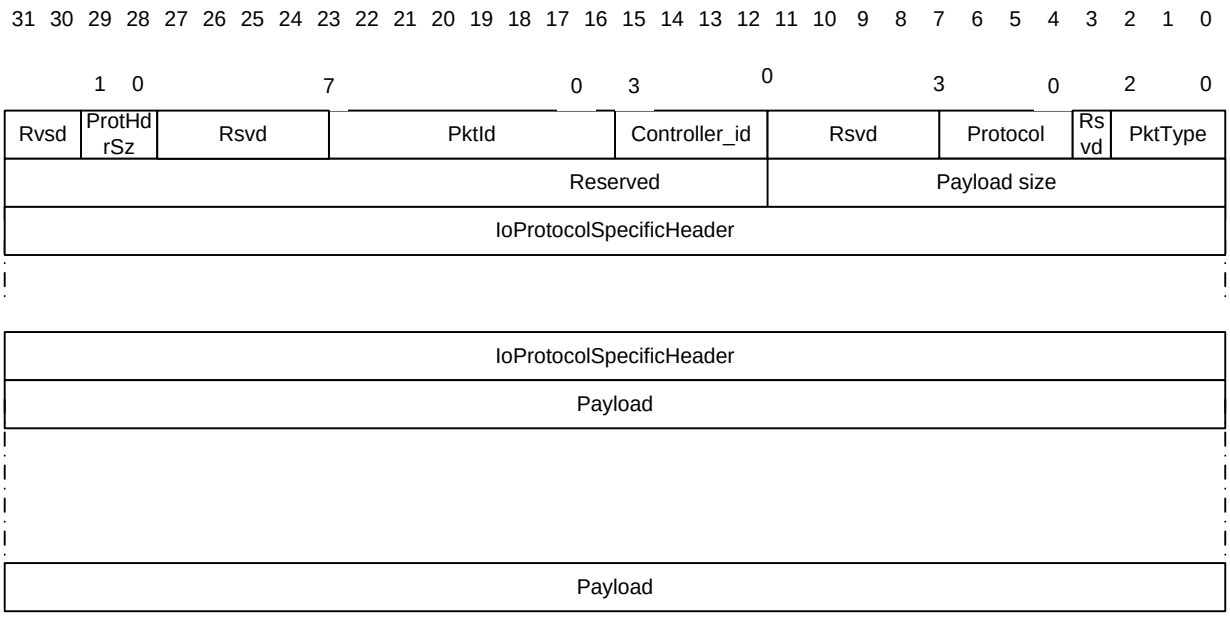
- ‘Request’ flow which can represent the register writes
- ‘Response’ flow for peripheral controller responses sent back to software, and
- ‘Interrupt’ flow for out-of-band handshake between hardware and software

Packets within a flow can be exchanged in a manner that requires full intervention from CPU (PIO mode) or least intervention from CPU (DMA mode). The I/O packet described below is a structure that can be used to represent various flows in the system.

33.2.2 I/O Packet Format

An I/O Packet consists of header and payload. The header consists of two parts: Two words of generic header, and one to four words of protocol specific header.

Figure 84 I/O Packet



33.2.2.1 I/O Packet Word 0

Word 0 of the I/O packet contains the Generic Header Word 0. The contents of generic header word 0 are described in the table below

Table 85. Generic I/O Header Word 0

Bits	Field Value	Description
31:30	Reserved	Reserved
29:28	ProtHdrSz	Size of the protocol specific header in words 0 = 1 words 1 = 2 words 2= 3 words 3 = 4 words For I2C ProtHdrSz = 0 for request packets and 1 for response packets
27:24	Reserved	Reserved
23:16	PktId	PktId is an 8-bit field that identifies the packet. A peripheral controller might choose to log the packet ID for a packet that causes errors
15:12	Controller ID	There might be multiple controllers supporting any format. For example there might be 4 I2C controllers. Controller ID field specifies the controller for which this packet is destined.
11:8	Reserved	Reserved
7:4	Protocol	The protocol is indicated in this field 0 = reserved 1= I2c 2-15 = reserved
3:3	Reserved	Reserved

Bits	Field Value	Description
2:0	PktType	Packet type information 0 = request 1 = response 2 = interrupt 3 = stop 4-7 = reserved

33.2.2.2 I/O Packet Word 1

Word 1 of the I/O packet contains the Generic Header Word 1. The contents of generic header word 1 are described in the table below.

Table 86. Generic I/O Header Word 1

Bits	Field Value	Description
31:12	Reserved	Reserved
11:0	PayloadSize	Payload size in bytes

Note about payload size:

For request packets that send transmit data, the total packet size is payload_size + 8 bytes of generic header + protocol specific header.

However for request packets with read command, payload size indicates the amount of data to be received. Hence the packet size = 8 bytes of generic header + protocol specific header, because there is no payload in this packet, just the receive command.

33.2.3 Transferring Packets

Packets can be transferred using PIO or DMA modes. A peripheral controller can choose to implement one or both modes. Header is a minimum of three words with the first two words reserved for packet information and the third word reserved for protocol specific requirements. A minimum of four words is needed to transfer one byte to the external peripheral.

33.2.4 I/O Protocol Specific Header

Depending on the implementation of the peripheral controller and the interface protocol, the header words can be defined. No restriction is placed on the organization of the fields or the number of protocol specific words (a minimum of one word and a maximum of four words) a particular implementation chooses.

I2C master supports two kinds of packets.

- Transmit packets that flow from Host to Controller.
- Receive data packets that flow from Controller to Host.

I2C has one word of Protocol Specific Header. The contents of I2C protocol specific header are described in the table below.

Table 87. I/O Protocol Specific Header

Bit	Name	Description
31:26	Reserved	Reserved
25	RESP_PKT_FREQ	Response packet frequency. This field is valid only if I2C master is transmitting (READ/WRITE field below). If it is receiving then response packets will be sent for every request packet received. 0: Send response packet at the end of last packet. 1: Send response packet for each packet transmitted.
24	RESP_PKT_ENABLE	Enable response packet. It qualifies RESP_PKT_FREQ field.

Bit	Name	Description
		0: Don't send response packets (status has to be obtained via interrupt status bits). 1. Send response packet.
23	Reserved	Reserved
22	HS_MODE	Enable high speed mode (3.4MHz operation)
21	CONTINUE_ON_NACK	Enable mode to handle devices that do not generate ACK upon the Reception of a byte.
20	SEND_START_BYTE	1 = send a start byte at the beginning of the transaction
19	READ/WRITE	1= READ
18	Address mode	1=10 bit mode 0 = 7 bit mode
17	IE	Generate interrupt upon packet completion
16	REPEAT_START/STOP	1 indicates to put a repeat start condition on the bus(to continue transaction) 0 indicates to put a stop condition on the bus
15	ContinueXfer	This bit overrides REPEAT_START/STOP command above. 0: Introduce repeat start or stop condition based on bit 16. 1: Continue with current transfer without stop or repeat start condition.
14:12	HS_MASTER_ADDR	High Speed mode Master code
11:10	Reserved	Reserved
9:0	SLAVE_ADDR	Slave address

33.3 Programming Guidelines

33.3.1 I2C Frequency Divisor Register

The FREQUENCY DIVISOR register (CLK_SOURCE_I2C register, whose address is: 0x600060A4) must be programmed as a function of the CLK_SOURCE Selected for I2C as follows:

```
I2C_CLK = CLK_SOURCE.I2C / (8 * I2C FREQUENCY DIVISOR)
```

The I^2C bus specification defines the minimum low period for the I2C_CLK as 4.7μs in standard mode and 1.3μs in fast mode. Because of this, the maximum I2C_CLK frequency in the standard mode can be 100 KHz but in fast mode, it is limited to 348 KHz, assuming I2C_CLK as rise and fall delays of 300ns per the I^2C specification.

The clock enable (bit-12 of CLK_OUT_ENB.L register) must also be given to I2C controller, before any of the registers are written.

33.3.2 I2C Slave ADDR Registers

There are two slave ADDR registers that are used to configure the address of the internal slave-- I2C_SL_ADDR1 and I2C_SL_ADDR2. The bit [0] of I2C_SL_ADDR2 determines the address-size of the internal slave. When this bit is programmed to be zero, the 7-bit slave address is taken from I2C_SL_ADDR1 [6:0]. When this bit is programmed to be one, the two most significant bits of the 10-bit slave address are taken from I2C_SL_ADDR2[2:1] and the least significant bits are taken from I2C_SL_ADDR1[7:0].

33.3.3 I2C Command ADDR Registers

These registers, I2C_CMD_ADDR0 and I2C_CMD_ADDR1, contain the address of the slave with which a transaction is intended. I2C Master Controller can be programmed to transact with both 7-bit and 10-bit addressed slaves. The bit [0] of I2C_CNFG register determines the size of the slave address to be transacted. If a 7-bit or a 10-bit slave address is chosen, the respective address is taken from I2C_CMD_ADDR0 [9:0] and the Read/Write command is taken from the bits 6 & 7 of the I2C_CNFG Register. In a 2 Slave configuration, the slave 1 address (7-bit or 10-bit) is taken from I2C_CMD_ADDR0 [9:0] and Slave 2 address (7-bit or 10-bit) from I2C_CMD_ADDR1 [9:0].

33.3.4 I2C Data Registers

There are two data registers, I2C_CMD_DATA1and I2C_CMD_DATA2, each of 32 bit length, which are to be loaded with the data to be transmitted or received as an I^2C Master. When used as I2C slave, the controller uses a separate byte-wide register to store the data to be transmitted (I2C_SL_SEND) or data received (I2C_SL_RCVD).

33.3.5 I2C Configuration Register

This register is to be configured with the following data:

- Number of bytes to be transmitted or received
- Select for 7 bit or 10 bit slave address
- Program to send a Start-Byte
- Single or two slave operations
- Support of noack from an external Peripheral

The bit I2C_CNGF [9] is used to issue a “Begin-Transaction” command to the I2C Master Controller. This bit is reset by hardware and other bits of the register are masked for writes, when this bit is programmed to be one. Hence, the firmware should first configure all the other registers and the bits [8:0] of I2C_CNFG register before the bit I2C_CNFG [9] is programmed to one.

33.3.6 I2C Controller STATUS Register

This register (I2C_STATUS) gives the status of the I^2C Master operation. It includes the busy status of the I^2C Bus and the completion status of the command executed.

33.3.7 I2C Controller Slave Status Register

This register (I2C_SL_STATUS) contains the status bits as I^2C Slave. ,

Tegra 3 contains status bits as follows:

- Receive Interrupt
- New Transaction Received
- Direction of transfer.
- Bit 4 contains END_TRANS bit. This bit is set when an I^2C transfer is complete (as indicated by either a stop or repeat start condition).
- Bit 5 contains RST_SL. The byte received following the receipt of general call address is 0x06. Therefore programmable part of the slave address needs to be reset and reprogrammed.
- Bit 6 contains REPROG_SL. The byte received following the receipt of general call address is 0x04. Therefore reprogram the programmable part of slave address.
- Bit 7 contains HW_MSTR_INT. When set this bit indicates that master address has been transmitted after general call address.
- Bits [14:8] contain the hardware master address. The contents of this field are meaningful only when bit 7 (HW_MSTR_INT) is set.

Note that the I^2C Controller generates an interrupt at the completion of each data byte received. In response to this interrupt, firmware must read I2C_SL_STATUS register to confirm the cause of the interrupt and the direction of data transfer. If the interrupt is due to a data byte received (R/W=0), firmware must read the data register, I2C_SL_RCVD in order to clear the SL.IRQ bit in the status register. The I^2C Controller will delay the release of the ACK handshake on the I^2C bus until the SL.IRQ bit has been cleared by this firmware read operation.

I2C_SL_STATUS needs to be either polled or the I2C interrupt must be enabled for transfers to occur in slave mode. The following steps outline slave operation in both read and write transactions.

If Tegra 3 as a slave is **receiving** data,

- I2C_SL_STATUS.SL_IRQ bit being set indicates a data byte has been received.
- Read to I2C_SL_STATUS clears SL_IRQ and returns the transfer direction in RNW field.
- Data byte is already present in I2C_SL_RCVD register. This can be read which causes the bus to be released.
- SL_IRQ is set again upon reception of next byte

If Tegra 3 as a slave is **transmitting** data,

- I2C_SL_STATUS.SL_IRQ bit being set indicates that address has been received.
- Read to I2C_SL_STATUS clears SL_IRQ and returns the transfer direction in RNW field.
- Data byte needs to be written to I2C_SL_RCVD register. This write causes the bus to be released.
- SL_IRQ is set again upon transfer of the byte. Another byte can be written to continue the operation

33.3.8 Interrupt Generation

The I^2C controller generates interrupts upon the completion of transmission or reception of the specified number of bytes. A Master-interrupt is generated when the number of bytes of transaction, as programmed in the LENGTH field of the I2C_CNFG register, is complete.

A Slave-interrupt is generated at the transmission/reception of each byte of data by the internal slave. In addition, if the internal Slave is in transmitter mode (Slave receives a Read command), an interrupt is generated for the address and read-command reception also, as shown in the next two figures below. Slave interrupts are to be cleared by the firmware as mentioned above.

Figure 85 Interrupt Generation: Master Transmits to Internal Slave

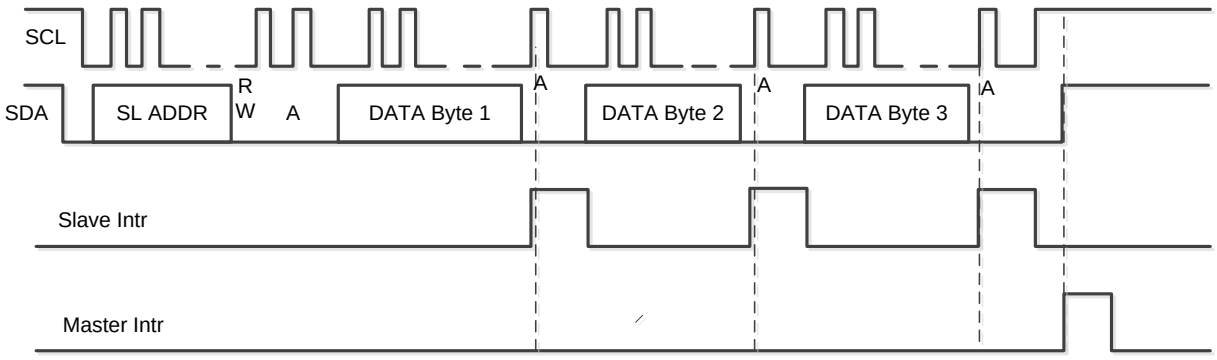


Figure 86 Interrupt Generation: Master Reads from Internal Slave

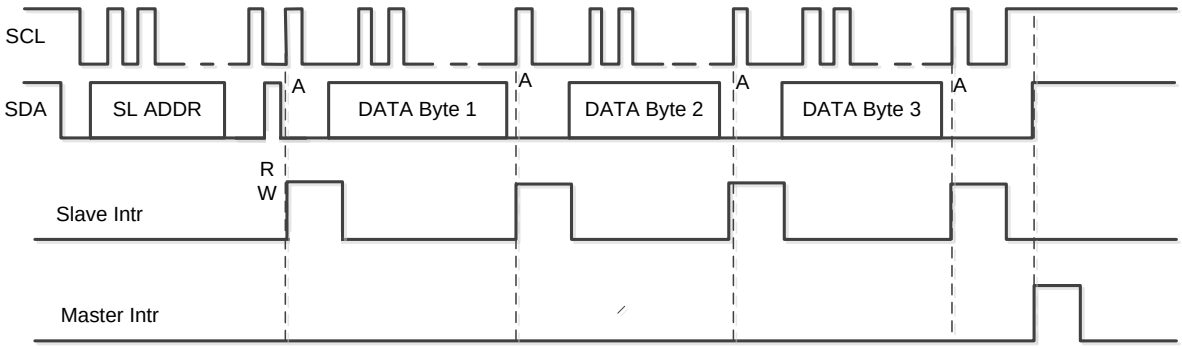

33.4 Programming Guidelines for Packet Based Interface

33.4.1 Packet Based Interface Registers

The following registers need to be programmed in case of packet based interface:

- I2C TX Packet FIFO Register
- I2C RX FIFO
- PACKET_TRANSFER_STATUS
- FIFO CONTROL
- FIFO STATUS
- Slave I2C TX FIFO
- Slave I2C RX FIFO
- Slave PACKET_TRANSFER_STATUS
- Slave FIFO CONTROL
- FIFO STATUS (common for both master and slave)
- INTERRUPT_MASK_REGISTER
- INTERRUPT_STATUS_REGISTER
- PACKET_MODE_EN , DEBOUNCE_CNT and NEW_MASTER_FSM field of I2C Controller Configuration Register

All other registers/fields have no meaning in packet mode and should be used only normal mode.

33.4.2 Programming Packet Header and Payload

SW should program the I2C_TX_PACKET_FIFO register. It writes packet header followed by payload. Header size is variable, could vary from 3 to 5 words. For I2C, it is 3 words for request packets and 4 words for response packets. The first two words of the header contain generic header. The third word of the Packet (and 4^{th} as well in case of response packet) contains I2C transaction specific information. Payload contains the actual data to be written to the slave. In case of read operation, payload is nil, and hence, packet contains only header.

33.4.3 Reading from Rx_fifo

The data received on the bus is pushed into rx_fifo. In PIO mode A, a request interrupt is generated when the attention level is reached and SW reads rx_fifo register to get the data. In DMA mode, a DMA trigger is asserted after reaching the attention level.

33.4.4 Error Handling

In case of an error due to nack or loss of arbitration or txfifo overflow or rxfifo underflow, the following steps describe what happens when an error occurs:

- A stop condition is put on the bus and interrupt is generated
- Status register is updated with the current error packet id, and the byte number at which the error occurred.
- SW should reset the controller
- In case of DMA transfer, DMA needs to be restarted

In packet mode special care should be taken to handle error recovery. If an error occurs during the transfer of a packet then the controller should be reset and DMA need to be restarted (if using DMA transfer) and the entire packet needs to be resent since there is no accurate way of knowing how many bytes made it to the I2C slave.

Repeat start bit in packet mode can complicate the situation further since when back to back packets are sent to a slave with repeat start bit set, and an error occurs then we can't reliably know during which packet transfer the error occurred. Therefore the entire stream of packets that were sent back to back using repeat start need to be sent again.

On the receive case it is a bit simpler since if an error occurs, and bytes for a packet have already been received then that packet can be deemed complete. Only incomplete transfers need to be retried.

33.4.5 Programming repeat_start/stop

This field indicates whether to put a stop condition after the current transaction. By default, this bit is zero and a stop condition is put on the bus. If this bit is set, a repeat start is put on the bus before proceeding with the next packet. Repeat_start/stop bit can be used for combining read operations and write operations within a single transaction with repeat start, or to do transfers beyond the 4Kbyte limit. This bit is present in the protocol specific header.

Tegra 3 supports transfer size beyond 4Kbytes without repeat start condition, again by combining multiple packets. This is in addition to ability to use repeat start condition to do continuous transfers over 4Kbyte limit.

33.4.6 FIFO Control

In DMA mode, TX_FIFO_TRIG indicates the number of words that need to be empty in TX FIFO for the DMA trigger to be asserted. RX_FIFO_TRIG indicates the number of words that need to be full in RX FIFO for the DMA trigger to be asserted.

In PIO mode, TFIFO_DATA_REQ in INTERRUPT_STATUS_REGISTER will be set, if the TX FIFO empty count is more than the value programmed in TX_FIFO_TRIG. Similarly RFIFO_DATA_REQ in INTERRUPT_STATUS_REGISTER will be set if RX FIFO full count is more than the value programmed in RX_FIFO_TRIG.CPU will be interrupted if status bits are set and their corresponding INT_EN is set in the INTERRUPT_MASK_REGISTER. The depth of TX and RX FIFOs is 8.

33.4.7 FIFO Status

This register indicates the number entries that are empty in the TX FIFO (TX_FIFO_EMPTY_CNT) and the number of entries that are full in the RX FIFO(RX_FIFO_FULL_CNT).

33.4.8 Example Transfer

A programming example for 1 byte read followed by 5 byte write

1. Program the PACKET_MODE_EN field to 1
2. Write the generic packet header
3. Write payload size = 0x0(which means 1 byte)
4. Write the i2c specific header read/write = 1 and repeat_start/stop =1
5. Write the generic packet header
6. Write payload size = 0x4(which means 5 bytes)
7. Write the i2c specific header read/write = 0 and repeat_start/stop
8. Write the 12 bytes(word aligned)

33.4.9 Removal of Register read side effects

Tegra 3 implements packet mode transfers for I2C slave. In packet mode, slave holds off ACK on the very last byte of transfer until the host explicitly indicates to I2C to release the bus by ACKing the last byte. The Host is responsible for providing this indication to I2C slave in a timely fashion before the SMBUS timeouts happens.

After checking the packet contents Host needs to send a control packet with:

- "ACK_LAST_BYTE" in protocol specific header set to 1'b1

- PAYLOAD_SIZE in generic packet header set to zero
- “READ/WRITE” bit in protocol specific header set to 1’b1 (READ).

Slave will release the bus as soon as it receives this control packet.

33.4.10 DMA capability for I2C slave

Packet mode capability of the slave combined with DMA transfer capabilities eliminates the need for byte by byte interaction between driver and hardware.

33.4.11 Programming Guidelines for Slave

The data is transmitted/received via single register **I2C_I2C_SL_RCVD_0**

To work in Tegra 3 mode where we can transfer one byte at a time

- Set I2C_I2C_SL_CNFG_0. ENABLE_SL

In Tegra 3, data can be transmitted/received through **I2C_I2C_SLV_TX_PACKET_FIFO_0** and **I2C_I2C_SLV_RX_FIFO_0** registers respectively. For this, FIFO_XFER_EN bit in **I2C_I2C_SL_CNFG_0** register needs to be set.

In fifo xfer mode, slave by default works in one byte mode, i.e initially when a single byte is received, ack is withheld and interrupt is generated. SW should indicate whether to ack this byte or not by writing into ACK_LAST_BYTE field of **I2C_I2C_SL_CNFG_0** register. Please note that ACK_LAST_BYTE_VALID field also needs to be set to indicate HW that ACK_LAST_BYTE is being updated. When SW receives interrupt due to SLV_RX_BUFFER_FILLED, it can check ACK_WITHHELD of I2C_**I2C_SLV_PACKET_STATUS_0** register to see if slave is withholding the ack for the last byte.

SW can update the buffer size from default to any number by programming BUFFER_SIZE or by writing a packet where it updates payload size.

Packet structure consists of header followed by data in case of Rd operation, whereas it consists of only header in case of Wr operation. Packets should be programmed into **I2C_I2C_SLV_TX_PACKET_FIFO_0** register .The data received will be stored in **I2C_I2C_SLV_RX_FIFO_0** register. When SW reads from this register, it causes pop.

Packet header consists of 3 Words, generic header, payload size, and protocol specific header.

Packet Wr operation works as follows.

After enabling packet

To work in Tegra 3 packet mode for Wr operation(Master writing to slave)

- Set I2C_I2C_SL_CNFG_0. ENABLE_SL
- Set I2C_I2C_SL_CNFG_0. FIFO_XFER_EN
- Set I2C_I2C_SL_CNFG_0. PACKET_MODE_EN
- Wait for interrupt SLV_RX_BUFFER_FILLED.By default buffer_size is one and interrupt will be generated after first byte and ack is withhold.
- Clear the interrupt and indicate whether to ack the last byte received by writing into I2C_I2C_SL_CNFG_0. ACK_LAST_BYTE_VALID and into I2C_I2C_SL_CNFG_0. ACK _LAST_BYTE
- Write Generic Packet Header
- Write Payload size
- Write protocol Specific header.

  The buffer_size will updated with payload size set in packet header. Interrupt will be generated again after receiving no.of bytes equal to buffer_size.Slave will withhold the ack for the last byte if ack_last_byte field in protocol specific header is not set or else it will ack the last byte immediately.

SW should read the bytes received from SLV_RX_FIFO register.This will generate a trigger if the fifo is above threshold. Please see FIFO_CONTROL register on how to program threshold levels.Last two steps will be repeated every time there is a transfer equal to buffer_size.

To work in Tegra 3 packet mode for Rd operation(Master reading from slave)

- Set I2C_I2C_SL_CNFG_0. ENABLE_SL
- Set I2C_I2C_SL_CNFG_0. FIFO_XFER_EN
- Set I2C_I2C_SL_CNFG_0. PACKET_MODE_EN
- When an rd transaction is received, interrupt will be generated and TX_BUFFER_REQ will be set.
- Clear the interrupt and write the data to be transmitted into the I2C_I2C_SLV_TX_PACKET_FIFO_0.
- If a new transaction is received, interrupt will again be generated and TX_BUFFER_REQ will be set.

The data can be sent/received without working in packet mode by only updating the following register field information

For ex, WR operation works as follows:

- Set I2C_I2C_SL_CNFG_0. ENABLE_SL
- Set I2C_I2C_SL_CNFG_0. FIFO_XFER_EN
- Set I2C_I2C_SL_CNFG_0. ACK_WITHHOLD_EN if HW needs to withhold ack for the last byte.
- After receiving SLV_RX_BUFFER_FILLED interrupt , clear the interrupt and update ACK_LAST_BYTE field. Also read the bytes from RX_FIFO

33.5 I2C Registers

33.5.1 I2C_I2C_CNFG_0

IC Controller Configuration Register (Master) I2C_CNFG register is used to configure, the number of bytes to be transmitted or received, the slave device type either a 7-bit device or a 10-bit device, enable mode to send Start-Byte or not, to select either a single slave transaction or two slave transaction, Enable mode to handle devices that do not generate ACK.

Offset: 000h | Read/Write: R/W | Reset: 0b0000100000000000

Bit	Reset	Description
15	0x0	MSTR_CLR_BUS_ON_TIMEOUT: When this bit is set,I2C master will force clock lowfor an extended period of time(>TIMEOUT) to force all SMB slavesto release the bus0 = Dont clear the bus on TLow:SEXT/TIMEOUT timeout1 = clear the bus on TLow:SEXT/TIMEOUT timeout
14:12	0x0	DE-BOUNCE_CNT: De-bounce period for sda and scl lines 0 = No De-bounce 1 = 2T 2 = 4T 3 = 6T etc where T is the period of the fix PLL clk source coming to i2c.Maximum De-bounce period programmable is 14T. A De-bounce period of >50ns is desirable
11	0x1	NEW_MASTER_FSM: Maintained for compatibility sake. 0 = DISABLE 1 = ENABLE
10	0x0	PACKET_MODE_EN: Write 1 to initiate transfer in packet mode. 0 = NOP 1 = GO
9	0x0	SEND: Writing a 1 causes the master to initiate the transaction in normal mode. Values of other bits are not affected when this bit is 1, Cleared by hardware. Other bits of the register are masked for writes when this bit is programmed to one. Hence, firmware should first configure all other registers and bits [8:0] of I2C_CNFG register before the bit I2C_CNFG[9] is programmed to Zero. 0 = NOP 1 = GO
8	0x0	NOACK: Enable mode to handle devices that do not generate ACK. 1 - don’t look for an

Bit	Reset	Description
		ack at the end of the Enable 0 = DISABLE 1 = ENABLE
7	0x0	CMD2: Read/Write Command for Slave 2: 1 - Read Transaction; 0 - write Transaction. For a 7-bit slave address, this bit must match with the LSB of address byte for slave 2. Valid only when bit-4 of this register is set 0 = DISABLE 1 = ENABLE
6	0x0	CMD1: Read/Write Command for Slave 1: 1 - Read Transaction; 0 - write Transaction. Command for Slave 1: For a 7-bit slave address this bit must match with the LSB of address byte for slave1. 0 = DISABLE 1 = ENABLE
5	0x0	START: 1 = Yes, a Start byte needs to be sent. 0 = DISABLE 1 = ENABLE
4	0x0	SLV2: 1 - Enables a two slave transaction; 0 = No command for Slave 2 present. 0 = DISABLE 1 = ENABLE
3:1	0x0	LENGTH: The Number of bytes to be transmitted per transaction 000= 1byte ... 111 = 8bytes; In a two slave transaction number of bytes should be programmed less than 011.
0	0x0	A_MOD: Address mode defines whether a 7-bit or a 10-bit slave address is programmed. 1 = 10-bit device address 0 = 7-bit device address 0 = SEVEN_BIT_DEVICE_ADDRESS 1 = TEN_BIT_DEVICE_ADDRESS

33.5.2 I2C_I2C_CMD_ADDR0_0

I2C_CMD_ADDR0 is programmed the 7 Bit or 10 Bit address of slave 1 with which the transaction is intended.

