TECHNICAL REFERENCE MANUAL

NVIDIA TEGRA 3
HD Mobile Processors

NVIDIA® Tegra® 3 HD Mobile Processors: T30 Series, AP30 Series

Abstract

The Technical Reference Manual focuses on the logical organization and control of NVIDIA® Tegra® 3 devices. It provides information for those modules that interface to external devices, or those that control fundamental chip operations. The modules detailed in this document provide an overview, any necessary programming guidelines, and a register listing for that module. Internal functional units such as video and graphics hardware acceleration are controlled by NVIDIA provided software and not documented here.

Revision History

Version	Date	Description
v01p	JAN 27, 2012	Public Release to support Open Source Development. The following sections are undergoing further review and should be considered preliminary: • CLOCK AND RESET CONTROLLER • MULTI-PURPOSE I/O PINS AND PIN MULTIPLEXING (PINMUXING) • POWER MANAGEMENT CONTROLLER
v02p	MAR 18, 2013	The following changes were made in this revision: • Added VI, GR2D, and EPP sections • Clock and Reset Controller: Removed references to unsupported clocking functions. • CPU: Changed timer divider rate to divide by 2. • Display Controller: Changed A_ADDR_V_OFFSET field definition and MAX value in DC_WIN_A_DDA_INCREMENT_0 calculations. Removed references to unsupported display modes. FIFO depth increased to 128 in “Interface to Memory”. • GMI Controller: In Programming Guidelines, added bullet about DMA completion in interrupt polling mode. • SPI Controller: Revised the APB DMA requester numbers for the SPI controllers. Updated clock frequencies in “Clock Initialization and Control”. • UART and VFIR Controller: Updated “Hardware Signaling”.
v03p	SEP 12, 2013	The following changes were made in this revision: • Added FLOW CONTROLLER section

Table of Contents

1.0 INTRODUCTION

NVIDIA® Tegra® 3 processors are complete applications and digital media systems built around these processing elements:

- CPU Complex: Quad Cortex®-A9 Symmetric Multi-Processing ARM® Cores with vSMP. The Cortex-A9 core features dual instruction issue and both out-of-order and speculative execution. It has full cache coherency support for the quad symmetric processors. All processors have 32 KB Instruction and 32 KB Data Level 1 caches; and there is a 1 MB shared Level 2 cache. The NVIDIA vSMP architecture adds a fifth Companion Core which operates exclusively with the main CPU complex, and allows low-power low-leakage operation at lighter CPU loads.
- Audio/Video Decoder: the AVP (Audio-Video Processor) subsystem includes dedicated audio and video decode hardware acceleration, an ARM7 processor, and embedded RAM. This subsystem provides full motion playback of up to 1080P high-definition video and supports the H.264, VC-1, and MPEG-4 video standards and multiple audio standards with dedicated hardware.
- Video Encoder: A high performance H.264 1080P capable hardware video encoder. This processor supports H.264 Baseline Profile Encoding and MPEG4 Simple Profile Encoding.
- Graphics: Ultra Low-power NVIDIA GeForce® Graphics Processing Unit (GPU). Handles 2D graphics rendering and 3D pixel and vertex shading. Dual pixel rendering pipes.
- Imaging: A high quality hardware accelerated still-image and video capture path supporting Bayer and YUV format sensors.
- Display: Dual display controllers with various output options for LCD panels and televisions, including HDMI output up to 1080p.

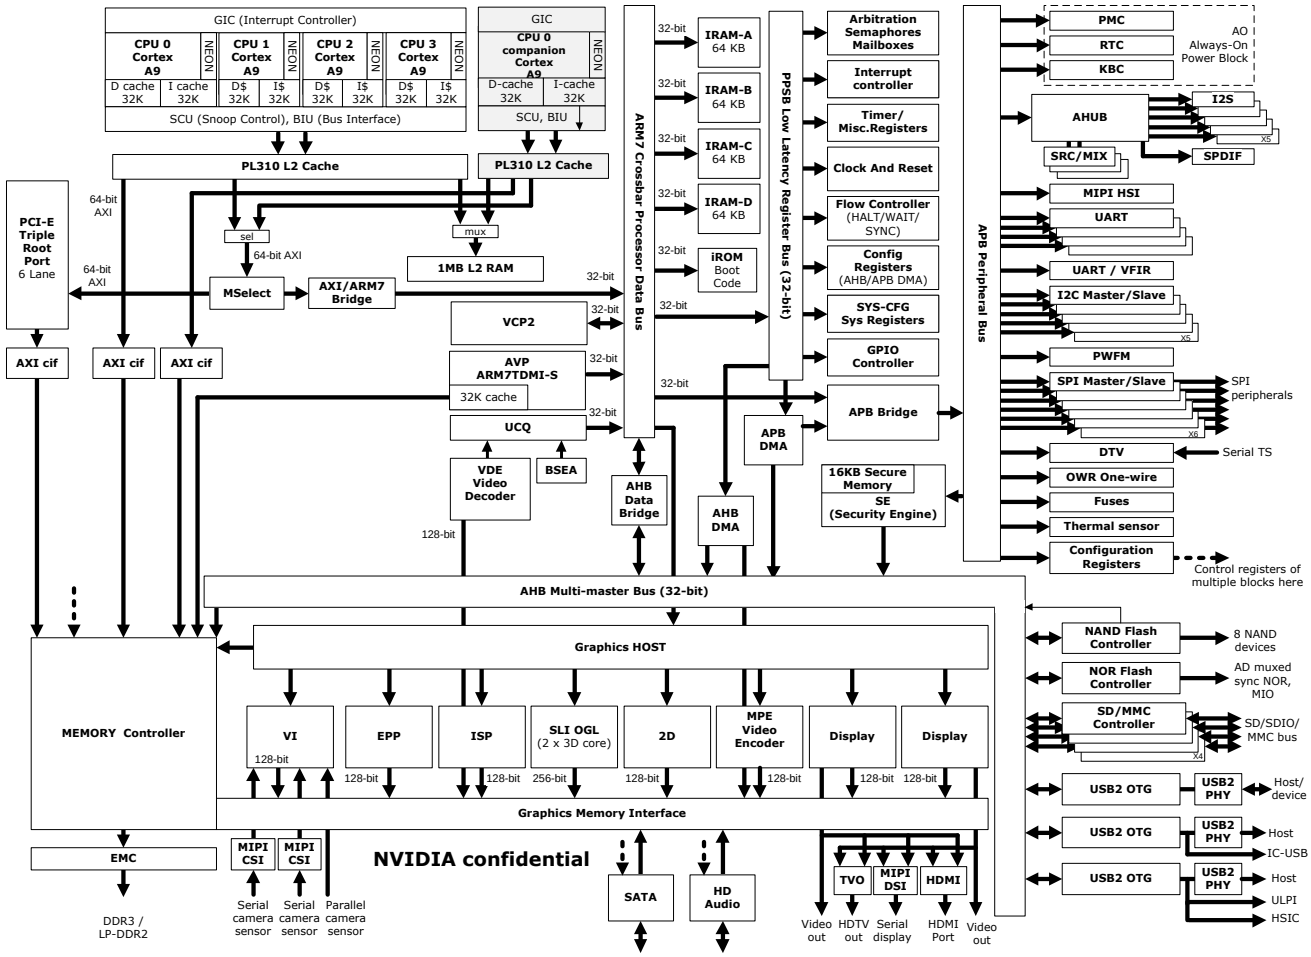
In addition to its processing elements, Tegra 3 has a broad range of peripheral interfaces to enable communication with wireless baseband, other communications peripherals, audio codecs, power management, and mass storage. When combined with baseband and PMU chips, the Tegra 3 processor provides the functionality needed to build a smart-phone or tablet. Dedicated high-performance mass storage controllers, with their own DMA engines, free the CPU Complex from routine data management tasks.

Intended as the heart of a low-powered portable multimedia device, the Tegra 3 device integrates a quad-core ARM Cortex-A9 MPCore™ processor to run the operating system, user interface, and required software applications. The video and audio acceleration hardware provide a highly optimized low-power system for 2D and 3D graphics rendering, audio and video recording and playback, video conferencing, high-quality image capture and display.

1.1 Block Diagram

This diagram provides an overview of a Tegra 3 processor.

Figure 1. Tegra 3 Block Diagram



1.2 Memory Controller and Internal Bus Architecture

The Tegra 3 device has a highly optimized memory controller, supporting low latency access for the CPU, optimized high bandwidth access for the graphics and video devices, and controlled latency for real time devices such as display.

There is a three-level hierarchy of memory clients:

1. Memory controller clients: The memory controller directly arbitrates between these using a complex algorithm optimizing DRAM efficiency. The highest bandwidth clients all fall into this class, and they communicate directly with the memory controller using a proprietary high-speed bus.
2. AHB devices: These generally have a built-in DMA engine, and share a single memory client using the AHB bus protocol.
3. APB devices: All APB devices are slaves, and are services by a shared multi-channel APB DMA controller which is also an APB device.

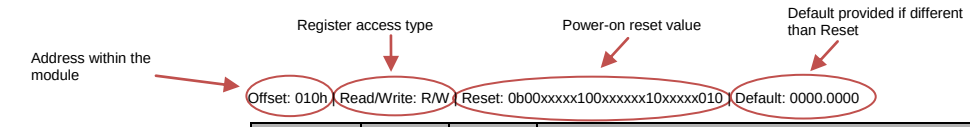
Special provision is made for the CPU to bypass much of the memory controller arbitration with low latency.

1.3 Reading Register Tables

Every register table has an address line followed by a table containing the bit descriptions for that register. The address line contains:

- **Offset:** is the address of the register within the specific module. Refer the system memory map for the start address of the module, apply the offset at the top of the table to get the register address
- **Read/Write:** the register access type. When a register table contains the R/W column, individual bits within the register will have different R/W properties. When there is no R/W column, all bits in that register have the same R/W property.
- **Reset:** gives the power-on reset value
- **Default:** will only be displayed if the default setting is different from the Reset value.

Unspecified bits may not appear in tables (see example below). Writes to unspecified bits are ignored, while reads return an unknown value.



Unspecified bits in this example register: 32:26, 23:19, 15:10, 7:3

Unspecified bits are shown as 'x' in the Reset field above the table.

Leading bits that are unspecified may not be displayed in the Reset value. In this example register, the leading bits (32:26) are unspecified and not shown in the Reset field. For example

Reset:
0bxxxxxxx00xxxxx100xxxxxx10xxxxx010
vs.
0b00xxxxx100xxxxxx10xxxxx010

Bit	R/W	Reset	Description
25:24	RW	N1	EMEM_NUMDEV 0 = N1 1 = N2
18:16	RO	D64MB	EMEM_DEVSIZE 0 = D4 MB 1 = D8 MB 2 = D16 MB 3 = D32 MB 4 = D64 MB 5 = D128 MB 6 = D256 MB 7 = D512 MB
9:8	RW	W2	EMEM_BANKWIDTH 1 = W1 2 = W2 3 = W3
2:0	RO	W9	EMEM_COLWIDTH 0 = W7 1 = W8 2 = W9 3 = W10 4 = W11

1.4 Glossary

Term	Definition
AHB	AMBA High-Speed Bus, a multi-master high-speed (relative to APB) bus supporting arbitration and split transactions, defined as part of AMBA 2.
AMBA™	Advanced Microcontroller Bus Architecture, a set of standard buses defined by ARM®.
APB	AMBA Peripheral Bus, a simple 32-bit single master bus for peripheral devices.
AVP	Audio-Video Processor, the term used both to describe the ARM7 processor in Tegra 3 devices, and to describe the broader audio and video decode acceleration hardware and RAM associated with the ARM7. Note that the AVP is sometimes known as COP in legacy documentation and registers.
AXI	AMBA Advanced eXtensible Interface, a more advanced bus than AHB defined as part of AMBA 3.
BSEA	Bit Stream Engine for Audio applications
CAR	Clock and Reset module allows controlling clocks and resets to all the modules and subsystems in Tegra 3.
COP	CO-Processor, an obsolete name for the AVP still present in legacy documentation and registers.
CSI	MIPI Camera Serial Interface, a standard high-speed serial interface for connecting cameras to Tegra 3.
CVE	Zoran TV Encoder
DSI	MIPI Display Serial Interface, a standard high-speed serial interface for connecting displays to Tegra 3.
DVC	Dynamic Voltage Controller module
EMC	External Memory Controller, a module that interfaces with external DDR/LPDDR devices.
EPP	The video Encoder Pre-Processor, on Tegra 3 capable of filtering, color-space conversion, rotation and pixel format conversion.
HDMI	High-Definition Multimedia Interface, a digital connection carrying uncompressed video and audio at high speed over a single connector.
HSI	MIPI High-Speed Synchronous Interface, a standard high-speed serial interface for bi-directional communications with baseband processors and other devices.
IDE	Integrated Drive Electronics (or Integrated Device Electronics)
ISP	Image Signal Processor
KBC	Keyboard Controller module allows Tegra 3 to be connected to keyboard matrices of sizes up to 16x8.
MC	Memory Controller module handles requests from internal clients and arbitrates among them to allocate memory bandwidth.
MIPI	The Mobile Industry Processor Interface and industry alliance promoting a number of standard interfaces for mobile devices.
MPE	Video Encoder in Tegra 3 capable of encoding raw video stream into MPEG
NAND	A type of flash memory supporting high densities, and commonly used for non-volatile mass storage in portable devices. Accessed in sequential blocks to be generally treated as a file system.
NOR	A type of flash memory, with a direct bus interface that allows random access so code can be executed in place. Generally more costly and less dense than NAND flash memory.
OGL	Open Graphics Library, also known as OpenGL. An API supported on Tegra 3 devices and accelerated in hardware by dedicated 3D and 2D engines.
PMC	Power Management Controller module controls the various power management features in the system.
PWFM	Pulse Width Frequency Modulation module generates programmed pulse widths typically used to control backlight in display panels.
PVT	Process, Voltage & Temperature

Term	Definition
SMP	Symmetric Multi-Processing
SOC	System On a Chip, an integrated circuit containing a CPU, memory controller and the peripheral devices needed for a computing system.
S/PDIF	Sony/Philips Digital Interconnect Format
TWC	Three-Wire Controller
TVO	TV Encoder Output
UCQ	Unified Command Queue – a sub module within Video Decoder Engine
VCP2	Vector Co-Processor version 2, a hardware acceleration block for the signal processing parts of audio decode and filtering. Use to offload the ARM7 AVP during audio playback.
VDE	Video Decode Engine, the Tegra 3 hardware acceleration block dedicated to decoding compressed video in various formats.
VI	Video Input block, the acronym used to describe the Tegra 3 block used for camera and related input functions.

2.2 Interrupt Mapping

The next five tables show the mapping of the interrupts from system devices to the bit fields in the interrupt controllers.

Interrupts to the Cortex-A9 embedded interrupt controller (GIC) are in this same order, but start at offset 32 as the first 32 are reserved for the CPU's internal interrupts. See the Interrupt Controller section of this document for more information on how interrupts are routed.

3.0 INTERRUPT CONTROLLER

The section describes the “legacy” interrupt controller, which is used for the AVP and is a backup option for the ARM® Cortex®-A9 CPU. The CPU’s local interrupt controller, the GIC, should be used in preference to the legacy interrupt controller because of its SMP support, and fast register access due to being local to the CPU.

The Tegra® 3 device has five sets of interrupt controllers, each handling 32 possible interrupt sources. A flexible interrupt controller allows priority scheduling and Interrupt Request steering. This allows any interrupt request to be re-routed to either processor to allow dynamic redistribution of workload, resulting in increased efficiency.

The interrupt controllers act as a centralized distribution center. There are two levels of interrupt priorities, Fast Interrupt Request (FIQ) and Regular Interrupt Request (IRQ). Each flag is evaluated by software to determine whether it gets the FIQ or IRQ. Generally, interrupts which require low latency get the FIQ. IRQ status is given to the remaining interrupts. Interrupt enable can mask or allow requests. The CPU and AVP (COP) can set priorities for valid interrupts. The ARM processor supports two types of hardware interrupts (nIRQ and nFIQ). The nIRQ signal is the normal active-LOW interrupt signal. The nFIQ signal is a fast interrupt signal that is used to manage time critical or short tasks such as USB transfer requests. Any of the interrupt requests can be routed to either the nIRQ or the nFIQ of either processor, based on the select bits set in the interrupt class and interrupt enable registers.

Interrupt enabling and steering is accomplished by programming the Interrupt Enable registers (CPU_IER or COP_IER) and the Interrupt Class registers (CPU_IEP_CLASS or COP_IEP_CLASS). The following text discusses routing as it relates to the CPU, but this discussion also applies to the AVP (COP).

When a 1 is set in the proper bit position in the CPU_IER register, that particular source is capable of interrupting the processor. The interrupt status register (ISR) allows the processor to view the state of the pending interrupt requests, whether enabled or disabled. The forced interrupt status register (FIR) allows the software to selectively force the execution of a specific interrupt service routine. The read-only VFIQ allows each processor to determine the actual source of the interrupt request(s) causing the processor to enter the interrupt service routine.

Tegra 3 devices can also use software DMA to handle DMA requests. The DMA interrupt requests are grouped into read requests and write requests and presented at bits 31 and 30 of the ISR register. Individual requests can be viewed by reading the DSR register. The Arbitration Semaphore module can also generate interrupt requests to the interrupt controller when a processor achieves Arbitration Grant Status. When a 1 is set in the proper bit position of the Arbitration Semaphore Interrupt Source Enable register (GNT0_CPU.ENABLE), that particular request causes an interrupt when the Grant Status becomes true.

3.1 Functionality

The programmable Interrupt Controller supports up to 160 interrupts and is built from five 32-bit interrupt controllers – Primary (PRI), Secondary (SEC), Tertiary (TRI), Quaternary (QUAD), and Quinary (PENTA).

Each interrupt request is treated individually, each with its own Interrupt_Enable bit (IER), Interrupt_Class steering bit (IEP_CLASS), and software forced interrupt bit (FIR). Each processor has its own set of IER and IEP_Class registers, so an interrupt can be steered to either (or both) processor as IRQ or FIQ.

When a 1 is set the proper bit position of the CPU_IER register, that particular interrupt source (ISR) is allowed to interrupt the processor. Whether it is sent to the processor as an IRQ or FIQ depends on the bit setting of the CPU_IEP_CLASS register. A '1' causes the interrupt to be routed to the processor nFIQ pin, a '0' to the nIRQ pin.

All the individual CPU IRQ bits are ORed together to form the final CPU IRQ.

All the individual CPU FIQ bits are ORed together to form the final CPU FIQ.

All the individual AVP (COP) IRQ bits are ORed together to form the final AVP (COP) IRQ.

All the individual AVP (COP) IRQ bits are ORed together to form the final AVP (COP) IRQ.

The individual interrupt bits are also output as a bus to be routed to the Exception Vector logic.

The CPU_IER register bits are SET by writing to the CPU_IER_SET register. Writing a '1' in individual bit positions will only alter those bits. The CPU_IER register bits are cleared by writing to the CPU_IER_CLR register. The same applies to the COP_IER registers. Using the SET/CLR methods avoids problems caused by two processors trying to perform Read-Modify-Write operations on respective bits at the same time. For testing, software can force individual interrupts by setting bits in the FIR register. These bits are ORed with the incoming interrupt to form the final interrupt for each bit position.

The Secondary Interrupt controller also supports Soft DMA. Since the APB_DMA controller has a limited number of DMA channels, it may not always be possible for every module to use hardware DMA. In this case the DMA request can be routed to the interrupt controller and treated like an interrupt. A software based DMA interrupt handler can then service the interrupt. This is especially useful for devices which are not latency sensitive. The Secondary interrupt controller has support for Soft DMA. There are 32 RX DRQ request inputs (DRX_RX_SOURCES), and 32 TX DRQ request inputs (DRX_TX_SOURCES). Masking for each request is programmed via the DRQ_RX_ENABLE and DRQ_TX_ENABLE registers. All the qualified DRQ_RX interrupts are ORed together and presented as Interrupt Request bit 31 input to the Primary interrupt controller. All the qualified DRQ_TX interrupts are ORed together and presented as Interrupt Request bit 30 input to the Primary interrupt controller. The DRQ_RX_STATUS and DRQ_TX_STATUS registers indicates DRQ status after masking.

The Primary Interrupt controller also supports Arbitration Grant interrupts. The Arbitration Semaphore module provides a mechanism for Processors or Processes to arbitrate for hardware or software resources. When a processor is granted access to a resource, the Arbitration Semaphore module can be programmed to send a Grant signal to the Interrupt Controller. The controller can then interrupt the processor to tell it that the Grant occurred. The Primary Interrupt control supports 32 bits of ARM.GNT sources. The ARB_GNT_ENABLE register controls the masking on the request. The ARB_GNT_STATUS register indicates status after masking. The OR of all the individual ARB_GNT bits is presented to the Primary Interrupt controller as IRQ bit 29.

3.1.1 Interrupt Function Mapping

The mapping of interrupts to the bits defined in this interrupt controller is described elsewhere in this document.

3.2 Interrupt Registers

The system has four sets of Interrupt Controllers, for a total of 128 bits. There are two levels of interrupt priority, Fast Interrupt Request (FIQ), and Regular Interrupt Request (IRQ). Any of the interrupt requests can be routed to either the nIRQ or the nFIQ of either processor, based on the select bits set in the interrupt class and interrupt enable registers.

Interrupt enabling and steering is accomplished by programming the Interrupt Enable registers (CPU_IER or COP_IER) and the Interrupt Class registers (CPU_IEP_CLASS or COP_IEP_CLASS). A discussion on routing as it relates to the CPU follows, but this is also applicable to the COP (AVP).

When a 1 is set in the proper bit position in the CPU_IER register, that particular source is capable of interrupting the processor. The interrupt status register (ISR) allows the processor to view the state of the pending interrupt requests, whether enabled or disabled. The forced interrupt status register (FIR) allows the software to selectively force the execution of a specific interrupt service routine.

The read-only VIRQ_CPU and VIRQ_COP registers allow the processor to determine the actual source of the interrupt request(s) causing the processor to enter the nIRQ interrupt service routine. The VIRQ is the logical OR of the FIR and ISR registers, ANDed with the CPU_IER register, and ANDed with the NOT of the CPU_IEP_CLASS register.

The read-only VFIQ allows the processor to determine the actual source of the interrupt request(s) causing the processor to enter the nFIQ interrupt service routine. The VFIQ is the logical OR of the FIR and ISR registers, ANDed with the CPU_IER register, and ANDed with the CPU_IEP_CLASS register.

The CPU_IER and FIR registers also have corresponding set and clear registers, which allow bits to be turned on or off in a single atomic operation.

It is also possible to perform software DMA for many modules, as the DMA requests are also routed to the interrupt controller so they can be satisfied by interrupt handlers.

The DMA requests are grouped into read requests and write requests and presented at bits 31 and 30 of the ISR register (Secondary interrupt controller only). Individual requests can be viewed by reading the DSR register.

The Arbitration Semaphore module can also generate interrupt requests to the interrupt controller when a processor achieves Arbitration Grant Status.

3.2.2 Arbitration Semaphore Interrupt Registers

3.2.2.1 PRI_ICTLR_ARBGNT_CPU_STATUS_0

Arbitration semaphores provide a mechanism by which the two processors can arbitrate for the use of various resources. These semaphores provide a hardware locking mechanism, so that when a processor is already using a resource, the second processor is not granted that resource. There are 32 bits of Arbitration semaphores provided in the system. The hardware does not enforce any resource association to these bits. It is left to the firmware to assign and use these bits.

The Arbitration Semaphores can also generate an interrupt when a hardware resource becomes available. The registers in this module configure these interrupts.

When a 1 is set in the corresponding bit position of the Arbitration Semaphore Interrupt Source Register (CPU_enable or COP_enable), an interrupt will be generated when the processor achieves Grant Status for that resource.

The current Grant status can be viewed in the CPU_STATUS or COP_STATUS registers.

CPU Arbitration Semaphore Interrupt Status Register

Offset: 040h | Read/Write: RO | Reset: 0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx

Bit	Reset	Description
31:0	X	GNT31_GNG0: Each bit is set by hardware when the corresponding arbitration semaphore ownership is granted to CPU. Interrupt is cleared when the CPU writes the ARB_SMP.PUT register with the corresponding bit set.

3.2.2.2 PRI_ICTLR_ARBGNT_CPU_ENABLE_0

CPU Arbitration Semaphore Interrupt Enable Register

Offset: 044h | Read/Write: R/W | Reset: 0b00000000000000000000000000000000

Bit	Reset	Description
31:0	0x0	GER31_GER0: Writing a 1 in any bit position will enable the corresponding arbitration semaphore interrupt.

3.2.2.3 PRI_ICTLR_ARBGNT_COP_STATUS_0

COP Arbitration Semaphore Interrupt Status Register

Offset: 048h | Read/Write: RO | Reset: 0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx

Bit	Reset	Description
31:0	X	GNT31_GNG0: Each bit is set by hardware when the corresponding arbitration semaphore ownership is granted to AVP (COP). Interrupt is cleared when the AVP (COP) writes the ARB_SMP.PUT register with the corresponding bit set.

3.2.2.4 PRI_ICTLR_ARBGNT_COP_ENABLE_0

COP Arbitration Semaphore Interrupt Enable Register

Offset: 04ch | Read/Write: R/W | Reset: 0b00000000000000000000000000000000

Bit	Reset	Description
31:0	0x0	GER31_GER0: Writing a 1 in any bit position will enable the corresponding arbitration semaphore interrupt.

3.2.3 Second Interrupt Controller

Second interrupt controller base registers.

3.2.3.1 SEC_ICTLR_VIRQ_CPU_0

4.0 ARBITRATION SEMAPHORES

4.1 Overview

Arbitration semaphores provide a mechanism by which the two processors can arbitrate for the use of various resources. An alternative mechanism has been added in Tegra® 3 devices called the Atomic block. Please refer to the corresponding section of this document for further details.

These semaphores provide a hardware locking mechanism to ensure that when a processor is already using a resource, the second processor is not granted that resource. There are 32 bits of arbitration semaphores provided in the system. The hardware does not enforce any resource association to these bits and it is left to the user to assign and use these bits.

Any processor that needs to access a particular resource will request for the corresponding bit in the arbitration semaphores by writing a one to that bit in the Arbitration Semaphore Request register (SMP_GET register). Firmware will then check the corresponding bit in the Semaphore Granted Status register (SMP_GNT_ST register). If the requesting processor has been granted the resource, then the status returned will be a one. Alternately, the processor can configure the interrupt controller to generate an interrupt when the resource becomes available.

When the processor has finished using the resource, it releases the resource by writing a one to the corresponding bit in the Arbitration Semaphore Put Request register (SMP_PUT register). Additionally, pending request status is provided through the Arbitration Request Pending Status register (SMP_REQ_ST register).

4.2 Semaphore Registers

4.2.1 ARB_SEMA_SMP_GNT_ST_0

Semaphore Granted Status Register

Offset: 000h | Read/Write: RO | Reset: 0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx

Bit	Reset	Description
31:0	X	ARB_31_ARB_0: A one in any bit indicates that the processor reading this register as granted status for that bit. A zero indicates semaphore not granted.

4.2.2 ARB_SEMA_SMP_GET_0

Request Arbitration Semaphore Register

Offset: 004h | Read/Write: WO | Reset: 0b00000000000000000000000000000000

Bit	Reset	Description
31:0	0x0	GET_31_GET_0: Writing a one in any bit is a request for that semaphore bit by the processor performing the register write.

4.2.3 ARB_SEMA_SMP_PUT_0

Arbitration Semaphore Put Request Register

Offset: 008h | Read/Write: R/W | Reset: 0b00000000000000000000000000000000

Bit	Reset	Description
31:0	0x0	PUT_31_PUT_0: Writing a one in any bit will clear the corresponding semaphore bit by the processor performing the register write.

4.2.4 ARB_SEMA_SMP_REQ_ST_0

Arbitration Request Pending Status (1=PENDING) Register

Offset: 00ch | Read/Write: RO | Reset: 0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx

Bit	Reset	Description
31:0	X	REQ_31_REQ_0: A one in any bit indicates a request pending status. The corresponding bits are set when the request for the individual resource is pending. The read by CPU of this register shows the pending status for CPU and a read of this register by AVP (COP) shows the pending status for AVP.

5.0 ATOMICS

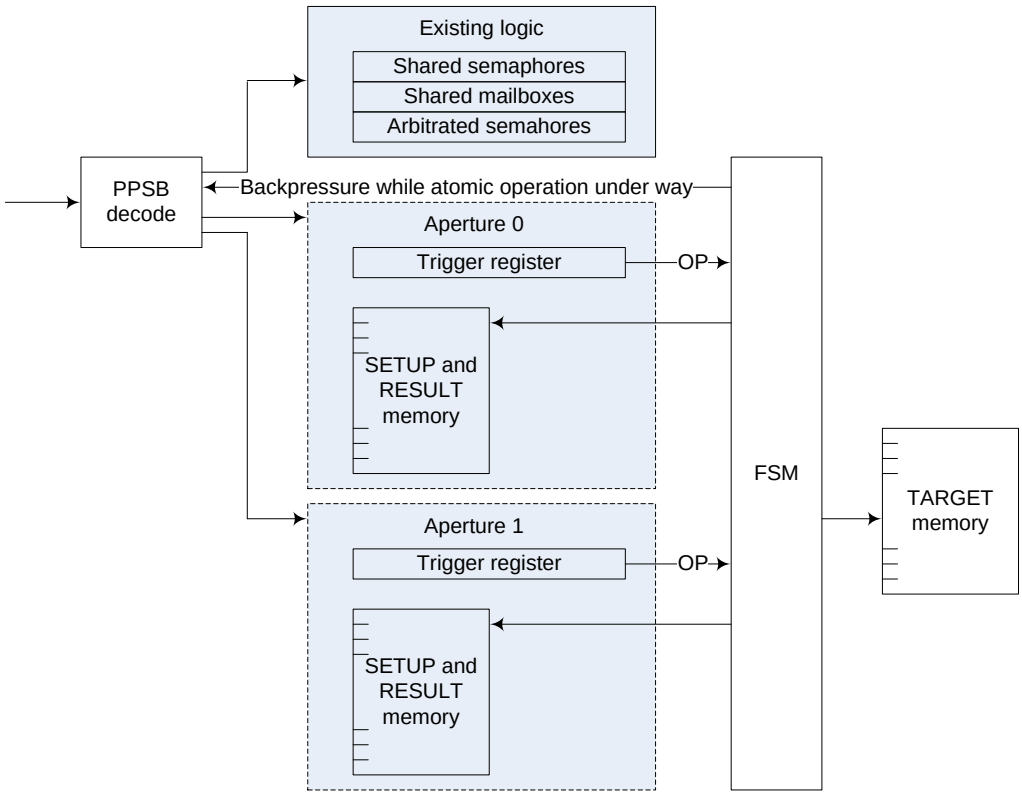
5.1 Introduction

The Atomics block is a new block added to Tegra® 3 to assist software tasks with maintaining synchronization. It is parallel to the existing Semaphores block, and intended to extend that block's functionality with new capabilities.

5.2 Functionality

The figure below shows a reference decomposition of the HW synchronization elements in functional blocks.

Figure 2. Reference Block Diagram



5.3 Synchronization Elements

The synchronization elements are atomic primitives. Their main advantage is to allow some specific algorithms that access shared resources to be performed lock free, for better performance.

In general, the atomic primitives below have results equivalent to atomic RMW operations on a target register. The cycle is made atomic without using locked bus accesses as explained below.

5.3.1 General Principles

Atomic primitives maintain atomicity by splitting the whole operation in three phases:

- A setup phase where parameters are prepared in registers. There are as many sets of setup registers as there are apertures.

- A trigger register that starts a specific operation. The trigger register fits in one 32-bit word to ensure atomic issue of the operation. There is one trigger register per aperture. The trigger register specifies:
  - The primitive operation to be performed.
  - The index of the target register for the primitive operation.
- A result phase where the results of the operation are made available. There are as many sets of result registers as there are sets of setup registers. The operation, once triggered, is executed atomically.

The setup, result and trigger registers are duplicated in separate apertures, one aperture per client of the block. There are two such apertures in Tegra 3, normally one used by CPU, the other by AVP, but this is not enforced by HW as it is for the arbitrated semaphores.

Setup, target and result registers are 32-bits each with no further structure imposed by HW. The trigger register is 32 bits, structured in command and target fields.

The description of the different operations is based on pseudo code that uses the following conventions:

- ATOMIC_OP identifies the exact operation and index ID identifies a given target register. Both ATOMIC_OP and ID are duplicated per aperture
- Index A identifies the aperture from which the operation is executed.
- The setup registers in a set are stored in arrays v and c. The result registers are stored in array old[1]. All of these are duplicated per aperture.
- The target registers are not duplicated per aperture and are stored in an array T.
- The semantic of assignment is like C. All assignments are assumed to take place instantaneously. Intermediate values are used to get the equivalent of clocked operations of the HW. Typically, the HW implementation has no intermediate values if operations are performed in one clock cycle.
- Arithmetic operations are performed as signed 32 bits operations modulo 2^{32} using 2s complement coding.

5.3.2 Atomic Exchange

In an atomic exchange, Its only purpose is to be able to read a value and replace it with another value in an atomic fashion.

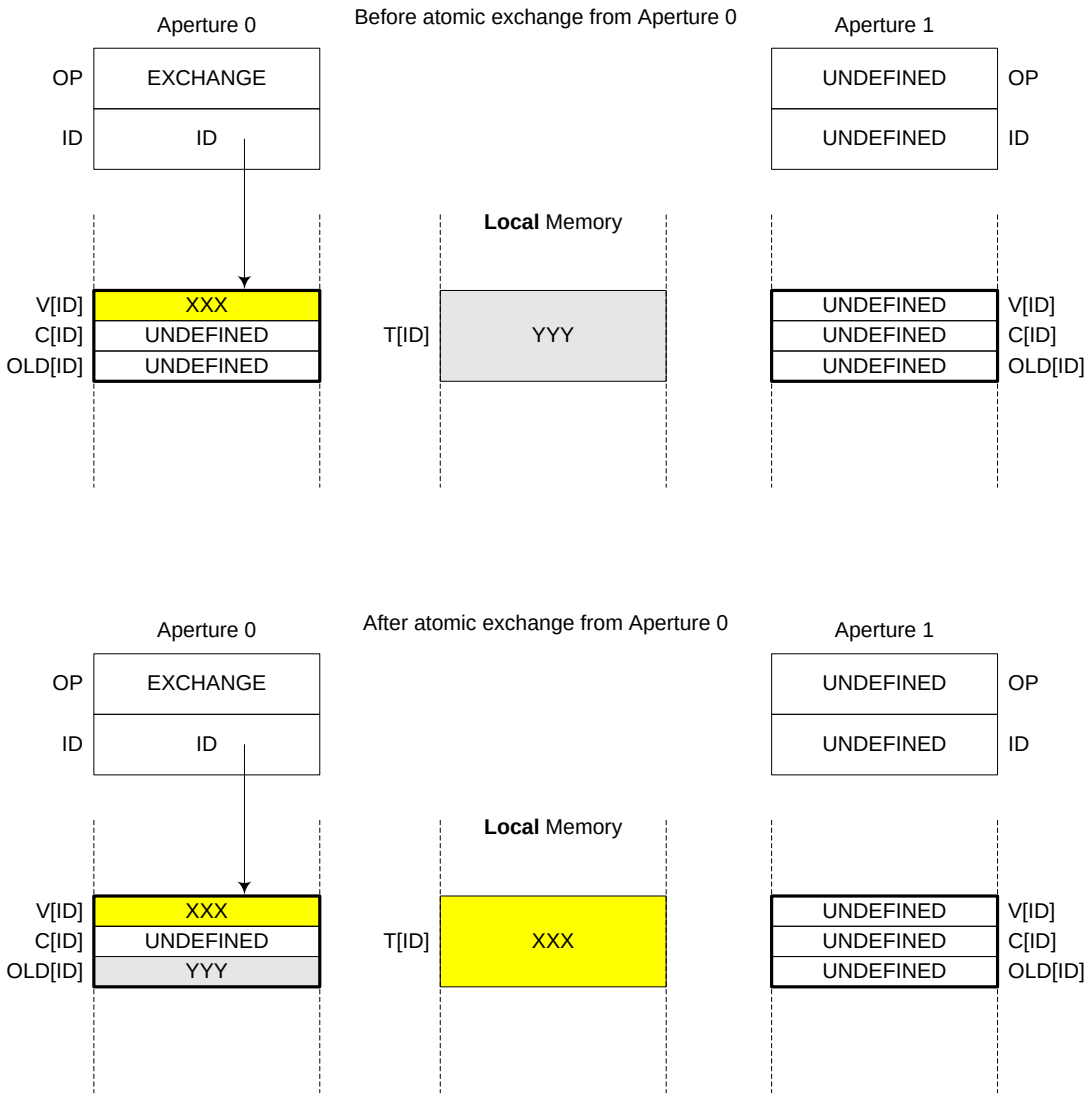
The corresponding pseudo code is

```
if (ATOMIC_OP[A] == EXCHANGE) {
  old[A][ID[A]] = T[ID[A]] ;
  T[ID[A]] = v[A][ID[A]]
```

The figure below illustrates an atomic exchange performed using aperture 0

[1] The result register always contains the old value of the target register, i.e. the value before applying the atomic operation. This is true even for PUT, so that PUT and EXCHANGE are semantically equivalent with the current definition.

Figure 3. Atomic Exchange Operation



5.3.3 Atomic Compare and Exchange

This is a variant of atomic exchange where the exchange only takes place if the old value matches the second setup register.

```
if (ATOMIC_OP[A] == COMPARE_AND_EXCHANGE) && (T[ID[A]] == c[A][ID[A}]) {
  old[A][ID[A]] = T[ID[A]]
  T[ID[A]] = v[A][ID[A]]
}
```

5.3.4 Atomic Increment

The atomic increment simply ensures that different processors can increment a shared value without losing any increment. The operation is labeled INCREMENT, but, for 32 bit operations, incrementing by 2^{32} – k is equivalent to decrementing by k.

```
if (ATOMIC OP[A] == INCREMENT) {
  old[A][ID[A]] = Target[ID[A]]
  T[ID[A]] += v[A][ID[A]]
}
```

The variant DECREMENT_WITH_ZERO_SATURATE is similar, adding a saturation to zero when going down. This may be used to manage shared resources that are present in finite numbers.

```
if (ATOMIC_OP[A] == DECREMENT_WITH_ZERO_SATURATE) {
  old[A][ID[A]] = T[ID[A]]
  T[ID[A]] -= v[A][ID[A]]
  if MSB(T[ID[A]]) == 1b && MSB(r[A][ID[A]]) == 0b { T[ID[A]] = 0 ; }
}
```

5.3.5 Atomic Get and Put

These are trivial for HW if there is only one access port, in which case they act as normal register operations. They are nevertheless defined to allow more complex future implementations where the atomic operation blocks could present multiple HW interfaces to the rest of the system.

```
if (ATOMIC OP[A] == GET) {
  old[A][ID[A]] = T[ID[A]]
}

if (ATOMIC OP[A] == PUT) {
  old[A][ID[A]] = T[ID[A]]
  T[ID[A]] = v[A][ID[A]]
}
```

5.3.6 Atomic Test and Set, Test and Clear, Test and Invert

These are simple extensions of previous cases, where the operation is either a bit set, bit clear or bit invert.

```
if (ATOMIC_OP[A] == TEST_AND_SET) {
  old[A][ID[A]] = T[ID[A]]
  T[ID[A]] |= v[A][ID[A]]
}

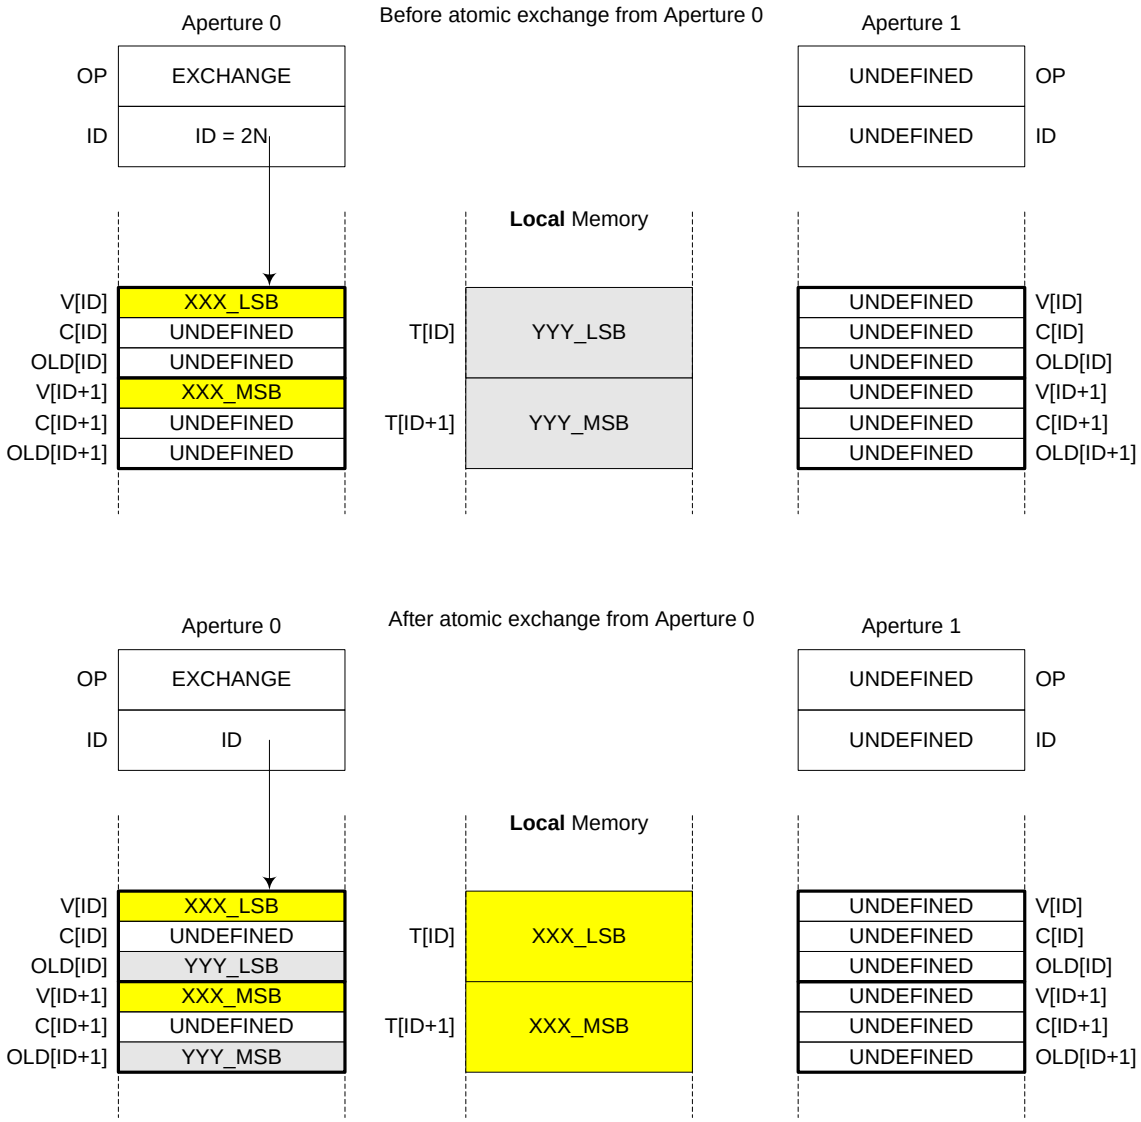
if (ATOMIC_OP[A] == TEST_AND_CLEAR) {
  old[A][ID[A]] = T[ID[A]]
  T[ID[A]] &= ~v[A][ID[A]]
}

if (ATOMIC_OP[A] == TEST_AND_INVERT) {
  old[A][ID[A]] = T[ID[A]]
  T[ID[A]] ^= v[A][ID[A]]
}
```

5.3.7 Width of Operations

All operations can operate on 32 bits or 64 bits. 64 bits operations use an even/odd pair of address, with the MSB at the odd address. The next figure shows how a 64 bits exchange operates. Other operations behave similarly. In the case of atomic increment and decrement operations, the carry will correctly propagate from the LSB to the MSB.

Figure 4. 64 bit atomic exchange operation



5.4 Atomics Registers

5.4.1 ATOMICS_AP0_TRIGGER_0

Trigger Registers

Offset: 000h | Read/Write: R/W | Reset: 0bxxxxxxxxxxxxxxxxxxxxxxxx

6.0 CLOCK AND RESET CONTROLLER

Note: PRELIMINARY pending review

The Clock and Reset (CAR) block comprises CLKGEN and RSTGEN.

CLKGEN provides the registers to program the PLLs and controls most of the clock source programming, and most of the clock dividers. CLKGEN input signals include the external clock for the reference frequency (12 MHz, 26 MHz,) and the external clock for the Real Time Clock (32.768 KHz). The outputs from CLKGEN are mostly clocks to the other blocks in the Tegra® 3 system.

RSTGEN provides the registers needed to control resetting each block in the Tegra 3 system.

6.1 Hardware Features

6.1.1 External Clock Sources

The CLKGEN block takes two external clock sources as input:

- A single external 32.768 KHz clock, normally provided by the Power Management Unit (PMU)
- A single crystal oscillator at either 12 MHz or 26 MHz. 12 MHz should be used when the Tegra 3 device has a dedicated crystal. Support for the 26 MHz rate may be useful for cell phone applications, where it is expected to be provided by the Baseband Processor. Lower frequencies are generally lower power.

6.1.2 PLLs

There are 12 PLLs in the Tegra 3 device's clock system:

- PLLX is dedicated to the CPU complex, and provides a high speed CPU clock when required. It operates up to 1.1 GHz or higher.
- PLLC is a general purpose PLL, whose nominal maximum frequency is 600 MHz. This PLL is available as a clock source to many modules.
- PLLP is a "fixed" 408 MHz source for most of the Peripherals on the Tegra 3 devices. It should always be set to this frequency. It is available as a source to most modules. In addition, PLLP is the source of a number of standard divided-down frequencies that are also available as clock sources to other modules.
- PLLM is the source for the External Memory Controller (EMC) 2x clock. It is dedicated to this function. The nominal maximum frequency required by EMC on the Tegra 3 devices is 800 MHz. PLLM is available as a source to other modules as well.
- PLLA is the source for Audio, and is used to generate exact 11.2896, 12.288 or 24.576 MHz for audio codecs and audio-related devices. When the audio clock is provided by a PLL in the external audio codec, PLLA is available as a general purpose PLL.
- PLLD and PLLD2 are the sources for DSI and for the Display subsystem in general. They provide the frequencies required by DSI and the Display controller when DSI is in use. They can also be used as dedicated Display PLLs to provide the frequencies required by Display, HDMI, TVOUT when a precise enough frequency cannot be provided by one of the other Tegra 3 device PLLs. Wherever possible, the Display subsystem should use a clock source other than PLLD and PLLD2, since these PLLs consumes higher power than the other (non-MIPI) PLLs in the system.
- PLLU is the source for the USB PHY and controllers. It is dedicated to provide the 12 MHz required by the USB PHY, and 60 MHz and 480 MHz USB clocks.

- refPLLe and PLLE work together to generate the required 100 MHz reference clock used for the USB3.0 and is capable of generating a spread-spectrum clock.
- Two additional PLLs are embedded in their respective interface controllers. The USB controller has an internal PLL as does the TMDS HDMI PHY. These PLLs are programmed via their respective controllers' registers, and the clocks generated by these PLLs are neither visible to CLKGEN nor to the rest of the system.

6.1.3 Clock Dividers / Skippers / Multipliers

There are a number of clock skippers, clock dividers, and clock multipliers in use in the Tegra 3 devices.

- An M/N clock-skipping divider that is used to generate the CPU clock and also the Tegra 3 "system clock" (sclk).
- Clock skippers that are used to generate the "AHB clock" (hclk) and "APB clock" (pclk). One that divides down by a 2-bit unsigned value (U2).
- An unsigned 16-bit divider (U16) that is the divider for the I2C and UART devices.
- A times-two multiplier used to double the external reference frequency, and used to double the audio clock.
- An unsigned 8b divider that provides 7b of mantissa and 1b of fraction (U7.1). Tegra 3 devices have reduced the number of divider types and in particular this U7.1 divider is the default divider for most all blocks in Tegra 3 devices.

Note that the clock-skipping divider and the U7.1 divider when programmed with the 1b fraction do not create 50/50 duty cycle clock waveforms and may not be suitable for all modules under all circumstances.

6.1.4 Clock Sources

The clock sources are described as follows:

- PLLM: Clock source for EMC 2x clock
- PLLX: Clock source for the CPU
- PLLC: Clock source for general use
- PLLP: Clock source for most peripherals
- PLLA: Audio clock sources:
  - 11.2896 MHz
  - 12.288 MHz
  - 24.576 MHz
- PLLU: Clock source for USB PHY, provides 12/60/480 MHz
- PLLD and PLLD2: Clock sources for the display subsystem
- OSC: Source from external crystal
- CLK_32K_IN: 32-KHz clock provided by the PMC

Almost every device or block in the Tegra 3 can be driven from a selection of clock sources. There are three general types of source selection:

- Single source to module (with or without a divider)
- 4-way MUX of clock sources to module (with or without divider)
- 8-way MUX of clock sources to module.

Inputs to clock MUXes are identified as primary (1o), secondary (2o), tertiary (3o), etc. The Power-On-Reset values of all MUXes always select the “osc” clock source. For those MUXes which has no “osc” as clock source, the Power-On-Reset values always select the primary clock source. The clocks available as sources in the Tegra 3 devices are shown in Table 9.

Table 9. Primary Clock Sources in the Tegra 3 Devices

Clock name	Description
dbg_oscout	This clock runs at 12 MHz or 26 MHz.
car_clk_m	This clock (with DFT control) runs at 12 MHz or 26 MHz.
ck32khz_IB	This clock runs at 32.768 KHz.
car_clk_s	This clock (with DFT control) runs at 32.768 KHz.
car_sclk	This is the system clock which can run at max 200 MHz.
pllP_out	This is the PLLP's output clock.
pllC_out	This is the PLLC's output clock.
pllM_out	This is the PLLM's output clock.
int_pllA_out	This is the PLLA's output clock.
pllD_out0	This is the divided-by-2 (max @ 500 MHz) from PLLD's output clock.
pllX_out	This is the PLLX's output clock (only use in mini-CAR CPU)

Table 10. Derived Clock Sources in the Tegra 3 Devices

Clock name	Description
clk_d:	This is the clock doubled from "dbg_oscout"
pllC_out1:	This is the NV divider output clocked by "pllC_out".
pllP_out1:	This is the NV divider output (fixed @ 9.6 MHz) clocked by "pllP_out".
pllP_out2:	This is the NV divider output (fixed @ 48 MHz) clocked by "pllP_out".
pllP_out3:	This is the NV divider output (fixed @ 102 MHz) clocked by "pllP_out".
pllP_out4:	This is the NV divider output (fixed @ (102 MHz) clocked by "pllP_out".
pllM_out1:	This is the NV divider output clocked by "pllM_out".
pllA_out0:	This is the NV divider output clocked by "int_pllA_out".
audio_sync_clk:	This clock is muxed from 9 possible audio clock inputs.
audio_2x_sync_clk:	This is the clock doubled from "audio_sync_clk".

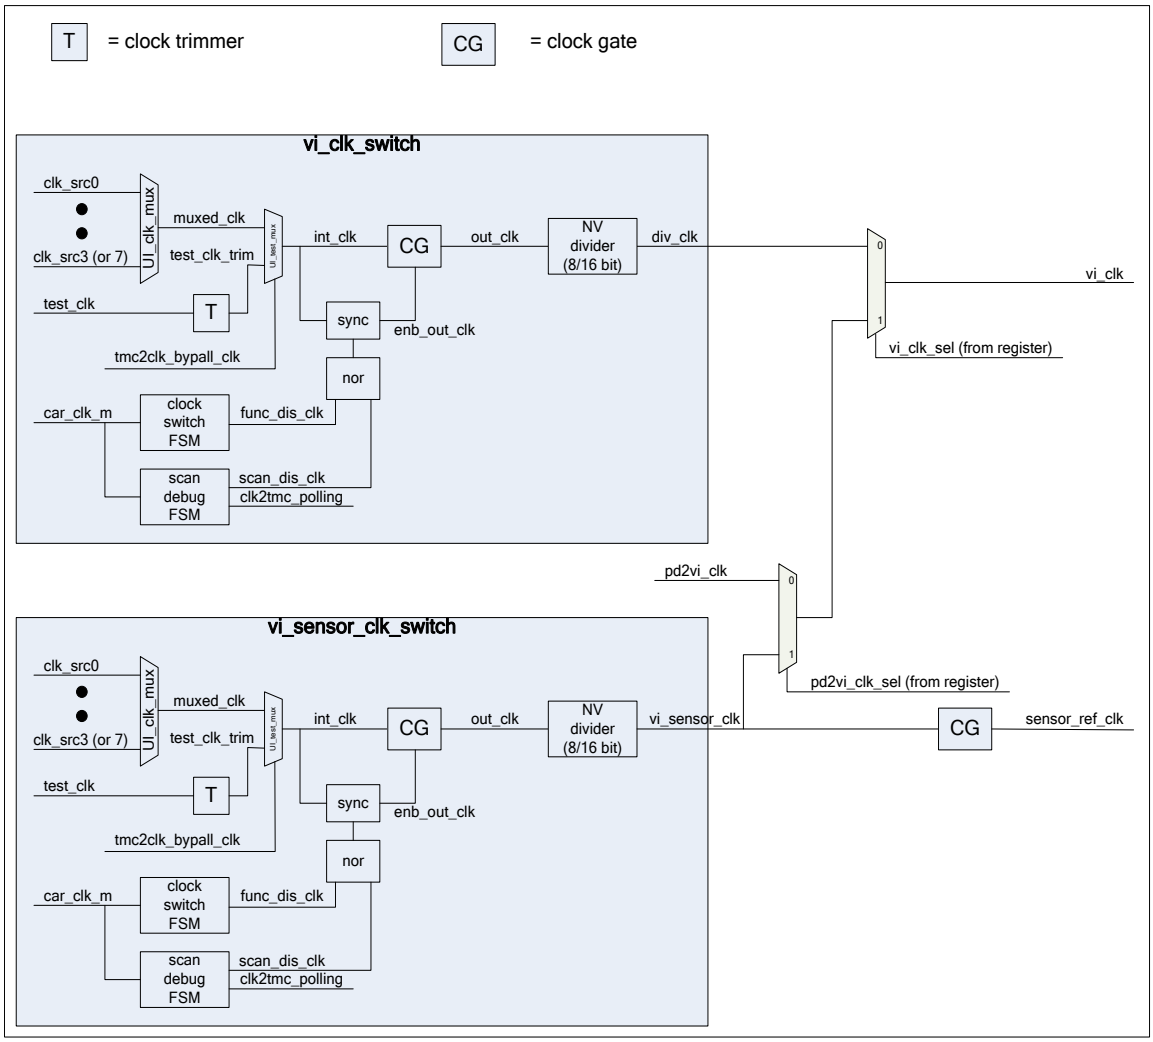
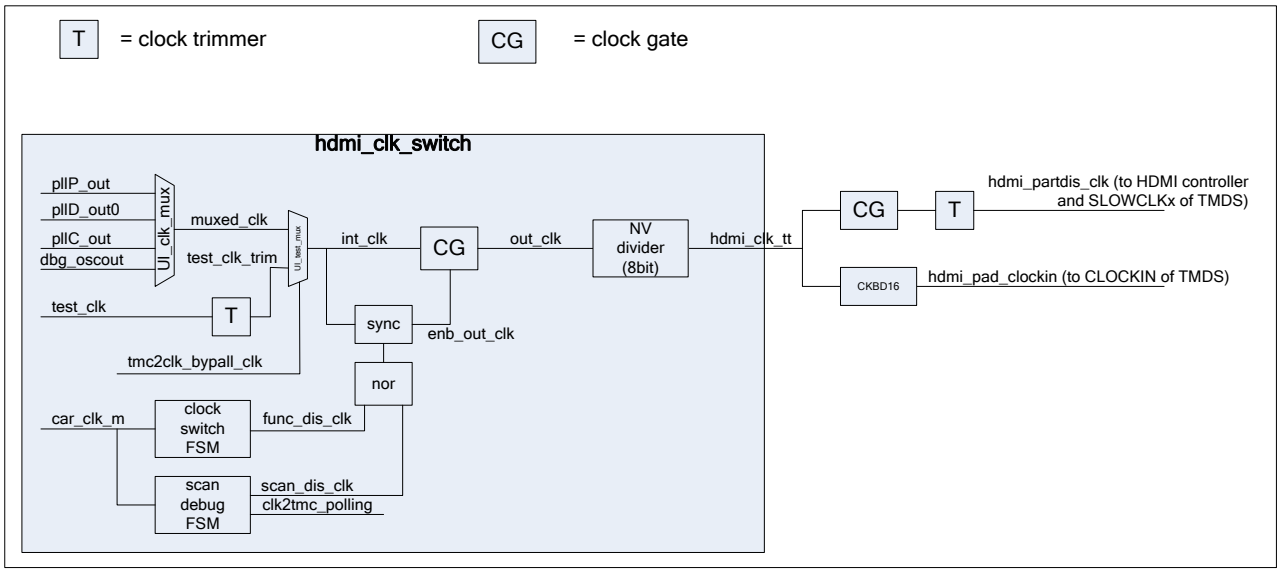
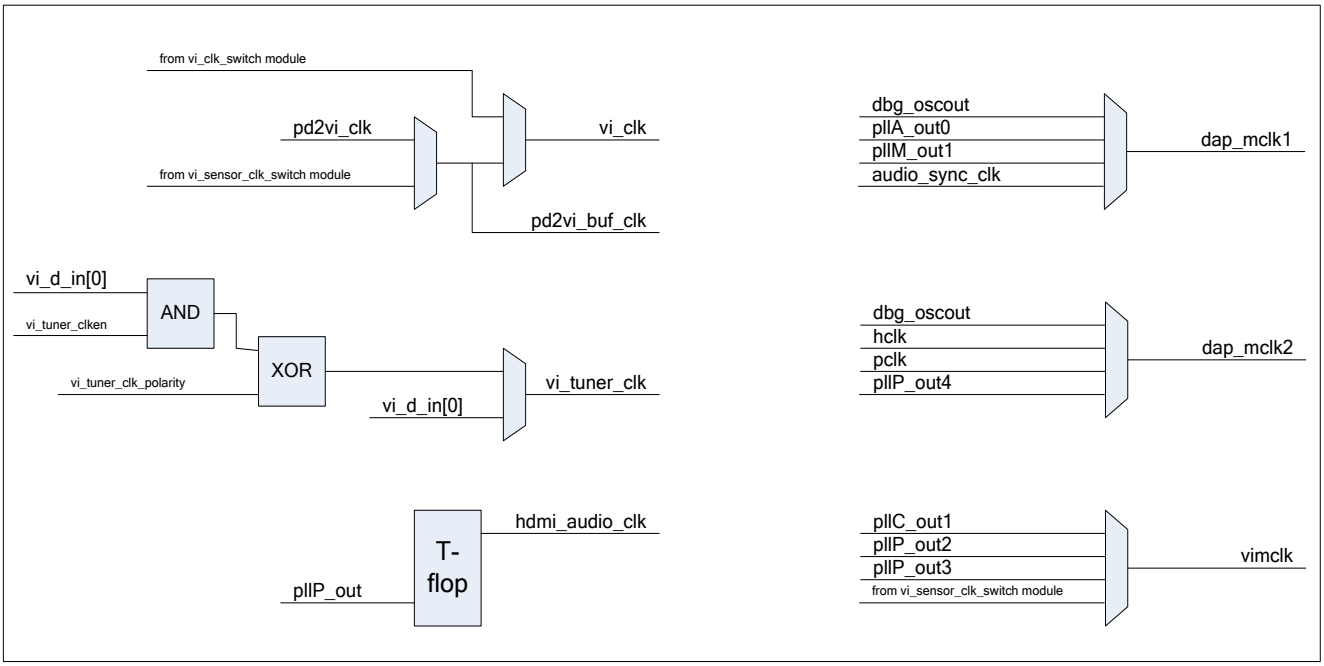
6.3.3 VI/VI Sensor



6.3.4 HDMI



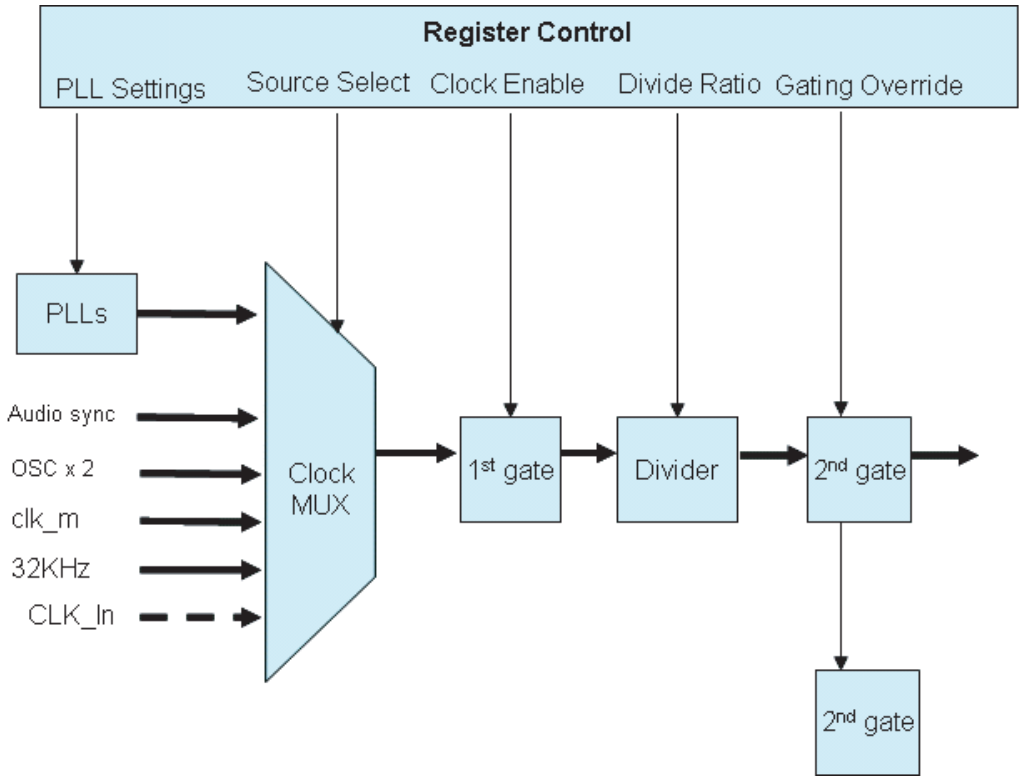
6.3.5 Miscellaneous Peripheral Clocks



6.4 Software Features and Programming Model

6.4.1 Clock Control

The figure below illustrates the software clock control model.



6.4.2 PLL Programming

PLL output frequencies are programmed by setting their N, M and P values. The governing equations are:

VCO = (Fi / M) * N

Fo = VCO / (2 ^ P)

where *Fo* is the output frequency from the PLL.

There are three requirements for each PLL that must be complied with:

- Each PLL has a legal input frequency (*Fi*) range.
- Each PLL has a legal comparison frequency (*CF*) range, where *CF = Fi / M*
- Each PLL has a legal *VCO* frequency range, where *VCO = CF * N*.

To change a PLL, do the following:

- Ensure that no enabled module is using the PLL that will change.
- Program the new PLL settings
- Wait for PLL stabilization
- Change the divider values for each clock that will use the PLL to divide-down to the target frequency.
- Change the module clock sources for all modules that will use the new PLL settings.

6.4.3 Clock Division Control

The ratio as defined by the *1/divisor* for an 8 bit fractional divider, of 7 bits of *d* and 1 bit of *h* is:

divisor = (ddddddd + 1) + (h * 0.5)

The divisor for UART 16b integer divider it is:

divisor = (dddddddddddddddd)

The divisor for the I2C 16b integer divider it is:

divisor = (ddddddddddddddddd + 1)

6.4.4 Changing Clock Sources and Clock Dividers

Changing a clock source (except the clock sources to the audio_sync_clk) to a running module is "glitch free" but incurs a delay of 400 ns to 600 ns. You must only write to the module's clock source register (See Clock Gating (Override)). The audio_sync_clk must be set up in advance and selected as sources before the devices that will use that source are enabled.