I2C Slave-1 Address

Offset: 004h | Read/Write: R/W | Reset: 0b0000000000

Bit	Reset	Description
9:0	0x0	ADDR0: In case of 7-Bit mode address is written in the I2C_CMD_ADDR0[7:1] and I2C_CMD_ADDR0[0] indicates the read/write transaction.I2C_CMD_ADDR0[0] bit must match with the I2C_CNFG[6]. In case of 10-Bit mode address is written in I2C_CMD_ADDR0[9:0] and I2C_CNFG[6] indicates the read/write transaction.

33.5.3 I2C_I2C_CMD_ADDR1_0

I2C_CMD_ADDR1 is programmed the 7 Bit or 10 Bit address of slave 2 with which the transaction is intended.

I2C Slave-2 Address

Offset: 008h | Read/Write: R/W | Reset: 0b0000000000

Bit	Reset	Description
9:0	0x0	ADDR1: In case of 7-Bit mode address is written in the I2C_CMD_ADDR0[7:1] and I2C_CMD_ADDR0[0] indicates the read/write transaction.I2C_CMD_ADDR0[0] bit must match with the I2C_CNFG[7]. In case of 10-Bit mode address is written in I2C_CMD_ADDR0[9:0] and I2C_CNFG[7] indicates the read/write transaction.

33.5.4 I2C_I2C_CMD_DATA1_0

The four Least Significant Bytes of Data to be transmitted is loaded into the register when I2c Master is in Write Mode.

The four Least Significant Bytes of Data are Read through this register when I2C Master is in Read mode.

IC Controller Data 1: Transmit/Receive

Offset: 00ch | Read/Write: R/W | Reset: 0b00000000000000000000000000000000

Bit	Reset	Description
31:24	0x0	DATA4: Fourth data byte to be sent/received
23:16	0x0	DATA3: Third data byte to be sent/received
15:8	0x0	DATA2: Second data byte to be sent/received
7:0	0x0	DATA1: This register contains the first data byte to be sent/received.

33.5.5 I2C_I2C_CMD_DATA2_0

The four Most Significant Bytes of Data to be transmitted is loaded into the register when I2C Master is in Write Mode.

The four Most Significant Bytes of Data are Read through this register when I2C Master is in Read mode.

IC Controller Data 2: Transmit/Receive

Offset: 010h | Read/Write: R/W | Reset: 0b00000000000000000000000000000000

Bit	Reset	Description
31:24	0x0	DATA8: Eighth data byte to be sent/received
23:16	0x0	DATA7: Seventh data byte to be sent/received
15:8	0x0	DATA6: Sixth data byte to be sent/received
7:0	0x0	DATA5: This register contains the Fifth data byte to be sent/received.

33.5.6 I2C_I2C_STATUS_0

I2C_STATUS gives the status of I2C master operation.

IC Controller Status (Master)

Offset: 01ch | Read/Write: RO | Reset: 0bxxxxxxxxx

Bit	Reset	Description
8	X	BUSY: 1 = Busy. 0 = NOT_BUSY 1 = BUSY
7:4	X	CMD2_STAT: Transaction for Slave2 for x byte failed. x is 'h0 to 'ha. all others invalid 0 = SL2_XFER_SUCCESSFUL 1 = SL2_NOACK_FOR_BYTE1 2 = SL2_NOACK_FOR_BYTE2 3 = SL2_NOACK_FOR_BYTE3 4 = SL2_NOACK_FOR_BYTE4 5 = SL2_NOACK_FOR_BYTE5 6 = SL2_NOACK_FOR_BYTE6 7 = SL2_NOACK_FOR_BYTE7 8 = SL2_NOACK_FOR_BYTE8 9 = SL2_NOACK_FOR_BYTE9 10 = SL2_NOACK_FOR_BYTE10
3:0	X	CMD1_STAT: Transaction for Slave1 for x byte failed. x is 'h0 to 'ha. all others invalid 0 = SL1_XFER_SUCCESSFUL 1 = SL1_NOACK_FOR_BYTE1 2 = SL1_NOACK_FOR_BYTE2 3 = SL1_NOACK_FOR_BYTE3

Bit	Reset	Description
		4 = SL1_NOACK_FOR_BYTE4 5 = SL1_NOACK_FOR_BYTE5 6 = SL1_NOACK_FOR_BYTE6 7 = SL1_NOACK_FOR_BYTE7 8 = SL1_NOACK_FOR_BYTE8 9 = SL1_NOACK_FOR_BYTE9 10 = SL1_NOACK_FOR_BYTE10

33.5.7 I2C_I2C_SL_CNFG_0

I2C_SL_CNFG register is used to configure,

- Enable mode of slave Ack
- Enable mode of slave response to general call address

The register should be programmed when I2C controller is configured as slave.

IC Controller Configuration (Slave)

Offset: 020h | Read/Write: R/W | Reset: 0b00000000000000000100

Bit	Reset	Description
20	0x0	FIFO_XFER_EN: If this bit is disabled, data is always communicated via I2C_SL_RCVD register. If enabled, it is through FIFOs 0 = DISABLE 1 = ENABLE
19:8	0x0	BUFFER_SIZE: Payload size in bytes

33.5.8 I2C_I2C_SL_RCVD_0

IC Controller Slave Receive/Transmit Data (Slave)

Offset: 024h | Read/Write: R/W | Reset: 0b00000000

Bit	Reset	Description
7:0	0x0	SL_DATA: slave Received data

33.5.9 I2C_I2C_SL_STATUS_0

IC Controller Slave Status (Slave)

Offset: 028h | Read/Write: R/W | Reset: 0bxxxxxxx000000x0

Bit	R/W	Reset	Description
14:8	RO	X	HW_MSTR_ADR: HW master addr received via general call addressing. This field is meaningful only if HW_MSTR_INT is set.
7	RW	0x0	HW_MSTR_INT: 1 = Interrupt has been generated by slave Hardware Master Address is received after General Call Address. 1 = Received HW Master Address 0 = No event.
6	RW	0x0	REPROG_SL: 1 = Interrupt has been generated by slave after General Call Address is 0x04. 1 = Reprogram slave address. 0 = No action.
5	RW	0x0	RST_SL: 1 = Interrupt has been generated by slave after General Call Address is 0x06. 1 = Reset and reprogram slave address. 0 = No action.
4	RW	0x0	END_TRANS: 1 = Interrupt has been generated by slave Transaction completed as indicated by stop/repeat start condition. 1 = Transaction completed. 0 = No transaction occurred or transaction in progress.
3	RW	0x0	SL_IRQ: 1 = Interrupt has been generated by slave 0 = No interrupt generated 0 = UNSET 1 = SET
2	RW	0x0	RCVD: New Transaction Received status 1 = Transaction occurred. 0 = No transaction occurred 0 = NO_TRANSACTION_OCCURED 1 = TRANSACTION_OCCURED
1	RO	X	RNW: Slave Transaction status 0 = Write 1=Read 0 = WRITE 1 = READ
0	RW	0x0	ZA: Zero Address Status 1 = Yes, slave responded. 0 = No, slave did not respond 0 = NO_SLAVE_RESPONSE 1 = SLAVE_RESPONSE

33.5.10 I2C_I2C_SL_ADDR1_0

IC Controller Slave Address 1 Register (Slave)

Offset: 02ch | Read/Write: R/W | Reset: 0b0000000000000000

Bit	Reset	Description
15:8	0x0	SL_ADDR1: For a 10-bit slave address, this field is the least significant 8 bits.
7:0	0x0	SL_ADDR0: For a 10-bit slave address, this field is the least significant 8 bits.

33.5.11 I2C_I2C_SL_ADDR2_0

IC Controller Slave Address 2 Register (Slave)

Offset: 030h | Read/Write: R/W | Reset: 0b0xxxxx000xxxxx000

Bit	Reset	Description
16	0x0	SELECT_SLAVE: 0 = Use slave addr0 1 = Use slave addr1
10:9	0x0	SL1_ADDR_HI: In 7 bit address mode these bits are don't care; In 10-bit address mode, they represent the 2 MSBs of the address.
8	0x0	SL1_VLD: 0 = 7-bit addressing. 0 = SEVEN_BIT_ADDR_MODE 1 = TEN_BIT_ADDR_MODE
2:1	0x0	SL_ADDR_HI: In 7-bit address mode these bits are don't care; In 10 bit address mode they represent the 2 MSB of the address.
0	0x0	VLD: 0 = 7-bit addressing. 1 - 10 bit addressing. 0 = SEVEN_BIT_ADDR_MODE 1 = TEN_BIT_ADDR_MODE

33.5.12 I2C_I2C_TLOW_SEXT_0

IC Controller SMBUS timeout thresholds

Offset: 034h | Read/Write: R/W | Reset: 0b00000000000000000000000000000000

Bit	Reset	Description
27	0x0	RST_SL_ON_TIMEOUT: Reset Slave state machine on time-out
26	0x0	TLOW_MEXT_EN: Enable TLOW_MEXT counter
25	0x0	TLOW_SEXT_EN: Enable TLOW_SEXT counter
24	0x0	TIMEOUT_EN: Enable TIMEOUT counter
23:16	0x0	TLOW_MEXT: cumulative clock low extend time(master device) accumulated over a byte transfer period in milliseconds(START to ACK,ACK to ACK, or ACK to STOP).
15:8	0x0	TLOW_SEXT: cumulative clock low extend time(slave device) accumulated over a complete transfer(START till STOP)
7:0	0x0	TIMEOUT: clock low timeout period in milliseconds

33.5.13 I2C_I2C_SL_DELAY_COUNT_0

IC Slave Controller Delay Count

Offset: 03ch | Read/Write: R/W | Reset: 0b0000000000011110

Bit	Reset	Description
15:0	0x1e	SL_DELAY_COUNT: The value determines the timing between an address cycle and a subsequent data cycle or two consecutive data cycles on the bus. The I2C_SL_DELAY_COUNT is valid only when internal slave is accessed. I2C_SL_DELAY_COUNT has to be programmed such that TIMING = T * DLY where T is period of clock source selected for I2c; and DLY is I2C_SL_DELAY_COUNT; TIMING is the desired timing, A value of >= 1250 ns is advisable.

33.5.14 I2C_I2C_SL_INT_MASK_0

IC Controller Slave Mask (Slave)

Offset: 040h | Read/Write: R/W | Reset: 0b111111x1

Bit	Reset	Description

3	0x0	SL_IRQ: 0 = UNSET 1 = SET
2	0x0	RCVD: 0 = UNSET 1 = SET
0	0x0	ZA: 0 = UNSET 1 = SET

Imp Note: Program the field PACKET_MODE_EN of I2C_CNFG register while working in packet mode.

The set of registers below describe the interface for packet mode only. With the packet mode interface changes, normal mode registers and the operation are not affected. The transition from normal mode to packet mode is suggested because packet mode allows:

1. There is no restriction on the no. of bytes before and the after the repeated start
2. The number of bytes that can be transferred with a single cmd is not limited to 8. Though a packet can contain 4k bytes, because any number of packets can be pushed into the fifo, there is no limit on the no. of bytes that can be transferred.
3. The transactions to different slaves can be chained together with repeat start and there is no limit on the no. of slaves it can address.

33.5.17 I2C_I2C_TX_PACKET_FIFO_0

A packet contains header and payload. Header size is variable and could vary from 2 to 5 words. For I2C it is 3 words. The first two words of the header contain generic information. The third word contains I2C transaction specific information. Payload contains actual data to be written to the slave. In case of read operation, payload is nil, hence the packet contains header only.

Offset: 050h | Read/Write: R/W | Reset: 0b00000000000000000000000000000000

Bit	Reset	Description

[THIS PAGE INTENTIONALLY LEFT BLANK]

34.0 UART AND VFIR CONTROLLER

There are five Universal Asynchronous Receiver/Transmitters (UARTs) built into Tegra® 3 devices. These UARTs support both 16450 and 16550 compatible modes. All UARTs are identical, though their pin connections will be different. One of the UARTs also contains VFIR functionality.

All UARTs provides serial data synchronization and data conversion (parallel-to-serial and serial-to-parallel) for both receiver and transmitter sections. Synchronization for serial data stream is accomplished by adding start and stop bits to the transmit data to form a data character. Data integrity is accomplished by attaching a parity bit to the data character. The parity bit can be checked by the receiver for any transmission bit errors.

The COM-HOST interface is fully programmable through an 8-bit CPU interface. The registers are 32-bit word aligned. The interface supports word lengths from five to eight bits, an optional parity bit and one or two stop bits. If enabled, parity can be odd, even, or forced to a defined state. Interrupts can be generated from any of 10 sources.

The UARTs support both 16450 and 16550 compatible modes. The default mode is 16450. This mode provides independent 16-byte FIFOs for transmit and receive and is selected by means of the FIFO control register. It also includes a 16-bit programmable baud rate generator and an 8-bit scratch register, eight modem control lines, and two DMA handshake lines that are used to indicate when the FIFOs are ready to transfer data to the CPU. The UARTs support a device clock of up to 72 MHz. The maximum baud rate is 16 clock cycles per symbol, and is therefore 4.5 Megabits per second.

Note: Mention of UART A/B/C/D/E in this document equates to UART 1/2/3/4/5, respectively.

The Tegra 3 device VFIR controller implements the control and data sections of the IrDA Physical layer version 1.4, handling handshaking and basic networking between devices, and interfaces to an external Infrared transceiver.

This controller implements three distinct speed ranges and protocols: 2400 to 115,200 bits per second (Serial IR or SIR), 4 Megabits per second (called Fast Infrared or FIR), and 16 Megabits per second (called Very Fast Infrared or VFIR). Initial communication starts at 9600 bits per second, and negotiations proceed either faster or slower as the link strength allows. Each of the three speed ranges has different communication protocols and encoding schemes.

Table 88 Protocols Supported by the IrDA

Signaling Rate (bps)	IrDA Name	Frame Wrapper and Encoding	IrDA Status	Tegra 3 Support
9.6 K	SIR	Async RZI (3/16)	Mandatory	Yes
2400 - 115.2K	SIR	Async RZI (3/16)	Recommended	Yes
576.0 K	MIR	Sync HDLC RZI (4/16)	Optional	No
1.152 M	MIR	Sync HDLC RZI (4/16)	Optional	No
4.0 M	FIR	Sync 4PPM	Optional	Yes
16.0 M	VFIR	Sync HHH(1,13)	Optional	Yes

34.1 Hardware Features

- Synchronization for the serial data stream with start and stop bits to transmit data to and from a data character
- Data integrity by attaching parity bit to the data character
- The COM-HOST interface is fully programmable through an 8-bit CPU interface
- Support for word lengths from five to eight bits, an optional parity bit and one or two stop bits

- The UART supports both 16450- and 16550-compatible modes. Default mode is 16450
- DMA capable for both TX and RX
- 8 bit x 16 deep FIFO
- Auto sense baud detection

The features supported by the VFIR controller are:

- Supports IrDA ver1.0 SIR protocol with maximum baud rate to 115.2 Kilobits per second
- Supports IrDA ver1.3 FIR protocol (4 Megabits per second)
- Supports IrDA ver1.4 VFIR protocol (16 Megabits per second)
- Programmable polarities on all the interface pins
- DMA capable for both TX and RX
- 32 bit x 16 deep FIFO
- Diagnostics for loopback and error insertion
- Interface control, such as transceiver signal strength, must be performed through GPIOs
- Maximum frequency of device clock is 72 MHz

34.2 Hardware Signaling

All Tegra UARTs are implemented by a HW block that supports modem control signals such as DTR, DSR, DCD.

UART A is, however, the only UART that allows those signals to be used externally. For UART A, when the pinmux is configured for 4- or 2-pin UART operation, the DSR and DCD input signals are tied low (active).

For UART B, the DTR output is routed back into the DSR and DCD inputs in HW. This means that if SW changes DTR state, the UART may raise an interrupt due to DSR/DCD changing state.

For UARTs C, D, and E, the DSR and DCD inputs are tied to an inactive value.

Table 89 Serial Bus Interface Signals

Signal Name	Description
Outputs	
TXD	Transmit Data Port
RTS	Request to Send
DTR	Data Terminal Ready
Inputs	
RXD	Receiver Data Port
CTS	Clear to Send
DSR	Data Set Ready
DCD	Data Carrier Detect
RI	Ring Indicator

Note: The DSR, DCD, and RI MODEM control signals do not control any hardware other than generating interrupts and status on change.

34.3 Functionality

The controller can operate in three different encodings and each is implemented separately. In SIR mode, a pulse encoder/decoder is inserted in the transmit/receive path of a standard UART. FIR and VFIR modes have their own control blocks. The outputs of the three blocks are multiplexed based on the current operating mode (SIR, FIR, or VFIR), before they leave the Tegra 3 device processor. The input signals are de-multiplexed in a similar fashion.

Note: The operating mode is selected with the Mode [2:0] bits of the VFIR.CTL register

Figure 87 UART Block Diagram with SIR Decoder and Encoder

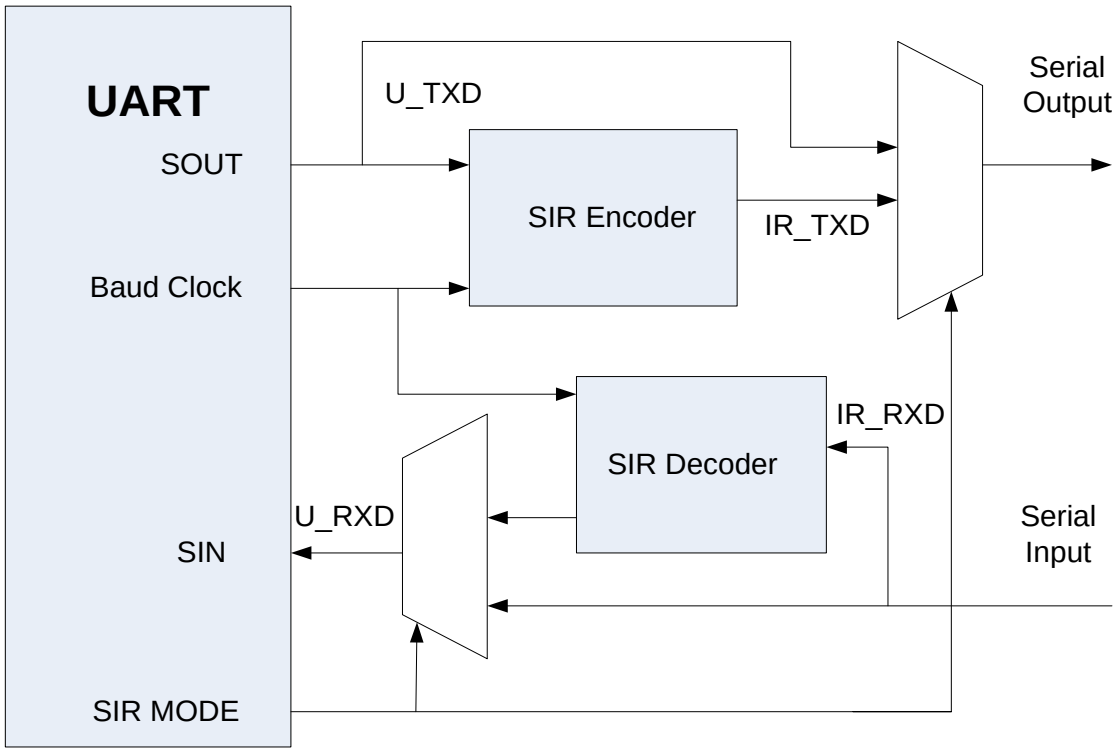

Figure 88 VFIR Controller Top-level Block Diagram

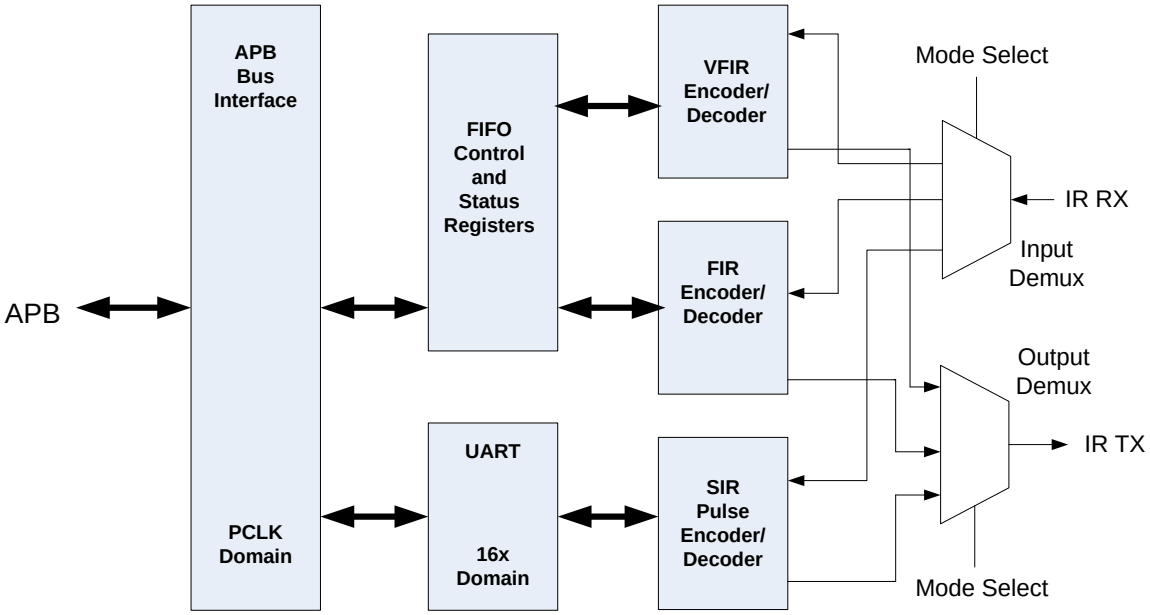


34.4 UART Programming Guidelines

34.4.1 16450 Mode Programming

1. Program pin mux settings to select UART
2. Enable UART clocks
3. For enabling internal loop-back, program MCR[4] to 1
4. Program FCR[0] to 0
5. Enable interrupts in IER register as needed
6. Write data into THR
7. Wait for THR interrupt if Interrupt is enabled or poll for LSR[5]
8. During receive, wait for RBR interrupt or poll for LSR[0]
9. Read the UART.LSR register to clear interrupts

34.4.2 16550 Mode Programming

1. Program pin mux settings to select UART
2. Enable UART clocks
3. For enabling internal loop-back, program MCR[4] to 1
4. Program FCR[0] to 1
5. Program trigger levels as required
6. Enable interrupts in IER register as needed
7. Write data into THR
8. Wait for THR interrupt if Interrupt is enabled or poll for LSR[5]
9. During receive wait for RBR interrupt or poll for LSR[0]
10. Read the UART.LSR register to clear interrupts
11. APB-DMA requestor number for UARTA, B and C are 8, 9 and 10 respectively

34.4.3 Transmitter and Receiver Holding Registers

The serial transmitter section consists of a Transmit Hold Register (THR) and Transmit Shift Register (TSR). The status of transmit hold register is provided in the Line Status Register (LSR). Writing to this register (THR) transfers the contents of data bus (D [7:0]) to the Transmit Holding Register whenever the Transmitter Holding Register or Transmitter Shift Register is empty. The Transmit Holding Register empty flag is set to 1 when the transmitter is empty or data is transferred to the transmit shift register. Note that a write operation is performed when the Transmit Holding Register empty flag is set.

The serial receiver section also contains an 8-bit Receiver Holding/Buffer Register (RBR). Receive data is removed from the UART and received by the processor by reading the RBR. The receiver contains a mechanism for preventing false starts as follows: On the falling edge of the start bit, the receiver internal counter starts to count 7.5 clocks (16x clock), which is the center of the start bit. The start bit is valid if the RX is still low at the mid-bit sample of the start bit. Verifying the start bit prevents the receiver from assembling a false data character due to a low going noise spike on the RX input. Receiver status codes are posted in the line status register.

34.4.4 FIFO Interrupt Mode Operation

When the receive FIFO (FCR bit 0 = 1) and receive interrupts (IER bit 0 = 1) are enabled, a receiver interrupt occurs as follows:

- The receive data available interrupts are issued to the CPU when the FIFO has reached its programmed trigger level; it is cleared as soon as the FIFO drops below its programmed trigger level.
- The ISR receive data available indication also occurs when the FIFO trigger level is reached, and like the interrupt, it is cleared when the FIFO drops below the trigger level.
- The data ready bit (LSR bit 0) is set as soon as a character is transferred from the shift register to the receiver FIFO. It is reset when the FIFO is empty.

34.4.5 FIFO Polled Mode Operation

When FCR bit 0 = 1; clearing IER bits [3:0] to zero puts the UART in the FIFO polled mode of operation. Since the receiver and transmitter are controlled separately, either one or both can be in the polled mode operation by using the line status register as follows:

- LSR bit 0 is set as long as there is one byte in the receive FIFO
- LST bits [4:1] specifies which error(s) have occurred
- LSR bit 5 indicates when the transmit FIFO is empty
- LSR bit 6 indicates when both transmit FIFO and transmit shift registers are empty
- LSR bit 7 indicates when there are any errors in the receive FIFO

The UART requires a two-step FIFO enable operation in order to enable receive trigger levels.

34.4.6 Programmable Baud Rate Generator

The UART contains a programmable baud rate generator that is capable of taking the UART clock input and dividing it by any divisor from 1 to 2^16-1. The UART clocks are defined in section 6.1 on Clocking. The output frequency of baudout is equal to 16X the transmission baud rate (Baudout=16 X baud rate). Customized baud rates are achieved by selecting proper divisor values for the MSB and LSB bits of the baud rate generator.

34.4.7 Enable Register (IER)

The is an Interrupt Enable Register for each UART (UART A Interrupt Enable and UART B Interrupt Enable). The Interrupt Enable Register(s) masks the incoming interrupts from the receiver ready, transmitter empty, line status and modem status registers to the INT output pin.

34.4.8 Interrupt Identification Register (IIR)

The UART provides four level prioritized interrupt conditions to minimize software overhead during data character transfers. The Interrupt Identification Register (IIR) provides the source of the interrupt in a prioritized manner.

During the read cycle the 16550 provides the highest interrupt level to be serviced by the CPU. No other interrupts are acknowledged until the particular interrupt is serviced. The prioritized interrupt levels are shown in the following table. The Receive Data Time-out mode is enabled when the UART is operating in the FIFO mode.

Receive time-out does not occur if receive FIFO is empty. The time-out counter is reset at the center of each stop bit received or each time the receive holding register is read. The actual time out value is:

- T (Time out length in bits) = 4 X P (Programmed work length) + 12

To convert the time-out value to a character value, divide this number to its complete word length + parity (if used) + number of stop bits and start bit.

Example

If you program the word length = 7, no parity, and one stop bit, the time-out is:

- T = 4X7 (programmed word length) + 12 = 40 bits.
- Character time = 40/9
- [(Programmed word length = 7) + (stop bit = 1) + (start bit = 1)] =4.4 characters

Table 90 Prioritized Interrupt Levels

Priority	D3	D2	D1	D0	Interrupt Source Description
1	0	1	1	0	LSR (Receiver Line Status Register)
2	0	1	0	0	RXRDY (Received Data Ready)
2	1	1	0	0	RXRDY (Received Data Timeout)
3	0	0	1	0	TXRDY (Transmitter Holding Register)
4	0	0	0	0	MSR (Modem Status Register)

34.4.9 FIFO Control Register (FCR) Modes

The FIFO control register is used to enable the FIFOs, clear the FIFOs, set the receiver FIFO trigger level, and select the type of DMA signaling. The operation of the FCR in the four DMA modes is given below.

34.4.9.1 Transmit operation in DMA mode 0 or mode 1

When the UART is in the 16450 mode (FCR bit 0 = 0) or in the FIFO mode (FCR bit 0 = 1, FCR bit 3 = 0) and when there are no characters in the transmit FIFO or transmit holding register, the TXRDY* pin goes low. Once active, the TXRDY* pin goes high (inactive) after the first character is loaded into the transmit holding register.

34.4.9.2 Receive operation in DMA mode 0

When UART is in 16450 mode (FCR bit 0 = 0) or in the FIFO mode (FCR bit 0 = 1,FCR bit 3 = 0) and there is at least 1 character in the receive FIFO, the RXRDY* pin goes low. Once active, the RXRDY* pin goes high (inactive) when there are no more characters in the receiver.

34.4.9.3 Receive operation in DMA mode 1

When UART is in the FIFO mode (FCR bit 0 = 1, FCR bit 3 = 1) and the trigger level or the timeout has been reached, the RXRDY* pin goes low. Once it is activated it goes high (inactive) when there are no more characters in the FIFO.

34.4.10 Line Control Register (LCR)

The Line Control Register is used to specify the asynchronous data communication format. The word length, stop bits, and parity can be selected by writing appropriate bits in this register.

34.4.11 Modem Control Register (MCR)

This register controls the interface with the modem or a peripheral device (RS232).

Loopback Mode

If MCR[4] = 1, the loopback mode is enabled and the following occurs:

The transmitter output (TX) is set high (Mark condition), and the receiver input (RX), CTS, DSR, CD, and RI are disabled. Internally the transmitter output is connected to the receiver input and DTR, RTS, OP1 and OP2 are connected to modem control inputs.

In this mode, the receiver and transmitter interrupts are fully operational, but the interrupt sources are now the lower four bits of the modem control register instead of the four modem control inputs. The interrupts are controlled by the IER register.

Table 91 Modem Control Register (MCR)

Bit	Name	Description
7:6	N/A	Not used. Set to 0 internally.
5	CTS.EN	1 = Enable Hardware Flow Control using CTS 0 = Disable Hardware Flow Control
4	LOOP	0 = Normal operating mode. 1 = Enable local loop-back mode (diagnostic).
3	OUT2	nOUT2 polarity
2	OUT1	nOUT1 polarity
1	RTS	1 = Force RTS (Request to Send) low 0 = Force RTS to high
0	DTR	1 = Force DTR (Data Terminal Ready) to low 1 = Force to high

34.4.12 Line Status Register (LSR)

The Line Status Register provides the status of data transfer to the CPU.

34.4.13 Modem Status Register (MSR)

The modem status register provides the current state of the control lines from the modem or peripheral to the CPU. Four bits of this register are used to indicate the changed information. These bits are set to 1 whenever a control input from the modem changes state. They are set to 0 whenever the CPU reads the register. The following table shows the bit format for the MSR register.

34.4.14 Scratchpad Register (SR)

Eight bits of information can be stored in this register. Information in this register does not affect the operation of the device in any way.

34.4.15 Autobaud Sense Register (ASR)

The UART has the ability to automatically determine the correct baud divisor by using the Autobaud Sense Register (UART offsets 0x3C). The most significant bit of this register is the valid flag. A write to this register will clear the valid flag and enable the autobaud process. When the first RX edge occurs, a counter running at 24 MHz starts counting and when another rx_edge occurs, the "complete" flag is set, the value frozen and the autobaud sense value register updated with the count value. The low 20 bits of the ASR gives the number of clocks within a single bit. Because the UART uses 16x over sampling, the resulting value needs to be adjusted by shifting right 4 bits, then loading the resulting count in the divisor latch of the UART. (In the code snippet below, the lower 4 bits are rounded to give slightly greater accuracy.)

Because the speed determination is made by measuring the start bit, special characters must be sent by the transmitting UART to guarantee that the next character after the start bit is a 1. Since bit 0 (rightmost bit) is sent first, the ASCII Carriage Return character (CR) is sufficient to enable proper speed sense.

The following code snippet returns the values for DLH and DLL in r9, r8:

```
       MOV     r0, #1  ; dummy write data
       STRB    r0, [r3, #U ASR]; Start autobaud sense (r3 as uart base)
; now poll the autobaud sense register MSB until Valid is truewait4valid
```

```
        LDR     r2, [r3, #U ASR]; Read ASR
        TST     r2, #0x80000000 ; the Valid bit (active high)
        BEQ     wait4valid
; autobaud sense check complete...
; r2 as number of 1x clocks in one bit time
; representing the number of 24MHz clocks in the start bit
; Since this represents 16 of the baud (16x) clocks, we
; will be dividing by 16 to get baud divisor, but first
; round to nearest by adding 8 before the divide:
        ADD     r4, r2, #8 ; add 1/2 resolution
        MOV     r6, r4, LSR #4 ; divide by 16... R6 will have total divisor
        AND     r8, r6, #0xFF  ; copy DLL to r8
        MOV     r9, r6, LSR #8 ; copy DLM to r9
        AND     r9, r9, #0xff ; mask upper bytes
```

34.4.16 Baud Rate Generator

The following table given below is a divisor table for the baud rate, assuming the oscillator is 24.000 MHz.

Table 92 Baud Rate Generator Programming

Baud Rate	Divisor
300	5000
1200	1250
2400	625
4800	312
9600	156
19.2K	78
38.4K	39
57.6K	26
115.2K	13

34.4.17 Power-up Defaults

The following defines the Power-Up defaults:

- IER = 0
- ISR = 1
- LCR = 0
- MCR = 0
- LSR = 60 HEX
- MSR = BITS 0-3 = 0, BITS 4-7 = inputs
- FCR = 0
- TX = High
- OP1 = High
- OP2 = High
- RTS = High
- DTR = High

- RXRDY = High
- TXRDY = Low
- INT = Low

34.5 VFIR Programming Guidelines

34.5.1 IRDA (FIR/VFIR) and UART B

The IRDA module includes a fully functional 16550 compatible UART for implementing the SIR protocol. The UART pins will be selected automatically when the VFIR.CTL Mode bits are set to UART or SIR modes. Set the UART IRDA.CSR register to SIR mode to convert the UART signals to SIR signals.

If the IRDA.CTL Mode bits are set the FIR or VFIR modes, the UART pins will be disabled, and the FIR/VFIR pins will be used.

34.5.2 APB Bus Interface to Control/Status/FIFO

The Control and Status registers, and the FIFO reside on the APB bus. The processor programs the Control registers to begin transactions, and can read progress and error status from the Status Register. FIFO access is normally performed via the APB_DMA module.

34.5.3 FIR Mode Programming

1. Set the CLK_SOURCE_VFIR for 48MHz and enable the UART_B Clock
2. Program IR.TX and IR.RX pin mux settings to select IR (UART B)
3. Set the VFIR.CTL Mode to binary 100 (FIR)
4. FIR mode is Half-Duplex. Set the VFIR.CTL Transmit bit to '1' for transmit, '0' for receive
5. Read the VFIR.STS register to clear interrupts
6. Program the APB_DMA to transfer data to/from the VFIR module
7. Enable the DMA bit in the VFIR.CTL register
8. Enable interrupts as needed
9. Set the GO bit in the VFIR.CTL register to start the action
10. Wait for DONE status or interrupt which indicates that the transaction has completed
11. Check for Errors when reading the VFIR.STS register
12. Clear status bits by writing a '1' to them before starting next packet.
13. For receive operations, the Incoming Frame Data Length (IFDL) register will contain the number of bytes received. DMA should have read this many bytes from the FIFO.

34.5.4 VFIR Mode Programming

1. Set the CLK_SOURCE_VFIR for 48MHz and enable the UART_B Clock
2. Program IR.TX and IR.RX pin mux settings to select IR (UART B)
3. Set the VFIR.CTL Mode to binary 101 (VFIR)
4. FIR mode is Half-Duplex. Set the VFIR.CTL Transmit bit to '1' for transmit, '0' for receive
5. Read the VFIR.STS register to clear interrupts
6. Program the APB_DMA to transfer data to/from the VFIR module
7. Enable the DMA bit in the VFIR.CTL register
8. Enable interrupts as needed

9. Set the GO bit in the VFIR.CTL register to start the action
10. Wait for DONE status or interrupt which indicates that the transaction has completed
11. Check for Errors when reading the VFIR.STS register
12. Clear status bits by writing a '1' to them before starting next packet.
13. For receive operations, the Incoming Frame Data Length (IFDL) register will contain the number of bytes received. DMA should have read this many bytes from the FIFO.

34.5.5 COM-SLAVE Interface (UART B)

The COM-SLAVE interface consists of a UART (Universal Asynchronous Receiver/Transmitter), which provides serial data synchronization, parallel-to-serial and serial-to-parallel data conversion for both receiver and transmitter sections. Synchronization for the serial data stream is accomplished by adding start and stop bits to the transmit data to form a data character. Data integrity is accomplished by attaching a parity bit to the data character. The parity bit can be checked by the receiver for any transmission bit errors.

The COM-SLAVE interface is fully programmable by an 8-bit CPU interface. The registers are 32-bit Word aligned. The interface supports word lengths from five to eight bits, an optional parity bit and one or two stop bits. If enabled, the parity can be odd, even or forced to a defined state. Interrupts can be generated from any of ten sources.

The UART supports both 16450 and 16550 compatible modes. Default mode is the 16450. The 16550 mode, which provides independent 16-byte FIFOs for transmit and receive, is selected via the FIFO control register. It also includes a 16-bit programmable baud rate generator and an 8-bit Scratch register, eight modem control lines and two DMA handshake lines that are used to indicate when the FIFOs are ready to transfer data to the CPU.

Table 93 Serial Bus Interface Signals for UART B

Signal Name	Direction	Description
UB3_RXD	I	Receiver Data Port
UB3_TXD	O	Transmit Data Port

34.5.6 SIR Pulse Encoder/Decoder

The UART transmit (TX) data is passed through this module prior to being muxed out to the IR transmitter. This module converts transmitted zeros into a 3/16 Return-To-Zero (RZ) pulse.

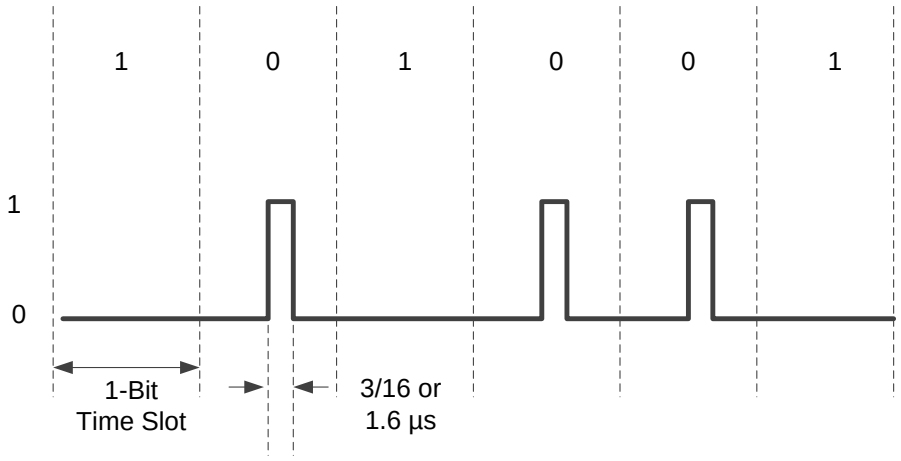
Similarly, received (RX) data is bit-synchronized using the 16X baud clock and the original serial data recovered from the IR bit stream. This data is then sent to the UART for reception.

The signal generated in SIR is as follows:

- On logic '1' the LED is off.
- On logic '0' a pulse is created starting the center of the bit time and lasting 3/16 of bit time period or 1.6µs (3/16 bit times at 115.2 kbps) depending on the current settings.

The figure below displays the output for the input 101001 (in sending order) in SIR encoding.

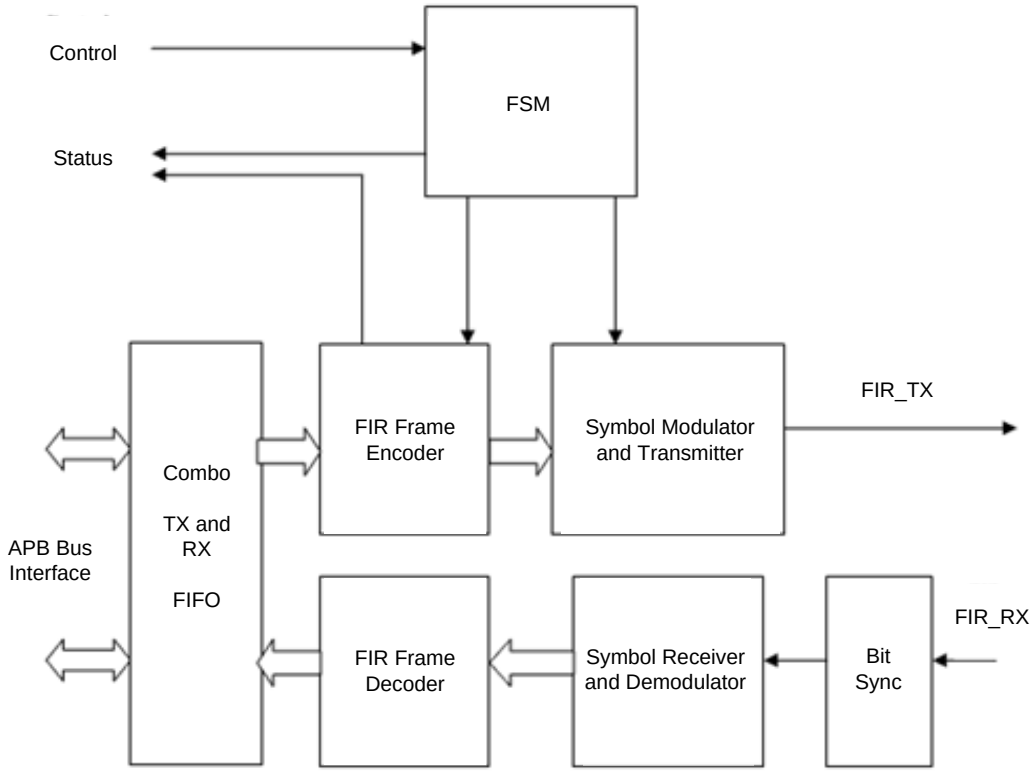
Figure 89 Output in Sending Order in SIR Encoding



34.5.7 FIR Encoder/Decoder

The Figure below shows the micro-architecture for FIR and VFIR modes. Although the architecture is the same, the FIR and VFIR encoding schemes are very different.

Figure 90 Architecture for FIR and VFIR Modes



The Frame Level Encoder calculates CRC for the sent data, performs bit stuffing, creates start and stop sequences and sends data down the line to the Data Shift Register. The Frame Level Decoder calculates the CRC on incoming data, performs bit de-stuffing, compares the calculated CRC to the received one and reports any errors detected in the process.

The 1-symbol modulator creates the signal to be sent to the IR transceiver bit by bit as received from the UART in SIR, 2-bit signals in FIR, and 3-bit signals in VFIR mode.

FIR mode uses a Pulse Position Modulation code called 4PPM. The encoding sends one symbol every four time slices called "chips". Because there are four unique chip positions within each symbol in 4PPM, four independent symbols exist in which only one chip is logically a "one" while all other chips are logically a "zero." These four unique symbols are defined to be the only legal data symbols (DD) allowed in 4PPM. Each DD represents two bits of payload data, so that a byte of payload data can be represented by four DDs in sequence. The table below defines the chip pattern representation of the four unique DDs defined for 4PPM.

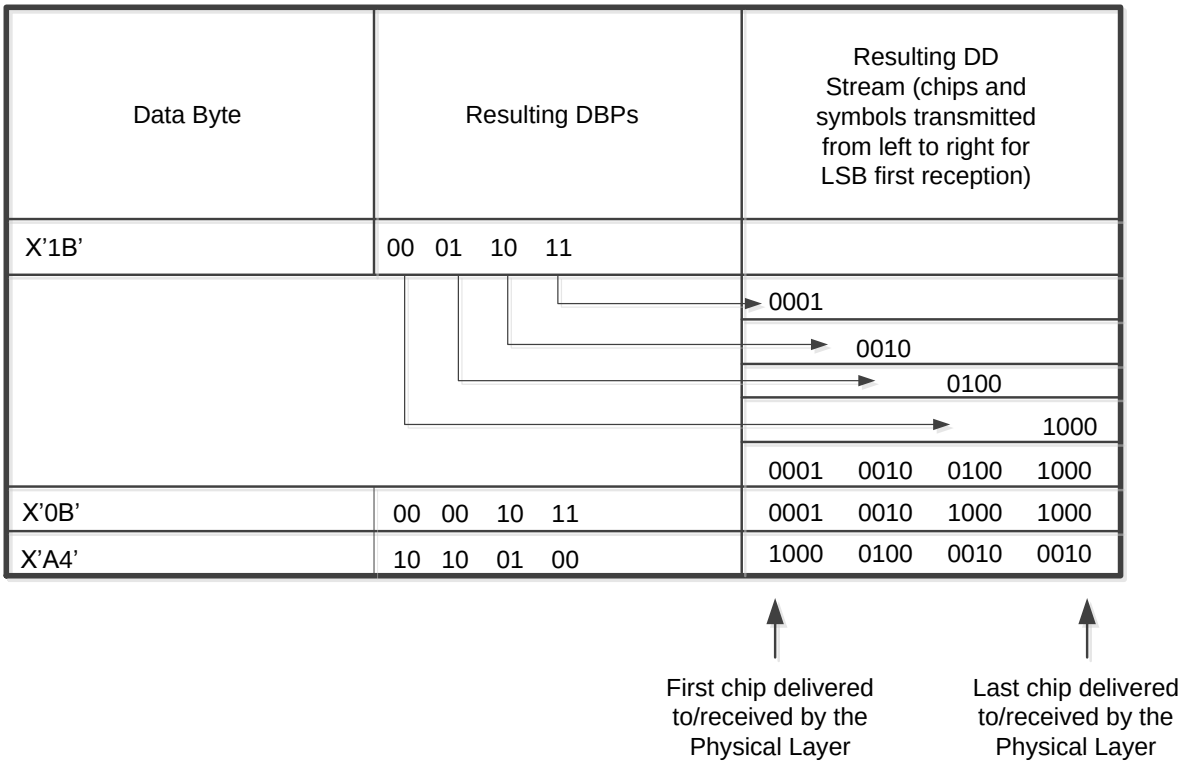
Table 94 Chip Pattern

Data Bit Pair	4PPM Data Symbol
00	1000
01	0100
10	0010
11	0001

Logical "1" represents a chip duration when the transmitting LED is emitting light, while logical "0" represents a chip duration when the LED is off. Data encoding for transmission is done LSB first.

The figure below shows how various data bytes would be represented after encoding for transmission. In these examples transmission time increases from left to right so that chips and symbols farthest to the left are transmitted first.

Figure 91 Various Data Bytes After Encoding for Transmission



34.5.8 PPM Packet Format

For FIR 4PPM packets the data rate is 4 Megabits per second and the signaling rate is 8.0 Mchips per second, where a chip is the smallest element of IrDA signaling. The following packet format is defined:

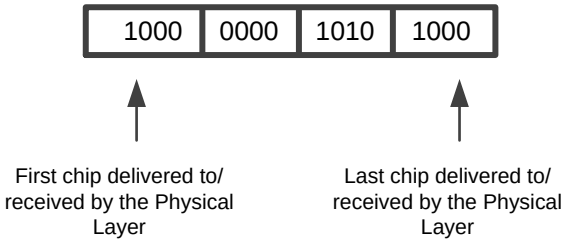
In this packet format, the payload data is encoded as described in the 4PPM encoding above, and the encoded symbols reside in the DD field. Maximum packet length is negotiated by the same mechanism as for the slower rates. The preamble field (PA) is used by the receiver to establish phase lock. During PA, the receiver begins to search for the start flag (STA) to establish symbol synchronization. If STA is received correctly, the receiver can begin to interpret the data symbols in the DD field. The receiver continues to receive and interpret data until the stop flag (STO) is recognized. STO indicates the end of a frame. The chip patterns and symbols for PA, STA, FCS field, and STO are defined below. Only complete packets that contain the entire format defined above are guaranteed to be decoded at the receiver (note that, as for the lower rates, the information field, I, may be of zero length).

The 4PPM data encoding described above defines only the legal encoded payload data symbols. All other4 chip combinations are by definition illegal symbols for encoded payload data. Some of these illegal symbols are used in the definition of the preamble, start flag, and stop flag fields because they are unambiguously not data.

34.5.8.1 Preamble Field Definition

The preamble field (PA) consists of exactly sixteen repeated transmissions of the following stream of symbols. In the PA field, transmission time increases from left to right so that chips and symbols on the left are transmitted first. See figure below.

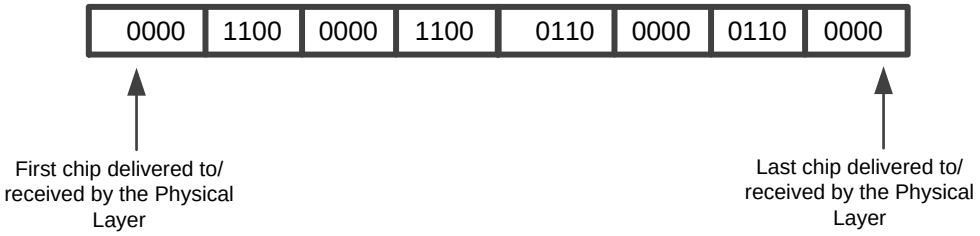
Figure 92 Preamble Field



34.5.8.2 Start Flag Definition

The start flag (STA) consists of exactly one transmission of the following stream of symbols. In the STA field, transmission time increases from left to right so that chips and symbols on the left are transmitted first. See figure below.

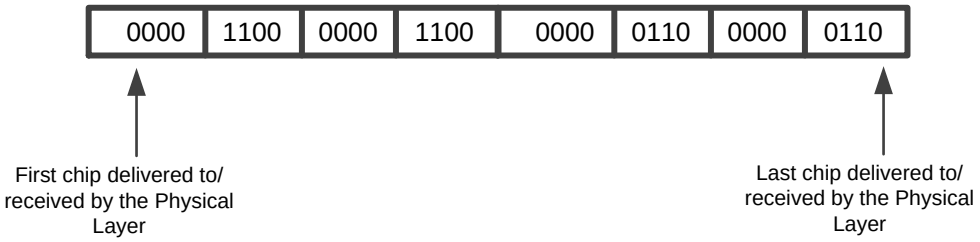
Figure 93 Start Flag



34.5.8.3 Stop Flag Definition

The stop flag (STO) consists of exactly one transmission of the following stream of symbols. In the STO field, transmission time increases from left to right so that chips and symbols on the left are transmitted first. See figure below.

Figure 94 Stop Flag



34.5.8.4 Frame Check Sequence Field Definition

Frame check sequence (FCS) field is a 32 bit field that contains a cyclic redundancy check (CRC) value. The CRC is a calculated, payload data dependent field, calculated before 4 PPM encoding. It consists of the 4PPM encoded data resulting from the IEEE 802 CRC32 algorithm for cyclic redundancy check as applied to the payload data contained in the packet. The CRC32 polynomial is defined as follows:

$$CRC(x) = x^{32} + x^{26} + x^{23} + x^{22} + x^{16} + x^{12} + x^{11} + x^{10} + x^{8} + x^{7} + x^{5} + x^{4} + x^{2} + x + 1$$

The CRC32 calculated result for each packet is treated as four data bytes, and each byte is encoded in the same fashion as is payload data. Payload data bytes are input to this calculation in LSB first format. The 32 bit CRC register is preset to all "1's" prior to calculation of the CRC on the transmit data stream. When data has ended and the CRC is being shifted for transmission at the end of the packet, a "0" should be shifted in so that the CRC register becomes a virtual shift register.

Note: The inverse of the CRC register is what is shifted as defined in the polynomial.

34.5.8.5 Aborted Packets

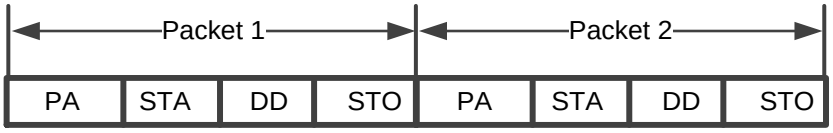
Receivers may only accept packets that have valid STA, DD, FCS, and STO fields as defined in the PPM Packet Format section. The PA field need not be valid in the received packet. All other packets are aborted and ignored.

Any packet may be aborted at any time after a valid STA but before transmission of a complete STO flag by two or more repeated transmissions of the illegal symbol "0000." Also, any packet may be aborted at any time after a valid STA by reception of any illegal symbol which is not part of a valid STO field.

34.5.8.6 Back to Back Packet Transmission

Back to back or "brick-walled" packets are allowed, but each packet must be complete (i.e., containing PA, STA, DD, and STO fields). Brick-walled packets are illustrated in the figure below.

Figure 95 Back-to-Back Packet Transmission



34.5.9 VFIR 16.0 Megabits per Second Rate

The 16.0 Megabits per second data transmission incorporates a new modulation code HHH (1,13) - low duty cycle, rate 2/3, (d,k) = (1, 13) run-length limited (RLL) code to achieve the specified data rate from a 24MHz reference clock. The HHH(1,13)

code guarantees for at least one empty chip and at most 13 empty chips between chips containing pulses in the transmitted IR signal. The data transmission packet/ frame is based on the 4.0 Megabits per second frame format with modifications introduced where necessary to accommodate the requirements that are specific to the new modulation code. The system includes a simple scrambling/descrambling scheme to randomize the duty cycle statistics. The signaling rate of the 16.0 Megabits per second data rate is 24.0 Mchips per second, where a chip is the smallest element of IrDA signaling.

34.5.10 HHH (1, 13) Modulation Code

The HHH (1, 13) modulation code has the following salient features:

- Code Rate: 2/3 ,
- Maximal Duty Cycle: 1/3 (~33%) ,
- Average Duty Cycle: ~26% ,
- Minimal Duty Cycle: 1/12 (~8.3%) ,
- Run-Length Constraints: (d, k) = (1, 13) ,
- Longest Run of '10's: yyy'000'101'010'101'000'yyy ,
- Chip Rate @ Data Rate 16 Megabits per second: 24 Mchips per second ,
- System Clock @ Data Rate 16 Megabits per second: N 12 MHz (where N ≥ 4)

The HHH(1,13) code is a Run Length Limited (RLL) code that provides both power efficiency and bandwidth efficiency at the high data rate. The signaling rate of the code is 24 Mchips per second allowing a rise and fall time of 19 ns. LED on time is further improved by having a 26% average duty cycle for random data. The lower duty cycle is achieved by scrambling the incoming data stream. The run length constraints (d, k) = (1, 13) ensure an inactive chip after each active chip, i.e. only single-chip-width pulses occur. This feature allows a source or a receiver to exhibit a long tail property. To take full advantage of the d = 1 feature of HHH(1, 13) in strong signal conditions, clock and data recovery circuitry ignores the level of the chip following an active chip and assumes these chips are inactive. The modulation code is enhanced with simple frame-synchronized scrambler/descrambler mechanisms as defined and described in later in this chapter.