The clock divider to a running module can also be changed by "glitch free". All modules support changing the clock divider ratio without disabling the clock; write the new divider to the appropriate register See the section on Power below.

Note that changing the clock source and divider simultaneously to a running module will have undefined results: hardware cannot guarantee which one will change first. To change both (either after system reset or for any other reason), follow one of these sequences:

Sequence 1 to change clock source and divider:

1. Assert reset to the module if it is not already asserted
2. Enable clock to the module if the clock is not already enabled
3. Change the clock divider to the module
4. Change the clock source to the module
5. Wait 2 us for the clock to flush through the pipe / logic.
6. Deassert reset to the module.

Sequence 2 to change clock source and divider:

1. Calculate maximum target frequency at which the device can run given the current divisor and desired clock source, and change the clock source so as not to exceed the device's maximum frequency, OR
2. Calculate the maximum target frequency at which the device can run given the current clock source and desired divisor, and change the divisor so as not to exceed the device's maximum frequency,
3. Then wait 2 us before changing the divisor (first case above) or clock source (second case above).

6.4.5 Clock Gating (Override)

Please refer to the register definition section for more information.

6.4.5.1 Power

The following guidelines should be followed in pursuit of the lowest use-case power consumption:

- Target the least number of PLLs running at their lowest allowable frequencies for the given use-case.
- For each module, use the source with the lowest frequency that provides adequate performance for the use case.
- Turn off all clocks not required for the given use-case - employ maximum clock-gating.

- Use hardware dynamic clock bursting whenever possible. Turn on the desired frequency, burst to completion, and then disable the input frequency (allowing PLLs to be turned off or their output frequencies to be lowered)
- Use the CPU and COP/system super clock divider for lower CPU frequency where possible.
- Disable the oscillator input and/or clock outputs when they are not in use.

6.4.6 Use-Case Restrictions

6.4.6.1 Use of PLLC for Display

Other than PLLD, there is no dedicated PLL for either Display controller. PLLD is required when one of the Display controllers outputs to DSI, but should be otherwise avoided due to its higher power. When DSI is not one of the output devices, or in dual-display use cases, the additional PLLs PLLC and PLLP must be used. The matrix of choices is shown in the table below.

Table 12 PLL Sources for Display Based on Use Case

Primary Head	PLL Choices	Secondary Head	PLL Choices
Parallel	P, C, D	--	--
DSI	D	--	--
Parallel	P, C	Sub	P
DSI	D	Sub	P
Parallel	P, C	DSI	D
Parallel	P, C, D	Parallel	P, C, D
Parallel	P, C, D	TVO	P
Parallel	P, C, D	HDMI	P (480p), C, D (720p)
Parallel	P, C, D	CRT	C, D
DSI	D	TVO	P
DSI	D	HDMI	P (480p), C, D (720p)
DSI	D	CRT	C, D

If possible, the first choice should use the fixed PLLP as Display source clock (divided-down to the required frequency). However, many Display resolutions and/or output devices cannot be driven within the required tolerance by a divided-down PLLP.

Second choice should be to use either PLLD or PLLC, depending on the trade-off that is acceptable. If PLLD is used, power consumption is 5x higher than PLLC. If PLLC is used, it may compromise some other use cases since the Display source PLL must be programmed to a precise frequency to achieve the required Display error tolerance.

Since PLLC is a possible source clock for the AVP, the high-speed serial devices (SFLASH and SPI), for the video encoder (MPE), and for 2D and 3D, these devices may not achieve their target (maximum) frequencies when Display must constrain PLLC directly. An example of this is shown in the Table below for a case where external memory is 166 MHz DDR (EMC 2x clock = 333 MHz).

Table 13. Example of Device Frequencies Possible when PLLC Frequency is Constrained for use by Display

PLLC	PLLP	AVP	HS serial	MPE	2D / 3D
600.0	408.0	150.0	200.0	200.0	216.0
590.0	408.0	147.5	196.7	196.7	216.0
580.0	408.0	145.0	193.3	193.3	216.0
570.0	408.0	144.0	190.0	190.0	216.0
560.0	408.0	144.0	186.7	186.7	216.0
550.0	408.0	144.0	183.3	183.3	275.0
540.0	408.0	144.0	180.0	180.0	270.0
530.0	408.0	144.0	176.7	176.7	265.0
520.0	408.0	144.0	173.3	173.3	260.0
510.0	408.0	144.0	170.0	170.0	255.0
500.0	408.0	144.0	166.7	166.7	250.0

6.5 Clock and Reset Controller Registers

Since this chip is the system controller, resets are now generated in hardware automatically as part of the power-on (POR) or system (either hardware or software) reset sequence.

In POR, all blocks will be held in reset (with clocks disabled) except the minimal set of modules that are needed for system boot-up. At POR, the appropriate bits in RST_DEVICES_L/H/U registers are set automatically by hardware. A "1" in the bit position signifies that block will be held at reset after POR. A "0" in the bit position signifies that block will have its reset de-asserted after POR.

Similarly for clocks, the appropriate bits in CLK_OUT_ENB_L/H/U registers are set automatically by hardware. A "1" in the bit position signifies that block will have clock running during and after POR. A "0" in the bit position signifies that block will not have clock running during or after POR.

The blocks necessary for boot (known as boot blocks) include:

- ARM7 (COP) and its L1 cache
- All system buses (PPSB, AHB, APB, etc.)
- Timer
- RTC
- NOR flash controller
- eFUSE
- GPIO
- CoreSight™ controller

Each of the boot block devices will have their reset deasserted at the end of the POR period (as well as their clocks enabled and use the Oscillator clock for their clock source). Boot blocks clock dividers are all set to divided-by-one.

During POR or system reset, the reset controller will de-assert reset to the boot blocks first and extend the resets to the MPCore/ARM7™ processor for another 511 oscillator clock periods. This will eliminate the chance of either processors trying to talk to a boot device while it is still in reset state.

Releasing a non-boot block/device from reset to bring into operation will require software to initiate a carefully controlled sequence with clock and reset control registers. This sequence must be implemented by software precisely to ensure correct operation of the hardware.

Precaution

- All modules support changing the clock divider ratio without disabling the clock.
- All modules' clock switching is glitch free except "audio_sync_clk".
- For "audio_sync_clk", the clock source select needs to be setup before changing the device clock source to use that audio clock or to enable the device which use that audio clock.
- Before stopping clock (via CLK_OUT_ENB_L/H/U registers) and/or asserting reset (via RST_DEVICES_L/H/U registers) to a module, it's very important to first check the module to make sure it's not active. Stopping clock/asserting reset while the module is still busy can cause relatively minor problem such as incorrect data read/written, or catastrophic problem such as system hang. To ensure a module is not active, (a) disable the module by programming its disable bit if not already done so, and (b) wait until the module is not active by checking for its busy bit, done bit, count, or similar mechanism.

To setup a non-boot device for operation (only apply if a device has a CLK_SOURCE_ register)

1. Make sure the device's reset is asserted (via RST_DEVICES_L/H/U registers).
2. Enable clock to the device (via CLK_OUT_ENB_L/H/U registers).
3. Change the clock divisor to the device (via CLK_SOURCE_ register).
4. Wait 1us to make sure clock divider has changed.
5. Change the clock source to the device (via CLK_SOURCE_ register).
6. Wait 2us to make sure clock source/device logic is stabilized.
7. Deassert device's reset (via RST_DEVICES_L/H/U registers).

To change a device's clock divider and/or source after boot-up (only apply if a device has a CLK_SOURCE_ register):

(A) Method 1 -- (using reset).

1. Make sure the device is disabled (via the device's register).
2. Assert device's reset (via RST_DEVICES_L/H/U registers).
3. Make sure clock to the device is enabled (via CLK_OUT_ENB_L/H/U registers).
4. Change the clock divisor to the device (via CLK_SOURCE_ register).
5. Wait 1us to make sure clock divider has changed.
6. Change the clock source to the device (via CLK_SOURCE_ register).
7. Wait 2us to make sure clock source/device logic is stabilized.
8. Deassert device's reset (via RST_DEVICES_L/H/U registers).

(B) Method 2 -- (not using reset).

1. Make sure clock to the device is enabled (via CLK_OUT_ENB_L/H/U registers).

2. Depending on the max rated frequency of the device, and the current and target clock source/divider value, either change the divider first or the clock source first so that it won't create a temporary situation where the max frequency for that device is violated. Wait for 1us between changing the divider and clock source programming.
3. Wait 2us to make sure device logic is stabilized.

To reset a device (without need to change clock) after boot-up:

1. Make sure the device's reset is asserted (via RST_DEVICES_L/H/U registers).
2. Wait 2us to make sure device logic is stabilized.
3. Deassert device's reset (via RST_DEVICES_L/H/U registers).

Method used to wait for 1 or 2 usec mentioned above.

(A) To use one of the four timers, please refer to the Timer section of this document.

1. Program TMR_PTV register's TMR_PTV field with desired USEC count.
2. Program TMR_PTV register's EN field to enable timer.
3. Poll TMR_PCR register's TMR_PCV field until it reaches 0 to indicate the USEC count has been reached.
4. Program TMR_PTV register's EN field to disable timer.

Main clock sources used by the system:

(A) Primary clocks.

- "osc" or "clk_m" which can be either 12 MHz or 26 MHz.
- "clk_s" which is 32 KHz.

(B) Derived clocks.

- "clk_d" which is clock doubled from "clk_m".

(C) PLL clocks.

- "PLLC" which is general purpose and its output is called "pllC_out0".
- "PLLM" (memory) which is general purpose and its output is called "pllM_out0".
- "PLLP" (peripheral) which is fixed at 408MHz and its output is called "pllP_out0".
- "PLLA" (audio) which is cascaded from PLLP and is used for audio purposes.
- "PLLU" (USB) which has 3 outputs and fixed at 12MHz, 60MHz, and 480MHz.
- "PLLD" (si) which can go up-to 1GHz and its output (after a fix /2) is called "pllD_out0".
- "PLLX" which is extra high frequency used only by Cortex® processors and is called "pllX_out0".
- "PLLE" which is only used by PCIE

(D) PLL divided down clocks (each divider has 7-integer bit and 1-fractional bit).

- "pllC_out1" is divided-down from "pllC_out0".
- "pllM_out1" is divided-down from "pllM_out0".
- "pllP_out1" is divided-down from "pllP_out0" and is fixed at 9.6 MHz.
- "pllP_out2" is divided-down from "pllP_out0" and is fixed at 48.0 MHz.
- "pllP_out3" is divided-down from "pllP_out0" and is fixed at 102.0 MHz.
- "pllP_out4" is divided-down from "pllP_out0" and is fixed at 102.0 MHz.
- "pllA_out0" is divided-down from "pllA" output.

Note: With the exception of PLLA, the other 7 PLLs all use "osc" as reference clock.

Multi-Address:

Register/Bit marked with Multi-Address tag denotes multiple addresses can access same register/bit.

CCLK Multi-Address (Legacy, CPUG and CPULP Multiple Address Registers and Bits):

For CCLK (CPU_CLK) related registers values:

- Three sets of addresses are provided to support legacy, and G+LP CPU clusters.
- Two sets of HW flops are used to store programmed values for G and LP CPU clusters.
- New addresses added for CPU G and LP clusters in Tegra 3.
- Original legacy address always read and write active cluster flop value.
- New address read and write corresponding G or LP flop value.
- In some cases, only CPU bit in an otherwise single access register is multi-address accessible. ex. CLK_ENB_CPU.

FUSE Multi-Address: Fuse and CAR Multiple Address Registers

- bond_out_* register can be programmed via fuse or car CLK_RST_CONTROLLER_BOND_OUT_L_0 register or fuse FUSE_SKU_BOND_OUT_L_0 register.
- fuse bond_out writes are updated on fuse2all_fuse_outputs_valid rising edge
- car bond_out writes are updated on reg wr

WatchDog (deadman) Timer

The purpose of the watchdog timer is to recover from hang/lockup condition by resetting either system and/or COP and/or CPU. Either timer1 or timer2 can be used as watchdog timer. Please refer to the Timer section of this document for more information on watchdog timer usage.

6.5.8 CLK_RST_CONTROLLER_CCLK_BURST_POLICY_0

CPU (CCLK) and COP/System (SCLK) Clock Control

Here, MPCore is referred to as CPU while ARM7 is referred to as COP. The clock control mechanism for CPU and COP/system are identical. Each CCLK and SCLK clock domain can have 5 states. They are SUSP (suspend) where the clock source is 32KHz, and normal states (IDLE, RUN, IRQ, FIQ). Each of the normal states can be selected by SW from 8 different clock sources. Furthermore, if any of the CPU/COP FIQ/IRQ bit is enabled, a hardware auto trigger feature will be enabled such that HW will jump from any state to IRQ or to FIQ automatically. Of course, if the source is from a PLL, SW needs to guarantee that the PLL clock is running and stable before changing clock sources.

There are many usage models that can be derived from this mechanism: For example:

- SW can simply just keep changing the clock source to one state (i.e. just CWAKEUP_IDLE_SOURCE) without changing the CPU_STATE field.
- SW can have the concept of multiple states by first setup CWAKEUP__SOURCE and then just keep changing CPU_STATE field.
- SW can enable HW auto detect of IRQ/FIQ to jump to IRQ or FIQ state.

> **Note:** Whenever clock source is switched, there is about a 400-600 ns time where clock will be stopped.

CCLK and SCLK Super Clock Divider Control

The super clock divider allows a very fine tune of clock frequency going to CPU and COP/system using clock skipping technique. It is different from traditional divider (1/n) in that both the numerator and denominator are programmable (m/n). Both the numerator and denominator are 8 bits each. Thus, "effective" frequency = source frequency * (m/n). Furthermore, if any of the CPU/COP FIQ/IRQ bit is enabled, hardware will auto disable the super clock divider functionality.

There are many usage models that can be derived from this mechanism. For example:

- It has no clock source switching penalty. SW can just pick a PLL output as a max frequency source via CCLK/SCLK_BURST_POLICY and just keep changing SUPER_CCLK/SCLK_DIVIDER to yield the desired lower "effective" frequency.

- For application where the "osc" or "osc*2" frequency is more than sufficient to do the job, PLLs can be turned off to save power and super clock divider can further divide down the "osc" or "osc*2" clock to yield even more power saving.
- If auto IRQ/FIQ feature is enabled, CCLK/SCLK will automatically jump back to full frequency to handle high priority interrupt routine.

Note:	From a dynamic voltage scaling (DVS) standpoint, the full clock frequency source (not the output frequency of the super clock divider) going into the super clock divider should be used to determine how low one can lower the voltage. If m > n, the resulting super clock divider output frequency will simply be the same as the input frequency. In other words, there will be no clock skip or divide down.

6.5.12 CLK_RST_CONTROLLER_CLK_SYSTEM_RATE_0

Audio Sync Clock

The purpose of the audio sync clock is to synchronize communication between 2 audio devices so that it will not get into a FIFO overrun/underrun problem in either of the audio devices. For example, one can receive data from SPDIFIN and transmit the same data back out to an I2S speaker. But if the SPDIFIN stream is 43.9 KHz while we are transmitting 44.1 KHz sample rate to I2S, SPDIFIN receive FIFO can get overrun while I2S transmit FIFO can get underrun.

Note: There's no clock switching protection for audio sync clock so one needs to setup the desired clock source before enabling the audio transmit/receive device.

HCLK/PCLK

SCLK is the main system clock of the Tegra 3 devices which can run up-to 275MHz.

HCLK is the AHB clock which can run at 1, 1/2, 1/3, or 1/4 of SCLK.

PCLK is the APB clock which can run at 1, 1/2, 1/3, or 1/4 of HCLK.

Offset: 030h | Read/Write: R/W | Reset: 0b0x000x00

Bit	Reset	Description
7	0x0	HCLK_DIS: 0=enable HCLK, 1=disable HCLK.

Bit	Reset	Description
15:12	0x7	CLK_D_DELCLK_SEL: 16 Taps of selectable delay for CLK_M clk doubler
11:8	0x7	SYNC_CLK_DELCLK_SEL: 16 Taps of selectable delay for SYNC_CLK clk doubler

6.5.14 CLK_RST_CONTROLLER_COP_CLK_SKIP_POLICY_0

COP Clock Skip

COP uses the same clock as the system (SCLK). The COP_CLK_SKIP_POLICY register provides a mechanism to slow down the COP without slowing down the system clock. This is done by deferring/delaying the ready signal back to the COP. Again, HW can auto detect CPU/COP IRQ/FIQ and change the skip rate as programmed by SW.

Offset: 040h | Read/Write: R/W | Reset: 0b00000000xxxxxxxxx000x000x000x000

Bit	Reset	Description
0	0x0	EN_PPSB_STOPCLK: 1 = enable, 0 = disable 0 = DISABLE 1 = ENABLE

6.5.17 CLK_RST_CONTROLLER_CLK_CPU_CMPLX_0

[CCLK Multi-Address]: Refer to details in file header cpu_divN moved to mselect clock. Programmable divider not available.

CPU complex consists of the CPU, L2-cache controller, and a number of bridge devices interfacing CPU/L2-cache to the rest of the system. Except the CPU, L2-cache controller, and bridge logic to external memory which always runs at non-divided-down CPU frequency, other bridge devices can run at various programmable divided-down CPU clock ratios.

Note: Since the CPU clock can be selected from 1-of-9 clock sources (refer to CCLK_BURST_POLICY register), it's the user's responsibility to not select a bridge divide down CPU clock ratio that will exceed 1/4 of the "MAX" CPU frequency supported.
For Tegra 3 devices, the "MAX" CPU frequency is 1.1 GHz.

Offset: 04ch | Read/Write: R/W | Reset: 0b0000xxxxxx00

6.5.18 CLK_RST_CONTROLLER_OSC_CTRL_0

Oscillator Control

"osc" can have either of the frequencies (12 MHz or 26 MHz) coming in, the OSC_FREQ field provides a way for SW to tell HW what frequency is the incoming clock runs at. This information is used by hardware to auto setup the parameters (DIVN, DIVM, DIVP, CPCON, LFCON, VCOCON, DCCON, OUT1_RATIO, OUT2_RATIO, OUT3_RATIO, and OUT4_RATIO) to PLLP and its dividers. In case a frequency other than those listed is used, there is a way to override the HW auto generated PLLP parameters.

Bit	Reset	Description
15:0	X	RND: Random number generated from PLL linear feedback shift register.

6.5.20 CLK_RST_CONTROLLER_OSC_FREQ_DET_0

Oscillator Frequency Detect

"osc" can have any one of the frequencies (12 MHz or 26 MHz) coming in, HW is providing a mechanism of detecting which one of the frequencies the "osc" is running at. To determine the "osc" frequency, user only needs to program the number of 32 KHz (actually, 32.768 KHz) clock periods used as a fix time window from which the "osc" will be used to increment a 16-bit counter and start the frequency detection process. Once the detection process is done, user simply just checks the 16-bit count value to determine the "osc" frequency.

OSC Frequency (MHz)	Approximate OSC_FREQ_DET_CNT (using two 32KHz period as window)
12.00	732 (0x02DC)
26.00	1587 (0x0633)

Offset: 058h | Read/Write: R/W | Reset: 0b0xxxxxxxxxxxxxxxxxxxxxxxxxxxx0000

Bit	Reset	Description
31	DISABLE	OSC_FREQ_DET_TRIG: 0 = default, 1 = enable osc frequency detect. 0 = DISABLE 1 = ENABLE
3:0	0x0	REF_CLK_WIN_CFG: Indicate the # of 32KHz clock period as window in n+1 scheme.

6.5.21 CLK_RST_CONTROLLER_OSC_FREQ_DET_STATUS_0

Offset: 05ch | Read/Write: RO | Reset: 0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx

Bit	Reset	Description
31	X	OSC_FREQ_DET_BUSY: 0 = not busy, 1 = busy.
15:0	X	OSC_FREQ_DET_CNT: indicate the number of osc count within the 32KHz clock reference window.

6.5.22 CLK_RST_CONTROLLER_PLLC_BASE_0

PLL Configuration

Tegra 3 devices have 10 PLLs controllable by clock control. Please consult the PLL specification for electrical requirements.

- "PLLC/PLLP/PLLA" is of type CLKPLL700_LP_A2.
- "PLLD/PLLD2" is of type CLKPLL1G_MIPI_B.
- "PLLU" is of type CLKPLL960_USB_A3.
- "PLLMis of type CLKPLL800_LP_B1 .
- "PLLX" are of type CLKPLL12G_LP_DV_B1.

- "PLLE" is of type PLL24G_SSA_LP_CML_ESD_B1 .

In general, there are 3 requirements for each PLL that SW needs to comply with:

- Input frequency range (REF).
- Comparison frequency range (CF). CF = REF/DIVM where DIVM is the input divider control.
- VCO frequency range (VCO). VCO = CF * DIVN where DIVN is the feedback divider control.

> **Note:** The final PLL output frequency (FO) = VCO >> DIVP where DIVP is the post divide control.

Table 14 PLL Requirements for software

	CLKPLL700_LP_A2	CLKPLL800_LP_B1	CLKPLL1G_MIPI_B	CLKPLL12G_LP_DV_B1	CLKPLL960_USB_A3
Input freq. (REF)	2-31MHz	2-31MHz	2-40MHz	2-31MHz	2-40MHz
Comparison freq. (CF)	1-6MHz	1-6MHz	1-6MHz	1-6MHz	1-6MHz
VCO freq. (VCO)	20-1400MHz	20-1200MHz	40-1000MHz	20-1200MHz	480-960MHz

Table 15 Charge pump current (CPCON) for CLKPLL700_LP_A2/CLKPLL800_LP_B1/CLKPLL12G_LP_DV_B1

N-divider	Comparison freq.(CF)	Charge pump current (CPCON)
>= 200	1MHz	4uA (1000)
	2-3MHz	2uA (0100)
	4-6MHz	1uA (0010)
< 200	x	0.5uA (0001)

Table 16 Charge pump current (CPCON) for CLKPLL1G_MIPI_B/CLKPLL960_USB_A3

CPCON	Description
0000	Charge Pump 0uA
0001	Charge Pump 1uA
0010	Charge Pump 2uA, when N-divider=50
0011	Charge Pump 3uA
0100	Charge Pump 4uA, when N-divider=300
1000	Charge Pump 8uA, when N-divider=600
1100	Charge Pump 12uA, when N-divider=1000
1101	Charge Pump 13uA
1110	Charge Pump 14uA
1111	Charge Pump 15uA

CPCON setting reference from CLKPLL700_LP_A2:

N >= 200

- CompFreq 1 MHz : CPCON 4uA (1000b)
- CompFreq 2-3 MHz : CPCON 2uA (0100b)
- CompFreq 4-6 MHz : CPCON 1uA (0010b)

N < 200 : CPCON 0.5uA (0001) with special note that this may not meet lock time spec

- - 19.2 MHz setting updated
- - 38.4 and 48 MHz requires PLL_REF_DIV setting of 2 and 4. Max(DIVM)=31. PLL_REF_DIV=1 would require 32, 48 respectively

Note: 15.36 MHz setting does not meet (1MHz < CompFreq < 6MHz) stability requirement. CompFreq(15.36 MHz) = 15.36/16.
15.36 support is removed because it doesn't support all PLLD frequency requirements

Table 17. PLLP Configuration Information (reference clock is osc/clk_m and PLLP-FO is fixed at 408MHz).

Reference Frequency	12.0 MHz	26.0 MHz	Resulting Frequency
DIVN	408(0d8h)	408 (0d8h)	N/A
DIVM	12 (0ch)	26 (1ah)	N/A

CPCON	8 (8h)	8 (8h)	N/A
LFCON	0 (0h)	0 (0h)	N/A
VCOCON	0 (0h)	0 (0h)	N/A
DCCON	0 (0b)	0 (0b)	N/A
OUT1 div ratio	42.5 (0dh)	42.5 (0dh)	9.6MHz.
OUT2 div ratio	8.5 (07h)	8.5 (07h)	48.0MHz.
OUT3 div ratio	4.0 (04h)	4.0 (04h)	102.0MHz.
OUT4 div ratio	4.0 (02h)	4.0 (02h)	102.0MHz.

Table 18 PLLA configuration information (reference clock is taken from PLLP_OUT1 = 28.8MHz).

Audio Frequency	56.448MHz	73.728MHz	11.2896MHz	12.2880MHz
DIVN	49 (031h)	64 (040h)	49 (031h)	64 (040h)
DIVM	25 (19h)	25 (19h)	25 (19h)	25 (19h)
DIVP	1 (0h)	1 (0h)	1 (0h)	1 (0h)
OUT0 div ratio	1.0 (0h)	1.0 (0h)	5.0 (08h)	6.0 (0ah)

Table 19 PLLU configuration information (reference clock is osc/clk_m and PLLU-FOs are fixed at 12 MHz/60 MHz/480 MHz).

Reference Frequency	12.0 MHz	26.0 MHz
DIVN	960 (3c0h)	960 (3c0h)

Reference Frequency	12.0 MHz	26.0 MHz
DIVM	12 (0ch)	26 (1ah)
CPCON	12 (ch)	12 (ch)
LFCON	1 (1h)	1 (1h)

Table 20 PLLD configuration information (reference clock is osc/clk_m and PLLD-FO is max of 1GHz).

PLLD rates of interest:

- Display/HDMI requires precise 27, 74.25, 148.5 MHz;
- For 16.8 MHz {M=14, N=495) gives FO=594MHz. Divide down to 148.5 and 74.25 MHz.
- HDA (48 MHz)
- audio/SPDIF (6.144 MHz etc.)

Reference Frequency	12.0MHz	26.0MHz
DIVN	1000(3e8h)	1000(3e8h)
DIVM	12 (0ch)	26 (1ah)
DIVP	1 (0h)	1 (0h)

Note: 1GHz is not an absolute requirement.

Table 21 PLLE configuration information (reference clock is osc/clk_m and PLLE-FO is 100 MHz).

Reference Frequency	12.0MHz (PLLE_REF_SRC==OSC_DIV)
NDIV	200 (c8h)
MDIV	1 (01h)
PLDIV	24 (18h)
PLDIV_CML	(dh)

Special Consideration when Using PLLX as a Clock Source for the CPU

PLLX is shared between G and LP CPU clusters. It is physically located at the GR power partition. The proper PLLX_FO_LP_DISABLE or PLLX_FO_G_DISABLE bit should be de-asserted to enable corresponding PLLX clock output. PLLX should not be disabled unless both CPU clusters are disabled.

0	RW	0x0	PLLE_KVCO: Base PLLE VCO gain.

6.5.43 CLK_RST_CONTROLLER_CLK_SOURCE_I2S1_0

Clock Configuration for Each Peripheral

In general, each block or module has a dedicated CLK_SOURCE_ register that provides clock source and clock divider control to that device. The clock source select is typically 2 bits to select one of the four clock sources. The divider is typically 8-bits which consist of 7 integer bits and 1 fractional bit. Furthermore, depending on the specific module, the CLOCK_SOURCE_ register may contain additional control bits.

Note: The 16-bit UARTA/UARTB/UARTC clock divider control is provided by the UART register set and not by the CLK_SOURCE_ registers.
In order to switch from one clock source to the next, both clock sources must be active/running.

Special PLL clock usage by certain peripheral

As mentioned previously, each peripheral has a clock source select in their corresponding CLK_SOURCE_ register. But in addition, there are a number of modules which also take in an additional fix PLL clock source for portion of their logic.

Listed below is the module/logic and the fix PLL clock source they use.

Module/Logic	Fix PLL Clock Source Used
LFSR	pllM_out0
DSI	pllP_out3
DSIB	pllP_out3
CSI	pllP_out3
I2C1	pllP_out3
I2C2	pllP_out3

6.5.61 CLK_RST_CONTROLLER_CLK_SOURCE_NDFLASH_0

NAND module now uses a combination of 3 clocks: nandfst_clk, nand_clk, and nand_speed_clk

- nandfst_clk and nand_clk are controlled by CLK_SOURCE_NDFLASH reg
- nand_speed_clk is controlled by CLK_SOURCE_NAND_SPEED reg

Output of clock switch is nandfst_clk at full rate.

An additional nand_clk is programmable to full or div2 rate of nandfst_clk.

6.5.89 CLK_RST_CONTROLLER_RST_DEV_L_SET_0

The RST_DEV_(L,H,U. V, W)_(SET,CLR) and CLK_ENB_(L,H,U, V, W)_(SET,CLR) registers are provided as an alternate method of programming the same registers found in RST_DEVICES_(L,H,U, V, W) and CLK_OUT_ENB_(L,H,U, V, W) registers, respectively.

Therefore, using either methods will change the same underlying peripherals reset, and clock enable control for write. As for read, again, user can use either method to retrieve the reset/clock-enable state of each peripheral.

6.5.113 CLK_RST_CONTROLLER_CLK_CPUG_CMPLX_0

[CCLK Multi-Address]: Refer to details in file header cpu_divN moved to mselect clock. Programmable divider not available.

CPUG complex consists of the CPUG, L2-cache controller, and a number of bridge devices interfacing CPUG/L2-cache to the rest of the system.

Except the CPUG, L2-cache controller, and bridge logic to external memory which always runs at non-divided-down CPUG frequency, other bridge devices can run at various of programmable divided-down CPUG clock ratios.

Note: However, since the CPUG clock can be selected from 1-of-9 clock sources (please refer to CCLKG_BURST_POLICY register), it's the users responsibility to not select a bridge divide-down CPUG clock ratio that will exceed 1/4 of the "MAX" CPUG frequency supported.

The "MAX" CPUG frequency is 1.1GHz.

Offset: 378h | Read/Write: R/W | Reset: 0b0000xxxxxx00

Bit	Reset	Description

6.5.159 CLK_RST_CONTROLLER_UTMIP_PLL_CFG0_0

The data sampling frequency relies on a 960MHz clock, so the goal of the PLL is to have: In_Frequency*(PLL_VCOMULTBY2+1)*(PLL_NDIV/PLL_MDIV) = 960MHz With a 12MHz input from PLL_U, the default setting of PLL_VCOMULTBY2=1, PLL_NDIV=40 and PLL_MDIV=1 results in a correct output.

This register is used to configure the PHY PLL contained in the UTMIP module.

UTMIP PLL Configuration Register 0

Offset: 480h | Read/Write: R/W | Reset: 0b00000000010100000000000110000000

Bit	Reset	Description
30:28	0x0	UTMIP_PLL_SELECT: Selects which of the eight 60MHz clock phases to produce at the output of the USB PHY PLL. This is for a test mode. See the cell specification.
27	0x0	UTMIP_PLL_PDIVRST: PDIVRST of the UTMIP PHY PLL. Reserved. Keep at 0x0. Currently there is no post divider on this PLL. See cell specification.
26:24	0x0	UTMIP_PLL_PDIV: PDIV[2:0] input of the UTMIP PLL. Reserved. Keep at 0x0. Currently there is no post divider on this PLL. See the cell specification.
23:16	0x28	UTMIP_PLL_NDIV: NDIV[7:0] input of UTMIP PLL. This is the feedback divider on the VCO feedback. 0x0 is not allowed. See the cell specification.
15:8	0x1	UTMIP_PLL_MDIV: MDIV[7:0] input of the UTMIP PLL. This is the predivide on the PLL. 0x0 is not allowed. See the cell specification.
7	0x1	UTMIP_PLL_VCOMULTBY2: VCOMULTBY2 control of the UTMIP PHY PLL. Recommended setting is on. Additional divide by 2 on the VCO feedback. Which is setting the bit to 1. See the cell specification.
6:1	0x0	UTMIP_PLL_LOCKSEL: LOCKSEL[5:0] input of UTMIP PLL. Used in test modes only. See the cell specification.
0	0x0	UTMIP_PLL_LOCKENABLE: LOCK_ENABLE input of UTMIP PLL. Normally only used during test. See the cell specification.

6.5.160 CLK_RST_CONTROLLER_UTMIP_PLL_CFG1_0

PLL CONFIGURATION & PARAMETERS

In normal operation, the following clock generators are in play for USB:

Xtal clock -> enters PLL_U to generate 12MHz clock -> enters USB_PHY PLL to generate 480/60 MHz clock

The following parameters control the bringup of the PLLs:

Coming out of reset or suspend

-> PllUOnState: start pllu_enable_count and pll_lock_count

-> Wait ~1us to actually enable the PLL_U (pllu_enable_count == ClkXtal * PLLU_ENABLE_DLY_COUNT * 8)

-> Wait ~1ms until PLL_U is actually stable (pll_lock_count == ClkXtal * PLLU_STABLE_COUNT * 256) => USB_PHY PLL_ENABLE pll_active_count = 0

-> Wait 5us to enable pll_active: pll_active_count == ClkXtal * PLL_ACTIVE_DLY_COUNT * 16 => USB_PHY PLL_ACTIVE

-> Wait ~2.5ms until USB_PHY is actually stable (pll_lock_count == ClkXtal * XTAL_FREQ_COUNT * 256) => USB_PHY

Numbers for a 19.2MHz Xtal clock

- PLLU_ENABLE_DLY_COUNT[4:0] = 1 * 19.2 / 8 = 2.4 = 3 = 0x03
- PLLU_STABLE_COUNT[11:0] = 1000 * 19.2 / 256 = 75 = 0x4b
- PLL_ACTIVE_DLY_COUNT[4:0] = 10 * 19.2 / 16 = 12 = 0x0c
- XTAL_FREQ_COUNT[11:0] = 2500 * 19.2 / 256 = 187 = 0xbb

UTMIP PLL and PLLU configuration register 1

Offset: 484h | Read/Write: R/W | Reset: 0b00011000001000010101000011000000

Bit	Reset	Description
31:27	0x3	UTMIP_PLLU_ENABLE_DLY_COUNT: Controls the wait time to enable PLL_U when coming out of suspend or reset.
26:18	0x8	UTMIP_PLL_SETUP: SETUP[8:0] input of USB_PHY PLL.
17	0x0	UTMIP_FORCE_PLLU_POWERUP: Force PLL_U into power up.
16	0x1	UTMIP_FORCE_PLLU_POWERDOWN: Force PLL_U into power down. (Overrides FORCE_PLLU_POWERUP.)
15	0x0	UTMIP_FORCE_PLL_ENABLE_POWERUP: Force UTMIP PLL pll_enable input on.
14	0x1	UTMIP_FORCE_PLL_ENABLE_POWERDOWN: Force UTMIP PLL pll_enable input off. (Overrides FORCE_PLL_ENABLE_POWERUP.)
13	0x0	UTMIP_FORCE_PLL_ACTIVE_POWERUP: Force UTMIP PLL pll_active input on.

6.5.163 CLK_RST_CONTROLLER_SATA_PLL_CFG0_0

SATA power sequencer input SW control program guide

SW control input can be used for test coverage or driving power sequencer SM via software.

SATA power sequencer is driven by 3 primary reset and powerdown input signals: reset, lane_pd, padpll_pd.

Normal power up sequence is to deassert in the order of padpll_pd->lane_pd->reset.

Normal power down sequence is to assert in the order of reset->lane_pd->padpll_pd.

It is acceptable to assert all three at the same time.

It is acceptable for reset or lane_pd to return to powerup state in the middle of a powerdown sequence.

6.5.166 CLK_RST_CONTROLLER_PROG_AUDIO_DLY_CLK_0

- Clock doubler with 1X/2X select for: I2S0..4, SPDIF.
- Clock doublers with 1x/2x select use by clock controller for each of I2S0..4, SPDIF sync clock.
- Clock doubler enable controlled by CLK_ENB_I2S[0..4]_DOUBLE and CLK_ENB_SPDIF_DOUBLE bits in

CLK_OUT_ENB_V register. CLK_ENB_*_DOUBLE bit must be enabled for either SYNC_1X_CLK or SYNC_2X_CLK to operate.

PROG_DLY_CLK is used to provide programmable delay for the clock doublers. Individual clock doubler is provided for each audio sync clock: I2S0..4, SPDIF.

Audio sync clock source mux options:

SPDIFIN, I2S0, I2S1, I2S2, I2S3, I2S4, PLLA_OUT0, EXT_VIMCLK

Enable sync clocks

There are 3 related clock enables/selects:

- CG_1. AUDIO_SYNC_CLK_I2S0-SYNC_CLK_DIS: disable output of sync_clk mux
- CG_2. CLK_OUT_ENB_V-CLK_ENB_I2S0_DOUBLER: disable input to doubler
- SEL_3. PROG_AUDIO_DLY_CLK-I2S0_1X_SEL: Select 1x sync clock. 0=2x 1=1x flow of clock logic: sync_clk mux (CG_1)-> (CG_2) (SEL_3) doubler -> clk switch

Suggested programming for sync clock enable:

- Leave CG_2 as default enabled.
- Use CG_1 to disable or enable (default) sync clock.
- Use SEL_3 to select 1x or 2x sync clock.

SYNC_CLK_DIS	CLK_ENB_I2S0_DOUBLER	I2S0_1X_SEL	SYNC_CLK
0	1	0	2x (Default)
0	1	1	1x
1	1	X	0 (off, recommended)
1	X	X	0 (off)
X	0	X	0(off)

7.0 TIMERS

The Timer Controller is a 29-bit compound controller. It counts ticks and evaluates/assigns a passage of time to the number of ticks.

Tegra® 3 devices have ten 29-bit timers that run at 1 MHz clock rate based on the crystal oscillator. Each timer can be programmed to generate single, periodic, or watchdog interrupts.

When the EN bit is set high, the timer loads the timer present trigger value (PTV) into its counter and starts decrementing at a 1 MHz clock rate (1 µsec increment). When the timer present count value (PCR) decrements to zero, it generates a timer interrupt. When the enable periodic interrupt (PER) bit is enabled, the timer generates an interrupt and reloads the counter with the PTV value and starts to decrement again. When the timer consecutively decrements to zero a second time, without the processor reading the first interrupt status register (PCR), it generates a watchdog timer (WDT) interrupt.

Watchdog timers facilitate recovery from system lockup conditions. Either of the two generic timers can be configured as the watchdog timer using the Reset Trigger Source (RST_SOURCE) register. The watchdog timer interrupts the processor when the selected counter expires. Under normal operation, this interrupt is serviced by the processor by reading the status register (timer register).

The Tegra 3 device adds five new watchdog timers, directly associated with the four CPU cores and the AVP. Any of the general-purpose timers can be used as a reference.

If the interrupt is not serviced by the processor before the watchdog timer counts down to zero a second time, this is treated as a lockup condition. When this occurs, the watchdog timer generates a reset to the system. Watchdog timer functionality is enabled using bit 5 (WDT.E) of the RST_SOURCE register. Depending on which timer is configured for the watchdog timer function, the processor needs to service the watchdog interrupts by reading the corresponding timer status registers TMR1_PCR and TMR2_PCR. The reset generated by the watchdog timer can be configured to reset the system (entire chip) or the processors individually. This configuration is done using bits [2:0] of the RST_SOURCE register. Software can determine the cause of the reset by checking the status flags (bits [13:8]) of the RST_SOURCE. The USEC_DIVIDEND" and "USEC_DIVISOR" are used to indicate what fraction of 1 microsecond each oscillator clock represents.

Note:	If the XTAL oscillator or clock source is disabled during low-power standby mode, the microsecond timers will not function. This also means that interrupts will not occur.

7.1 Functionality

The programmable timer block contains ten 29-bit programmable timer counters and a 32-bit time-stamp counter.

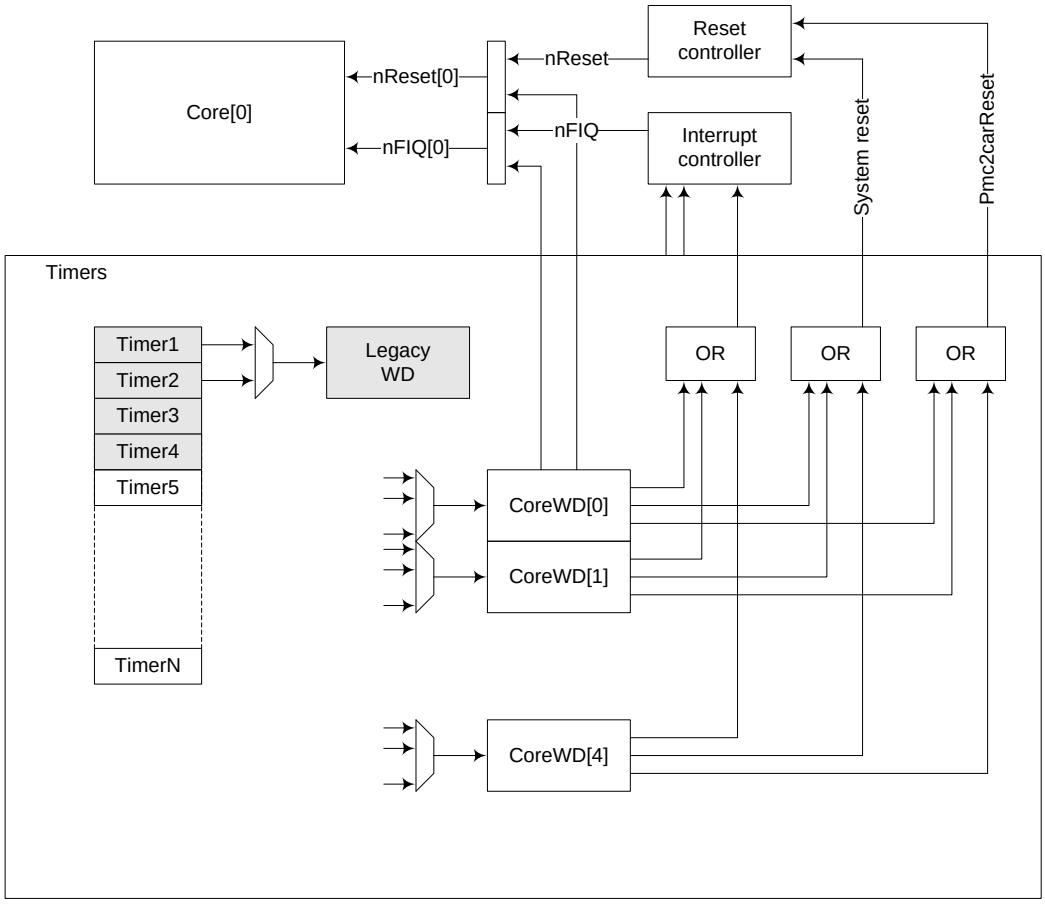
Each Timer can be programmed to generate a periodic interrupt or a one-time interrupt. The Timer count decrements by one microsecond when a timer is programmed via a corresponding Enable-bit. The timer generates a timer request whenever the count reaches Zero. If the periodic control bit is set, the timer will reload itself with the count value and decrement again. If the Periodic bit is not set, the timer will generate a single interrupt, clear its enable bit and not reload.

The timer count is 29 bits wide, therefore, it will support a periodic interrupt every 16.384 ms maximum or a minimum of 1 µs. Bit 30 of the periodic Timer Value (PTV) is the enable bit for the timer. Reading the PTV Register clears any pending timer interrupt.

A read-only Preset count register (PCR) allows the processor to inspect the current value of the Decrement counter. The time-stamp counter (32 bits wide) is cleared to Zero on reset, and counts upwards every 1 µs.

The figure below shows a reference decomposition of the timers in functional blocks. This reference decomposition is for documentation purposes only and the designer may choose a different structure for HW implementation as long as functional requirements are met.

Figure 5. Timer Functional Block Diagram



- The timers are numbered 0 to 9
- Timers 1 to 5 have a dedicated interrupt bit
- Timers 0,6,7,8,9 share a common interrupt called SharedTimerInterrupt.

7.2 Watchdog Timer Programming Guide

The watchdog timer function facilitates recovery from system lockup. The watchdog can be programmed to reset just the CPU, just the AVP, or the entire system.

If only the CPU is reset, then AVP will just continue running as-is. The CPU reset vector should be programmed in advance so that it skips the iROM boot code and jumps directly into its own CPU boot routine (which can be anywhere.)

If only the AVP is reset, the same is true. The CPU keeps running as-is. If the AVP reset vector is set to default, it will run the normal boot code. It would be up to the boot loader to decide if it needs to restart the CPU as well.

The watchdog timer can be programmed to a maximum timeout value of 0x3fffffff which is more than 1 billion. At 1µs/count, this is more than one thousand seconds.

It is operated as follows:

1. Watchdog generates Interrupt based on Timer
    a. TMR1 or TMR2 can be selected as source
    b. Timer should be programmed as Periodic with Interrupt.

c. CAR.RST_SOURCE.WDT_EN = 1

d. CAR.RST_SOURCE.WDT_SEL selects TMR2/TMR1

2. Processor must handle interrupt or Reset is issued

a. First timeout -- interrupt is generated

b. If interrupt is not handled by next timeout, reset issued

3. Reset can be for AVP, CPU, or full system

a. CAR.RST_SOURCE.WDT_***_RST_EN = 1

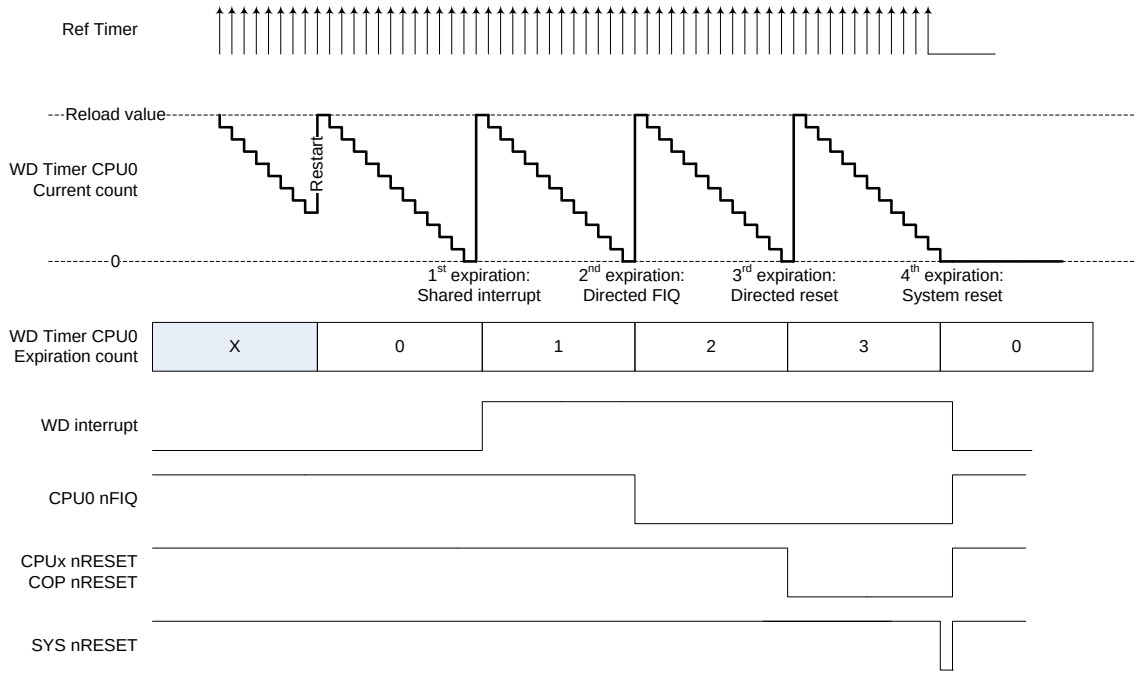
4. Upon reboot, CAR.RST_SOURCE.WDT_*_RST_STA indicates cause of the reset

Tegra 3 devices have 5 watchdog timers that operate in the following way:

- Directly associated with a processor core, i.e., four CPU cores[1] and the COP
  - The watchdog is reset by the corresponding core reset signal
  - WD timers 0 to 3 are associated with CPU 0 to 3, WD 4 is associated with COP
- Select any one of the general purpose timers as timing reference
- Standard down counter with programmable period, that also counts expirations, specific action are taken at the counter expiration
  - If the expiration count is 0, a normal interrupt may be generated (probably pooled)
  - If the expiration count is 1, the FIQ for the corresponding processor may be asserted, this operation bypasses the normal interrupt controller
  - If the expiration count is 2, the reset for a programmable set of processors is asserted, this may be the null set
  - If the expiration count is 3, a system wide reset may be asserted (two variants, standard system or closer to external HW reset)

[1] CPU Core 0 is treated in a specific manner so that the watchdog process is transparent to SW migration from the G to the LP process.

Figure 6. Watchdog Example Timing Diagram

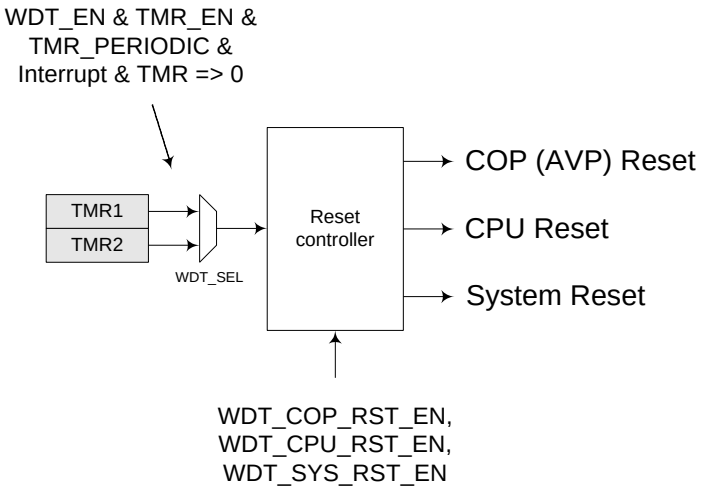


Any operation that targets CPU0 is done in the following way:

- Any output is broadcast to both instances of CPU0, in CPU cluster 0 (G) and 1 (LP). This applies to the reset and FIQ signals.
- Resetting any of the CPU0 results in resetting the WD associated with CPU 0

Although the Timing diagram implies that you need to restart the timer when you service the interrupt, this is not necessary as long as you can always service the interrupt (clear the TMR interrupt) before the next timeout occurs. The reset only happens if a new timeout occurs when the TMR interrupt is still active.

Figure 7. Watchdog Block Diagram



7.3 Timer Registers

7.3.1 TIMER_TMR1_TMR_PTV_0

Before programming timer:

- Input oscillator frequency must be specified in the TIMERUS_USEC_CFG to support multiple frequencies
- Program the number of 1us timer counts per "tick" in the PTV (Present Trigger Value) register.
- Set the PTV EN (enable bit) to start counting down.
- When the count reaches zero, interrupt is generated.
- To auto-reload the timer counter, set the PTV PER (periodic) bit. Otherwise, leave it clear for a one-shot.

Timer Present Trigger Value (Set) Register

Offset: 000h | Read/Write: R/W | Reset: 0b00x00000000000000000000000000000

Bit	Reset	Description
31	0x0	EN: Enable Timer 0 = DISABLE 1 = ENABLE
30	0x0	PER: Enable Periodic Interrupt 0 = DISABLE 1 = ENABLE
28:0	0x0	TMR_PTV: Trigger Value: count trigger value (count length). This is in n+1 scheme. If you program the value n, the count trigger value will actually be n+1.

7.3.2 TIMER_TMR1_TMR_PCR_0

When interrupt is generated, write "1" to PCR[30] present count Register to clear the interrupt

Timer interrupt assignments:

- Timer 1 = primary interrupt controller bit 0
- Timer 2 = primary interrupt controller bit 1
- Timer 3 = secondary interrupt controller bit 9
- Timer 4 = secondary interrupt controller bit 10

7.3.15 TIMER_TMR8_TMR_PTV_0

Timer Present Trigger Value (Set) Register

Offset: 078h | Read/Write: R/W | Reset: 0b00x00000000000000000000000000000

Bit	Reset	Description
31	0x0	EN: Enable Timer 0 = DISABLE 1 = ENABLE
30	0x0	PER: Enable Periodic Interrupt 0 = DISABLE 1 = ENABLE
28:0	0x0	TMR_PTV: Trigger Value: count trigger value (count length). This is in n+1 scheme. If you program the value n, the count trigger value will actually be n+1.

7.3.16 TIMER_TMR8_TMR_PCR_0

Timer Present Count Value (Status) Register

Offset: 07ch | Read/Write: R/W | Reset: 0b0xxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx

Bit	R/W	Reset	Description
30	RW	0x0	INTR_CLR: 1 = clears the interrupt, 0 = no affect. Write-1-to-Clear
28:0	RO	X	TMR_PCV: Counter value: decrements from PTV.

7.3.17 TIMER_TMR9_TMR_PTV_0

Timer Present Trigger Value (Set) Register

Offset: 080h | Read/Write: R/W | Reset: 0b00x00000000000000000000000000000

Bit	Reset	Description
31	0x0	EN: Enable Timer 0 = DISABLE 1 = ENABLE
30	0x0	PER: Enable Periodic Interrupt 0 = DISABLE 1 = ENABLE

Bit	Reset	Description
28:0	0x0	TMR_PTV: Trigger Value: count trigger value (count length). This is in n+1 scheme. If you program the value n, the count trigger value will actually be n+1.

7.3.18 TIMER_TMR9_TMR_PCR_0

Timer Present Count Value (Status) Register

Offset: 084h | Read/Write: R/W | Reset: 0b0xxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx

Bit	R/W	Reset	Description
30	RW	0x0	INTR_CLR: 1 = clears the interrupt, 0 = no affect. Write-1-to-Clear
28:0	RO	X	TMR_PCV: Counter value: decrements from PTV.

7.3.19 TIMER_TMR0_TMR_PTV_0

Timer Present Trigger Value (Set) Register

Offset: 088h | Read/Write: R/W | Reset: 0b00x00000000000000000000000000000

Bit	Reset	Description
31	0x0	EN: Enable Timer 0 = DISABLE 1 = ENABLE
30	0x0	PER: Enable Periodic Interrupt 0 = DISABLE 1 = ENABLE
28:0	0x0	TMR_PTV: Trigger Value: count trigger value (count length). This is in n+1 scheme. If you program the value n, the count trigger value will actually be n+1.

7.3.20 TIMER_TMR0_TMR_PCR_0

Timer Present Count Value (Status) Register

Offset: 08ch | Read/Write: R/W | Reset: 0b0xxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx

Bit	R/W	Reset	Description
30	RW	0x0	INTR_CLR: 1 = clears the interrupt, 0 = no affect. Write-1-to-Clear
28:0	RO	X	TMR_PCV: Counter value: decrements from PTV.

7.4 Timer USEC CFG

The purpose of USEC_CFG/CNTR_1US registers is to provide a fixed time base (in microseconds) to be used by the rest of the system regardless of the oscillator frequency (i.e. 12 MHz, 13 MHz, 19.2 MHz, 26 MHz, or other frequencies).

7.4.1 USEC_CFG Register

Software should first configure this register by telling what fraction of 1 microsecond each oscillator clock represents. For example, if the oscillator clock is running at 12 MHz, then each oscillator clock represents 1/12 of a micro-second.

"USEC_DIVIDEND" and "USEC_DIVISOR" are used to indicate what fraction of 1 microsecond each oscillator clock represents.

Table 22 Oscillator Clock Frequency Indicator for USEC

Oscillator Clock Frequency	Dividend/Divisor	USEC_DIVIDEND/USEC_DIVISOR
12 MHz	1/12	0x00 / 0x0b
13 MHz	1/13	0x00 / 0x0c
19.2 MHz	5/96	0x04 / 0x5f
26 MHz	1/26	0x00 / 0x19
16.8 MHz	5/84	0x04 / 0x53
38.4 MHz	5/192	0x04 / 0xbf
48 MHz	1/48	0x00 / 0x2f

7.5 CNTR_1US Register

This free-running read-only register/counter changes once every micro-second and is used mainly by hardware (can also be used by software). It starts counting from 0 once it's out of system reset and will continue counting forever, unless the oscillator clock is stopped or during a system reset.

(A) Software Use

Although there's no interrupt mechanism for this register, software can read the content of this register multiple times to determine the amount of time that has elapsed.

(B) Hardware Use

- Used by the 4 timers to determine whether the programmed timer value has been reached; these 4 timers can trigger interrupts.
- To provide a periodic USEC pulse to be used by the flow controller to count the programmable number of micro-second before a flow control condition is triggered.
- Used by secure boot logic.

7.5.1 TIMERUS_CNTR_1US_0

Offset: 000h | Read/Write: RO | Reset: 0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx

Bit	Reset	Description
31:16	x	HIGH_VALUE: Elapsed time in micro-second
15:0	x	LOW_VALUE: Elapsed time in micro-second

7.5.2 TIMERUS_USEC_CFG_0

Offset: 004h | Read/Write: R/W | Reset: 0b0000000000001100

Bit	Reset	Description
15:8	0x0	USEC_DIVIDEND: usec dividend. (n+1)
7:0	0xc	USEC_DIVISOR: usec divisor. (n+1)

7.5.3 TIMERUS_CNTR_FREEZE_0

The timer disable logic freezes (stops incrementing or decrementing) the timer counters when one or both of the ARM cores enters debug state. The timers remain frozen while either core is in debug state or its freeze enable bit is asserted:

freeze = (cpu_timer_freeze && cpu_debug_state) || (cop_timer_freeze && cop_debug_state)

Offset: 03ch | Read/Write: R/W | Reset: 0b00000

Bit	Reset	Description
4	0x0	DBG_FREEZE_COP: 1 = freeze timers when COP is in debug state, 0 = no freeze.
3	0x0	DBG_FREEZE_CPU3: 1 = freeze timers when CPU3 is in debug state, 0 = no freeze.
2	0x0	DBG_FREEZE_CPU2: 1 = freeze timers when CPU2 is in debug state, 0 = no freeze.
1	0x0	DBG_FREEZE_CPU1: 1 = freeze timers when CPU1 is in debug state, 0 = no freeze.
0	0x0	DBG_FREEZE_CPU0: 1 = freeze timers when CPU0 is in debug state, 0 = no freeze.

7.6 WatchDog Timers

- WDT0 dedicated to CPU0 (either cluster)
- WDT1 dedicated to CPU1
- WDT2 dedicated to CPU2
- WDT3 dedicated to CPU3
- WDT4 dedicated to COP (AVP)

Offset relative to TMR block base.

Each Watchdog timer has the following registers

- Timer sources are numbers 1 thru 10.
- 0 not used and results in undefined behavior
- Period of 0 results in MAX period
- The generated interrupt is dependent on WD index.
- WD0 to 3 generate a CPU_WD_Interrupt,
- WD4 generates a COP_WD_Interrupt
- CPU0 settings apply to both clusters
- Core numbering: 0-3 applies to CPU0-CPU3, 4 applies to COP

7.6.1 TIMER_WDT0_CONFIG_0

Core Watchdog Configuration Register

Offset: 100h | Read/Write: R/W | Reset: 0b00000000000000000000

Bit	Reset	Description
20:16	0x0	CoreResetBitmapEn: Enable reset of a set of cores at 3rd expiration counter (one bit per proc) same level the signal from PMC asserted in case of external reset.
15	0x0	Pmc2CarResetEn: Enable Full system reset at 4th expiration of the counter, at 0 = DISABLE 1 = ENABLE
14	0x0	SystemResetEnable: Enable system reset at 4th expiration of the counter, at same level as existing watchdog interrupt 0 = DISABLE 1 = ENABLE
13	0x0	FIQEnable: Enable FIQ assertion at 2nd expiration of the counter 0 = DISABLE 1 = ENABLE
12	0x0	InterruptEnable: Enable interrupt at first expiration of the counter 0 = DISABLE 1 = ENABLE
11:4	0x0	Period: Measured in periods of selected timer, this is reload value
3:0	0x0	TimerSource: Select the timer used as reference (1..10) 0 = TMR0 1 = TMR1 2 = TMR2 3 = TMR3 4 = TMR4 5 = TMR5 6 = TMR6 7 = TMR7 8 = TMR8 9 = TMR9

7.6.2 TIMER_WDT0_STATUS_0

Core Watchdog Status

Offset: 104h | Read/Write: RO | Reset: 0bxxxxxxxxxxxxxxx

Bit	Reset	Description
13:12	X	CurrentExpirationCount: Current count of expiration since the last start of expiration
11:4	X	CurrentCount: Current value of the counter
2	X	FiqStatus: Current status of FIQ, cleared by start
1	X	InterruptStatus: Current status of interrupt, cleared by start
0	X	Enabled: 1 when counter is active. When true, writes to corresponding config reg are ignored

7.6.3 TIMER_WDT0_COMMAND_0

When the StartCounter bit is set, it enables the counter operation, loads the counter with Period and starts downcounting, resets the expiration count to 0 and clears all flags. Also used as restart.

The counter can be disabled by setting the DisableCounter bit, but only if the unlock register has been programmed before with the correct pattern. Writing to the command register always clears the disable unlock register. When set while StartCounter is 0 and the unlock register contains the unlock pattern the Watchdog transitions back to disabled.

The register fields are Write to set only.

CoreWatchdogCommand Register

Offset: 108h | Read/Write: R/W | Reset: 0b00

Bit	Reset	Description
1	0x0	DisableCounter: Write 1 to disable WDT counter if unlocked
0	0x0	StartCounter: Write 1 to enable WDT counter

7.6.4 TIMER_WDT0_UNLOCK_PATTERN_0

CoreWatchdogDisableUnlock Register

When the StartCounter bit is set, it enables the counter operation, loads the couner with Period and starts downcounting, resets the expiration count to 0 and clears all flags. Also used as restart.

The counter can be disabled by setting the DisableCounter bit, but only if the unlock register has been programmed before with the correct pattern. Writing to the command register always clears the disable unlock register. When set while StartCounter is 0 and the unlock register contains the unlock pattern the Watchdog transitions back to disabled.

Offset: 10ch | Read/Write: R/W | Reset: 0b0000000000000000

Bit	Reset	Description
15:0	0x0	UnlockPattern: Must be written with value 0xC45A to allow write to DisableCounter to take effect. The pattern is reset at each write to Command Reg.

7.6.5 TIMER_WDT1_CONFIG_0

Offset: 120h | Read/Write: R/W | Reset: 0b00000000000000000000

Bit	Reset	Description
20:16	0x0	CoreResetBitmapEn: Enable reset of a set of cores at 3rd expiration counter (one bit per proc) same level the signal from PMC asserted in case of external reset.
15	0x0	Pmc2CarResetEn: Enable Full system reset at 4th expiration of the counter, at 0 = DISABLE 1 = ENABLE
14	0x0	SystemResetEnable: Enable system reset at 4th expiration of the counter, at same level as existing watchdog interrupt 0 = DISABLE 1 = ENABLE
13	0x0	FIQEnable: Enable FIQ assertion at 2nd expiration of the counter 0 = DISABLE 1 = ENABLE

Bit	Reset	Description
12	0x0	InterruptEnable: Enable interrupt at first expiration of the counter 0 = DISABLE 1 = ENABLE
11:4	0x0	Period: Measured in periods of selected timer, this is reload value
3:0	0x0	TimerSource: Select the timer used as reference (1..10) 0 = TMR0 1 = TMR1 2 = TMR2 3 = TMR3 4 = TMR4 5 = TMR5 6 = TMR6 7 = TMR7 8 = TMR8 9 = TMR9

7.6.6 TIMER_WDT1_STATUS_0

CoreWatchdogStatus

Offset: 124h | Read/Write: RO | Reset: 0bxxxxxxxxxxxxxx

Bit	Reset	Description
13:12	X	CurrentExpirationCount: Current count of expiration since the last start of expiration
11:4	X	CurrentCount: Current value of the counter
2	X	FiqStatus: Current status of FIQ, cleared by start
1	X	InterruptStatus: Current status of interrupt, cleared by start
0	X	Enabled: 1 when counter is active. When true, writes to corresponding config reg are ignored

7.6.7 TIMER_WDT1_COMMAND_0

CoreWatchdogCommand Register

Offset: 128h | Read/Write: R/W | Reset: 0b00

Bit	Reset	Description
1	0x0	DisableCounter: Write 1 to disable WDT counter if unlocked
0	0x0	StartCounter: Write 1 to enable WDT counter

7.6.8 TIMER_WDT1_UNLOCK_PATTERN_0

CoreWatchdogDisableUnlock Register

Offset: 12ch | Read/Write: R/W | Reset: 0b0000000000000000

Bit	Reset	Description
15:0	0x0	UnlockPattern: Must be written with value 0xC45A to allow write to DisableCounter to take effect. The pattern is reset at each write to Command Reg.

7.6.9 TIMER_WDT2_CONFIG_0

Offset: 140h | Read/Write: R/W | Reset: 0b00000000000000000000

Bit	Reset	Description
20:16	0x0	CoreResetBitmapEn: Enable reset of a set of cores at 3rd expiration counter (one bit per proc) same level the signal from PMC asserted in case of external reset.
15	0x0	Pmc2CarResetEn: Enable Full system reset at 4th expiration of the counter, at 0 = DISABLE 1 = ENABLE
14	0x0	SystemResetEnable: Enable system reset at 4th expiration of the counter, at same level as existing watchdog interrupt 0 = DISABLE 1 = ENABLE
13	0x0	FIQEnable: Enable FIQ assertion at 2nd expiration of the counter 0 = DISABLE 1 = ENABLE
12	0x0	InterruptEnable: Enable interrupt at first expiration of the counter 0 = DISABLE 1 = ENABLE
11:4	0x0	Period: Measured in periods of selected timer, this is reload value
3:0	0x0	TimerSource: Select the timer used as reference (1..10) 0 = TMR0 1 = TMR1 2 = TMR2 3 = TMR3 4 = TMR4 5 = TMR5 6 = TMR6 7 = TMR7 8 = TMR8 9 = TMR9

7.6.10 TIMER_WDT2_STATUS_0

CoreWatchdogStatus

Offset: 144h | Read/Write: RO | Reset: 0bxxxxxxxxxxxxxx

Bit	Reset	Description
13:12	X	CurrentExpirationCount: Current count of expiration since the last start of expiration
11:4	X	CurrentCount: Current value of the counter

Bit	Reset	Description
2	X	FiqStatus: Current status of FIQ, cleared by start
1	X	InterruptStatus: Current status of interrupt, cleared by start
0	X	Enabled: 1 when counter is active. When true, writes to corresponding config reg are ignored

7.6.11 TIMER_WDT2_COMMAND_0

CoreWatchdogCommand Register

Offset: 148h | Read/Write: R/W | Reset: 0b00

Bit	Reset	Description
1	0x0	DisableCounter: Write 1 to disable WDT counter if unlocked
0	0x0	StartCounter: Write 1 to enable WDT counter

7.6.12 TIMER_WDT2_UNLOCK_PATTERN_0

CoreWatchdogDisableUnlock Register

Offset: 14ch | Read/Write: R/W | Reset: 0b0000000000000000

Bit	Reset	Description
15:0	0x0	UnlockPattern: Must be written with value 0xC45A to allow write to DisableCounter to take effect. The pattern is reset at each write to Command Reg.

7.6.13 TIMER_WDT3_CONFIG_0

CoreWatchdogConfiguration Register

Offset: 160h | Read/Write: R/W | Reset: 0b00000000000000000000

Bit	Reset	Description
20:16	0x0	CoreResetBitmapEn: Enable reset of a set of cores at 3rd expiration counter (one bit per proc) same level the signal from PMC asserted in case of external reset.
15	0x0	Pmc2CarResetEn: Enable Full system reset at 4th expiration of the counter, at 0 = DISABLE 1 = ENABLE
14	0x0	SystemResetEnable: Enable system reset at 4th expiration of the counter, at same level as existing watchdog interrupt 0 = DISABLE 1 = ENABLE
13	0x0	FIQEnable: Enable FIQ assertion at 2nd expiration of the counter 0 = DISABLE 1 = ENABLE
12	0x0	InterruptEnable: Enable interrupt at first expiration of the counter 0 = DISABLE 1 = ENABLE

Bit	Reset	Description
11:4	0x0	Period: Measured in periods of selected timer, this is reload value
3:0	0x0	TimerSource: Select the timer used as reference (1..10) 0 = TMR0 1 = TMR1 2 = TMR2 3 = TMR3 4 = TMR4 5 = TMR5 6 = TMR6 7 = TMR7 8 = TMR8 9 = TMR9

7.6.14 TIMER_WDT3_STATUS_0

CoreWatchdogStatus

Offset: 164h | Read/Write: RO | Reset: 0bxxxxxxxxxxxxxx

Bit	Reset	Description
13:12	X	CurrentExpirationCount: Current count of expiration since the last start of expiration
11:4	X	CurrentCount: Current value of the counter
2	X	FiqStatus: Current status of FIQ, cleared by start
1	X	InterruptStatus: Current status of interrupt, cleared by start
0	X	Enabled: 1 when counter is active. When true, writes to corresponding config reg are ignored

7.6.15 TIMER_WDT3_COMMAND_0

CoreWatchdogCommand Register

Offset: 168h | Read/Write: R/W | Reset: 0b00

Bit	Reset	Description
1	0x0	DisableCounter: Write 1 to disable WDT counter if unlocked
0	0x0	StartCounter: Write 1 to enable WDT counter

7.6.16 TIMER_WDT3_UNLOCK_PATTERN_0

CoreWatchdogDisableUnlock Register

Offset: 16ch | Read/Write: R/W | Reset: 0b0000000000000000

Bit	Reset	Description
15:0	0x0	UnlockPattern: Must be written with value 0xC45A to allow write to DisableCounter to take effect. The pattern is reset at each write to Command Reg.

7.6.17 TIMER_WDT4_CONFIG_0

Offset: 180h | Read/Write: R/W | Reset: 0b00000000000000000000

Bit	Reset	Description
20:16	0x0	CoreResetBitmapEn: Enable reset of a set of cores at 3rd expiration counter (one bit per proc) same level the signal from PMC asserted in case of external reset.
15	0x0	Pmc2CarResetEn: Enable Full system reset at 4th expiration of the counter, at 0 = DISABLE 1 = ENABLE
14	0x0	SystemResetEnable: Enable system reset at 4th expiration of the counter, at same level as existing watchdog interrupt 0 = DISABLE 1 = ENABLE
13	0x0	FIQEnable: Enable FIQ assertion at 2nd expiration of the counter 0 = DISABLE 1 = ENABLE
12	0x0	InterruptEnable: Enable interrupt at first expiration of the counter 0 = DISABLE 1 = ENABLE
11:4	0x0	Period: Measured in periods of selected timer, this is reload value
3:0	0x0	TimerSource: Select the timer used as reference (1..10) 0 = TMR0 1 = TMR1 2 = TMR2 3 = TMR3 4 = TMR4 5 = TMR5 6 = TMR6 7 = TMR7 8 = TMR8 9 = TMR9

7.6.18 TIMER_WDT4_STATUS_0

CoreWatchdogStatus

Offset: 184h | Read/Write: RO | Reset: 0bxxxxxxxxxxxxxx

Bit	Reset	Description
13:12	X	CurrentExpirationCount: Current count of expiration since the last start of expiration
11:4	X	CurrentCount: Current value of the counter
2	X	FiqStatus: Current status of FIQ, cleared by start
1	X	InterruptStatus: Current status of interrupt, cleared by start
0	X	Enabled: 1 when counter is active. When true, writes to corresponding config reg are ignored

7.6.19 TIMER_WDT4_COMMAND_0

CoreWatchdogCommand Register

Offset: 188h | Read/Write: R/W | Reset: 0b00

Bit	Reset	Description
1	0x0	DisableCounter: Write 1 to disable WDT counter if unlocked
0	0x0	StartCounter: Write 1 to enable WDT counter

7.6.20 TIMER_WDT4_UNLOCK_PATTERN_0

CoreWatchdogDisableUnlock Register

Offset: 18ch | Read/Write: R/W | Reset: 0b0000000000000000

Bit	Reset	Description
15:0	0x0	UnlockPattern: Must be written with value 0xC45A to allow write to DisableCounter to take effect. The pattern is reset at each write to Command Reg.

7.7 Timer Shared Interrupt Status

TimerSrcBitmap is used for Timers 6 thru 10 which share a common interrupt line to the controller. Bit b is set if timer 6+b generated an interrupt. The corresponding bit is cleared by writing INTR_CLR bit of the TMR_PCR register.

WatchdogSrcBitmap is used for the 5 watchdog timers. This is the set of Interrupt Status bits from the corresponding CoreWatchdogStatus, but as a bitmap.

7.7.1 SHARED_INTR_STATUS_0

Offset: 000h | Read/Write: RO | Reset: 0bxxxxxxxxxxx

Bit	Reset	Description
10:6	X	TimerSrcBitmap: Timer[0,9:6] interrupt status in bitmap form
4:0	X	WatchdogSrcBitmap: WDT[4:0] interrupt status in bitmap form

8.0 MULTI-PURPOSE I/O PINS AND PIN MULTIPLEXING (PINMUXING)

Note: PRELIMINARY pending review

8.1 Overview

Many of the pins on Tegra® 3 devices are connected to multi-purpose I/O (MPIO) pads. Each MPIO can function as a GPIO. Additionally, each MPIO supports up to four Special-Function I/O (SFIO) roles. For example, the ball named LCD_CS0_N can act as the following:

- A GPIO
- The signal LCSN for the first LCD controller
- The signal LCSN for the second LCD controller
- The signal CS2 for SPI5A (i.e. interface A of SPI controller 5)

Though each MPIO has up to 5 functions (a GPIO function and up to 4 SFIO functions), a given MPIO can only act as a single function at a given point in time. The pinmux controller on Tegra 3 devices includes the “pin multiplexing” logic and registers to select a particular function for each MPIO.

This section describes the following features of MPIOs and the pinmux controller:

- Basic capabilities of the MPIO pads
- Differences between the variety of MPIO pads
- Mapping of MPIO pads to I/O controllers (i.e. pinmuxing)
- Behavior of the MPIO pads during power-up
- Behavior of the MPIO pads before, during, and after deep sleep and
- Recommendations for software programming related to the MPIO pads.

This section covers Tegra 3 technology Multi-Purpose digital I/O pads. It does not address the special-purpose I/O pads on Tegra 3 devices such as those used for USB, IC_USB, SATA, PCIE, TVO/DAC, MIPI DSI, MIPI CSI, the oscillator, or DRAM interfaces.

8.2 Terms and Acronyms

Some common terms used with Tegra 3 processor pinmuxing are as follows:

- MPIO = Multi-Purpose I/O
- GPIO = General-Purpose I/O
- SFIO = Special-Function I/O
- ST = Standard MPIO pads
- DD = Dual-driver MPIO pads
- OD = Open-drain MPIO pads
- CZ = Controlled-output impedance MPIO pads
- LV = Low-voltage MPIO pads
- Deep sleep

8.3 MPIO Pad Description

Each MPIO pad consists of

- An output driver with
  - Tristate capability
  - drive strength controls AND
  - push-pull mode, open-drain mode, or both
- An input receiver with
  - Either Schmitt mode, CMOS mode, or both
- A weak pull-up and a weak pull-down

Though each MPIO pad shares a similar structure, there are in fact several varieties of such pads. The varieties are designed to minimize the number of on-board components (such as level shifters or pull-up resistors) required in designs based on the Tegra 3 devices. The following table summarizes the differences between the five MPIO pad types.

Table 23: MPIO Pad Types

Pad Type	I.O rail voltage	Input Buffer	Output Buffer	I/O voltage tolerance	Nominal Pull Strength	"Slew Rate" Control	Drive Strength Control
CZ	1.8, 2.8-3.3	Schmitt & CMOS	push-pull	VDDIO	15 kΩ	2 bits, up & down	7 bits, up & down
DD	1.8, 2.8-3.3	Schmitt & CMOS	push-pull & open-drain	3.3V for open-drain, VDDIO otherwise	50 kΩ	2 bits, up & down	5 bits, up & down. LPMD
LV	1.2, 1.8	CMOS	push-pull	VDDIO	15 kΩ	4 bits, up & down	5 bits, up & down
OD	1.8, 2.8-3.3	Schmitt & CMOS	open-drain	5V	100 kΩ -- down only	2 bits, down only	5 bits, down only. LPMD
ST	1.8, 2.8-3.3	Schmitt & CMOS	push-pull	VDDIO	50 kΩ or 100 kΩ	2 bits, up & down	5 bits, up & down. LPMD

The ST (standard) MPIO pads are the most common pads on the chip.

The DD (dual-driver) MPIO pads are similar to the ST pads with the addition of a 3.3V tolerant true open-drain mode. A DD pad can tolerate its I/O pin being pulled to 3.3V (regardless of supply voltage) as long as the pad's output-driver is set to open-drain mode. During power-up sequencing, do NOT pull up a DD pad's IO until after both VDD_CORE and VDD_RTC are powered.

Note: Refer to Section 2.5, Power Sequencing, in *NVIDIA Tegra 3 Mobile Quad-Core Processors Data Sheet* (DS-05160) for a complete description of the power-up sequencing requirements for Tegra 3 processors.

The OD (open drain) MPIO pads are optimized to tolerate 5V on the IO pin regardless of the supply voltage. They are similar to ST pads except for an improved I/O voltage tolerance, the absence of a weak pull-up, and the absence of a push-pull output driver.

The CZ (controlled output impedance) MPIO pads are similar to the ST pads except for changes in the drive strength circuitry and in the weak pull-ups/pull-downs. Tegra 3 processors include CZ pads on the VDDIO_SDMMC1 and VDDIO_SDDMC3 power rails. Each of those rails also includes a pair of SDMEMCOMP pads. When the CZ pads are used with an SDMMC controller, a state machine within the SDMMC controller can adjust the output impedance of the CZ pads to match the resistors attached to the corresponding SDMEMCOMP pads.

Note: See SDMMC_SDMEMCOMPPADCTRL_0 in SDMMC section of this document, for more information.

The LV (low voltage) MPIO pads are optimized for use with a 1.2V supply voltage (and signaling level). They support a 1.8V supply voltage (and signaling level) as a secondary mode. The Tegra 3 processors include LV pads on the VDDIO_SDMMC4

and VDDIO_VI power rails. Each of those rails also includes LV_VTTGEN cells designed to protect the LVDIO pads from damage when the supply voltage is 1.8V.

Note: Refer to Section 4.2.1, Multi-Purpose I/O Pads, in *NVIDIA Tegra 3 Mobile Quad-Core Processors Data Sheet* (DS-05160) for the list of the pad type, the nominal pull-up/-down strength, and the IO power rail information associated with each MPIO. See the columns labeled “Pad Type”, “Pull Strength”, and “Power Rail.”

8.4 Pad Controls

The Tegra 3 devices include many controls for each MPIO pad. Some of these controls can be set on a per-pin basis. Other controls are shared across multiple pins.

The following controls can be independently configured on a per-pad basis

PUPD	Internal Pull-up/down option: Option to enable internal Pull-up, Pull-down resistors or neither
TRISTATE	Tristate (high-z) option: Disables or enables the pad’s output driver
E_INPUT	Input Receiver (Enable/Disable): Enables or disables input receiver.
OD	Open Drain option: (applies to DD pads only) Selects between open-drain output driver and push-pull driver.
IO_RESET	Input/Output Reset: (applies to LV pads only). See section 8.8.5

During normal operation, these per-pad controls are driven by the pinmux controller registers. See the section called “Pinmuxing” below for more information.

During deep sleep, PMC bypasses and then resets the pinmux controller registers. Software should reprogram these registers as necessary after returning from deep sleep.

The MPIO pads are partitioned into 41 “pad control groups”. The following controls can be configured independently for each pad control group.

HSM	High Speed Mode (Enable/Disable)
SCHMT	Schmitt Trigger (Enable/Disable): (Not applicable to LV pads)
LPMD	Low Power Mode
DRVDN / UP	Drive Down / Up
SLWR/ SLWF	Slew Falling / Rising

The controls are configured via the “pad control registers”. There is one pad control register per pad control group. During deep sleep, all of these pad control registers automatically return to their power-on-reset state. Software should reprogram these registers as necessary following deep sleep.

Table 24 lists the register address for each pad control group. Additionally, the table describes the bit positions of the controls within each register.

Table 26 lists the pad control group for each MPIO.

For example, writing a 1 to bit 3 of register 0x700000884 will enable the Schmitt trigger mode for the pads in group “cdev1cfg” pins, CLK1_OUT and CLK1_REQ. Similarly, clearing bits 14 through 23 of register 0x70000900 will minimize the drive strength (both up and down) of pads in the gmacfg pad control group.

Table 24. Pad Control Groups Register Addresses

Pad Control Group	Register Address	HSM	SCHMT	LPMD	DRVDN	DRVUP	SLWR	SLWF

gmhcfg	0x7000091c	2	3	5:4	18:14	23:19	29:28	31:30

Note: The “dbgcfg” pad control group includes pads on both the VDDIO_SYS and VDDIO_UART power rails. Consider tying those two rails together if accurate drive strength is required.

Note: The “uabcfg” pad control group includes pads on the VDDIO_BB power rail and two pads on the VDDIO_SDMMC1 rail. Consider tying those two rails together (or not using the affected VDDIO_SDMMC1 pads) if accurate drive strength is required.

8.5 Pinmuxing

Tegra 3 processors include many types of IO controllers (such as I2C, SDMMC, NAND, and GMI). For some of these controller types, Tegra 3 processors include multiple “controller instances”. For example, Tegra 3 processors include five I2C controller instances.

Each controller instance on a Tegra 3 processor communicates with external devices via a set of “external signals”. For each controller instance, each signal can be brought out on (at least) one MPIO. For example, each I2C controller has two external signals: CLK and DAT. The CLK signal of the I2C1 controller is available on the MPIO whose ball name is GEN1_I2C_SCL.

Though each MPIO has up to five functions (such as a GPIO function and up to four SFIO functions), a given MPIO can only act as a single function at a given point in time. The pinmux controller on a Tegra 3 device includes the logic and registers to select a particular function for each MPIO.

Some controller instances have a particular signal available on more than one MPIO. **Before using any controller, make sure that the pinmux registers are programmed to bring each signal out on at most ONE MPIO.** For example, UART1’s TXD signal is available on the MPIO’s whose ball names are GPIO_PU1, UART2_RTS_N, ULPIO_DATA0, etc. In a system which brings out UART1’s TXD signal on the GPIO_PU1 ball, the pinmux registers for UART2_RTS_N and ULPI_DATA0 should be programmed to select some other signal.

Some controller instances make their entire set of signals available on two or more sets of MPIO’s. To say it another way, such controllers have more than one “interface”. **Before using any controller, make sure that the pinmux registers are programmed to bring out the controller’s signals on at most ONE interface.** For example, the SDMMC4 controller has two interfaces – SDMMC4A and SDMMC4B. In a system which uses the SDMMC4A interface, all of the pinmux controller registers should be programmed to avoid selecting any signal from the SDMMC4B interface.

The pinmux controller includes one register per MPIO. Note that this is a significant change from Tegra 2 devices. In Tegra 2 devices, pinmuxing operated on a per-group basis. In Tegra 3 devices, it can be controlled on a per-pin basis.

Table 25 describes the layout of each pinmux controller register. Refer to the Excel spreadsheet, *Tegra 3 PinMux* (DA-05692) for a list of the pinmux register address and the default values for the pinmux register fields for each MPIO. See the columns labeled “pinmux register”, “PINMUX”, “TRISTATE”, “E_INPUT”, and “PUPD”.

Table 26 provides the register address for each pad that can be used for pinmuxing. It also lists the pad control group for each pad.

Figure 8 shows the pinmux logic associated with a single MPIO.

Figure 8. Structure of Pinmux Controller (per MPIO)

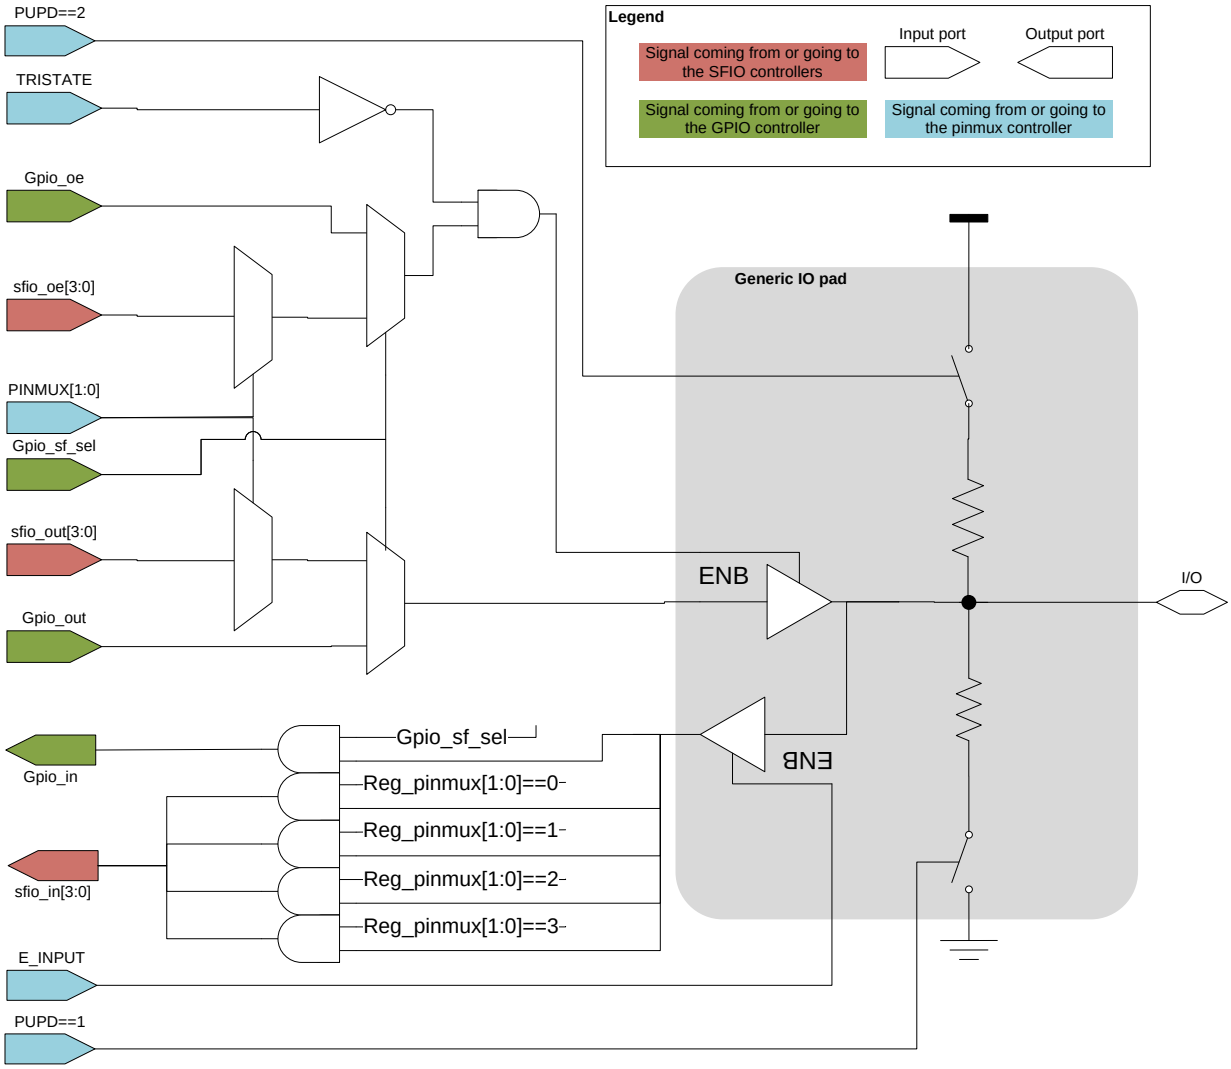

Table 25: Pinmux Register Format

Field Name	Bit Position	Default Value	Description
IO_RESET	8	LV pads: 1	Software should clear this bit after correctly programming the relevant E_18V bit in PMC. See the section in this chapter called “VDDIO_VI, VDDIO_SDMMC4, PMC, and IO_RESET” for more information.
		Other pads: 0	This bit only matters for LV pads. It is not implemented for other MPIO pad types.
LOCK	7	0	0: Writes to this register are accepted 1: Writes to this register are ignored (until the next wake from Deep Sleep) This is a sticky bit. Once software sets this bit to 1, the only way to clear it is to reset the chip or enter & exit Deep Sleep.
E_OD	6	DD pads:1	0: the pad’s output driver operates in push-pull mode. 1: the pad’s output driver operates in open-drain mode. WARNING: the DD pads are only 3.3V tolerant when this bit is set. When this bit is cleared, the voltage tolerance is limited to the IO power supply voltage.
		Other pads: 0	This bit only matters for DD pads. It is not implemented for other MPIO pad types.
E_INPUT	5	Refer to the Excel spreadsheet, *Tegra 3 PinMux* (DA-05692)	0: the pad’s input receiver is disabled. 1: the pad’s input receiver is enabled.
TRISTATE	4	Refer to the Excel spreadsheet, *Tegra 3 PinMux* (DA-05692)	0: the pad’s output driver is enabled. 1: the pad’s output driver is disabled (i.e. the output driver is in a high-impedance state).
PUPD	3:2	Refer to the Excel spreadsheet, *Tegra 3 PinMux* (DA-05692)	0: the pad’s weak pull-up and pull-down are both disabled 1: the pad’s weak pull-down is enabled and the weak pull-up is disabled. 2: the pad’s weak pull-up is enabled and the weak pull-down is disabled. 3: this is an illegal combination.
PINMUX	1:0	Refer to the Excel spreadsheet, *Tegra 3 PinMux* (DA-05692)	0: set the pinmux logic for SFIO0. 1: set the pinmux logic for SFIO1. 2: set the pinmux logic for SFIO2. 3: set the pinmux logic for SFIO3. Note that the choice between SFIO and GPIO is controlled via the GPIO registers.

Refer to the Excel spreadsheet, *Tegra 3 PinMux* (DA-05692) for a list of the SFIO functions supported by each MPIO on Tegra 3 devices. Each SFIO is listed in the table with the following format: <ControllerType><ControllerInstance><InterfaceLetter>-<Signal>

- **ControllerType** indicates the type of IO controller associated with this SFIO function
- **ControllerInstance** indicates the IO controller if the Tegra 3 processor has more than one I/O controller of the specified type
- **InterfaceLetter** differentiates between the pin sets If the controller instance can connect to more than one set of pins
- **Signal** identifies the particular role this SFIO plays for the I/O controller.

For some of the MPIOs, the hardware includes SFIO functions which are omitted from the spreadsheet. Many of these are deprecated. Contact NVIDIA for more information.

8.6 Deep Sleep Behaviors

Deep Sleep is an ultra-low-power standby state in which a Tegra 3 device maintains much of its IO state while most of the chip is powered off. The following lists offer a simplified description of the deep sleep entry and exit concentrating on those aspects which relate to the MPIO pads.

8.6.1 Deep Sleep Entry

The steps to enter deep sleep are as follows:

1. Software programs PMC to enter deep sleep
2. PMC latches much of the Tegra 3 device's I/O state, takes control of the I/O's, and resets the I/O controllers
3. PMC deasserts CORE_PWR_REQ
4. The PMU/PMIC powers down VDD_CORE
5. PMC continues driving the IO state that it has latched

> **Note:** For more information about deep sleep entry, refer to Section 2.5.3 in *NVIDIA Tegra 3 Mobile Quad-Core Processors Data Sheet* (DS-05160).

8.6.2 Deep Sleep Exit

1. PMC detects a wake event (for example, a rising edge on an appropriately configured MPIO)
2. PMC asserts CORE_PWR_REQ
3. The PMU/PMIC powers up VDD_CORE
4. PMC resets the logic within VDD_CORE

5. PMC yields control of some of the MPIO's to the I/O controllers (note that the controllers are in a power-on-reset state.)
6. The boot ROM executes and wakes up software
7. Software re-initializes the I/O controllers
8. When software requests, PMC yields control of the remaining MPIO's to the I/O controllers.

> **Note:** For more information about deep sleep exits, refer to Section 2.5.4 in *NVIDIA Tegra 3 Mobile Quad-Core Processors Data Sheet* (DS-05160).

8.6.3 Pad Capabilities During Deep Sleep

The MPIO pads do not all have identical behavior during deep sleep. They differ with regards to

- Output buffer behavior during deep sleep:
  - Does it maintain a programmable (0, 1, or tristate) constant value.
  - Is it capable of changing state while the chip is still in deep sleep (for example, a pin related to the keyboard controller)?
- Input buffer behavior during deep sleep:
  - Is it forcibly disabled OR
  - Can it be enabled for use as a "GPIO wake event" OR
  - Can it be enabled for some other purpose (for example, a "clock request" pin)?
- Weak pull-up/pull-down behavior during deep sleep
  - Are they forcibly disabled OR
  - Can they be configured?
- Behavior coming out of deep sleep
  - Does it maintain its deep sleep state until software requests OR
  - Does PMC forcibly return the pad to its power-on-reset state before software is running?

Refer to Section 4.2.1, Multi-Purpose I/O Pads, in the document entitled *NVIDIA Tegra 3 Mobile Quad-Core Processors Data Sheet* (DS-05160) for a summary of the capabilities of each MPIO during deep sleep. See the columns labeled "Output Buffer", "Input Buffer", "Weak PU/PD", and "After Wake". The following sections describe in more detail how to interpret those columns.

8.6.3.1 OUTPUT Buffers During Deep Sleep

The output buffers of most MPIO pads are "configurable" during deep sleep. Immediately prior to entering deep sleep, PMC latches the state of the output buffers for such pads. If the pad was driving high (or low) prior to entering deep sleep, PMC ensures that it continues to drive high (or low) throughout deep sleep. If the pad was tri-stated during deep sleep, PMC ensures that it remains tri-stated throughout deep sleep.

Some MPIO pads have an output buffer which behaves in a "special" way during deep sleep. The output state of these pads may change while Tegra 3 device remains in deep sleep. For example, the keyboard controller may continue scanning the keypad matrix during deep sleep.

8.6.3.2 Input Buffers During Deep Sleep

The input buffers of most MPIO pads are "disabled" during deep sleep. The input buffers are placed in an ultra-low power state. The Tegra 3 device will not respond to transitions on these pads while it is in deep sleep.

Some MPIO pads have an input buffer which has a “special” behavior during deep sleep. Most of these pads can act as “Deep Sleep Wake Sources”. Others offer some other functional behavior. For example CLK_REQ1 can function as a clock request pin even during deep sleep.

8.6.3.3 Pull-Ups/-Downs During Deep Sleep

The weak pull-ups and pull-downs of most of the MPIO pads are “disabled” during deep sleep to reduce the Tegra 3 device’s static current consumption. For the remainder of the MPIO pads, the weak pull-up and pull-down are “configurable” during deep sleep. If the pull-up (or pull-down) was enabled prior to entering deep sleep, PMC ensures that it remains enabled throughout deep sleep. Similarly, if the pull-up (or pull-down) was disabled prior to entering deep sleep, PMC ensures that it remains enabled throughout deep sleep.

8.6.3.4 Behavior During Deep Sleep Exit

Many of the MPIO pads “reset” to their power-on-reset state as part of the deep sleep exit procedure. For such pads, it is advisable to ensure that their output state during deep sleep matches their power-on-reset state. Otherwise, the pad outputs might glitch during a wake from deep sleep.

The rest of the MPIO pads “hold” their deep sleep state until system-dependent software de-asserts the TRISTATE bit in the associated pinmux controller registers. This gives software the opportunity to re-initialize the pinmux and IO controllers without any glitches in the state of the MPIO pads.

8.7 GPIO Controller

The GPIO controller for Tegra 3 devices provides the tools for configuring each MPIO for use as a software-controlled GPIO.

The GPIO controller is divided into 8 banks. Each bank handles the GPIO functionality for up to 32 MPIO’s. Within a bank, the GPIO’s are arranged as four ports of 8-bits each. The ports are labeled consecutively from A through Z and then AA through FF. Ports A through D are in bank 0. Ports E through E are in bank 1.

> **Note:** Refer to Section 4.2.1, Multi-Purpose I/O Pads, in *NVIDIA Tegra 3 Mobile Quad-Core Processors Data Sheet* (DS-05160) for a map of each of the Tegra 3 device MPIO pads to a particular GPIO port and bit. See the column labeled “GPIO.”

Refer to the section on “GPIO controller” in this document for more information on Tegra’s GPIO controller capabilities.

8.8 Programming Considerations

8.8.1 Controller Instances with Multiple Pin-outs

Several of the IO controller instances on a Tegra 3 device have more than one pin-out. That is, the controller can communicate with the outside world via more than one set of pins. Special care is warranted when programming the pinmux controller for these SFIO’s. For a given signal on a given controller’s interface, only a single pin-out should be selected in the pinmux registers.

For example, TXD is an output signal from UART A. It is available on four pins: ULPI_DATA0, SDMMC3_CLK, GPIO_PU0, and UART2_RTS_N. Depending on the value programmed into the corresponding pinmux registers, each of those four pins might toggle when UART A transmits data.

Similarly, RXD is an input signal to UART A. It is available on four pins: ULPI_DATA1, SDMMC3_CMD, GPIO_PU1, and UART2_CTS_N. Depending on the value programmed into the corresponding pinmux registers, UART A might see the logical-OR of the signal on those four pins. This scenario will almost certainly lead to data corruption. If the UART A RXD signal is brought out on ULPI_DATA1, the pinmux registers for the other three pins should be programmed to some other function.

8.8.2 Resume From Deep Sleep

As the Tegra 3 device enters Deep Sleep, most of its register state is lost. In particular the pinmux, GPIO, and pad control registers lose their state during LP0. Software is responsible for reprogramming those registers upon resume from deep sleep.

8.8.3 Unused Pins

For each unused MPIO, assert its tristate and disable its input buffer. For pins whose internal pull-up is enabled during power-on-reset, assert the internal pull-up. Otherwise, assert the internal pull-down.

If all of the pins in a pad-control group are unused, set the drive strengths and slew rates to minimum.

If all of the pins on a power-rail are unused, assert E_NOIOPOWER for that rail in the PMC registers.

8.8.4 Drive Strengths

Using a weaker drive strength can reduce ringing which can reduce EMI and power dissipation.

8.8.5 VDDIO_VI, VDDIO_SDMMC4, PMC, and IO_RESET

Two power rails on the Tegra 3 devices, VDDIO_VI and VDDIO_SDMMC4, can operate at either 1.2V or 1.8V. VDDIO_VI and VDDIO_SDMMC4 supply power to LV (low voltage) MPIO pads.

To ensure the MPIOs on VDDIO_VI operate correctly at 1.2V, set bit 0 of APBDEV_PMC_DDR_PWR_0 to 0. To ensure the LV pads on VDDIO_SDMMC4 operate correctly at 1.2V, set bit 0 of APBDEV_PMC_DDR_PWR_0 to 1.

Bit 0 of APBDEV_PMC_DDR_PWR_0 **must** be set to 1 when VDD_VI is powered at 1.8V. Violating this constraint may permanently damage Tegra 3 device. Bit 1 of APBDEV_PMC_DDR_PWR_0 **must** be set to 1 when VDD_SDMMC4 is powered at 1.8V. Violating this constraint may permanently damage the Tegra 3 device.

The bits in APBDEV_PMC_DDR_PWR_0 reset to 1 during power-on-reset. This protects the chip from damage in case VDDIO_VI or VDDIO_SDMMC4 powers up at 1.8V. Early during boot, software should set APBDEV_PMC_DDR_PWR_0 to the appropriate values depending on the operating voltages of VDDIO_VI and VDDIO_SDMMC4. Once software has programmed APBDEV_PMC_DDR_PWR_0 correctly, software can clear the IO_RESET bits in the pinmux registers associated with LV pads.

APBDEV_PMC_DDR_PWR_0 is a register in the PMC. APBDEV_PMC_DDR_PWR_0 retains its state before, during, and after deep sleep. However, the pinmux registers (including their IO_RESET fields) lose their state during deep sleep. Software is responsible for reprogramming the pinmux registers upon resume from deep sleep.

Note: See the PMC section in this document for more information on APBDEV_PMC_DDR_PWR_0 and other PMC registers.

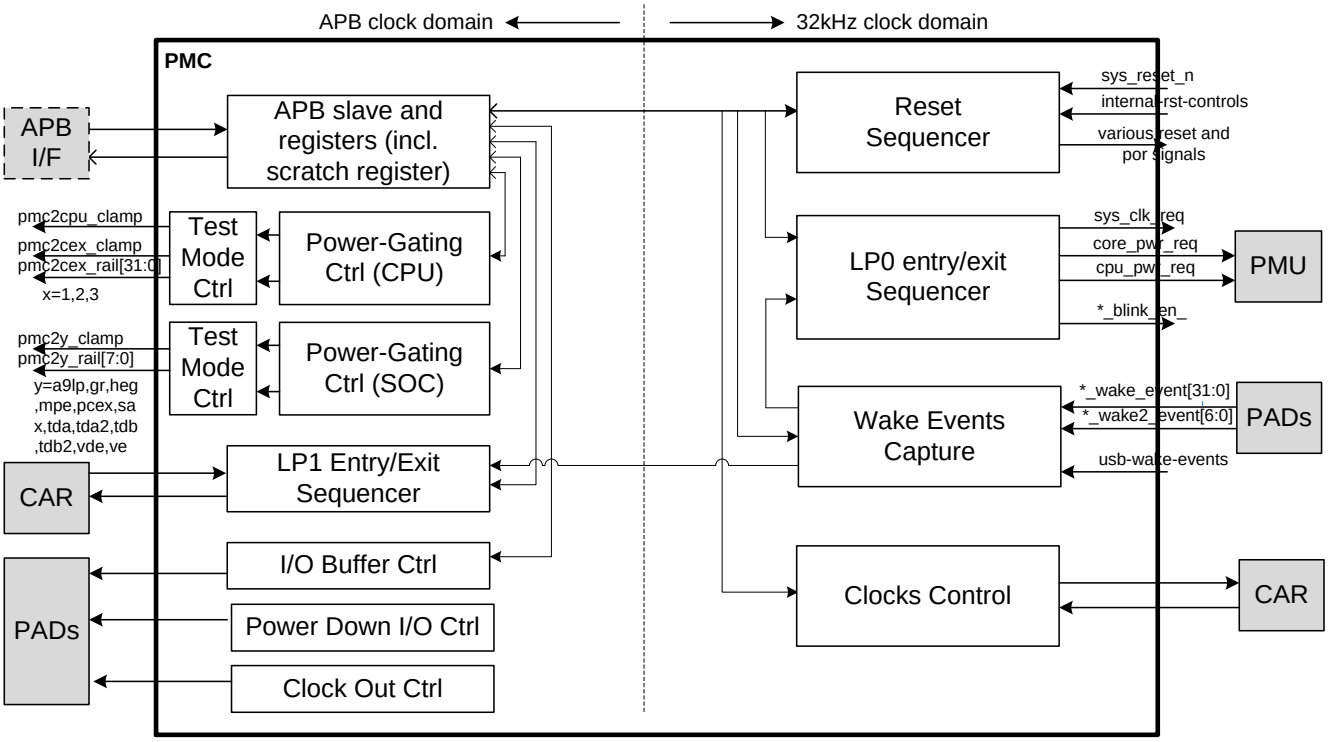
9.0 POWER MANAGEMENT CONTROLLER

Note: PRELIMINARY pending review

The Power Management Controller (PMC) block interacts with an external or Power Manager Unit (PMU). The PMC mostly controls the entry and exit of the system from different sleep modes. It provides power-gating controllers for SOC and CPU power-islands and also provides scratch storage to save some of the context during sleep modes (when CPU and/or SOC power rails are off). Additionally, PMC interacts with the external Power Manager Unit (PMU).

Sleep and deep sleep require specific logic to maintain some state and control the power domains, including signaling to the external PMU, to provide power to the main logic in the Tegra® 3 devices. All this logic is centralized in the PMC block.

Figure 9. PMC Block Diagram



Glossary

- Frozen boot: The RTC partition power transitions from OFF to ON
- Cold boot: The main partition power transitions from OFF to ON with no previous state available, SW must construct all state from scratch. Boot ROM is executed. DRAM is brought on-line.
- Warm boot: The main partition power transitions from OFF to ON with previous state available, SW checks for the preserved state integrity and restores the saved state from DRAM, which was in self-refresh prior to warm-boot. This is also called Deep Sleep wake-up or LP0 exit.
- LP0: Low Power 0 state in which, OS is suspended, DRAM is put in self-refresh, system state is saved in PMC + DRAM , VDD_SOC and VDD_CPU rails are powered off, and PMC is configured to monitor “LP0 wake events” which would trigger LP0 exit. This is also called Deep Sleep state.

- LP1: Low Power 1 state in which, OS is suspended, DRAM is put in self-refresh, VDD_CPU rail is powered off, Devices are power-gated, SoC clock domains are put into min frequency (32Khz) and Flow-Controller is configured to monitor “LP1 wake events” which would trigger LP1 exit.

9.1 External Interface

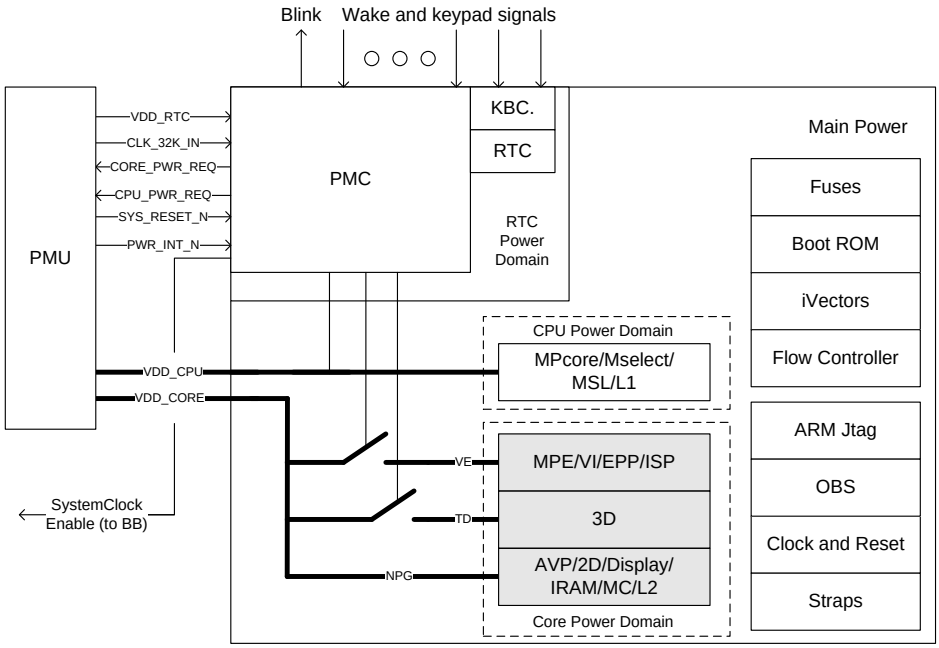
Table 27 PMC External Interface Signals

Signal Name	Type	Signal Description
SYS_RESET_N	In	Hardware reset, active low outside the chip
CORE_PWR_REQ	Out	Used to signal the external PMU device when to toggle the Main power state
CPU_PWR_REQ	Out	
Wake-up Inputs	In	Up to 38 pins designated as wake-up are used for triggering wake-up from Deep Sleep mode. Note, there 4 additional (internal) wake events from Deep Sleep mode for USB (UTMIP and UHSIC).
SYS_CLK_REQ	Out	For systems where the system clock reference can be disabled during sleep
CLK_32K_OUT	Out	32 kHz clock out (active even during Deep Sleep). Can be used for systems that want a blinking LED during Deep Sleep
CLK1_REQ	In	
CLK2_REQ	In	
CLK3_REQ	In	
CLK1_OUT	Out	
CLK2_OUT	Out	
CLK3_OUT	Out	

9.2 Functionality

PMC is a part of the RTC power domain. PMC manages the interface with the external PMU, including the hardware reset pin, the 32.768 kHz clock and the power request signal. A schematic view of the power domains inside the Tegra 3 devices is shown below.

Figure 10. Power Domains in Tegra 3 Devices



The most important aspect of PMC is wake-up and reset logic. The following diagrams show the expected behavior of PMC under three scenarios:

- Frozen boot, that is, the VDD_RTC transitioning from OFF to ON, with or without VDD_CORE and VDD_CPU also transitioning from OFF to ON
- Deep Sleep wake-up, where the PMC is responsible to track wake-up events and to request a transition of VDD_CORE and optionally VDD_CPU from OFF to ON
- Suspend mode wake-up, where the PMC is responsible for establishing the power back to the CPU partition

When reset is deasserted to the Tegra 3 devices, the PMC logic performs minimal processing. It forwards a reset signal and the 32.768 kHz clock to the Clock And Reset (CAR) block.

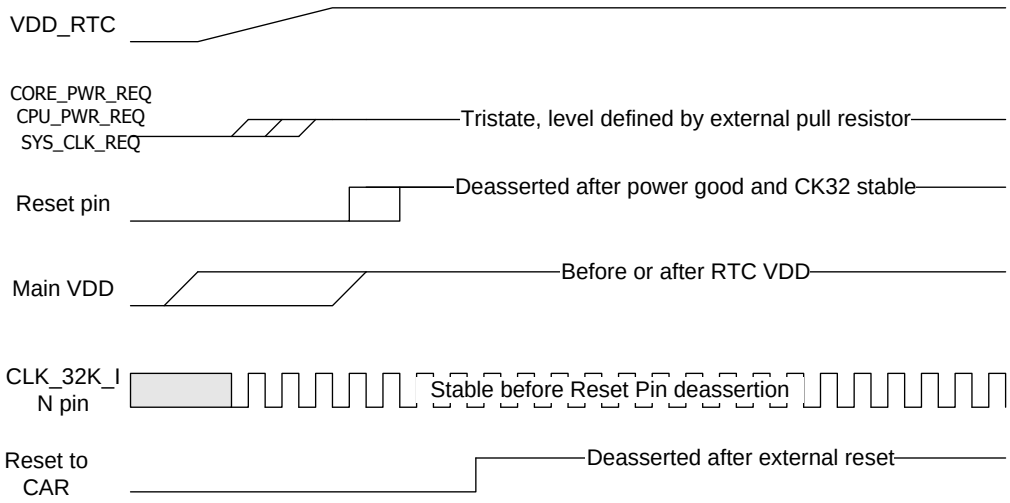
9.2.1 Frozen Boot Sequence

The Frozen Boot wake-up sequence happens when power has been de-asserted to the RTC domain:

1. PMU detects a turn-on condition and enables power to the VDD_RTC
2. Simultaneously to VDD_RTC enable or shortly afterwards, PMU enables power to VDD_CORE and optionally to VDD_CPU.
3. >1ms later PMU enables power to 1.8V I/O rails that need to be enabled for boot
4. >1ms later PMU enables power to 2.8V/3.3V I/O rails that need to be enabled for boot
5. PMU drives 32.768 kHz clock to Tegra 3 devices
6. >1ms later PMU deasserts reset to Tegra 3 devices, 32.768 kHz clock and all power rails must be stable and at their nominal value before reset deassertion

7. PMC block resets and deasserts reset to CAR block
8. Tegra 3 devices begins boot from internal ROM

Figure 11. Frozen Boot Sequence



9.2.2 The Deep Sleep Wake-up Sequence

The Deep Sleep wake-up sequence is the most complex for PMC. A large part of the complexity comes from the need to operate specific part of the logic and of the I/O using the VDD_RTC voltage and to avoid race conditions when going to sleep or waking up.

The corresponding I/O rail for a given wakeup pin needs to be powered on in order for the wakeup to function. The VDD_CORE and VDD_CPU power rails are turned off during DEEP SLEEP. Wakeup signals are routed from the pads directly to RTC for wakeup sequence to be initiated.

A full Deep Sleep / Wake-Up sequence proceeds according to the following steps:

Setting up Deep Sleep

1. SW disables unneeded logic blocks and peripherals not needed and disables their clocks.
2. SW programs PMC with the wake-up condition
3. SW programs scratch registers with information needed to restore state after wake-up
4. SW interacts with PMC to establish the idle conditions on the I/O
5. SW programs external SDRAM to enter self-refresh mode
6. SW programs the PMC to enter Deep Sleep
7. PMC asserts the clamping signals for all power gated islands
8. PMC deasserts power request (polarity previously programmed)
9. PMU removes VDD_CORE and VDD_CPU, Deep Sleep entered

Note: To Power-off VDD_CPU:

1. Assert resets to CPU via CLK_RST_CONTROLLER_RST_CPU_CMPLX_SET
2. Disable clock to CPU via CLK_RST_CONTROLLER_CLK_OUT_ENB_L_0_CLK_ENB_CPU
3. Remove VDD_CPU

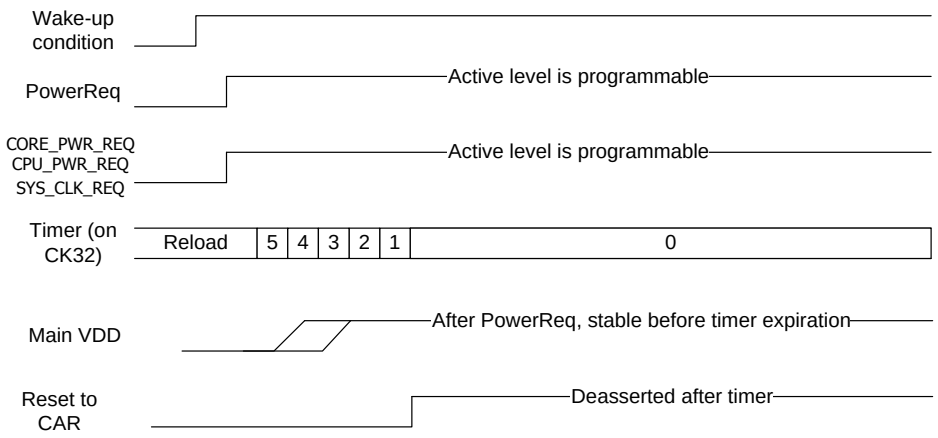
Deep Sleep Wakeup

1. PMC detects a wake-up condition and latches the condition into a register
2. PMC asserts the power request signal, asserts reset to CAR and starts timer (power good delay)
3. PMU restores VDD_CORE and optionally VDD_CPU
4. Timer expires, PMC releases the reset to main

Note: To Power-on VDD_CPU:

1. Restore VDD_CPU
2. Enable clock to CPU via CLK_RST_CONTROLLER_CLK_OUT_ENB_L_0_CLK_ENB_CPU
3. If using PLLX as CPU clock source is desired, configure/enable PLLX and switch to PLLX (this step can be done after step 4).
4. De-assert resets to CPU via CLK_RST_CONTROLLER_RST_CPU_CMPLX_CLR

Figure 12. Deep Sleep Wake-Up Sequence

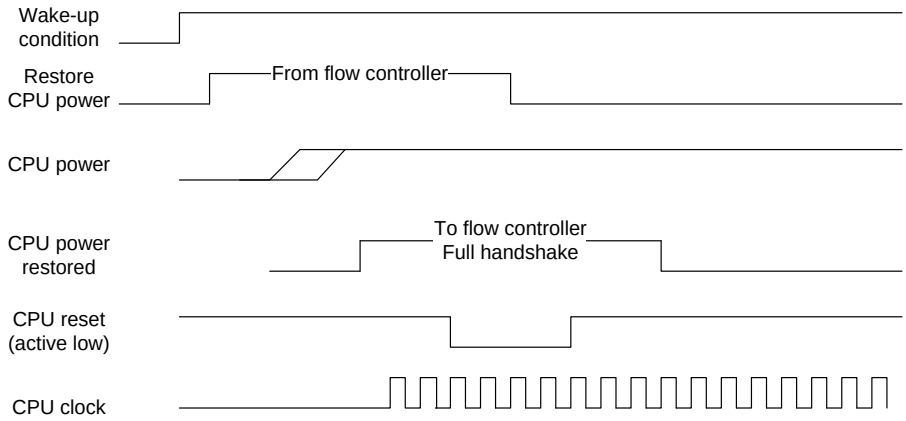


9.2.3 Suspend Mode Wake-up Sequence

The Suspend Mode wake-up sequence is simpler. PMC needs to wake-up CPU by removing the power gating:

1. SW configures flow controller with the Suspend Mode wake-up conditions.
2. Flow controller interacts with CPU to ensure that no transactions are in flight
3. Flow controller indicates to CAR to reset CPU
4. PMC clamps CPU signals and removes power from CPU
5. Flow controller detects Suspend mode wake-up condition
6. Flow controller sends a trigger event to PMC
7. PMC restores power to CPU
8. PMC sends an acknowledge to flow controller
9. Flow controller restores clock to CPU
10. CAR asserts reset to CPU
11. PMC removes clamping to the CPU
12. CAR deasserts reset to CPU

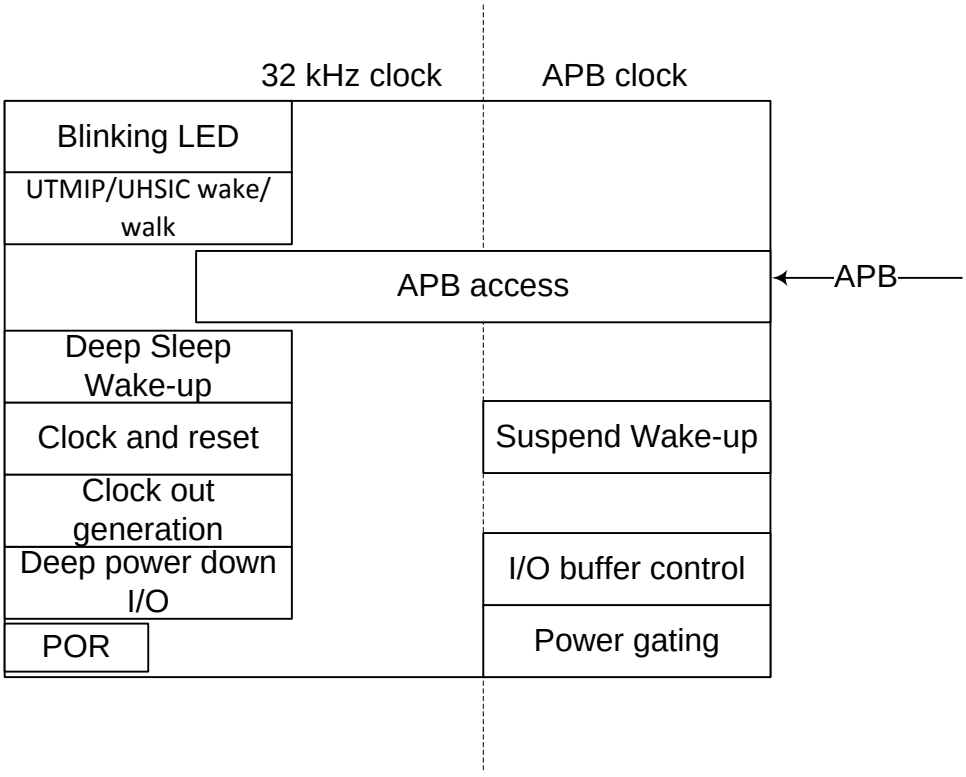
Figure 13. Suspend Mode Wake-Up Sequence



9.3 Reference Block Decomposition

The next figure shows a reference decomposition of PMC to simplify the description. The design uses a different functional partitioning.

Figure 14. Reference Block Decomposition Diagram



The blocks inside PMC are:

- Wake-up logic for Deep Sleep and Suspend modes
- Power gating logic
- External clock and reset

- Blinking LED
- I/O buffer control
- APB interface
- UTMIP/UHSIC wake/walk logic
- Deep power down I/O logic (independent on LP0)
- Clock out generation

9.3.1 Deep Sleep Entry Logic

There are two ways to enter Deep Sleep mode:

- Writing into the DPD register
- Interaction with the power gating logic when the DPD trigger enable (side effect) bit is set.

The second method is the recommended usage as described before. The exact sequence has been described in more detail earlier in this section.

Note that entering Deep sleep mode should happen after an ordered shutdown of Tegra 3 devices. As part of the shutdown procedure, external interfaces must be placed in their idle condition. PMC provides the logic that ensures that interfaces maintain their idle state during Deep Sleep itself. The SW is responsible to sample the idle state by writing to the DPD sample bit before entering Deep Sleep mode.

SW must also ensure that I/O paths that must remain active during Deep Sleep mode are identified as such, by correct configuration of ownership bits in a PMC register. These ownership bits are present for the signals used by KBC (where the size of the scan matrix is defined by the customer, the exact required size is reflected in the ownership bits) and for the clock request signal (that may not be required depending on the customer clock logic).

SW must also ensure that wake-up conditions are programmed properly. Wake-up level and wake-up mask should reflect expected wake-up events. Power Good Timer and Power Down Timer must be set according to Power Management Unit Specification.

The Deep Sleep mode entry/wake-up logic operates largely on the 32.768 kHz clock, so SW must respect a minimal delay between a Deep Sleep mode exit and before issuing the next Deep Sleep mode entry command. This delay is of the order of 2 periods of the 32.768 kHz clock. This should never be a problem given that the code to restore the processor state requires much more time.

There are two ways to enter Deep Sleep:

- Option1 (side-effect): First CPU power is gated, and as a result (“side-effect”) PMC performs an orderly LP0 entry. PMC HW also sets the PMC_DPD_ENABLE (automatically). Normally, this is the only option for LP0 entry.
- Option2 (direct-write): Writing directly into the PMC_DPD_ENABLE register. This is not a safe option and is only for debug or diagnostic workaround purposes.

9.3.2 Deep Sleep Wake-Up Logic

The wake-up logic performs the following tasks:

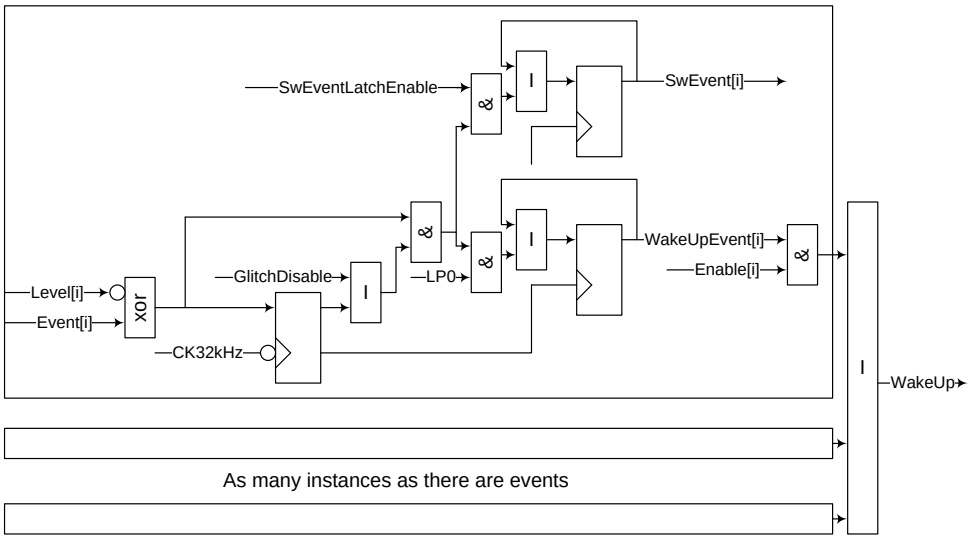
- Tracks the state of a programmable set of wake-up conditions
- Detects a wake-up condition
- Starts the sequence of action required by the Deep Sleep mode wake-up

A wake-up event is either a change of level on one in a set of specified pins or an assertion of RTC or KBC interrupts.

The logic that tracks for change of levels in external pins contains a glitch filter that may be optionally disabled. Internal interrupts don't require deglitching logic, but are passed through the same logic, as this is also the synchronization logic. A conceptual schematic is shown in the next figure. The different stages are:

- Normalizing the active level to high by inverting the wake-up signals identified as active low
- Latching either the direct signal or a deglitched version of it (global enable)
- Masking the latched signals to generate the wake-up signal

Figure 15. Deep Sleep Wake-up Logical Circuit



Note that the WakeUp signal shown is not directly the CORE_PWR_REQ signal, and there are two further processing steps defining the CORE_PWR_REQ signal:

- The polarity of the CORE_PWR_REQ signal is programmable
- CORE_PWR_REQ signal is disabled at reset. It should be enabled only after polarity is set accordingly to PMU specification
- Furthermore, there is a System Clock enable signal that is equal to CORE_PWR_REQ, but with its own independent control bits for polarity and output enable.

The set of latched wake-up events are readable by SW once the processors are active. The logic accumulates all events that take place while in Deep Sleep mode. Normally only one enabled event is present in the set, but simultaneous events could take place. Each bit of the latched wake-up event register is cleared by writing a 1b to it.

A second set of latches is also present, with the same structure as the wake-up event register but under software control. The most important difference between the two sets is that events that occur outside of the Deep Sleep mode will be captured in the second set, including:

- Events that could occur during the Deep Sleep mode transition itself, i.e. before the HW enters the Deep Sleep state, but after SW has instructed HW to enter Deep Sleep.
- Events that occur after the HW wake-up, but before SW has enabled the peripheral functions in the NPG that process the signals tied to the wake-up events, i.e. the GPIO event logic.

9.3.3 Deep Sleep Wake-up Event Input Path

The wake-up signals can be configured to be level (active high or low based on PMC_WAKE*_LVL registers), or pulse (based on WAKE2_LVL[ALLOW_PULSE_WAKE]). However, there has to be a minimum delay between two consecutive wake events handling (which is programmed in PMC_WAKE_DELAY). A level wake-up signal must be valid when PMC can act upon it. For

pulse wake-up signals, PMC registers them even if they trigger during PMC_WAKE_DELAY window. However, PMC will act upon (registered) pulse event only after PMC_WAKE_DELAY window has expired.

PMC detects wake signals by using 32kHz logic. Therefore, in either case (level or pulse), a signal has to last long enough for PMC to recognize the change in signal. In addition, PMC provides option to filter out glitches.

The wake-up logic as defined, recognizes wake-up signals matching the programmed wake-up active level that exceed certain time limits and rejects events less than another limit as defined in the following table.

Table 28. Deep Sleep Wake-up Logic

Glitch disable bit	Never wake-up if event is less than	Always wake-up if more than
0 (Glitch reject)	0.5 period of 32.768 kHz clock = 15.25 us	1.5 period of 32.768 kHz clock = 45.755 us
1 (No glitch reject)	0 period of 32.768 kHz clock = 0 us	1 period of 32.768 kHz clock = 30.50 us

Between these two values, the probability of detection increases linearly from 0 to 1 when events are asynchronous to the 32.768 kHz clock. The latency delay is also a probabilistic function, varying linearly between the two limits presented in the above table.

Note that the logic doesn't contain any formal synchronization stage and so theoretically metastability cannot be precluded at this time. However the MTBF linked to metastability will be insignificant given the very low active duty of the wake-up circuitry and the low frequency of the sample clock (32.768 kHz). Adding an explicit synchronization stage increases the latency of the circuit.

9.3.4 Suspend Wake-up Logic

The only Suspend mode wake-up specific logic in PMC is related to the power gating logic as described previously.

9.3.5 Power Gating Logic

The power gating logic is a simple programmable sequencer. When the power gating logic is triggered, it sequences the set of power gating signals with a programmable period (measured in cycles) between the toggling of consecutive power gating signals.

There are three power gated domains. For all of them the trigger can be a register write (see register definition). The CPU power gated domain has an extra trigger coming from the flow controller. PMC and flow controller provides a full handshake, with PMC providing an acknowledge back to flow controller when the CPU power has completed its transition (this would normally only be for OFF to ON transition at Suspend mode wake-up).

The power gating logic operates on APB clock. The timing sequence may be dependent on the exact frequency, with a hardware limit that the minimum transition period is at least 64 ns.