34.5.10.1 HHH Data Encoding Definition

The encoding definition of the HHH (1, 13) code is provided by a state transition table described as follows:

Specific data pair D ≡ □D* = (d1, d2) arriving at the encoder input is first associated with a corresponding next state N ≡□N*. This occurs as soon as the data D* have advanced into the positions of the internal data bits B1 = (b1, b2), i.e., when (b1, b2, b3, b4, b5, b6) is identical to (d1, d2, x, x, x, x). In a second step, during the next encoding cycle, the state S takes on the value of N*, i.e., S ≡ S* ← □N* so that S is now associated with (d1, d2). In the same cycle, the inner codeword C ≡ □C* now carrying the information of D* is computed. Thus, referring the Figure below, a given internal input vector (b1, b2, b3, b4, b5, b6) associates the bits (b1, b2) with the next state N and a given state S associates the data pair ahead of (b1, b2) to the output C. In other words, the pair-wise values for N and C as listed in the Figure below are not associated with the same input data pair.

Encoder initialization: The state S = (s1, s2, s3) = (1, 0, 0) is also used as the initial state of the encoder, i.e., denoting with (α, β), the first pair of data bits to be encoded, the state S is forced to take on the value (1, 0, 0) when the bits (α, β) have advanced into the encoding circuits such that the internal inputs B1 = (b1, b2) is identical to (α, β)

Table 95: Encoder Initialization

Present State: S = (s_1, s_2, s_3)	**Next State/Internal Output: N = (n_1 n_2, n_3) / C = (c_1, c_2, c_3)**

Note: Refer to the IrDA specification 1.4 for further details.

34.5.10.2 HHH (1, 13) Packet Format

The packet format for 16.0 Megabits per second HHH(1,13) has the following form:

PREAMBLE (PA)	START (STA)	IrLAP Frame	CRC	Flush Byte (FB)	STOP (STO)	NULL

The payload data is encoded as described in the HHH (1,13) encoding above, and the encoded symbols reside in the IrLAP Frame field. The preamble field (PA) is used by the receiver to establish phase lock. During PA, the receiver begins to search for the start flag (STA) to establish symbol synchronization. If STA is received correctly, the receiver can begin to interpret the data symbols in the IrLAP Frame field. The receiver continues to receive and interpret data until the stop flag (STO) is recognized. STO indicates the end of a frame. The chip patterns and symbols for PA, STA, CRC field, and STO are defined below.

Only complete packets that contain the entire format defined above are guaranteed to be decoded at the receiver (note that, as for the lower rates, the information field, I, that is part of the IrLAP field, may be of zero length).

The 16.0 Megabits per second packet contains several fields for the purposes of clock recovery, synchronization and data transmission. In concept, the packet format is similar to that used in 4.0 Megabits per second, however, there are specific controller elements like clock recovery, synchronization and encoding/decoding circuits that need to be implemented specifically for 16.0 Megabits per second data rate.

34.5.10.3 Preamble Field Definition

The transmitted PREAMBLE (PA) is constructed by concatenating ten times (10) the 24-chip (1 µs) PREAMBLE PERIOD (PP), where

PP = '100'010'010'001'001'001'000'100'

to form the complete 240-chip (10 µs) preamble

PA = 'PP'PP'PP'PP'PP'PP'PP'PP'PP'PP'

The left-most/right-most chip of PP and PA, respectively, is transmitted first/last and a '1' in PP means an active chip (pulse) and a '0' means an empty chip (no pulse).

34.5.10.4 Start (STA) Flag Definition

The transmitted START (STA) delimiter is the 48-chip (2 $^{\mu}$s) chip sequence

STA = '100'101'010'100'100'010'000'001'001'010'101'001'000'001'010'000'

The left-most/right-most chip of STA is transmitted first/last and a '1' in STA means an active chip (pulse) and a '0' means an empty chip (no pulse). The Start Flag Delimiter allows for packet synchronization. A delimiter detection circuit should declare a flag as having been found when there is a perfect match between the receiver chip stream and a particular delimiter. The Start and Stop delimiters contain a subsequence '1001010101001' that violates the HHH (1,13) code. This subsequence occurs twice in the Start Flag delimiter and never occurs within the main HHH code.

34.5.10.5 IrLAP Frame

The structure remains unchanged from that defined in the IrLAP Specification, Version 1.1. The content of the IrLAP frame is first scrambled and then encoded with HHH(1,13). Note that the 32 CRC bits for the IrLAP frame are calculated before the IrLAP frame is scrambled. For reference, the IrLAP frame as the following structure:

| Address (8 bits) | Control (8 bits) | Information (M times 8 bits) |

34.5.10.6 CRC

Computation remains unchanged from the 32-bit CRC defined for the 4 Megabits per second data rate. The content of the CRC field is first scrambled with the scheme described later and then encoded with HHH(1, 13) as described previously. Note that the 32 CRC bits for the IrLAP frame are calculated before the IrLAP frame is scrambled. The transmitted CRC field is a 48-chip (2 s) sequence.

34.5.10.7 FLUSH BYTE (FB)

The Flush Byte (FB) is the 8-bit sequence:

FB = '00'00'00'00'.

These 8 bits are not scrambled but directly sent to the HHH(1,13) encoder. The transmitted FB field is a 12-chip (0.5 s) sequence. Note that the FB field is required to enable complete decoding of the CRC field. The flush byte denotes the end of the main body. Since the flush byte is not scrambled, a well balanced HHH(1,13) sequence precedes the STOP delimiter. This sequence would be equivalent to the UART "Break" command.

34.5.10.8 STOP (STO)

The transmitted STOP (STO) delimiter is the 48-chip (2 µs) sequence

STO = '001'001'010'101'001'000'100'000'100'101'010'100'100'000'100'000'.

The left-most/right-most chip of STO is transmitted first/last and a '1' in STO means an active chip (pulse) and a '0' means an empty chip (no pulse). As in the Start Flag delimiter, the Stop flag also contains a subsequence '1001010101001' that violates the HHH (1,13) code. This subsequence also occurs twice in the Stop Flag delimiter.

34.5.10.9 NULL Sequence

The transmitted NULL sequence is the 24-chip (1 µs) sequence

NULL = '000'000'000'000'000'000'000'000'.

The NULL field is a new field for the purpose of providing an HHH(1,13) code pattern violation that permits terminating reception of the packet in the event that the STO field is not recognized. The left-most/right-most chip in NULL is transmitted first/last and all chips of NULL are empty chips (no pulses). The NULL field increases the probability that the packet is terminated close to the STOP flag. The NULL field also reduces the probability that two back to back packets are interpreted as a single packet, should the STOP flag delimiter of the first packet be missed.

34.5.10.10 Scrambling and Descrambling Functions

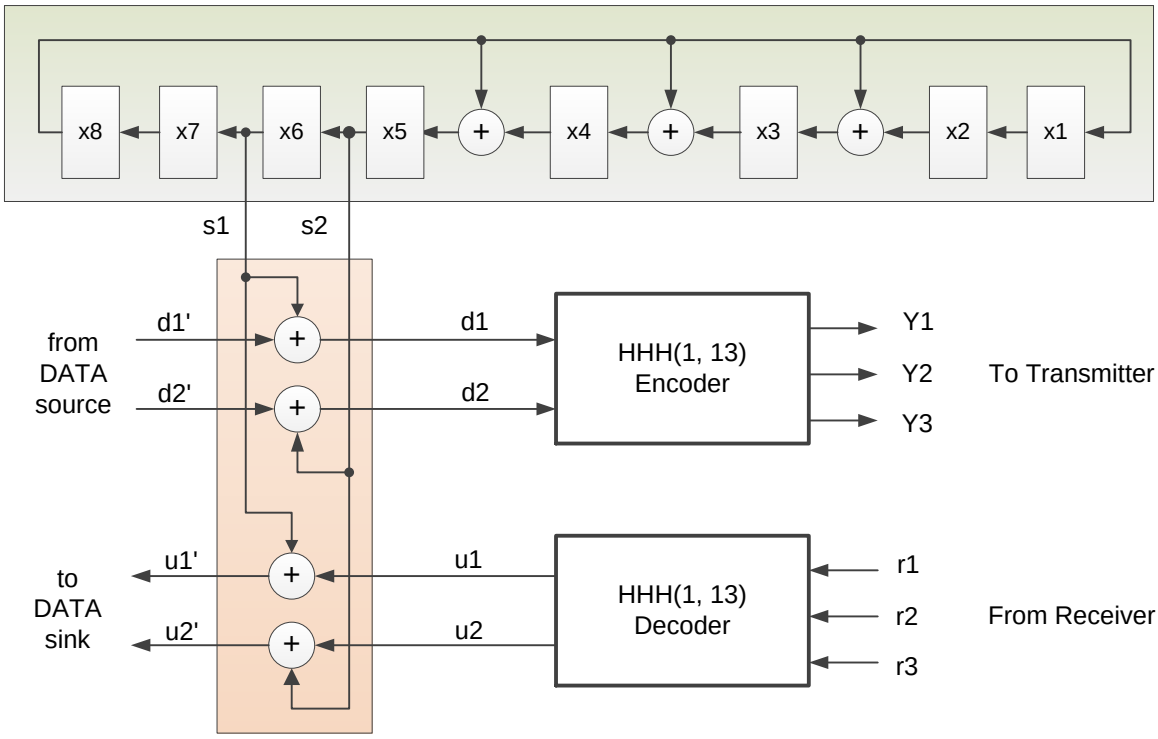
It is advantageous to enhance the encoder/decoder system with simple scrambler/descrambler functions.

The primitive polynomial: $x^8 \oplus x^4 \oplus x^3 \oplus x^2 \oplus 1$,

where ⊕ indicates a modulo-2 addition or, equivalently, a logic exclusive OR (XOR) operation The operations of the proposed scrambling and descrambling functions are performed according to the principles of frame synchronized scrambling/descrambling (FSS) mechanisms. The scrambling/descrambling scheme is shown in the Figure below. The linear feedback shift register (LFSR) produces a maximum-length pseudo-random sequence with period 255. The output of register cell x6 shown in the figure is defined to be the equivalent serial output of the LFSR.

The modulo-2 adders shown in the figure below correspond to logic XOR (exclusive OR) gates. During transmission, each new pair of source bits (d1', d2') is XOR-ed with a new pair of scrambling bits (s1, s2) to produce the scrambled data bit pair (d1, d2) entering the encoder. Similarly, during reception, each new pair of decoded bits (u1, u2) is XOR-ed with a new pair of descrambling bits (s1, s2) to produce the descrambled user bit pair (u1', u2') that is sent to the data sink. A scrambling/descrambling cycle has duration 3T seconds where T = 41.7 ns is the chip period.

Figure 96 Scrambling / Descrambling Scheme



34.5.10.11 Effects and Limits of Scrambling/Descrambling

By enhancing the system with scrambling/descrambling functions during data transmission/reception, one achieves generally better duty cycle statistics in the HHH(1,13) coded channel chip stream; the resulting duty cycle converges towards the average duty cycle of the code (≈ 26%) for typical payload data. Scrambling can greatly reduce the probability of occurrence of worst-case patterns.

34.5.10.12 Aborted Packets

Receivers may only accept packets that have valid STA, IrLAP frame, CRC, and STO fields as defined in the Packet Format section. The PA field need not be valid in the received packet. All other packets are aborted and ignored.

34.5.10.13 Back to Back Packet Transmission

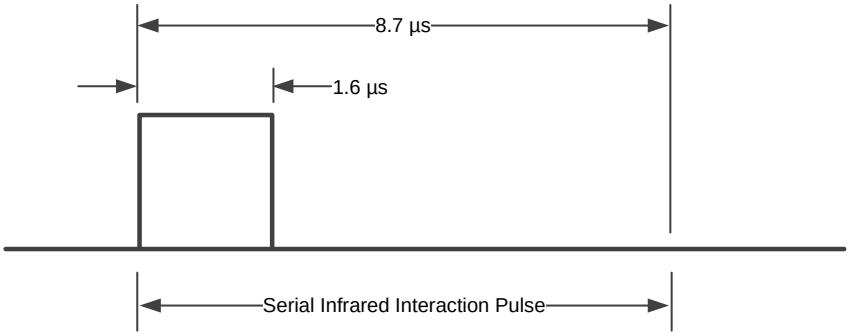
Back to back, or "brick-walled" packets are allowed, but each packet must be complete (i.e., containing PA, STA, IrLAP Frame, CRC and STO fields).

34.5.11 SIR - Serial Interaction Pulse

In order to guarantee non-disruptive coexistence with slower (up to 115.2 Kilobits per second) systems, once a higher speed (above 115.2 Kilobits per second) connection has been established, the higher speed system must emit a Serial infrared Interaction Pulse (SIP) at least once every 500 ms as long as the connection lasts to quiet slower systems that might interfere with the link. The pulse can be transmitted immediately after a packet has been transmitted. Initiation of this pulse will be performed by software by setting a bit in the VFIR Control register.

The pulse is shown below.

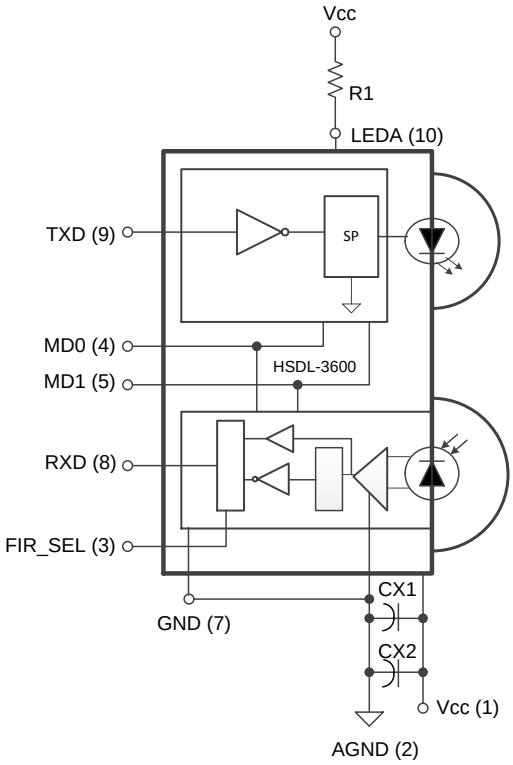
Figure 97 SIP



34.5.11.1 External Interface

The SIR/FIR/VFIR signals are muxed to external transceiver. The transceiver has TX and RX pins, and may optionally have controls for receiver gain and transmitter power. This module provides the TX and RX pins, and each has a polarity control for compatibility will all venders. Other transceiver pins are not directly supported, although they could be provided using GPIO signals. Refer to the drawing below for typical interface. TXD and RXD are VFIR module pins. MD and FIR_SEL pins would be GPIO. MD pins are for transmit power. FIR_SEL controls gain of receiver, and should be set to zero for SIR mode.

Figure 98 Typical Interface



34.6 UART Registers

34.6.1 UART_THR_DLAB_0_0

This UART is based on the 16550 industry standard Universal Asynchronous Receiver/Transmitter (UART), with enhancements to support Autobaud detection and End-of-Received Data timeout detection.

The UART supports a device clock of up to 72 MHz, for a maximum baud rate of 4.5 Megabits per second.

The THR, RBR and DLL registers all occupy the same address space.

- The Transmitter Holding Register (THR) is Write-Only, and can be accessed if the LSR.DLAB bit is clear.
- The Receiver Buffer Register (RBR) is Read-Only, and can be accessed if the LSR.DLAB bit is clear.
- The Divisor Latch LSByte Register (DLL) is Read/Write and can be accessed if the LSR.DLAB bit is set.

UART Transmit Holding Register

Offset: 000h | Read/Write: R/W | Reset: 0b00000000

Bit	R/W	Reset	Description
7:0	RO	0x0	THR_A: Transmit holding register, holds the character to be transmitted by the UART. In FIFO mode, a write to this FIFO places the data at the end of the FIFO.
7:0	RO	X	RBR_A: Receive Buffer Register. Rx Data read from here.
7:0	RO	0x0	DLL_A: Divisor Latch LSB (low 8 bits of 16-bit Baud Divisor)

34.6.2 UART_IER_DLAB_0_0

The IER and DLH registers occupy the same address space, selected by the LSR.DLAB bit. The Interrupt Enable Register (IER) is selected if the LSR.DLAB bit is clear. The Divisor Latch MSByte register (DLM) is selected if the LSR.DLAB bit is set. The DLM register holds the upper 8 bits of the 16-bit Baud Divisor (16x).

UART Interrupt Enable por=0x00000000

RX_TIMEOUT occurs when data has been sitting in the Rx FIFO for more than 4 character times without being read because there is not enough data to reach the trigger level. Interrupt needed to handle this case so that all data is received in a timely manner. Note that this normally occurs at the end of an incoming data stream.

EORD (End of Receive Data) Interrupt occurs when the receiver detects that data stops coming in for more than 4 character times. Useful for determining that the sending device has completed sending all its data. EORD timeout will not occur if the receiving data stream is stopped because of hardware handshaking.

To clear the EORD timeout interrupt you must DISABLE the EORD interrupt enable (IE_EORD).

Interrupt Enable and Divisor Latch MSByte Registers

Offset: 004h | Read/Write: R/W | Reset: 0b000000

Bit	Reset	Description
5	0x0	IE_EORD: Interrupt Enable for End of Received Data 1 = Enable 0 = DISABLE 1 = ENABLE
4	0x0	IE_RX_TIMEOUT: Interrupt Enable for Rx FIFO timeout 1 = Enable 0 = DISABLE 1 = ENABLE
3	0x0	IE_MSI: Interrupt Enable for Modem Status Interrupt 0 = DISABLE 1 = ENABLE
2	0x0	IE_RXS: Interrupt Enable for Receiver Line Status Interrupt 0 = DISABLE 1 = ENABLE
1	0x0	IE_THR: Interrupt Enable for Transmitter Holding Register Empty interrupt 0 = DISABLE 1 = ENABLE
0	0x0	IE_RHR: Interrupt Enable for Received Data Interrupt 0 = DISABLE 1 = ENABLE

34.6.3 UART_IIR_FCR_0

The FCR and IIR registers occupy the same address space. The FIFO Control Register (FCR) is Write-Only. The Interrupt Identification Register (IIR) is Read-Only

UART FIFO Control Register por=0x00000000

The DMA can run in one of two modes:

- If Mode0 is selected (NO_CHANGE) the Rx DMA request will go active whenever the Rx FIFO is not empty. Only single byte transactions can be performed in this mode. If the FIFO is not enabled, Mode0 MUST be used.
- If Mode1 is selected (CHANGE) the Rx DMA request will go active whenever the Rx FIFO trigger level is reached.

For best performance, always enable the FIFO and select DMA Mode 1.

For RX_TRIG the FIFO_COUNT references the number of bytes in the receive FIFO.

For TX_TRIG the FIFO_COUNT references the number of empty bytes in the transmit FIFO. For example, FIFO_COUNT_GREATER_16 means that there are at least 16 empty byte slots in the TX_FIFO

UART Interrupt ID Register por=0x00000001

The Interrupt ID field indicates the current highest priority interrupt. If more than one interrupt is pending the one with the highest priority will be shown.

The table below shows the encoding. Priority flows from top (highest) to bottom (lowest).

Table 96 Interrupt ID encoding

IIR[3:0]	Priority Level
0001	no interrupt
0110	Overrun Error, Parity Error, Framing Error, Break
0100	Receiver Data Available
1100	rx_timeout_intr
1000	eord_timeout_intr
0010	transmitter holding register empty
0000	modem_status interrupt

UART FIFO Control and Interrupt Identification Registers

Offset: 008h | Read/Write: R/W | Reset: 0b00000000

Bit	Reset	Description
7:6	X	EN_FIFO: FIFO Mode Status 0=16450 mode(no FIFO), 1 = 16550 mode (FIFO) 1 = MODE_16550 0 = MODE_16450

2	X	IS_PRI1: Encoded Interrupt ID Refer to IIR[3:0] table above 0 = DISABLE 1 = ENABLE

Bit	Reset	Description
2	0x0	TX_CLR: 1 = Clears the contents of the transmit FIFO and resets its counter logic to 0 (the transmit shift register is not cleared or altered). This bit returns to 0 after clearing the FIFOs. 0 = NO_CLEAR 1 = CLEAR
1	X	IS_PRI0: Encoded Interrupt ID Refer to IIR[3:0] table above 0 = DISABLE 1 = ENABLE
1	0x0	RX_CLR: 1 = Clears the contents of the receive FIFO and resets its counter logic to 0 (the receive shift register is not cleared or altered). This bit returns to 0 after clearing the FIFOs. 0 = NO_CLEAR 1 = CLEAR
0	X	IS_STA: Interrupt Pending if ZERO 0 = INTR_PEND 1 = NO_INTR_PEND
0	0x0	FCR_EN_FIFO: 1 = Enable the transmit and receive FIFO. This bit should be enabled 0 = DISABLE 1 = ENABLE

34.6.4 UART_LCR_0

UART Line Control Register

Offset: 00ch | Read/Write: R/W | Reset: 0b00000000

Bit	Reset	Description
7	0x0	DLAB: Divisor Latch Access Bit (set to allow programming of the DLH, DLM Divisors) 0 = DISABLE 1 = ENABLE
6	0x0	SET_B: Set BREAK condition -- Transmitter will send all zeroes to indicate BREAK 0 = NO_BREAK 1 = BREAK
5	0x0	SET_P: Set (force) parity to value in LCR [4] 0 = NO_PARITY 1 = PARITY
4	0x0	EVEN: Even parity format. There will always be an even number of 1s in the binary representation (PAR = 1) 0 = DISABLE 1 = ENABLE
3	0x0	PAR: 0 = No parity sent 0 = NO_PARITY 1 = PARITY
2	0x0	STOP: 0 = Transmit 1 stop bit, 1 = Transmit 2 stop bits (receiver always checks for 1 stop bit) 0 = DISABLE 1 = ENABLE
1:0	0x0	WD_SIZE: 3=Word length of 8 0 = WORD_LENGTH_5

Bit	Reset	Description
		1 = WORD_LENGTH_6 2 = WORD_LENGTH_7 3 = WORD_LENGTH_8

34.6.5 UART_MCR_0

The RTS and CTS pins are used for hardware handshaking with and external serial device. RTS (Request-To-Send) informs the device that the UART is ready to accept data. CTS (Clear-To-Send) comes from the RTS of the external device and informs us that it is OK to send data.

The RTS pin can be controlled manually with the RTS bit in the MCR, or automatically by setting the RTS_EN bit.

If RTS_EN is set, the RTS pin will automatically remove the Request-To-Send when the FIFO reaches the trigger level.

If the CTS_EN bit is set, the UART transmitter will stop transmitting when the Clear-To-Send input is taken away.

UART Modem Control Register

Offset: 010h | Read/Write: R/W | Reset: 0b00000000

Bit	Reset	Description

34.6.8 UART_SPR_0

UART Scratch Pad Register

Offset: 01ch | Read/Write: R/W | Reset: 0b00000000

Bit	Reset	Description
7:0	0x0	SPR_A: Scratchpad register (not used internally)

34.6.9 UART_IRDA_CSR_0

Bits [7:6] control the InfraRed (SIR) encoding. If enabled, each zero bit sent will be transmitted as a short IR pulse. No pulse is sent during idle or '1' data bits. The IR pulse can be either 3/16 or 4/16 of a normal bit time.

The low 4 bits control signal polarity and apply whether or not SIR coding is enabled.

UART IrDA Pulse Coding CSR Register

Offset: 020h | Read/Write: R/W | Reset: 0b00xx0000

Bit	Reset	Description
7	0x0	SIR_A: 1 = Enable SIR coder 0 = Disable SIR coder 0 = DISABLE 1 = ENABLE
6	0x0	PWT_A: 0=3/16th Baud Pulse, 1=4/16 0 = BAUD_PULSE_3_14 1 = BAUD_PULSE_4_14
3	0x0	INVERT_RTS: Inverts the normally inactive high nRTS pin 0 = DISABLE 1 = ENABLE
2	0x0	INVERT_CTS: Inverts the normally inactive high nCTS pin 0 = DISABLE 1 = ENABLE
1	0x0	INVERT_TXD: Inverts the normally inactive high TXD pin 0 = DISABLE 1 = ENABLE
0	0x0	INVERT_RXD: Inverts the normally inactive high RXD pin 0 = DISABLE 1 = ENABLE

34.6.10 UART_RX_FIFO_CFG_0

Offset: 024h | Read/Write: R/W | Reset: 0b0x000001

Bit	Reset	Description
7	0x0	EN_RX_FIFO_TRIG: Enable use of RX_FIFO_TRIG count (obsoletes RX_TRIG when enabled) 0 = DISABLE 1 = ENABLE
5:0	0x1	RX_FIFO_TRIG: Set RX_FIFO trigger level (any value 1 through 32)

34.6.11 UART_ASR_0

The UART has auto-Baud sensing logic which can measure the width of the start bit of incoming data to determine baud rate. For this to work the incoming character must have its LSB set. A <cr> works well (0x0d). The logic will use the UART device clock to count how wide the start pulse is and the BUSY bit will be set when the sensing is complete. The value in {RX_RATE_SENSE_H,RX_RATE_SENSE_L} should be divided by 16 with Round-to-Nearest, and the resulting value loaded into the DLM,DLL register pair to set the Baud Clock to 16X the Baud Rate.

UART Auto Sense Baud Register

Offset: 03ch | Read/Write: R/W | Reset: 0b00xxxxxxxxxxxxxx0000000000000000

Bit	Reset	Description
31	0x0	VALID: This bit is set when the controller finishes counting the clocks between two successive clock edges after there is a write to ASR with don't care data. 0 = UN_SET 1 = SET
30	0x0	BUSY: This bit is set when there is a write to ASR and is reset when the controller finishes counting the clock edges between two successive clock edges. 0 = NO_BUSY 1 = BUSY
15:8	0x0	RX_RATE_SENSE_H: Shows bits [15:8] of the count of clock edges between two successive clock edges.
7:0	0x0	RX_RATE_SENSE_L: Shows bits [7:0] of the count of clock edges between two successive clock edges.

34.7 VFIR Registers

34.7.1 VFIR_CTL_0

VFIR Control register is used

- to enable/disable entire IRDA module
- to configure the controller in FIR mode or VFIR mode or SIR or UART mode
- to configure either in Transmit mode or Receive mode to invert the polarity of Tx or Rx line
- to enable/disable DMA
- to know the attention levels of Transmit FIFO and Receive FIFO
- to start Transmit or Receive operation
- to select the Frequency
- to clear Transmitter FIFO/Receiver FIFO

VFIR Control Register

Offset: 000h | Read/Write: R/W | Reset: 0b00000000000000000000000000100000

Bit	Reset	Description
31	0x0	GLOBAL_ENABLE: 0 = Entire IRDA module is disabled 0 = DISABLE 1 = ENABLE
30	0x0	GO: Set to 1 to start transmit or receive operation, self-clearing 0 = STOP 1 = START
29	0x0	AUTO_RESTART: Set to 1 to restart another operation when previous is done 0 = STOP 1 = RE_START
24	0x0	FORCE_BAD_CRC: Debugging bit to force a CRC error 0 = DISABLE 1 = ENABLE
22	0x0	TX_FIFO_CLR: Clear the Transmitter FIFO 0 = DISABLE 1 = ENABLE
21:20	0x0	TX_ATN_LVL: 00: when not full 3 = slots_empty_12 2 = slots_empty_8 1 = slots_empty_4 0 = not_full
18	0x0	RX_FIFO_CLR: Clear the Receiver FIFO 0 = DISABLE 1 = ENABLE
17:16	0x0	RX_ATN_LVL: 00: when not empty 3 = slots_full_12 2 = slots_full_8 1 = slots_full_4 0 = not_empty
13	0x0	START_SIP: Self-clearing bit to initiate a Serial Ir Interaction Pulse.
12	0x0	EN_PULSECORR: Fixes single pulse errors caused by VFIR propagation effects. 0 = DISABLE 1 = ENABLE
11	0x0	DMA_EN: DMA Enable Allow requests to go APB_DMA controller. 0 = DISABLE 1 = ENABLE
10	0x0	TX_TERM: of outgoing frame, i.e. the calculated CRC will be sent, followed by the frame stop sequence. The interrupt will be generated if enabled. 0 = ABORT 1 = NORMAL
9	0x0	COUNT_ODATA: When enabled, the controller will end the frame when the Outgoing Frame Data Length (OFDL) count is reached. Use in conjunction with TX_Term above so controller will know when and how to end the frame. 0 = DISABLE 1 = ENABLE
8	0x0	FORCEBRK: break state (zero) regardless of what the transmitter is doing. 0 = TX_ENABLE 1 = TX_DISABLE

Bit	Reset	Description
7	0x0	NEGATE_RX: Invert polarity on incoming RX pin (applies to all modes) 0 = DISABLE 1 = ENABLE
6	0x0	NEGATE_TX: Invert polarity on outgoing TX pin (applies to all modes) 0 = DISABLE 1 = ENABLE
5:4	0x2	FREQUENCY: The 8 and 24 MHz clocks can be used to save power during transmit. The 72MHz clock can be used in case the 48MHz clock is not available due to system constraints. 0 = F8MHz 1 = F24MHz 2 = F48MHz 3= F72MHz
3	0x0	TRANSMIT: 0 = Receive (FIR/VFIR modes) 1 = TRANSMIT 0 = RECEIVE
2:0	0x0	MODE: 000: UART use UART B module 7 = RSVD 6 = RSVD1 5 = VFIR 4 = FIR 3 = RSVD2 2 = MIR 1 = SIR 0 = UARTB

34.7.2 VFIR_STS_0

VFIR Status and Interrupt Identification Register is used to know the status of:

- Transmitter/Receiver FIFO Trigger level status
- Transmitter/Receiver FIFO FULL/EMPTY status
- Transmitter/Receiver FIFO empty slots
- Whether Transmit or Receive operation is done or not
- Whether End of Frame is received or not
- Whether there is any CRC error in received data or not
- Whether there is any Error in the received data
- Whether the controller is Busy in Transmitting/Receiving the data
- Whether the VFIR interrupt is generated or not. To generate interrupt the corresponding the enable bits has to be set in the VFIR Interrupt Enable Register

VFIR Status and Interrupt Identification Register

Offset: 004h | Read/Write: R/W | Reset: 0bxxxxxxxxxxxxxxxxxxxxx0xxx0x000000

Bit	R/W	Reset	Description
31	RO	X	TX_FTRIG: Transmitter FIFO Trigger level Reached
30	RO	X	TX_FIFO_FULL: Transmitter FIFO is Full
29	RO	X	TX_FIFO_EMPTY: Transmitter FIFO is Empty
28:24	RO	X	TX_FIFO_EMPTY_COUNT: Number of empty slots (words) in Tx FIFO
23	RO	X	RX_FTRIG: Receiver FIFO Trigger level Reached

Bit	R/W	Reset	Description
22	RO	X	RX_FIFO_FULL: Receiver FIFO is Full
21	RO	X	RX_FIFO_EMPTY: Receiver FIFO is Empty
20:16	RO	X	RX_FIFO_FULL_COUNT: Number of words available to Read in Rx FIFO
15	RO	X	INTR: Global VFIR interrupt (OR of all FIR/VFIR interrupts)
14	RO	X	BUSY: transmitting or receiving data. It is clear when the controller is idle or transmits a Serial infrared Interaction Pulse (SIP)
11	RW	0x0	TX_UNDRN: break. This bit is cleared upon reading from the register.
7	RW	0x0	MISSED_PACKET: Another Rx arrived before the previous was serviced. Serviced is defined as clearing the Rx_EOF flag. This bit is cleared by writing a 1 to this bit.
6	RO	X	BITSYNC_LOCK: Debug status bit which indicates that receiver is Locked to incoming bit stream.
5	RW	0x0	RX_DETECT: Activity detected on Rx pin. This bit is cleared by writing a 1 to this bit.
4	RW	0x0	RX_ERR: Receiver Error. This bit is set when an unexpected or illegal data has been received. This can be a break in transmission, illegal chip values or framing errors. This bit is cleared by writing a 1 to this bit.
3	RW	0x0	RX_FOVRN: Receiver FIFO overrun error occurred. This bit is cleared by writing a 1 to this bit.
2	RW	0x0	RX_CRC_ERR: CRC check on input data failed. This bit is cleared by writing a 1 to this bit.
1	RW	0x0	RX_EOF: Received End of Frame. Set when the last byte in frame is within the receiver FIFO. This bit is cleared by writing a 1 to this bit.
0	RW	0x0	DONE: Done flag. Set when controller completes a Transmit or Receive packet, even if the packet finished early due to errors. This bit is cleared by writing a 1 to this bit.

34.7.3 VFIR_IER_0

VFIR Interrupt Enable Register is used to generate VFIR interrupt for different conditions. VFIR Interrupt bit is present in VFIR.

Status and Interrupt Identification Register

For example when the controller finishes the Transmitting/Receiving operation and if IE_DONE is set then Interrupt is generated. Similar is the case for other bits in this register

VFIR Interrupt Enable Register

Offset: 008h | Read/Write: R/W | Reset: 0b00000000000000000000000000000000

Bit	Reset	Description
31	0x0	IE_TX_FTRIG: Enable Interrupt on Transmitter FIFO Trigger level reached 0 = DISABLE 1 = ENABLE
23	0x0	IE_RX_FTRIG: Enable Interrupt on Receiver FIFO Trigger level reached 0 = DISABLE 1 = ENABLE
11	0x0	IE_TX_UNDRN: transmit a break for the receiving side to abort reception. 0 = DISABLE 1 = ENABLE

Bit	Reset	Description
7	0x0	IE_MISSED_PACKET: Enable Interrupt for Missed Packet error 0 = DISABLE 1 = ENABLE
5	0x0	IE_RX_DETECT: Enable Interrupt on Activity on Rx Pin 0 = DISABLE 1 = ENABLE
4	0x0	IE_RX_ERR: Enable Interrupt on Receiver Error 0 = DISABLE 1 = ENABLE
3	0x0	IE_RX_FOVRN: Enable Interrupt on Receiver FIFO overrun 0 = DISABLE 1 = ENABLE
2	0x0	IE_RX_CRC: Enable Interrupt for input CRC check failure 0 = DISABLE 1 = ENABLE
1	0x0	IE_RX_EOF: Enable Interrupt for Received End of Frame 0 = DISABLE 1 = ENABLE
0	0x0	IE_DONE: Enable Interrupt for Done Status 0 = DISABLE 1 = ENABLE

34.7.4 VFIR_OFDL_0

VFIR Outgoing Frame Data Length is used to configure the number of bytes of data to be sent.

VFIR Outgoing Frame Data Length

Offset: 00ch | Read/Write: R/W | Reset: 0b0000000000000000

Bit	Reset	Description
15:0	0x0	OFDL: Set to the length in bytes of the outgoing frame. Length is calculated on the information field only (address, control and data fields only) without the CRC and flags. When in this mode, the amount of data transferred to the controller is counted and when the count is reached the controller finishes sending the frame in normal fashion by transmitting CRC field, STO flag and then the SIP.

34.7.5 VFIR_IFDL_0

VFIR Incoming Frame Data Length gives the information of the data received in bytes.

VFIR Incoming Frame Data Length

Offset: 010h | Read/Write: RO | Reset: 0bxxxxxxxxxxxxxxxx

Bit	Reset	Description
15:0	X	IFDL: Running length in bytes of the incoming data stream. At the end of frame reception when the Received End of Frame interrupt occurs, this register reflects the length of the information field received in that frame, not counting the CRC field and other flags. Resets on the start of next frame reception, when a new STA field has been detected.

34.7.6 VFIR_FIFO_0

VFIR FIFO is a shared FIFO. Holds the data in Transmitter/Receiver mode

VFIR.FIFO (VFIR FIFO)

Offset: 040h | Read/Write: R/W | Reset: 0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx

Bit	Reset	Description
31:0	X	DATA: Shared FIFO. When transmitting, this FIFO holds the data to be transmitted. When receiving, this FIFO holds the received data.

[THIS PAGE INTENTIONALLY LEFT BLANK]

35.0 SLINK: SPI PERIPHERAL INTERFACE

The SPI bus is a master-slave based bus that is used to interconnect different devices to a central master.

It allows full-duplex synchronous-serial communication between the controller and external peripheral devices. It consists of 4 signals, SS_N (Chip select), SCK (clock), MOSI (Master data out and Slave data in) and MISO (Slave data out and master data in). The data is transferred on MOSI or MISO based on the data transfer direction on every SCK edge. The receiver always receives the data on the other edge of SCK.

The clock polarity and clock phase determine which edge of the SCK clock will be used to latch the data in the receiver. If the clock polarity is 0, then the SCK signal is 0 when idle and transitions to 1 whenever doing a data transfer. If the clock polarity is 1, then the SCK signal is 1 when idle and transitions to 0 when doing a data transfer. If the clock phase is 0, then the receiver latches the data on the first transition of SCK from idle state. If the clock phase is 1, then the receiver latches the data on the second transition of SCK.

This makes up 4 modes for SPI protocol that are described below:

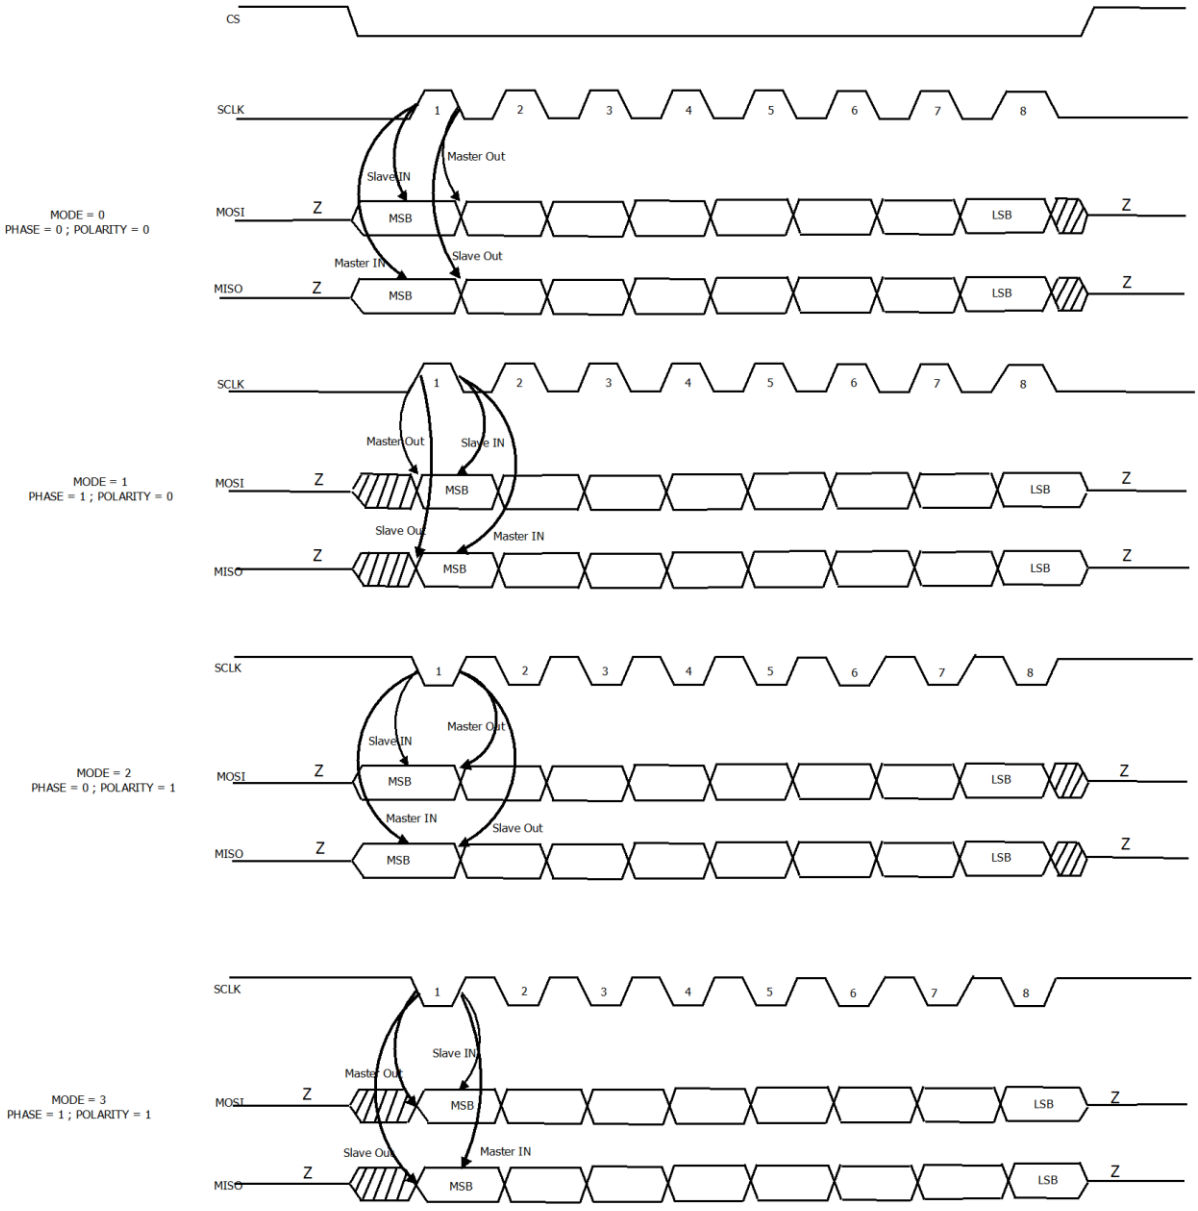
Table 97. SPI Protocols

SPI Mode	Clock Polarity	Clock Phase	Description
0	0	0	Clock is positive polarity and the data is latched on the positive edge of SCK.
1	0	1	Clock is positive polarity and the data is latched on the negative edge of SCK.
2	1	0	Clock is negative polarity and the data is latched on the negative edge of SCK.
3	1	1	Clock is negative polarity and the data is latched on the positive edge of SCK.

In this protocol, data is transferred on every edge of SCK whenever CS is active. CS can be active high or low. The data transfer consists of packets of varying bit lengths from 1 to 32 bits in any direction. Within a packet, the transfer starts with MSB first. The clock can stay in idle state in between different packets. CS can be active for either single packet or multiple packets including transmit and receive.

This protocol is shown in the diagram below.

Figure 99. SPI Interface Timing



Features

- Independent RX FIFO and TX FIFO.
- FIFO depth of 32x32 bits.
- Software controlled bit-length from 0 to 31 resulting in packet sizes of 1 to 32 bits.
- Packed mode support for bit-length of 7 (8-bit packet size) and 15 (16-bit packet size).
- SS_N can be selected to be controlled by software, or it can be generated automatically by the hardware on packet boundaries.
- Receive compare mode where the controller listens for a particular pattern on the incoming data before receiving the data in the FIFO.
- Simultaneous receive and transmit supported.
- Maximum transfer rate is 50 Mbits/sec, subject to board electrical characteristics.

35.1 Programming Guidelines

There are two basic modes of operation: DMA_EN and GO modes. It is required that software sets up all the parameters in the SBCx_COMMAND and SBCx_COMMAND2 registers before enabling transfers in any of these modes.

35.1.1 DMA_EN Mode

This mode is enabled by writing 1 to DMA_EN bit in SBCx_COMMAND register. In this mode, SPI controller transmits or receives the number of packets as indicated by the field DMA_BLOCK_SIZE in SBCx_DMA_CTL register

If PACKED bit is set and the BIT_LENGTH is set to 7, then all FIFO words contain 4 packets to transfer (transmit or receive). Packets will be transferred in little-endian format, with packet 0 being in byte 0 of the FIFO and packet 3 in byte 3 of the FIFO.

If PACKED bit is set and the BIT_LENGTH is set to 15, then all FIFO words contain 2 packets to transfer (transmit or receive). Packets will be transferred in little-endian format, with packet 0 being in bits [15-0] of the FIFO and packet 1 in bits [31-16] of the FIFO.

If BIT_LENGTH is set to N, each packet will consist of N + 1 bits. These bits will be transmitted/received in the TX_FIFO/RX_FIFO with the MSB in bit N and LSB in bit 0, following little-endian architecture. Any remaining bits in the FIFO will be ignored by the hardware. Maximum packet length is 32, which can be selected by setting BIT_LENGTH to 31. In this case, all data bits in FIFO contain valid packet data.

DMA request will be generated to APB_DMA in this mode depending on the setting of IE.TXC and IE.RXC. If transmit is enabled, setting IE.TXC to 00 will generate a TX DMA request whenever the TX FIFO has one word of space available (is not full). Setting IE.TXC to 01 will generate a TX DMA request whenever the TX FIFO has 4 words of space available (is empty). If receive is enabled, setting IE.RXC to 00 will generate a RX DMA request whenever the RX FIFO has one word of data available (is not empty). Setting IE.RXC to 01 will generate a RX DMA request whenever the RX FIFO has 4 words of data available (is full).

The APB DMA requester numbers for the SPI controllers are 15, 16, 17, 18, 27, and 28.

35.1.2 GO Mode

> **Note:** GO Mode is NOT supported in Full Duplex mode of operation. Full duplex is simultaneous transmit and receive.

This mode is enabled by writing 1 to GO bit in SBCX_COMMAND register. In this mode, if transmit is enabled, then the SPI controller transmits the data in the TX FIFO until TX FIFO is empty. If receive is enabled, then the SPI controller receives one packet of data in the RX FIFO.

Packed mode is supported in transmit only. If PACKED bit is set and the BIT_LENGTH is set to 7, then all TX FIFO words contain 4 packets to transfer. If PACKED bit is set and the BIT_LENGTH is set to 15, then all TX FIFO words contain 2 packets to transfer.

35.1.3 Interrupt Generation

SPI controller generates an interrupt to processor at the end of a transfer or when an error is detected if IE.TXC or IE.RXC bit in SBCX_DMA_CTL register is enabled for transmit and receive modes of operation respectively. This functionality is common to both DMA_EN and GO modes.

If IE.TXC is enabled during transmit, an interrupt is generated whenever RDY or TXF_OVF bit in SBCX_STATUS register is set to 1. During transmit, if software/APB DMA cannot fill the transmit FIFO fast enough, hardware waits for the software to fill up the TX FIFO and an under run condition is never generated. However, if software tries to write to a full TX FIFO, hardware sets TXF_OVF bit as an indication that software attempted to overflow the TX FIFO. Hardware makes sure that the overflowing data is never written to the TX FIFO.

If IE.RXC is enabled during receive, an interrupt is generated whenever RDY or RXF_UNR bit in SBCX_STATUS register is set to 1. During receive, if software/APB DMA cannot read the receive FIFO fast enough, hardware waits for the software to read out the RX FIFO and an overflow condition is never generated. However, if software tries to read from an empty RX FIFO, hardware sets RXF_UNR bit as an indication that software attempted to under run the RX FIFO. Hardware makes sure that the read actually never goes to an empty RX FIFO.

The interrupt can be cleared by clearing the source of the interrupt. If the interrupt is generated by assertion of RDY, then writing a 1 to RDY bit clears the interrupt. If the interrupt is generated by assertion of TXF_OVF, then writing a 1 to TXF_OVF bit clears the interrupt. If the interrupt is generated by assertion of RXF_UNR, then writing a 1 to RXF_UNR bit clears the interrupt.

SPI Controller interrupt source is bit SPI (bit 7) in secondary interrupt controller.

35.1.4 Packet Parameters

Clock signal (SCK) output format: The SCK clock signal output format is controlled by the field IDLE.SCLK in SBCX_COMMAND register.

Clock Phase: The phase of the SCK signal is determined by the field CK.SDA in SBCx_COMMAND

Both clock polarity and clock phase together determine the SPI mode as described earlier.

Data signal (SDO) output format: The output format of the SDO signal is determined by IDLE.SDA field in SBCX_COMMAND register.

Transmit mode: Transmit mode is enabled by setting TXEN bit in SBCX_COMMAND register.

Receive mode: Receive mode is enabled by setting RXEN bit in SBCX_COMMAND register.

Chip select: The SPI CS signal can be controlled either by software or by hardware based on the value programmed in CS_SW bit in SBCX_COMMAND register.

If CS_SW bit is set to 1, the SPI CS works in software mode and any value programmed in CS bit in SBCX_COMMAND register appears on SPI CS. In this mode, software is responsible to generate appropriate chip select polarity by writing correct values in CS bit. This mode can be used to do data transfers that require multiple packets within a single chip select assertion.

If CS_SW bit is set to 0, the SPI CS works in hardware mode. In this mode, CS bit in SBCX_COMMAND register works as polarity of the SPI_CS signal. The SPI_CS will be driven active on a per-packet basis. It will be driven inactive in between packets and when the SPI bus is idle. In this mode, CS_DELAY determines the number of cycles the SPI_CS signal stays inactive in between two packets. Setting CS_DELAY to 0 gives a delay of 2 SPI_SCK cycles in between two packets if receive mode is enabled. Any other number N written to this field will give a delay of N + 2 cycles if receive mode is enabled. If only transmit mode is enabled, setting CS_DELAY to N will give a delay of N cycles.

35.1.5 Status Information

There are certain bits of status information in SBCX_STATUS register that software can use to determine the status of the currently ongoing transfer.

BSY bit: This bit is set to 1 at the start of every transfer and is cleared when the transfer has finished.

RDY bit: This bit is set to 1 at the end of every transfer. It is cleared when software writes a 1 to this bit.

RXF_UNR bit: This bit indicates an under run in RX FIFO and is set to 1 whenever an error is detected during a receive operation.

TXF_OVF bit: This bit indicates an overflow in TX FIFO and is set to 1 whenever an error is detected during a transmit operation.

RXF_FULL: This bit indicates whether the RX FIFO is full or not and is set to 1 when RX FIFO is full. If this bit is set to 1 during a reception and BSY is 1, it indicates that the controller has received data in the RX FIFO and is waiting for the firmware to read these data before receiving any more data.

RXF_EMPTY: This bit indicates whether the RX FIFO is empty or not and is set to 1 when RX FIFO is empty.

TXF_FULL: This bit indicates whether the TX FIFO is full or not and is set to 1 when TX FIFO is full.

TXF_EMPTY: This bit indicates whether the TX FIFO is empty or not and is set to 1 when TX FIFO is empty. If this bit is set to 1 during a transmission and BSY is 1, it indicates that the controller has transmitted all data from the TX FIFO and is waiting for firmware/APB DMA to write more data before continuing with the transmission.

CUR_BLOCK_COUNT: This field contains the no. of packets that have been transferred (sent or received) during current transfer.

If both transmit and receive are enabled and either RXF_FULL or TXF_EMPTY is set, controller will pause both the transmission and reception regardless of whether RXF_FULL or TXF_EMPTY is set.

35.1.6 Clock Initialization and Control

The SPI controller is targeted to run at 25 MHz at its interface to external SPI devices. The internal SPI controller clock should then run at 4X of the external SPI interface clock. Hence, the internal SPI controller clock sources for SPI 1, SPI 2, and SPI 3 all need to run at 100 MHz in this case. This 4X ratio is required for the correct operation of the SPI controllers.

The CLK_OUT_ENB_H register in the CAR (Clock and Reset) contains the enable bits for the 3 instances of the SPI controller – SPI 1 (bit 9 - CLK_ENB_SBC1), SPI 2 (bit 12 - CLK_ENB_SBC2) and SPI 3 (bit 14 - CLK_ENB_SBC3).

In addition, the clock source and divider registers CLK_SOURCE_SBC1, CLK_SOURCE_SBC2 and CLK_SOURCE_SBC3 registers contain the 2-bit field SBCx_CLK_SRC to decide the PLL clock source while the field SBCx_CLK_DIVISOR determines the divide ratio.

35.1.7 Programming Limitations

In packed transfers, you must follow a 3 step sequence.

- Program the bit length and packet parameters
- Enable packed mode
- Enable DMA

If the SPI interface is running at slow speeds such as at 1 MHz then there is an additional delay up to 1us required between enabling Packed mode and enabling DMA.

- Programming of both the bit lengths and pack_size. When in packed mode, the controller should not depend on bit-length. Alternatively, the controller can rely on bit_length if the controller is not in packed mode.
- In packed mode the number of blocks transferred need to be aligned by boundary. i.e. for a packed 4 the number of packets should be multiple of 8 and for packed 8 it has to be multiple of 4.
- With SPI clock 4 times faster than APB clock, there is a restriction on the bit-length. If the number of bits are <4, then the busy goes low as soon as the words are received on the SPI clock. But it doesn't wait till these are written into FIFO. And since APB clock is running slow, there is a possibility of data lost if less number of bits are transferred.
- Busy bit does not go low if the transfer is terminated in the middle. Hence termination in the middle of a transfer is not recommended.
- DMA should be programmed after APB is programmed in APB-DMA transfers.
  - If more than 32 words need to be transferred, then wait for the FIFO to be full before you start the SPI controller to transmit
  - 32 or less words need to be transferred, then first fill up the FIFO before the SPI controller is started to transmit

- Full duplex transfer in GO mode - First word in RXFIFO is always 0x00. It is recommended to use the DMA mode instead.
- Programming of IDLE_SCK. The requirement is to always program the same value in IDLE_SCK.
- Similar is the case for IDLE_SDA as for IDLE_SCK.
- Implementation of WAIT for preventing writes to command register till the current transfer is finished.
- Use of master and slave buffers. As of now they don't do anything except storing the last word transmitted/received from/to TX/RX FIFO.
- SS_SETUP bit is reserved.
- If the SPI interface clock is run at very low frequencies (such as 1 MHz), it may be necessary to add delays in the programming sequence as specified in (1) above so that the programming can take effect.

35.2 SPI Controller as a Slave

The SPI controller can also be used as a slave. In this mode the controller receives the chip select and the clock from the external master. In addition, data input and outputs are swapped on the two data lines - MOSI and MISO. The table below provides additional information on the SPI signals in master and slave configurations:

Table 98. SPI Signals in Master and Slave Configurations

	Slave	Master
MOSI	Input	Output
MISO	Output	Input
SPI_CSx_N	Input	Output
SCK	Input	Output

SCK

The slave derives the clock from the external master. It is required that between two consecutive words (up to 32 bits), 1 cycle delay be provided for correct operation. This is mandatory for both the DMA and GO mode of operation. If the packed mode is selected (either one of 4, 8, 16 or 32 bits), a 1 cycle delay is required between two consecutive packets.

SS_N

The chip select will need to be asserted by the external master and will stay asserted during the entire duration of the operation. If the chip select is de-asserted during the middle of a transfer, the SPI controller will cease operation until the chip select is asserted. If the external master continues to provide clocks while the chip select stays de-asserted, it has no effect on the SPI controller. It is required that the chip select be asserted and the operation completed in full if such an event should occur.

MOSI and MISO

The data pins MOSI and MISO are now swapped while the SPI controller is operated as a slave. The SPI controller now drives out the data on MISO (instead of on MOSI when it is used as a master) and receives data on MOSI (as supposed to on MISO when it is used as a slave).

PIO and DMA Modes

For large transfers of data over the SPI interface, APB DMA could be used and the DMA mode should be selected in the SPI. This will enable the transfer of 2**16 packets (4, 8, 16, or 32 bits in each packet) over the SPI interface. The PIO mode can also be used to fill up the FIFO in the controller but may require higher latency to transfer such high data rates.