The power gating logic may be triggered either by direct register writes using the toggle register or by interaction with the flow controller. The second control path is used when entering Deep Sleep or Suspend mode to allow for an orderly shutdown of the processor. The sequence can be summarized in the following manner:

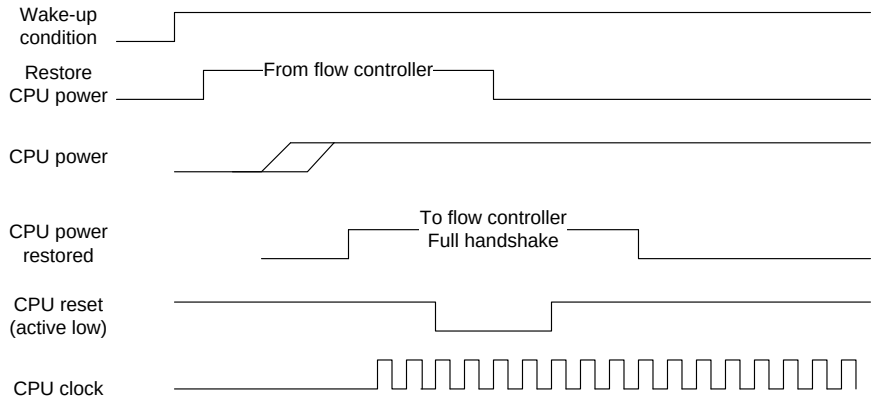
1. The CPU decides to enter either Deep Sleep or Suspend mode.
2. In both cases, the power to the CPU must be gated off
3. CPU does any required clean up job. This is especially important for Deep Sleep (all interfaces in idle, save context, etc.)
4. The CPU informs flow controller it wants to remove its power, with two variants:

5. For Suspend mode, the CPU also defines the set of events that will wake up the CPU (the flow controller is not power gated together with the CPU)
6. For Deep Sleep, write to sample register preserves I/O state to be driven when the chip enters Deep Sleep mode
7. For Deep Sleep, CPU must define in PMC the set of wake-up events for the whole Tegra 3 devices, and set the DPD trigger enable bit
8. CPU enters an endless loop
9. The flow controller asserts reset to the CPU
10. The flow controller informs the PMC that CPU power gating OFF is requested
11. The PMC power gates the CPU OFF and then informs the flow controller
12. If the DPD trigger enable was set, PMC also performs an Deep Sleep entry, this will result after awhile in the core power disappearing

The Deep Sleep wake-up was described before and is essentially a full reset of the core logic. The Suspend mode wake-up logic includes an interlock with the flow controller that works like this:

1. The flow controller detects the Suspend mode wake-up condition
2. The flow controller informs PMC that power gating ON is requested
3. The PMC power gates the CPU ON then informs the flow controller
4. The flow controller deasserts the reset to the CPU
5. CPU checks different status registers to establish this was in fact a Suspend mode wake-up.

Figure 16. Power Gating Logic



9.3.6 I/O Buffer Control

The logic for Deep Power Down I/O buffer management ensures that the I/Os are maintained in an idle state while in Deep Sleep mode. The procedure has been described before and requires SW sequencing:

1. SW makes sure that the affected I/O ports are in their idle state, i.e. the state that will persist during Deep Sleep
2. When SW sets the DPD sample register , the idle state of the I/O control signals is captured, i.e. the driving direction and the data driven if the direction indicates output.
3. SW writes the DPD enable bit and muxes inside the I/O buffers now drive the stored idle state, while the corresponding control signals coming from the core are ignored.
4. SW triggers the Deep Sleep mode, killing itself
5. HW detects the Deep Sleep wake-up condition
6. SW wakes-up and restores the state

7. SW clears the DPD sample bit
8. SW clears the DPD enable bit
9. I/O control can be sequenced back to the controlling block once SW has initialized the core block to drive outputs to the same idle state they maintained before entering DPD.

PMC also contains a SW programmable register, with one bit per I/O rail. Each bit disables internal logic inside the I/O buffer that would otherwise consume power when the I/O power is OFF. Each bit should be set by SW before shutting off the corresponding I/O power. Reversely, each bit should be reset after transitioning back the IO voltage to On (and before enabling the set of interfaces using the corresponding I/O rail).

PMC also contains two registers related to 3.3V I/O support. Specific power detector cells indicate per I/O voltage domain if their supply voltage is low or high. This signal must be reflected in a corresponding signal of the I/O pads part of that I/O voltage domain. The detector cells consume significant power, so they cannot be left on all the time. PMC contains a register enabling the detector cells. The output of the detector cell can then be sampled and written in another register linked to the control signal going to each I/O voltage domain.

9.3.7 Power Down I/O Logic

The new deep power-down domains are created for pad control. They allow enabling deep power down mode on single power rail or single pad brick without entering LP0. Unlike in LP0 mode, the function is implemented in ABP clock domain; therefore, some extra controls are needed to guarantee proper timing on the pads. The DPD domain groups added include:

CSIA, CSIB, DSI, POP_CLK, POP_ADDR_CMD, DDR_ADDR_CMD, DISC_ADDR_CMD, DDR_DATA, SYS, NAND, UART, BB, VI, AUDIO, LCD, SD, IPI_BIAS, PEX_BIAS, PEX_CLK1, PEX_CLK2, COMP, POP_VTTGEN, DISC_VTTGEN, DAC, USB0, USB1, USB2, USB_BIAS, HSIC, HDMI, SDMMC1, SDMMC3, SDMMC4, CAM, PEX_CNTRL

- **DISC_VTTGEN** includes mem_addr_vttgen_1_pad, mem_addr_vttgen_2_pad, mem_vttgen_26_pad, mem_vttgen_27_pad, mem_vttgen_28_pad, mem_vttgen_29_pad
- **COMP** includes xm2_comp_pd_pad, xm2_comp_pu_pad
- **POP_CLK** includes xm2_mclk_addr_pad
- **POP_ADDR_CMD** includes dvi_d10_pad, dvi_d11_pad, dvi_vsync_pad, dvi_hsync_pad dvi_d0_pad, dvi_d1_pad, dvi_d2_pad, dvi_d3_pad, dvi_d4_pad, dvi_d5_pad, dvi_d6_pad, dvi_d7_pad, dvi_d8_pad, dvi_d9_pad
  DDR_ADDR_CMD includes xm2_mcas_n_pad, xm2_mras_n_pad, xm2_mwe_n_pad, xm2_mba[2:0]_pad, xm2_ma[14:10]_pad,xm2_odt0_pad, xm2_odt1_pad, xm2_reset_pad
- **DISC_ADDR_CMD** includes xm2_mclk_pad, xm2_mcke0_pad, xm2_mcke1_pad, xm2_mcsc_n_pad, xm2_mcsd_n_pad, xm2_ma[9:0]
- **DDR_DATA** includes xm2_data0_pad, xm2_data1_pad, xm2_data2_pad, xm2_data3_pad, xm2_mckfb0_pad, xm2_mckfb1_pad, xm2_mckfb2_pad, xm2_mckfb3_pad

Entering DPD mode for single DPD domain has simplified steps of LP0 entry. To set a domain in DPD mode:

- Program interface to drive idle state out
- Set sample register (PMC_DPD_SAMPLE)
- Set fields corresponding to dpd domains to 1 in PMC_IO_DPD_REQ register or PMC_IO_DPD2_REQ register and CODE to DPD_ON
  - Note, Fields set to 0 will mean no status change
  - Note, IO_DPD_STATUS and IO_DPD2_STATUS are read only registers which display status of each rail. PMC_DPD_SAMPLE register must be reset before next sample operation.
- Set PMC_SEL_DPD_TIM to value corresponding to minimum 80 ns (this allows for proper timing sequence between sel_dpd, e_dpd)
- Set interface to drive idle state

- Set fields corresponding to dpd domains to 1 in PMC_IO_DPD_REQ register or PMC_IO_DPD2_REQ register and CODE to DPD_OFF
- Set tristate field in miscellaneous register to disable **for all pads in the set of affected domains** (this will deassert sel_dpd in mini pad macros). Some bricks do not have mini_pad_macros. For those, this step will be skipped.
  - Note, fields set to 0 will mean no status change

The following DPD domains do not have mini pad macros or do not drive state out during deep power down mode:

MIPI_BIAS, PEX_BIAS, PEX_CLK1, PEX_CLK2, COMP, POP_VTTGEN, DISC_VTTGEN, DAC, USB0, USB1, USB2, USB_BIAS, HSIC, HDMI, DDR_ADDR_CMD, DISC_ADDR_CMD, DDR_DATA, POP_CLK.

For the above domains the sequence of entering and leaving DPD mode is simpler:

To set domain in DPD mode:

- Set fields corresponding to dpd domains to 1 in MC_IO_DPD_REQ register or MC_IO_DPD2_REQ register and CODE to DPD_ON
  - Note, fields set to 0 will mean no status change

To reset DPD mode for the DPD domain:

- Set PMC_SEL_DPD_TIM to value corresponding to minimum 80 ns (this allows for proper timing sequence between sel_dpd, e_dpd)
- Set fields corresponding to dpd domains to 1 in PMC_IO_DPD_REQ register or PMC_IO_DPD2_REQ register and CODE to DPD_OFF
  - Note, fields set to 0 will mean no status change

> **Note:** In current architecture only one sample signal exists to perform sampling while entering dpd_mode. This means that all interfaces are sampled at the same time. Sequence of multiple DPD sets require keeping all interfaces already in DPD mode, and driven as idle. *We can either add sample bit per interface, or try to modify mini pad macros to prevent sample for pads which are already in DPD mode*.

For regular LP0 mode all pads enter/exit DPD at the same time.

Note about VI (called PVI): all pads in this group with exception of sdmmc2_vi_sclk_lb, dvi_mclk, dvi_pclk are covered by 2 groups –POP_ADDR_CMD, POP_CLK. So to fully turn off vi, we need to turn off all three groups.

The new registers associated with this feature:

- PMC_IO_DPD_REQ
- PMC_IO_DPD_STATUS
- PMC_IO_DPD2_REQ
- PMC_IO_DPD2_STATUS
- PMC_SEL_DPD_TIM

9.3.8 Clock Control Logic

The Tegra 3 device has a new functionality to allow oscillator to run in LP0 mode. It is combined with the ability to output clock (CLK_OUT) which can be extended outside LP0. Based on register setup, PMC can take over the control of Oscillator during DPD mode. When enabled, PMC takes over oscillator pad control by setting oscfi_d, oscfi_s, oscfi_en. See PMC_OSC_EDPD_OVER and PMC_CLK_OUT_CNTRL registers for register description.

There are two functions embedded in this feature:

- Programmable option of keeping oscillator ON during DPD mode
- For low cost systems, ability to output clock on dap_mclk1, dap_mclk2, clk3_out pins.

Programmable option of keeping oscillator ON during DPD mode

When programmed in PMC_OSC_EDPD_OVER register to take over the control of oscillator (OSC_CTRL_SELECT bit), PMC starts controlling all inputs to oscillator pad, including enable. However, setting EN bit to 0 (disabling oscillator) would be allowed only during deep power down mode, with automatic enabling on leaving LP0 (this is to avoid system lockup). Based on PMC_OSC_EDPD_OVER setup oscillator can be controlled as follows:

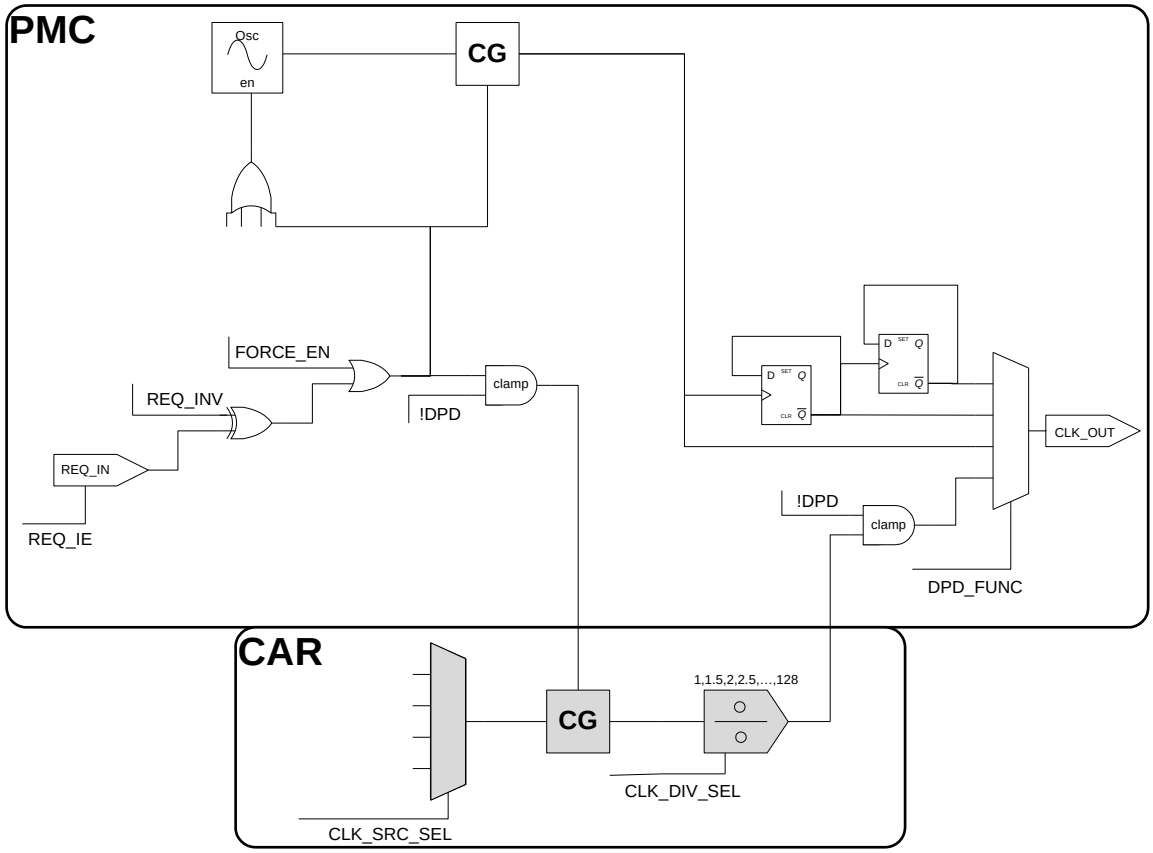
- Completely controlled by CAR, entering deep power down mode on LP0 (shutting down oscillator)
- Controlled by PMC, entering deep power down mode on LP0
- Controlled by PMC, not entering deep power down mode, but oscillator output is disabled (used to accelerate warm boot time)
- Controlled by PMC, not entering deep power down mode, oscillator output enabled – used for clk out feature.

For low cost systems, ability to output clock on dap_mclk1, dap_mclk2, clk3_out pins

The Clock out function is illustrated below. Three independent request lines: dap_mclk1_req, dap_mclk2_req, clk3_req are used to assert clock requests on corresponding clock outputs: dap_mclk1, dap_mclk2, clk3_out. When such a request is decoded, PMC switches controls on new clock pad_macros to bypass regular pinmux route and output clock instead. There are a variety of options available for decoding clock request and for source of clock output itself.

Request can be decoded as active high, low, or clock output could be forced out independently of the state of request line. The clock output line, when idle, could be driving out 0, 1, or be tri-stated. Once request is accepted, clock source could be CAR output, or oscillator output divided by 1, 2 or 4. The request can be issued outside or in LP0, and the only difference in behavior should be that during LP0 CAR output as clock source is not available.

Figure 17. CLK_OUT paths



9.3.9 Clamping

This is related to power gating, when a partition is OFF. All signals leaving that partition are clamped to their idle value, normally 0, as most signals are active high.

Applying the clamping presents no specific problem, as all blocks into the partition being powered OFF are assumed to be in reset prior to the power gate transition.

Removing the clamping is more complex because Tegra 3 devices use a synchronous reset strategy, so the correct sequence is the following:

- Restore power, reset and clamping both active at that time
- Restore clocks, so that reset conditions propagate
- Remove clamping
- Remove reset

For maximum flexibility, removing the clamping can be controlled by SW. Writing to a trigger register removes the clamping for the identified set of partitions. This doesn't work for Suspend mode exit, where the CPU must be restarted by HW only.

In Suspend mode exit, there is an interlock between the CAR (Clock And Reset block) and PMC, so that the correct sequence is performed. CAR indicates to PMC when the CPU clamping may be removed. This signal is asserted after the clock to CPU is restarted. The reset to CPU will only be removed after a known delay following the request to remove the clamping. PMC removes the CPU clamping as soon as it receives the request to do so. This is similar to the interlock between PMC and flow controller, except that this is not a full handshake.

9.3.10 Scratch Registers

PMC provides a number of scratch, secure scratch and bondout registers. The scratch registers are used to save some of the system context information during LP0.

There are 57 PMC scratch registers, 8 secure registers, and 5 bondout registers in all. To save area, secure scratch registers 4-7, scratch registers 1-55, and 5 bondout registers are implemented in RAM. Due to requirement of being backward compatible with Tegra 2 address space, none of the three types has continuous address space.

9.3.11 Blinking

Tegra 3 devices support a blinking LED whenever the cell phone is not powered OFF, including in Deep Sleep mode. The blinking LED is controlled from the RTC partition.

PMC contains a counter with two programmable values indicating the On and Off periods (in multiple of 16 cycles of the 32.768 kHz clock). The counter is 16 bits long, for a maximum On or Off period of 2^{16} * 16 / 32.768 10^{3} or about 16 seconds.

9.3.12 Pin Muxing

Some of the signals controlled by PMC may not be required in certain customer designs, especially:

- The system clock may not support an enable function, so the system clock enable (SYS_CLK_REQ) is not used
- The system may not require a LED active in Deep Sleep or another device (BB) may drive the LED, so the power LED is not used.

It is important to allow the corresponding balls to be reused for other purposes via pin muxing. This is not directly a responsibility of PMC but the correct pin muxing must be present. PMC provides a set of ownership registers that control if the RTC logic (PMC or KBC) has control of pins with multiple uses (KBC, PMC or typically GPIO), some of which are not controlled by RTC logic. The ownership bit controls a final stage of muxing on top of the more general pin muxing stage.

As an important special case, the system clock enable is one of the Deep Sleep wake-up event pin. Obviously usage as a wake-up event pin is incompatible with usage as a system clock enable pin.

9.3.13 APB Access

The APB access logic is complicated by the need to not unduly block the bus for extended periods of time even when accessing registers that are logically in the 32 kHz domain. The following principles are used to avoid any delay when accessing registers logically in the 32 kHz domain:

- Write operations always take place in the APB clock domain, i.e. the corresponding registers are placed in the APB clock domain and passed as wires to the 32 kHz domain where they are used without further synchronization. This only works because values passed in this manner are considered essentially static. There is an insignificant probability that the 32 kHz logic sees an intermediate value of a multiple bit field, but an enumeration of the affected fields shows that this can't result in any significant problem at the system level.
- Read operations are to shadow registers in the APB clock domain. The shadow registers continuously reflect the values of the equivalent registers found in the 32 kHz clock domain. Only registers reflecting status present in the 32 kHz domain are affected.

9.4 Sensor Reset

PMC monitors temperature sensor signal. When the signal becomes active, PMC resets the whole chip and might also power gate CPU1-3. Both reset and power gating are configurable and can be enabled or disabled. Reset of whole chip automatically causes CPU1-3 power gating and request for turning down cpu_power.

Power gating is simplified version of regular power gating function. In first cycle clamping is enabled. In next cycle CPU1-3 is power gated. The above approach simplifies the logic and allows for performing the function before apb_clk is shut down by reset.

The reset status register bit is set to indicate that thermal sensor event has happened. If PMC is entering LP0 mode while temp sensor triggers, the reset as a direct result of sensor active will not happen (to avoid destruction of PMC state). However, process of entering LP0 causes reset a few cycles later. CPU1-3 will be shutdown in each situation.

9.5 Register Definition for PMC

To speed up operation, this register file operates in the local peripheral interface bus domain (APB) rather than in the 32 KHz clock domain used for PMC processing.

Registers in PMC control entering/exiting Deep Sleep /Suspend mode, power detect, and I/O power functions. They also control CORE_PWR_REQ, SYS_CLK_REQ, and LED_BLINK pins.

The following registers should be programmed/read for different power events in order for PMC to function properly.

IMPORTANT:	**NO_IO_POWER REGISTER (APBDEV_PMC_NO_IOPOWER_0)** This register is used to disable pads which have I/O power turned off. When an I/O power rail is turned off, ramping up, or no longer used and ready to turn off, the corresponding bit in this register should be set to 1. The bit only needs to be turned on when the I/O power rail is stable and you are ready to enable some interface on the I/O power rail. Leaving no_io_power set to 0 **for greater than 500ms** when rail is off may reduce the lifetime of the pad. Setting it to 1 when power rail is on will disable pad from voltage stress.

BEFORE/ON ENTERING DEEP SLEEP MODE

- PMC Control Register (bits PWRREQ_POLARITY, PWRREQ_OE, SYSCLK_POLARITY,SYSCLK_OE, LATCHWAKE_EN)
- WAKE_MASK
- WAKE_LVL
- DPD_PADS_ORIDE (for required overrides)
- PWRGOOD_TIMER
- DPD_SAMPLE
- DPD_ENABLE

AFTER WAKE-UP FROM DEEP SLEEP

- WAKE_STATUS
- SW_WAKE_SATUS
- DPD_ENABLE
- PMC Control Register (bit LATCHWAKE_EN)

BEFORE/ON POWERING DOWN PARTITIONS

- PWRGATE_STATUS
- PWRGATE_TIMER_OFF (for power down)
- PWRGATE_TIMER_ON (for power up) .. This has been defunct
- PWRGATE_TOGGLE
- REMOVE_CLAMPING_CMD (for power up)

FOR POWER DETECT SEQUENCE

- PWR_DET
- PWR_DET_LATCH

FOR BLINK

- BLINK_TIMER
- PMC Control Register (bit BLINK_EN)
- DPD_PADS_ORIDE (for blink field)

All other operations require single register access.

9.6 PMC Registers

9.6.1 APBDEV_PMC_CNTRL_0

Base offset in APB device space.

This register controls clock to KBC, RTC, reset to car, KBC, RTC. It also manages polarity and output enable of sys_clk_req pin and core_pwr_req pin at reset both are disabled since PMU properties are unknown.

Auxiliary functions - enables blinking functions, and software wake-up latching.

PMC Control Register

Offset: 000h | Read/Write: R/W | Reset: 0b0000000000000000

Bit	Reset	Description
18	0x0	FUSE_OVERRIDE: Fuse override 0 = DISABLE 1 = ENABLE
17	0x0	INTR_POLARITY: Inverts INTR polarity 0 = DISABLE 1 = ENABLE
16	0x0	CPUPWRREQ_OE: Power request output enable. resets to tri-state 0 = DISABLE 1 = ENABLE
15	0x0	CPUPWRREQ_POLARITY: Inverts power request polarity 0 = NORMAL 1 = INVERT
14	0x0	SIDE_EFFECT_LP0: when set causes side effect of entering LP0 after powering down CPU 0 = DISABLE 1 = ENABLE
13	0x0	AOINIT: AO (Always On or RTC domain) initialized purely SW diagnostic and interpretation 0 = NOTDONE 1 = DONE
12	0x0	PWRGATE_DIS: Disable power gating - global override, will override function of PWRGATE_TOGGLE register. all partitions will stay enabled. 0 = DISABLE 1 = ENABLE
11	0x0	SYSCLK_OE: Enables output of system enable clock - works only if SYS_CLK field in DPD_PADS_ORIDE is set to 1. 0 = DISABLE 1 = ENABLE
10	0x0	SYSCLK_POLARITY: Inverts SYS_CLK_REQ enable polarity 0 = NORMAL 1 = INVERT
9	0x0	PWRREQ_OE: CORE_PWR_REQ output enable. resets to tristate 0 = DISABLE 1 = ENABLE
8	0x0	PWRREQ_POLARITY: Inverts CORE_PWR_REQ polarity 0 = NORMAL 1 = INVERT

Bit	Reset	Description
7	0x0	BLINK_EN: Enables blinking counter and blink output works only if BLINK field in DPD_PADS_ORIDE is set to 1. 0 = DISABLE 1 = ENABLE
6	0x0	GLITCHDET_DIS: Disable detecting glitch on wake-up event. In default operation glitches are ignored on wakeup lines. if this bit is set to 1, glitch (event shorter than half 32khz clock, will be causing wakeup from lp0 0 = DISABLE 1 = ENABLE
5	0x0	LATCHWAKE_EN: Enables latching wakeup events - stops latching on transition from 1 to 0(sequence - set to 1,set to 0) 0 = DISABLE 1 = ENABLE
4	0x0	MAIN_RST: now resets everything but scratch 0 and reset status 0 = DISABLE 1 = ENABLE
3	0x0	KBC_RST: Software reset to KBC 0 = DISABLE 1 = ENABLE
2	0x0	RTC_RST: Software reset to RTC. Defunct for Tegra 3 0 = DISABLE 1 = ENABLE
1	0x0	RTC_CLK_DIS: Disable 32KHz clock to RTC 0 = DISABLE 1 = ENABLE
0	0x0	KBC_CLK_DIS: Disable 32KHz clock to KBC 0 = DISABLE 1 = ENABLE

9.6.2 APBDEV_PMC_SEC_DISABLE_0

On separate reset (same as car), disables access (read/write to secure scratch registers). Once write is disabled, secure registers cannot be written until power on reset or reset on exiting Deep Sleep.

Once read is disabled, read from scratch registers will return 0 until power on reset or reset on exiting Deep Sleep mode.

Single register can be disabled for read/write, bit 0,1 have overwrite function

Secure Register Disable

Offset: 004h | Read/Write: R/W | Reset: 0b00000000000000000000

Bit	Reset	Description
19	0x0	READ7: disable read from secure register 7 0 = OFF 1 = ON
18	0x0	WRITE7: disable write to secure register 7 0 = OFF 1 = ON

Bit	Reset	Description
17	0x0	READ6: disable read from secure register 6 0 = OFF 1 = ON
16	0x0	WRITE6: disable write to secure register 6 0 = OFF 1 = ON
15	0x0	READ5: disable read from secure register 5 0 = OFF 1 = ON
14	0x0	WRITE5: disable write to secure register 5 0 = OFF 1 = ON
13	0x0	READ4: disable read from secure register 4 0 = OFF 1 = ON
12	0x0	WRITE4: disable write to secure register 4 0 = OFF 1 = ON
11	0x0	READ3: disable read from secure register 3 0 = OFF 1 = ON
10	0x0	WRITE3: disable write to secure register 3 0 = OFF 1 = ON
9	0x0	READ2: disable read from secure register 2 0 = OFF 1 = ON
8	0x0	WRITE2: disable write to secure register 2 0 = OFF 1 = ON
7	0x0	READ1: disable read from secure register 1 0 = OFF 1 = ON
6	0x0	WRITE1: disable write to secure register 1 0 = OFF 1 = ON
5	0x0	READ0: disable read from secure register 0 0 = OFF 1 = ON
4	0x0	WRITE0: disable write to secure register 0 0 = OFF 1 = ON
3:2	0x0	NOT_USED: legacy - redundant - not used
1	0x0	READ: disable read from secure registers - all 0 = OFF 1 = ON
0	0x0	WRITE: disable write to secure registers - all 0 = OFF 1 = ON

9.6.3 APBDEV_PMC_PMC_SWRST_0

Reset only by por cell and sets itself back to inactive after 2 clock cycles. Only for emergency debugging purposes and not to be used in any functional mode.

Note: Defunct for Tegra 3 devices. Kept only for binary code compatibility only. Will not do anything

Register write which resets PMC only

Offset: 008h | Read/Write: R/W | Reset: 0b0

Bit	Reset	Description
0	0x0	RST: software reset to pmc only 0 = DISABLE 1 = ENABLE

9.6.4 APBDEV_PMC_WAKE_MASK_0

Masks which event can cause wake-up from Deep Sleep mode. Has to be setup before entering Deep Sleep. Works in conjunction with WAKE_LVL register.

Only enabled events at the proper wake_lvl will cause exit from Deep Sleep mode.

Current pin assignments wake_mask, wake_status, sw_wake_status and wake levels:

- WAKE_STATUS[0] = ulpi_data4
- WAKE_STATUS[1] = gp3_pv[1]
- WAKE_STATUS[2] = dvi_d3
- WAKE_STATUS[3] = sdmmc3_dat1
- WAKE_STATUS[4] = hdmi_int
- WAKE_STATUS[5] = sdmmc4_dat6
- WAKE_STATUS[6] = gp3_pu[5]
- WAKE_STATUS[7] = gp3_pu[6]
- WAKE_STATUS[8] = gmi_wp_n
- WAKE_STATUS[9] = gp3_ps[2]
- WAKE_STATUS[10] = gmi_ad21
- WAKE_STATUS[11] = spi2_cs2
- WAKE_STATUS[12] = spi2_cs1
- WAKE_STATUS[13] = sdmmc1_dat1
- WAKE_STATUS[14] = pe_wake_1
- WAKE_STATUS[15] = gmi_cs1_n
- WAKE_STATUS[16] = rtc_irq
- WAKE_STATUS[17] = kbc_interrupt
- WAKE_STATUS[18] = pwr_int
- WAKE_STATUS[19] = usb_vbus_wakeup[0]
- WAKE_STATUS[20] = usb_vbus_wakeup[1]
- WAKE_STATUS[21] = usb_iddig[0]
- WAKE_STATUS[22] = usb_iddig[1]

- WAKE_STATUS[23] = gmi_iordy
- WAKE_STATUS[24] = gp3_pv[0]
- WAKE_STATUS[25] = gp3_ps[4]
- WAKE_STATUS[26] = gp3_ps[5]
- WAKE_STATUS[27] = gp3_ps[0]
- WAKE_STATUS[28] = gp3_ps[6]
- WAKE_STATUS[29] = gp3_ps[7]
- WAKE_STATUS[30] = dap1_dout
- WAKE_STATUS[31] = 0

PMC Wake-up Event Mask

Offset: 00ch | Read/Write: R/W | Reset: 0b00000000000000000000

Bit	Reset	Description
31	0x0	RESET_N: external reset wake enable 0 = DISABLE 1 = ENABLE
30:23	0x0	EVENT_RES: 0 = DISABLE 1 = ENABLE
22:19	0x0	USB_EVENT: 0 = ACTIVE_LOW 1 = ACTIVE_HIGH
18	0x0	PWR_INT_N: PWR_INT_N wake enable 0 = DISABLE 1 = ENABLE
17	0x0	KBC: KBC wake enable 0 = DISABLE 1 = ENABLE
16	0x0	RTC: RTC wake enable 0 = DISABLE 1 = ENABLE
15:0	0x0	EVENT: pin 0-15 wake enable 0 = DISABLE 1 = ENABLE

9.6.5 APBDEV_PMC_WAKE_LVL_0

This register sets level which is active level for wake event. Will cause exit from Deep Sleep mode if input signal level matches level set in this register and WAKE_MASK is set for the event to 1

PMC Wake Level

Offset: 010h | Read/Write: R/W | Reset: 0b01111111100111111111111111111111

Bit	Reset	Description
31	0x0	RESET_N: external reset wake level (low active!) 0 = ACTIVE_LOW 1 = ACTIVE_HIGH
30:23	0xff	EVENT_RES: 0 = ACTIVE_LOW 1 = ACTIVE_HIGH
22:19	0x3	USB_EVENT: 0 = ACTIVE_LOW 1 = ACTIVE_HIGH
18	0x1	PWR_INT_N: power interrupt - now permanently tied to bit 18 0 = ACTIVE_LOW 1 = ACTIVE_HIGH
17	0x1	KBC: KBC wake level 0 = ACTIVE_LOW 1 = ACTIVE_HIGH
16	0x1	RTC: RTC wake level 0 = ACTIVE_LOW 1 = ACTIVE_HIGH
15:0	0xffff	EVENT: pin 0-15 wake level 0 = ACTIVE_LOW 1 = ACTIVE_HIGH

9.6.6 APBDEV_PMC_WAKE_STATUS_0

This register stores status of the wake events. Event will be set if level matches and is not masked.

Write will reset wake event set.

PMC Wake Status

Offset: 014h | Read/Write: R/W | Reset: 0b00000000000000000000000000000000

Bit	Reset	Description
31	0x0	RESET_N: external reset 0 = NOT_SET 1 = SET
30:23	0x0	EVENT_RES: 0 = NOT_SET 1 = SET
22:19	0x0	USB_EVENT: USB wake events 0 = NOT_SET 1 = SET
18	0x0	PWR_INT_N: power interrupt 0 = NOT_SET 1 = SET

Bit	Reset	Description
17	0x0	KBC: KBC wake 0 = NOT_SET 1 = SET
16	0x0	RTC: RTC wake 0 = NOT_SET 1 = SET
15:0	0x0	EVENT: pin 0-15 wake 0 = NOT_SET 1 = SET

9.6.7 APBDEV_PMC_SW_WAKE_STATUS_0

This register stores status of the wake events. Latching of the events in software wake status is enabled by PMC_CNRL register bit LATCHWAKE_EN.

Latching will stop at 1 to 0 transition on this bit. Event will be set if level matches. Masking is not affecting this register. Write will reset wake events set.

PMC Software Wake Status

Offset: 018h | Read/Write: R/W | Reset: 0b00000000000000000000000000000000

Bit	Reset	Description
31	0x0	RESET_N: external reset 0 = NOT_SET 1 = SET
30:23	0x0	EVENT_RES: 0 = NOT_SET 1 = SET
22:19	0x0	USB_EVENT: USB wake events 0 = NOT_SET 1 = SET
18	0x0	PWR_INT: power interrupt 0 = NOT_SET 1 = SET
17	0x0	KBC: KBC wake 0 = DISABLE 1 = ENABLE
16	0x0	RTC: RTC wake 0 = DISABLE 1 = ENABLE
15:0	0x0	EVENT: pin 0-15 wake 0 = DISABLE 1 = ENABLE

9.6.8 APBDEV_PMC_DPD_PADS_ORIDE_0

This register enables overrides idle state values and deep power down mode with values driven by KBC (keyboard) or PMC (SYS_CLK_REQ, LED_BLINK).

If bit is set to 1, particular I/O will drive core value, not DPD idle value (dpd_io_0/1). Pad will not be put in deep power down mode. It will not drive data from mini pad macros stored during sample cycle, but direct data from KBC or PMC.

> **Note:** This register has to be set before entering Deep Sleep mode.

DPD Pads Override

Offset: 01ch | Read/Write: R/W | Reset: 0b00001000000000000000000000

Bit	Reset	Description
25	0x0	KBC_ROW10: override dpd idle state with row 10 output 0 = DISABLE 1 = ENABLE
24	0x0	KBC_ROW9: override dpd idle state with row 9 output 0 = DISABLE 1 = ENABLE
23	0x0	KBC_ROW8: override dpd idle state with row 8 output 0 = DISABLE 1 = ENABLE
22	0x0	KBC_ROW7: override dpd idle state with row 7 output 0 = DISABLE 1 = ENABLE

0	0x0	KBC_COL0: override dpd idle state with column 0 output 0 = DISABLE 1 = ENABLE

9.6.9 APBDEV_PMC_DPD_SAMPLE_0

Setting this register will trigger sampling pads data and direction in which pad will be driven during Deep Sleep mode.

Before writing to this register, all interfaces going to pads must be set to ideal "idle" mode, which is expected to be driven by pads when chip enters Deep Sleep.

DPS Power Down Sample has to precede Deep Power Down Enable write. DPD Sample should not be deasserted until transition from Deep Sleep to WB0.

Deep Power Down Sample

Offset: 020h | Read/Write: R/W | Reset: 0b0

Bit	Reset	Description
0	0x0	ON: will set sampling of pads value 0 = DISABLE 1 = ENABLE

9.6.10 APBDEV_PMC_DPD_ENABLE_0

Setting this register will trigger entering Deep Sleep state. Must be preceded by DPD_SAMPLE write.

Entering deep power down mode (Deep Sleep) will trigger shut down core power request and shut down system clock request. PLLs, I/Os will enter power deep down mode. All signals going from core power to RTC and pads will be cut off (clamped)

If none of the wake-up events is set, only power on reset can enable back access to the chip.

After serving wake-up event is completed, the register should be set back to 0 to complete Deep Sleep cycle.

Deed Power Down Enable

Offset: 024h | Read/Write: R/W | Reset: 0b0

Bit	Reset	Description
0	0x0	ON: will set sampling of pads value 0 = DISABLE 1 = ENABLE

9.6.11 APBDEV_PMC_PWRGATE_TIMER_OFF_0

Specifies number of APB cycles after which the rail line goes off (turns the power to part of power gated partition). Each rail controls part of powered partition. This register should be set before write to Power Gate Toggle. Shared between all power partitions.

Power Gate Timer Off Register

Offset: 028h | Read/Write: R/W | Reset: 0b11101100101010010111010100110001

Bit	Reset	Description
31:28	0xe	RAIL7: timer value for rail 7
27:24	0xc	RAIL6: timer value for rail 6
23:20	0xa	RAIL5: timer value for rail 5
19:16	0x9	RAIL4: timer value for rail 4
15:12	0x7	RAIL3: timer value for rail 3
11:8	0x5	RAIL2: timer value for rail 2
7:4	0x3	RAIL1: timer value for rail 1

Bit	Reset	Description
3:0	0x1	RAIL0: timer value for rail 0

9.6.12 APBDEV_PMC_PWRGATE_TIMER_ON_0

Specifies number of APB cycles after which the rail line goes on. Shared between all power partitions. Has to be reloaded before each power gate on/off command.

Note: For Tegra 3 this register is being kept for backward code compatibility, timer is based on PWRGATE_TIMER_OFF only

Power Gate Timer On Register

Offset: 02ch | Read/Write: R/W | Reset: 0b11101100101010010111010100110001

Bit	Reset	Description
31:28	0xe	RAIL7: timer value for rail 7
27:24	0xc	RAIL6: timer value for rail 6
23:20	0xa	RAIL5: timer value for rail 5
19:16	0x9	RAIL4: timer value for rail 4
15:12	0x7	RAIL3: timer value for rail 3
11:8	0x5	RAIL2: timer value for rail 2
7:4	0x3	RAIL1: timer value for rail 1
3:0	0x1	RAIL0: timer value for rail 0

9.6.13 APBDEV_PMC_PWRGATE_TOGGLE_0

Write to this register will turn power on/off on to specified power gated partition. Only one partition will be turned on/off at the time.

PWRGATE_STATUS should be read to determine state of the partition before writing to this register.

Turning partition off will cause automatic clamping of all signals generated by the power gated partition being turned off. Before partition is turned off, all clocks to the partition should be stopped and reset to the partition should be asserted.

Turning partition on will not remove clamping. Clamping will be removed only after REMOVE_CLAMPING_CMD write.

User must allow minimum 20 apb clock cycles between consecutive partition Power Gate Toggle requests.

Power Gate Toggle

Offset: 030h | Read/Write: R/W | Reset: 0b0xxxx0000

Bit	Reset	Description
8	0x0	START: start power down/up 0 = DISABLE 1 = ENABLE

Bit	Reset	Description
3:0	0x0	PARTID: id of partition to be toggled 0 = CP 1 = TD 2 = Video Encode 4 = Video Decode 3 = PCI Express 5 = L2 Cache 6 = MPEG Encode 7 = HEG 8 = SAX 9 = CE1 10 = CE2 11 = CE3 12 = A9LP 13 = TD2

9.6.14 APBDEV_PMC_REMOVE_CLAMPING_CMD_0

This is a bit map with one bit per power partition controller by PMC.

When written to 1b, the PMC removes the clamp signals to the corresponding partition. If the partition is not powered on, the register write will be ignored and clamping of the partition will continue

The bit is automatically reset to 0b when the clamping has been removed. SW is responsible to write to this register at a correct time, that is, when the clocks are started but the blocks in that partition are still held in reset.

Remove Clamping

Offset: 034h | Read/Write: R/W | Reset: 0b00000000000000

Bit	Reset	Description
13	0x0	TD2: remove clamping to TD2 0 = DISABLE 1 = ENABLE
12	0x0	A9LP: remove clamping to A9LP 0 = DISABLE 1 = ENABLE
11	0x0	CE3: remove clamping to CE3 0 = DISABLE 1 = ENABLE
10	0x0	CE2: remove clamping to CE2 0 = DISABLE 1 = ENABLE
9	0x0	CE1: remove clamping to CE1 0 = DISABLE 1 = ENABLE
8	0x0	SAX: remove clamping to SAX 0 = DISABLE 1 = ENABLE
7	0x0	HEG: remove clamping to HEG 0 = DISABLE 1 = ENABLE

Bit	Reset	Description
6	0x0	MPE: remove clamping to MPE_CACHE 0 = DISABLE 1 = ENABLE
5	0x0	L2C: remove clamping to L2_CACHE 0 = DISABLE 1 = ENABLE
4	0x0	PCX: remove clamping to PCX 0 = DISABLE 1 = ENABLE
3	0x0	VDE: remove clamping to VDE 0 = DISABLE 1 = ENABLE
2	0x0	VE: remove clamping to VE 0 = DISABLE 1 = ENABLE
1	0x0	TD: remove clamping to TD 0 = DISABLE 1 = ENABLE
0	0x0	CPU: remove clamping to CPU 0 = DISABLE 1 = ENABLE

9.6.15 APBDEV_PMC_PWRGATE_STATUS_0

Displays status of the power partitions. This register should be read before writing to PWRGATE_TOGGLE. Read only register.

Power Gate Status

Offset: 038h | Read/Write: RO | Reset: 0bxxxxxxxxxxxxxx

Bit	Reset	Description
13	X	TD2: status of TD2 partition 0 = OFF 1 = ON
12	X	A9LP: status of A9LP partition 0 = OFF 1 = ON
11	X	CE3: status of CE3 partition 0 = OFF 1 = ON
10	X	CE2: status of CE2 partition 0 = OFF 1 = ON
9	X	CE1: status of CE1 partition 0 = OFF 1 = ON

Bit	Reset	Description
8	X	SAX: status of SAX partition 0 = OFF 1 = ON
7	X	HEG: status of HEG partition 0 = OFF 1 = ON
6	X	MPE: status of MPE partition 0 = OFF 1 = ON
5	X	L2C: status of L2C partition 0 = OFF 1 = ON
4	X	VDE: status of VDE partition 0 = OFF 1 = ON

2	X	VE: status of VE partition 0 = OFF 1 = ON
1	X	TD: status of TD Partition 0 = OFF 1 = ON
0	X	CPU: status of CPU partition 0 = OFF 1 = ON

9.6.16 APBDEV_PMC_PWRGOOD_TIMER_0

Programs length of wakeup reset, asserted after wakeup from lp0. The register should be set before entering lp0 mode.

Programmed values depend on the properties of the power management unit.

Timer value x 30.51 us = reset pulse length

Power Good Timer

Offset: 03ch | Read/Write: R/W | Reset: 0b0000000001111111

Bit	Reset	Description
15:8	0x0	DATA: xtal timer * 32
7:0	0x7f	PMU_TIM: pmu timer * 32

9.6.17 APBDEV_PMC_BLINK_TIMER_0

Will output value to pad only if extra secure scratch register has BLINK_EN set and DPD_PADS_ORIDE has blink bit set.

Setting bit 15 to 1 will output 32 KHz clock (the registers above still have to be set)

- On time DATA_ON<<2 x 30.51 us
- Off time DATA_OFF<<2 x 30.51 us.

Blinker Timer, for External Blinker

Offset: 040h | Read/Write: R/W | Reset: 0b11111111111111111111111111111111

Bit	Reset	Description
31:16	0xffff	DATA_OFF: time off
15	0x1	FORCE_BLINK: if 0 32khz clock
14:0	0x7fff	DATA_ON: time on

9.6.18 APBDEV_PMC_NO_IOPOWER_0

Controls power rails for each I/O level. Can only be set when specific power rail is off. Setting it otherwise will damage the pad.

No I/O Power Register

Offset: 044h | Read/Write: R/W | Reset: 0b0000000000000000

Bit	Reset	Description
14	0x0	SDMMC4: rail sdmmc4 I/Os 0 = DISABLE 1 = ENABLE
13	0x0	SDMMC3: rail sdmmc3 I/Os 0 = DISABLE 1 = ENABLE
12	0x0	SDMMC1: rail sdmmc1 I/Os 0 = DISABLE 1 = ENABLE
11	0x0	PEX_CNTRL: rail pex_cntrl I/Os 0 = DISABLE 1 = ENABLE
10	0x0	CAM: CAM rail I/Os 0 = DISABLE 1 = ENABLE
9	0x0	MIPI: MIPI rail I/Os 0 = DISABLE 1 = ENABLE
8	0x0	SD: rail sd I/Os 0 = DISABLE 1 = ENABLE
7	0x0	MEM: rail mem I/Os 0 = DISABLE 1 = ENABLE
6	0x0	LCD: rail LCD I/Os 0 = DISABLE 1 = ENABLE

Bit	Reset	Description
5	0x0	AUDIO: rail I2S I/Os 0 = DISABLE 1 = ENABLE
4	0x0	VI: rail DVI I/Os 0 = DISABLE 1 = ENABLE
3	0x0	BB: rail dlcd I/Os 0 = DISABLE 1 = ENABLE
2	0x0	UART: rail DBG I/Os 0 = DISABLE 1 = ENABLE
1	0x0	NAND: rail at3 I/Os 0 = DISABLE 1 = ENABLE
0	0x0	SYS: rail AO I/Os 0 = DISABLE 1 = ENABLE

9.6.19 APBDEV_PMC_PWR_DET_0

Active high, sets power detection, only for nine power rails - MIPI doesn't have power detect.

The proper sequence for turning on power detects:

- write 1 to PWR_DET register for fields requiring power detect
- Allow for 3 us delay (in APB clock cycles)
- write 1 to PWR_DET_LATCH

For turning PWR_DET off:

- write 0 to PWR_DET_LATCH
- no delay necessary
- write 0 to PWR_DET

Power Detect

Offset: 048h | Read/Write: R/W | Reset: 0b11111111111111

Bit	Reset	Description
13	0x1	SDMMC3: rail SDMMC3 I/Os 0 = ENABLE 1 = DISABLE

9.6.51 APBDEV_PMC_CPUPWRGOOD_TIMER_0

CPU Power Good Timer

SW 33V override - will work only if SW_E33V_OVR_EN is enabled. 1 will set value to 33V, 0 to 2.5

WARNING! Setting 0 on 3.3V interface will damage the chip!

Each rail has an enable bit, only when enable is set, the value is written.

The behavior for timer DATA of zero and one will be the same (i.e., 1 cycle of delay)

Offset: 0c8h | Read/Write: R/W | Reset: 0b00000000000000001111111111111111

9.6.60 APBDEV_PMC_USB_DEBOUNCE_DEL_0

Determines number of 32kHz clock cycles to debounce USB signal events. A value of 0 means only an NP synchronizer to the 32KHz domain, with no debouncing.

Reset values are for Cold Hardware Reset only

Offset: 0ech | Read/Write: R/W | Reset: 0b000000000000000000000000

Bit	Reset	Description
23:20	0x0	UHSIC_LINE_DEB_CNT: Number of 32kHz debounce cycles for UHSIC port 0
19:16	0x0	UTMIP_LINE_DEB_CNT: Number of 32kHz debounce cycles for UTMIP port 0
15:0	0x0	VAL: Debounce period for ID and VBUS events on all USB ports

9.6.61 APBDEV_PMC_USB_AO_0

Power downs for various USB features controlled by the PMC.

Each UTMIP has the following power downs for features that can lead to wakeup events.

- USBOP_VAL_PD: Power down for D+ value detector (io pad)
- USBON_VAL_PD: Power down for D- value detector (io pad)
- ID_PD: Power down for ID detector (bias pad)
- VBUS_WAKEUP_PD: Power down for VBUS detector (bias pad)

Each UHSIC port has the following power downs for features that can lead to wakeup events:

- STROBE_VAL_PD: Power down for STROBE VALUE detector
- DATA_VAL_PD: Power down for DATA VALUE detector

> **Note:** These HSIC pins have not been added to the pad yet.

Line debounce periods for UTMIP and HSIC PORTS

9.6.62 APBDEV_PMC_CRYPTO_OP_0

A complete solution requires a "semi-sticky" bit in the always-on domain. The Boot ROM would clear this semi-sticky bit for cold boots, but use its value to propagate the crypto-disable flag across LP0. (The Boot ROM always requires crypto functionality, so a pure hardware solution probably isn't reasonable.)

The Boot ROM would be able to clear (to zero) and read the sticky bit, but outside the Boot ROM users would only be able to set (to one) and read the sticky bit. On cold boot, the Boot ROM would always clear the stick bit. On WB0, the Boot ROM would read the sticky bit and copy it's setting to the crypto disable flag.

Crypto Engine Disable Sticky Bit

Offset: 0f4h | Read/Write: R/W | Reset: 0b1

Bit	Reset	Description
0	0x1	VAL: Disabled by default 0 = ENABLE 1 = DISABLE

9.6.63 APBDEV_PMC_PLLP_WB0_OVERRIDE_0

Bit	Reset	Description
0	0x0	BWRITE: disable write to bondout secure registers 0 = OFF 1 = ON

9.6.88 APBDEV_PMC_GATE_0

This register is used for SW controlled synchronization between APB domain and the 32 KHz domain. SW is expected to set the GAKE_WAKE/GATE_DBNS field high to cut the 32 KHz gated clock before updating WAKE_LVL, AUTO_WAKE_LVL, WAKE_MASK and USB_DEBOUNCE_DEL registers. After these registers have been written the GATE_WAKE/GATE_DBNS bit should be written back to '0' to enable the 32 kHz gated clock.

This gates the 32 KHz clock to just the flops that store the above fields.

Offset: 15ch | Read/Write: R/W | Reset: 0b00

Bit	Reset	Description
1	0x0	GATE_WAKE: 0 = OFF 1 = ON
0	0x0	GATE_DBNS: 0 = OFF 1 = ON

9.6.89 APBDEV_PMC_WAKE2_MASK_0

New wake registers due to wake events number exceeding 32

wake2 alignments foo masks, level, status

- WAKE2_*[0] = ulpi_data3
- WAKE2_*[1] = gmi_cs0_n
- WAKE2_*[2] = gmi_cs4_n

5:0	0x3b	RAIL30: timer value for rail 30

9.6.105 APBDEV_PMC_PCX_EDPD_CNTRL_0

Extra secure scratch register

Offset: 1a0h | Read/Write: R/W | Reset: 0b0

Bit	Reset	Description
0	0x0	EN: when set sets the edpd to pcx (pll toggle) 0 = OFF 1 = ON

9.6.106 APBDEV_PMC_OSC_EDPD_OVER_0

This register can be programmed to keep oscillator ON during lp0 mode. It cuts the latency time on lp0 wake if oscillator pad does not have to be restarted.

When oscillator pad is on, during lp0 mode, dspare, duty, strength, bypass are controlled by fields below.

Oscillator can be in one of four modes during lp0 - in dpd, not dpd but not enabled, running, running only when external request is active.

Offset: 1a4h | Read/Write: R/W | Reset: 0b00000000000000001111110

Bit	Reset	Description
22	0x0	OSC_CTRL_SELECT: select whether CAR's OSC_CTRL or PMC's OSC_CTRL_OVER affects the oscillator cell 0 = CAR 1 = PMC
21:20	0x0	XO_LP0_MODE: control the behavior of the oscillator during LP0 (assuming OSC_CTRL_SELECT is set to PMC during LP0, put oscillator in dpd mode during LP0, bypass dpd, but do not enable oscillator during LP0, force the oscillator to run during LP0, run the oscillator when requested by an external clock request pin 0 = DPD 1 = OFF 2 = ON 3 = EXT_REQ

Bit	Reset	Description
19:12	0x0	OSCFI_SPARE: Crystal oscillator spare register control.
11:7	0x0	XODS: Crystal oscillator duty cycle control.
6:1	0x3f	XOFS: Crystal oscillator drive strength control.
0	0x0	XOBP: Crystal oscillator bypass enable (1 = enable bypass).

9.6.107 APBDEV_PMC_CLK_OUT_CNTRL_0

This register was added to control 3 clock outputs of the chip. Each of the clock outputs can be in one of 4 modes - not running, running when request is active high, running when request is active low, always running clock output when not running can be tristated, high or low.

Clock source might be from car unit (not avail when in lp0 mode), Osc, osc_div2, osc_div4

9.6.109 APBDEV_PMC_SENSOR_CTRL_0

For sensor shutdown and control.

Sensor control register defines chip behavior when sensor request is triggered. It can power gate down all CPUs if enabled. It can trigger reset - (will cause CPU power request to go down and power gating down all CPUs)

IMPORTANT-- to preserve RAM content, any reads/writes to scratch registers will be blocked after sensor triggered reset.

SW must reset BLOCK_SCRATCH_WRITE to enable writes to scratch registers.

Offset: 1b0h | Read/Write: R/W | Reset: 0b000

Bit	Reset	Description
2	0x0	BLOCK_SCRATCH_WRITE: reset by user, set by pmc when entering sensor reset 0 = OFF 1 = ON
1	0x0	ENABLE_RST: enables reset on sensor going up. 0 = OFF 1 = ON
0	0x0	ENABLE_PG: power gate cpus on temp sensor going up 0 = OFF 1 = ON

9.6.110 APBDEV_PMC_RST_STATUS_0

Simplified reset and reset source

Offset: 1b4h | Read/Write: R/W | Reset: 0b000

Bit	Reset	Description
2:0	0x0	RST_SOURCE: source of reset 0 = POR 1 = WATCHDOG 2 = SENSOR 3 = SW_MAIN 4 = LP0

9.6.111 APBDEV_PMC_IO_DPD_REQ_0

Puts I/O rails in DPD mode or out of DPD mode, even though the chip is not in lp0. Multiple bits are allowed to be set at the same time. No new operation will be triggered until previous one completes. Consecutive operations issued by completion time of first one, will be dropped. Register will be still updated.

Setting IO_DPD_REQ should be preceded by writing to DPD_SAMPLE registers to enable snapshot of data to be driven and SEL_DPD_TIM register. SEL_DPD_TIM is set to safe value, but it can be lowered if sys clock is slower. (minimum 200 ns required)

DPD Request

Offset: 1b8h | Read/Write: R/W | Reset: 0b00000000000000000000000000000000

14:5	0x1	PLLM_DIVN: PLL feedback divider.
4:0	0xc	PLLM_DIVM: PLL input divider.

9.6.120 APBDEV_PMC_TEST_PWRGATE_0

Force test power gate override off/on

Offset: 1e0h | Read/Write: R/W | Reset: 0b00

Bit	Reset	Description
1:0	0x0	OP: FORCE_ON - force power gated partition to be powered, FORCE_OFF - force power gating partition to be powered down 0 = NONE 1 = FORCE_ON 2 = FORCE_OFF

9.6.121 APBDEV_PMC_PWRGATE_TIMER_MULT_0

Adding register which would allow for multiply of power gating time set by PWRGATE_TIMER_OFF.

Need separate multiplier for CPU, since timing requirements might be different.

The time for each rail set by PWRGATE_TIMER_OFF will be multiplied by MULT for power-gating up/down any power-gated region except CPU. In CPU power-gated case, MULT_CPU will be used with PWRGATE_TIMER_CE* registers value. All timers are in sys_clk units.

Offset: 1e4h | Read/Write: R/W | Reset: 0b0000

Bit	Reset	Description
3:2	0x0	MULT_CPU: 0 = ONE 1 = TWO 2 = FOUR
1:0	0x0	MULT: 0 = ONE 1 = TWO

Bit	Reset	Description
		2 = FOUR

9.6.122 APBDEV_PMC_DSI_SEL_DPD_0

Register to control sel_dpd for DSI pad. Allows driving lp0 value on DSI pad beyond lp0 exit. This enables DSI to be programmed properly at lp0 exit while lp0 value is still driven by brick pad.

Offset: 1e8h | Read/Write: R/W | Reset: 0b00

Bit	Reset	Description
1	0x0	SET_DSIB: 0 = OFF 1 = ON
0	0x0	SET_DSIA: 0 = OFF 1 = ON

9.6.123 APBDEV_PMC_UTMIP_UHSIC_TRIGGERS_0

PMC trigger events for the UTMIP ports as well as the UHSIC port. Sleep walk clearing returns the walk pointer to 00, the first entry in a USB line walk. This is the only way to return a pointer to 0.

Pad configuration captures a set of FLLS parameters prior to resting the port so their value can be retained in deep sleep.

The trigger should only happen on the fields that are set to TRIG (1) when writing. Returned read value should always be all NULL fields.

The FORCE_WALK bits trigger a SLEEP.

This does not need to be a real register, so it should not consume much area.

Any value read back should be 0.

Triggers for USB ports

Offset: 1ech | Read/Write: R/W | Reset: 0bxxxxxxxxxxxxxxxx

Bit	Reset	Description
15	X	UHSIC_CLR_WAKE_ALARM_P0: Clear wake event for UHSIC port 0 0 = NULL 1 = TRIG

3:2	X	LS_FSLEW_P0: I/O pad LS_FSLEW1..0 for UTMIP P0
1:0	X	LS_RSLEW_P0: I/O pad LS_RSLEW1..0 for UTMIP P0

9.6.126 APBDEV_PMC_UTMIP_TERM_PAD_CFG_0

Set of termination config values for USB I/O pads under DPD mode. These are config values programmed, not captured, at a time prior to entering DPD. Capturing them would be complex because it would require costly synchronizers as well as some logic. The range for RCTRL and TCTRL is 0 to 16.

These values need to be converted to a thermal encoding (only one 0 to 1 transition allowed in the word from MSB to LSB). For example:

0 - 0000_0000_0000_0000

1 - 0000_0000_0000_0001

2 - 0000_0000_0000_0011

...

15 - 0111_1111_1111_1111

16 - 1111_1111_1111_1111

I/O termination config for all UTMIP ports

Offset: 1f8h | Read/Write: R/W | Reset: 0b0100001000

Bit	Reset	Description
9:5	0x8	TCTRL_VAL: HS termination calibration value, range 0 to 16
4:0	0x8	RCTRL_VAL: 1.5kOhm pull up calibration value, range 0 to 16

9.6.127 APBDEV_PMC_UTMIP_UHSIC_SLEEP_CFG_0

Register that config the value of the line that could cause a wakeup event.

ANY -- signifies any line change DM EDGE or DP EDGE for UTMIP.

NONE -- signifies no wakeup possible.

One can use the two most significant bits (3:2) of the WAKE_VAL to 4x1 select whether:

- 00 Check both bits for value on two LSB (1:0).
- 01 Check bit DM (or strobe for HSIC) against bit 0

- 10 Check bit DP (or DATA for HSIC) against bit 1
- 11 Check for edge on DP against bit 1, edge on DM against bit 0

9.6.128 APBDEV_PMC_UTMIP_UHSIC_SLEEPWALK_CFG_0

Register determines when sleep walking should take effect. Upon a specific GPIO event, on any wake event or on a linevalue change.

Note that it is also possible to force a sleep walk, see register UTMIP_UHSIC_TRIGGERS to force the event.

Sleep Walk Sequence Enables

Offset: 200h | Read/Write: R/W | Reset: 0b00000000000000000000000000000000

9.6.129 APBDEV_PMC_UTMIP_SLEEPWALK_P0_0

Registers that hold the sequence of control values to the UTMIP pads on the four consecutive cycles of a walk. The pad pins that are controlled are:

MASTER_USBOP_RPD

MASTER_USBON_RPD

MASTER_USBOP_RPU

MASTER_USBON_RPU

MASTER_AP

MASTER_AN

MASTER_HIGHZ

For the walk to take effect at the pad, the pin MASTER_ENABLE must be set high in the config register. Otherwise the pad will ignore the values.

If no walk is enabled or forced, then the walk pointer remains stuck on phase A. The walk pointer should use a 2 bit Gray code so that Phase A is 00, Phase B is 01, Phase C is 11 and Phase D is 10. Once Phase D is reached, only a reset of the phase pointer can bring it back to Phase A.

Four phases should be sufficient to handle most wakeup events.

Signaling Sequence for UTMIP Port 0 Wakeup

9.6.132 APBDEV_PMC_UHSIC_SLEEPWALK_P0_0

Registers that hold the sequence of control values to the UTMIP pads on the four consecutive cycles of a walk. The pad pins that are controlled are:

STROBE_RPD

DATA_RPD

STROBE_RPU

DATA_RPU

At this time there are no STROBE, DATA ports that should be driven by the host. So these outputs from the module should be left dangling (unconnected) until a time that departure may be implemented.

Signaling Sequence for UHSIC Port 0 Wakeup

9.6.134 APBDEV_PMC_UTMIP_UHSIC_FAKE_0

Instead of using the pad value for USBOP_VAL, USBON_VAL, STROBE_VAL, DATA_VAL, VBUS_WAKEUP, ID from the UTMIP and HSIC pads, force a 2x1 mux at the input of the PMC pad macro when fake values are enabled. This could the useful feature of putting a line at rest when needed. It also has important debug merits. This mux should be placed in front of the NP synchronizer for these signals (saved power on the synchronizer). This will have to be waived in our sync checks.

Fake the line value for the PMC pad macro

Offset: 218h | Read/Write: R/W | Reset: 0b00010001000100010001000100010001

Bit	Reset	Description

10.0 REAL-TIME CLOCK

The Real-Time Clock (RTC) module maintains seconds and milliseconds counters, and five alarm registers. RTC is in 'always-on' power domain, allowing for the counters to run and alarms to trigger when the system is in low-power state. If configured, interrupts triggered by RTC can cause the system to wake up from a low-power state.

Features

- 10-bit milliseconds counter that runs off of a 32.768 KHz clock source.
- 32-bit seconds counter that increments for every 1000 milliseconds.
- Alarm feature that triggers an interrupt when the specified value matches the milliseconds counter.
- Alarm feature that triggers an interrupt when the specified value matches the seconds counter.
- Count-down alarm feature that triggers an alarm after counting down the specified number of seconds.
- Count-down alarm feature that triggers an alarm after counting down the specified number of milliseconds.
- Security bit that disables further processor writes to the seconds counter and ensures that the RTC clock keeps running.
- Hardware adjusts drift in clock which can occur due to PPM variations in oscillator output.

10.1 Functional Description

The RTC operates in two clock domains; APB clock domain, and 32 KHz clock domain. RTC continues updating the millisecond and second counters and continues triggering interrupts even when the MAIN partition is powered down. Since the APB clock is disabled when MAIN is powered down, registers are implemented in the 32 KHz clock domain.

All the registers except the BUSY register are implemented in 32 KHz clock domain. Writes are transferred to 32 KHz domain with BUSY.STATUS set as BUSY until the transfer is completed. Reads are shadowed in APB clock domain and return immediately.

RTC implements a Seconds Counter register, three Alarm registers, two countdown alarms, and various interrupt related registers.

At boot, the seconds counter is updated to reflect the current time. Writes to seconds counter can be disabled by writing to CONTROL.DIS_WR_SEC_CNT bit. Alarm registers and countdown alarm registers set interrupt bits when corresponding events occur. Interrupt status, mask, set and source registers reflect the status and also allow setting and clearing of various bits. All registers (except the BUSY register) are implemented in 32K clock domain. Writes are transferred to 32K domain with BUSY STATUS set as BUSY until the transfer completes. Reads are shadowed in APB domain and will return immediately.

Resets

RTC receives an asynchronous reset which is synchronized to APB clock and RTC clock domains.

10.2 RTC Registers

10.2.1 APBDEV_RTC_CONTROL_0

Control register.

Offset: 000h | Read/Write: R/W | Reset: 0b0

Bit	Reset	Description
0	0x0	WR_SEC_CNT: When set, writes to SECONDS counter are disabled. can only cleared by resetting the RTC module 0 = DISABLE 1 = ENABLE

10.2.2 APBDEV_RTC_BUSY_0

Busy register.

Offset: 004h | Read/Write: RO | Reset: 0bx

Bit	Reset	Description
0	X	STATUS: This bit is set when a write is initiated on the APB side. It is cleared once the write completes in RTC 32KHz clock domain which could be several thousands of APB clocks. This must be IDLE before a write is initiated. Note that this bit is only for writes. 0 = IDLE 1 = BUSY

10.2.3 APBDEV_RTC_SECONDS_0

Seconds counter register.

SECONDS register is copied over to APB side every eight 32KHz clocks (~250uS). Because of this, performing a read immediately after a write might return old value. This covers 49710.26 Days (or) 136.192 Years of 365 days each

Offset: 008h | Read/Write: R/W | Reset: 0b00000000000000000000000000000000

Bit	Reset	Description
31:0	0x0	SECONDS: seconds counter is incremented for every 1000 milli-seconds

10.2.4 APBDEV_RTC_SHADOW_SECONDS_0

Shadowed seconds counter register.

Shadow SECONDS register is updated over to APB side whenever there is a read to milliseconds counter. Since the software cannot read both registers at any given point of time, the Seconds register is snapshotted in this Register. If the software needs to read two registers, then it should read MILLI_SECONDS Register and then this Register. It should not read the SECONDS register, as it contains the updated value.

Offset: 00ch | Read/Write: RO | Reset: 0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx

Bit	Reset	Description
31:0	X	SHADOW_SECONDS: A snapshot of the SECONDS counter is taken whenever there is a read to MILLI_SECONDS Register.

10.2.5 APBDEV_RTC_MILLI_SECONDS_0

Milliseconds counter register.

Milli SECONDS register is copied over to APB side every eight 32KHz clocks (~250uS). Because of this, performing a read immediately after a write might return old value.

Offset: 010h | Read/Write: RO | Reset: 0bxxxxxxxxxx

Bit	Reset	Description
9:0	X	MILLI_SECONDS: milliseconds counter is incremented using Bresenham algorithm

10.2.6 APBDEV_RTC_SECONDS_ALARM0_0

Seconds alarm0 register.

When the value in this register matches the seconds counter, corresponding interrupt status bit is set.

If enabled, the interrupt line is asserted. A value of zero disables the alarm.

Offset: 014h | Read/Write: R/W | Reset: 0b00000000000000000000000000000000

Bit	Reset	Description
31:0	0x0	SECS_MATCH_VALUE: match value to trigger the alarm

10.2.7 APBDEV_RTC_SECONDS_ALARM1_0

Seconds alarm1 register.

When the value in this register matches the seconds counter, corresponding interrupt status bit is set.

If enabled, the interrupt line is asserted. A value of zero disables the alarm.

Offset: 018h | Read/Write: R/W | Reset: 0b00000000000000000000000000000000

Bit	Reset	Description
31:0	0x0	SECS_MATCH_VALUE: match value to trigger the alarm

10.2.8 APBDEV_RTC_MILLI_SECONDS_ALARM_0

Milliseconds alarm register.

When the value in this register matches the milliseconds counter, corresponding interrupt status bit is set.

If enabled, the interrupt line is asserted. A value of zero disables the alarm.

Offset: 01ch | Read/Write: R/W | Reset: 0b0000000000

Bit	Reset	Description
9:0	0x0	MSEC_MATCH_VALUE: milliseconds match value.

10.2.9 APBDEV_RTC_SECONDS_COUNTDOWN_ALARM_0

Countdown alarm registers.

If ENABLE_ENABLED, an internal counter is loaded with VALUE and counted down. The interrupt bit corresponding to the countdown_alarm_0 is set after the specified number of seconds have elapsed.

The interrupt bit corresponding to the countdown_alarm_1 is set after the specified number of milliseconds have elapsed. If REPEAT is ENABLED, the countdown operation is performed repeatedly.

Offset: 020h | Read/Write: R/W | Reset: 0b00000000000000000000000000000000

Bit	Reset	Description
31	0x0	ENABLE: enable bit for the countdown operation. If repeat is not set, this bit is cleared once the internal counters counts down to specified value. 0 = DISABLED 1 = ENABLED
30	0x0	REPEAT: repeat bit for the countdown operation 0 = DISABLED 1 = ENABLED
29:0	0x0	VALUE: number of milliseconds to countdown

10.2.10 APBDEV_RTC_MILLI_SECONDS_COUNTDOWN_ALARM_0

Offset: 024h | Read/Write: R/W | Reset: 0b00000000000000000000000000000000

Bit	Reset	Description
31	0x0	ENABLE: enable bit for the countdown operation. If repeat is not set, this bit is cleared once the internal counters counts down to specified value. 0 = DISABLED 1 = ENABLED
30	0x0	REPEAT: repeat bit for the countdown operation 0 = DISABLED 1 = ENABLED
29:0	0x0	VALUE: number of milliseconds to countdown

10.2.11 APBDEV_RTC_INTR_MASK_0

Interrupt mask register.

This register stores the masks for the interrupts. If a bit is set 1 and the corresponding interrupt condition is satisfied, interrupt line to system interrupt controller is asserted.

Offset: 028h | Read/Write: R/W | Reset: 0b00000

Bit	Reset	Description
4	0x0	MSEC_CDN_ALARM
3	0x0	SEC_CDN_ALARM
2	0x0	MSEC_ALARM
1	0x0	SEC_ALARM1
0	0x0	SEC_ALARM0

10.2.12 APBDEV_RTC_INTR_STATUS_0

Interrupt status register.

Bits in this register are high after the interrupt condition is satisfied.

A write to this register clears the bits corresponding to the data bits that are high in the write data.

Offset: 02ch | Read/Write: R/W | Reset: 0b00000

Bit	Reset	Description
4	0x0	MSEC_CDN_ALARM
3	0x0	SEC_CDN_ALARM
2	0x0	MSEC_ALARM
1	0x0	SEC_ALARM1
0	0x0	SEC_ALARM0

10.2.13 APBDEV_RTC_INTR_SOURCE_0

Interrupt source register.

This is a read-only register which returns the AND of interrupt source and interrupt mask registers.

Offset: 030h | Read/Write: R/W | Reset: 0b00000

Bit	Reset	Description
4	0x0	MSEC_CDN_ALARM
3	0x0	SEC_CDN_ALARM
2	0x0	MSEC_ALARM
1	0x0	SEC_ALARM1
0	0x0	SEC_ALARM0

10.2.14 APBDEV_RTC_INTR_SET_0

Interrupt set register.

This is a write-only register which can be used to set the interrupt status bit.

A write to this register causes the bits in status register to be set if the corresponding bit in write data is 1'b1. Read always returns 'h0.

Offset: 034h | Read/Write: R/W | Reset: 0b00000

Bit	Reset	Description
4	0x0	MSEC_CDN_ALARM
3	0x0	SEC_CDN_ALARM
2	0x0	MSEC_ALARM
1	0x0	SEC_ALARM1
0	0x0	SEC_ALARM0

10.2.15 APBDEV_RTC_CORRECTION_FACTOR_0

Correction factor (digital trimming) register

Support is for +/- 500ppm, but +/- 50 ppm is maximum

Offset: 038h | Read/Write: R/W | Reset: 0b0000000000

Bit	Reset	Description
9	0x0	DIRECTION: 0 = DECREMENT 1 = INCREMENT
8:0	0x0	PPM

11.0 GR2D

11.1 Introduction

GR2D is a 2D graphics acceleration block, capable of performing a range of copying, blending, scaling, rotation and other 2D graphics operations. It is also sometimes used in conjunction with the Encode Pre-Processor (EPP), to which it has a direct path.

This section is not intended to be a programming guide to GR2D, as it is expected that NVIDIA supplied drivers will always be used with it. However, the register interface is documented to aid with understanding those drivers.

11.2 Registers

11.2.1 G2SB_G2SBFORMAT_0

Offset: 0x1c │ Byte Offset: 0x70 │ Read/Write: R/W │ Reset: 0x00000000 (0bxxxxxxxxxxxxxx)

Bit	Reset	Description
12:8	X	DIFMT: Destination Image Data Format. This parameter defines the data format of destination output. There are two groups of data formats, RGB and YCbCr (YUV) format. CbCr (UV) components may be represented in either offset binary or 2's complement. 00000 U8Y8V8Y8, YUV 4:2:2, 8-bit for each component, U/V in offset binary format 00001 Y8U8Y8V8, YUV 4:2:2, 8-bit for each component, U/V in offset binary format 00010 Y8V8Y8U8, YUV 4:2:2, 8-bit for each component, U/V in offset binary format 00011 V8Y8U8Y8, YUV 4:2:2, 8-bit for each component, U/V in offset binary format 00100 U8Y8V8Y8, YUV 4:2:2, 8-bit for each component, U/V is 2's complement 00101 Y8U8Y8V8, YUV 4:2:2, 8-bit for each component, U/V is 2's complement 00110 Y8V8Y8U8, YUV 4:2:2, 8-bit for each component, U/V is 2's complement 00111 V8Y8U8Y8, YUV 4:2:2, 8-bit for each component, U/V is 2's complement 01000 bpp16 5-6-5 {R[4:0], G[5:0], B[4:0]} 01001 RESERVED 01010 RESERVED 01011 RESERVED 01100 bpp16 5-6-5 Byte-swapped {G[2:0], B[4:0], R[4:0], G[5:3]} 01101 RESERVED 01110 R8G8B8A8 01111 B8G8R8A8 1xxxx RESERVED 0 = U8Y8V8Y8_OB 1 = Y8U8Y8V8_OB 2 = Y8V8Y8U8_OB 3 = V8Y8U8Y8_OB 4 = U8Y8V8Y8_TC 5 = Y8U8Y8V8_TC 6 = Y8V8Y8U8_TC 7 = V8Y8U8Y8_TC 8 = B5G6R5 9 = RESERVED9 10 = RESERVED10 11 = RESERVED11 12 = B5G6R5BS 13 = RESERVED13 14 = R8G8B8A8 15 = B8G8R8A8 16 = RESERVED16 17 = RESERVED17 18 = RESERVED18 19 = RESERVED19

Offset: 0x1d │ Byte Offset: 0x74 │ Read/Write: R/W │ Reset: 0x00000000 (0b00x00000000000000x0xx0xx00000)

Bit	Reset	Description
31	0x0	DISDW: Output destination writes go either to image memory or the EPP. 0: Output data is sent to memory 1: YUV or RGB data is passed directly to the EPP module, and no destination writes take place. 0 = GOTO_IMAGE_BUFFER 1 = GOTO_EPP
30	0x0	ENDITH: Enable Dithering (ENDITH) For 16 bit RGB output modes, the LSB of the color components can be modified by adding a variable residual value that will reduce the banding artifacts that can appear on the display. 0 Normal operation 1 Enable dithering 0 = DISABLE 1 = ENABLE
28	0x0	KPOL: Key Signal Polarity (KPOL) Color/Chroma key signal is generated by comparing source input pixel color to a range of a color specified by lower and upper limit values. The key signal is interpreted in two ways, depending on which one of video and graphics images is foreground (and the other is background). This is effective only if Key signal generator is enabled. (see G2CMKEYL, G2CMKEYU) 0 Key signal is set to 1 when source pixel is within the lower and upper limit color range. 1 Key signal is set to 1 when source pixel is outside the lower and upper limit color range. 0 = WITHIN_BOUNDS 1 = OUTSIDE_BOUNDS
27	0x0	KEYEN: Key Signal Generator Enable (KEYEN) Key signal generator generates either chroma key signal (from YCbCr signal) or color

Bit	Reset	Description
		key signal (from RGB signal) 0 Key signal generator is disabled. 1 Key signal generator is enabled. 0 = DISABLE 1 = ENABLE
26	0x0	DBSEL: StretchBLT Destination Buffer Selection (DBSEL) StretchBLT processing involves frame-rate conversion from a series of source images to another series of destination images (field-rate of the source video to frame-rate of the PC display). In order to avoid image tearing, it is preferred to use two buffer sections in the destination video area. This bit selects one of the two buffering blocks to which this StretchBLT command delivers the destination image. The two buffering memory blocks are called A and B. 0 Destination image goes to ‘A’ buffer. 1 Destination image goes to ‘B’ buffer. 0 = DST_A 1 = DST_B
25	0x0	SBSEL: StretchBLT Source Buffer Selection (SBSEL) StretchBLT processing involves frame-rate conversion from a series of source images to another series of destination images (field-rate of the source video to frame-rate of the PC display). In order to avoid image tearing, it is preferred to use two buffer sections in the source video area. This bit selects one of the two buffering blocks from which this StretchBLT command receives the source image. The two buffering memory blocks are called source-A and source-B. 0 Source image comes from ‘source-A’ buffer. 1 Source image comes from ‘source-B’ buffer. 0 = SRC_A 1 = SRC_B
24	0x0	SITYPE: StretchBLT Source Type (SITYPE) This bit identifies two types of source images. If source image is 2-to-1 interlaced and StretchBLT processes either one of the two interlaced field-images, physical (positional) displacement between the two interlaced fields must be taken into account. One field-image that is placed higher in position than the other field-image is called top-field and the other is called bottom-field. StretchBLT processing has to lower the top-field (or raise the bottom-field) to match the corresponding two target images in the overlay window (that is progressively scanned) right at the same position. If source image is full frame-image obtained from two interlaced field-images, its type is ‘top-field’. If source images are progressively scanned, the type identification is not significant and they may be designated as one of the two types 0 Source image is ‘top-field’. 1 Source image is ‘bottom-field’. 0 = TOP_FIELD 1 = BOTTOM_FIELD
23	0x0	RANGEREDFRM: In the VC-1 specification, when the value of RANGEREDFRM variable (1-bit) for a picture is equal to 1, the picture shall be scaled up according to the following equation: Y = clip(((Y-128)*2) + 128);Cb = clip(((Cb-128)*2) + 128);Cr = clip(((Cr-128)*2) + 128);The clip operator limits the output to [0, 255].The input is also limited to [0, 255].In the VC-1 nomenclature, the output (Y, Cb, Cr) tuple corresponds to the 'decoded' picture. The input (Y, Cb, Cr) tuple corresponds to the 'reconstructed' picture. The above equations create the decoded picture while keeping the reconstructed picture intact. Only YUV _OB formats are supported with range reducation enabled, not the YUV _TC or RGB formats. The YUV data coming from the video frame buffers (reconstructed picture) in DRAM was scaled up using the above equations and given to the display. The value of 1-bit wide RANGEREDFRM variable was configured in the DVO per frame and the frame was scaled whenever RANGEREDFRM == 1.

Bit	Reset	Description
		0 = DISABLE 1 = ENABLE
22:20	0x0	HFTYPE: StretchBLT Horizontal Filter Mode (HFTYPE[2:0]) The six-tap horizontal interpolation filter can be operated in various operation modes. For the image expansion, it should be programmed as a pure 6-tap interpolator. For the image contraction, it can work as partly lowpass filter and partly interpolater with varying degree depending on the contraction ratio. For StretchBLT, this parameter is used as an index (selection) to an internal lookup table that stores the group of filter-coefficients for the different modes of horizontal filtering. 000: Pure interpolation filter. 001 010 011 100 101 110: mix of interpolation and low pass filters 111: DISABLE. 0 = INTERP 1 = LPF1 2 = LPF2 3 = LPF3 4 = LPF4 5 = LPF5 6 = LPF6 7 = DISABLE

11.2.4 G2SB_G2CONTROLMAIN_0

G2 Blit Formats:

(1) G2 Blit size is based on height in lines, width in pixels, stride in bytes, and pixel size (color depth). Unless alpha blending is enabled, G2 doesn't care about pixel components.

Source color depths supported by G2 Blit:

- color depth same as destination: G2CONTROLMAIN.SRCCD = 1
- monochrome: G2CONTROLMAIN.SRCCD = 0

(source monochrome color determined by G2SRCBGC, G2SRCFGC)

Pattern color depths supported by G2 Blit:

- color depth same as destination: G2PATOS.PATCD = 1
- monochrome: G2PATOS.PATCD = 0

(pattern monochrome color determined by G2PATBGC, G2PATFGC)

Destination color depths supported by G2 Blit:

- 1 byte per pixel: G2CONTROLMAIN.DSTCD = BPP8
- 2 bytes per pixel: G2CONTROLMAIN.DSTCD = BPP16
- 4 bytes per pixel: G2CONTROLMAIN.DSTCD = BPP32

(2) Alpha blending operates on 3 or 4 component pixels of a specified color depth. One of the components may be alpha (A), depending on the alpha blend format, which is only allowed in certain component positions defined below. The only format rule of the remaining components is that they must be in the same source and destination position because the alpha blend engine does not support component swapping. For example, valid 32BPP formats are: RGBA_8888->RGBA_8888, BGRA_8888->BGRA_8888, GRBA_8888->GRBA_8888, etc.

Source formats supported by G2 alpha blend:

- color depth BPP8: no supported formats
- color depth BPP16:

- ALPTYPE_PLS1BPP: xxxA_5551 (ex: BGRA_5551 = A[15] R[14:10] G[9:5] B[4:0])
- ALPTYPE_PLS4BPP: xxxA_4444 (ex: BGRA_4444 = A[15:12] R[11:8] G[7:4] B[3:0])
- (other): xxx_565 (ex: BGR_565 = R[15:11] G[10:5] B[4:0])

- color depth BPP32:
  - (all) : xxxA_8888 (ex: BRGA_8888 = A[31:24] R[23:16] G[15:8] B[7:0])

Destination formats supported by G2 alpha blend:

- color depth BPP8: no supported formats
- color depth BPP16: xxx_565 (ex: BGR_565 = R[15:11] G[10:5] B[4:0])
- color depth BPP32: xxxA_8888 (ex: BRGA_8888 = A[31:24] R[23:16] G[15:8] B[7:0])

srcColor format	srcCoverage format	legal dest format(s)
A1B5G5R5	VCAA	A1B5G5R5
R8G8B8A8	VCAA	R8G8B8A8, B5G6R5
B5G6R5	VCAA	B5G6R5

To program resolve type:

ALPTYPE == FIX: B5G6R5 -> B5G6R5

ALPTYPE == PLS1BPPAL: A1B5G5R5 -> A1B5G5R5

ALPTYPE == PLS8BPP: R8G8B8A8 -> R8G8B8A8

ALPTYPE == PLS8BX: R8G8B8A8 -> B5G6R5

(2) Color surface programming

- color surface base address: SRCBA
- sub-surface start x: SRCX (pixel index)
- sub-surface start y: SRCY (line index)
- color surface stride: SRCS (bytes)

The engine supports sub-surface resolve. One can imagine a full color buffer of 1024x768, but

```
[pseudo_code]
  color_surface_start_address_fetch = pcurctx->regs.rG2SRCBA.uSRCBA() +
   (pcurctx->regs.rG2SRCPS.uSRCX() * VCAAState.color_surface_depth) +
   (pcurctx->regs.rG2SRCPS.uSRCY() * VCAAState.color_surface_stride);
```

(3) VCAA surface programming

- vcaa surface base address: PATBA

- vcaa surface stride: PATST (bytes)

```
[pseudo_code]
      vcaa_surface_start_address_fetch = pcurctx->regs.rG2PATBA.uPATBA();
```

SW *MUST* directly program this register to the proper sub-surface location in the vcaa surface which corresponds to the SRCX and SRCY programming. The calculation is PATBA = vcaa_base_address + SRCX * (1) + SRCY * PATST;

(4) Resolve surface programming

- resolve window width: DSTWIDTH (pixels)
- resolve window height: DSTHEIGHT (lines)
- resolve output stride: DSTS (bytes)

These values program the width and height of the resolved surface. In the base case,

- DSTWIDTH = color surface width
- DSTHEIGHT = color sufrace height
- DSTS = resolve surface format bpp * DSTWIDTH

The vcaa engine technically supports DSTX and DSTY (like SRCX and SRCY).

```
  [pseudo_code]
     resolve_surface_start_address_put = pcurctx->regs.rG2DSTBA.uDSTBA() +
       (pcurctx->regs.rG2DSTPS.uDSTX() * resolve_surface_color_depth) +
       (pcurctx->regs.rG2DSTPS.uDSTY() * resolve_surface_color_stride);
```

(5) Resolving a pixel

The coverage surface is a 8 bits per pixel surface (C4X4). The surface is initialized to all 1s by 3d.

For a given pixel, we need to look up 4 bits of coverage data. If the data is 0xf, the pixel does not need to be resolved. Otherwise, we need to reblend the pixel with certain weightings of its neighbors (i.e. we're on the edge of some geometry)

If any coverage bit is 0, we need to resolve the color. To do so, we calculate the following equation:

```
   color_new = (
                 20*color_old +
                 27*(
                     ((cover_down  == 0) ? color_down  : color_old) +
                     ((cover_right == 0) ? color_right : color_old) +
                     ((cover_left  == 0) ? color_left  : color_old) +
                     ((cover_up    == 0) ? color_up    : color_old)
                     )
               ) / 128;
```

If coverage bit == 0, then we use the neighbor color value in the resolve

If coverage bit == 1, then we use the center color value in the resolve

The resolve is done on a per channel (r/g/b/a) basis:

- format convert input channel to 8-bit
- perform resolve equation above
- format convert to output format

For the resolution of the alpha channel:

- In B5G6R5: no alpha information. do nothing.
- In A1B5G5R5: no resolve. keep the source color alpha bit.
- In R8G8B8A8: normal 8-bit channel resolve

(6) Resolving a pixel on the edge

When on an edge, the vcaa engine treats the coverage bit as a 1. Use the center color value. This holds true even on the edge of the sub-surface resolve window when located in the middle of the larger surface

(7) Maximum dimensions

The maximum resolve sub-surface is 4096 pixels wide.

(8) Surface restrictions

The VCAA engine has the following restrictions with respect to input surfaces

- input base address is 128-bit memory word aligned
- input stride is multiple of 128-bits (16 bytes)

The VCAA engine has the following restrictions with respect to output surfaces

- output base address is 128-bit memory word aligned
- output stride is multiple of 128 bits (16 bytes)

(9) Coverage surface layout

The surface is C4X4.

Surface layout (C4X4)

```
        (lsb2msb)  C0_C1_C2_C3_X_X_X_X     (X is a don't care.  Qrast inits to 1)
        (msb2lsb)  X_X_X_X_C3_C2_C1_C0

      +          o          o
           C0
              C1   Cov(0,1)
         C2
           C3
      o          o          o

        Cov(1,0)   Cov(1,1)

      o          o          o

      +/o = pixel centers
```

In the example above,

```
         Cov(0,0) = X_X_X_X_C3_C2_C1_C0
         C3       = V_C3(Cov(0,0));
         ..         ..
         C0       = V_C0(Cov(0,0));
      #define V_C3(bits) (bits & 0x8)
      #define V_C2(bits) (bits & 0x4)
```

```
#define V_C1(bits)  (bits & 0x2)
#define V_C0(bits)  (bits & 0x1)
```

Resolving a pixel

In an ideal world, the coverage would be simply laid out such that when resolving Pixel(x,y), we would need only to fetch Cov(x,y) to get all 4 bits of information.

In actuality, the coverage surface was rearranged to help qrast in performance. To resolve Pixel(x,y) gr2d has to fetch 4 C4X4 bytes [Cov(x,y), Cov(x-1,y), Cov(x,y-1), Cov(x-1,y-1)]. From each C4X4 byte, it extracts one bit which is used in the resolve equations shown in (5).

Need the logical vcaa bits (DRLU) for blend which is spread across four C4X4 coverage bytes

```
      U
L
   o
      R
  D
```

where

```
o = Pixel(x,y)
D = V_C1(Cov(x-1,y))
R = V_C0(Cov(x,y))
L = V_C3(Cov(x-1,y-1))
U = V_C2(Cov(x,y-1))
```

Offset: 0x1f | Byte Offset: 0x7c | Read/Write: R/W | Reset: 0x00000000 (0b000000x00xx00xx0000000000000000)

Bit	Reset	Description
31:0	X	PAT_BASE: pattern base address in tile mode, PATBA is the linear address where pixel start

11.2.45 G2SB_G2SRCBA_SB_SURFBASE_0

SB_SURFBASE registers

These registers need only be programmed when using SB. They point to the base of the various source and destination surfaces. Technically they are only needed when tiling is enabled, but there is no harm in always programming them.

Their counterpart registers (_SB_SURFBASE with SB_SURFBASE stripped off) indicate the location of the first pixel to be sourced or written within the surface.

This register exists to mimic the X, Y (SRCX, SRCY) functionality found in the BitBlt engine.

For example, to get at pixel X, Y:

SRCBA = SRCBA_SB_SURFBASE + Y*stride + X*Bpp

Offset: 0x48 | Byte Offset: 0x120 | Read/Write: R/W | Reset: 0x00000000 (0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx)

Bit	Reset	Description
8	0x0	INCR_SYNCPT_NO_STALL: If NO_STALL is 1, then when fifos are full, INCR_SYNCPT methods will be dropped and the INCR_SYNCPT_ERROR[COND] bit will be set. If NO_STALL is 0, then when fifos are full, the client host interface will be stalled.
0	0x0	INCR_SYNCPT_SOFT_RESET: If SOFT_RESET is set, then all internal state of the client syncpt block will be reset. To do soft reset, first set SOFT_RESET of all host1x clients affected, then clear all SOFT_RESETs.

11.3.3 G2SB_CTX1_INCR_SYNCPT_ERROR_0

Offset: 0x4002 | Byte Offset: 0x10008 | Read/Write: R/W | Reset: 0x00000000 (0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx)

Bit	Reset	Description
31:0	X	COND_STATUS: COND_STATUS[COND] is set if the fifo for COND overflows. This bit is sticky and will remain set until cleared. Cleared by writing 1.

11.3.4 G2SB_CTX1_G2CLASSCHANNEL_REGONLY_0

This register can be accessed by both register read/write and command fifo in order not to break exsting code , keep suffix REGONLY.

2D syncpt behavior

- Each 2D context has its own syncpt client.
- OP_DONE increments when 2D's memory write client is idle, meaning all preceding operations are complete.
- RD_DONE behaves like OP_DONE
- REG_WR_SAFE behaves like IMMEDIATE meaning a syncpt increment returns immediately and does not indicate that a register write will NOT block. The implications are that 2D's host FIFO can fill and block access to 2D, which will indeterminately block a direct CPU access.

Bit	Reset	Description
31:0	X	VDSTEP: Vertical Scaling DDAReset value: xxxx-xxxxh Vertical DDA Step (Increment) Value (VDSTEP[18:0]) (upper 13 bits should be set to '0')This parameter specifies the increment value of the DDA used for vertical scaling and it is in the form of 6-bit integer and 12-bit fraction. This value is determined by the equation: (Actual_source_height-1-VDTINI) / (Actual_destination_height-1) Truncate the remaining bits to keep the 12-bit fraction. Since we have to meet (Actual_source_height-1)*1.0 >= (Actual_destination_height - 1)*VDSTEP + VDTINI. The 6-bit integer allows maximum contraction ratio of 1/64, and 12-bit fraction ensures the maximum limit of accumulated error less than half line-spacing for up to approximately 2000 target lines. For example, image expansion from 240 lines to 400 lines VDSTEP[17:0] = 19'b00_0000_1001_1001_1010 and image contraction from 240 lines to 150 lines VDSTEP[17:0] = 19'b00_0001_1001_1001_1010.

11.3.13 G2SB_CTX1_G2VDDAINI_0

Offset: 0x4012 | Byte Offset: 0x10048 | Read/Write: R/W | Reset: 0x00000000 (0bxxxxxxxxxxxxxxxx)

Bit	Reset	Description
15:8	X	VDBINI: Vertical DDA Initial Value for Bottom-Field (VDBINI[7:0]) (see description above)
7:0	X	VDTINI: Vertical Scaling DDA Initial Values Vertical DDA Initial Value for Top-Field (VDTINI[7:0]) This parameter specifies the fraction part of initial value of the DDA used for vertical scaling. Given a pair of consecutive source image lines representing positions 0.0 and 1.0, a destination line-image will be created at any position in [0.0, 1.0), that is specified by the fraction part of the vertical DDA. The 8-bit initial fraction value specifies the position of the first output (destination) line-image located between the first and the second input (source) line-images, respectively at position 0.0 and 1.0. This parameter provides a way to compensate relative displacement of top and bottom fields of a source image. Suppose, 2-to-1 interlaced original video field images #1 and #2 are in the image buffer, to be displayed in an overlay window. Assume that the #1 field image is the top-field. Using VDTINI = 8'hC0 for the top-field image and VDBINI = 8'h40 for the bottom-field image, for example, the two images from #1 and #2 fields get mapped to identically positioned destination images in the overlay window.

11.3.14 G2SB_CTX1_G2HDDA_0

Offset: 0x4013 | Byte Offset: 0x1004c | Read/Write: R/W | Reset: 0x00000000 (0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx)

Bit	Reset	Description
31:0	X	HDSTEP: Horizontal Scaling DDA Reset value: xxxx-xxxxh Horizontal DDA Step (Increment) Value (HDSTEP[18:0]) (upper 13 bits should be set to '0')

Bit	Reset	Description
		This parameter specifies the increment value of the DDA used for horizontal scaling and it is in the form of 6-bit integer and 12-bit fraction. This value is determined by the equation: (Actual_source_width-1-HDINI) / (Actual_destination_width-1) Truncate the remaining bits to keep the 12-bit fraction. The 6-bit integer allows maximum contraction ratio of 1/64, and 12-bit fraction ensures the maximum limit of accumulated error less than half pixel-spacing for up to approximately 2000 destination pixels. For example, image expansion from 720 pixels to 800 pixels HDSTEP[17:0] = 19'b000_0000_1110_0110_0111 and image contraction from 720 pixels to 250 pixels HDSTEP[17:0] = 19'b000_0010_1110_0001_0101.

11.3.15 G2SB_CTX1_G2HDDAINILS_0

Offset: 0x4014 │ Byte Offset: 0x10050 │ Read/Write: R/W │ Reset: 0x00000000 (0bxxxxxxxx)

Bit	Reset	Description
7:0	X	HDINI: Horizontal Scaling DDA Initial Value Horizontal DDA Initial Value (HDINI[7:0]) This parameter specifies the fraction part of initial value of the DDA used for horizontal scaling. Given a group of six consecutive source pixels that the two pixels at the center representing positions 0.0 and 1.0, a destination pixel will be created at any position in [0.0, 1.0), that is specified by the fraction part of the horizontal DDA. The 8-bit initial fraction value specifies the position of the first output (destination) pixel located between the first and the second input (source) pixels, respectively at position 0.0 and 1.0.For horizontal scaling this value may normally be set to 0.

11.3.16 G2SB_CTX1_G2CSCFIRST_0

The next 3 registers contain 8 parameters used by the YCbCr (YUV) to RGB color space conversion logic. This logic can also be used for RGB gain/gamma correction in RGB to RGB modes, and for luma gain in YUV to YUV modes.

Two new parameters (G2U, G2V) have been added for RGB to YUV conversion. These are in address 0x38. The equations have the form:

if (yuv2rgb)

(r,g,b) = matrix*(y+sbreg_yos,u,v)

matrix: sbreg_cyx, sbreg_cur, sbreg_cvr,
sbreg_cyx, sbreg_cug, sbreg_cvg,
sbreg_cyx, sbreg_cub, sbreg_cvb,

else if (rgb2rgb)

(r,g,b) = matrix*(r,g+sbreg_yos,b)

matrix: sbreg_cvr, 0, sbreg_cur,
sbreg_cvg, sbreg_cyx, sbreg_cug,
sbreg_cvb, 0, sbreg_cub,

else if (yuv2yuv)

(y,u,v) = matrix*(y,u,v)

matrix: sbreg_cub, 0, sbreg_cvb,
sbreg_cug, sbreg_cyx, sbreg_cvg,
sbreg_cur, 0, sbreg_cvr,

else if (rgb2yuv)

(y,u,v) = matrix*(r,g,b) + (sbreg_yos,0,0)

matrix: sbreg_cvb, sbreg_cyx, sbreg_cub,
sbreg_cvg, sbreg_g2u, sbreg_cug,
sbreg_cvr, sbreg_g2v, sbreg_cur,

Offset: 0x4015 | Byte Offset: 0x10054 | Read/Write: R/W | Reset: 0x00000000 (0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx)

Bit	Reset	Description
31:24	X	YOS:Y-Offset (YOFFSET[7:0]) for YUV generation. This parameter consists of 8-bit 2's complement in the range [-128,127]. For YUV->RGB the recommended value is -16 (decimal) or 0xF0 For YUV->YUV & RGB->RGB, this parameter should be set to 0 For RGB->YUV the recommended value is +16 (decimal) or 0x10
21:12	X	CVR: multiplier for V/R for V or R generation. This parameter consists of a sign bit and 9-bit magnitude (s2.7) For YUV->RGB the recommended value is 1.5960 (decimal) or 0x0CC. If source data is in RGB format, this parameter may be used as gain adjustment for R component. For RGB->YUV the recommended value is +0.439 (decimal) or 0x038
9:0	X	CUB: multiplier for U/B for Y or B generation. Consists of a sign bit and 9-bit magnitude (s2.7). For YUV->RGB, the recommended value is 2.0172 (decimal) or 0x102. If source data is in RGB format, this parameter may be used as gain adjustment for B component. This register changes precision when doing RGB to YUV conversion (SIFMT=1xxx, DIFMT=0xxx). CUB becomes s1.8 and the recommended value is +0.098 or 0x019

11.3.17 G2SB_CTX1_G2CSCSECOND_0

Bit	Reset	Description
25:16	X	CVB: multiplier for V/R for Y or B generation. This parameter consists of a sign bit and 9-bit magnitude (s2.7). For YUV->RGB, normally this parameter is programmed to 0.0. This coefficient takes non-zero value if hue is rotated. For YUV->YUV & RGB->RGB, this parameter should be set to 0 For RGB->YUV the recommended value is +0.257 (decimal) or 0x021
8:0	X	CVG: multiplier for V/R for U or G generation. This parameter consists of a sign bit and 8-bit magnitude (s1.7). For YUV->RGB the recommended value is -0.8130 (decimal) or 0x168. For YUV->YUV & RGB->RGB, this parameter should be set to 0 For RGB->YUV the recommended value is -0.148 (decimal) or 0x113

11.3.19 G2SB_CTX1_G2CMKEYL_0

When key generation is enabled, the value of this register is the lower color/chroma limit and G2CMKEYU is the upper color/chroma limit for component pixel data. Three component signal values (YCrCb/YUV or RGB) of every output pixel are compared to a set of three ranges that are specified by three pairs of lower and upper color/chroma key values.

If the Key Polarity is 0, the Key is set to 1 only when all three component values of an input pixel are respectively within the set of ranges (inclusive of the limit values), else the Key is set to 0.

If the Key Polarity is 1, the Key is set to 1 when any of the three component values of an input pixel are outside the set of ranges, else the Key is set to 0.

StretchBLT, Color/Chroma Key Lower Limit Register

Offset: 0x4018 │ Byte Offset: 0x10060 │ Read/Write: R/W │ Reset: 0x00000000 (0bxxxxxxxxxxxxxxxxxxxxxxxx)

Offset: 0x401d │ Byte Offset: 0x10074 │ Read/Write: R/W | Reset: 0x00000000 (0b00x00000000000000x0xx0xx00000)

Bit	Reset	Description
31	0x0	DISDW: Output destination writes go either to image memory or the EPP. 0: Output data is sent to memory 1: YUV or RGB data is passed directly to the EPP module, and no destination writes take place. 0 = GOTO_IMAGE_BUFFER 1 = GOTO_EPP
30	0x0	ENDITH: Enable Dithering (ENDITH) For 16 bit RGB output modes, the LSB of the color components can be modified by adding a variable residual value that will reduce the banding artifacts that can appear on the display. 0 Normal operation 1 Enable Dithering 0 = DISABLE 1 = ENABLE
28	0x0	KPOL: Key Signal Polarity (KPOL) Color/Chroma key signal is generated by comparing source input pixel color to a range of a color specified by lower and upper limit values. The key signal is interpreted in two ways, depending on which one of video and graphics images is foreground (and the other is background). This is effective only if Key signal generator is enabled. (see G2CMKEYL, G2CMKEYU) 0 Key signal is set to 1 when source pixel is within the lower and upper limit color range. 1 Key signal is set to 1 when source pixel is outside the lower and upper limit color range. 0 = WITHIN_BOUNDS 1 = OUTSIDE_BOUNDS
27	0x0	KEYEN: Key Signal Generator Enable (KEYEN) Key signal generator generates either chroma key signal (from YCbCr signal) or color key signal (from RGB signal) 0 Key signal generator is disabled. 1 Key signal generator is enabled. 0 = DISABLE 1 = ENABLE
26	0x0	DBSEL: StretchBLT Destination Buffer Selection (DBSEL) StretchBLT processing involves frame-rate conversion from a series of source images to another series of destination images (field-rate of the source video to frame-rate of the PC display). In order to avoid image tearing, it is preferred to use two buffer sections in the destination video area. This bit selects one of the two buffering blocks to which this StretchBLT command delivers the destination image. The two buffering memory blocks are called A and B. 0 Destination image goes to ‘A’ buffer. 1 Destination image goes to ‘B’ buffer. 0 = DST_A 1 = DST_B

Bit	Reset	Description
25	0x0	SBSEL: StretchBLT Source Buffer Selection (SBSEL) StretchBLT processing involves frame-rate conversion from a series of source images to another series of destination images (field-rate of the source video to frame-rate of the PC display). In order to avoid image tearing, it is preferred to use two buffer sections in the source video area. This bit selects one of the two buffering blocks from which this StretchBLT command receives the source image. The two buffering memory blocks are called source-A and source-B. 0 Source image comes from ‘source-A’ buffer. 1 Source image comes from ‘source-B’ buffer. 0 = SRC_A 1 = SRC_B
24	0x0	SITYPE: StretchBLT Source Type (SITYPE) This bit identifies two types of source images. If source image is 2-to-1 interlaced and StretchBLT processes either one of the two interlaced field-images, physical (positional) displacement between the two interlaced fields must be taken into account. One field-image that is placed higher in position than the other field-image is called top-field and the other is called bottom-field. StretchBLT processing has to lower the top-field (or raise the bottom-field) to match the corresponding two target images in the overlay window (that is progressively scanned) right at the same position. If source image is full frame-image obtained from two interlaced field-images, its type is ‘top-field’. If source images are progressively scanned, the type identification is not significant and they may be designated either one of the two types 0 Source image is ‘top-field’. 1 Source image is ‘bottom-field’. 0 = TOP_FIELD 1 = BOTTOM_FIELD
23	0x0	RANGEREDFRM:In the VC-1 specification, when the value of RANGEREDFRM variable (1-bit) for a picture is equal to 1, the picture shall be scaled up according to the following equation:Y = clip(((Y-128)*2) + 128);Cb = clip(((Cb-128)*2) + 128);Cr = clip(((Cr-128)*2) + 128);The clip operator limits the output to [0, 255].The input is also limited to [0, 255].In the VC-1 nomenclature, the output (Y, Cb, Cr) tuple corresponds to the 'decoded' picture. The input (Y, Cb, Cr) tuple corresponds to the 'reconstructed' picture. The above equations create the decoded picture while keeping the reconstructed picture intact.Only YUV _OB formats are supported with range reducation enabled, not the YUV _TC or RGB formats The YUV data coming from the video frame buffers (reconstructed picture) in the SDRAM was scaled up using the above equations and given to the display. the value of 1-bit wide RANGEREDFRM variable was configured in the DVO per frame and the frame was scaled whenever RANGEREDFRM == 1. 0 = DISABLE 1 = ENABLE
22:20	0x0	HFTYPE: StretchBLT Horizontal Filter Mode (HFTYPE[2:0]) The six-tap horizontal interpolation filter can be operated in various operation modes. For the image expansion, it should be programmed as a pure 6-tap interpolator. For the image contraction, it can work as partly lowpass filter and partly interpolater with varying degree depending on the contraction ratio. For StretchBLT, this parameter is used as an index (selection) to an internal lookup table that stores the group of filter-coefficients for the different modes of horizontal filtering. 000: Pure interpolation filter. 001 010 011 100 101 110: mix of interpolation and low pass filters 111: DISABLE. 0 = INTERP 1 = LPF1 2 = LPF2 3 = LPF3 4 = LPF4 5 = LPF5 6 = LPF6 7 = DISABLE
19	0x0	DISCSC: enabled color space converter by default 0 = ENABLE 1 = DISABLE
18	0x0	VFEN: StretchBLT Vertical Filter Enable (VFEN) Vertical filter shall be disabled if source images

Bit	Reset	Description
		come from host CPU via CPU Read-FIFO. (SISEL) Vertical filter may be disabled to save some memory bandwidth but this will likely result in degradation of image quality. This option may also be used in the case where source image is progressive scanning and there is no vertical scaling. 0 Vertical filter is disabled. 1 Vertical filter is enabled. 0 = DISABLE 1 = ENABLE
17:16	0x0	VFTYPE: StretchBLT Vertical Filter Mode (VFTYPE[1:0]) This bit is effective when the Vertical Filter is enabled. (bit 18) The two-tap vertical interpolation filter can be operated in various modes. For the image expansion, it should be programmed as a pure 2-tap interpolator. For the image contraction, it can work as partly averager and partly interpolator with varying degree depending on the contraction ratio. For StretchBLT, this parameter is used as an index (selection) to an internal lookup table that stores the group of filter-coefficients for the different modes of vertical filtering. 00 Pure interpolation filter. 01 25% averager, 75% interpolator. 10 50% averager, 50% interpolator. 11 100% averager. 0 = INTERP 1 = AVG25_INTERP75 2 = AVG50_INTERP50 3 = AVG
9:8	X	UVST: 00= 1/2 of Luma Buffer Stride; in this case Luma Buffer Stride should be multiple of 2 bytes. 01= Equal to Luma Buffer Stride 10= 1/4 of Luma Buffer Stride; in this case Luma Buffer Stride should be multiple of 4 bytes. 11= use uvstride. Note: Use care when using a tiled surface, since 1/2 or 1/4 of luma stride may yield an invalid pitch (stride). 0 = UVS2X 1 = UVS1X 2 = UVS4X 3 = UVS_G2UVSTRIDE
7	0x0	ENAHF: enable horizontal alpha filtering if disabled, use the alpha value of third tap for output pixelU,V line stride in 4:2:0 Format, 0 = DISABLE 1 = ENABLE
6	0x0	ENAVF:enable alpha vertical filter 0 = DISABLE 1 = ENABLE
5	0x0	IMODE: Source (input) Data Mode (IMODE) This parameter defines the data mode of source input. 0: Multiplexed Mode (data format is specified by SIFMT[2:0]) One block of source data in the Image Buffer memory contains multiplexed component signals. 1: Planar mode, 4:2:0 YUV (SIFMT[2] specifies data format of U/V components) Three blocks of source data in the Image Buffer memory contain separate Y, U, and V component signals. For circular buffer input to gr2d, the input format cannot be planar. It must be multiplex. i.e. no YUV420 planar circular buffer input to gr2d. 0 = MULTIPLEX 1 = PLANAR
4	0x0	YUV422PLANAR: Source data is yuv422 planar valid when imode==PLANAR
3	0x0	YUV422ROTATION: YUV422 planar rotated.

11.3.26 G2SB_CTX1_G2CONTROLMAIN_0

G2 Blit Formats:

(1) G2 Blit size is based on height in lines, width in pixels, stride in bytes, and pixel size (color depth). Unless alpha blending is enabled, G2 doesn't care about pixel components.

Source color depths supported by G2 Blit:

- color depth same as destination: G2CONTROLMAIN.SRCCD = 1
- monochrome: G2CONTROLMAIN.SRCCD = 0

(source monochrome color determined by G2SRCBGC, G2SRCFGC)

Pattern color depths supported by G2 Blit:

- color depth same as destination: G2PATOS.PATCD = 1
- monochrome: G2PATOS.PATCD = 0

(pattern monochrome color determined by G2PATBGC, G2PATFGC)

Destination color depths supported by G2 Blit:

- 1 byte per pixel: G2CONTROLMAIN.DSTCD = BPP8
- 2 bytes per pixel: G2CONTROLMAIN.DSTCD = BPP16
- 4 bytes per pixel: G2CONTROLMAIN.DSTCD = BPP32

(2) Alpha blending operates on 3 or 4 component pixels of a specified color depth. One of the components may be alpha (A), depending on the alpha blend format, which is only allowed in certain component positions defined below. The only format rule of the remaining components is that they must be in the same source and destination position because the alpha blend engine does not support component swapping. For example, valid 32BPP formats are: RGBA_8888->RGBA_8888, BGRA_8888->BGRA_8888, GRBA_8888->GRBA_8888, etc.

Source formats supported by G2 alpha blend:

- color depth BPP8: no supported formats
- color depth BPP16:
  - ALPTYPE_PLS1BPP: xxxA_5551 (ex: BGRA_5551 = A[15] R[14:10] G[9:5] B[4:0])
  - ALPTYPE_PLS4BPP: xxxA_4444 (ex: BGRA_4444 = A[15:12] R[11:8] G[7:4] B[3:0])

VCAA Resolve engine

(1) Format support

srcColor format	srcCoverage format	legal dest format(s)
A1B5G5R5	VCAA	A1B5G5R5

srcColor format	srcCoverage format	legal dest format(s)
R8G8B8A8	VCAA	R8G8B8A8, B5G6R5
B5G6R5	VCAA	B5G6R5

To program resolve type:

- ALPTYPE == FIX: B5G6R5 -> B5G6R5
- ALPTYPE == PLS1BPPAL: A1B5G5R5 -> A1B5G5R5
- ALPTYPE == PLS8BPP: R8G8B8A8 -> R8G8B8A8
- ALPTYPE == PLS8BX: R8G8B8A8 -> B5G6R5

(2) Color surface programming

- color surface base address: SRCBA
- sub-surface start x: SRCX (pixel index)
- sub-surface start y: SRCY (line index)
- color surface stride: SRCS (bytes)

The engine supports sub-surface resolve. One can imagine a full color buffer of 1024x768, but

```
[pseudo_code]
      color_surface_start_address_fetch = pcurctx->regs.rG2SRCBA.uSRCBA() +
       (pcurctx->regs.rG2SRCPS.uSRCX() * VCAAState.color_surface_depth) +
       (pcurctx->regs.rG2SRCPS.uSRCY() * VCAAState.color_surface_stride);
```

(3) VCAA surface programming

- VCAA surface base address: PATBA
- VCAA surface stride: PATST (bytes)

```
[pseudo_code]
      vcaa_surface_start_address_fetch = pcurctx->regs.rG2PATBA.uPATBA();
```

SW *MUST* directly program this register to the proper sub-surface location in the vcaa surface which corresponds to the SRCX and SRCY programming. The calculation is PATBA = vcaa_base_address + SRCX * (1) + SRCY * PATST;

(4) Resolve surface programming

- resolve window width: DSTWIDTH (pixels)
- resolve window height: DSTHEIGHT (lines)
- resolve output stride: DSTS (bytes)

These values program the width and height of the resolved surface. In the base case,

- DSTWIDTH = color surface width
- DSTHEIGHT = color sufrace height
- DSTS = resolve surface format bpp * DSTWIDTH

The VCAA engine technically supports DSTX and DSTY (like SRCX and SRCY).

```
 [pseudo_code]
    resolve_surface_start_address_put = pcurctx->regs.rG2DSTBA.uDSTBA() +
      (pcurctx->regs.rG2DSTPS.uDSTX() * resolve_surface_color_depth) +
      (pcurctx->regs.rG2DSTPS.uDSTY() * resolve_surface_color_stride);
```

(5) Resolving a pixel

The coverage surface is a 8 bits per pixel surface (C4X4). The surface is initialized to all 1s by 3d.

For a given pixel, we need to look up 4 bits of coverage data. If the data is 0xf, the pixel does not need to be resolved. Otherwise, we need to reblend the pixel with certain weightings of its neighbors (i.e. we're on the edge of some geometry).

If any coverage bit is 0, we need to resolve the color. To do so, we calculate the following equation:

```
color_new = (
              20*color_old +
              27*(
                  ((cover_down  == 0) ? color_down  : color_old) +
                  ((cover_right == 0) ? color_right : color_old) +
                  ((cover_left  == 0) ? color_left  : color_old) +
                  ((cover_up    == 0) ? color_up    : color_old)
                  )
            ) / 128;
```

If coverage bit == 0, then we use the neighbor color value in the resolve

If coverage bit == 1, then we use the center color value in the resolve

The resolve is done on a per channel (r/g/b/a) basis:

- format convert input channel to 8-bit
- perform resolve equation above
- format convert to output format

For the resolution of the alpha channel:

- In B5G6R5: no alpha information. do nothing.
- In A1B5G5R5: no resolve. keep the source color alpha bit.
- In R8G8B8A8: normal 8-bit channel resolve

(6) Resolving a pixel on the edge

When on an edge, the vcaa engine treats the coverage bit as a 1. Use the center color value. This holds true even on the edge of the sub-surface resolve window when located in the middle of the larger surface

(7) Maximum dimensions

The maximum resolve sub-surface is 4096 pixels wide.

(8) Surface restrictions

The VCAA engine has the following restrictions with respect to input surfaces

- input base address is 128-bit memory word aligned

- input stride is multiple of 128-bits (16 bytes)

The VCAA engine has the following restrictions with respect to output surfaces

- output base address is 128-bit memory word aligned

- output stride is multiple of 128-bits (16 bytes)

(9) Coverage surface layout

The surface is C4X4.

Surface layout (C4X4)

```
(lsb2msb)   C0_C1_C2_C3_X_X_X_X     (X is a don't care.  Qrast inits to 1)
(msb2lsb)   X_X_X_X_C3_C2_C1_C0
```

```
     +          o          o
          C0
             C1    Cov(0,1)
        C2
          C3
     o          o          o

       Cov(1,0)    Cov(1,1)

     o          o          o

     +/o = pixel centers
```

In the example above,

```
        Cov(0,0) = X_X_X_X_C3_C2_C1_C0
        C3       = V_C3(Cov(0,0));
        ..         ..
        C0       = V_C0(Cov(0,0));
     #define V_C3(bits) (bits & 0x8)
     #define V_C2(bits) (bits & 0x4)
     #define V_C1(bits) (bits & 0x2)
     #define V_C0(bits) (bits & 0x1)
```

Resolving a pixel

In an ideal world, the coverage would be simply laid out such that when resolving Pixel(x,y), we would need only to fetch Cov(x,y) to get all 4 bits of information.

In actuality, the coverage surface was rearranged to help qrast in performance. To resolve Pixel(x,y) gr2d has to fetch 4 C4X4 bytes [Cov(x,y), Cov(x-1,y), Cov(x,y-1), Cov(x-1,y-1)]. From each C4X4 byte, it extracts one bit which is used in the resolve equations shown in (5).

Need the logical vcaa bits (DRLU) for blend which is spread across four C4X4 coverage bytes

```
          U
    L
        o
            R
      D
```

where

o = Pixel(x,y)

D = V_C1(Cov(x-1,y))

R = V_C0(Cov(x,y))

L = V_C3(Cov(x-1,y-1))

U = V_C2(Cov(x,y-1))

Offset: 0x401f | Byte Offset: 0x1007c | Read/Write: R/W | Reset: 0x00000000 (0b000000x00xx00xx0000000000000000)

11.3.67 G2SB_CTX1_G2SRCBA_SB_SURFBASE_0

SB_SURFBASE Registers

These registers need only be programmed when using SB. They point to the base of the various source and destination surfaces. Technically they are only needed when tiling is enabled, but there is no harm in always programming them.

Their counterpart registers (_SB_SURFBASE with SB_SURFBASE stripped off) indicate the location of the first pixel to be sourced or written within the surface.

This register exists to mimic the X, Y (SRCX, SRCY) functionality found in the BitBlt engine.

For example, to get at pixel X, Y:

SRCBA = SRCBA_SB_SURFBASE + Y*stride + X*Bpp

Offset: 0x4048 │ Byte Offset: 0x10120 │ Read/Write: R/W │ Reset: 0x00000000 (0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx)

8	0x0	INCR_SYNCPT_NO_STALL: If NO_STALL is 1, then when fifos are full, INCR_SYNCPT methods will be dropped and the INCR_SYNCPT_ERROR[COND] bit will be set. If NO_STALL is 0, then when fifos are full, the client host interface will be stalled.
0	0x0	INCR_SYNCPT_SOFT_RESET: If SOFT_RESET is set, then all internal state of the client syncpt block will be reset. To do soft reset, first set SOFT_RESET of all host1x clients affected, then clear all SOFT_RESETs.

11.4.3 G2SB_CTX2_INCR_SYNCPT_ERROR_0

Offset: 0x8002 │ Byte Offset: 0x20008 │ Read/Write: R/W │ Reset: 0x00000000 (0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx)

Bit	Reset	Description
31:0	X	COND_STATUS: COND_STATUS[COND] is set if the fifo for COND overflows. This bit is sticky and will remain set until cleared. Cleared by writing 1.

11.4.4 G2SB_CTX2_G2CLASSCHANNEL_REGONLY_0

This register can be accessed by both register read/write and command fifo in order not to break exsting code , keep suffix REGONLY.

2D syncpt behavior

- Each 2D context has its own syncpt client.
- OP_DONE increments when 2D's memory write client is idle, meaning all preceding operations are complete.
- RD_DONE behaves like OP_DONE
- REG_WR_SAFE behaves like IMMEDIATE meaning a syncpt increment returns immediately and does not indicate that a register write will NOT block. The implications are that 2D's host FIFO can fill and block access to 2D, which will indeterminately block a direct CPU access.

Bit	Reset	Description
31:0	X	VDSTEP: Vertical Scaling DDA Reset value: xxxx-xxxxh Vertical DDA Step (Increment) Value (VDSTEP[18:0]) (upper 13 bits should be set to '0') This parameter specifies the increment value of the DDA used for vertical scaling and it is in the form of 6-bit integer and 12-bit fraction. This value is determined by the equation: (Actual_source_height-1-VDTINI) / (Actual_destination_height-1) Truncate the remaining bits to keep the 12-bit fraction. Since we have to meet (Actual_source_height-1)*1.0 >= (Actual_destination_height - 1)*VDSTEP + VDTINI. The 6-bit integer allows maximum contraction ratio of 1/64, and 12-bit fraction ensures the maximum limit of accumulated error less than half line-spacing for up to approximately 2000 target lines. For example, image expansion from 240 lines to 400 lines VDSTEP[17:0] = 19'b00_0000_1001_1001_1010 and image contraction from 240 lines to 150 lines VDSTEP[17:0] = 19'b00_0001_1001_1001_1010.

11.4.13 G2SB_CTX2_G2VDDAINI_0

Offset: 0x8012 | Byte Offset: 0x20048 | Read/Write: R/W | Reset: 0x00000000 (0bxxxxxxxxxxxxxxxx)

Bit	Reset	Description
15:8	X	VDBINI: Vertical DDA Initial Value for Bottom-Field (VDBINI[7:0]) (see description above)
7:0	X	VDTINI: Vertical Scaling DDA Initial Values Vertical DDA Initial Value for Top-Field (VDTINI[7:0]) This parameter specifies the fraction part of initial value of the DDA used for vertical scaling. Given a pair of consecutive source image lines representing positions 0.0 and 1.0, a destination line-image will be created at any position in [0.0, 1.0), that is specified by the fraction part of the vertical DDA. The 8-bit initial fraction value specifies the position of the first output (destination) line-image

Bit	Reset	Description
		located between the first and the second input (source) line-images, respectively at position 0.0 and 1.0.This parameter provides a way to compensate relative displacement of top and bottom fields of a source image. Suppose, 2-to-1 interlaced original video field images #1 and #2 are in the image buffer, to be displayed in an overlay window. Assume that the #1 field image is the top-field. Using VDTINI = 8'hC0 for the top-field image and VDBINI = 8'h40 for the bottom-field image, for example, the two images from #1 and #2 fields get mapped to identically positioned destination images in the overlay window.

11.4.14 G2SB_CTX2_G2HDDA_0

Offset: 0x8013 | Byte Offset: 0x2004c | Read/Write: R/W | Reset: 0x00000000 (0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx)

Bit	Reset	Description
31:0	X	HDSTEP: Horizontal Scaling DDA Reset value: xxxx-xxxxh Horizontal DDA Step (Increment) Value (HDSTEP[18:0]) (upper 13 bits should be set to '0') This parameter specifies the increment value of the DDA used for horizontal scaling and it is in the form of 6-bit integer and 12-bit fraction. This value is determined by the equation: (Actual_source_width-1-HDINI) / (Actual_destination_width-1) Truncate the remaining bits to keep the 12-bit fraction. The 6-bit integer allows maximum contraction ratio of 1/64, and 12-bit fraction ensures the maximum limit of accumulated error less than half pixel-spacing for up to approximately 2000 destination pixels. For example, image expansion from 720 pixels to 800 pixels HDSTEP[17:0] = 19'b000_0000_1110_0110_0111 and image contraction from 720 pixels to 250 pixels HDSTEP[17:0] = 19'b000_0010_1110_0001_0101.

11.4.15 G2SB_CTX2_G2HDDAINILS_0

Offset: 0x8014 | Byte Offset: 0x20050 | Read/Write: R/W | Reset: 0x00000000 (0bxxxxxxxx)

Bit	Reset	Description
7:0	X	HDINI: Horizontal Scaling DDA Initial Value Horizontal DDA Initial Value (HDINI[7:0]) This parameter specifies the fraction part of initial value of the DDA used for horizontal scaling. Given a group of six consecutive source pixels that the two pixels at the center representing positions 0.0 and 1.0, a destination pixel will be created at any position in [0.0, 1.0), that is specified by the fraction part of the horizontal DDA. The 8-bit initial fraction value specifies the position of the first output (destination) pixel located between the first and the second input (source) pixels, respectively at position 0.0 and 1.0.For horizontal scaling this value may normally be set to 0.

11.4.16 G2SB_CTX2_G2CSCFIRST_0

The next 3 registers contain 8 parameters used by the YCbCr (YUV) to RGB color space conversion logic. This logic can also be used for RGB gain/gamma correction in RGB to RGB modes, and for luma gain in YUV to YUV modes.

Two new parameters (G2U, G2V) have been added for RGB to YUV conversion. These are in address 0x38. The equations have the form:

if (yuv2rgb)

(r,g,b) = matrix*(y+sbreg_yos,u,v)

matrix: sbreg_cyx, sbreg_cur, sbreg_cvr,
sbreg_cyx, sbreg_cug, sbreg_cvg,
sbreg_cyx, sbreg_cub, sbreg_cvb,

else if (rgb2rgb)

(r,g,b) = matrix*(r,g+sbreg_yos,b)

matrix:	sbreg_cvr,	0,	sbreg_cur,
	sbreg_cvg,	sbreg_cyx,	sbreg_cug,
	sbreg_cvb,	0,	sbreg_cub,

else if (yuv2yuv)

(y,u,v) = matrix*(y,u,v)

matrix:	sbreg_cub,	0,	sbreg_cvb,
	sbreg_cug,	sbreg_cyx,	sbreg_cvg,
	sbreg_cur,	0,	sbreg_cvr,

else if (rgb2yuv)

(y,u,v) = matrix*(r,g,b) + (sbreg_yos,0,0)

matrix:	sbreg_cvb,	sbreg_cyx,	sbreg_cub,
	sbreg_cvg,	sbreg_g2u,	sbreg_cug,
	sbreg_cvr,	sbreg_g2v,	sbreg_cur,

Offset: 0x8015 │ Byte Offset: 0x20054 │ Read/Write: R/W │ Reset: 0x00000000 (0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx)

Bit	Reset	Description
31:24	X	YOS:Y-Offset (YOFFSET[7:0]) for YUV generation. This parameter consists of 8-bit 2's complement in the range [-128,127]. For YUV->RGB the recommended value is -16 (decimal) or 0xF0 For YUV->YUV & RGB->RGB, this parameter should be set to 0 For RGB->YUV the recommended value is +16 (decimal) or 0x10
21:12	X	CVR: multiplier for V/R for V or R generation. This parameter consists of a sign bit and 9-bit magnitude (s2.7) For YUV->RGB the recommended value is 1.5960 (decimal) or 0x0CC. If source data is in RGB format, this parameter may be used as gain adjustment for R component. For RGB->YUV the recommended value is +0.439 (decimal) or 0x038
9:0	X	CUB: multiplier for U/B for Y or B generation. Consists of a sign bit and 9-bit magnitude (s2.7). For YUV->RGB, the recommended value is 2.0172 (decimal) or 0x102. If source data is in RGB format, this parameter may be used as gain adjustment for B component. This register changes precision when doing RGB to YUV conversion (SIFMT=1xxx, DIFMT=0xxx). CUB becomes s1.8 and the recommended value is +0.098 or 0x019

11.4.17 G2SB_CTX2_G2CSCSECOND_0

Bit	Reset	Description
25:16	X	CVB: multiplier for V/R for Y or B generation. This parameter consists of a sign bit and 9-bit magnitude (s2.7) For YUV->RGB, normally this parameter is programmed to 0.0. This coefficient takes non-zero value if hue is rotated. For YUV->YUV & RGB->RGB, this parameter should be set to 0 For RGB->YUV the recommended value is +0.257 (decimal) or 0x021
8:0	X	CVG: multiplier for V/R for U or G generation. This parameter consists of a sign bit and 8-bit magnitude (s1.7) For YUV->RGB the recommended value is -0.8130 (decimal) or 0x168. For YUV->YUV & RGB->RGB, this parameter should be set to 0 For RGB->YUV the recommended value is -0.148 (decimal) or 0x113

11.4.19 G2SB_CTX2_G2CMKEYL_0

When key generation is enabled, the value of this register is the lower color/chroma limit and G2CMKEYU is the upper color/chroma limit for component pixel data. Three component signal values (YCrCb/YUV or RGB) of every output pixel are compared to a set of three ranges that are specified by three pairs of lower and upper color/chroma key values. If the Key Polarity is 0, the Key is set to 1 only when all three component values of an input pixel are respectively within the set of ranges (inclusive of the limit values), else the Key is set to 0. If the Key Polarity is 1, the Key is set to 1 when any of the three component values of an input pixel are outside the set of ranges, else the Key is set to 0.

StretchBLT, Color/Chroma Key Lower Limit Register

Offset: 0x8018 | Byte Offset: 0x20060 | Read/Write: R/W | Reset: 0x00000000 (0bxxxxxxxxxxxxxxxxxxxxxxxxxxxx)

Bit	Reset	Description
23:16	X	CKRL:R or Cr Color Chroma Key Lower Limit (CKRL[7:0]) Cr signal must be treated in offset binary format so that the binary interpretation retains monotonicity from the minimum signal level to the maximum signal level.
15:8	X	CKGL:G or Cb Color Chroma Key Lower Limit (CKGL[7:0]) Cb signal must be treated in offset binary format so that the binary interpretation retains monotonicity from the minimum signal level to the maximum signal level.
7:0	X	CKBL: B or Y Color/Chroma Key Lower Limit (CKBL[7:0])

Bit	Reset	Description
31	0x0	DISDW: Output destination writes go either to image memory or the EPP. 0: Output data is sent to memory 1: YUV or RGB data is passed directly to the EPP module, and no destination writes take place. 0 = GOTO_IMAGE_BUFFER 1 = GOTO_EPP
30	0x0	ENDITH: Enable Dithering (ENDITH) For 16 bit RGB output modes, the LSB of the color components can be modified by adding a variable residual value that will reduce the banding artifacts that can appear on the display. 0 Normal operation 1 Enable Dithering 0 = DISABLE 1 = ENABLE
28	0x0	KPOL: Key Signal Polarity (KPOL) Color/Chroma key signal is generated by comparing source input pixel color to a range of a color specified by lower and upper limit values. The key signal is interpreted in two ways, depending on which one of video and graphics images is foreground (and the other is background). This is effective only if Key signal generator is enabled. (see G2CMKEYL, G2CMKEYU) 0 Key signal is set to 1 when source pixel is within the lower and upper limit color range. 1 Key signal is set to 1 when source pixel is outside the lower and upper limit color range. 0 = WITHIN_BOUNDS 1 = OUTSIDE_BOUNDS
27	0x0	KEYEN: Key Signal Generator Enable (KEYEN) Key signal generator generates either chroma key signal (from YCbCr signal) or color key signal (from RGB signal) 0 Key signal generator is disabled. 1 Key signal generator is enabled. 0 = DISABLE 1 = ENABLE

Bit	Reset	Description
26	0x0	DBSEL: StretchBLT Destination Buffer Selection (DBSEL) StretchBLT processing involves frame-rate conversion from a series of source images to another series of destination images (field-rate of the source video to frame-rate of the PC display). In order to avoid image tearing, it is preferred to use two buffer sections in the destination video area. This bit selects one of the two buffering blocks to which this StretchBLT command delivers the destination image. The two buffering memory blocks are called A and B. 0 Destination image goes to 'A' buffer. 1 Destination image goes to 'B' buffer. 0 = DST_A 1 = DST_B
25	0x0	SBSEL: StretchBLT Source Buffer Selection (SBSEL) StretchBLT processing involves frame-rate conversion from a series of source images to another series of destination images (field-rate of the source video to frame-rate of the PC display). In order to avoid image tearing, it is preferred to use two buffer sections in the source video area. This bit selects one of the two buffering blocks from which this StretchBLT command receives the source image. The two buffering memory blocks are called source-A and source-B. 0 Source image comes from 'source-A' buffer. 1 Source image comes from 'source-B' buffer. 0 = SRC_A 1 = SRC_B
24	0x0	SITYPE: StretchBLT Source Type (SITYPE) This bit identifies two types of source images. If source image is 2-to-1 interlaced and StretchBLT processes either one of the two interlaced field-images, physical (positional) displacement between the two interlaced fields must be taken into account. One field-image that is placed higher in position than the other field-image is called top-field and the other is called bottom-field. StretchBLT processing has to lower the top-field (or raise the bottom-field) to match the corresponding two target images in the overlay window (that is progressively scanned) right at the same position. If source image is full frame-image obtained from two interlaced field-images, its type is 'top-field'. If source images are progressively scanned, the type identification is not significant and they may be designated either one of the two types 0 Source image is 'top-field'. 1 Source image is 'bottom-field'. 0 = TOP_FIELD 1 = BOTTOM_FIELD
23	0x0	RANGEREDFRM:In the VC-1 specification, when the value of RANGEREDFRM variable (1-bit) for a picture is equal to 1, the picture shall be scaled up according to the following equation:Y = clip(((Y-128)*2) + 128);Cb = clip(((Cb-128)*2) + 128);Cr = clip(((Cr-128)*2) + 128);The clip operator limits the output to [0, 255].The input is also limited to [0, 255]. In the VC-1 nomenclature, the output (Y, Cb, Cr) tuple corresponds to the 'decoded' picture. The input (Y, Cb, Cr) tuple corresponds to the 'reconstructed' picture. The above equations create the decoded picture while keeping the reconstructed picture intact.Only YUV _OB formats are supported with range reducation enabled, not the YUV _TC or RGB formats The YUV data coming from the video frame buffers (reconstructed picture) in the SDRAM was scaled up using the above equations and given to the display. the value of 1-bit wide RANGEREDFRM variable was configured in the DVO per frame and the frame was scaled whenever RANGEREDFRM == 1. 0 = DISABLE 1 = ENABLE
22:20	0x0	HFTYPE: StretchBLT Horizontal Filter Mode (HFTYPE[2:0]) The six-tap horizontal interpolation filter can be operated in various operation modes. For the image expansion, it should be programmed as a pure 6-tap interpolator. For the image contraction, it can work as partly lowpass filter and partly interpolater with varying degree depending on the contraction ratio. For StretchBLT, this parameter is used as an index (selection) to an internal lookup table that stores the group of filter-coefficients for the different modes of horizontal filtering. 000: Pure interpolation filter. 001 010 011 100 101 110: mix of interpolation and low pass filters 111: DISABLE. 0 = INTERP

11.4.26 G2SB_CTX2_G2CONTROLMAIN_0

G2 Blit Formats:

(1) G2 Blit size is based on height in lines, width in pixels, stride in bytes, and pixel size (color depth). Unless alpha blending is enabled, G2 doesn't care about pixel components.