35.3 SLINK Registers

35.3.1 Programming Sequence for Basic Data Transmission

After the module-initialization (reset and clock programming), program the corresponding bits of the following registers, preferably in the same sequence:

For Go Mode:

COMMAND2: Set the type of transfer i.e. Receive (Bit31), transmit (Bit 30)

COMMAND1: Set the bit_length (bits [4:0]), number of words (bits [9:5]), mode (mode0, mode1, mode2 and mode3) as below

Table 99. Go Mode Command 1 for Different Modes

Mode	IDLE_SCLK	CK_SDA	Notes
Mode0	00	0	Clock is positive polarity and the data is latched on the positive edge of SCK
Mode1	00	1	Clock is positive polarity and the data is latched on the negative edge of SCK
Mode2	01	0	Clock is negative polarity and the data is latched on the negative edge of SCK
Mode3	01	1	Clock is negative polarity and the data is latched on the positive edge of SCK

TX_FIFO: Write data into TXFIFO

COMMAND1: Enable the Go Bit (bit 30)

For DMA mode:

COMMAND2: Set the type of transfer i.e. Receive (Bit31), transmit (Bit30)

COMMAND1: Set the bit_length (bits [4:0]), and mode as described above. Please note that the bit length to be set accordingly depending on the PACK_SIZE (bits [22:21] when packed mode(Bit 20)is set in the DMA_CTL register

```
PACK_SIZE       BIT_LENGTH
00              0x03
01              0x07
10              0x0f
11              0x1f
```

DMA_CTL: Set the DMA_BLOCK_LENGTH (bits [15:0]), RX_TRIG (bits [19:18]), TX_TRIG (bits [17:16]). For interrupts set IE_RXC (bit27), IE_TXC(bit26) to 1. For packed mode set PACK_SIZE (bits [22:21]) and PACKED (bit 20).

> **Note:** PACKED should be set after programming all the other parameters (except DMA_EN) in the COMMAND,COMMAND2 and DMA_CTL registers after setting all the parameters set DMA_EN(bit 31) to 1.

The DMA request signals to the APBDMA controller are enabled by the SLINK COMMAND2.TXEN and RXEN bits. Always program the DMA channels first. Enable the COMMAND2.TXEN and RXEN bits last.

35.3.2 SLINK_COMMAND_0

Used for the setting of bit_length, number of words, and for selecting the transfer mode. Chip Select can also be selected to be in HW mode as SW mode with both active high and active low polarities for supporting devices with varying CS polarities.

Serial Link-2 Sub Block Command Register

Offset: 000h | Read/Write: R/W | Reset: 0b0000xx000000xx00xx00000000000000

Bit	Reset	Description
31	0x0	ENB: RD/WD access to Data Register would start the next transfer. (This allows continuous Receive via RD of Buffer and Automated Transmit per WD of Buffer Register) 0 = DISABLE 1 = ENABLE
30	0x0	GO: Program 1 after all the other bits in the COMMAND2 and COMMAND are programmed to start the transfer HW clears this bit automatically after the transfer is done Clearing of the bit by SW will stop the Shifter and latch the partial data into buffer. 0 = STOP 1 = GO

18	0x0	RX_UNF: RX FIFO Underflow 0 = OK 1 = ERROR
16	0x0	MODF: Mode fault 0 = OK 1 = ERROR
9:5	0x0	WORD: In GO mode indicates number of words transferred (word count)
15:0	0x0	BLK_CNT: Number of blocks transferred (BLOCK count) during DMA
4:0	0x0	COUNT: In Go mode indicates number of bits transferred (bit count)

35.3.5 SLINK_MAS_DATA_0

Serial Link-2 Sub Block Transmit Data Page Buffer Register

Offset: 010h | Read/Write: R/W | Reset: 0b00000000000000000000000000000000

Bit	Reset	Description
31:0	0x0	MASTER_BUFFER: Tx/Rx Shift Pattern

35.3.6 SLINK_SLAVE_DATA_0

Serial Link-2 Sub Block Slave Data Page Buffer Register

Offset: 014h | Read/Write: R/W | Reset: 0b00000000000000000000000000000000

Bit	Reset	Description
31:0	0x0	SLAVE_BUFFER: Tx/Rx Shift Pattern

35.3.7 SLINK_DMA_CTL_0

SLINK DMA Control Register: Used in the DMA transfers. Set packed mode transfers and the trigger levels in this register.

Serial Link-2 Sub Block DMA Control Register

Offset: 018h | Read/Write: R/W | Reset: 0b00xx00xxx00000000000000000000000

Bit	Reset	Description
31	0x0	DMA_EN: 1 = ENABLE DMA mode is enabled, 0 = DISABLE DMA disabled
30	0x0	CONT: 1 = continuous mode is enabled, 0 = continuous mode disabled 0 = DISABLE 1 = ENABLE
27	0x0	IE_RXC: Interrupt enable on receive completion. 1 = ENABLE Enable interrupt generation at the end of a receive transfer. 0 = DISABLE Disable interrupt generation for receive.
26	0x0	IE_TXC: Interrupt enable on transmit completion. 1 = ENABLE Enable interrupt generation at the end of a transmit transfer. 0 = DISABLE Disable interrupt generation for transmit.
22:21	0x0	PACK_SIZE: Specifies the packet size during the DMA mode 00 = 4 bits in a pack 01 = 8 bits in a pack 10 = 16 bits in a pack 10 = 32 bits in a pack 0 = PACK4 1 = PACK8 2 = PACK16 3 = PACK32
20	0x0	PACKED: Packed mode enable bit. 1 = Packed mode is enabled. This is only valid if BIT_LENGTH in SBCX_COMMAND register is set to 3, 7, 15 or 31. When enabled, all 32-bits of data in the FIFO contain valid data packets of either 8-bit or 16-bit length. 0 = Packed mode is disabled. 0 = DISABLE 1 = ENABLE

Bit	Reset	Description
19:18	0x0	RX_TRIG: Receive FIFO trigger level. 00 = 1 word. DMA trigger is asserted whenever there is at least 1 word in the RX FIFO. 01 = 4 words. DMA trigger is asserted when there are at least 4 words in the RX FIFO. 10 = 8 words. DMA trigger is asserted when there are at least 8 words in the RX FIFO. 11 = 16 words. DMA trigger is asserted when there are at least 16 words in the RX FIFO. 0 = TRIG1 1 = TRIG4 2 = TRIG8 3 = TRIG16
17:16	0x0	TX_TRIG: Transmit FIFO trigger level. 00 = 1 word. DMA trigger is asserted whenever there is at least 1 word in the TX FIFO. 01 = 4 words. DMA trigger is asserted when there are at least 4 words in the TX FIFO. 10 = 8 words. DMA trigger is asserted when there are at least 8 words in the TX FIFO. 11 = 16 words. DMA trigger is asserted when there are at least 16 words in the TX FIFO. 0 = TRIG1 1 = TRIG4 2 = TRIG8 3 = TRIG16
15:0	0x0	DMA_BLOCK_SIZE: N = N+1 packets number of packets should be aligned in the packed mode transfers. packed mode --> Number of packets 3 multiple of 8 7 multiple of 4 15 multiple of 2 31 from 0 to N.

35.3.8 SLINK_STATUS2_0

Serial Link-2 Status2 Register

SLINK Status2 Register: Contains the empty count for the transmit FIFO and the full count for receive FIFO

Offset: 01ch | Read/Write: R/W | Reset: 0b0000000xxxxxxxxxxx00000000xxxxxx

Bit	R/W	Reset	Description
31:26	RW	0x0	TAP_DELAY: Indicates the tap delay for the SPI external clock
25	RW	0x0	SBC_CE: Indicates the SBC clock enable to CAR
24	RO	X	CS_INACTIVE: 0 = CS active during continuous, 1 = CS inactive during continuous
23	RO	X	FRAME_END: 1 = End of frame
21:16	RO	X	RX_FIFO_FULL_COUNT: Indicates the number of words in the receive FIFO
13:10	RW	0x0	BETWEEN_CS: Indicates the number of cycles between two transfers
9:6	RW	0x0	HOLD_TIME: Indicates the number of cycles in hold time for CS staying asserted at the end of transfer
5:0	RO	X	TX_FIFO_EMPTY_COUNT: Indicates the number of empty slots in the transmit FIFO

35.3.9 SLINK_TX_FIFO_0

Serial Link-2 Sub Block TX FIFO Buffer Register

Offset: 100h | Read/Write: R/W | Reset: 0b00000000000000000000000000000000 | Default: 0000.0000

Bit	Reset	Description
31:0	0x0	TX_FIFO_REGISTER: Tx/Rx Shift Pattern

35.3.10 SLINK_RX_FIFO_0

Serial Link-2 Sub Block RX FIFO Buffer Register

Offset: 180h | Read/Write: R/W | Reset: 0b00000000000000000000000000000000 | Default: 0000.0000

Bit	Reset	Description
31:0	0x0	RX_FIFO_REGISTER: Tx/Rx Shift Pattern

36.0 ONE WIRE BATTERY CONTROLLER

The One Wire Controller (OWR) implements a device communications bus system that provides low-speed data, signaling and power over a single signal. The OWR uses two wires for this--one for ground, and the other for power and data.

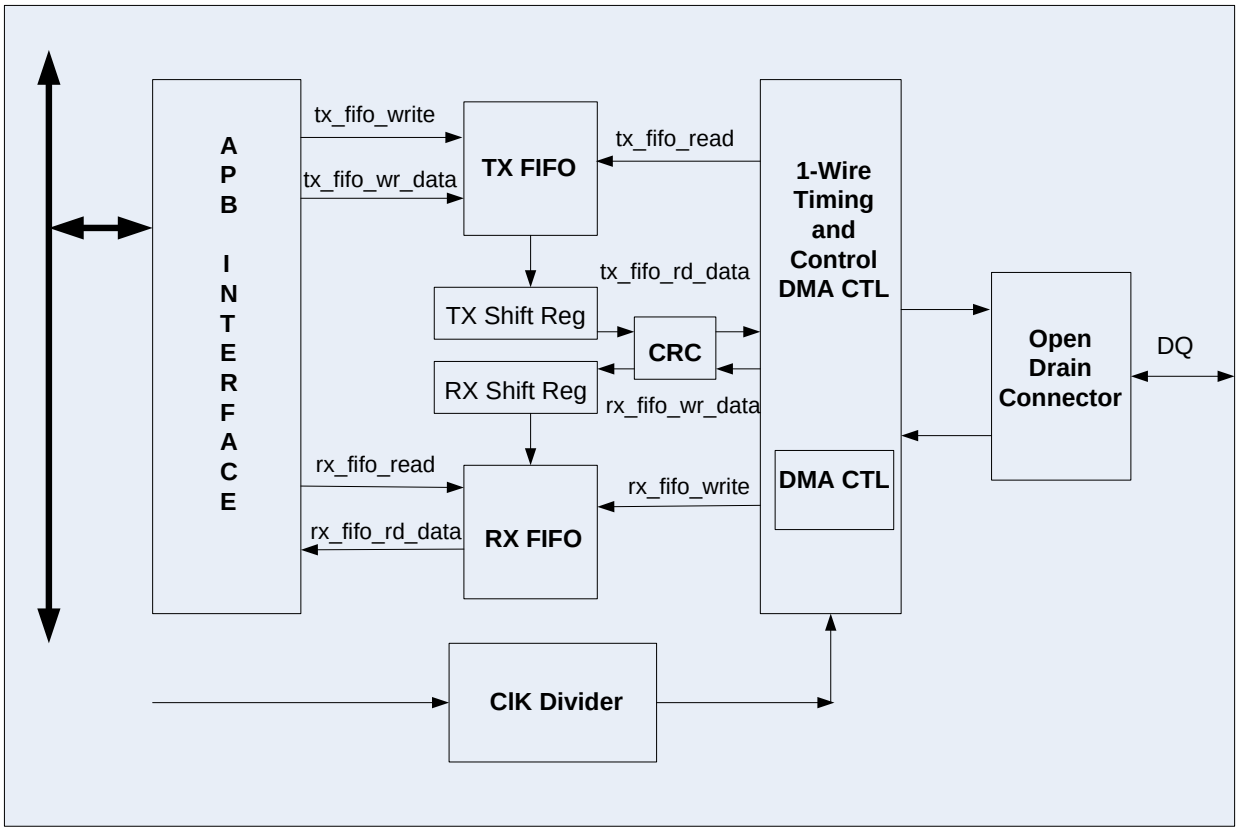
In Tegra® 3 devices, the one wire protocol is intended to communicate with battery controller chips.

Features

- Independent RX and TX FIFO's
- FIFO depth of 32 x 32 bits
- Hardwired implementation of one wire protocol to eliminate need for external bridge chip
- Software programmable registers
- Software readable status registers
- Receive transmission with interrupt-based operation
- 1 MHz device clock required. Capable of running at higher frequencies provided timing parameters are programmed
- Supports deglitch
- Supports Byte transfers or 1 Bit transfers
- Supports following commands: Read ROM, Skip ROM, Read Mem, Read Status, Read Data/Generate 8 bit CRC, Write Memory, Write Status
- Supports CRC 8/16 bit implementation
- Supports different battery devices, up to a memory size of 256K in byte transfer
- OWR generic controller support added in Tegra 3 with device DS2784. The features supported in DS2784 are:
  - Command
  - Command and Address
  - Command, Address and Write Command
  - Command, Address and Read Command

36.1 Functionality

Figure 100. OWR Block Diagram



Specific command sequences as per the OWR protocol have to be followed for any data transaction over OWR interface.

The protocol involves first issuing a reset command where the controller looks for a presence from the device, and then issuing ROM commands before the EPROM is accessible, once the presence pulse is received.

The following ROM Commands are supported:

- Read ROM (33hex command)
- Skip ROM (CChex command)

When the read ROM command is issued, the controller receives a 64 bit ID from the device. This is an optional command, in case there is only a single slave present. One can directly issue a Skip Rom Command and issue memory commands to access EPROM.

EPROM accessible commands are:

- Read Memory (F0hex command)
- Read Status (AAhex command)
- Read Data/Generate 8 Bit CRC (C3hex command)
- Write Memory (0Fhex command)
- Write Status (55hex command)

The other commands can be used with 1-bit read/write. Contact your NVIDIA FAE for more details.

36.1.1 CRC Generation

To ensure data integrity, the controller has 8-bit and 16-bit CRC calculations. The equivalent polynomial function of this CRC is: $X^8 + X^5 + X^4 + 1$.

The CRC is calculated on the data being received from the device. During a Read Memory command the software has a provision to enable the CRC check bit where the CRC is calculated on the data received from the device (RD_MEM_CRC_REQ bit in Control Register).When this bit is enabled after the data is read from the EPROM, the device sends CRC to the controller .The controller then checks the received CRC against the calculated CRC and sets an crc_error flag in case of mismatch. The CRC can be 8 bit /16 bit depending on CRC_16BIT_EN bit in the Control Register. By programming the BY_PASS_CRC_ERR bit in the Control Register, the crc_error is ignored by the controller & continues with the command operation.

For other commands, i.e., read data CRC, read status, and write memory commands, the CRC checks are done by default as part of the protocol, unlike in read memory where it is optional.

Note: CRC 16bit is also supported in some battery devices.

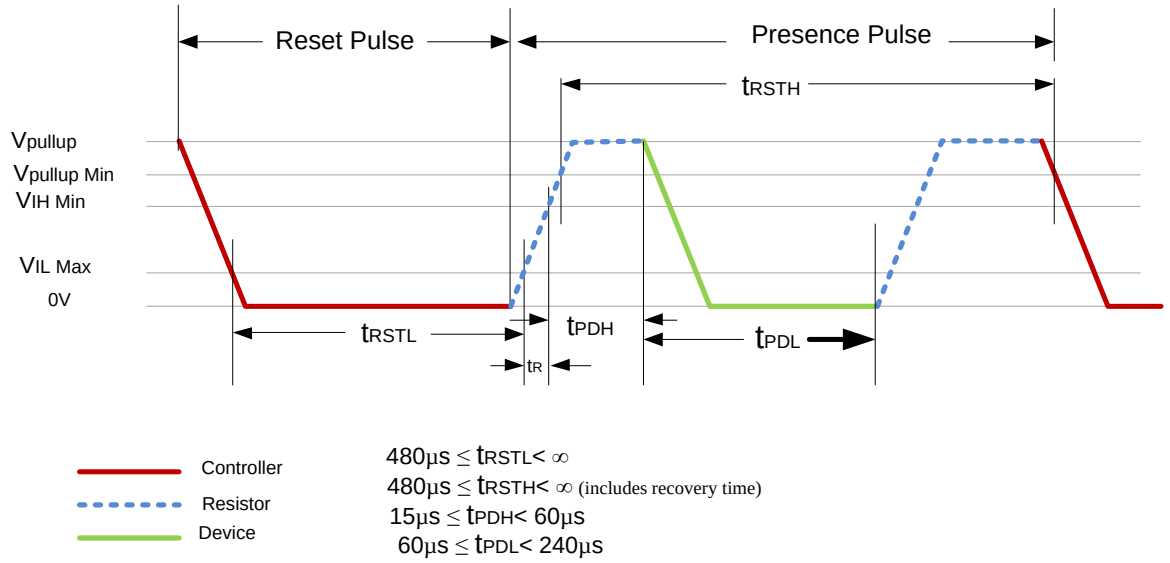
36.1.2 OWR Data Transfer Sequence

The OWR protocol consists of five types of data transfer:

- Reset & presence pulse
- Write 0
- Write 1
- Read Data
- Program Pulse

All data transfers (except presence pulse) are initiated by the controller. The communication should always begin with the initialization sequence, shown in the Figure 101 below.

Figure 101. Initialization Sequence



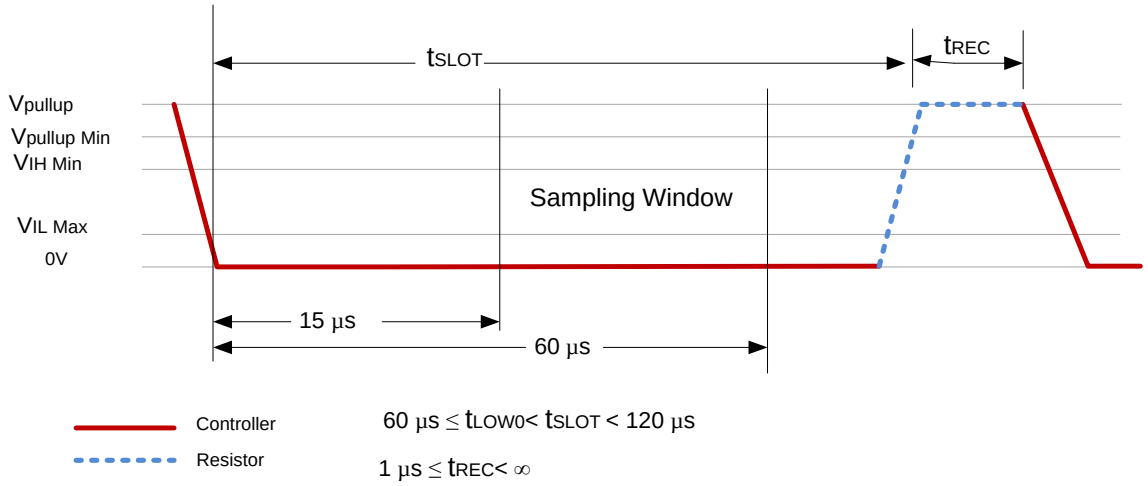
The reset pulse begins the initialization sequence. It is initiated when the GO bit in the control register (Control[GO]) is set.

36.1.2.1 Read/Write Time Slots

Write 0 Timing Slot

During a write memory command, for writing a bit 0, the data can be sampled and written into the scratch pad any time between t_{LOW0} and t_{SLOT} duration as shown in Figure 102 below

Figure 102. Write 0 Timing



Write 1/Read Data Timing Slot

The Write 1 and Read timing slots are identical. The data bus is pulled low for t_{LOW1} time. The device can sample the data in sampling window (Figure 103). Similarly during a read slot the controller can read the data from the device in sampling window (Figure 104)

Figure 103. Write 1 Timing

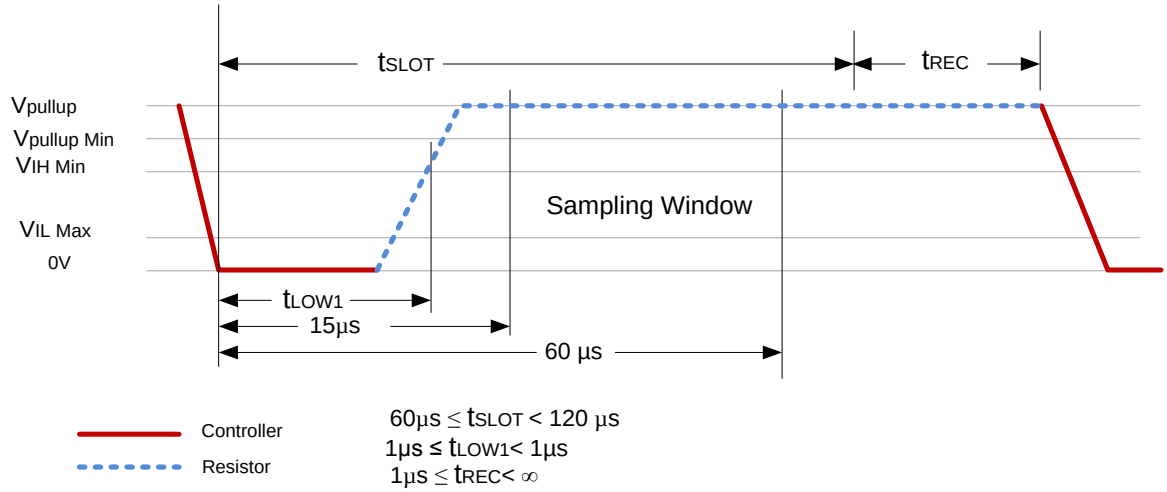


Figure 104. Read Timing

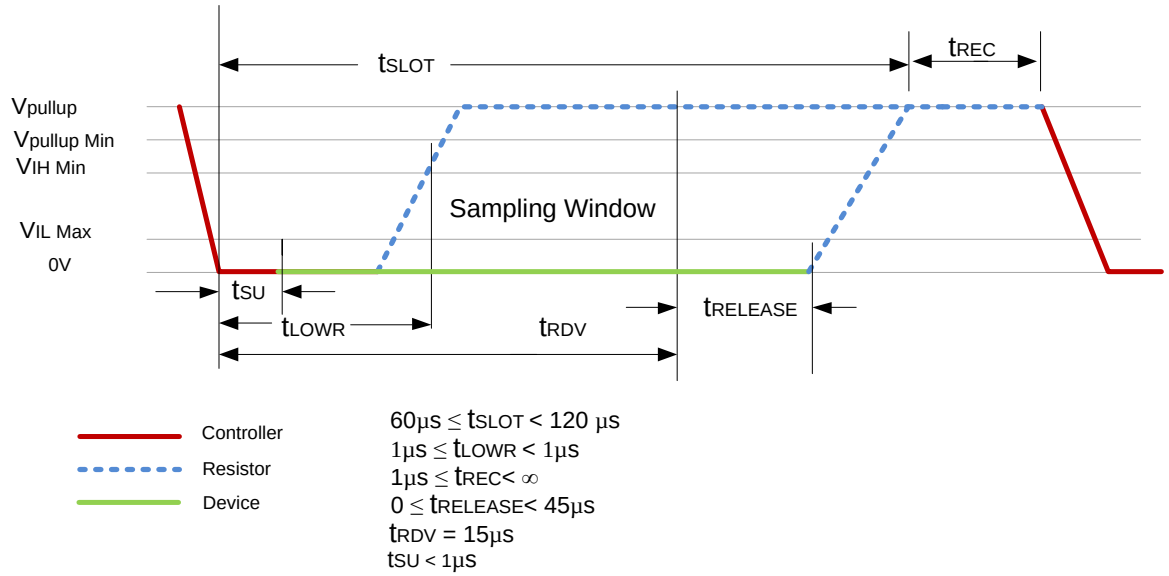
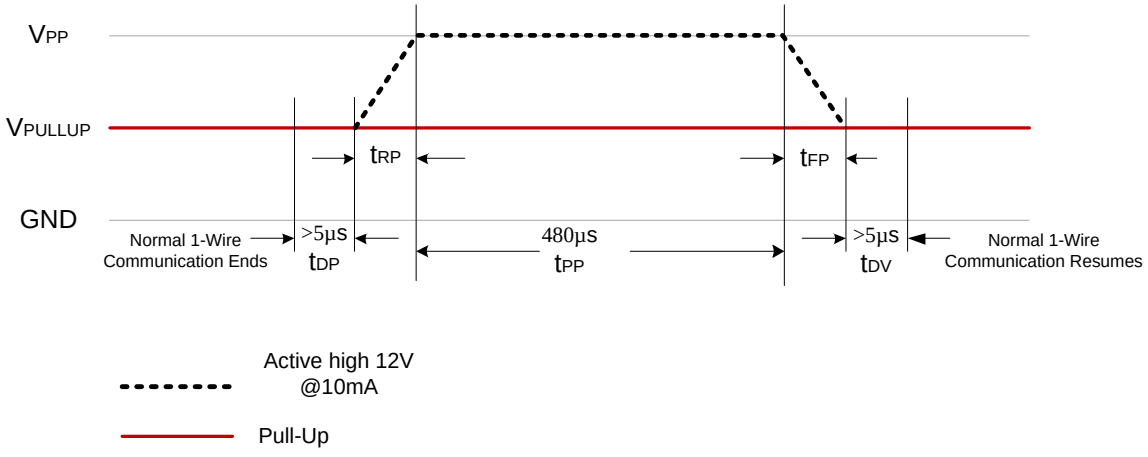


36.1.2.2 Programming Pulse

During a write memory command, data is first copied to the scratch pad. To shift the data from the scratch pad to the EPROM, a program pulse of 12 volts is applied to the data line after the controller has confirmed that the CRC is correct.

- In byte mode transfer the controller controls the generation of programming pulse.
- In single bit Write mode programming pulse is generated using GPIO's
- In Programming pulse window OWR bus is controlled by 12V voltage providing minimum of 10mA of current.

Figure 105. Programming Timing Pulse

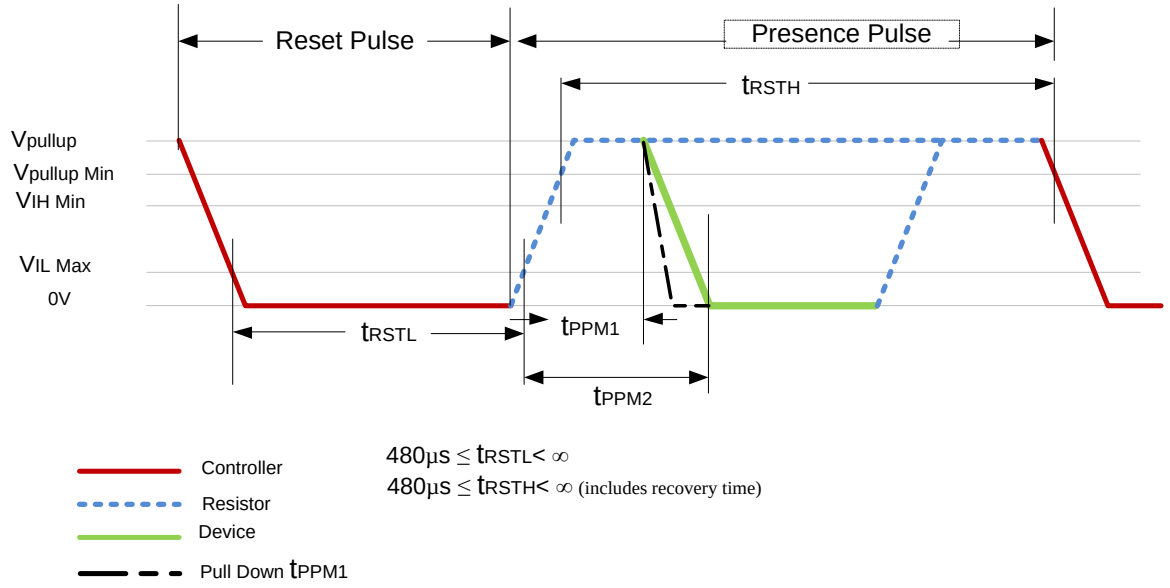


36.1.2.3 Presence-Pulse Masking (PPM)

Presence-Pulse Masking is used when battery devices are propagated through networks and get reflected. Glitches may occur due to reflections in network which may cause slave devices to lose synchronization.