Source color depths supported by G2 Blit:

- color depth same as destination: G2CONTROLMAIN.SRCCD = 1
- monochrome: G2CONTROLMAIN.SRCCD = 0

(source monochrome color determined by G2SRCBGC, G2SRCFGC)

Pattern color depths supported by G2 Blit:

- color depth same as destination: G2PATOS.PATCD = 1
- monochrome: G2PATOS.PATCD = 0

(pattern monochrome color determined by G2PATBGC, G2PATFGC)

Destination color depths supported by G2 Blit:

- 1 byte per pixel: G2CONTROLMAIN.DSTCD = BPP8
- 2 bytes per pixel: G2CONTROLMAIN.DSTCD = BPP16
- 4 bytes per pixel: G2CONTROLMAIN.DSTCD = BPP32

(2) Alpha blending operates on 3 or 4 component pixels of a specified color depth. One of the components may be alpha (A), depending on the alpha blend format, which is only allowed in certain component positions defined below. The only format rule of the remaining components is that they must be in the same source and destination position because the alpha blend engine does not support component swapping. For example, valid 32BPP formats are: RGBA_8888->RGBA_8888, BGRA_8888->BGRA_8888, GRBA_8888->GRBA_8888, etc.

Source formats supported by G2 alpha blend:

- color depth BPP8: no supported formats
- color depth BPP16:
  - ALPTYPE_PLS1BPP: xxxA_5551 (ex: BGRA_5551 = A[15] R[14:10] G[9:5] B[4:0])
  - ALPTYPE_PLS4BPP: xxxA_4444 (ex: BGRA_4444 = A[15:12] R[11:8] G[7:4] B[3:0])
  - (other) : xxx_565 (ex: BGR_565 = R[15:11] G[10:5] B[4:0])
- color depth BPP32:
  - (all) : xxxA_8888 (ex: BRGA_8888 = A[31:24] R[23:16] G[15:8] B[7:0])

Destination formats supported by G2 alpha blend:

- color depth BPP8: no supported formats
- color depth BPP16: xxx_565 (ex: BGR_565 = R[15:11] G[10:5] B[4:0])
- color depth BPP32: xxxA_8888 (ex: BRGA_8888 = A[31:24] R[23:16] G[15:8] B[7:0])

src cd	src format	dst cd	dst format	examples
BPP8	no support	BPP8	no support	
BPP16	xyzA_5551, xyzA_4444, xyz_565	BPP16	xyz_565	BGRA_5551->BGR_565, RGB_565->RGB565
BPP32	xyzA_8888	BPP32	xyzA_8888	RGBA_8888->RGBA_8888, BGRA_8888->BGRA_8888
BPP32	xyzA_8888	BPP16	xyz_565	RGBA_8888->RGB_565, BGRA_8888->BGR_565

VCAA Resolve engine

(1) Format support

srcColor format	srcCoverage format	legal dest format(s)
A1B5G5R5	VCAA	A1B5G5R5
R8G8B8A8	VCAA	R8G8B8A8, B5G6R5
B5G6R5	VCAA	B5G6R5

To program resolve type:

- ALPTYPE == FIX: B5G6R5 -> B5G6R5
- ALPTYPE == PLS1BPPAL: A1B5G5R5 -> A1B5G5R5
- ALPTYPE == PLS8BPP: R8G8B8A8 -> R8G8B8A8
- ALPTYPE == PLS8BX: R8G8B8A8 -> B5G6R5

(2) Color surface programming

- color surface base address: SRCBA
- sub-surface start x: SRCX (pixel index)
- sub-surface start y: SRCY (line index)
- color surface stride: SRCS (bytes)

The engine supports sub-surface resolve. One can imagine a full color buffer of 1024x768, but

```
[pseudo_code]
      color_surface_start_address_fetch = pcurctx->regs.rG2SRCBA.uSRCBA() +
       (pcurctx->regs.rG2SRCPS.uSRCX() * VCAAState.color_surface_depth) +
       (pcurctx->regs.rG2SRCPS.uSRCY() * VCAAState.color_surface_stride);
```

(3) VCAA surface programming

- vcaa surface base address: PATBA
- vcaa surface stride: PATST (bytes)

```
[pseudo_code]
      vcaa_surface_start_address_fetch = pcurctx->regs.rG2PATBA.uPATBA();
```

SW *MUST* directly program this register to the proper sub-surface location in the vcaa surface which corresponds to the SRCX and SRCY programming. The calculation is PATBA = vcaa_base_address + SRCX * (1) + SRCY * PATST;

(4) Resolve surface programming

- resolve window width: DSTWIDTH (pixels)
- resolve window height: DSTHEIGHT (lines)
- resolve output stride: DSTS (bytes)

These values program the width and height of the resolved surface. In the base case,

- DSTWIDTH = color surface width
- DSTHEIGHT = color sufrace height
- DSTS = resolve surface format bpp * DSTWIDTH

The vcaa engine technically supports DSTX and DSTY (like SRCX and SRCY).

```
 [pseudo_code]
    resolve_surface_start_address_put = pcurctx->regs.rG2DSTBA.uDSTBA() +
      (pcurctx->regs.rG2DSTPS.uDSTX() * resolve_surface_color_depth) +
      (pcurctx->regs.rG2DSTPS.uDSTY() * resolve_surface_color_stride);
```

(5) Resolving a pixel

The coverage surface is a 8 bits per pixel surface (C4X4). The surface is initialized to all 1s by 3d.

For a given pixel, we need to look up 4 bits of coverage data. If the data is 0xf, the pixel does not need to be resolved. Otherwise, we need to reblend the pixel with certain weightings of its neighbors (i.e. we're on the edge of some geometry).

If any coverage bit is 0, we need to resolve the color. To do so, we calculate the following equation:

```
color_new = (
              20*color_old +
              27*(
                  ((cover_down  == 0) ? color_down  : color_old) +
                  ((cover_right == 0) ? color_right : color_old) +
                  ((cover_left  == 0) ? color_left  : color_old) +
                  ((cover_up    == 0) ? color_up    : color_old)
                  )
            ) / 128;
```

If coverage bit == 0, then we use the neighbor color value in the resolve

If coverage bit == 1, then we use the center color value in the resolve

The resolve is done on a per channel (r/g/b/a) basis:

- format convert input channel to 8-bit
- perform resolve equation above
- format convert to output format

For the resolution of the alpha channel:

- In B5G6R5: no alpha information. do nothing.
- In A1B5G5R5: no resolve. keep the source color alpha bit.
- In R8G8B8A8: normal 8-bit channel resolve

(6) Resolving a pixel on the edge

When on an edge, the vcaa engine treats the coverage bit as a 1. Use the center color value. This holds true even on the edge of the sub-surface resolve window when located in the middle of the larger surface

(7) Maximum dimensions

The maximum resolve sub-surface is 4096 pixels wide.

(8) Surface restrictions

The VCAA engine has the following restrictions with respect to input surfaces

- input base address is 128-bit memory word aligned
- input stride is multiple of 128-bits (16 bytes)

The VCAA engine has the following restrictions with respect to output surfaces

- output base address is 128-bit memory word aligned
- output stride is multiple of 128-bits (16 bytes)

(9) Coverage surface layout

The surface is C4X4.

Surface layout (C4X4)

```
(lsb2msb)  C0_C1_C2_C3_X_X_X_X     (X is a don't care.  Qrast inits to 1)
(msb2lsb)  X_X_X_X_C3_C2_C1_C0

    +          o          o
         C0
            C1   Cov(0,1)
       C2
         C3
    o          o          o

      Cov(1,0)   Cov(1,1)

    o          o          o
    +/o = pixel centers
```

In the example above,

```
       Cov(0,0) = X_X_X_X_C3_C2_C1_C0
       C3       = V_C3(Cov(0,0));
       ..         ..
       C0       = V_C0(Cov(0,0));
    #define V_C3(bits)  (bits & 0x8)
    #define V_C2(bits)  (bits & 0x4)
    #define V_C1(bits)  (bits & 0x2)
    #define V_C0(bits)  (bits & 0x1)
```

Resolving a pixel

In an ideal world, the coverage would be simply laid out such that when resolving Pixel(x,y), we would need only to fetch Cov(x,y) to get all 4 bits of information.

In actuality, the coverage surface was rearranged to help qrast in performance. To resolve Pixel(x,y) gr2d has to fetch 4 C4X4 bytes [Cov(x,y), Cov(x-1,y), Cov(x,y-1), Cov(x-1,y-1)]. From each C4X4 byte, it extracts one bit which is used in the resolve equations shown in (5).

Need the logical VCAA bits (DRLU) for blend which is spread across four C4X4 coverage bytes

```
          U
   L
       o
           R
     D
```

where

o = Pixel(x,y)

D = V_C1(Cov(x-1,y))

R = V_C0(Cov(x,y))

L = V_C3(Cov(x-1,y-1))

U = V_C2(Cov(x,y-1))

11.4.44 G2SB_CTX2_G2SRCBA_B_0

SB only

Offset: 0x8032 | Byte Offset: 0x200c8 | Read/Write: R/W | Reset: 0x00000000 (0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx)

Bit	Reset	Description
31:0	X	SRCBA_B: This parameter specifies the start address of source image stored in the image buffer memory. In 4:2:0 format mode, this image block accommodates for Y-image. This address specifies byte-position, however, bits [2:0] are restricted with respect to the data formats to fit multiple pixels in one memory word (8 bytes),. For example, {0, 4} for any YcrCb formats, {0, 2, 4, 6} for RGB 16-bit format. Since one Y pixel takes 8-bit, all 8 byte-positions are valid in 4:2:0 mode. (Unlike multiplexed pixels format, there are no restrictions

Bit	Reset	Description
		on this value.)

11.4.45 G2SB_CTX2_G2SRCST_0

Offset: 0x8033 | Byte Offset: 0x200cc | Read/Write: R/W | Reset: 0x00000000 (0bxxxxxxxxxxxxxxxx)

11.4.66 G2SB_CTX2_G2SRCBA_SB_SURFBASE_0

SB_SURFBASE registers

These registers need only be programmed when using SB. They point to the base of the various source and destination surfaces. Technically they are only needed when tiling is enabled, but there is no harm in always programming them.

Their counterpart registers (_SB_SURFBASE with SB_SURFBASE stripped off) indicate the location of the first pixel to be sourced or written within the surface.

This register exists to mimic the X, Y (SRCX, SRCY) functionality found in the BitBlt engine.

For example, to get at pixel X, Y:

SRCBA = SRCBA_SB_SURFBASE + Y*stride + X*Bpp

Offset: 0x8048 | Byte Offset: 0x20120 | Read/Write: R/W | Reset: 0x00000000 (0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx)

11.5.2 G2SB_CTX3_INCR_SYNCPT_CNTRL_0

Offset: 0x1001 │ Byte Offset: 0x4004 │ Read/Write: R/W │ Reset: 0x00000000 (0b0xxxxxx0)

Bit	Reset	Description
8	0x0	INCR_SYNCPT_NO_STALL: If NO_STALL is 1, then when fifos are full, INCR_SYNCPT methods will be dropped and the INCR_SYNCPT_ERROR[COND] bit will be set. If NO_STALL is 0, then when fifos are full, the client host interface will be stalled.
0	0x0	INCR_SYNCPT_SOFT_RESET: If SOFT_RESET is set, then all internal state of the client syncpt block will be reset. To do soft reset, first set SOFT_RESET of all host1x clients affected, then clear all SOFT_RESETs.

11.5.3 G2SB_CTX3_INCR_SYNCPT_ERROR_0

Offset: 0x1002 │ Byte Offset: 0x4008 │ Read/Write: R/W │ Reset: 0x00000000 (0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx)

Bit	Reset	Description
31:0	X	COND_STATUS: COND_STATUS[COND] is set if the fifo for COND overflows. This bit is sticky and will remain set until cleared. Cleared by writing 1.

11.5.4 G2SB_CTX3_G2CLASSCHANNEL_REGONLY_0

This register can be accessed by both register read/write and command fifo in order not to break exsting code , keep suffix REGONLY.

2D syncpt behavior

- Each 2D context has its own syncpt client.
- OP_DONE increments when 2D's memory write client is idle, meaning all preceding operations are complete.
- RD_DONE behaves like OP_DONE
- REG_WR_SAFE behaves like IMMEDIATE meaning a syncpt increment returns immediately and does not indicate that a register write will NOT block. The implications are that 2D's host FIFO can fill and block access to 2D, which will indeterminately block a direct CPU access.

Bit	Reset	Description
31:0	X	VDSTEP: Vertical Scaling DDA Reset value: xxxx-xxxxh Vertical DDA Step (Increment) Value (VDSTEP[18:0]) (upper 13 bits should be set to '0') This parameter specifies the increment value of the DDA used for vertical scaling and it is in the form of 6-bit integer and 12-bit fraction. This value is determined by the equation: (Actual_source_height-1-VDTINI) / (Actual_destination_height-1) Truncate the remaining bits

Bit	Reset	Description
		to keep the 12-bit fraction. Since we have to meet (Actual_source_height-1)*1.0 >= (Actual_destination_height - 1)*VDSTEP + VDTIN. The 6-bit integer allows maximum contraction ratio of 1/64, and 12-bit fraction ensures the maximum limit of accumulated error less than half line-spacing for up to approximately 2000 target lines. For example, image expansion from 240 lines to 400 lines VDSTEP[17:0] = 19'b00_0000_1001_1001_1010 and image contraction from 240 lines to 150 lines VDSTEP[17:0] = 19'b00_0001_1001_1001_1010.

11.5.13 G2SB_CTX3_G2VDDAINI_0

Offset: 0x1012 | Byte Offset: 0x4048 | Read/Write: R/W | Reset: 0x00000000 (0bxxxxxxxxxxxxxxxx)

Bit	Reset	Description
15:8	X	VDBINI: Vertical DDA Initial Value for Bottom-Field (VDBINI[7:0]) (see description above)
7:0	X	VDTINI: Vertical Scaling DDA Initial Values Vertical DDA Initial Value for Top-Field (VDTINI[7:0]) This parameter specifies the fraction part of initial value of the DDA used for vertical scaling. Given a pair of consecutive source image lines representing positions 0.0 and 1.0, a destination line-image will be created at any position in [0.0, 1.0), that is specified by the fraction part of the vertical DDA. The 8-bit initial fraction value specifies the position of the first output (destination) line-image located between the first and the second input (source) line-images, respectively at position 0.0 and 1.0. This parameter provides a way to compensate relative displacement of top and bottom fields of a source image. Suppose, 2-to-1 interlaced original video field images #1 and #2 are in the image buffer, to be displayed in an overlay window. Assume that the #1 field image is the top-field. Using VDTINI = 8'hC0 for the top-field image and VDBINI = 8'h40 for the bottom-field image, for example, the two images from #1 and #2 fields get mapped to identically positioned destination images in the overlay window.

11.5.14 G2SB_CTX3_G2HDDA_0

Offset: 0x1013 | Byte Offset: 0x404c | Read/Write: R/W | Reset: 0x00000000 (0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx)

Bit	Reset	Description
31:0	X	HDSTEP: Horizontal Scaling DDA Reset value: xxxx-xxxxh Horizontal DDA Step (Increment) Value (HDSTEP[18:0]) (upper 13 bits should be set to '0') This parameter specifies the increment value of the DDA used for horizontal scaling and it is in the form of 6-bit integer and 12-bit fraction. This value is determined by the equation: (Actual_source_width-1-HDINI) / (Actual_destination_width-1) Truncate the remaining bits to keep the 12-bit fraction. The 6-bit integer allows maximum contraction ratio of 1/64, and 12-bit fraction ensures the maximum limit of accumulated error less than half pixel-spacing for up to approximately 2000 destination pixels. For example, image expansion from 720 pixels to 800 pixels HDSTEP[17:0] = 19'b000_0000_1110_0110_0111 and image contraction from 720 pixels to 250 pixels HDSTEP[17:0] = 19'b000_0010_1110_0001_0101.

11.5.15 G2SB_CTX3_G2HDDAINILS_0

Offset: 0x1014 | Byte Offset: 0x4050 | Read/Write: R/W | Reset: 0x00000000 (0bxxxxxxxx)

Bit	Reset	Description
7:0	X	HDINI: Horizontal Scaling DDA Initial Value Horizontal DDA Initial Value (HDINI[7:0]) This parameter specifies the fraction part of initial value of the DDA used for horizontal scaling. Given a group of six consecutive source pixels that the two pixels at the center representing

Bit	Reset	Description
		positions 0.0 and 1.0, a destination pixel will be created at any position in [0.0, 1.0), that is specified by the fraction part of the horizontal DDA. The 8-bit initial fraction value specifies the position of the first output (destination) pixel located between the first and the second input (source) pixels, respectively at position 0.0 and 1.0.For horizontal scaling this value may normally be set to 0.

11.5.16 G2SB_CTX3_G2CSCFIRST_0

The next 3 registers contain 8 parameters used by the YCbCr (YUV) to RGB color space conversion logic. This logic can also be used for RGB gain/gamma correction in RGB to RGB modes, and for luma gain in YUV to YUV modes.

Two new parameters (G2U, G2V) have been added for RGB to YUV conversion. These are in address 0x38. The equations have the form:

if (yuv2rgb)

(r,g,b) = matrix*(y+sbreg_yos,u,v)

matrix: sbreg_cyx, sbreg_cur, sbreg_cvr,
sbreg_cyx, sbreg_cug, sbreg_cvg,
sbreg_cyx, sbreg_cub, sbreg_cvb,

else if (rgb2rgb)

(r,g,b) = matrix*(r,g+sbreg_yos,b)

matrix: sbreg_cvr, 0, sbreg_cur,
sbreg_cvg, sbreg_cyx, sbreg_cug,
sbreg_cvb, 0, sbreg_cub,

else if (yuv2yuv)

(y,u,v) = matrix*(y,u,v)

matrix: sbreg_cub, 0, sbreg_cvb,
sbreg_cug, sbreg_cyx, sbreg_cvg,
sbreg_cur, 0, sbreg_cvr,

else if (rgb2yuv)

(y,u,v) = matrix*(r,g,b) + (sbreg_yos,0,0)

matrix: sbreg_cvb, sbreg_cyx, sbreg_cub,
sbreg_cvg, sbreg_g2u, sbreg_cug,
sbreg_cvr, sbreg_g2v, sbreg_cur,

Bit	Reset	Description
25:16	X	CVB: multiplier for V/R for Y or B generation. This parameter consists of a sign bit and 9-bit magnitude (s2.7). For YUV->RGB, normally this parameter is programmed to 0.0. This coefficient takes non-zero value if hue is rotated. For YUV->YUV & RGB->RGB, this parameter should be set to 0 For RGB->YUV the recommended value is +0.257 (decimal) or 0x021
8:0	X	CVG: multiplier for V/R for U or G generation. This parameter consists of a sign bit and 8-bit magnitude (s1.7). For YUV->RGB the recommended value is -0.8130 (decimal) or 0x168. For YUV->YUV & RGB->RGB, this parameter should be set to 0 For RGB->YUV the recommended value is -0.148 (decimal) or 0x113

11.5.19 G2SB_CTX3_G2CMKEYL_0

When key generation is enabled, the value of this register is the lower color/chroma limit and G2CMKEYU is the upper color/chroma limit for component pixel data. Three component signal values (YCrCb/YUV or RGB) of every output pixel are compared to a set of three ranges that are specified by three pairs of lower and upper color/chroma key values. If the Key Polarity is 0, the Key is set to 1 only when all three component values of an input pixel are respectively within the set of ranges (inclusive of the limit values), else the Key is set to 0. If the Key Polarity is 1, the Key is set to 1 when any of the three component values of an input pixel are outside the set of ranges, else the Key is set to 0.

11.5.24 G2SB_CTX3_G2CONTROLSB_0

Offset: 0x101d │ Byte Offset: 0x4074 │ Read/Write: R/W │ Reset: 0x00000000 (0b00x00000000000000x0xx0xx00000)

Bit	Reset	Description
31	0x0	DISDW: Output destination writes go either to image memory or the EPP.

Bit	Reset	Description
		0: Output data is sent to memory 1: YUV or RGB data is passed directly to the EPP module, and no destination writes take place. 0 = GOTO_IMAGE_BUFFER 1 = GOTO_EPP
30	0x0	ENDITH: Enable Dithering (ENDITH). For 16 bit RGB output modes, the LSB of the color components can be modified by adding a variable residual value that will reduce the banding artifacts that can appear on the display. 0 Normal operation 1 Enable Dithering 0 = DISABLE 1 = ENABLE
28	0x0	KPOL: Key Signal Polarity (KPOL). Color/Chroma key signal is generated by comparing source input pixel color to a range of a color specified by lower and upper limit values. The key signal is interpreted in two ways, depending on which one of video and graphics images is foreground (and the other is background). This is effective only if Key signal generator is enabled. (see G2CMKEYL, G2CMKEYU) 0 Key signal is set to 1 when source pixel is within the lower and upper limit color range. 1 Key signal is set to 1 when source pixel is outside the lower and upper limit color range. 0 = WITHIN_BOUNDS 1 = OUTSIDE_BOUNDS
27	0x0	KEYEN: Key Signal Generator Enable (KEYEN) Key signal generator generates either chroma key signal (from YCbCr signal) or color key signal (from RGB signal) 0 Key signal generator is disabled. 1 Key signal generator is enabled. 0 = DISABLE 1 = ENABLE
26	0x0	DBSEL: StretchBLT Destination Buffer Selection (DBSEL) StretchBLT processing involves frame-rate conversion from a series of source images to another series of destination images (field-rate of the source video to frame-rate of the PC display). In order to avoid image tearing, it is preferred to use two buffer sections in the destination video area. This bit selects one of the two buffering blocks to which this StretchBLT command delivers the destination image. The two buffering memory blocks are called A and B. 0 Destination image goes to ‘A’ buffer. 1 Destination image goes to ‘B’ buffer. 0 = DST_A 1 = DST_B
25	0x0	SBSEL: StretchBLT Source Buffer Selection (SBSEL) StretchBLT processing involves frame-rate conversion from a series of source images to another series of destination images (field-rate of the source video to frame-rate of the PC display). In order to avoid image tearing, it is preferred to use two buffer sections in the source video area. This bit selects one of the two buffering blocks from which this StretchBLT command receives the source image. The two buffering memory blocks are called source-A and source-B. 0 Source image comes from ‘source-A’ buffer. 1 Source image comes from ‘source-B’ buffer. 0 = SRC_A 1 = SRC_B
24	0x0	SITYPE: StretchBLT Source Type (SITYPE) This bit identifies two types of source images. If source image is 2-to-1 interlaced and StretchBLT processes either one of the two interlaced field-images, physical (positional) displacement between the two interlaced fields must be taken into account. One field-image that is placed higher in position than the other field-image is called top-field and the other is called bottom-field. StretchBLT processing has to lower the top-field (or raise the bottom-field) to match the corresponding two target images in the overlay window (that is progressively scanned) right at the same position. If source image is full frame-image obtained from two interlaced field-images, its type is ‘top-field’. If source images are progressively scanned, the type identification is not significant and they may be designated either one of the two types 0 Source image is ‘top-field’. 1 Source image is ‘bottom-field’.

Bit	Reset	Description
		0 = TOP_FIELD 1 = BOTTOM_FIELD
23	0x0	RANGEREDFRM:In the VC-1 specification, when the value of RANGEREDFRM variable (1-bit) for a picture is equal to 1, the picture shall be scaled up according to the following equation:Y = clip(((Y-128)*2) + 128);Cb = clip(((Cb-128)*2) + 128);Cr = clip(((Cr-128)*2) + 128);The clip operator limits the output to [0, 255].The input is also limited to [0, 255]. In the VC-1 nomenclature, the output (Y, Cb, Cr) tuple corresponds to the 'decoded' picture. The input (Y, Cb, Cr) tuple corresponds to the 'reconstructed' picture. The above equations create the decoded picture while keeping the reconstructed picture intact.Only YUV _OB formats are supported with range reducation enabled, not the YUV _TC or RGB formats. The YUV data coming from the video frame buffers (reconstructed picture) in the SDRAM was scaled up using the above equations and given to the display. the value of 1-bit wide RANGEREDFRM variable was configured in the DVO per frame and the frame was scaled whenever RANGEREDFRM == 1. 0 = DISABLE 1 = ENABLE
22:20	0x0	HFTYPE: StretchBLT Horizontal Filter Mode (HFTYPE[2:0]) The six-tap horizontal interpolation filter can be operated in various operation modes. For the image expansion, it should be programmed as a pure 6-tap interpolator. For the image contraction, it can work as partly lowpass filter and partly interpolater with varying degree depending the contraction ratio. For StretchBLT, this parameter is used as an index (selection) to an internal lookup table that stores the group of filter-coefficients for the different modes of horizontal filtering. 000: Pure interpolation filter. 001 010 011 100 101 110: mix of interpolation and low pass filters 111: DISABLE. 0 = INTERP 1 = LPF1 2 = LPF2 3 = LPF3 4 = LPF4 5 = LPF5 6 = LPF6 7 = DISABLE

11.5.26 G2SB_CTX3_G2CONTROLMAIN_0

G2 Blit Formats:

(1) G2 Blit size is based on height in lines, width in pixels, stride in bytes, and pixel size (color depth). Unless alpha blending is enabled, G2 doesn't care about pixel components.

Source color depths supported by G2 Blit:

- color depth same as destination: G2CONTROLMAIN.SRCCD = 1
- monochrome: G2CONTROLMAIN.SRCCD = 0

(source monochrome color determined by G2SRCBGC, G2SRCFGC)

Pattern color depths supported by G2 Blit:

- color depth same as destination: G2PATOS.PATCD = 1
- monochrome: G2PATOS.PATCD = 0

(pattern monochrome color determined by G2PATBGC, G2PATFGC)

Destination color depths supported by G2 Blit:

- 1 byte per pixel: G2CONTROLMAIN.DSTCD = BPP8
- 2 bytes per pixel: G2CONTROLMAIN.DSTCD = BPP16
- 4 bytes per pixel: G2CONTROLMAIN.DSTCD = BPP32

(2) Alpha blending operates on 3 or 4 component pixels of a specified color depth. One of the components may be alpha (A), depending on the alpha blend format, which is only allowed in certain component positions defined below. The only format rule

of the remaining components is that they must be in the same source and destination position because the alpha blend engine does not support component swapping. For example, valid 32BPP formats are: RGBA_8888->RGBA_8888, BGRA_8888->BGRA_8888, GRBA_8888->GRBA_8888, etc.

Source formats supported by G2 alpha blend:

- color depth BPP8: no supported formats
- color depth BPP16:

a. ALPTYPE_PLS1BPP: xxxA_5551 (ex: BGRA_5551 = A[15] R[14:10] G[9:5] B[4:0])

b. ALPTYPE_PLS4BPP: xxxA_4444 (ex: BGRA_4444 = A[15:12] R[11:8] G[7:4] B[3:0])

c. (other) : xxx_565 (ex: BGR_565 = R[15:11] G[10:5] B[4:0])

- color depth BPP32:

a. (all) : xxxA_8888 (ex: BRGA_8888 = A[31:24] R[23:16] G[15:8] B[7:0])

Destination formats supported by G2 alpha blend:

- color depth BPP8: no supported formats
- color depth BPP16: xxx_565 (ex: BGR_565 = R[15:11] G[10:5] B[4:0])
- color depth BPP32: xxxA_8888 (ex: BRGA_8888 = A[31:24] R[23:16] G[15:8] B[7:0])
- Destination formats supported by G2 alpha blend:

src cd	src format	dst cd	dst format	examples
BPP8	no support	BPP8	no support	
BPP16	xyzA_5551, xyzA_4444, xyz_565	BPP16	xyz_565	BGRA_5551->BGR_565, RGB_565->RGB565
BPP32	xyzA_8888	BPP32	xyzA_8888	RGBA_8888->RGBA_8888, BGRA_8888->BGRA_8888
BPP32	xyzA_8888	BPP16	xyz_565	RGBA_8888->RGB_565, BGRA_8888->BGR_565

VCAA Resolve engine

(1) Format support

srcColor format	srcCoverage format	legal dest format(s)
A1B5G5R5	VCAA	A1B5G5R5
R8G8B8A8	VCAA	R8G8B8A8, B5G6R5
B5G6R5	VCAA	B5G6R5

To program resolve type:

- ALPTYPE == FIX: B5G6R5 -> B5G6R5
- ALPTYPE == PLS1BPPAL: A1B5G5R5 -> A1B5G5R5
- ALPTYPE == PLS8BPP: R8G8B8A8 -> R8G8B8A8
- ALPTYPE == PLS8BX: R8G8B8A8 -> B5G6R5

(2) Color surface programming

- color surface base address: SRCBA
- sub-surface start x: SRCX (pixel index)
- sub-surface start y: SRCY (line index)
- color surface stride: SRCS (bytes)

The engine supports sub-surface resolve. One can imagine a full color buffer of 1024x768, but

```
[pseudo_code]
      color_surface_start_address_fetch = pcurctx->regs.rG2SRCBA.uSRCBA() +
       (pcurctx->regs.rG2SRCPS.uSRCX() * VCAAState.color_surface_depth) +
       (pcurctx->regs.rG2SRCPS.uSRCY() * VCAAState.color_surface_stride);
```

(3) VCAA surface programming

- VCAA surface base address: PATBA
- VCAA surface stride: PATST (bytes)

```
[pseudo_code]
      vcaa_surface_start_address_fetch = pcurctx->regs.rG2PATBA.uPATBA();
```

SW *MUST* directly program this register to the proper sub-surface location in the vcaa surface which corresponds to the SRCX and SRCY programming. The calculation is PATBA = vcaa_base_address + SRCX * (1) + SRCY * PATST;

(4) Resolve surface programming

- resolve window width: DSTWIDTH (pixels)
- resolve window height: DSTHEIGHT (lines)
- resolve output stride: DSTS (bytes)

These values program the width and height of the resolved surface. In the base case,

- DSTWIDTH = color surface width
- DSTHEIGHT = color sufrace height
- DSTS = resolve surface format bpp * DSTWIDTH

The vcaa engine technically supports DSTX and DSTY (like SRCX and SRCY).

```
  [pseudo_code]
     resolve_surface_start_address_put = pcurctx->regs.rG2DSTBA.uDSTBA() +
       (pcurctx->regs.rG2DSTPS.uDSTX() * resolve_surface_color_depth) +
       (pcurctx->regs.rG2DSTPS.uDSTY() * resolve_surface_color_stride);
```

(5) Resolving a pixel

The coverage surface is a 8 bits per pixel surface (C4X4). The surface is initialized to all 1s by 3d.

For a given pixel, we need to look up 4 bits of coverage data. If the data is 0xf, the pixel does not need to be resolved. Otherwise, we need to reblend the pixel with certain weightings of its neighbors (i.e. we're on the edge of some geometry).

If any coverage bit is 0, we need to resolve the color. To do so, we calculate the following equation:

```
   color_new = (
                 20*color_old +
                 27*(
                     ((cover_down  == 0) ? color_down  : color_old) +
                     ((cover_right == 0) ? color_right : color_old) +
                     ((cover_left  == 0) ? color_left  : color_old) +
                     ((cover_up    == 0) ? color_up    : color_old)
                    )
               ) / 128;
```

If coverage bit == 0, then we use the neighbor color value in the resolve

If coverage bit == 1, then we use the center color value in the resolve

The resolve is done on a per channel (r/g/b/a) basis:

- format convert input channel to 8-bit
- perform resolve equation above

- format convert to output format

For the resolution of the alpha channel:

- In B5G6R5: no alpha information. do nothing.
- In A1B5G5R5: no resolve. keep the source color alpha bit.
- In R8G8B8A8: normal 8-bit channel resolve

(6) Resolving a pixel on the edge

When on an edge, the vcaa engine treats the coverage bit as a 1. Use the center color value. This holds true even on the edge of the sub-surface resolve window when located in the middle of the larger surface

(7) Maximum dimensions

The maximum resolve sub-surface is 4096 pixels wide.

(8) Surface restrictions

The VCAA engine has the following restrictions with respect to input surfaces

- input base address is 128-bit memory word aligned

- input stride is multiple of 128-bits (16 bytes)

The VCAA engine has the following restrictions with respect to output surfaces

- output base address is 128-bit memory word aligned

- output stride is multiple of 128-bits (16 bytes)

(9) Coverage surface layout

The surface is C4X4.

Surface layout (C4X4)

```
(lsb2msb)  C0_C1_C2_C3_X_X_X_X     (X is a don't care.  Qrast inits to 1)
(msb2lsb)  X_X_X_X_C3_C2_C1_C0

    +          o          o
         C0
            C1   Cov(0,1)
       C2
         C3
    o          o          o

      Cov(1,0)   Cov(1,1)

    o          o          o

    +/o = pixel centers
```

In the example above,

```
        Cov(0,0) = X_X_X_X_C3_C2_C1_C0
```

```
        C3        = V_C3(Cov(0,0));
        ..          ..
        C0        = V_C0(Cov(0,0));
      #define V_C3(bits)  (bits & 0x8)
      #define V_C2(bits)  (bits & 0x4)
      #define V_C1(bits)  (bits & 0x2)
      #define V_C0(bits)  (bits & 0x1)
```

Resolving a pixel

In an ideal world, the coverage would be simply laid out such that when resolving Pixel(x,y), we would need only to fetch Cov(x,y) to get all 4 bits of information.

In actuality, the coverage surface was rearranged to help qrast in performance. To resolve Pixel(x,y) gr2d has to fetch 4 C4X4 bytes [Cov(x,y), Cov(x-1,y), Cov(x,y-1), Cov(x-1,y-1)]. From each C4X4 byte, it extracts one bit which is used in the resolve equations shown in (5).

Need the logical VCAA bits (DRLU) for blend which is spread across four C4X4 coverage bytes

```
          U
    L
        o
            R
      D
```

Where

- o = Pixel(x,y)
- D = V_C1(Cov(x-1,y))
- R = V_C0(Cov(x,y))
- L = V_C3(Cov(x-1,y-1))
- U = V_C2(Cov(x,y-1))

SB only

Offset: 0x1032 | Byte Offset: 0x40c8 | Read/Write: R/W | Reset: 0x00000000 (0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx)

Bit	Reset	Description
31:0	X	SRCBA_B: This parameter specifies the start address of source image stored in the image buffer memory. In 4:2:0 format mode, this image block accommodates for Y-image. This address specifies byte-position, however, bits [2:0] are restricted with respect to the data formats to fit multiple pixels in one memory word (8 bytes). For example, {0, 4} for any YcrCb formats, {0, 2, 4, 6} for RGB 16-bit format. Since one Y pixel takes 8-bit, all 8 byte-positions are valid in 4:2:0 mode. (Unlike multiplexed pixels format, there are no restrictions on this value.)

11.5.46 G2SB_CTX3_G2SRCST_0

31:0	X	PAT_BASE: pattern base address in tile mode, PATBA is the linear address where pixel start

11.5.67 G2SB_CTX3_G2SRCBA_SB_SURFBASE_0

SB_SURFBASE registers

These registers need only be programmed when using SB. They point to the base of the various source and destination surfaces. Technically they are only needed when tiling is enabled, but there is no harm in always programming them.

Their counterpart registers (_SB_SURFBASE with SB_SURFBASE stripped off) indicate the location of the first pixel to be sourced or written within the surface.

This register exists to mimic the X, Y (SRCX, SRCY) functionality found in the BitBlt engine.

For example, to get at pixel X, Y:

SRCBA = SRCBA_SB_SURFBASE + Y*stride + X*Bpp

Offset: 0x1048 │ Byte Offset: 0x4120 │ Read/Write: R/W │ Reset: 0x00000000 (0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx)

Offset: 0x5001 | Byte Offset: 0x14004 | Read/Write: R/W | Reset: 0x00000000 (0b0xxxxxxx0)

Bit	Reset	Description
8	0x0	INCR_SYNCPT_NO_STALL: If NO_STALL is 1, then when fifos are full, INCR_SYNCPT methods will be dropped and the INCR_SYNCPT_ERROR[COND] bit will be set. If NO_STALL is 0, then when fifos are full, the client host interface will be stalled.
0	0x0	INCR_SYNCPT_SOFT_RESET: If SOFT_RESET is set, then all internal state of the client syncpt block will be reset. To do soft reset, first set SOFT_RESET of all host1x clients affected, then clear all SOFT_RESETs.

11.6.3 G2SB_CTX4_INCR_SYNCPT_ERROR_0

Offset: 0x5002 | Byte Offset: 0x14008 | Read/Write: R/W | Reset: 0x00000000 (0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx)

Bit	Reset	Description
31:0	X	COND_STATUS: COND_STATUS[COND] is set if the fifo for COND overflows. This bit is sticky and will remain set until cleared. Cleared by writing 1.

11.6.4 G2SB_CTX4_G2CLASSCHANNEL_REGONLY_0

This register can be accessed by both register read/write and command fifo in order not to break exsting code , keep suffix REGONLY.

2D syncpt behavior

- Each 2D context has its own syncpt client.
- OP_DONE increments when 2D's memory write client is idle, meaning all preceding operations are complete.
- RD_DONE behaves like OP_DONE
- REG_WR_SAFE behaves like IMMEDIATE meaning a syncpt increment returns immediately and does not indicate that a register write will NOT block.
- The implications are that 2D's host FIFO can fill and block access to 2D, which will indeterminately block a direct CPU access.

Offset: 0x5011 | Byte Offset: 0x14044 | Read/Write: R/W | Reset: 0x00000000 (0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx)

Bit	Reset	Description
31:0	X	VDSTEP: Vertical Scaling DDA Reset value: xxxx-xxxxh Vertical DDA Step (Increment) Value (VDSTEP[18:0]) (upper 13 bits should be set to '0') This parameter specifies the increment value of the DDA used for vertical scaling and it is in the form of 6-bit integer and 12-bit fraction. This value is determined by the equation: (Actual_source_height-1-VDTINI) / (Actual_destination_height-1) Truncate the remaining bits to keep the 12-bit fraction. Since we have to meet (Actual_source_height-1)*1.0 >= (Actual_destination_height - 1)*VDSTEP + VDTINI. The 6-bit integer allows maximum contraction ratio of 1/64, and 12-bit fraction ensures the maximum limit of accumulated error less than half line-spacing for up to approximately 2000 target lines. For example, image expansion from 240 lines to 400 lines VDSTEP[17:0] = 19'b00_0000_1001_1001_1010 and image contraction from 240 lines to 150 lines VDSTEP[17:0] = 19'b00_0001_1001_1001_1010.

11.6.13 G2SB_CTX4_G2VDDAINI_0

Offset: 0x5012 | Byte Offset: 0x14048 | Read/Write: R/W | Reset: 0x00000000 (0bxxxxxxxxxxxxxxxx)

Bit	Reset	Description
15:8	X	VDBINI: Vertical DDA Initial Value for Bottom-Field (VDBINI[7:0]) (see description above)
7:0	X	VDTINI: Vertical Scaling DDA Initial Values Vertical DDA Initial Value for Top-Field (VDTINI[7:0]) This parameter specifies the fraction part of initial value of the DDA used for vertical scaling. Given a pair of consecutive source image lines representing positions 0.0 and 1.0, a destination line-image will be created at any position in [0.0, 1.0), that is specified by the fraction part of the vertical DDA. The 8-bit initial fraction value specifies the position of the first output (destination) line-image located between the first and the second input (source) line-images, respectively at position 0.0 and 1.0. This parameter provides a way to compensate relative displacement of top and bottom fields of a source image. Suppose, 2-to-1 interlaced original video field images #1 and #2 are in the image buffer, to be displayed in an overlay window. Assume that the #1 field image is the top-field. Using VDTINI = 8'hC0 for the top-field image and VDBINI = 8'h40 for the bottom-field image, for example, the two images from #1 and #2 fields get mapped to identically positioned destination images in the overlay window.

11.6.14 G2SB_CTX4_G2HDDA_0

Offset: 0x5013 | Byte Offset: 0x1404c | Read/Write: R/W | Reset: 0x00000000 (0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx)

Bit	Reset	Description
31:0	X	HDSTEP: Horizontal Scaling DDA Reset value: xxxx-xxxxh Horizontal DDA Step (Increment) Value (HDSTEP[18:0]) (upper 13 bits should be set to '0') This parameter specifies the increment value of the DDA used for horizontal scaling and it is in the form of 6-bit integer and 12-bit fraction. This value is determined by the equation: (Actual_source_width-1-HDINI) / (Actual_destination_width-1) Truncate the remaining bits to keep the 12-bit fraction. The 6-bit integer allows maximum contraction ratio of 1/64, and 12-bit fraction ensures the maximum limit of accumulated error less than half pixel-spacing for up to approximately 2000 destination pixels. For example, image expansion from 720 pixels to 800 pixels HDSTEP[17:0] = 19'b000_0000_1110_0110_0111 and image contraction from 720 pixels to 250 pixels HDSTEP[17:0] = 19'b000_0010_1110_0001_0101.

Bit	Reset	Description
7:0	X	HDINI: Horizontal Scaling DDA Initial Value Horizontal DDA Initial Value (HDINI[7:0]) This parameter specifies the fraction part of initial value of the DDA used for horizontal scaling. Given a group of six consecutive source pixels that the two pixels at the center representing positions 0.0 and 1.0, a destination pixel will be created at any position in [0.0, 1.0), that is specified by the fraction part of the horizontal DDA. The 8-bit initial fraction value specifies the position of the first output (destination) pixel located between the first and the second input (source) pixels, respectively at position 0.0 and 1.0.For horizontal scaling this value may normally be set to 0.

11.6.16 G2SB_CTX4_G2CSCFIRST_0

The next 3 registers contain 8 parameters used by the YCbCr (YUV) to RGB color space conversion logic. This logic can also be used for RGB gain/gamma correction in RGB to RGB modes, and for luma gain in YUV to YUV modes.

Two new parameters (G2U, G2V) have been added for RGB to YUV conversion. These are in address 0x38. The equations have the form:

if (yuv2rgb)

(r,g,b) = matrix*(y+sbreg_yos,u,v)

matrix: sbreg_cyx, sbreg_cur, sbreg_cvr,
sbreg_cyx, sbreg_cug, sbreg_cvg,
sbreg_cyx, sbreg_cub, sbreg_cvb,

else if (rgb2rgb)

(r,g,b) = matrix*(r,g+sbreg_yos,b)
matrix: sbreg_cvr, 0, sbreg_cur,
sbreg_cvg, sbreg_cyx, sbreg_cug,
sbreg_cvb, 0, sbreg_cub,

else if (yuv2yuv)

(y,u,v) = matrix*(y,u,v)

matrix: sbreg_cub, 0, sbreg_cvb,
sbreg_cug, sbreg_cyx, sbreg_cvg,
sbreg_cur, 0, sbreg_cvr,

else if (rgb2yuv)

(y,u,v) = matrix*(r,g,b) + (sbreg_yos,0,0)

matrix: sbreg_cvb, sbreg_cyx, sbreg_cub,
sbreg_cvg, sbreg_g2u, sbreg_cug,
sbreg_cvr, sbreg_g2v, sbreg_cur,

Bit	Reset	Description
31:24	X	YOS:Y-Offset (YOFFSET[7:0]) for YUV generation. This parameter consists of 8-bit 2's complement in the range [-128,127]. For YUV->RGB the recommended value is -16 (decimal) or 0xF0 For YUV->YUV & RGB->RGB, this parameter should be set to 0 For RGB->YUV the recommended value is +16 (decimal) or 0x10
21:12	X	CVR: multiplier for V/R for V or R generation. This parameter consists of a sign bit and 9-bit magnitude (s2.7) For YUV->RGB the recommended value is 1.5960 (decimal) or 0x0CC. If source data is in RGB format, this parameter may be used as gain adjustment for R component. For RGB->YUV the recommended value is +0.439 (decimal) or 0x038
9:0	X	CUB: multiplier for U/B for Y or B generation. Consists of a sign bit and 9-bit magnitude (s2.7). For YUV->RGB, the recommended value is 2.0172 (decimal) or 0x102. If source data is in RGB format, this parameter may be used as gain adjustment for B component. This register changes precision when doing RGB to YUV conversion (SIFMT=1xxx, DIFMT=0xxx). CUB becomes s1.8 and the recommended value is +0.098 or 0x019

25:16	X	CVB: multiplier for V/R for Y or B generation. This parameter consists of a sign bit and 9-bit magnitude (s2.7)For YUV->RGB, normally this parameter is programmed to 0.0. This coefficient takes non-zero value if hue is rotated. For YUV->YUV & RGB->RGB, this parameter should be set to 0 For RGB->YUV the recommended value is +0.257 (decimal) or 0x021

Bit	Reset	Description
8:0	X	CVG: multiplier for V/R for U or G generation. This parameter consists of a sign bit and 8-bit magnitude (s1.7) For YUV->RGB the recommended value is -0.8130 (decimal) or 0x168. For YUV->YUV & RGB->RGB, this parameter should be set to 0 For RGB->YUV the recommended value is -0.148 (decimal) or 0x113

11.6.19 G2SB_CTX4_G2CMKEYL_0

When key generation is enabled, the value of this register is the lower color/chroma limit and G2CMKEYU is the upper color/chroma limit for component pixel data. Three component signal values (YCrCb/YUV or RGB) of every output pixel are compared to a set of three ranges that are specified by three pairs of lower and upper color/chroma key values.

If the Key Polarity is 0, the Key is set to 1 only when all three component values of an input pixel are respectively within the set of ranges (inclusive of the limit values), else the Key is set to 0.

If the Key Polarity is 1, the Key is set to 1 when any of the three component values of an input pixel are outside the set of ranges, else the Key is set to 0.

31	0x0	DISDW: Output destination writes go either to image memory or the EPP. 0: Output data is sent to memory 1: YUV or RGB data is passed directly to the EPP module, and no destination writes take place. 0 = GOTO_IMAGE_BUFFER 1 = GOTO_EPP
30	0x0	ENDITH: Enable Dithering (ENDITH) For 16 bit RGB output modes, the LSB of the color components can be modified by adding a variable residual value that will reduce the banding artifacts that can appear on the display. 0 Normal operation 1 Enable Dithering 0 = DISABLE 1 = ENABLE
28	0x0	KPOL: Key Signal Polarity (KPOL) Color/Chroma key signal is generated by comparing source input pixel color to a range of a color specified by lower and upper limit values. The key signal is interpreted in two ways, depending on which one of video and graphics images is foreground (and the other is background). This is effective only if Key signal generator is enabled. (see G2CMKEYL, G2CMKEYU) 0 Key signal is set to 1 when source pixel is within the lower and upper limit color range. 1 Key signal is set to 1 when source pixel is outside the lower and upper limit color range. 0 = WITHIN_BOUNDS 1 = OUTSIDE_BOUNDS
27	0x0	KEYEN: Key Signal Generator Enable (KEYEN) Key signal generator generates either chroma key signal (from YCbCr signal) or color key signal (from RGB signal). 0 Key signal generator is disabled.1 Key signal generator is enabled. 0 = DISABLE 1 = ENABLE
26	0x0	DBSEL: StretchBLT Destination Buffer Selection (DBSEL) StretchBLT processing involves

Bit	Reset	Description
		frame-rate conversion from a series of source images to another series of destination images (field-rate of the source video to frame-rate of the PC display). In order to avoid image tearing, it is preferred to use two buffer sections in the destination video area. This bit selects one of the two buffering blocks to which this StretchBLT command delivers the destination image. The two buffering memory blocks are called A and B. 0 Destination image goes to ‘A’ buffer. 1 Destination image goes to ‘B’ buffer. 0 = DST_A 1 = DST_B
25	0x0	SBSEL: StretchBLT Source Buffer Selection (SBSEL) StretchBLT processing involves frame-rate conversion from a series of source images to another series of destination images (field-rate of the source video to frame-rate of the PC display). In order to avoid image tearing, it is preferred to use two buffer sections in the source video area. This bit selects one of the two buffering blocks from which this StretchBLT command receives the source image. The two buffering memory blocks are called source-A and source-B. 0 Source image comes from ‘source-A’ buffer. 1 Source image comes from ‘source-B’ buffer. 0 = SRC_A 1 = SRC_B
24	0x0	SITYPE: StretchBLT Source Type (SITYPE) This bit identifies two types of source images. If source image is 2-to-1 interlaced and StretchBLT processes either one of the two interlaced field-images, physical (positional) displacement between the two interlaced fields must be taken into account. One field-image that is placed higher in position than the other field-image is called top-field and the other is called bottom-field. StretchBLT processing has to lower the top-field (or raise the bottom-field) to match the corresponding two target images in the overlay window (that is progressively scanned) right at the same position. If source image is full frame-image obtained from two interlaced field-images, its type is ‘top-field’. If source images are progressively scanned, the type identification is not significant and they may be designated either one of the two types 0 Source image is ‘top-field’. 1 Source image is ‘bottom-field’. 0 = TOP_FIELD 1 = BOTTOM_FIELD
23	0x0	RANGEREDFRM:In the VC-1 specification, when the value of RANGEREDFRM variable (1-bit) for a picture is equal to 1, the picture shall be scaled up according to the following equation:Y = clip(((Y-128)*2) + 128);Cb = clip(((Cb-128)*2) + 128);Cr = clip(((Cr-128)*2) + 128);The clip operator limits the output to [0, 255].The input is also limited to [0, 255]. In the VC-1 nomenclature, the output (Y, Cb, Cr) tuple corresponds to the 'decoded' picture. The input (Y, Cb, Cr) tuple corresponds to the 'reconstructed' picture. The above equations create the decoded picture while keeping the reconstructed picture intact.Only YUV _OB formats are supported with range reducation enabled, not the YUV _TC or RGB formats The YUV data coming from the video frame buffers (reconstructed picture) in the SDRAM was scaled up using the above equations and given to the display. the value of 1-bit wide RANGEREDFRM variable was configured in the DVO per frame and the frame was scaled whenever RANGEREDFRM == 1. 0 = DISABLE 1 = ENABLE
22:20	0x0	HFTYPE: StretchBLT Horizontal Filter Mode (HFTYPE[2:0]) The six-tap horizontal interpolation filter can be operated in various operation modes. For the image expansion, it should be programmed as a pure 6-tap interpolator. For the image contraction, it can work as partly lowpass filter and partly interpolater with varying degree depending the contraction ratio. For StretchBLT, this parameter is used as an index (selection) to an internal lookup table that stores the group of filter-coefficients for the different modes of horizontal filtering. 000: Pure interpolation filter. 001 010 011 100 101 110: mix of interpolation and low pass filters 111: DISABLE. 0 = INTERP 1 = LPF1

Bit	Reset	Description

19	0x0	DISCSC: enabled color space converter by default 0 = ENABLE 1 = DISABLE
18	0x0	VFEN: StretchBLT Vertical Filter Enable (VFEN) Vertical filter shall be disabled if source images come from host CPU via CPU Read-FIFO. (SISEL) Vertical filter may be disabled to save some memory bandwidth but this will likely result in degradation of image quality. This option may also be used in the case where source image is progressive scanning and there is no vertical scaling. 0 Vertical filter is disabled.1 Vertical filter is enabled. 0 = DISABLE 1 = ENABLE
17:16	0x0	VFTYPE: StretchBLT Vertical Filter Mode (VFTYPE[1:0]) This bit is effective when the Vertical Filter is enabled. (bit 18) The two-tap vertical interpolation filter can be operated in various modes. For the image expansion, it should be programmed as a pure 2-tap interpolator. For the image contraction, it can work as partly averager and partly interpolator with varying degree depending on the contraction ratio. For StretchBLT, this parameter is used as an index (selection) to an internal lookup table that stores the group of filter-coefficients for the different modes of vertical filtering. 00 Pure interpolation filter. 01 25% averager, 75% interpolator.1 0 50% averager, 50% interpolator. 11 100% averager. 0 = INTERP 1 = AVG25_INTERP75 2 = AVG50_INTERP50 3 = AVG
9:8	X	UVST: 00= 1/2 of Luma Buffer Stride; in this case Luma Buffer Stride should be multiple of 2 bytes. 01= Equal to Luma Buffer Stride 10= 1/4 of Luma Buffer Stride; in this case Luma Buffer Stride should be multiple of 4 bytes. 11= use uvstride. Note: Use care when using a tiled surface, since 1/2 or 1/4 of luma stride may yield an invalid pitch (stride). 0 = UVS2X 1 = UVS1X 2 = UVS4X 3 = UVS_G2UVSTRIDE

11.6.26 G2SB_CTX4_G2CONTROLMAIN_0

G2 Blit Formats:

(1) G2 Blit size is based on height in lines, width in pixels, stride in bytes, and pixel size (color depth). Unless alpha blending is enabled, G2 doesn't care about pixel components.

Source color depths supported by G2 Blit:

- color depth same as destination: G2CONTROLMAIN.SRCCD = 1
- monochrome: G2CONTROLMAIN.SRCCD = 0

(source monochrome color determined by G2SRCBGC, G2SRCFGC)

Pattern color depths supported by G2 Blit:

- color depth same as destination: G2PATOS.PATCD = 1
- monochrome: G2PATOS.PATCD = 0

(pattern monochrome color determined by G2PATBGC, G2PATFGC)

Destination color depths supported by G2 Blit:

- 1 byte per pixel: G2CONTROLMAIN.DSTCD = BPP8
- 2 bytes per pixel: G2CONTROLMAIN.DSTCD = BPP16
- 4 bytes per pixel: G2CONTROLMAIN.DSTCD = BPP32

(2) Alpha blending operates on 3 or 4 component pixels of a specified color depth. One of the components may be alpha (A), depending on the alpha blend format, which is only allowed in certain component positions defined below. The only format rule of the remaining components is that they must be in the same source and destination position because the alpha blend engine does not support component swapping. For example, valid 32BPP formats are: RGBA_8888->RGBA_8888, BGRA_8888->BGRA_8888, GRBA_8888->GRBA_8888, etc.

Source formats supported by G2 alpha blend:

- color depth BPP8: no supported formats
- color depth BPP16:
  - ALPTYPE_PLS1BPP: xxxA_5551 (ex: BGRA_5551 = A[15] R[14:10] G[9:5] B[4:0])
  - ALPTYPE_PLS4BPP: xxxA_4444 (ex: BGRA_4444 = A[15:12] R[11:8] G[7:4] B[3:0])
  - (other) : xxx_565 (ex: BGR_565 = R[15:11] G[10:5] B[4:0])
- color depth BPP32:
  - (all) : xxxA_8888 (ex: BRGA_8888 = A[31:24] R[23:16] G[15:8] B[7:0])

Destination formats supported by G2 alpha blend:

- color depth BPP8: no supported formats
- color depth BPP16: xxx_565 (ex: BGR_565 = R[15:11] G[10:5] B[4:0])
- color depth BPP32: xxxA_8888 (ex: BRGA_8888 = A[31:24] R[23:16] G[15:8] B[7:0])

src cd	src format	dst cd	dst format	examples
BPP8	no support	BPP8	no support	
BPP16	xyzA_5551, xyzA_4444, xyz_565	BPP16	xyz_565	BGRA_5551->BGR_565, RGB_565->RGB565
BPP32	xyzA_8888	BPP32	xyzA_8888	RGBA_8888->RGBA_8888, BGRA_8888->BGRA_8888
BPP32	xyzA_8888	BPP16	xyz_565	RGBA_8888->RGB_565, BGRA_8888->BGR_565

VCAA Resolve engine

(1) Format support

srcColor format	srcCoverage format	legal dest format(s)
A1B5G5R5	VCAA	A1B5G5R5
R8G8B8A8	VCAA	R8G8B8A8, B5G6R5
B5G6R5	VCAA	B5G6R5

To program resolve type:

- ALPTYPE == FIX: B5G6R5 -> B5G6R5
- ALPTYPE == PLS1BPPAL: A1B5G5R5 -> A1B5G5R5
- ALPTYPE == PLS8BPP: R8G8B8A8 -> R8G8B8A8
- ALPTYPE == PLS8BX: R8G8B8A8 -> B5G6R5

(2) Color surface programming

- color surface base address: SRCBA
- sub-surface start x: SRCX (pixel index)
- sub-surface start y: SRCY (line index)
- color surface stride: SRCS (bytes)

The engine supports sub-surface resolve. One can imagine a full color buffer of 1024x768, but

```
[pseudo_code]
      color_surface_start_address_fetch = pcurctx->regs.rG2SRCBA.uSRCBA() +
       (pcurctx->regs.rG2SRCPS.uSRCX() * VCAAState.color_surface_depth) +
       (pcurctx->regs.rG2SRCPS.uSRCY() * VCAAState.color_surface_stride);
```

(3) VCAA surface programming

- vcaa surface base address: PATBA
- vcaa surface stride: PATST (bytes)

```
[pseudo_code]
      vcaa_surface_start_address_fetch = pcurctx->regs.rG2PATBA.uPATBA();
```

SW *MUST* directly program this register to the proper sub-surface location in the vcaa surface which corresponds to the SRCX and SRCY programming. The calculation is PATBA = vcaa_base_address + SRCX * (1) + SRCY * PATST;

(4) Resolve surface programming

- resolve window width: DSTWIDTH (pixels)
- resolve window height: DSTHEIGHT (lines)
- resolve output stride: DSTS (bytes)

These values program the width and height of the resolved surface. In the base case,

- DSTWIDTH = color surface width
- DSTHEIGHT = color sufrace height
- DSTS = resolve surface format bpp * DSTWIDTH

The vcaa engine technically supports DSTX and DSTY (like SRCX and SRCY).

```
 [pseudo_code]
    resolve_surface_start_address_put = pcurctx->regs.rG2DSTBA.uDSTBA() +
      (pcurctx->regs.rG2DSTPS.uDSTX() * resolve_surface_color_depth) +
      (pcurctx->regs.rG2DSTPS.uDSTY() * resolve_surface_color_stride);
```

(5) Resolving a pixel

The coverage surface is a 8 bits per pixel surface (C4X4). The surface is initialized to all 1s by 3d.

For a given pixel, we need to look up 4 bits of coverage data. If the data is 0xf, the pixel does not need to be resolved. Otherwise, we need to reblend the pixel with certain weightings of its neighbors (i.e. we're on the edge of some geometry).

If any coverage bit is 0, we need to resolve the color. To do so, we calculate the following equation:

```
color_new = (
              20*color_old +
              27*(
                  ((cover_down  == 0) ? color_down  : color_old) +
                  ((cover_right == 0) ? color_right : color_old) +
                  ((cover_left  == 0) ? color_left  : color_old) +
                  ((cover_up    == 0) ? color_up    : color_old)
                  )
            ) / 128;
```

If coverage bit == 0, then we use the neighbor color value in the resolve

If coverage bit == 1, then we use the center color value in the resolve

The resolve is done on a per channel (r/g/b/a) basis:

format convert input channel to 8-bit

perform resolve equation above

format convert to output format

For the resolution of the alpha channel:

- In B5G6R5: no alpha information. do nothing.
- In A1B5G5R5: no resolve. keep the source color alpha bit.
- In R8G8B8A8: normal 8-bit channel resolve

(6) Resolving a pixel on the edge

When on an edge, the vcaa engine treats the coverage bit as a 1. Use the center color value. This holds true even on the edge of the sub-surface resolve window when located in the middle of the larger surface

(7) Maximum dimensions

The maximum resolve sub-surface is 4096 pixels wide.

(8) Surface restrictions

The VCAA engine has the following restrictions with respect to input surfaces

- input base address is 128-bit memory word aligned

- input stride is multiple of 128-bits (16 bytes)

The VCAA engine has the following restrictions with respect to output surfaces

- output base address is 128-bit memory word aligned

- output stride is multiple of 128-bits (16 bytes)

(9) Coverage surface layout

The surface is C4X4.

Surface layout (C4X4)

```
(lsb2msb)  C0_C1_C2_C3_X_X_X_X     (X is a don't care.  Qrast inits to 1)
(msb2lsb)  X_X_X_X_C3_C2_C1_C0

    +          o          o
         C0
            C1   Cov(0,1)
       C2
         C3
    o          o          o

      Cov(1,0)   Cov(1,1)

    o          o          o

    +/o = pixel centers
```

In the example above,

```
       Cov(0,0) = X_X_X_X_C3_C2_C1_C0
       C3       = V_C3(Cov(0,0));
       ..         ..
       C0       = V_C0(Cov(0,0));
    #define V_C3(bits) (bits & 0x8)
    #define V_C2(bits) (bits & 0x4)
    #define V_C1(bits) (bits & 0x2)
    #define V_C0(bits) (bits & 0x1)
```

Resolving a pixel

In an ideal world, the coverage would be simply laid out such that when resolving Pixel(x,y), we would need only to fetch Cov(x,y) to get all 4 bits of information.

In actuality, the coverage surface was rearranged to help qrast in performance. To resolve Pixel(x,y) gr2d has to fetch 4 C4X4 bytes [Cov(x,y), Cov(x-1,y), Cov(x,y-1), Cov(x-1,y-1)]. From each C4X4 byte, it extracts one bit which is used in the resolve equations shown in (5).

Need the logical vcaa bits (DRLU) for blend which is spread across four C4X4 coverage bytes

```
          U
   L
       o
           R
     D
```

where

- o = Pixel(x,y)
- D = V_C1(Cov(x-1,y))
- R = V_C0(Cov(x,y))
- L = V_C3(Cov(x-1,y-1))
- U = V_C2(Cov(x,y-1))

SB only

Offset: 0x5032 │ Byte Offset: 0x140c8 │ Read/Write: R/W │ Reset: 0x00000000 (0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx)

Bit	Reset	Description
31:0	X	SRCBA_B: This parameter specifies the start address of source image stored in the image buffer memory. In 4:2:0 format mode, this image block accommodates for Y-image. This address specifies byte-position, however, bits [2:0] are restricted with respect to the data formats to fit multiple pixels in one memory word (8 bytes). For example, {0, 4} for any YcrCb formats, {0, 2, 4, 6} for RGB 16-bit format. Since one Y pixel takes 8-bit, all 8 byte-positions are valid in 4:2:0 mode. (Unlike multiplexed pixels format, there are no restrictions on this value.)

11.6.46 G2SB_CTX4_G2SRCST_0

Bit	Reset	Description
31:0	X	PAT_BASE: pattern base address in tile mode, PATBA is the linear address where pixel start

11.6.67 G2SB_CTX4_G2SRCBA_SB_SURFBASE_0

SB_SURFBASE registers

These registers need only be programmed when using SB. They point to the base of the various source and destination surfaces. Technically they are only needed when tiling is enabled, but there is no harm in always programming them.

Their counterpart registers (_SB_SURFBASE with SB_SURFBASE stripped off) indicate the location of the first pixel to be sourced or written within the surface.

This register exists to mimic the X, Y (SRCX, SRCY) functionality found in the BitBlt engine.

For example, to get at pixel X, Y:

SRCBA = SRCBA_SB_SURFBASE + Y*stride + X*Bpp

Offset: 0x5048 | Byte Offset: 0x14120 | Read/Write: R/W | Reset: 0x00000000 (0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx)

7:0	0x0	INDX: syncpt index value

11.7.2 G2SB_CTX5_INCR_SYNCPT_CNTRL_0

Offset: 0x2001 │ Byte Offset: 0x8004 │ Read/Write: R/W │ Reset: 0x00000000 (0b0xxxxxx0)

Bit	Reset	Description
8	0x0	INCR_SYNCPT_NO_STALL: If NO_STALL is 1, then when fifos are full, INCR_SYNCPT methods will be dropped and the INCR_SYNCPT_ERROR[COND] bit will be set. If NO_STALL is 0, then when fifos are full, the client host interface will be stalled.
0	0x0	INCR_SYNCPT_SOFT_RESET: If SOFT_RESET is set, then all internal state of the client syncpt block will be reset. To do soft reset, first set SOFT_RESET of all host1x clients affected, then clear all SOFT_RESETs.

11.7.3 G2SB_CTX5_INCR_SYNCPT_ERROR_0

Offset: 0x2002 │ Byte Offset: 0x8008 │ Read/Write: R/W │ Reset: 0x00000000 (0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx)

Bit	Reset	Description
31:0	X	COND_STATUS: COND_STATUS[COND] is set if the fifo for COND overflows. This bit is sticky and will remain set until cleared. Cleared by writing 1.

11.7.4 G2SB_CTX5_G2CLASSCHANNEL_REGONLY_0

This register can be accessed by both register read/write and command fifo in order not to break existing code , keep suffix REGONLY.

2D syncpt behavior

- Each 2D context has its own syncpt client.
- OP_DONE increments when 2D's memory write client is idle, meaning all preceding operations are complete.
- RD_DONE behaves like OP_DONE
- REG_WR_SAFE behaves like IMMEDIATE meaning a syncpt increment returns immediately and does not indicate that a register write will NOT block. The implications are that 2D's host FIFO can fill and block access to 2D, which will indeterminately block a direct CPU access.

Bit	Reset	Description
31:0	X	VDSTEP: Vertical Scaling DDA Reset value: xxxx-xxxxh Vertical DDA Step (Increment) Value (VDSTEP[18:0]) (upper 13 bits should be set to '0') This parameter specifies the increment value of the DDA used for vertical scaling and it is in the form of 6-bit integer and 12-bit fraction. This value is determined by the equation: (Actual_source_height-1-VDTINI) / (Actual_destination_height-1) Truncate the remaining bits to keep the 12-bit fraction. Since we have to meet (Actual_source_height-1)*1.0 >= (Actual_destination_height - 1)*VDSTEP + VDTINI. The 6-bit integer allows maximum contraction ratio of 1/64, and 12-bit fraction ensures the maximum limit of accumulated error less than half line-spacing for up to approximately 2000 target lines. For example, image expansion from 240 lines to 400 lines VDSTEP[17:0] = 19'b00_0000_1001_1001_1010 and image contraction from 240 lines to 150 lines VDSTEP[17:0] = 19'b00_0001_1001_1001_1010.

11.7.13 G2SB_CTX5_G2VDDAINI_0

Offset: 0x2012 | Byte Offset: 0x8048 | Read/Write: R/W | Reset: 0x00000000 (0bxxxxxxxxxxxxxxxx)

Bit	Reset	Description
15:8	X	VDBINI: Vertical DDA Initial Value for Bottom-Field (VDBINI[7:0]) (see description above)
7:0	X	VDTINI: Vertical Scaling DDA Initial Values Vertical DDA Initial Value for Top-Field (VDTINI[7:0]) This parameter specifies the fraction part of initial value of the DDA used for vertical scaling. Given a pair of consecutive source image lines representing positions 0.0 and 1.0, a destination line-image will be created at any position in [0.0, 1.0), that is specified by the fraction part of the vertical DDA. The 8-bit initial fraction value specifies the position of the first output (destination) line-image located between the first and the second input (source) line-images, respectively at position 0.0 and 1.0. This parameter provides a way to compensate relative displacement of top and bottom fields of a source image. Suppose, 2-to-1 interlaced original video field images #1 and #2 are in the image buffer, to be displayed in an overlay window. Assume that the #1 field image is the top-field. Using VDTINI = 8'hC0 for the top-field image and VDBINI = 8'h40 for the bottom-field image, for example, the two images from #1 and #2 fields get mapped to identically positioned destination images in the overlay window.

11.7.14 G2SB_CTX5_G2HDDA_0

Offset: 0x2013 | Byte Offset: 0x804c | Read/Write: R/W | Reset: 0x00000000 (0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx)

Bit	Reset	Description
31:0	X	HDSTEP: Horizontal Scaling DDAReset value: xxxx-xxxxh Horizontal DDA Step (Increment) Value (HDSTEP[18:0]) (upper 13 bits should be set to '0') This parameter specifies the increment value of the DDA used for horizontal scaling and it is in the form of 6-bit integer and 12-bit fraction. This value is determined by the equation: (Actual_source_width-1-HDINI) / (Actual_destination_width-1) Truncate the remaining bits to keep the 12-bit fraction. The 6-bit integer allows maximum contraction ratio of 1/64, and 12-bit fraction ensures the maximum limit of accumulated error less than half pixel-spacing for up to approximately 2000 destination pixels. For example, image expansion from 720 pixels to 800 pixels HDSTEP[17:0] = 19'b000_0000_1110_0110_0111 and image contraction from 720 pixels to 250 pixels HDSTEP[17:0] = 19'b000_0010_1110_0001_0101.

11.7.15 G2SB_CTX5_G2HDDAINILS_0

Offset: 0x2014 | Byte Offset: 0x8050 | Read/Write: R/W | Reset: 0x00000000 (0bxxxxxxxx)

Bit	Reset	Description
7:0	X	HDINI: Horizontal Scaling DDA Initial Value Horizontal DDA Initial Value (HDINI[7:0]) This parameter specifies the fraction part of initial value of the DDA used for horizontal scaling. Given a group of six consecutive source pixels that the two pixels at the center representing positions 0.0 and 1.0, a destination pixel will be created at any position in [0.0, 1.0), that is specified by the fraction part of the horizontal DDA. The 8-bit initial fraction value specifies the position of the first output (destination) pixel located between the first and the second input (source) pixels, respectively at position 0.0 and 1.0.For horizontal scaling this value may normally be set to 0.

11.7.16 G2SB_CTX5_G2CSCFIRST_0

The next 3 registers contain 8 parameters used by the YCbCr (YUV) to RGB color space conversion logic. This logic can also be used for RGB gain/gamma correction in RGB to RGB modes, and for luma gain in YUV to YUV modes.

Two new parameters (G2U, G2V) have been added for RGB to YUV conversion. These are in address 0x38. The equations have the form:

if (yuv2rgb)

(r,g,b) = matrix*(y+sbreg_yos,u,v)

matrix: sbreg_cyx, sbreg_cur, sbreg_cvr,
sbreg_cyx, sbreg_cug, sbreg_cvg,
sbreg_cyx, sbreg_cub, sbreg_cvb,

else if (rgb2rgb)

(r,g,b) = matrix*(r,g+sbreg_yos,b)

matrix: sbreg_cvr, 0, sbreg_cur,
sbreg_cvg, sbreg_cyx, sbreg_cug,
sbreg_cvb, 0, sbreg_cub,

else if (yuv2yuv)

(y,u,v) = matrix*(y,u,v)

matrix: sbreg_cub, 0, sbreg_cvb,
sbreg_cug, sbreg_cyx, sbreg_cvg,
sbreg_cur, 0, sbreg_cvr,

else if (rgb2yuv)

(y,u,v) = matrix*(r,g,b) + (sbreg_yos,0,0)

matrix: sbreg_cvb, sbreg_cyx, sbreg_cub,
sbreg_cvg, sbreg_g2u, sbreg_cug,
sbreg_cvr, sbreg_g2v, sbreg_cur,

Offset: 0x2015 │ Byte Offset: 0x8054 │ Read/Write: R/W │ Reset: 0x00000000 (0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx)

Bit	Reset	Description
31:24	X	YOS:Y-Offset (YOFFSET[7:0]) for YUV generation. This parameter consists of 8-bit 2's complement in the range [-128,127]. For YUV->RGB the recommended value is -16 (decimal) or 0xF0 For YUV->YUV & RGB->RGB, this parameter should be set to 0 For RGB->YUV the recommended value is +16 (decimal) or 0x10
21:12	X	CVR: multiplier for V/R for V or R generation. This parameter consists of a sign bit and 9-bit magnitude (s2.7) For YUV->RGB the recommended value is 1.5960 (decimal) or 0x0CC. If source data is in RGB format, this parameter may be used as gain adjustment for R component. For RGB->YUV the recommended value is +0.439 (decimal) or 0x038
9:0	X	CUB: multiplier for U/B for Y or B generation. Consists of a sign bit and 9-bit magnitude (s2.7). For YUV->RGB, the recommended value is 2.0172 (decimal) or 0x102. If source data is in RGB format, this parameter may be used as gain adjustment for B component. This register changes precision when doing RGB to YUV conversion (SIFMT=1xxx, DIFMT=0xxx). CUB becomes s1.8 and the recommended value is +0.098 or 0x019

11.7.17 G2SB_CTX5_G2CSCSECOND_0

Bit	Reset	Description
25:16	X	CVB: multiplier for V/R for Y or B generation. This parameter consists of a sign bit and 9-bit magnitude (s2.7). For YUV->RGB, normally this parameter is programmed to 0.0. This coefficient takes non-zero value if hue is rotated. For YUV->YUV & RGB->RGB, this parameter should be set to 0 For RGB->YUV the recommended value is +0.257 (decimal) or 0x021
8:0	X	CVG: multiplier for V/R for U or G generation. This parameter consists of a sign bit and 8-bit magnitude (s1.7) For YUV->RGB the recommended value is -0.8130 (decimal) or 0x168. For YUV->YUV & RGB->RGB, this parameter should be set to 0 For RGB->YUV the recommended value is -0.148 (decimal) or 0x113

11.7.19 G2SB_CTX5_G2CMKEYL_0

When key generation is enabled, the value of this register is the lower color/chroma limit and G2CMKEYU is the upper color/chroma limit for component pixel data. Three component signal values (YCrCb/YUV or RGB) of every output pixel are compared to a set of three ranges that are specified by three pairs of lower and upper color/chroma key values.

If the Key Polarity is 0, the Key is set to 1 only when all three component values of an input pixel are respectively within the set of ranges (inclusive of the limit values), else the Key is set to 0.

If the Key Polarity is 1, the Key is set to 1 when any of the three component values of an input pixel are outside the set of ranges, else the Key is set to 0.

StretchBLT, Color/Chroma Key Lower Limit Register

Bit	Reset	Description
31	0x0	DISDW: Output destination writes go either to image memory or the EPP. 0: Output data is sent to memory 1: YUV or RGB data is passed directly to the EPP module, and no destination writes take place. 0 = GOTO_IMAGE_BUFFER 1 = GOTO_EPP

Bit	Reset	Description
30	0x0	ENDITH: Enable Dithering (ENDITH) For 16 bit RGB output modes, the LSB of the color components can be modified by adding a variable residual value that will reduce the banding artifacts that can appear on the display. 0 Normal operation. 1 Enable Dithering 0 = DISABLE 1 = ENABLE
28	0x0	KPOL: Key Signal Polarity (KPOL) Color/Chroma key signal is generated by comparing source input pixel color to a range of a color specified by lower and upper limit values. The key signal is interpreted in two ways, depending on which one of video and graphics images is foreground (and the other is background). This is effective only if Key signal generator is enabled. (see G2CMKEYL, G2CMKEYU) 0 Key signal is set to 1 when source pixel is within the lower and upper limit color range. 1 Key signal is set to 1 when source pixel is outside the lower and upper limit color range. 0 = WITHIN_BOUNDS 1 = OUTSIDE_BOUNDS
27	0x0	KEYEN: Key Signal Generator Enable (KEYEN) Key signal generator generates either chroma key signal (from YCbCr signal) or color key signal (from RGB signal)0 Key signal generator is disabled.1 Key signal generator is enabled. 0 = DISABLE 1 = ENABLE
26	0x0	DBSEL: StretchBLT Destination Buffer Selection (DBSEL) StretchBLT processing involves frame-rate conversion from a series of source images to another series of destination images (field-rate of the source video to frame-rate of the PC display). In order to avoid image tearing, it is preferred to use two buffer sections in the destination video area. This bit selects one of the two buffering blocks to which this StretchBLT command delivers the destination image. The two buffering memory blocks are called A and B. 0 Destination image goes to ‘A’ buffer. 1 Destination image goes to ‘B’ buffer. 0 = DST_A 1 = DST_B
25	0x0	SBSEL: StretchBLT Source Buffer Selection (SBSEL) StretchBLT processing involves frame-rate conversion from a series of source images to another series of destination images (field-rate of the source video to frame-rate of the PC display). In order to avoid image tearing, it is preferred to use two buffer sections in the source video area. This bit selects one of the two buffering blocks from which this StretchBLT command receives the source image. The two buffering memory blocks are called source-A and source-B. 0 Source image comes from ‘source-A’ buffer. 1 Source image comes from ‘source-B’ buffer. 0 = SRC_A 1 = SRC_B
24	0x0	SITYPE: StretchBLT Source Type (SITYPE) This bit identifies two types of source images. If source image is 2-to-1 interlaced and StretchBLT processes either one of the two interlaced field-images, physical (positional) displacement between the two interlaced fields must be taken into account. One field-image that is placed higher in position than the other field-image is called top-field and the other is called bottom-field. StretchBLT processing has to lower the top-field (or raise the bottom-field) to match the corresponding two target images in the overlay window (that is progressively scanned) right at the same position. If source image is full frame-image obtained from two interlaced field-images, its type is ‘top-field’. If source images are progressively scanned, the type identification is not significant and they may be designated either one of the two types 0 Source image is ‘top-field’. 1 Source image is ‘bottom-field’. 0 = TOP_FIELD 1 = BOTTOM_FIELD
23	0x0	RANGEREDFRM:In the VC-1 specification, when the value of RANGEREDFRM variable (1-bit) for a picture is equal to 1, the picture shall be scaled up according to the following equation:Y = clip(((Y-128)*2) + 128);Cb = clip(((Cb-128)*2) + 128);Cr = clip(((Cr-128)*2) + 128);The clip operator limits the output to [0, 255].The input is also limited to [0, 255].

Bit	Reset	Description
		In the VC-1 nomenclature, the output (Y, Cb, Cr) tuple corresponds to the 'decoded' picture. The input (Y, Cb, Cr) tuple corresponds to the 'reconstructed' picture. The above equations create the decoded picture while keeping the reconstructed picture intact.Only YUV _OB formats are supported with range reducation enabled, not the YUV _TC or RGB formats The YUV data coming from the video frame buffers (reconstructed picture) in the SDRAM was scaled up using the above equations and given to the display. the value of 1-bit wide RANGEREDFRM variable was configured in the DVO per frame and the frame was scaled whenever RANGEREDFRM == 1. 0 = DISABLE 1 = ENABLE
22:20	0x0	HFTYPE: StretchBLT Horizontal Filter Mode (HFTYPE[2:0]) The six-tap horizontal interpolation filter can be operated in various operation modes. For the image expansion, it should be programmed as a pure 6-tap interpolator. For the image contraction, it can work as partly lowpass filter and partly interpolater with varying degree depending the contraction ratio. For StretchBLT, this parameter is used as an index (selection) to an internal lookup table that stores the group of filter-coefficients for the different modes of horizontal filtering. 000: Pure interpolation filter. 001 010 011 100 101 110: mix of interpolation and low pass filters 111: DISABLE. 0 = INTERP 1 = LPF1 2 = LPF2 3 = LPF3 4 = LPF4 5 = LPF5 6 = LPF6 7 = DISABLE

11.7.26 G2SB_CTX5_G2CONTROLMAIN_0

G2 Blit Formats:

(1) G2 Blit size is based on height in lines, width in pixels, stride in bytes, and pixel size (color depth). Unless alpha blending is enabled, G2 doesn't care about pixel components.

Source color depths supported by G2 Blit:

- color depth same as destination: G2CONTROLMAIN.SRCCD = 1
- monochrome: G2CONTROLMAIN.SRCCD = 0

(source monochrome color determined by G2SRCBGC, G2SRCFGC)

Pattern color depths supported by G2 Blit:

- color depth same as destination: G2PATOS.PATCD = 1
- monochrome: G2PATOS.PATCD = 0

(pattern monochrome color determined by G2PATBGC, G2PATFGC)

Destination color depths supported by G2 Blit:

- 1 byte per pixel: G2CONTROLMAIN.DSTCD = BPP8
- 2 bytes per pixel: G2CONTROLMAIN.DSTCD = BPP16
- 4 bytes per pixel: G2CONTROLMAIN.DSTCD = BPP32

(2) Alpha blending operates on 3 or 4 component pixels of a specified color depth. One of the components may be alpha (A), depending on the alpha blend format, which is only allowed in certain component positions defined below. The only format rule of the remaining components is that they must be in the same source and destination position because the alpha blend engine does not support component swapping. For example, valid 32BPP formats are: RGBA_8888->RGBA_8888, BGRA_8888->BGRA_8888, GRBA_8888->GRBA_8888, etc.

Source formats supported by G2 alpha blend:

- color depth BPP8: no supported formats
- color depth BPP16:
  - ALPTYPE_PLS1BPP: xxxA_5551 (ex: BGRA_5551 = A[15] R[14:10] G[9:5] B[4:0])
  - ALPTYPE_PLS4BPP: xxxA_4444 (ex: BGRA_4444 = A[15:12] R[11:8] G[7:4] B[3:0])

- (other) : xxx_565 (ex: BGR_565 = R[15:11] G[10:5] B[4:0])
- color depth BPP32:
  - (all) : xxxA_8888 (ex: BRGA_8888 = A[31:24] R[23:16] G[15:8] B[7:0])

Destination formats supported by G2 alpha blend:

- color depth BPP8: no supported formats
- color depth BPP16: xxx_565 (ex: BGR_565 = R[15:11] G[10:5] B[4:0])
- color depth BPP32: xxxA_8888 (ex: BRGA_8888 = A[31:24] R[23:16] G[15:8] B[7:0])

src cd	src format	dst cd	dst format	examples
BPP8	no support	BPP8	no support	
BPP16	xyzA_5551, xyzA_4444, xyz_565	BPP16	xyz_565	BGRA_5551->BGR_565, RGB_565->RGB565
BPP32	xyzA_8888	BPP32	xyzA_8888	RGBA_8888->RGBA_8888, BGRA_8888->BGRA_8888

VCAA Resolve engine

(1) Format support

srcColor format	srcCoverage format	legal dest format(s)
A1B5G5R5	VCAA	A1B5G5R5
R8G8B8A8	VCAA	R8G8B8A8, B5G6R5
B5G6R5	VCAA	B5G6R5

To program resolve type:

- ALPTYPE == FIX: B5G6R5 -> B5G6R5
- ALPTYPE == PLS1BPPAL: A1B5G5R5 -> A1B5G5R5
- ALPTYPE == PLS8BPP: R8G8B8A8 -> R8G8B8A8
- ALPTYPE == PLS8BX: R8G8B8A8 -> B5G6R5

(2) Color surface programming

- color surface base address: SRCBA
- sub-surface start x: SRCX (pixel index)
- sub-surface start y: SRCY (line index)
- color surface stride: SRCS (bytes)

The engine supports sub-surface resolve. One can imagine a full color buffer of 1024x768, but

```
[pseudo_code]
      color_surface_start_address_fetch = pcurctx->regs.rG2SRCBA.uSRCBA() +
       (pcurctx->regs.rG2SRCPS.uSRCX() * VCAAState.color_surface_depth) +
       (pcurctx->regs.rG2SRCPS.uSRCY() * VCAAState.color_surface_stride);
```

(3) VCAA surface programming

- VCAA surface base address: PATBA
- VCAA surface stride: PATST (bytes)

```
[pseudo_code]
      vcaa_surface_start_address_fetch = pcurctx->regs.rG2PATBA.uPATBA();
```

SW *MUST* directly program this register to the proper sub-surface location in the vcaa surface which corresponds to the SRCX and SRCY programming. The calculation is PATBA = vcaa_base_address + SRCX * (1) + SRCY * PATST;

(4) Resolve surface programming

- resolve window width: DSTWIDTH (pixels)
- resolve window height: DSTHEIGHT (lines)
- resolve output stride: DSTS (bytes)

These values program the width and height of the resolved surface. In the base case,

- DSTWIDTH = color surface width
- DSTHEIGHT = color sufrace height
- DSTS = resolve surface format bpp * DSTWIDTH

The VCAA engine technically supports DSTX and DSTY (like SRCX and SRCY).

```
[pseudo_code]
   resolve_surface_start_address_put = pcurctx->regs.rG2DSTBA.uDSTBA() +
     (pcurctx->regs.rG2DSTPS.uDSTX() * resolve_surface_color_depth) +
     (pcurctx->regs.rG2DSTPS.uDSTY() * resolve_surface_color_stride);
```

(5) Resolving a pixel

The coverage surface is an 8 bit per pixel surface (C4X4). The surface is initialized to all 1s by 3d.

For a given pixel, we need to look up 4 bits of coverage data. If the data is 0xf, the pixel does not need to be resolved. Otherwise, we need to reblend the pixel with certain weightings of its neighbors (i.e. we're on the edge of some geometry).

If any coverage bit is 0, we need to resolve the color. To do so, we calculate the following equation:

```
color_new = (
              20*color_old +
              27*(
                  ((cover_down  == 0) ? color_down  : color_old) +
                  ((cover_right == 0) ? color_right : color_old) +
                  ((cover_left  == 0) ? color_left  : color_old) +
                  ((cover_up    == 0) ? color_up    : color_old)
                  )
            ) / 128;
```

If coverage bit == 0, then we use the neighbor color value in the resolve

If coverage bit == 1, then we use the center color value in the resolve

The resolve is done on a per channel (r/g/b/a) basis:

format convert input channel to 8-bit

perform resolve equation above

format convert to output format

For the resolution of the alpha channel:

- In B5G6R5: no alpha information. do nothing.
- In A1B5G5R5: no resolve. keep the source color alpha bit.
- In R8G8B8A8: normal 8-bit channel resolve

(6) Resolving a pixel on the edge

When on an edge, the vcaa engine treats the coverage bit as a 1. Use the center color value. This holds true even on the edge of the sub-surface resolve window when located in the middle of the larger surface

(7) Maximum dimensions

The maximum resolve sub-surface is 4096 pixels wide.

(8) Surface restrictions

The VCAA engine has the following restrictions with respect to input surfaces

- input base address is 128-bit memory word aligned
- input stride is multiple of 128-bits (16 bytes)

The VCAA engine has the following restrictions with respect to output surfaces

- output base address is 128-bit memory word aligned
- output stride is multiple of 128-bits (16 bytes)

(9) Coverage surface layout

The surface is C4X4.

Surface layout (C4X4)

```
(lsb2msb)  C0_C1_C2_C3_X_X_X_X     (X is a don't care.  Qrast inits to 1)
(msb2lsb)  X_X_X_X_C3_C2_C1_C0

    +          o          o
         C0
            C1   Cov(0,1)
       C2
         C3
    o          o          o

      Cov(1,0)   Cov(1,1)

    o          o          o

    +/o = pixel centers
```

In the example above,

```
       Cov(0,0) = X_X_X_X_C3_C2_C1_C0
       C3       = V_C3(Cov(0,0));
       ..         ..
       C0       = V_C0(Cov(0,0));
    #define V_C3(bits) (bits & 0x8)
    #define V_C2(bits) (bits & 0x4)
```

```
#define V_C1(bits) (bits & 0x2)
#define V_C0(bits) (bits & 0x1)
```

Resolving a pixel

In an ideal world, the coverage would be simply laid out such that when resolving Pixel(x,y), we would need only to fetch Cov(x,y) to get all 4 bits of information.

In actuality, the coverage surface was rearranged to help qrast in performance. To resolve Pixel(x,y) gr2d has to fetch 4 C4X4 bytes [Cov(x,y), Cov(x-1,y), Cov(x,y-1), Cov(x-1,y-1)]. From each C4X4 byte, it extracts one bit which is used in the resolve equations shown in (5).

Need the logical vcaa bits (DRLU) for blend which is spread across four C4X4 coverage bytes

```
      U
  L
    o
       R
   D
```

where

- o = Pixel(x,y)
- D = V_C1(Cov(x-1,y))
- R = V_C0(Cov(x,y))
- L = V_C3(Cov(x-1,y-1))
- U = V_C2(Cov(x,y-1))

SB only

Offset: 0x2032 | Byte Offset: 0x80c8 | Read/Write: R/W | Reset: 0x00000000 (0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx)

Bit	Reset	Description
31:0	X	SRCBA_B: This parameter specifies the start address of source image stored in the image buffer memory. In 4:2:0 format mode, this image block accommodates for Y-image.This address specifies byte-position, however, bits [2:0] are restricted with respect to the data formats to fit multiple pixels in one memory word (8 bytes),. For example, {0, 4} for any YcrCb formats, {0, 2, 4, 6} for RGB 16-bit format. Since one Y pixel takes 8-bit, all 8 byte-positions are valid in 4:2:0 mode. (Unlike multiplexed pixels format, there is no restrictions on this value.)

11.7.67 G2SB_CTX5_G2SRCBA_SB_SURFBASE_0

SB_SURFBASE Registers

These registers need only be programmed when using SB. They point to the base of the various source and destination surfaces. Technically they are only needed when tiling is enabled, but there is no harm in always programming them.

Their counterpart registers (_SB_SURFBASE with SB_SURFBASE stripped off) indicate the location of the first pixel to be sourced or written within the surface.

This register exists to mimic the X, Y (SRCX, SRCY) functionality found in the BitBlt engine.

For example, to get at pixel X, Y:

SRCBA = SRCBA_SB_SURFBASE + Y*stride + X*Bpp

Offset: 0x2048 │ Byte Offset: 0x8120 │ Read/Write: R/W │ Reset: 0x00000000 (0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx)

Bit	Reset	Description
31:0	X	COND_STATUS: COND_STATUS[COND] is set if the FIFO for COND overflows. This bit is sticky and will remain set until cleared. Cleared by writing 1.

11.8.4 G2SB_CTX6_G2CLASSCHANNEL_REGONLY_0

This register can be accessed by both register read/write and command fifo in order not to break exsting code, keep suffix REGONLY.

2D syncpt behavior

- Each 2D context has its own syncpt client.
- OP_DONE increments when 2D's memory write client is idle, meaning all preceding operations are complete.
- RD_DONE behaves like OP_DONE
- REG_WR_SAFE behaves like IMMEDIATE meaning a syncpt increment returns immediately and does not indicate that a register write will NOT block. The implications are that 2D's host FIFO can fill and block access to 2D, which will indeterminately block a direct CPU access.

Bit	Reset	Description
31:0	X	VDSTEP: Vertical Scaling DDA Reset value: xxxx-xxxxh Vertical DDA Step (Increment) Value (VDSTEP[18:0]) (upper 13 bits should be set to '0') This parameter specifies the increment value of the DDA used for vertical scaling and it is in the form of 6-bit integer and 12-bit fraction. This value is determined by the equation: (Actual_source_height-1-VDTINI) / (Actual_destination_height-1) Truncate the remaining bits to keep the 12-bit fraction. Since we have to meet (Actual_source_height-1)*1.0 >= (Actual_destination_height - 1)*VDSTEP + VDTINI. The 6-bit integer allows maximum contraction ratio of 1/64, and 12-bit fraction ensures the maximum limit of accumulated error less than half line-spacing for up to approximately 2000 target lines. For example, image expansion from 240 lines to 400 lines VDSTEP[17:0] = 19'b00_0000_1001_1001_1010 and image contraction from 240 lines to 150 lines VDSTEP[17:0] = 19'b00_0001_1001_1001_1010.

11.8.13 G2SB_CTX6_G2VDDAINI_0

Offset: 0x6012 | Byte Offset: 0x18048 | Read/Write: R/W | Reset: 0x00000000 (0bxxxxxxxxxxxxxxxx)

Bit	Reset	Description
15:8	X	VDBINI:Vertical DDA Initial Value for Bottom-Field (VDBINI[7:0]) (see description above)
7:0	X	VDTINI:Vertical Scaling DDA Initial ValuesVertical DDA Initial Value for Top-Field (VDTINI[7:0]) This parameter specifies the fraction part of initial value of the DDA used for vertical scaling. Given a pair of consecutive source image lines representing positions 0.0 and 1.0, a destination line-image will be created at any position in [0.0, 1.0), that is specified by the fraction part of the vertical DDA. The 8-bit initial fraction value specifies the position of the first output (destination) line-image located between the first and the second input (source) line-images, respectively at position 0.0 and 1.0. This parameter provides a way to compensate relative displacement of top and bottom fields of a source image. Suppose, 2-to-1 interlaced original video field images #1 and #2 are in the image buffer, to be displayed in an overlay window. Assume that the #1 field image is the top-field. Using VDTINI = 8'hC0 for the top-field image and VDBINI = 8'h40 for the bottom-field image, for example, the two images from #1 and #2 fields get mapped to identically positioned destination images in the overlay window.

11.8.14 G2SB_CTX6_G2HDDA_0

Offset: 0x6013 | Byte Offset: 0x1804c | Read/Write: R/W | Reset: 0x00000000 (0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx)

Bit	Reset	Description
31:0	X	HDSTEP: Horizontal Scaling DDA Reset value: xxxx-xxxxh Horizontal DDA Step (Increment) Value (HDSTEP[18:0]) (upper 13 bits should be set to '0') This parameter specifies the increment value of the DDA used for horizontal scaling and it is in the form of 6-bit integer and 12-bit fraction. This value is determined by the equation: (Actual_source_width-1-HDINI) / (Actual_destination_width-1) Truncate the remaining bits to keep the 12-bit fraction. The 6-bit integer allows maximum contraction ratio of 1/64, and 12-bit fraction ensures the maximum limit of accumulated error less than half pixel-spacing for up to approximately 2000 destination pixels. For example, image expansion from 720 pixels to 800 pixels HDSTEP[17:0] = 19'b000_0000_1110_0110_0111 and image contraction from 720 pixels to 250 pixels HDSTEP[17:0] = 19'b000_0010_1110_0001_0101.

11.8.15 G2SB_CTX6_G2HDDAINILS_0

Offset: 0x6014 | Byte Offset: 0x18050 | Read/Write: R/W | Reset: 0x00000000 (0bxxxxxxxx)

Bit	Reset	Description
7:0	X	HDINI: Horizontal Scaling DDA Initial ValueHorizontal DDA Initial Value (HDINI[7:0]) This parameter specifies the fraction part of initial value of the DDA used for horizontal scaling.Given a group of six consecutive source pixels that the two pixels at the center representing positions 0.0 and 1.0, a destination pixel will be created at any position in [0.0, 1.0), that is specified by the fraction part of the horizontal DDA. The 8-bit initial fraction value specifies the position of the first output (destination) pixel located between the first and the second input (source) pixels, respectively at position 0.0 and 1.0.For horizontal scaling this value may normally be set to 0.

11.8.16 G2SB_CTX6_G2CSCFIRST_0

The next 3 registers contain 8 parameters used by the YCbCr (YUV) to RGB color space conversion logic. This logic can also be used for RGB gain/gamma correction in RGB to RGB modes, and for luma gain in YUV to YUV modes.

Two new parameters (G2U, G2V) have been added for RGB to YUV conversion. These are in address 0x38. The equations have the form:

if (yuv2rgb)

(r,g,b) = matrix*(y+sbreg_yos,u,v)

matrix: sbreg_cyx, sbreg_cur, sbreg_cvr,
sbreg_cyx, sbreg_cug, sbreg_cvg,
sbreg_cyx, sbreg_cub, sbreg_cvb,

else if (rgb2rgb)

(r,g,b) = matrix*(r,g+sbreg_yos,b)
matrix: sbreg_cvr, 0, sbreg_cur,
sbreg_cvg, sbreg_cyx, sbreg_cug,
sbreg_cvb, 0, sbreg_cub,

else if (yuv2yuv)

(y,u,v) = matrix*(y,u,v)

matrix: sbreg_cub, 0, sbreg_cvb,
sbreg_cug, sbreg_cyx, sbreg_cvg,
sbreg_cur, 0, sbreg_cvr,

else if (rgb2yuv)

(y,u,v) = matrix*(r,g,b) + (sbreg_yos,0,0)

matrix: sbreg_cvb, sbreg_cyx, sbreg_cub,
sbreg_cvg, sbreg_g2u, sbreg_cug,
sbreg_cvr, sbreg_g2v, sbreg_cur,

Bit	Reset	Description
25:16	X	CVB: multiplier for V/R for Y or B generation. This parameter consists of a sign bit and 9-bit magnitude (s2.7). For YUV->RGB, normally this parameter is programmed to 0.0. This coefficient takes non-zero value if hue is rotated. For YUV->YUV & RGB->RGB, this parameter should be set to 0 For RGB->YUV the recommended value is +0.257 (decimal) or 0x021

Bit	Reset	Description
8:0	X	CVG: multiplier for V/R for U or G generation.This parameter consists of a sign bit and 8-bit magnitude (s1.7) For YUV->RGB the recommended value is -0.8130 (decimal) or 0x168. For YUV->YUV & RGB->RGB, this parameter should be set to 0 For RGB->YUV the recommended value is -0.148 (decimal) or 0x113

11.8.19 G2SB_CTX6_G2CMKEYL_0

When key generation is enabled, the value of this register is the lower color/chroma limit and G2CMKEYU is the upper color/chroma limit for component pixel data. Three component signal values (YCrCb/YUV or RGB) of every output pixel are compared to a set of three ranges that are specified by three pairs of lower and upper color/chroma key values.

If the Key Polarity is 0, the Key is set to 1 only when all three component values of an input pixel are respectively within the set of ranges (inclusive of the limit values), else the Key is set to 0.

If the Key Polarity is 1, the Key is set to 1 when any of the three component values of an input pixel are outside the set of ranges, else the Key is set to 0.

StretchBLT, Color/Chroma Key Lower Limit Register

11.8.24 G2SB_CTX6_G2CONTROLSB_0

Offset: 0x601d │ Byte Offset: 0x18074 │ Read/Write: R/W │ Reset: 0x00000000 (0b00x00000000000000x0xx0xx00000)

Bit	Reset	Description
31	0x0	DISDW: Output destination writes go either to image memory or the EPP. 0: Output data is sent to memory 1: YUV or RGB data is passed directly to the EPP module, and no destination writes take place. 0 = GOTO_IMAGE_BUFFER 1 = GOTO_EPP
30	0x0	ENDITH: Enable Dithering (ENDITH) For 16 bit RGB output modes, the LSB of the color components can be modified by adding a variable residual value that will reduce the banding artifacts that can appear on the display. 0 Normal operation 1 Enable Dithering 0 = DISABLE 1 = ENABLE
28	0x0	KPOL: Key Signal Polarity (KPOL) Color/Chroma key signal is generated by comparing source input pixel color to a range of a color specified by lower and upper limit values. The key signal is interpreted in two ways, depending on which one of video and graphics images is foreground (and the other is background). This is effective only if Key signal generator is enabled. (see G2CMKEYL, G2CMKEYU) 0 Key signal is set to 1 when source pixel is within the lower and upper limit color range. 1 Key signal is set to 1 when source pixel is outside the lower and upper limit color range. 0 = WITHIN_BOUNDS 1 = OUTSIDE_BOUNDS
27	0x0	KEYEN: Key Signal Generator Enable (KEYEN) Key signal generator generates either chroma key signal (from YCbCr signal) or color key signal (from RGB signal) 0 Key signal generator is disabled. 1 Key signal generator is enabled. 0 = DISABLE

Bit	Reset	Description
		1 = ENABLE
26	0x0	DBSEL: StretchBLT Destination Buffer Selection (DBSEL) StretchBLT processing involves frame-rate conversion from a series of source images to another series of destination images (field-rate of the source video to frame-rate of the PC display). In order to avoid image tearing, it is preferred to use two buffer sections in the destination video area. This bit selects one of the two buffering blocks to which this StretchBLT command delivers the destination image. The two buffering memory blocks are called A and B. 0 Destination image goes to 'A' buffer. 1 Destination image goes to 'B' buffer. 0 = DST_A 1 = DST_B
25	0x0	SBSEL: StretchBLT Source Buffer Selection (SBSEL) StretchBLT processing involves frame-rate conversion from a series of source images to another series of destination images (field-rate of the source video to frame-rate of the PC display). In order to avoid image tearing, it is preferred to use two buffer sections in the source video area. This bit selects one of the two buffering blocks from which this StretchBLT command receives the source image. The two buffering memory blocks are called source-A and source-B. 0 Source image comes from 'source-A' buffer. 1 Source image comes from 'source-B' buffer. 0 = SRC_A 1 = SRC_B
24	0x0	SITYPE: StretchBLT Source Type (SITYPE) This bit identifies two types of source images. If source image is 2-to-1 interlaced and StretchBLT processes either one of the two interlaced field-images, physical (positional) displacement between the two interlaced fields must be taken into account. One field-image that is placed higher in position than the other field-image is called top-field and the other is called bottom-field. StretchBLT processing has to lower the top-field (or raise the bottom-field) to match the corresponding two target images in the overlay window (that is progressively scanned) right at the same position. If source image is full frame-image obtained from two interlaced field-images, its type is 'top-field'. If source images are progressively scanned, the type identification is not significant and they may be designated either one of the two types 0 Source image is 'top-field'. 1 Source image is 'bottom-field'. 0 = TOP_FIELD 1 = BOTTOM_FIELD
23	0x0	RANGEREDFRM:In the VC-1 specification, when the value of RANGEREDFRM variable (1-bit) for a picture is equal to 1, the picture shall be scaled up according to the following equation:Y = clip(((Y-128)*2) + 128);Cb = clip(((Cb-128)*2) + 128);Cr = clip(((Cr-128)*2) + 128);The clip operator limits the output to [0, 255].The input is also limited to [0, 255]. In the VC-1 nomenclature, the output (Y, Cb, Cr) tuple corresponds to the 'decoded' picture. The input (Y, Cb, Cr) tuple corresponds to the 'reconstructed' picture. The above equations create the decoded picture while keeping the reconstructed picture intact.Only YUV _OB formats are supported with range reducation enabled, not the YUV _TC or RGB formats. The YUV data coming from the video frame buffers (reconstructed picture) in the SDRAM was scaled up using the above equations and given to the display. The value of 1-bit wide RANGEREDFRM variable was configured in the DVO per frame and the frame was scaled whenever RANGEREDFRM == 1. 0 = DISABLE 1 = ENABLE
22:20	0x0	HFTYPE: StretchBLT Horizontal Filter Mode (HFTYPE[2:0]) The six-tap horizontal interpolation filter can be operated in various operation modes. For the image expansion, it should be programmed as a pure 6-tap interpolator. For the image contraction, it can work as partly lowpass filter and partly interpolater with varying degree depending on the contraction ratio. For StretchBLT, this parameter is used as an index (selection) to an internal lookup table that stores the group of filter-coefficients for the different modes of horizontal filtering. 000: Pure interpolation filter. 001 010 011 100 101 110: mix of interpolation and low pass filters 111: DISABLE. 0 = INTERP 1 = LPF1

11.8.26 G2SB_CTX6_G2CONTROLMAIN_0

G2 Blit Formats:

(1) G2 Blit size is based on height in lines, width in pixels, stride in bytes, and pixel size (color depth). Unless alpha blending is enabled, G2 doesn't care about pixel components.

Source color depths supported by G2 Blit:

- color depth same as destination: G2CONTROLMAIN.SRCCD = 1
- monochrome: G2CONTROLMAIN.SRCCD = 0

(source monochrome color determined by G2SRCBGC, G2SRCFGC)

Pattern color depths supported by G2 Blit:

- color depth same as destination: G2PATOS.PATCD = 1
- monochrome: G2PATOS.PATCD = 0

(pattern monochrome color determined by G2PATBGC, G2PATFGC)

Destination color depths supported by G2 Blit:

- 1 byte per pixel: G2CONTROLMAIN.DSTCD = BPP8
- 2 bytes per pixel: G2CONTROLMAIN.DSTCD = BPP16
- 4 bytes per pixel: G2CONTROLMAIN.DSTCD = BPP32

(2) Alpha blending operates on 3 or 4 component pixels of a specified color depth. One of the components may be alpha (A), depending on the alpha blend format, which is only allowed in certain component positions defined below. The only format rule of the remaining components is that they must be in the same source and destination position because the alpha blend engine does not support component swapping. For example, valid 32BPP formats are: RGBA_8888->RGBA_8888, BGRA_8888->BGRA_8888, GRBA_8888->GRBA_8888, etc.

Source formats supported by G2 alpha blend:

- color depth BPP8: no supported formats
- color depth BPP16:
  - ALPTYPE_PLS1BPP: xxxA_5551 (ex: BGRA_5551 = A[15] R[14:10] G[9:5] B[4:0])
  - ALPTYPE_PLS4BPP: xxxA_4444 (ex: BGRA_4444 = A[15:12] R[11:8] G[7:4] B[3:0])
  - (other) : xxx_565 (ex: BGR_565 = R[15:11] G[10:5] B[4:0])
- color depth BPP32:
  - (all) : xxxA_8888 (ex: BRGA_8888 = A[31:24] R[23:16] G[15:8] B[7:0])

Destination formats supported by G2 alpha blend:

- color depth BPP8: no supported formats
- color depth BPP16: xxx_565 (ex: BGR_565 = R[15:11] G[10:5] B[4:0])
- color depth BPP32: xxxA_8888 (ex: BRGA_8888 = A[31:24] R[23:16] G[15:8] B[7:0])

VCAA Resolve engine

(1) Format support

srcColor format	srcCoverage format	legal dest format(s)
A1B5G5R5	VCAA	A1B5G5R5
R8G8B8A8	VCAA	R8G8B8A8, B5G6R5
B5G6R5	VCAA	B5G6R5

To program resolve type:

- ALPTYPE == FIX: B5G6R5 -> B5G6R5
- ALPTYPE == PLS1BPPAL: A1B5G5R5 -> A1B5G5R5
- ALPTYPE == PLS8BPP: R8G8B8A8 -> R8G8B8A8
- ALPTYPE == PLS8BX: R8G8B8A8 -> B5G6R5

(2) Color surface programming

- color surface base address: SRCBA
- sub-surface start x: SRCX (pixel index)
- sub-surface start y: SRCY (line index)
- color surface stride: SRCS (bytes)

The engine supports sub-surface resolve. One can imagine a full color buffer of 1024x768, but

```
[pseudo_code]
      color_surface_start_address_fetch = pcurctx->regs.rG2SRCBA.uSRCBA() +
       (pcurctx->regs.rG2SRCPS.uSRCX() * VCAAState.color_surface_depth) +
       (pcurctx->regs.rG2SRCPS.uSRCY() * VCAAState.color_surface_stride);
```

(3) VCAA surface programming

- VCAA surface base address: PATBA
- VCAA surface stride: PATST (bytes)

```
[pseudo_code]
      vcaa_surface_start_address_fetch = pcurctx->regs.rG2PATBA.uPATBA();
```

SW *MUST* directly program this register to the proper sub-surface location in the vcaa surface which corresponds to the SRCX and SRCY programming. The calculation is PATBA = vcaa_base_address + SRCX * (1) + SRCY * PATST;

(4) Resolve surface programming

- resolve window width: DSTWIDTH (pixels)
- resolve window height: DSTHEIGHT (lines)
- resolve output stride: DSTS (bytes)

These values program the width and height of the resolved surface. In the base case:

- DSTWIDTH = color surface width
- DSTHEIGHT = color sufrace height
- DSTS = resolve surface format bpp * DSTWIDTH

The VCAA engine technically supports DSTX and DSTY (like SRCX and SRCY).

```
 [pseudo_code]
    resolve_surface_start_address_put = pcurctx->regs.rG2DSTBA.uDSTBA() +
      (pcurctx->regs.rG2DSTPS.uDSTX() * resolve_surface_color_depth) +
      (pcurctx->regs.rG2DSTPS.uDSTY() * resolve_surface_color_stride);
```

(5) Resolving a pixel

The coverage surface is a 8 bits per pixel surface (C4X4). The surface is initialized to all 1s by 3d.

For a given pixel, we need to look up 4 bits of coverage data. If the data is 0xf, the pixel does not need to be resolved. Otherwise, we need to reblend the pixel with certain weightings of its neighbors (i.e. we're on the edge of some geometry).

If any coverage bit is 0, we need to resolve the color. To do so, we calculate the following equation:

```
color_new = (
              20*color_old +
              27*(
                  ((cover_down  == 0) ? color_down  : color_old) +
                  ((cover_right == 0) ? color_right : color_old) +
                  ((cover_left  == 0) ? color_left  : color_old) +
                  ((cover_up    == 0) ? color_up    : color_old)
                  )
            ) / 128;
```

If coverage bit == 0, then we use the neighbor color value in the resolve

If coverage bit == 1, then we use the center color value in the resolve

The resolve is done on a per channel (r/g/b/a) basis:

format convert input channel to 8-bit

perform resolve equation above

format convert to output format

For the resolution of the alpha channel:

- In B5G6R5: no alpha information. do nothing.
- In A1B5G5R5: no resolve. keep the source color alpha bit.
- In R8G8B8A8: normal 8-bit channel resolve

(6) Resolving a pixel on the edge

When on an edge, the vcaa engine treats the coverage bit as a 1. Use the center color value. This holds true even on the edge of the sub-surface resolve window when located in the middle of the larger surface

(7) Maximum dimensions

The maximum resolve sub-surface is 4096 pixels wide.

(8) Surface restrictions

The VCAA engine has the following restrictions with respect to input surfaces:

- input base address is 128-bit memory word aligned
- input stride is multiple of 128-bits (16 bytes)

The VCAA engine has the following restrictions with respect to output surfaces:

- output base address is 128-bit memory word aligned
- output stride is multiple of 128-bits (16 bytes)

(9) Coverage surface layout

The surface is C4X4.

Surface layout (C4X4)

```
(lsb2msb)  C0_C1_C2_C3_X_X_X_X     (X is a don't care.  Qrast inits to 1)
(msb2lsb)  X_X_X_X_C3_C2_C1_C0

    +          o          o
         C0
            C1   Cov(0,1)
       C2
         C3
    o          o          o

      Cov(1,0)   Cov(1,1)

    o          o          o
    +/o = pixel centers
```

In the example above,

```
    Cov(0,0) = X_X_X_X_C3_C2_C1_C0
    C3       = V_C3(Cov(0,0));
    ..         ..
    C0       = V_C0(Cov(0,0));

#define V_C3(bits) (bits & 0x8)
#define V_C2(bits) (bits & 0x4)
#define V_C1(bits) (bits & 0x2)
#define V_C0(bits) (bits & 0x1)
```

Resolving a pixel

In an ideal world, the coverage would be simply laid out such that when resolving Pixel(x,y), we would need only to fetch Cov(x,y) to get all 4 bits of information.

In actuality, the coverage surface was rearranged to help qrast in performance. To resolve Pixel(x,y) gr2d has to fetch 4 C4X4 bytes [Cov(x,y), Cov(x-1,y), Cov(x,y-1), Cov(x-1,y-1)]. From each C4X4 byte, it extracts one bit which is used in the resolve equations shown in (5).

Need the logical VCAA bits (DRLU) for blend which is spread across four C4X4 coverage bytes

```
        U
  L
      o
          R
    D
```

Where:

- o = Pixel(x,y)
- D = V_C1(Cov(x-1,y))

11.8.67 G2SB_CTX6_G2SRCBA_SB_SURFBASE_0

SB_SURFBASE registers

These registers need only be programmed when using SB. They point to the base of the various source and destination surfaces. Technically they are only needed when tiling is enabled, but there is no harm in always programming them.

Their counterpart registers (_SB_SURFBASE with SB_SURFBASE stripped off) indicate the location of the first pixel to be sourced or written within the surface.

This register exists to mimic the X, Y (SRCX, SRCY) functionality found in the BitBlt engine.

For example, to get at pixel X, Y:

SRCBA = SRCBA_SB_SURFBASE + Y*stride + X*Bpp

Offset: 0x6048 | Byte Offset: 0x18120 | Read/Write: R/W | Reset: 0x00000000 (0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx)

Bit	Reset	Description
8	0x0	INCR_SYNCPT_NO_STALL: If NO_STALL is 1, then when fifos are full, INCR_SYNCPT methods will be dropped and the INCR_SYNCPT_ERROR[COND] bit will be set. If NO_STALL is 0, then when fifos are full, the client host interface will be stalled.
0	0x0	INCR_SYNCPT_SOFT_RESET: If SOFT_RESET is set, then all internal state of the client syncpt block will be reset. To do soft reset, first set SOFT_RESET of all host1x clients affected, then clear all SOFT_RESETs.

11.9.3 G2SB_CTX7_INCR_SYNCPT_ERROR_0

Offset: 0xa002 │ Byte Offset: 0x28008 │ Read/Write: R/W │ Reset: 0x00000000 (0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx)

Bit	Reset	Description
31:0	X	COND_STATUS: COND_STATUS[COND] is set if the fifo for COND overflows. This bit is sticky and will remain set until cleared. Cleared by writing 1.

11.9.4 G2SB_CTX7_G2CLASSCHANNEL_REGONLY_0

This register can be accessed by both register read/write and command fifo in order not to break exsting code , keep suffix REGONLY.

2D syncpt behavior

- Each 2D context has its own syncpt client.
- OP_DONE increments when 2D's memory write client is idle, meaning all preceding operations are complete.
- RD_DONE behaves like OP_DONE
- REG_WR_SAFE behaves like IMMEDIATE meaning a syncpt increment returns immediately and does not indicate that a register write will NOT block.
- The implications are that 2D's host FIFO can fill and block access to 2D, which will indeterminately block a direct CPU access.

Bit	Reset	Description
31:0	X	VDSTEP:Vertical Scaling DDAReset value: xxxx-xxxxhVertical DDA Step (Increment) Value (VDSTEP[18:0]) (upper 13 bits should be set to '0') This parameter specifies the increment value of the DDA used for vertical scaling and it is in the form of 6-bit integer and 12-bit fraction. This value is determined by the equation: (Actual_source_height-1-VDTINI) / (Actual_destination_height-1) Truncate the remaining bits to keep the 12-bit fraction. Since we have to meet (Actual_source_height-1)*1.0 >= (Actual_destination_height - 1)*VDSTEP + VDTINI. The 6-bit integer allows maximum contraction ratio of 1/64, and 12-bit fraction ensures the maximum limit of accumulated error less than half line-spacing for up to approximately 2000 target lines. For example, image expansion from 240 lines to 400 lines VDSTEP[17:0] = 19'b00_0000_1001_1001_1010 and image contraction from 240 lines to 150 lines VDSTEP[17:0] = 19'b00_0001_1001_1001_1010.

11.9.13 G2SB_CTX7_G2VDDAINI_0

Offset: 0xa012 | Byte Offset: 0x28048 | Read/Write: R/W | Reset: 0x00000000 (0bxxxxxxxxxxxxxxxx)

Bit	Reset	Description

Bit	Reset	Description
15:8	X	VDBINI: Vertical DDA Initial Value for Bottom-Field (VDBINI[7:0]) (see description above)
7:0	X	VDTINI: Vertical Scaling DDA Initial Values Vertical DDA Initial Value for Top-Field (VDTINI[7:0]) This parameter specifies the fraction part of initial value of the DDA used for vertical scaling. Given a pair of consecutive source image lines representing positions 0.0 and 1.0, a destination line-image will be created at any position in [0.0, 1.0), that is specified by the fraction part of the vertical DDA. The 8-bit initial fraction value specifies the position of the first output (destination) line-image located between the first and the second input (source) line-images, respectively at position 0.0 and 1.0.This parameter provides a way to compensate relative displacement of top and bottom fields of a source image. Suppose, 2-to-1 interlaced original video field images #1 and #2 are in the image buffer, to be displayed in an overlay window. Assume that the #1 field image is the top-field. Using VDTINI = 8'hC0 for the top-field image and VDBINI = 8'h40 for the bottom-field image, for example, the two images from #1 and #2 fields get mapped to identically positioned destination images in the overlay window.

11.9.14 G2SB_CTX7_G2HDDA_0

Offset: 0xa013 | Byte Offset: 0x2804c | Read/Write: R/W | Reset: 0x00000000 (0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx)

Bit	Reset	Description
31:0	X	HDSTEP: Horizontal Scaling DDA Reset value: xxxx-xxxxh Horizontal DDA Step (Increment) Value (HDSTEP[18:0]) (upper 13 bits should be set to '0') This parameter specifies the increment value of the DDA used for horizontal scaling and it is in the form of 6-bit integer and 12-bit fraction. This value is determined by the equation: (Actual_source_width-1-HDINI) / (Actual_destination_width-1) Truncate the remaining bits to keep the 12-bit fraction. The 6-bit integer allows maximum contraction ratio of 1/64, and 12-bit fraction ensures the maximum limit of accumulated error less than half pixel-spacing for up to approximately 2000 destination pixels. For example, image expansion from 720 pixels to 800 pixels HDSTEP[17:0] = 19'b000_0000_1110_0110_0111 and image contraction from 720 pixels to 250 pixels HDSTEP[17:0] = 19'b000_0010_1110_0001_0101.

11.9.15 G2SB_CTX7_G2HDDAINILS_0

Offset: 0xa014 | Byte Offset: 0x28050 | Read/Write: R/W | Reset: 0x00000000 (0bxxxxxxxx)

Bit	Reset	Description
7:0	X	HDINI: Horizontal Scaling DDA Initial ValueHorizontal DDA Initial Value (HDINI[7:0]) This parameter specifies the fraction part of initial value of the DDA used for horizontal scaling.Given a group of six consecutive source pixels that the two pixels at the center representing positions 0.0 and 1.0, a destination pixel will be created at any position in [0.0, 1.0), that is specified by the fraction part of the horizontal DDA. The 8-bit initial fraction value specifies the position of the first output (destination) pixel located between the first and the second input (source) pixels, respectively at position 0.0 and 1.0.For horizontal scaling this value may normally be set to 0.

11.9.16 G2SB_CTX7_G2CSCFIRST_0

The next 3 registers contain 8 parameters used by the YCbCr (YUV) to RGB color space conversion logic. This logic can also be used for RGB gain/gamma correction in RGB to RGB modes, and for luma gain in YUV to YUV modes.

Two new parameters (G2U, G2V) have been added for RGB to YUV conversion. These are in address 0x38. The equations have the form:

if (yuv2rgb)

(r,g,b) = matrix*(y+sbreg_yos,u,v)

matrix:	sbreg_cyx,	sbreg_cur,	sbreg_cvr,
	sbreg_cyx,	sbreg_cug,	sbreg_cvg,
	sbreg_cyx,	sbreg_cub,	sbreg_cvb,

else if (rgb2rgb)

(r,g,b) = matrix*(r,g+sbreg_yos,b)

matrix:	sbreg_cvr,	0,	sbreg_cur,
	sbreg_cvg,	sbreg_cyx,	sbreg_cug,
	sbreg_cvb,	0,	sbreg_cub,

else if (yuv2yuv)

(y,u,v) = matrix*(y,u,v)

matrix:	sbreg_cub,	0,	sbreg_cvb,
	sbreg_cug,	sbreg_cyx,	sbreg_cvg,
	sbreg_cur,	0,	sbreg_cvr,

else if (rgb2yuv)

(y,u,v) = matrix*(r,g,b) + (sbreg_yos,0,0)

matrix:	sbreg_cvb,	sbreg_cyx,	sbreg_cub,
	sbreg_cvg,	sbreg_g2u,	sbreg_cug,
	sbreg_cvr,	sbreg_g2v,	sbreg_cur,

Offset: 0xa015 │ Byte Offset: 0x28054 │ Read/Write: R/W │ Reset: 0x00000000 (0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx)

Bit	Reset	Description
31:24	X	YOS:Y-Offset (YOFFSET[7:0]) for YUV generationThis parameter consists of 8-bit 2's complement in the range [-128,127]. For YUV->RGB the recommended value is -16 (decimal) or 0xF0 For YUV->YUV & RGB->RGB, this parameter should be set to 0. For RGB->YUV the recommended value is +16 (decimal) or 0x10
21:12	X	CVR: multiplier for V/R for V or R generation.This parameter consists of a sign bit and 9-bit magnitude (s2.7) For YUV->RGB the recommended value is 1.5960 (decimal) or 0x0CC. If source data is in RGB format, this parameter may be used as gain adjustment for R component. For RGB->YUV the recommended value is +0.439 (decimal) or 0x038
9:0	X	CUB: multiplier for U/B for Y or B generation. consists of a sign bit and 9-bit magnitude (s2.7). For YUV->RGB, the recommended value is 2.0172 (decimal) or 0x102. If source data is in RGB format, this parameter may be used as gain adjustment for B component. This register changes precision when doing RGB to YUV conversion (SIFMT=1xxx, DIFMT=0xxx). CUB becomes s1.8 and the recommended value is +0.098 or 0x019

11.9.17 G2SB_CTX7_G2CSCSECOND_0

Bit	Reset	Description
25:16	X	CVB: multiplier for V/R for Y or B generation. This parameter consists of a sign bit and 9-bit magnitude (s2.7). For YUV->RGB, normally this parameter is programmed to 0.0. This coefficient takes non-zero value if hue is rotated. For YUV->YUV & RGB->RGB, this parameter should be set to 0 For RGB->YUV the recommended value is +0.257 (decimal) or 0x021
8:0	X	CVG: multiplier for V/R for U or G generation.This parameter consists of a sign bit and 8-bit magnitude (s1.7) For YUV->RGB the recommended value is -0.8130 (decimal) or 0x168. For YUV->YUV & RGB->RGB, this parameter should be set to 0 For RGB->YUV the recommended value is -0.148 (decimal) or 0x113

11.9.19 G2SB_CTX7_G2CMKEYL_0

When key generation is enabled, the value of this register is the lower color/chroma limit and G2CMKEYU is the upper color/chroma limit for component pixel data. Three component signal values (YCrCb/YUV or RGB) of every output pixel are compared to a set of three ranges that are specified by three pairs of lower and upper color/chroma key values.

If the Key Polarity is 0, the Key is set to 1 only when all three component values of an input pixel are respectively within the set of ranges (inclusive of the limit values), else the Key is set to 0.

If the Key Polarity is 1, the Key is set to 1 when any of the three component values of an input pixel are outside the set of ranges, else the Key is set to 0.

Offset: 0xa01d │ Byte Offset: 0x28074 │ Read/Write: R/W │ Reset: 0x00000000 (0b00x00000000000000x0xx0xx00000)

Bit	Reset	Description
31	0x0	DISDW: Output destination writes go either to image memory or the EPP. 0: Output data is sent to memory 1: YUV or RGB data is passed directly to the EPP module, and no destination writes take place. 0 = GOTO_IMAGE_BUFFER 1 = GOTO_EPP
30	0x0	ENDITH: Enable Dithering (ENDITH) For 16-bit RGB output modes, the LSB of the color components can be modified by adding a variable residual value that will reduce the banding artifacts that can appear on the display. 0 Normal operation 1 Enable Dithering 0 = DISABLE 1 = ENABLE
28	0x0	KPOL: Key Signal Polarity (KPOL) Color/Chroma key signal is generated by comparing source input pixel color to a range of a color specified by lower and upper limit values. The key signal is interpreted in two ways, depending on which one of video and graphics images is foreground (and the other is background). This is effective only if Key signal generator is enabled. (see G2CMKEYL, G2CMKEYU)

Bit	Reset	Description
		0 Key signal is set to 1 when source pixel is within the lower and upper limit color range. 1 Key signal is set to 1 when source pixel is outside the lower and upper limit color range. 0 = WITHIN_BOUNDS 1 = OUTSIDE_BOUNDS
27	0x0	KEYEN: Key Signal Generator Enable (KEYEN) Key signal generator generates either chroma key signal (from YCbCr signal) or color key signal (from RGB signal)0 Key signal generator is disabled.1 Key signal generator is enabled. 0 = DISABLE 1 = ENABLE
26	0x0	DBSEL: StretchBLT Destination Buffer Selection (DBSEL) StretchBLT processing involves frame-rate conversion from a series of source images to another series of destination images (field-rate of the source video to frame-rate of the PC display). In order to avoid image tearing, it is preferred to use two buffer sections in the destination video area. This bit selects one of the two buffering blocks to which this StretchBLT command delivers the destination image. The two buffering memory blocks are called A and B. 0 Destination image goes to ‘A’ buffer. 1 Destination image goes to ‘B’ buffer. 0 = DST_A 1 = DST_B
25	0x0	SBSEL: StretchBLT Source Buffer Selection (SBSEL) StretchBLT processing involves frame-rate conversion from a series of source images to another series of destination images (field-rate of the source video to frame-rate of the PC display). In order to avoid image tearing, it is preferred to use two buffer sections in the source video area. This bit selects one of the two buffering blocks from which this StretchBLT command receives the source image. The two buffering memory blocks are called source-A and source-B. 0 Source image comes from ‘source-A’ buffer. 1 Source image comes from ‘source-B’ buffer. 0 = SRC_A 1 = SRC_B
24	0x0	SITYPE: StretchBLT Source Type (SITYPE) This bit identifies two types of source images. If source image is 2-to-1 interlaced and StretchBLT processes either one of the two interlaced field-images, physical (positional) displacement between the two interlaced fields must be taken into account. One field-image that is placed higher in position than the other field-image is called top-field and the other is called bottom-field. StretchBLT processing has to lower the top-field (or raise the bottom-field) to match the corresponding two target images in the overlay window (that is progressively scanned) right at the same position. If source image is full frame-image obtained from two interlaced field-images, its type is ‘top-field’. If source images are progressively scanned, the type identification is not significant and they may be designated either one of the two types 0 Source image is ‘top-field’. 1 Source image is ‘bottom-field’. 0 = TOP_FIELD 1 = BOTTOM_FIELD
23	0x0	RANGEREDFRM:In the VC-1 specification, when the value of RANGEREDFRM variable (1-bit) for a picture is equal to 1, the picture shall be scaled up according to the following equation:Y = clip(((Y-128)*2) + 128);Cb = clip(((Cb-128)*2) + 128);Cr = clip(((Cr-128)*2) + 128);The clip operator limits the output to [0, 255].The input is also limited to [0, 255]. In the VC-1 nomenclature, the output (Y, Cb, Cr) tuple corresponds to the 'decoded' picture. The input (Y, Cb, Cr) tuple corresponds to the 'reconstructed' picture. The above equations create the decoded picture while keeping the reconstructed picture intact.Only YUV _OB formats are supported with range reducation enabled, not the YUV _TC or RGB formats. The YUV data coming from the video frame buffers (reconstructed picture) in the SDRAM was scaled up using the above equations and given to the display. the value of 1-bit wide RANGEREDFRM variable was configured in the DVO per frame and the frame was scaled whenever RANGEREDFRM == 1. 0 = DISABLE 1 = ENABLE
22:20	0x0	HFTYPE: StretchBLT Horizontal Filter Mode (HFTYPE[2:0]) The six-tap horizontal interpolation filter can be operated in various operation modes. For the image expansion, it

Bit	Reset	Description
		should be programmed as a pure 6-tap interpolator. For the image contraction, it can work as partly lowpass filter and partly interpolater with varying degree depending on the contraction ratio. For StretchBLT, this parameter is used as an index (selection) to an internal lookup table that stores the group of filter-coefficients for the different modes of horizontal filtering. 000: Pure interpolation filter. 001 010 011 100 101 110: mix of interpolation and low pass filters 111: DISABLE. 0 = INTERP 1 = LPF1 2 = LPF2 3 = LPF3 4 = LPF4 5 = LPF5 6 = LPF6 7 = DISABLE

11.9.26 G2SB_CTX7_G2CONTROLMAIN_0

G2 Blit Formats:

(1) G2 Blit size is based on height in lines, width in pixels, stride in bytes, and pixel size (color depth). Unless alpha blending is enabled, G2 doesn't care about pixel components.