When Presence-Pulse Masking is enabled, the controller pulls the OWR bus to low at t_{PPM1} till t_{PPM2}. At t_{PPM2} battery device further pulls down to low.

Figure 106. Presence-Pulse Masking



36.1.3 Interrupts

Interrupts are used to indicate the status of the design at different stages, so that the next data transfer can be determined.

Done signals indicate the data transfer has been done without any interruptions.

Error signals indicate an error has occurred and data transfer should start again. Error can be CRC err, presence error, memory write error etc.

Overflow/underrun indicates the FIFO status.

Data request indicates FIFO's are ready to accept or send the data.

All the Interrupts can be controlled by Interrupt MASK enables and Interrupt SET register.

36.1.4 Error handling

If OWR controller receives an error like CRC error, presence error, memory write error, or an error command; a reset pulse must be issued and the entire sequence must be repeated.

The OWR controller can bypass these errors by enabling register bits in the control register.

CTL.BYPASS_CRC_ERR: Transfer doesn't stops on CRC error

CTL.BYPASS_DGLITCH: Stops the execution of deglitch logic

CTL.PRESENCE_PULSE_MASKING: Transfer doesn't stops on presence error.

36.1.5 Clock Control

OWR controller clocking has following clock source options:

Option 0: pllP_out0 = 432MHZ (Fixed 432 MHz directly from PLLP)

Option 1: pllC_out0 = Up to 600MHz, Programmable clock output directly from PLLC.

Option 2: pllM_out0 = Up to 400MHz, Programmable clock output directly from PLLM.

Option 3: dbg_oscout = External clock source determined by the customer. 12 MHz, 13 MHz, 19.2 MHz, or 26 MHz are supported frequencies.

An 8-bit divider is used to generate a 1 MHz clock

The clock divider generates a 1 MHz clock that is used as a time reference by the state machine. Transitions between the states of the state machine as well as actions triggered at precise time deadlines are expressed using the 1-MHz clock. The state machine performs all required actions to dialog with the external device.

36.1.6 Deglitch/Debounce

To overcome the glitches on the input dq line, deglitch logic is used to make sure the data is stable for at least one microsecond. If a glitch occurs, an interrupt is generated and the transfer should start again. There is a bit to bypass deglitch logic. If that bit is set, deglitch is bypassed and if glitches occur they are not reported.

When to sample the data is determined by programming the control reg presence_sample_clk for reset initialization and read_data_sample_clk for read time slots.

There is a limitation to the value programmed in Presence/read_data sample clk: the hardware requires 6 clock cycles to implement deglitch generation logic (Synchronizer output requires 2 clks and deglitch 1 clk. If there is a glitch on dq line, HW samples the data on next clk edge, 2 clks later, to store the sampled data 1 clk pulse).

Presence sample clk = Tpdl - 6 clks

Rd_data_sample_clk = Trdv - 6 clks

36.1.7 Read/Write 1 Bit

The controller also supports sending or receiving data bit by bit. In bit by bit transfer, the software:

- calculates all the required calculations like when to send the wr0/wr1/rd
- calculates the CRC for received data
- check CRC and
- preserves the received data

The hardware does not preserve any data in registers, except the received 1 bit data, in RD_SAMPLE_DATA register.

The controller can only send the Time slots (Wr1/Wr0/Rd) and store the received sampled data in a reg. Time slots are controlled by the value programmed in the timing registers.

In case of writes the program pulse generation can be done using GPIO pins.

36.1.7.1 Programming Sequence

OWR communication always begins with reset initialization. To start reset initialization, program the CTRL.GO Bit in the control register. Program all the timing registers before the GO Bit. If device presence is detected, program the rom command and then program Memory Command.

Programming Rom Cmd

Transmit LSB first to send ReadRom Command (33h, 0011-0011).

Time Slots

- LSB of ReadRom command is 1'b1. Program CTRL.WR1_BIT in control register. After controller generates write-1 time slot, wait for the write-1 time slot to be completed by looking into INTR_STATUS.BIT_TRANSFER_DONE.
- After this is complete, program the next bit (in this case it's again 1'b1). Program CTRL.WR1_BIT in control register. After Controller generates write-1 time slot, wait for the write-1 time slot to be completed by looking into INTR_STATUS.BIT_TRANSFER_DONE
- Program the next bit then (in this case it is 1'b0). Program CTRL.WR0_BIT in control register. After controller generates write-0 time slot, wait for the write-0 time slot to be completed by looking into INTR_STATUS.BIT_TRANSFER_DONE

Repeat this for the remaining bits.

- After the ReadRom Command is sent, read 64 bits rom data. To receive 64 bits, 64 read time slots have to be sent. To generate Read time slot, program CTRL.RD_BIT in control register. After the controller generates read time slot, the read bit is stored in READ_SAMPLED_BIT. Sampled Bit should always be read after the bit transfer is done.
- Next, program the CTRL.RD_BIT, to read 2nd bit. Read time slot is generated by the controller. Wait for done and read the sampled bit.

Repeat the sequence for remaining bits.

After receiving all 64 bits, Memory data has to be read.

Reading EPROM data using ReadMem Command

- To read Memory data, first send memory cmd followed by memory address. After memory cmd and address is sent, verify the data sent. This can be done by checking CRC of cmd and address sent. To receive CRC, send 8 read-slots, read the CRC data and check with computed value if it matches. Read the EPROM data from memory or else start with initialization procedure.
- To read data from EPROM, send read time slots. The number of read time slots should be memory address – eprom endoffset. After reading EPROM data, read CRC and check the received data if CRC is required. Normally CRC is embedded within the EPROM data. To receive 8 bit CRC data send 8 read time slots.

36.2 Programming Guidelines

36.2.1 Programming Registers

All the registers should be programmed and CTL.GO bit should be programmed to start the controller.

Registers to Program Prior to the Control Register

- **All the timing registers**: Program the timing values according to battery device data sheet
- **Command reg**: Program the device Rom Cmd, Mem Cmd, EPROM starting address
- **EPROM size offset**: Program the number of bytes to transfer
- **Interrupt mask enables**: Program the respective interrupt mask enables to enable the interrupts to CPU/COP
- **Control Reg**: Programming this register depends on the type of execution required.

Program the G0 bit only after programming all of the above.

Registers to Monitor

- **Interrupt Status & Source**: These are used to monitor the design status (like done, error etc).
- **CRC**: Stores the calculated CRC 8/16 bit value

- **Byte Count**: Indicates the number of bytes transferred/received
- **Read_ROM0/ROM1**: Stores the received Rom Family code, Serial Number, CRC.

FIFO Registers

- Tx/Rx FIFO: Data to transmit/Receive data.

36.2.2 Byte Data Transfer Sequence

Reset Initialization → Rom Cmd → Mem Cmd → Reset Initialization → Rom Cmd → Mem Cmd etc

In case of an error, the entire sequence should start again from the beginning:

Reset Initialization → Error → Reset Initialization →Rom Cmd → Error → Reset Initialization → Rom Cmd → Mem Cmd etc.

36.3 OWR Registers

36.3.1 OWR_CONTROL_0

This register is the main control register. It should be configured last after configuring all other settings.

OWR control Register

Offset: 000h | Read/Write: R/W | Reset: 0b00000000000000000000000000000000

Bit	Reset	Description
31	0x0	RD_BIT: if 0 no transfer is done. If 1 read time slot is executed. This bit is a write only. Read to this register will return 0 0 = NO_TRANSFER 1 = TRANSFER_READ_SLOT
30	0x0	WR0_BIT: if 0 no transfer is done. If 1 write zero time slot is executed. This bit is a write only. Read to this register will return 0 0 = NO_TRANSFER 1 = TRANSFER_ZERO
29	0x0	WR1_BIT: if 0 no transfer is done. If 1 write one time slot is executed. This bit is a write only. Read to this register will return 0 0 = NO_TRANSFER 1 = TRANSFER_ONE
28	0x0	BY_PASS_CRC_ERR: this bit is set to 1, if transfer needs to continue on crc err else on err transfer stops, and again transfer starts on setting rpp reset(go bit) 0 = STOP_TRANSFER_ON_CRC_ERR 1 = CONTINUE_TRANSFER_ON_CRC_ERR
27	0x0	BY_PASS_DGLITCH: This bit is used to bypass the deglitch logic, If 1, just takes the sync output If 0, looks for any glitch in the sample window for at least 1us, Deglitch requires a minimum of 6 clks(2 for sync, 2 for deglitch, if glitch, checks for 2 more clks, still glitch exists, err interrupt is asserted and data transfer should start from first) 0 = START_DGLITCH 1 = NO_DGLITCH
26:23	0x0	RD_DATA_SAMPLE_CLK: read data sample window, master samples the data_in which should be less than or equal to (tlow1 - 6) clks 6 clks are used for Deglitch, if Deglitch bypassed 3 clks should be enough
22:15	0x0	PRESENCE_SAMPLE_CLK: presence pulse sample clk, master samples the data_in which should be less than or equal to (tpdl - 6) clks 6 clks are used for dglitch, if Deglitch bypassed 3 clks should be enough
14	0x0	RD_MEM_CRC_REQ: This bit is set to 1, if CRC is required for read memory cmd at end of memory 0 = NO_CRC_READ

Bit	Reset	Description
		1 = CRC_READ
13:9	0x0	RX_FIFO_ATTEN_LEVEL: Receive FIFO attention level 000 = 1 word, fifo req is asserted when least one word full in the fifo 001 = 2 word, fifo req is asserted when least 2 words full in the fifo etc.
8:4	0x0	TX_FIFO_ATTEN_LEVEL: Transmit fifo attention level 000 = 1 word, fifo req is asserted when least one word empty in the fifo 001 = 2 word, fifo req is asserted when least 2 words empty in the fifo etc.
3	0x0	CRC_16BIT_EN: if set to 1 16bit CRC is executed if set to 0 8bit crc is executed 0 = CRC_8BIT_EN 1 = CRC_16BIT_EN
2	0x0	DATA_TRANSFER_MODE: if set to 1 data transfer is done bit by bit if set to 0 data transfer is done through byte 0 = BYTE_TRANSFER_MODE 1 = BIT_TRANSFER_MODE
1	0x0	PRESENCE_PULSE_MASKING: when set, dq is driven to low by master before the slave does clearing this bit disables the ppm 0 = NO_PPM 1 = START_PPM
0	0x0	GO: Generate Reset Presence Pulse This bit is a write only read to this register will return 0this bit should be programed after all the registers are programed 0 = NO_PRESENCE_PULSE 1 = START_PRESENCE_PULSE

36.3.2 OWR_COMMAND_0

Rom Cmd, Mem Cmd and Mem Addr should be program at the same time.

OWR Command Register

Offset: 004h | Read/Write: R/W | Reset: 0b00000000000000000000000000000000

Bit	Reset	Description
31:16	0x0	MEM_ADDR: EPROM Starting Address[15:0] to write/read data into EPROM
15:8	0x0	MEM_CMD: one wire MEM commands
7:0	0x0	ROM_CMD: one wire ROM commands

36.3.3 OWR_EPROM_0

Indicates the number of bytes to transfer, supports up to 256K EPROM size. MEM_ADDR and MEMORY_BYTES_TRANSFER/STATUS_BYTES_TRANSFER should always be in sync as in if EPROM end offset address is 7f, and we want to read data from 4th location address of EPROM.

Programming should be in the following way:

MEM_ADDR = 0x4;

MEMORY_BYTES_TRANSFER = 0x7B; (0x4 - 0x7f) similarly for status bytes.

OWR Eprom Size offset

Offset: 008h | Read/Write: R/W | Reset: 0b00000000000000000000000000000000

Bit	Reset	Description
31:16	0x0	STATUS_BYTES_TRANSFER: Number of EPROM Status bytes to transfer Mem_Addr - Status bytes end address

Bit	Reset	Description
15:0	0x0	MEMORY_BYTES_TRANSFER: Number of EPROM memory bytes to transfer, Mem_Addr - EPROM end address

36.3.4 OWR_WR_RD_TCTL_0

Controls the one wire DQ output (Pullup or pullDown) to write and read time slots timings are in microseconds. Note : <= means less than or equal to.

OWR Write Read Timing Control Register

Offset: 00ch | Read/Write: R/W | Reset: 0b00000000000000000000000000000000

Bit	Reset	Description
29:28	0x0	TSU: Read Data Setup, Tsu = N owr clks, Range = tsu < 1
27:22	0x0	TRELEASE: Release one wire Time, Trelease = N owr clks, Range = 0 <= trelease < 45
21:18	0x0	TRDV: Read data valid time, Trdv = N+1 owr clks, Range = Exactly 15
17:11	0x0	TLOW0: Write Zero time Low, Tlow0 = N+1 owr clks, Range = 60 <= tlow0 < tslot < 120
10:7	0x0	TLOW1: Write one time Low, or TLOWR both are same Tlow1 = N+1 owr clks, Range = 1 <= tlow1 < 15 TlowR = N+1 owr clks, Range = 1 <= tlowR < 15
6:0	0x0	TSLOT: Active time slot for write or read data, Tslot = N+1 owr clks, Range = 60 <= tslot < 120

36.3.5 OWR_RST_PRESENCE_TCTL_0

Controls the one wire DQ output (Pullup or pullDown) to reset initialization time slots timings are in microseconds.

Note : <= means less than or equal to

OWR Reset Presence Timing Control Register

Offset: 010h | Read/Write: R/W | Reset: 0b00000000000000000000000000000000

Bit	Reset	Description
31:24	0x0	TPDL: PRESENCE_DETECT_LOW Tpdl = N owr clks, Range = 60 <= tpdl < 240
23:18	0x0	TPDH: PRESENCE_DETECT_HIGH Tpdh = N+1 owr clks, Range = 15 <= tpdh < 60
17:9	0x0	TRSTL: RESET_TIME_LOW Trstl = N+1 owr clks, Range = 480 <= trstl < infinity
8:0	0x0	TRSTH: RESET_TIME_HIGH, Trsth = N+1 owr clks, Range = 480 <= trsth < infinity

36.3.6 OWR_PPM_CORRECTION_TCTL_0

Drives the DQ line to low before slave does

OWR Presence Pulse Masking Timing Control

Offset: 014h | Read/Write: R/W | Reset: 0b0000000000000000

Bit	Reset	Description
15:6	0x0	TPPM2: PRESENCE PULSE MASK STOP
5:0	0x0	TPPM1: PRESENCE PULSE MASK START

36.3.7 OWR_PROG_PULSE_TCTL_0

Controls the 12V programming pulse used to write data to EPROM. Timings are in microseconds.

OWR Program Pulse Timing Control Register

Offset: 018h | Read/Write: R/W | Reset: 0b00000000000000000000000000000000

Bit	Reset	Description
31:16	0x0	TPP: Program Pulse Width Tpp = N OWR clks Range = 480 to 5000
15:12	0x0	TFP: Program Voltage Fall Time Tfp = N OWR clks Range = 0.5 to 5
11:8	0x0	TRP: Program Voltage Rise Time Trp = N OWR clks Range = 0.5 to 5
7:4	0x0	TDV: Delay to verify Tdv = N OWR clks, Range = > 5
3:0	0x0	TPD: Delay to program Tpd = N+1 OWR clks, Range = > 5

36.3.8 OWR_READ_ROM0_0

Read ROM Cmd Reads 8-bit family code, 48-bit serial number and 8-bit CRC. Total of 64 bits, Register can have a maximum of 32 bits. Read Rom Cmd data is split into 2 registers 1. READ_ROM0 2. READ_ROM1

OWR Read ROM DATA0 Register

Offset: 01ch | Read/Write: RO | Reset: 0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx

Bit	Reset	Description
31:8	X	SERIAL_NUM0: Reads the first 24 bits of ROM serial number
7:0	X	FAMILY_CODE: Reads the 8 bit family code of ROM

36.3.9 OWR_READ_ROM1_0

OWR Read ROM DATA1 Register

Offset: 020h | Read/Write: RO | Reset: 0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx

Bit	Reset	Description
31:24	X	CRC_BYTE: Reads the 8-bit CRC code of ROM
23:0	X	SERIAL_NUM1: Reads the next 24 bits of ROM serial number

36.3.10 OWR_INTR_MASK_0

This register stores the masks for the interrupts. If a bit is set 1 and the corresponding interrupt condition is satisfied, interrupt line to system interrupt controller is asserted.

OWR INTR Mask Register

Offset: 024h | Read/Write: R/W | Reset: 0b00000000000000

Bit	Reset	Description
13	0x0	BIT_TRANSFER_DONE_INT_EN: 0 = DISABLE 1 = ENABLE
12	0x0	RXFIFO_DATA_REQ_INT_EN: 0 = DISABLE

Bit	Reset	Description
		1 = ENABLE
11	0x0	TXFIFO_DATA_REQ_INT_EN: 0 = DISABLE 1 = ENABLE
10	0x0	DGLITCH_INT_EN: 0 = DISABLE 1 = ENABLE
9	0x0	RXF_UNR_INT_EN: 0 = DISABLE 1 = ENABLE
8	0x0	TXF_OVF_INT_EN: 0 = DISABLE 1 = ENABLE
7	0x0	MEM_CMD_DONE_INT_EN: 0 = DISABLE 1 = ENABLE
6	0x0	ROM_CMD_DONE_INT_EN: 0 = DISABLE 1 = ENABLE
5	0x0	PRESENCE_DONE_INT_EN: 0 = DISABLE 1 = ENABLE
4	0x0	RESET_DONE_INT_EN: 0 = DISABLE 1 = ENABLE
3	0x0	ERR_CMD_INT_EN: 0 = DISABLE 1 = ENABLE
2	0x0	MEM_WR_ERR_INT_EN: 0 = DISABLE 1 = ENABLE
1	0x0	CRC_ERR_INT_EN: 0 = DISABLE 1 = ENABLE
0	0x0	PRESENCE_ERR_INT_EN: 0 = DISABLE 1 = ENABLE

36.3.11 OWR_INTR_STATUS_0

OWR Status Register

Offset: 028h | Read/Write: R/W | Reset: 0b0xx00000000000

Bit	R/W	Reset	Description
13	RW	0x0	BIT_TRANSFER_DONE: This bit is set when transfer of each bit done this is set on in one bit transfer mode software writes 1 to clear this bit 0 = NOT_DONE 1 = DONE
12	RO	X	RXFIFO_DATA_REQ: RX FIFO data req 0 = RX_NOT_RDY 1 = RX_RDY
11	RO	X	TXFIFO_DATA_REQ: TX FIFO data req 0 = TX_NOT_RDY 1 = TX_RDY

Bit	R/W	Reset	Description
10	RW	0x0	DGLITCH: This bit is set when data is not stable for at least 1us, Software writes a 1 to clear this bit. if deglitch detected data transfer should start from 1st. 0 = DGLITCH_NOT_DETECTED 1 = DGLITCH_DETECTED
9	RW	0x0	RXF_UNR: RX FIFO Under run: RO. This bit is set to 1 whenever software tries to read from an empty RX FIFO. Software writes a 1 to clear this bit. 0 = NOT_EMPTY 1 = EMPTY
8	RW	0x0	TXF_OVF: TX FIFO Overflow: RO. This bit is set to 1 whenever software tries to write to a full TX FIFO. Software writes a 1 to clear this bit. 0 = NOT_EMPTY 1 = EMPTY
7	RW	0x0	MEM_CMD_DONE: This Indicates the master has written data into EPROM or data received from EPROM without any error. Software writes a 1 to clear it. 0 = NOT_DONE 1 = DONE
6	RW	0x0	ROM_CMD_DONE: This indicates master has received the rom data from battery. Software writes a 1 to clear it. 0 = NOT_DONE 1 = DONE
5	RW	0x0	PRESENCE_DONE: This indicates the presence done, master has detected the device. Software writes a 1 to clear it. 0 = NOT_DONE 1 = DONE
4	RW	0x0	RESET_DONE: This indicates the master has sent the reset, then waits for presence. Software writes a 1 to clear it. 0 = NOT_DONE 1 = DONE
3	RW	0x0	ERR_CMD: ERROR CMD: Indicates error command written in the register. Software writes a 1 to clear it. 0 = CORRECT_CMD 1 = ERROR_CMD
2	RW	0x0	MEM_WR_ERR: MEM WR ERROR: Indicates the received data from EPROM is correct or not. Software writes a 1 to clear it. 0 = N0_ERROR 1 = ERROR
1	RW	0x0	CRC_ERR: CRC ERROR: Indicates the received data is correct or not. Software writes a 1 to clear it. 0 = N0_ERROR 1 = ERROR
0	RW	0x0	PRESENCE_ERR: Presence ERROR. This bit is set when device presence not found 0 = SLAVE_DETECTED 1 = NO_SLAVE_DETECTED

36.3.12 OWR_INTR_SOURCE_0

This is a read-only register which returns the AND of Interrupt Source and Interrupt Mask registers.

OWR INTR Source Register

Offset: 02ch | Read/Write: RO | Reset: 0bxxxxxxxxxxxxxx

Bit	Reset	Description
13	X	BIT_TRANSFER_DONE: 0 = NOT_DONE

Bit	Reset	Description
		1 = DONE
12	X	RXFIFO_DATA_REQ: 0 = RX_NOT_RDY 1 = RX_RDY
11	X	TXFIFO_DATA_REQ: 0 = TX_NOT_RDY 1 = TX_RDY
10	X	DGLITCH: 0 = DGLITCH_NOT_DETECTED 1 = DGLITCH_DETECTED
9	X	RXF_UNR: 0 = NOT_EMPTY 1 = EMPTY
8	X	TXF_OVF: 0 = NOT_EMPTY 1 = EMPTY
7	X	MEM_CMD_DONE: 0 = NOT_DONE 1 = DONE
6	X	ROM_CMD_DONE: 0 = NOT_DONE 1 = DONE
5	X	PRESENCE_DONE: 0 = NOT_DONE 1 = DONE
4	X	RESET_DONE: 0 = NOT_DONE 1 = DONE
3	X	ERR_CMD: 0 = CORRECT_CMD 1 = ERROR_CMD
2	X	MEM_WR_ERR: 0 = N0_ERROR 1 = ERROR
1	X	CRC_ERR: 0 = N0_ERROR 1 = ERROR
0	X	PRESENCE_ERR: 0 = SLAVE_DETECTED 1 = NO_SLAVE_DETECTED

36.3.13 OWR_INTR_SET_0

This is a write-only register which can be used to set the interrupt status bit. A write to this register causes the bits in status register to be set 1 Read always returns 0.

Interrupt Set Register

Offset: 030h | Read/Write: R/W | Reset: 0b0xx00000000000

Bit	Reset	Description
13	0x0	BIT_TRANSFER_DONE: 0 = NOT_DONE 1 = DONE

Bit	Reset	Description
10	0x0	DGLITCH: 0 = DGLITCH_NOT_DETECTED 1 = DGLITCH_DETECTED
9	0x0	RXF_UNR: 0 = NOT_EMPTY 1 = EMPTY
8	0x0	TXF_OVF: 0 = NOT_EMPTY 1 = EMPTY
7	0x0	MEM_CMD_DONE: 0 = NOT_DONE 1 = DONE
6	0x0	ROM_CMD_DONE: 0 = NOT_DONE 1 = DONE
5	0x0	PRESENCE_DONE: 0 = NOT_DONE 1 = DONE
4	0x0	RESET_DONE: 0 = NOT_DONE 1 = DONE
3	0x0	ERR_CMD: 0 = CORRECT_CMD 1 = ERROR_CMD
2	0x0	MEM_WR_ERR: 0 = N0_ERROR 1 = ERROR
1	0x0	CRC_ERR: 0 = N0_ERROR 1 = ERROR
0	0x0	PRESENCE_ERR: 0 = SLAVE_DETECTED 1 = NO_SLAVE_DETECTED

36.3.14 OWR_STATUS_0

OWR Status Register

Offset: 034h | Read/Write: R/W | Reset: 0bxxxxxxxxxxxxxxxxxx00xxxxx

Bit	R/W	Reset	Description
23	RO	X	READ_SAMPLED_BIT: the bit is valid only RD_BUSY is cleared 0 = READ_ZERO 1 = READ_ONE
22	RO	X	RD_BUSY: READ : This is a self-clearing bit and is cleared when read time slot completes on read sequence the sampled read bit is stored in READ_BIT 0 = IDLE 1 = BUSY
21	RO	X	WR1_BUSY: WRITE1 : This is a self-clearing bit and is cleared when write one time slot completes on write sequence 1 is transferred 0 = IDLE 1 = BUSY
20	RO	X	WR0_BUSY: WRITE 0 : This bit is self-clearing, and is cleared when write zero time slot completes on write sequence 0 is transferred 0 = IDLE

Bit	R/W	Reset	Description
			1 = BUSY
19	RO	X	RPP: this is sent reset is set(go), auto cleared on completion of reset initialization sequence. 0 = IDLE 1 = RESET_PRESENCE_PULSE
18:13	RO	X	TX_FIFO_EMPTY_CNT: The number of slots that can be written to the tx fifo
12:7	RO	X	RX_FIFO_FULL_CNT: The number of slots to be read from the rx fifo
6	RW	0x0	RX_FLUSH: flush the rx fifo, cleared after fifo is empty 0 = DISABLE 1 = ENABLE
5	RW	0x0	TX_FLUSH: flush the tx FIFO, cleared after fifo is empty 0 = DISABLE 1 = ENABLE
4	RO	X	RXF_EMPTY: RX FIFO empty status: RO. Hardware sets this bit to 1 if RX FIFO is empty Otherwise, this bit is set to 0. 0 = NOT_EMPTY 1 = EMPTY
3	RO	X	RXF_FULL: RX FIFO full status: RO. Hardware sets this bit to 1 if RX FIFO is full. Otherwise, this bit is set to 0. 0 = NOT_FULL 1 = FULL
2	RO	X	TXF_EMPTY: TX FIFO empty status: RO. Hardware sets this bit to 1 if TX FIFO is empty Otherwise, this bit is set to 0. 0 = NOT_EMPTY 1 = EMPTY
1	RO	X	TXF_FULL: TX FIFO full status: RO.Hardware sets this bit to 1 if TX FIFO is full. Otherwise, this bit is set to 0. 0 = NOT_FULL 1 = FULL
0	RO	X	RDY: Ready bit. This bit is set at the end of every transfer and its cleared by hardware when next transfer starts 0 = NOT_READY 1 = READY

36.3.15 OWR_CRC_0

OWR CRC Register

Offset: 038h | Read/Write: RO | Reset: 0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx

Bit	Reset	Description
31:16	X	CRC_CALC: CRC calculated by OWR current wr/rd operation
15:0	X	CRC_RECEV: CRC Received on Read Data

36.3.16 OWR_BYTE_CNT_0

OWR BYTE_CNT Register

Offset: 03ch | Read/Write: RO | Reset: 0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx

Bit	Reset	Description
31:16	X	TRANSMITTED: Number of bytes transmitted on wr cmds or address sent
15:0	X	RECEIVED: Number of bytes received on Read Data includes CRC byte count

36.3.17 OWR_TX_FIFO_0

OWR TX FIFO Register

Offset: 040h | Read/Write: R/W | Reset: 0b00000000000000000000000000000000

Bit	Reset	Description
31:0	0x0	WR_DATA: TX FIFO

36.3.18 OWR_RX_FIFO_0

OWR RX FIFO Register

Offset: 044h | Read/Write: RO | Reset: 0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx

Bit	Reset	Description
31:0	X	RD_DATA: RX FIFO

36.3.19 OWR_RECOVERY_TIME_TCTL_0

OWR RECOVERY TIME Register

Offset: 04ch | Read/Write: R/W | Reset: 0b0000000000000000

Bit	Reset	Description
15:0	0x0	TREC: Recovery time slot for write or read data, Trec= N+1 OWR clks

36.3.20 OWR_RST_TIME_TCTL_0

OWR RST PRESENCE HIGH AND LOW TIME Register

Offset: 050h | Read/Write: R/W | Reset: 0b00000000000000000000000000000000

Bit	Reset	Description
31:16	0x0	TRSTL: RESET_TIME_LOW Trstl = N+1 OWR clks
15:0	0x0	TRSTH: RESET_TIME_HIGH, Trsth = N+1 OWR clks

36.3.21 OWR_RST_PRESENCE_DETECT_TCTL_0

OWR RST PRESENCE DETECT HIGH AND LOW TIME Register

Offset: 054h | Read/Write: R/W | Reset: 0b00000000000000000000000000000000

Bit	Reset	Description
31:16	0x0	TPDL: PRESENCE_DETECT_LOW Tpdl = N owr clks
15:0	0x0	TPDH: PRESENCE_DETECT_HIGH Tpdh = N+1 owr clks

36.3.22 OWR_WRITE_ONE_ZERO_TCTL_0

OWR WRITE 1 OR WRITE 0 TIME Register

Offset: 058h | Read/Write: R/W | Reset: 0b00000000000000000000000000000000

Bit	Reset	Description
31:16	0x0	TLOW0: Write Zero time Low Tlow0 = N+1 OWR clks
15:0	0x0	TLOW1: Write one time Low, or TLOWR both are same Tlow1 = N+1 OWR clks TlowR = N+1 OWR clks

36.3.23 OWR_TIME_SLOT_RELEASE_TCTL_0

OWR TIME SLOT OR RELEASE TIME Register

Offset: 05ch | Read/Write: R/W | Reset: 0b00000000000000000000000000000000

Bit	Reset	Description
31:16	0x0	TRELEASE: Release 1-wire Time Trelease = N OWR clks
15:0	0x0	TSLOT: Active time slot for write or read data, Tslot = N+1 OWR clks

36.3.24 OWR_READ_DATA_TCTL_0

OWR WRITE 1 OR WRITE 0 LOW TIME Register

Offset: 060h | Read/Write: R/W | Reset: 0b00000000000000000000000000000000

Bit	Reset	Description
31:16	0x0	TRDV: Read data valid time Trdv = N+1 OWR clks
15:0	0x0	TSU: Read Data Setup Tsu = N OWR clks

36.3.25 OWR_PROGRAM_PULSE_TCTL_0

OWR PROGRAM PULSE TIMING CONTROL Register

Offset: 064h | Read/Write: R/W | Reset: 0b00000000000000000000000000000000

Bit	Reset	Description
31:24	0x0	TFP: Program Voltage Fall Time Tfp = N OWR clks
23:16	0x0	TRP: Program Voltage Rise Time Trp = N OWR clks
15:8	0x0	TDV: Delay to verify Tdv = N OWR clks
7:0	0x0	TPD: Delay to program Tpd = N+1 OWR clks

36.3.26 OWR_PROGRAM_PULSE_WIDTH_TCTL_0

OWR PROGRAM PULSE TIMING CONTROL Register

Offset: 068h | Read/Write: R/W | Reset: 0b0000000000000000

Bit	Reset	Description
15:0	0x0	TPP: Program Pulse Width Tpp = N OWR clocks. Range = 480 to 5000

36.3.27 OWR_PPM_TCTL_0

OWR PRESENCE PULSE MASKING TIMING CONTROL

Offset: 06ch | Read/Write: R/W | Reset: 0b00000000000000000000000000000000

Bit	Reset	Description
31:16	0x0	TPPM2: PRESENCE PULSE MASK STOP
15:0	0x0	TPPM1: PRESENCE PULSE MASK START

36.3.28 OWR_SAMPLE_DATA_0

OWR SAMPLE DATA Register

Offset: 070h | Read/Write: R/W | Reset: 0b00000000000000000000000000000000

Bit	Reset	Description
31	0x0	RD_DATA_SAMPLE_CLK_EN: 0 = DISABLE 1 = ENABLE
30:16	0x0	RD_DATA_SAMPLE_CLK: read data sample window, master samples the data_in which should be less than or equal to (tlow1 - 6) clks. 6 clocks are used for deglitch, if Deglitch bypassed 3 clocks should be enough
15	0x0	PRESENCE_SAMPLE_CLK_EN: 0 = DISABLE 1 = ENABLE
14:0	0x0	PRESENCE_SAMPLE_CLK: presence pulse sample clk, master samples the data_in which should be less than or equal to (tpdl - 6) clocks. 6 clks are used for deglitch, if Deglitch bypassed 3 clocks should be enough

36.3.29 OWR_GENERIC_CTL_0

GENERIC OWR COMMAND TRANSFER CONTROL

Offset: 074h | Read/Write: R/W | Reset: 0b00000000000

Bit	Reset	Description
10	0x0	RD_DATA_CRC: 0 = READ 1 = NO_READ

0	0x0	CMD_XFER: 0 = SEND 1 = NO_SEND

36.3.30 OWR_CMD_XFER_TCTL_0

OWR COMMAND TRANSFER TIMING CONTROL Register

Offset: 078h | Read/Write: R/W | Reset: 0b00000000000000000000000000000000

Bit	Reset	Description
31:0	0x0	TWAIT

36.3.31 OWR_ADDR_XFER_TCTL_0

OWR ADDRESS TRANSFER TIMING CONTROL Register

Offset: 07ch | Read/Write: R/W | Reset: 0b00000000000000000000000000000000

Bit	Reset	Description
31:0	0x0	TWAIT

36.3.32 OWR_DATA_XFER_TCTL_0

OWR DATA TRANSFER TIMING CONTROL Register

Offset: 080h | Read/Write: R/W | Reset: 0b00000000000000000000000000000000

Bit	Reset	Description
31:0	0x0	TWAIT

[THIS PAGE INTENTIONALLY LEFT BLANK]

37.0 PWFM CONTROLLER

The Pulse Width Frequency Modulator (PWFM) controller is a four-channel frequency divider whose pulse width varies. Each channel has a programmable frequency divider and a programmable pulse width generator.

Frequency division is a 13-bit programmable value and pulse division is an 8-bit value.

The PWFM runs off a device clock which is programmed in the Clock and Reset controller, and can be any frequency up to the device clock maximum speed of 48 MHz. The device clock frequency is then divided by 256, before subdividing it further based on the programmable value locally.

There is an APB interface which interfaces the register logic to the APB bus.

The Tegra® 3 PWFM contains four independently programmable pulse width modulators. Each generated pulse has an n/256 duty cycle. PWM signals are useful for LCD contrast and brightness control, VCO-generated clocks and other analog voltage references where high precision is not required.

37.1 Functionality

There are four PWFM controllers on four individual pins on the chip.

Pulse Width [23:16] determines the output pulse width and must be programmed appropriately. Frequency Divider [12:0] determines the divided clock.

The output is generated from the dividers, with each divider generating one output.

37.2 PWFM Registers

37.2.1 PWM_CONTROLLER_PWM_CSR_0_0

PWM Output-0 Configuration Control Register

Offset: 000h | Read/Write: R/W | Reset: 0b00000000000000000xxx0000000000000

Bit	Reset	Description
31	0x0	ENB: Enable Pulse width modulator 0 = DISABLE 1 = ENABLE
30:16	0x0	PWM_0: Pulse width that needs to be programmed. 0=Always low 1=1/256 Pulse high 2=2/256 Pulse high N=N/256 Pulse high
12:0	0x0	PFM_0: Frequency divider that needs to be programmed.

37.2.2 PWM_CONTROLLER_PWM_CSR_1_0

PWM Output-1 Configuration Control Register

Offset: 010h | Read/Write: R/W | Reset: 0b0000000000000000xxx0000000000000

Bit	Reset	Description
31	0x0	ENB: Enable pulse width modulator 0 = DISABLE 1 = ENABLE
30:16	0x0	PWM_0: pulse width that needs to be programmed 0=Always low 1=1/256 Pulse high 2=2/256 Pulse high ------- N=N/256 Pulse high
12:0	0x0	PFM_1: Frequency divider that needs to be programmed.

37.2.3 PWM_CONTROLLER_PWM_CSR_2_0

PWM Output-2 Configuration Control Register

Offset: 020h | Read/Write: R/W | Reset: 0b0000000000000000xxx0000000000000

Bit	Reset	Description
31	0x0	ENB: Enable pulse width modulator 0 = DISABLE 1 = ENABLE
30:16	0x0	PWM_0: Pulse Width that needs to be programmed 0=Always low 1=1/256 Pulse high 2=2/256 Pulse high ------ N=N/256 Pulse high
12:0	0x0	PFM_2: Frequency divider that needs to be programmed

37.2.4 PWM_CONTROLLER_PWM_CSR_3_0

PWM Output-3 Configuration Control Register

Offset: 030h | Read/Write: R/W | Reset: 0b0000000000000000xxx0000000000000

Bit	Reset	Description
31	0x0	ENB: Enable pulse width modulator 0 = DISABLE 1 = ENABLE
30:16	0x0	PWM_0: pulse width that needs to be programmed 0=Always low 1=1/256 Pulse high 2=2/256 Pulse High ------- N=N/256 Pulse high
12:0	0x0	PFM_3: Frequency divider that needs to be programmed.

38.0 THERMAL SENSOR

Thermal and voltage sensors are used to constantly monitor the temperature and voltage on the chip. Sensors are placed across the die to gauge the temperature of the whole chip. The Tsensor module:

- Generates an interrupt to SW to lower temperature via DVFS, on reaching a certain thermal/voltage threshold
- Generates a signal to the CAR to reduce CPU frequency by half, on reaching a certain thermal/voltage threshold
- Generates a signal to the PMC when the temperature reaches dangerously high levels to reset the chip and sets a flag in the PMC

38.1 TSensor Registers

38.1.1 TSENSOR_COMMON_STATUS_0

Offset: 0x000 | Read/Write: R/W | Reset: 0b0

Bit	Reset	Description
0	DISABLE	WR_PROTECT_EN: When enabled no longer can values for N, TH2. TH3, SENSOR_STOP HW_FREQ_DIV_EN, THERMAL_RST_EN, TS_ADJ be changed. This bit should be written only when SW is sure of the above stated values 0 = DISABLE 1 = ENABLE

38.1.2 TSENSOR_SENSOR0_CONFIG0_0

Offset: 0x040 | Read/Write: R/W | Reset: 0b00000000000000000000000000000001

Bit	Reset	Description
31:24	0x0	N: Number of reference clock counts for which the counter runs
23:8	0x0	M: Number of reference clock pulses after which every temperature/voltage measurement is made.
7	TS_OSC_OUT	DEBUG_SEL: selects between TS and VS output to the debug bus 0 = TS_OSC_OUT 1 = VS_OSC_OUT
6	DISABLE	INTR_THERMAL_RST_EN: Enable interrupt when transitioning to level3 (.i.e thermal reset) 0 = DISABLE 1 = ENABLE
5	DISABLE	INTR_HW_FREQ_DIV_EN: Enable interrupt when transitioning to level2 (.i.e. clk slowdown) 0 = DISABLE 1 = ENABLE
4	DISABLE	INTR_OVERFLOW_EN: Enable interrupt if there is an overflow detected 0 = DISABLE 1 = ENABLE
3	DISABLE	DVFS_EN: Enable interrupts for SW based interrupts for level1 breach. 0 = DISABLE 1 = ENABLE
2	DISABLE	THERMAL_RST_EN: Enable HW based thermal reset 0 = DISABLE 1 = ENABLE
1	DISABLE	HW_FREQ_DIV_EN: Enable HW based frequency reduction 0 = DISABLE 1 = ENABLE

Bit	Reset	Description
0	ENABLE	SENSOR_STOP: Disables the sensor from taking any reading. Set this bit to 1 to stop the sensor from taking measurements, set to 0 to start taking measurements 0 = DISABLE 1 = ENABLE

38.1.3 TSENSOR_SENSOR0_CONFIG0_VS_0

Offset: 0x044 | Read/Write: R/W | Reset: 0b00

Bit	Reset	Description
3	DISABLE	INTR_OVERFLOW_EN: Enable interrupt if there is an overflow detected 0 = DISABLE 1 = ENABLE
2	DISABLE	DVFS_EN: Enable interrupts for SW based interrupts for level1 breach. 0 = DISABLE 1 = ENABLE

38.1.4 TSENSOR_SENSOR0_CONFIG1_0

TEMPERATURE_REF Configuration Register

Offset: 0x048 | Read/Write: R/W | Reset: 0b0000000000000000xxxxxxxxxxxxxxxx

Bit	Reset	Description
31:16	0x0	TH2: Counter reference value for temperature threshold 2. Note this value can be written as long as till the Wr_En_ bit is active.
15:0	X	TH1: Counter reference value for temperature threshold 1.

38.1.5 TSENSOR_SENSOR0_CONFIG2_0

Offset: 0x04c | Read/Write: R/W | Reset: 0b0000000000000000xxxxxxxxxxxxxxxx

Bit	Reset	Description
31:16	0x0	TH0: Difference between TH1 and a safe level when we can restore the normal operation of the chip.
15:0	X	TH3: Counter reference value for temperature threshold 3. Note this value can be written as long as till the Wr_En_ bit is active.

38.1.6 TSENSOR_SENSOR0_CONFIG1_VS_0

VOLTAGE_REF Configuration Register

Offset: 0x050 | Read/Write: R/W | Reset: 0b0000000000000000xxxxxxxxxxxxxxxx

Bit	Reset	Description
31:16	0x0	TH2: Counter reference value for voltage threshold 2. Note this value can be written as long as till the Wr_En_ bit is active.
15:0	X	TH1: Counter reference value for voltage threshold 1.

38.1.7 TSENSOR_SENSOR0_CONFIG3_0

Offset: 0x054 | Read/Write: R/W | Reset: 0b00000000

Bit	Reset	Description
7:0	0x0	TS_ADJ: Reserved bit

38.1.8 TSENSOR_SENSOR0_STATUS0_0

Offset: 0x058 | Read/Write: R/W | Reset: 0bxxxxxxxxxxxxxxx0xxxxxxxx

Bit	R/W	Reset	Description
22:20	RO	X	VS_PREV_STATE: previous STATE for voltage sensor 0 = INVALID 1 = LEVEL0 2 = LEVEL1 3 = LEVEL2 4 = OVERFLOW
18:16	RO	X	VS_STATE: CURRENT STATE for voltage sensor 0 = INVALID 1 = LEVEL0 2 = LEVEL1 3 = LEVEL2 4 = OVERFLOW
10	RO	X	AVG_MIN_MAX_VALID: Valid signal for avg_count, min_count, max_count. Look at status1 and status2 registers for avg, min, max values. 0 = INVALID 1 = VALID
9	RO	X	CURRENT_VALID: Valid signal for the CURRENT_COUNT value. 0 = INVALID 1 = VALID
8	RW	CLEAR	INTR: Status of Interrupt bit. A write to this bit will clear the interrupt. This interrupt is raised when transitioning from one level to the next. 0 = CLEAR 1 = SET
6:4	RO	X	PREV_STATE: Previous STATE 0 = INVALID 1 = LEVEL0 2 = LEVEL1 3 = LEVEL2 4 = LEVEL3 5 = OVERFLOW
2:0	RO	X	STATE: CURRENT STATE for thermal sensor 0 = INVALID 1 = LEVEL0 2 = LEVEL1 3 = LEVEL2 4 = LEVEL3 5 = OVERFLOW

38.1.9 TSENSOR_SENSOR0_TS_STATUS1_0

Offset: 0x05c | Read/Write: RO | Reset: 0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx

Bit	Reset	Description
31:16	X	CURRENT_COUNT: Current value of the counter for the sensor (note 0xFFFF will signify overflow). Look at CURRENT_VALID to check if this value is valid.
15:0	X	AVG_COUNT: Average counter for the past 8 values of the sensor. Look at AVG_MIN_MAX_VALID to see if this value is valid.

38.1.10 TSENSOR_SENSOR0_TS_STATUS2_0

Offset: 0x060 | Read/Write: RO | Reset: 0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx

Bit	Reset	Description
31:16	X	MAX_COUNT: Maximum counter value, based on the last 8 values. Look at AVG_MIN_MAX_VALID bit to see if this value is valid.
15:0	X	MIN_COUNT: Minimum counter value, based on the last 8 values. Look at AVG_MIN_MAX_VALID bit to see if this value is valid.

38.1.11 TSENSOR_SENSOR0_VS_STATUS1_0

Offset: 0x064 | Read/Write: RO | Reset: 0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx

Bit	Reset	Description
31:16	X	CURRENT_COUNT: Current value of the counter for voltage sensor (note 0xFFFF will signify overflow). Look at CURRENT_VALID to check if this value is valid.
15:0	X	AVG_COUNT: Average counter for the past 8 values. Look at AVG_MIN_MAX_VALID to see if this value is valid.

38.1.12 TSENSOR_SENSOR0_VS_STATUS2_0

Offset: 0x068 | Read/Write: RO | Reset: 0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx

Bit	Reset	Description
31:16	X	MAX_COUNT: Maximum counter value, based on the last 8 values. Look at AVG_MIN_MAX_VALID bit to see if this value is valid.
15:0	X	MIN_COUNT: Minimum counter value, based on the last 8 values. Look at AVG_MIN_MAX_VALID bit to see if this value is valid.

38.1.13 TSENSOR_SENSOR1_CONFIG0_0

Offset: 0x080 | Read/Write: R/W | Reset: 0b00000000000000000000000000000001

Bit	Reset	Description
31:24	0x0	N: Number of ref clk counts for which the counter runs
23:8	0x0	M: Number of reference clock pulses after which every temperature/voltage measurement is made.
7	TS_OSC_OUT	DEBUG_SEL: selects between TS and VS output to the debug bus 0 = TS_OSC_OUT 1 = VS_OSC_OUT
6	DISABLE	INTR_THERMAL_RST_EN: Enable interrupt when transitioning to level3 (.i.e thermal reset) 0 = DISABLE 1 = ENABLE
5	DISABLE	INTR_HW_FREQ_DIV_EN: Enable interrupt when transitioning to level2 (.i.e. clk slowdown) 0 = DISABLE 1 = ENABLE
4	DISABLE	INTR_OVERFLOW_EN: Enable interrupt if there is an overflow detected 0 = DISABLE 1 = ENABLE
3	DISABLE	DVFS_EN: Enable interrupts for SW based interrupts for level1 breach. 0 = DISABLE 1 = ENABLE

Bit	Reset	Description
2	DISABLE	THERMAL_RST_EN: Enable HW based thermal reset 0 = DISABLE 1 = ENABLE
1	DISABLE	HW_FREQ_DIV_EN: Enable HW based frequency reduction 0 = DISABLE 1 = ENABLE
0	ENABLE	SENSOR_STOP: Disables the sensor from taking any reading. Set this bit to 1 to stop the sensor from taking measurements, set to 0 to start taking measurements 0 = DISABLE 1 = ENABLE

38.1.14 TSENSOR_SENSOR1_CONFIG0_VS_0

Offset: 0x084 | Read/Write: R/W | Reset: 0b00

Bit	Reset	Description
3	DISABLE	INTR_OVERFLOW_EN: Enable interrupt if there is an overflow detected 0 = DISABLE 1 = ENABLE
2	DISABLE	DVFS_EN: Enable interrupts for SW based interrupts for level1 breach. 0 = DISABLE 1 = ENABLE

38.1.15 TSENSOR_SENSOR1_CONFIG1_0

TEMPERATURE_REF Configuration Register

Offset: 0x088 | Read/Write: R/W | Reset: 0b0000000000000000xxxxxxxxxxxxxxxx

Bit	Reset	Description
31:16	0x0	TH2: Counter reference value for temperature threshold 2. Note this value can be written as long as till the Wr_En_ bit is active.
15:0	X	TH1: Counter reference value for temperature threshold 1.

38.1.16 TSENSOR_SENSOR1_CONFIG2_0

Offset: 0x08c | Read/Write: R/W | Reset: 0b0000000000000000xxxxxxxxxxxxxxxx

Bit	Reset	Description
31:16	0x0	TH0: Difference between TH1 and a safe level when we can restore the normal operation of the chip.
15:0	X	TH3: Counter reference value for temperature threshold 3. Note this value can be written as long as till the Wr_En_ bit is active.

38.1.17 TSENSOR_SENSOR1_CONFIG1_VS_0

VOLTAGE_REF Configuration Register

Offset: 0x090 | Read/Write: R/W | Reset: 0b0000000000000000xxxxxxxxxxxxxxxx

Bit	Reset	Description
31:16	0x0	TH2: Counter reference value for voltage threshold 2. Note this value can be written as long as till the Wr_En_ bit is active.
15:0	X	TH1: Counter reference value for voltage threshold 1.

38.1.18 TSENSOR_SENSOR1_CONFIG3_0

Offset: 0x094 | Read/Write: R/W | Reset: 0b00000000

Bit	Reset	Description
7:0	0x0	TS_ADJ: Reserved bit

38.1.19 TSENSOR_SENSOR1_STATUS0_0

Offset: 0x098 | Read/Write: R/W | Reset: 0bxxxxxxxxxxxxxxx0xxxxxxxx

Bit	R/W	Reset	Description
22:20	RO	X	VS_PREV_STATE: previous STATE for voltage sensor 0 = INVALID 1 = LEVEL0 2 = LEVEL1 3 = LEVEL2 4 = OVERFLOW
18:16	RO	X	VS_STATE: CURRENT STATE for voltage sensor 0 = INVALID 1 = LEVEL0 2 = LEVEL1 3 = LEVEL2 4 = OVERFLOW
10	RO	X	AVG_MIN_MAX_VALID: Valid signal for avg_count, min_count, max_count. Look at status1 and status2 registers for avg, min, max values. 0 = INVALID 1 = VALID
9	RO	X	CURRENT_VALID: Valid signal for the CURRENT_COUNT value. 0 = INVALID 1 = VALID
8	RW	CLEAR	INTR: Status of Interrupt bit. A write to this bit will clear the interrupt. This interrupt is raised when transitioning from one level to the next. 0 = CLEAR 1 = SET
6:4	RO	X	PREV_STATE: Previous STATE 0 = INVALID 1 = LEVEL0 2 = LEVEL1 3 = LEVEL2 4 = LEVEL3 5 = OVERFLOW
2:0	RO	X	STATE: CURRENT STATE for thermal sensor 0 = INVALID 1 = LEVEL0 2 = LEVEL1 3 = LEVEL2 4 = LEVEL3 5 = OVERFLOW

38.1.20 TSENSOR_SENSOR1_TS_STATUS1_0

Offset: 0x09c | Read/Write: RO | Reset: 0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx

Bit	Reset	Description
31:16	X	CURRENT_COUNT: Current value of the counter for sensor (note 0xFFFF will signify overflow). Look at CURRENT_VALID to check if this value is valid.
15:0	X	AVG_COUNT: Average counter for the past 8 values of the sensor. Look at AVG_MIN_MAX_VALID to see if this value is valid.

38.1.21 TSENSOR_SENSOR1_TS_STATUS2_0

Offset: 0x0a0 | Read/Write: RO | Reset: 0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx

Bit	Reset	Description
31:16	X	MAX_COUNT: Maximum counter value, based on the last 8 values. Look at AVG_MIN_MAX_VALID bit to see if this value is valid.
15:0	X	MIN_COUNT: Minimum counter value, based on the last 8 values. Look at AVG_MIN_MAX_VALID bit to see if this value is valid.

38.1.22 TSENSOR_SENSOR1_VS_STATUS1_0

Offset: 0x0a4 | Read/Write: RO | Reset: 0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx

Bit	Reset	Description
31:16	X	CURRENT_COUNT: Current value of the counter for voltage sensor (note 0xFFFF will signify overflow). Look at CURRENT_VALID to check if this value is valid.
15:0	X	AVG_COUNT: Average counter for the past 8 values. Look at AVG_MIN_MAX_VALID to see if this value is valid.

38.1.23 TSENSOR_SENSOR1_VS_STATUS2_0

Offset: 0x0a8 | Read/Write: RO | Reset: 0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx

Bit	Reset	Description
31:16	X	MAX_COUNT: Maximum counter value, based on the last 8 values. Look at AVG_MIN_MAX_VALID bit to see if this value is valid.
15:0	X	MIN_COUNT: Minimum counter value, based on the last 8 values. Look at AVG_MIN_MAX_VALID bit to see if this value is valid.

Notice

The information provided in this specification is believed to be accurate and reliable as of the date provided. However, NVIDIA Corporation (“NVIDIA”) does not give any representations or warranties, expressed or implied, as to the accuracy or completeness of such information. NVIDIA shall have no liability for the consequences or use of such information or for any infringement of patents or other rights of third parties that may result from its use. This publication supersedes and replaces all other specifications for the product that may have been previously supplied.

NVIDIA reserves the right to make corrections, modifications, enhancements, improvements, and other changes to this specification, at any time and/or to discontinue any product or service without notice. Customer should obtain the latest relevant specification before placing orders and should verify that such information is current and complete.

NVIDIA products are sold subject to the NVIDIA standard terms and conditions of sale supplied at the time of order acknowledgement, unless otherwise agreed in an individual sales agreement signed by authorized representatives of NVIDIA and customer. NVIDIA hereby expressly objects to applying any customer general terms and conditions with regard to the purchase of the NVIDIA product referenced in this specification.

NVIDIA products are not designed, authorized or warranted to be suitable for use in medical, military, aircraft, space or life support equipment, nor in applications where failure or malfunction of the NVIDIA product can reasonably be expected to result in personal injury, death or property or environmental damage. NVIDIA accepts no liability for inclusion and/or use of NVIDIA products in such equipment or applications and therefore such inclusion and/or use is at customer’s own risk.

NVIDIA makes no representation or warranty that products based on these specifications will be suitable for any specified use without further testing or modification. Testing of all parameters of each product is not necessarily performed by NVIDIA. It is customer’s sole responsibility to ensure the product is suitable and fit for the application planned by customer and to do the necessary testing for the application in order to avoid a default of the application or the product. Weaknesses in customer’s product designs may affect the quality and reliability of the NVIDIA product and may result in additional or different conditions and/or requirements beyond those contained in this specification. NVIDIA does not accept any liability related to any default, damage, costs or problem which may be based on or attributable to: (i) the use of the NVIDIA product in any manner that is contrary to this specification, or (ii) customer product designs.

No license, either express or implied, is granted under any NVIDIA patent right, copyright, or other NVIDIA intellectual property right under this specification. Information published by NVIDIA regarding third-party products or services does not constitute a license from NVIDIA to use such products or services or a warranty or endorsement thereof. Use of such information may require a license from a third party under the patents or other intellectual property rights of the third party, or a license from NVIDIA under the patents or other intellectual property rights of NVIDIA. Reproduction of information in this specification is permissible only if reproduction is approved by NVIDIA in writing, is reproduced without alteration, and is accompanied by all associated conditions, limitations, and notices.

ALL NVIDIA DESIGN SPECIFICATIONS, REFERENCE BOARDS, FILES, DRAWINGS, DIAGNOSTICS, LISTS, AND OTHER DOCUMENTS (TOGETHER AND SEPARATELY, “MATERIALS”) ARE BEING PROVIDED “AS IS.” NVIDIA MAKES NO WARRANTIES, EXPRESSED, IMPLIED, STATUTORY, OR OTHERWISE WITH RESPECT TO THE MATERIALS, AND EXPRESSLY DISCLAIMS ALL IMPLIED WARRANTIES OF NONINFRINGEMENT, MERCHANTABILITY, AND FITNESS FOR A PARTICULAR PURPOSE. Notwithstanding any damages that customer might incur for any reason whatsoever, NVIDIA’s aggregate and cumulative liability towards customer for the products described herein shall be limited in accordance with the NVIDIA terms and conditions of sale for the product.