Source color depths supported by G2 Blit:

- color depth same as destination: G2CONTROLMAIN.SRCCD = 1
- monochrome: G2CONTROLMAIN.SRCCD = 0

(source monochrome color determined by G2SRCBGC, G2SRCFGC)

Pattern color depths supported by G2 Blit:

- color depth same as destination: G2PATOS.PATCD = 1
- monochrome: G2PATOS.PATCD = 0

(pattern monochrome color determined by G2PATBGC, G2PATFGC)

Destination color depths supported by G2 Blit:

- 1 byte per pixel: G2CONTROLMAIN.DSTCD = BPP8
- 2 bytes per pixel: G2CONTROLMAIN.DSTCD = BPP16
- 4 bytes per pixel: G2CONTROLMAIN.DSTCD = BPP32

(2) Alpha blending operates on 3 or 4 component pixels of a specified color depth. One of the components may be alpha (A), depending on the alpha blend format, which is only allowed in certain component positions defined below. The only format rule of the remaining components is that they must be in the same source and destination position because the alpha blend engine does not support component swapping. For example, valid 32BPP formats are: RGBA_8888->RGBA_8888, BGRA_8888->BGRA_8888, GRBA_8888->GRBA_8888, etc.

Source formats supported by G2 alpha blend:

- color depth BPP8: no supported formats
- color depth BPP16:
  - ALPTYPE_PLS1BPP: xxxA_5551 (ex: BGRA_5551 = A[15] R[14:10] G[9:5] B[4:0])
  - ALPTYPE_PLS4BPP: xxxA_4444 (ex: BGRA_4444 = A[15:12] R[11:8] G[7:4] B[3:0])
  - (other) : xxx_565 (ex: BGR_565 = R[15:11] G[10:5] B[4:0])
- color depth BPP32:
  - (all) : xxxA_8888 (ex: BRGA_8888 = A[31:24] R[23:16] G[15:8] B[7:0])

Destination formats supported by G2 alpha blend:

- color depth BPP8: no supported formats
- color depth BPP16: xxx_565 (ex: BGR_565 = R[15:11] G[10:5] B[4:0])
- color depth BPP32: xxxA_8888 (ex: BRGA_8888 = A[31:24] R[23:16] G[15:8] B[7:0])

src cd	src format	dst cd	dst format	examples
BPP8	no support	BPP8	no support	
BPP16	xyzA_5551, xyzA_4444, xyz_565	BPP16	xyz_565	BGRA_5551->BGR_565, RGB_565->RGB565

VCAA Resolve engine

(1) Format support

srcColor format	srcCoverage format	legal dest format(s)
A1B5G5R5	VCAA	A1B5G5R5
R8G8B8A8	VCAA	R8G8B8A8, B5G6R5
B5G6R5	VCAA	B5G6R5

To program resolve type:

- ALPTYPE == FIX: B5G6R5 -> B5G6R5
- ALPTYPE == PLS1BPPAL: A1B5G5R5 -> A1B5G5R5
- ALPTYPE == PLS8BPP: R8G8B8A8 -> R8G8B8A8
- ALPTYPE == PLS8BX: R8G8B8A8 -> B5G6R5

(2) Color surface programming

- color surface base address: SRCBA
- sub-surface start x: SRCX (pixel index)
- sub-surface start y: SRCY (line index)
- color surface stride: SRCS (bytes)

The engine supports sub-surface resolve. One can imagine a full color buffer of 1024x768, but

```
[pseudo_code]
      color_surface_start_address_fetch = pcurctx->regs.rG2SRCBA.uSRCBA() +
       (pcurctx->regs.rG2SRCPS.uSRCX() * VCAAState.color_surface_depth) +
       (pcurctx->regs.rG2SRCPS.uSRCY() * VCAAState.color_surface_stride);
```

(3) VCAA surface programming

- VCAA surface base address: PATBA
- VCAA surface stride: PATST (bytes)

```
[pseudo_code]
      vcaa_surface_start_address_fetch = pcurctx->regs.rG2PATBA.uPATBA();
```

SW *MUST* directly program this register to the proper sub-surface location in the vcaa surface which corresponds to the SRCX and SRCY programming. The calculation is PATBA = vcaa_base_address + SRCX * (1) + SRCY * PATST;

(4) Resolve surface programming

- resolve window width: DSTWIDTH (pixels)
- resolve window height: DSTHEIGHT (lines)

- resolve output stride: DSTS (bytes)

These values program the width and height of the resolved surface. In the base case,

- DSTWIDTH = color surface width
- DSTHEIGHT = color sufrace height
- DSTS = resolve surface format bpp * DSTWIDTH

The vcaa engine technically supports DSTX and DSTY (like SRCX and SRCY).

```
[pseudo_code]
   resolve_surface_start_address_put = pcurctx->regs.rG2DSTBA.uDSTBA() +
     (pcurctx->regs.rG2DSTPS.uDSTX() * resolve_surface_color_depth) +
     (pcurctx->regs.rG2DSTPS.uDSTY() * resolve_surface_color_stride);
```

(5) Resolving a pixel

The coverage surface is an 8 bit per pixel surface (C4X4). The surface is initialized to all 1s by 3d.

For a given pixel, we need to look up 4 bits of coverage data. If the data is 0xf, the pixel does not need to be resolved. Otherwise, we need to reblend the pixel with certain weightings of its neighbors (i.e. we're on the edge of some geometry).

If any coverage bit is 0, we need to resolve the color. To do so, we calculate the following equation:

```
color_new = (
              20*color_old +
              27*(
                  ((cover_down  == 0) ? color_down  : color_old) +
                  ((cover_right == 0) ? color_right : color_old) +
                  ((cover_left  == 0) ? color_left  : color_old) +
                  ((cover_up    == 0) ? color_up    : color_old)
                 )
            ) / 128;
```

If coverage bit == 0, then we use the neighbor color value in the resolve

If coverage bit == 1, then we use the center color value in the resolve

The resolve is done on a per channel (r/g/b/a) basis:

format convert input channel to 8-bit

perform resolve equation above

format convert to output format

For the resolution of the alpha channel:

- In B5G6R5: no alpha information. do nothing.
- In A1B5G5R5: no resolve. keep the source color alpha bit.
- In R8G8B8A8: normal 8-bit channel resolve

(6) Resolving a pixel on the edge

When on an edge, the vcaa engine treats the coverage bit as a 1. Use the center color value. This holds true even on the edge of the sub-surface resolve window when located in the middle of the larger surface

(7) Maximum dimensions

The maximum resolve sub-surface is 4096 pixels wide.

(8) Surface restrictions

The VCAA engine has the following restrictions with respect to input surfaces

- input base address is 128-bit memory word aligned

- input stride is multiple of 128 bits (16 bytes)

The VCAA engine has the following restrictions with respect to output surfaces

- output base address is 128-bit memory word aligned

- output stride is multiple of 128 bits (16 bytes)

(9) Coverage surface layout

The surface is C4X4.

Surface layout (C4X4)

```
(lsb2msb)  C0_C1_C2_C3_X_X_X_X     (X is a don't care.  Qrast inits to 1)
(msb2lsb)  X_X_X_X_C3_C2_C1_C0

     +          o          o
          C0
             C1   Cov(0,1)
        C2
          C3
     o          o          o

       Cov(1,0)   Cov(1,1)

     o          o          o

     +/o = pixel centers
```

In the example above,

```
        Cov(0,0) = X_X_X_X_C3_C2_C1_C0
        C3       = V_C3(Cov(0,0));
        ..         ..
        C0       = V_C0(Cov(0,0));
     #define V_C3(bits) (bits & 0x8)
     #define V_C2(bits) (bits & 0x4)
     #define V_C1(bits) (bits & 0x2)
     #define V_C0(bits) (bits & 0x1)
```

Resolving a pixel

In an ideal world, the coverage would be simply laid out such that when resolving Pixel(x,y), we would need only to fetch Cov(x,y) to get all 4 bits of information.

In actuality, the coverage surface was rearranged to help qrast in performance. To resolve Pixel(x,y) gr2d has to fetch 4 C4X4 bytes [Cov(x,y), Cov(x-1,y), Cov(x,y-1), Cov(x-1,y-1)]. From each C4X4 byte, it extracts one bit which is used in the resolve equations shown in (5).

Need the logical VCAA bits (DRLU) for blend which is spread across four C4X4 coverage bytes

```
          U
   L
       o
```

R
D

where

- o = Pixel(x,y)
- D = V_C1(Cov(x-1,y))
- R = V_C0(Cov(x,y))
- L = V_C3(Cov(x-1,y-1))
- U = V_C2(Cov(x,y-1))

Bit	Reset	Description
31:0	X	PAT_BASE:pattern base address in tile mode, PATBA is the linear address where pixel start

11.9.67 G2SB_CTX7_G2SRCBA_SB_SURFBASE_0

SB_SURFBASE registers

These registers need only be programmed when using SB. They point to the base of the various source and destination surfaces. Technically they are only needed when tiling is enabled, but there is no harm in always programming them.

Their counterpart registers (_SB_SURFBASE with SB_SURFBASE stripped off) indicate the location of the first pixel to be sourced or written within the surface.

This register exists to mimic the X, Y (SRCX, SRCY) functionality found in the BitBlt engine.

For example, to get at pixel X, Y:

SRCBA = SRCBA_SB_SURFBASE + Y*stride + X*Bpp

Offset: 0xa048 | Byte Offset: 0x28120 | Read/Write: R/W | Reset: 0x00000000 (0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx)

Bit	Reset	Description
31:0	X	SRC_ADDR: surface address corresponding to G2SRCBA: -base of interleaved sources (RGB, YUV) -base of Y plane. Only used by the StretchBlit Engine

11.10 G2SB Switch Registers

11.10.1 G2SB_SWITCH_G2INTERRUPT_0

Interrupt Status Register

These registers can be only accessed by register read/write not command fifo interface. When context switch fails, CPU received interrupt from G2.

Context switch steps

1. clears G2INTERRUPT/CTXSW_INT bit
2. Read out G2NXTCXTSWITCH/NEXT_CLASS NEXT_CHANNEL to determine failing on which class channel
3. Decide which context can be switched to
4. Back up the context contents that will be overwritten
5. Write channel into G2CLASSCHANNEL_REGONLY/CURR_CHANNEL
6. Command FIFO flow resumes.

11.10.10 G2SB_SWITCH_G2_MCCIF_FIFOCTRL_0

Memory Client Interface FIFO Control Register

Note: The FIFO timing aspects of this register are no longer supported, but retained for software compatibility.

The clockenable fields of this register control the 2nd-level clock gating for the mc side of the mccif.

A '1' written to the override field will result in that clock reverting to the legacy mode of operation (where the msc*clk is on whenever the client clk is enabled.

12.0 EPP – ENCODER PRE-PROCESSOR

The Encoder Pre-Processor (EPP) is an engine used for pixel manipulation, usually in conjunction with GR2D, the 2D graphics engine.

This section is not intended to be a programming guide to EPP, as it is expected that NVIDIA supplied drivers will always be used with it. However, the register interface is documented to aid with understanding those drivers.

12.1 Capabilities

The EPP receives input stream or surface data from VI or GR2D.

EPP receives input data on a 24-bit data bus with the format compatible to CSI output format. The input data formats are in six possible formats as far as EPP is concerned:

- 24-bit YUV444 (Y in bits 23:16, U in bits 15:8, V in bits 7:0)
- 24-bit RGB888 (R in bits 23:16, G in bits 15:8, B in bits 7:0)
- 1-byte Raw in bits 7:0
- 2-byte Raw in bits 15:0
- MIPI CSI YUV420 8-bit legacy
- MIPI CSI YUV420 8-bit

EPP supports various output data formats to memory: planar YUV, non-planar YUV, RGB, and Raw formats.

Supported YUV planar output formats

a. YUV420P: planar YUV420 (3-plane YUV420)

Y-plane: YYYY...

YYYY...

U-plane: UU...

V-plane: VV...

b. YUV422P: planar YUV422 (3-plane YUV422)

Y-plane: YYYY...

U-plane: UU...

V-plane: VV...

c. YUV422R: planar YUV422 rotated (3-plane YUV422 rotated)

Y-plane: YYYY...

YYYY...

U-plane: UUUU...

V-plane: VVVV...

d. YUV420SP: semi-planar YUV420 (2-plane YUV420)

Y-plane: YYYY...

YYYY...

UV-plane: UVUV...

e. YUV422SP: semi-planar YUV422 (2-plane YUV422)

Y-plane: YYYY...

UV-plane: UVUV...

f. YUV422SPR: semi-planar YUV422 rotated (2-plane YUV422 rotated)

Y-plane: YY...

YY...

UV-plane: UVUV...

Supported YUV and RGB 32-bit non-planar output formats

                                    0123456789111111
                                              012345
```

For all output formats that require alpha (A), the alpha value is programmed by host and the same programmed value is used for all output pixels.

If EPP output processing is stalled due to stall from memory controllers or due to output trigger stall, EPP will propagate the stall condition to its input FIFO. If input FIFO becomes full, then EPP will not accept any more input data.

This stall may cause input data stream to be dropped (thrown away) if input stream cannot be stalled or if input stream comes from host via VI, then VI will stall host input stream processing.

12.2 Reset Sequence for EPP

1. Raise VI at end of EPP frame.

   If the first_output of VI is connected to EPP, then RAISE_FRAME_1_VECTOR should be sent to register NV_VI_RAISE_VIP_FRAME_FIRST_OUTPUT_0 (offset 0x3e). If the second output of VI is connected to EPP, then RAISE_FRAME_2_VECTOR should be sent to register NV_VI_RAISE_VIP_FRAME_SECOND_OUTPUT_0 (offset 0x40).
2. Disable VI output to EPP by setting bits 4:2 to 0 of register NV_VI_VI_CORE_CONTROL_0 (offset 0x3)
3. Raise EPP at end of frame from host, NV_EPP_RAISE_FRAME_0 (offset 0x1a)
4. Read NV_EPP_CTXW_0 (0ffset 0) register, save the value as EPP_CTXSW_DATA

5. Write 0 to NV_MC_CLIENT_CTRL_0 (offset 0x18) bit 4 to block EPP requests inside MC.
6. Reset EPP by writing 0 to bit 6 of NV_HOST1X_ASYNC_RSTREG_0 (offset 0x14). Do read modify write.
7. Write 0 to NV_MC_CLIENT_HOTRESETN_0 (offset 0x19) bit 4 to clear EPP requests blocked inside MC.
8. Poll on NV_MC_EPP_ORRC_0 (offset 0x1e), MC_EPP_ORRC_0_EPP_OUTREQCNT_RANGE field (0xFF), till it is zero.
9. Write 1 to NV_MC_CLIENT_HOTRESETN_0 bit 4 to disable clear of EPP requests inside MC.
10. Write 1 to NV_MC_CLIENT_CTRL_0 bit 4 to unblock EPP request inside MC.
11. Bring EPP out of reset by writing 1 to bit 6 of NV_HOST1X_ASYNC_RSTREG_0 (offset 0x14). Do read modify write.
12. Program NV_EPP_CTXSW_0 (0x0) with previously saved EPP_CTXSW_DATA.
13. Program EPP registers
14. Enable encoder
15. Enable VI EPP output by programming bits 4:2 to the desired format of NV_VI_VI_CORE_CONTROL_0 (offset 0x3)

12.3 EPP Registers

12.3.1 EPP_INCR_SYNCPT_0

Offset: 0x0 | Byte Offset: 0x0 | Read/Write: R/W | Reset: 0x00000000 (0b0000000000000000)

Bit	Reset	Description
15:8	0x0	COND: Condition mapped from raise/wait 0 = IMMEDIATE 1 = OP_DONE 2 = RD_DONE 3 = REG_WR_SAFE 4 = COND_4 5 = COND_5 6 = COND_6 7 = COND_7 8 = COND_8 9 = COND_9 10 = COND_10 11 = COND_11 12 = COND_12 13 = COND_13 14 = COND_14 15 = COND_15
7:0	0x0	INDX: syncpt index value

12.3.2 EPP_INCR_SYNCPT_CNTRL_0

Offset: 0x1 | Byte Offset: 0x4 | Read/Write: R/W | Reset: 0x00000000 (0b0xxxxxxx0)

Bit	Reset	Description
8	0x0	INCR_SYNCPT_NO_STALL: If NO_STALL is 1, then when fifos are full, INCR_SYNCPT methods will be dropped and the INCR_SYNCPT_ERROR[COND] bit will be set. If NO_STALL is 0, then when fifos are full, the client host interface will be stalled.
0	0x0	INCR_SYNCPT_SOFT_RESET: If SOFT_RESET is set, then all internal states of the client syncpt block will be reset. To do soft reset, first set SOFT_RESET of all host1x clients affected, then clear all SOFT_RESETs.

12.3.3 EPP_INCR_SYNCPT_ERROR_0

Offset: 0x2 | Byte Offset: 0x8 | Read/Write: R/W | Reset: 0x00000000 (0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx)

Bit	Reset	Description
31:0	X	COND_STATUS: COND_STATUS[COND] is set if the fifo for COND overflows. This bit is sticky and will remain set until cleared. Cleared by writing 1.

12.3.4 EPP_EPP_SYNCPT_DEST_0

This is for COND_FIFO_DEPTH (ignored for COND 0). COND_TRIG_MODE applies to COND 1..x (ignored for 0,1).

Offset: 0x8 | Byte Offset: 0x20 | Read/Write: R/W | Reset: 0x00000001 (0b01)

Bit	Reset	Description
1	0x0	MPE
0	0x1	HOST

12.3.5 EPP_CTXSW_0

Context Switch Register. Should be common to all modules. Includes the current channel/class (which is writable by SW) and the next channel/class (which the hardware sets when it receives a context switch).

Context switch works like this:

Any context switch request triggers an interrupt to the host and causes the new channel/class to be stored in NEXT_CHANNEL/NEXT_CLASS (see vmod/chexample). SW sees that there is a context switch interrupt and does the necessary operations to make the module ready to receive traffic from the new context. It clears the context switch interrupt and writes CURR_CHANNEL/CLASS to the same value as NEXT_CHANNEL/CLASS, which causes a context switch acknowledge packet to be sent to the host. This completes the context switch and allows the host to continue sending data to the module.

Context switches can also be pre-loaded. If CURR_CLASS/CHANNEL are written and updated to the next CLASS/CHANNEL before the context switch request occurs, an acknowledge will be generated by the module and no interrupt will be triggered. This is one way for software to avoid dealing with context switch interrupts.

Another way to avoid context switch interrupts is to set the AUTO_ACK bit.

This bit tells the module to automatically acknowledge any incoming context switch requests without triggering an interrupt. CURR_* and NEXT_* will be updated by the module so they will always be current.

Offset: 0x9 | Byte Offset: 0x24 | Read/Write: R/W | Reset: 0xf000f800 (0bxxxxxxxxxxxxxxxx11111x0000000000)

Bit	R/W	Reset	Description
31:28	RO	X	NEXT_CHANNEL: Next requested channel
25:16	RO	X	NEXT_CLASS: Next requested class
15:12	RW	0xf	CURR_CHANNEL: Current working channel, reset to 'invalid'
11	RW	0x1	AUTO_ACK: Automatically acknowledge any incoming context switch requests 0 = MANUAL 1 = AUTOACK
9:0	RW	0x0	CURR_CLASS: Current working class

12.3.6 EPP_INTSTATUS_0

Interrupt Status. This reflects status of all pending interrupts which is valid as long as the interrupt is not cleared even if the interrupt is masked. A pending interrupt can be cleared by writing a '1' to the corresponding interrupt status bit in this register.

Offset: 0xa │ Byte Offset: 0x28 │ Read/Write: R/W │ Reset: 0xff000000 (0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx)

Bit	R/W	Reset	Description
31:24	RO	X	LAST_BUFFER_INDEX: Last buffer index status. This indicates the index of the previous (last) buffer written to memory by EPP.
8	RW	X	SHORT_FRAME_INT: Short Frame Interrupt Status. If enabled, interrupt is generated when shorter than expected frame is detected. Input stream end-of-frame flag and OUTPUT_FRAME_SIZE is used to determine this condition. 0 = NOTPENDING : interrupt not pending 1 = PENDING : interrupt pending
2	RW	X	BUFFER_END_INT: Output Buffer End Interrupt Status. If enabled, interrupt is generated every time end of buffer is reached. Typically this is determined when OB0_V_SIZE count expires and after all buffer data is written to memory. Note that buffer may not be completely filled for first and last buffer of each frame. This interrupt should be used together with LAST_BUFFER_INDEX status. 0 = NOTPENDING : interrupt not pending 1 = PENDING : interrupt pending
1	RW	X	FRAME_END_INT: Frame End Interrupt Status. If enabled, interrupt is generated every time FRAME_HEIGHT count expires after all frame data is written to memory. 0 = NOTPENDING : interrupt not pending 1 = PENDING : interrupt pending
0	RW	X	CTXSW_INT: Context Switch Interrupt Status (this is cleared on write). 0 = NOTPENDING : interrupt not pending 1 = PENDING : interrupt pending

12.3.7 EPP_EPP_CONTROL_0

EPP Control Register. This specifies processing control.

Offset: 0xb │ Byte Offset: 0x2c │ Read/Write: R/W │ Reset: 0x00000000 (0b0xx00000000000000000000)

Bit	Reset	Description
24	0x0	SW_FLOW_CONTROL: enable SW flow control default is disabled. 0 = DISABLE 1 = ENABLE
21:18	0x0	OUTPUT_FORMAT_EXT: Output data format extension. This specifies output data format together with OUTPUT_FORMAT. RGB formats are specified from lsb to msb. 0 = EXT0 : YUV420: planar YUV422: non-planar if OUTPUT_PLANAR=DISABLE, planar if OUTPUT_PLANAR=ENABLE. YUV422R: planar YUV444: AYUV444 non-planar if OUTPUT_PLANAR=DISABLE RGB888: B8G8R8A8 if OUTPUT_PLANAR=DISABLE, R8G8B8A8 if OUTPUT_PLANAR=ENABLE. RGBRAW: B5G6R5 if OUTPUT_PLANAR=DISABLE, R5G6B5 if OUTPUT_PLANAR=ENABLE. BAYERRAW: 2-byte bayer/raw 1 = EXT1: YUV420: semi-planar YUV422: semi-planar if OUTPUT_PLANAR=ENABLE. YUV422R: semi-planar RGB888: A8B8G8R8 if OUTPUT_PLANAR=DISABLE, A8R8G8B8 if OUTPUT_PLANAR=ENABLE. RGBRAW: A1B5G5R5 if OUTPUT_PLANAR=DISABLE, A1R5G5B5 if OUTPUT_PLANAR=ENABLE. BAYERRAW: 1-byte bayer/raw 2 = EXT2 : YUV420: planar, CSI YUV420 legacy input RGBRAW: B5G5R5A1 if OUTPUT_PLANAR=DISABLE, R5G5B5A1 if OUTPUT_PLANAR=ENABLE. 3 = EXT3 : YUV420: semi-planar, CSI YUV420 legacy input RGBRAW: A4B4G4R4 if OUTPUT_PLANAR=DISABLE, A4R4G4B4 if OUTPUT_PLANAR=ENABLE.

Bit	Reset	Description
		4 = EXT4 : YUV420: planar, CSI YUV420 input. RGBRAW: B4G4R4A4 if OUTPUT_PLANAR=DISABLE, R4G4B4A4 if OUTPUT_PLANAR=ENABLE. 5 = EXT5 : YUV420: semi-planar, CSI YUV420 input.
17	0x0	ENABLE_DUP: Pixel duplication at start and end of lines. This enables duplication of first pixel and last pixel of each line to 128-bit boundary if there is unused space in the 128-bit memory word that contains the first and last pixel. This may be enabled if output of EPP is used as input of JPEG encoder. JPEGE encoder can duplicate lines to ensure JPEGE has a full MCU to encode. If EPP Is used as input to MPEG encoder, output height of EPP has to be set to multiples of 16 for MPEG encoder does not duplicate lines. This is only applicable for planar YUV output formats (OUTPUT_PLANAR=ENABLE and output Format!=RAWRGB and output Format!=RGB888). Pixel duplication occurs prior to XY swap process therefore if XY_SWAP is set to ENABLE, the duplicated pixels will be placed on top and bottom of the image instead of left and right of the image and therefore may not help in JPEG encoding process. If image is to be rotated prior to JPEG encoding, it is preferred to do the rotation in the JPEG encoder rather than in EPP. 0 = DISABLE : First and last pixel duplication is disabled. 1 = ENABLE : First and last pixel duplication is enabled for each line.
16	0x0	DMA_ENABLE: DMA enable. S/W should program this bit to a 1 every time DMA is enabled and buffer configuration changes This bit is now sent out as init for all the host counters and logic. This enables EPP trigger at end of each buffer to be sent to Read DMA. The Read DMA must be properly programmed to fetch EPP buffers in memory upon receiving these triggers. 0 = DISABLE : EPP trigger to Read DMA is disabled 1 = ENABLE : EPP trigger to Read DMA is enabled
15	0x0	CHROMA_SIGN: Chroma data sign. This indicates chroma data format. 0 = UNSIGNED : unsigned chroma data, Cb/Cr 1 = SIGNED : signed chroma data, U/V, in 2's complement
14:12	0x0	OUTPUT_FORMAT: Output data format. This specifies output data format together with OUTPUT_FORMAT_EXT. 0 = YUV420 : YUV420 planar/semi-planar. ENABLE_422 must be set to ENABLE for this output format. ENABLE_420 must be set to ENABLE if the input format is not MIPI CSI YUV420 formats and must be set to DISABLE if the input format is MIPI CSI YUV420 formats. 1 = YUV422 : YUV422 non-planar/planar/semi-planar. If YUV422 planar/semi-planar format is selected and XY swap is enabled, then output will be written to memory in YUV422R planar/semi-planar format correspondingly. YUV422 non-planar format cannot be used with XY swap enabled. ENABLE_422 must be set to ENABLE and ENABLE_420 must be set to DISABLE for this output format. 2 = YUV422R : YUV422R planar/semi-planar. If YUV422R planar/semi-planar format is selected and XY swap is enabled, then output will be written to memory in YUV422 planar/semi-planar format correspondingly. ENABLE_422 must be set to DISABLE and ENABLE_420 must be set to ENABLE for this output format. 3 = YUV444 : AYUV444 non-planar if OUTPUT_PLANAR=DISABLE. 4 = RGB888 : ARGB888 5 = RGBRAW : RGBRAW 6 = BAYERRAW : BAYERRAW
11	0x0	CHROMA_FILTER_422: Chroma YUV444 to YUV422 conversion. This controls chroma reduction when YUV444 to YUV422 conversion is enabled. This is effective only when ENABLE_422 is set to ENABLE. 0 = DROP : Even chroma pixels are dropped. This may be used if the incoming YUV444 stream has chroma pixel duplication of odd and even pixels. 1 = FILTER : Horizontal chroma filtering is applied for YUV444 to YUV422 conversion.
10	0x0	OUTPUT_PLANAR: Output planar format. This should be set to ENABLE if output format is YUV planar or semi-planar and should be DISABLE if output format is YUV non-planar. For RGB output data formats, this bit has alternate function of swapping R and B. 0 = DISABLE : For YUV output formats, output is YUV non-planar format. For RGB output formats, R is in upper bits and B is in lower bits. 1 = ENABLE : Output is YUV planar/semi-planar format. For RGB output formats, B is in upper bits and R is in lower bits.
9:8	0x0	OUTPUT_NP_FORMAT: Non-planar YUV422 output format. This selects output format when output format is set to YUV422 non-planar. 0 = UYVY : UY0VY1, where U is LSB and Y1 is MSB 1 = VYUY : VY0UY1, where V is LSB and Y1 is MSB

Bit	Reset	Description
		2 = YUYV : Y0UY1V, where Y0 is LSB and V is MSB 3 = YVYU : Y0VY1U, where Y0 is LSB and U is MSB
7:6	0x0	CHROMA_FILTER_420: Chroma YUV422 to YUV420 conversion. This controls chroma reduction when YUV422 to YUV420 conversion is enabled. This is effective only when ENABLE_420 is set to ENABLE. 0 = DROP: Even chroma lines are dropped. 1 = AVERAGE: Averaging is done for each pair (odd and even) of chroma lines.
5	0x0	ENABLE_PP: Luma PreProcess filter enable. This controls luma pre-encoding filter for YUV output formats including YUV420 when input format is YUV420 CSI format. Enabling the luma pre-encoding filter will reduce noise in the input stream and may result in more compact encoding. 0 = DISABLE: Luma pre-encoding filter is disabled. 1 = ENABLE: Luma pre-encoding filter is enabled.
4	0x0	ENABLE_420: YUV422 to YUV420 enable. If set to ENABLE, chroma data is vertically reduced by half. YUV422 to YUV420 conversion must be enabled when OUTPUT_FORMAT is YUV420 and input format is not MIPI CSI YUV420. YUV422 to YUV420 conversion must also be enabled when OUTPUT_FORMAT is YUV422R. The vertical chroma reduction method is controlled by CHROMA_FILTER_420 field. 0 = DISABLE: YUV422 to YUV420 conversion is disabled. 1 = ENABLE: YUV422 to YUV420 conversion is enabled.
3	0x0	ENABLE_422: YUV444 to YUV422 enable. If set to ENABLE, chroma data is horizontally reduced by half. YUV444 to YUV422 conversion must be enabled when OUTPUT_FORMAT is YUV422 or YUV420. YUV444 to YUV422 conversion must be disabled when OUTPUT_FORMAT is YUV422R. The horizontal chroma reduction method is controlled by CHROMA_FILTER_422 field. 0 = DISABLE : YUV444 to YUV422 conversion is disabled. 1 = ENABLE: YUV444 to YUV422 conversion is enabled.
2	0x0	ENABLE_CC: Color Space Converter enable. This enables RGB to YUV color space converter and should be enabled only for RGB input format if output format is YUV. If enabled, the output of the color space converter is YUV444 therefore conversion to YUV422 or YUV420 may be needed also. 0 = DISABLE: RGB input format is not converted to YUV. 1 = ENABLE: RGB input format is converted to YUV.
1:0	0x0	INPUT_SOURCE: Input source. 0 = VI: Input source from VI. 1 = SB: Input source from StretchBLT (2D). 2 = DISPLAY: Input source from DISPLAY. 3 = DISPLAYB : Input source from DISPLAY B

12.3.8 EPP_OUTPUT_FRAME_SIZE_0

Captured, input frame size

This specifies width and height of input frame with respect to size of active area to be processed by EPP. For some planar and semi-planar YUV output formats, there are 2:1 ratio of luma vs chroma pixels horizontally and/or vertically. In this case, output frame size specifies luma plane size and should be programmed to even values if the corresponding chroma plane dimension is half of the luma plane dimension.

Offset: 0xc │ Byte Offset: 0x30 │ Read/Write: R/W │ Reset: 0x00000000 (0b00000000000000000000000000000000)

Bit	Reset	Description
31:16	0x0	FRAME_HEIGHT: Frame height in lines (min 1 line).
15:0	0x0	FRAME_WIDTH: Frame width in pixels (min 16 pixels).

12.3.9 EPP_INPUT_FRAME_AOI_0

Input frame area of interest

This specifies position of the first pixel in the input frame to be processed by EPP. Together with output frame size, this parameter defines the active size of the input surface.

Offset: 0xd │ Byte Offset: 0x34 │ Read/Write: R/W │ Reset: 0x00000000 (0b00000000000000000000000000000000)

Bit	Reset	Description
31:16	0x0	FRAME_VERT_OFFSET: Vertical offset in term of line position (min 0).
15:0	0x0	FRAME_HORI_OFFSET: Horizontal offset in term of pixel position (min 0).

12.3.10 EPP_OUTPUT_SCAN_DIR_0

Output scan direction

This register can be used to program the output frame orientation as follows:

XY_SWAP	VERT_DIR	HORI_DIR	Output frame orientation
0	0	0	Normal (same as input frame orientation)
0	0	1	H flip (mirror on vertical axis)
0	1	0	V flip (mirror on horizontal axis)
0	1	1	180-degree rotation
1	0	0	XY swap (mirror on 315-degree diagonal)
1	0	1	270-degree rotation
1	1	0	90-degree rotation
1	1	1	XY swap and H,V flips (mirror on 45-degree diagonal)

Notes:

a. XY swap, if enabled, is performed first prior to H-flip and V-flip.

b. Output buffer start address should be programmed in consideration of the scan directions.

If xy-swap=0 (XY swap disabled):

OB0_Start_Address = OBSA + hsd * (width * bpp - 1) + vsd * (height - 1) * line_stride, where line_stride >= ((width * bpp) + 15) & 0xFFFFFFF0).

If xy-swap=1 (XY swap enabled):

OB0_Start_Address = OBSA + hsd * (height * bpp - 1) + vsd * (width - 1) * line_stride, where line_stride >= ((height * bpp) + 15) & 0xFFFFFFF0).

In the above formulae, OBSA is the start address of output buffer 0, hsd and vsd are H/V scan direction, bpp is byte per pixel, width and height are the sizes of input image in pixels, and line_stride is the line stride of output buffer in bytes.

c. For YUV422 non-planar, since chroma data is shared by multiple pixels, XY swap can NOT be performed.

Offset: 0xe │ Byte Offset: 0x38 │ Read/Write: R/W │ Reset: 0x00000000 (0b000)

Bit	Reset	Description
2	0x0	XY_SWAP: XY_SWAP IS NO LONGER SUPPORTED 0 = DISABLE : XY swap disabled. 1 = ENABLE : XY swap enabled.
1	0x0	VERT_DIR: Vertical scan direction. 0 = INCREASE : Increasing address. 1 = DECREASE : Decreasing address.

Bit	Reset	Description
0	0x0	HORI_DIR: Horizontal scan direction. 0 = INCREASE : Increasing address. 1 = DECREASE : Decreasing address.

Output buffer start addresses define the start address of the first buffer (buffer index 0) and taking into account the output orientation. Note that since output buffer start addresses depend on output orientation, therefore it must be reprogrammed when output orientation is changed.

All addresses must be on pixel boundaries.

Output format is either Planar or Non-planar format. For non-planar output format, only luma buffer is used.

For semi-planar output formats, only 2 planes are used. Chroma data is interleaved in a single plane. So for semi-planar outputs, only OB0_START_ADDRESS_U is used to specify chroma buffer start address. Enough memory should be reserved to store U and V data for the chroma buffer.

12.3.11 EPP_OB0_BASE_ADDRESS_Y_0

Offset: 0x10 │ Byte Offset: 0x40 │ Read/Write: R/W │ Reset: 0x00000000 (0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx)

Bit	Reset	Description
31:0	X	OB0_BASE_ADDRESS_Y: OB0 Y BASE address.

12.3.12 EPP_OB0_BASE_ADDRESS_U_0

Output buffer 0 U base address. This is used to specify U buffer base address for planar output format. This is also used for semi-planar chroma buffer base address. This is not used for non-planar output format.

Offset: 0x12 │ Byte Offset: 0x48 │ Read/Write: R/W │ Reset: 0x00000000 (0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx)

Bit	Reset	Description
31:0	X	OB0_BASE_ADDRESS_U: OB0 U start address.

12.3.13 EPP_OB0_START_ADDRESS_V_0

Output buffer 0 V start address. This is used to specify V buffer start address for planar output format. This is not used for semi-planar and for non-planar output format.

Offset: 0x13 │ Byte Offset: 0x4c │ Read/Write: R/W │ Reset: 0x00000000 (0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx)

Bit	Reset	Description
31:0	X	OB0_START_ADDRESS_V: OB0 V start address.

12.3.14 EPP_OB0_BASE_ADDRESS_V_0

Output buffer 0 V base address. This is used to specify V buffer base address for planar output format. This is not used for semi-planar and for non-planar output format.

Offset: 0x14 │ Byte Offset: 0x50 │ Read/Write: R/W │ Reset: 0x00000000 (0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx)

Bit	Reset	Description
31:0	X	OB0_BASE_ADDRESS_V: OB0 V start address.

12.3.15 EPP_OB0_XY_OFFSET_LUMA_0

XY Offset to first pixel in the image. The value is expressed in pixels. For non-rotated surfaces, this points to the top-left of the image.

Offset: 0x15 | Byte Offset: 0x54 | Read/Write: R/W | Reset: 0x00000000 (0b00000000000000000000000000000000)

Bit	Reset	Description
31:16	0x0	START_Y_LUMA: Y offset in pixels for the first pixel in the image in the Y buffer.
15:0	0x0	START_X_LUMA: X offset in pixels for the first pixel written in the image in the Y buffer

12.3.16 EPP_OB0_XY_OFFSET_CHROMA_0

XY Offset to first pixel in the image. The value is expressed in pixels. For non-rotated surfaces, this points to the top-left of the image.

Offset: 0x16 | Byte Offset: 0x58 | Read/Write: R/W | Reset: 0x00000000 (0b00000000000000000000000000000000)

Bit	Reset	Description
31:16	0x0	START_Y_CHROMA: Y offset in pixels for the first pixel in the image in the U and V buffer.
15:0	0x0	START_X_CHROMA: X offset in pixels for the first pixel written in the image in the U and V buffer For YUV422R or YUV420P with Chroma Averaging on START_X_CHROMA must be aligned to a 16 byte boundary.

12.3.17 EPP_OB0_SIZE_0

Output buffer 0 size. This specifies the number of output buffers and the vertical size of each buffer. Note that horizontal size of each buffer is implied from OB_LINE_STRIDE.

Offset: 0x17 | Byte Offset: 0x5c | Read/Write: R/W | Reset: 0x00000000 (0bxxxxxxxxxxxxxxxxxxxxxxx00000000)

Bit	Reset	Description
28:16	X	OB0_V_SIZE: Output buffer vertical size. This specifies the number of lines. In the case of xyswap, vertical size should be programmed as vertical size before xyswap.
7:0	0x0	OB0_COUNT: Output buffer count. This specifies the number of buffers in output buffer set 0.

12.3.18 EPP_OB0_LINE_STRIDE_L_0

Output buffer line stride. Line stride should be programmed taking into account XY swap. If XY swap is enabled, line stride should be programmed as after xyswap.

Offset: 0x18 | Byte Offset: 0x60 | Read/Write: R/W | Reset: 0x00000000 (0b00000000000000000000000000000000)

Bit	Reset	Description
31:16	0x0	OB0_LINE_STRIDE_C: Output buffer chroma line stride. This parameter must be programmed as 16-byte multiple so 4 lsbs must be set to zeros.
15:0	0x0	OB0_LINE_STRIDE_L: Output buffer luma line stride. This parameter must be programmed as 16-byte multiple so 4 lsbs must be set to zeros.

Color Space Converter related registers are CSC_RGB2Y_COEFF, CSC_RGB2U_COEFF, CSC_RGB2V_COEFF and CSC_YOFFSET_COEFF.

The recommended coefficient values differ based on the type of conversion either RGB to ITU-R BT.601 Y/Cb/Cr or RGB to ITU-R BT.709 Y/Cb/Cr is used. For both the type of conversions, R,G,B values are expected to be in the range of [0,255] and

after Color Space Conversion operation, Y value is in the range of [16,235] with Y-Offset of 16, Cb and Cr are in the range of [16,240] with offset of 128. The Offset of 128 for Cb and Cr are hard-coded in the design.

12.3.19 EPP_CSC_RGB2Y_COEFF_0

RGB to Y coefficients

The coefficient for R component CSC_R2Y_COEFF is represented as Unsigned U0.8 (8-bit), the coefficient for G component CSC_G2Y_COEFF is represented as Unsigned U1.8 (9-bits), the coefficient for B component CSC_B2Y_COEFF is represented as Unsigned U0.8 (8-bits).

For RGB to ITU-R BT.601 Y/Cb/Cr conversion, the recommended coefficient values are:

[CSC_R2Y_COEFF CSC_G2Y_COEFF CSC_B2Y_COEFF] = [0.256788 0.504129 0.097906]

The coefficients are represented with 8-bit fraction (U1.8 or U0.8) therefore for a dynamic range of 256 (8-bits), the programmed coefficient values are [66 129 25] = [42h 81h 19h]

For RGB to ITU-R BT.709 Y/Cb/Cr conversion, the recommended coefficient values are:

[CSC_R2Y_COEFF CSC_G2Y_COEFF CSC_B2Y_COEFF] = [0.182586 0.614231 0.062007]

The coefficients are represented with 8-bit fraction (U1.8 or U0.8) therefore for a dynamic range of 256 (8-bits), the programmed coefficient values are [47 157 16] = [2fh 9dh 10h]

Offset: 0x1b │ Byte Offset: 0x6c │ Read/Write: R/W │ Reset: 0x00000000 (0b00000000000000000000000000)

Bit	Reset	Description
24:17	0x0	CSC_B2Y_COEFF: Coefficient for B to Y component.
16:8	0x0	CSC_G2Y_COEFF: Coefficient for G to Y component.
7:0	0x0	CSC_R2Y_COEFF: Coefficient for R to Y component.

12.3.20 EPP_CSC_RGB2U_COEFF_0

RGB to U Coefficients

The coefficient for R component CSC_R2U_COEFF is represented as Sign Magnitude S0.8 (9-bits), the coefficient for G component CSC_G2U_COEFF is represented as Sign Magnitude S0.8 (9-bits), the coefficient for B component CSC_B2U_COEFF is represented as Sign Magnitude S0.8 (9-bits).

The most significant bit (9th bit) is either set to 0 or 1 based on the coefficient value being positive or negative respectively.

For RGB to ITU-R BT.601 Y/Cb/Cr conversion, the recommended coefficient values are:

[CSC_R2U_COEFF CSC_G2U_COEFF CSC_B2U_COEFF] = [-0.148223 -0.290993 0.439216]

The coefficients are represented with 8-bit fraction (S0.8) therefore for a dynamic range of 256 (8-bits), the programmed coefficient values are [-38 -74 112] = [-26h -4ah 70h] = [126h 14ah 70h]

For RGB to ITU-R BT.709 Y/Cb/Cr conversion, the recommended coefficient values are:

[CSC_R2U_COEFF CSC_G2U_COEFF CSC_B2U_COEFF] = [-0.100644 -0.338572 0.439216]

The coefficients are represented with 8-bit fraction (S0.8) therefore for a dynamic range of 256 (8-bits), the programmed coefficient values are [-26 -87 112] = [-1ah -57h 70h] = [11ah 157h 70h]

Offset: 0x1c │ Byte Offset: 0x70 │ Read/Write: R/W │ Reset: 0x00000000 (0b00000000000000000000000000000000)

Bit	Reset	Description
26:18	0x0	CSC_B2U_COEFF: Coefficient for B to U component.
17:9	0x0	CSC_G2U_COEFF: Coefficient for G to U component.
8:0	0x0	CSC_R2U_COEFF: Coefficient for R to U component.

12.3.21 EPP_CSC_RGB2V_COEFF_0

RGB to V Coefficients

The coefficient for R component CSC_R2V_COEFF is represented as Sign Magnitude S0.8 (9-bits), the coefficient for G component CSC_G2V_COEFF is represented as Sign Magnitude S0.8 (9-bits), the coefficient for B component CSC_B2V_COEFF is represented as Sign Magnitude S0.8 (9-bits).

The most significant bit (9th bit) is either set to 0 or 1 based on the coefficient value being positive or negative, respectively.

For RGB to ITU-R BT.601 Y/Cb/Cr conversion, the coefficient values recommended are:

[CSC_R2V_COEFF CSC_G2V_COEFF CSC_B2V_COEFF] = [0.439216 -0.367788 -0.040274]

The coefficients are represented with 8-bit fraction (S0.8) therefore for a dynamic range of 256 (8-bits), the programmed coefficient values are [112 -94 -18] = [70h -5eh -12h] = [70h 15eh 112h]

For RGB to ITU-R BT.709 Y/Cb/Cr conversion, the coefficient values recommended are:

[CSC_R2V_COEFF CSC_G2V_COEFF CSC_B2V_COEFF] = [0.439216 -0.398942 -0.071427]

The coefficients are represented with 8-bit fraction (S0.8) therefore for a dynamic range of 256 (8-bits), the programmed coefficient values are [112 -102 -10] = [70h -66h -0ah] = [70h 166h 10ah]

Offset: 0x1d │ Byte Offset: 0x74 │ Read/Write: R/W │ Reset: 0x00000000 (0b00000000000000000000000000000000)

Bit	Reset	Description
26:18	0x0	CSC_B2V_COEFF: Coefficient for B to V component.
17:9	0x0	CSC_G2V_COEFF: Coefficient for G to V component.
8:0	0x0	CSC_R2V_COEFF: Coefficient for R to V component.

12.3.22 EPP_CSC_YOFFSET_COEFF_0

Y Offset for the Color Space Conversion

Offset: 0x1e │ Byte Offset: 0x78 │ Read/Write: R/W │ Reset: 0x00000000 (0b00000000) │ Default: 0x00000010

Bit	Reset	SW Default	Description
7:0	0x0	0x10	CSC_YOFF_COEFF: Coefficient for Y Offset.

There are two filters in EPP -- luma pre-processing filter and chroma 444 to 420 filter. Each filter is designed to be 7 tab, LPF.

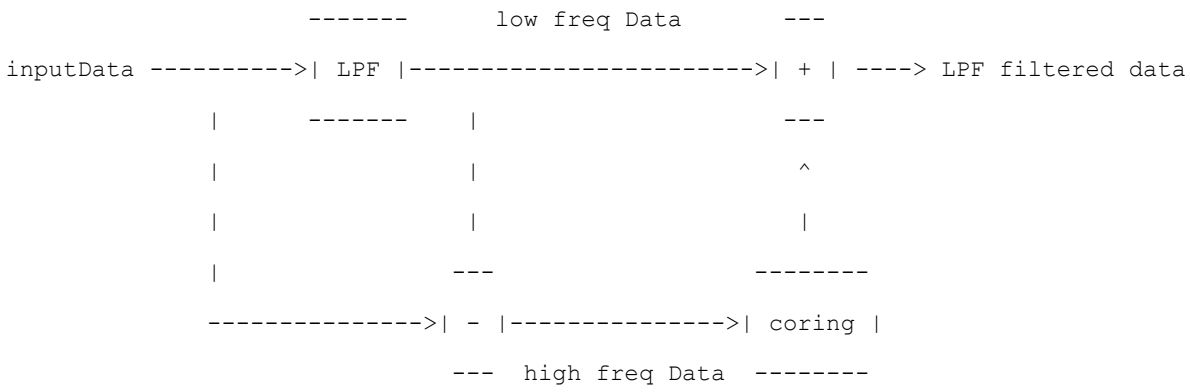
The recommended coefficients for luma pre-processing filter are: (0 1 4 6 4 1 0)/16. The filter coefficients are symmetric, therefore only four coefficients are programmed.

The recommended coefficient base is 16 and programmed to 4, in terms of power of 2. The sum of all coefficients should not exceed the coefficient base value.

The recommended coefficients for chroma 444-to-422 filter are: (-1 0 9 16 9 0 -1)/64. The filter coefficients are symmetric, therefore only four coefficients are programmed.

The recommended coefficient base is 64 and programmed to 6, in terms of power of 2. The sum of all coefficients should not exceed the coefficient base value.

The basic concept for this filter is:



12.3.23 EPP_FILTER_BOUND_0

Filter coring bound. This specifies min/max values for filter coring for both luma pre-processing filter and chroma 444-to-422 filter.

Offset: 0x1f | Byte Offset: 0x7c | Read/Write: R/W | Reset: 0x00000000 (0b00000000000000000000000000000000) | Default: 0xff00ff00

Bit	Reset	SW Default	Description
31:24	0x0	0xff	CHROMA_THRESHOLD_HIGH: Chroma high bound
23:16	0x0	_NONE_	CHROMA_THRESHOLD_LOW: Chroma low bound
15:8	0x0	0xff	LUMA_THRESHOLD_HIGH: Luma high bound
7:0	0x0	_NONE_	LUMA_THRESHOLD_LOW: Luma low bound

12.3.24 EPP_FILTER_BASE_0

Filter coefficient base

Offset: 0x20 | Byte Offset: 0x80 | Read/Write: R/W | Reset: 0x00000000 (0b00000000xxxxxxxx00000000) | Default: 0x00040004

Bit	Reset	SW Default	Description
23:16	0x0	0x4	CHROMA_BASE: Chroma 444-to-422 filter coefficient base. This is a positive value programmed in terms of power of 2.
7:0	0x0	0x4	PP_BASE: Luma pre-processing filter coefficient base. This is a positive value programmed in terms of power of 2.

12.3.25 EPP_PP_FILTER_COEF_0

Luma pre-processing filter coefficients. This 7-tap filter is symmetric therefore only four coefficients are programmed. Sum of all 7 coefficients should not exceed the filter base value.

Recommended luma pre-processing filter is a 5-tap filter (0,1,4,6,4,1,0)/16.

An alternate recommendation is a 7-tap filter (1,6,15,20,15,6,1)/64.

Offset: 0x21 | Byte Offset: 0x84 | Read/Write: R/W | Reset: 0x00000000 (0b00000000000000000000) | Default: 0x00031020

Bit	Reset	SW Default	Description
18:13	0x0	0x18	PP_COEF_3: Luma pre-processing filter coefficients 4. This is an unsigned value 0 to 63
12:8	0x0	0x10	PP_COEF_2: Luma pre-processing filter coefficients 3, 5. This is a unsigned value 0 to 31.
7:3	0x0	0x4	PP_COEF_1: Luma pre-processing filter coefficients 2, 6. This is a signed value -16 to +15.
2:0	0x0	0x0	PP_COEF_0: Luma pre-processing filter coefficients 1, 7. This is a signed value -4 to +3.

12.3.26 EPP_CHROMA_FILTER_COEF_0

Chroma 444-to-422 filter coefficients. This 7-tap filter is symmetric therefore only four coefficients are programmed. Sum of all 7 coefficients should not exceed the filter base value.

Recommended chroma 444-to-422 filter is a 5-tap filter (0,1,4,6,4,1,0)/16.

An alternate recommendation is a 7-tap filter (-1,0,9,16,9,0,-1)/64.

Offset: 0x22 | Byte Offset: 0x88 | Read/Write: R/W | Reset: 0x00000000 (0b00000000000000000000) | Default: 0x00031020

Bit	Reset	SW Default	Description
18:13	0x0	0x18	CHROMA_COEF_3: Chroma 444-to-422 filter coefficients 4. This is an unsigned value 0 to 63
12:8	0x0	0x10	CHROMA_COEF_2: Chroma 444-to-422 filter coefficients 3, 5. This is a unsigned value 0 to 31.
7:3	0x0	0x4	CHROMA_COEF_1: Chroma 444-to-422 filter coefficients 2, 6. This is a signed value -16 to +15.
2:0	0x0	0x0	CHROMA_COEF_0: Chroma 444-to-422 filter coefficients 1, 7. This is a signed value -4 to +3.

12.3.27 EPP_ALFA_VALUE_0

Output alpha value. This is appended alpha value for RGB and or YUV444 output data formats that requires alpha. If the data format requires less than 8 bits of alpha then the necessary least significant bits are used.

Offset: 0x23 | Byte Offset: 0x8c | Read/Write: R/W | Reset: 0x00000000 (0b00000000)

Bit	Reset	Description
7:0	0x0	ALFA: Output alpha value.

12.3.28 EPP_U_LINE_BUFFER_ADDR_0

Chroma line buffer for U & V data. Chroma buffer needs to be allocated whenever ENABLE_420 is set to ENABLE and CHROMA_FILTER_420 is set to AVERAGE.

Offset: 0x24 | Byte Offset: 0x90 | Read/Write: R/W | Reset: 0x00000000 (0b00000000000000000000000000000000)

Bit	Reset	Description
31:0	0x0	U_LINE_BUFFER_ADDR: Chroma line buffer for U & V data. This must be specified in 16-byte boundary (the four lsbs must be set to zeros). The size of this line buffer must be sufficient to store one line of U & V.

12.3.29 EPP_V_LINE_BUFFER_ADDR_0

Note: This register is no longer used.

Offset: 0x25 | Byte Offset: 0x94 | Read/Write: R/W | Reset: 0x00000000 (0b00000000000000000000000000000000)

Bit	Reset	Description
31:0	0x0	V_LINE_BUFFER_ADDR: Reserved.

EPP may accept a raise from VI via the same input data bus from VI or two types of raises from host.

A raise from VI is returned when all preceding input data have been processed and written to memory.

Two types of raises maybe sent from host:

- Raise Buffer
- Raise Frame

For raises from host, EPP tags last write for each buffer and each frame when sending it to memory client and then it waits for the tag to be returned. Typically, raise buffer will be acknowledged when the next end of buffer tag is returned by the memory write client.

Similarly, typically, raise frame will be acknowledged when the next end of frame tag is returned by the memory write client.

If raise buffer or raise frame is issued during vertical blank time (between end-of-frame marker of previous frame and start-of-frame of next frame) then an option bit is added to either acknowledge the raise immediately or return the raise when the next end of buffer or end of frame tag is returned by the memory write client correspondingly.

When one or more event that returns data to host are pending, priority will be assigned as follows:

1. Context Switch Acknowledgement
2. Raise from VI
3. Raise Buffer
4. Raise Frame
5. Refcount or register read

12.3.30 EPP_RAISE_BUFFER_0

Raise Buffer (end of buffer raise). The end of buffer event is generated when the last data of the output buffer is written to memory. This is independent of output trigger so the end of buffer raise acknowledge is returned even though there maybe output trigger stall pending.

Offset: 0x26 | Byte Offset: 0x98 | Read/Write: R/W | Reset: 0x00000000 (0b00000xxxxxxxxxx00000)

Bit	Reset	Description
19:16	0x0	CHANNEL_ID_BUFFER: 4 bit channel ID which will be returned when the end-of-buffer event occurs after raise buffer is issued.
15	0x0	RAISE_BUFFER_VBLANK: Raise buffer control during V Blank. This specifies when to return raise buffer if it is issued during vertical blank time. 0 = IMMEDIATE : Raise buffer is acknowledged immediately if it is issued during vertical blank time. 1 = DELAYED : Raise buffer is acknowledged at the end of the first buffer of the next frame if it is issued during vertical blank time.
4:0	0x0	RAISE_VECTOR_BUFFER: 5-bit raise vector

12.3.31 EPP_RAISE_FRAME_0

Raise Frame (end of frame raise). The end of frame event is generated when the last data of the output buffer is written to memory. This is independent of output trigger so the end of buffer raise acknowledge is returned even though there maybe output trigger stall pending.

Offset: 0x27 │ Byte Offset: 0x9c │ Read/Write: R/W │ Reset: 0x00000000 (0b00000xxxxxxxxxx00000)

Bit	Reset	Description
19:16	0x0	CHANNEL_ID_FRAME: 4 bit channel ID which will be returned when the end-of-frame event occurs after raise frame is issued.
15	0x0	RAISE_FRAME_VBLANK: Raise frame control during V Blank. This specifies when to return raise frame if it is issued during vertical blank time. 0 = IMMEDIATE : Raise frame is acknowledged immediately if it is issued during vertical blank time. 1 = DELAYED : Raise frame is acknowledged at the end of the next frame if it is issued during vertical blank time.
4:0	0x0	RAISE_VECTOR_FRAME: 5-bit raise vector

[THIS PAGE INTENTIONALLY LEFT BLANK]

13.0 KEYBOARD CONTROLLER

The Keyboard Controller (KBC) is used to interface a maximum of 24 pins with an external keypad. The number of pins used in the KBC depends on the external keypad row and column count, and is less in some Tegra® 3 package variations.

A keyboard controller for a keypad matrix implemented completely in software can result in significant overhead. The KBC lowers the burden on software by supporting keypad scan, debounce and wake-up on any key-press in hardware. It also reduces power consumption in keypad associated operations. The remaining pins can be used as GPIO. If no external keypad is connected all the pins can be used as GPIO. The KBC module is a slave on APB bus.

The typical software scanning flow is shown in Figure 18. Most of the tasks in the flowchart can be done in hardware, off-loading them from software. The three main operations done by KBC are:

- Keypad scan
- Debounce
- Control SM

In the presence of a KBC, the software flowchart for keyboard control is reduced to what is shown in Figure 19. The software only needs to configure the keyboard controller and serve the interrupts. This automatically reduces the power consumption related to keypad operations.

Features

The KBC supports:

- Keypad matrix sizes of up to 16X8.
- Wake-up on interrupt mode
- Continuous polling mode
- Multi-key press support (dependency on keypad HW)
- Joystick (16 ms key-press speed)

The keypad matrix provides ghost key protection in case of three or more simultaneous key presses. The system has a power ON/OFF key. The handling of this key is a little different from the rest of the keys. KBC is not aware of this difference and treats it as any other key; different modules in the Tegra 3 devices (e.g., Always ON) monitor this key when the device is powered off.

Row 0 should always be enabled. Rows that are enabled must be contiguous. For example, if we need to enable three rows, then they must be rows 0, 1 and 2. Enabling rows 0, 1, and 3, for example, is an invalid combination since the rows are not contiguous.

All the wakeup keys must be on the same column [n], other non-wakeup keys should not be part of the column [n] to avoid spurious wake-up interrupts.

Figure 18 Typical Software Scanning Flow

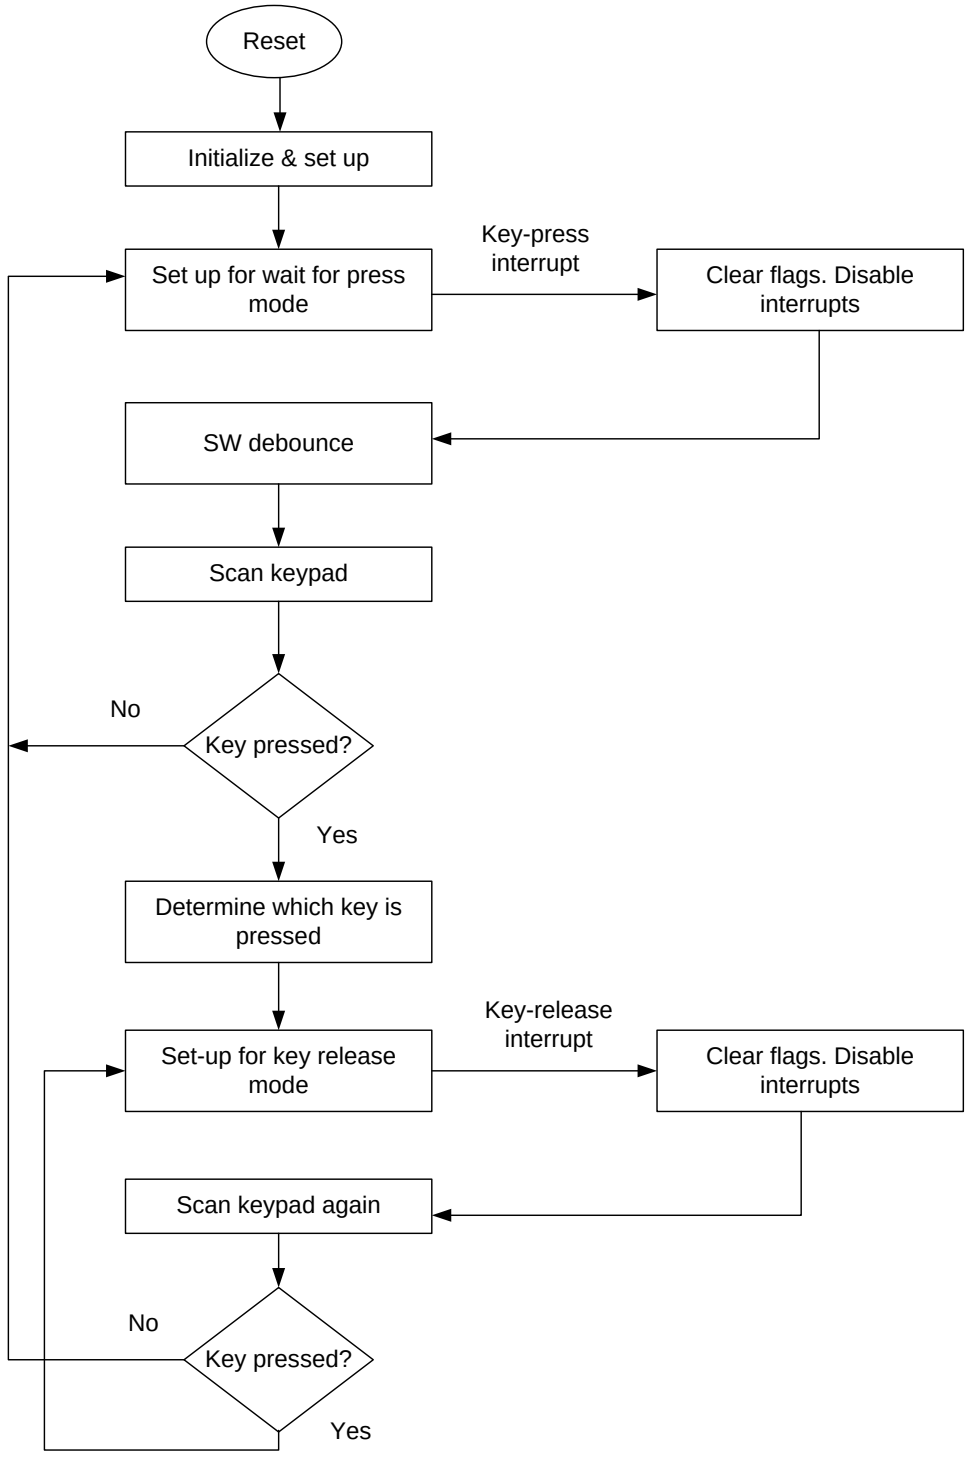


Figure 19 Software Flow with Hardware Keyboard Controller

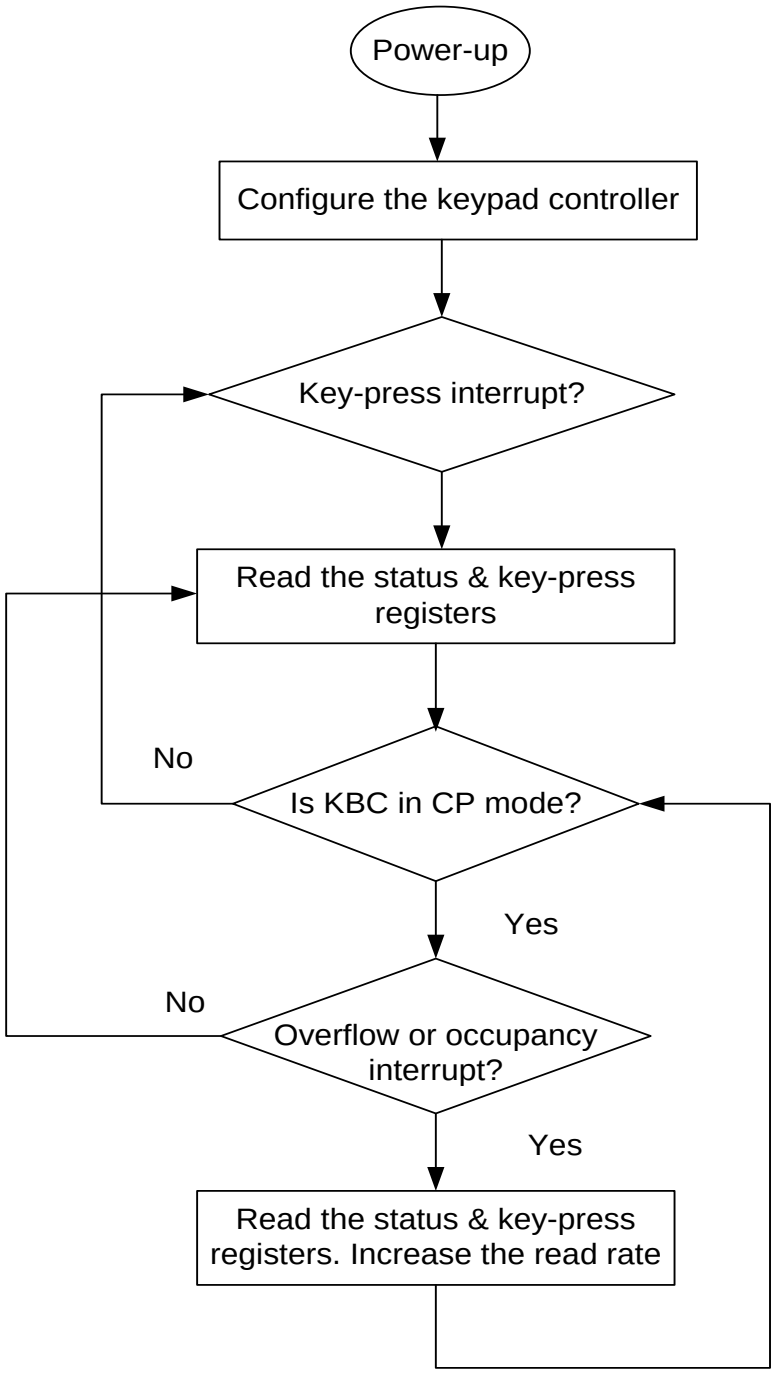

Figure 20 Power ON/OFF Key Example

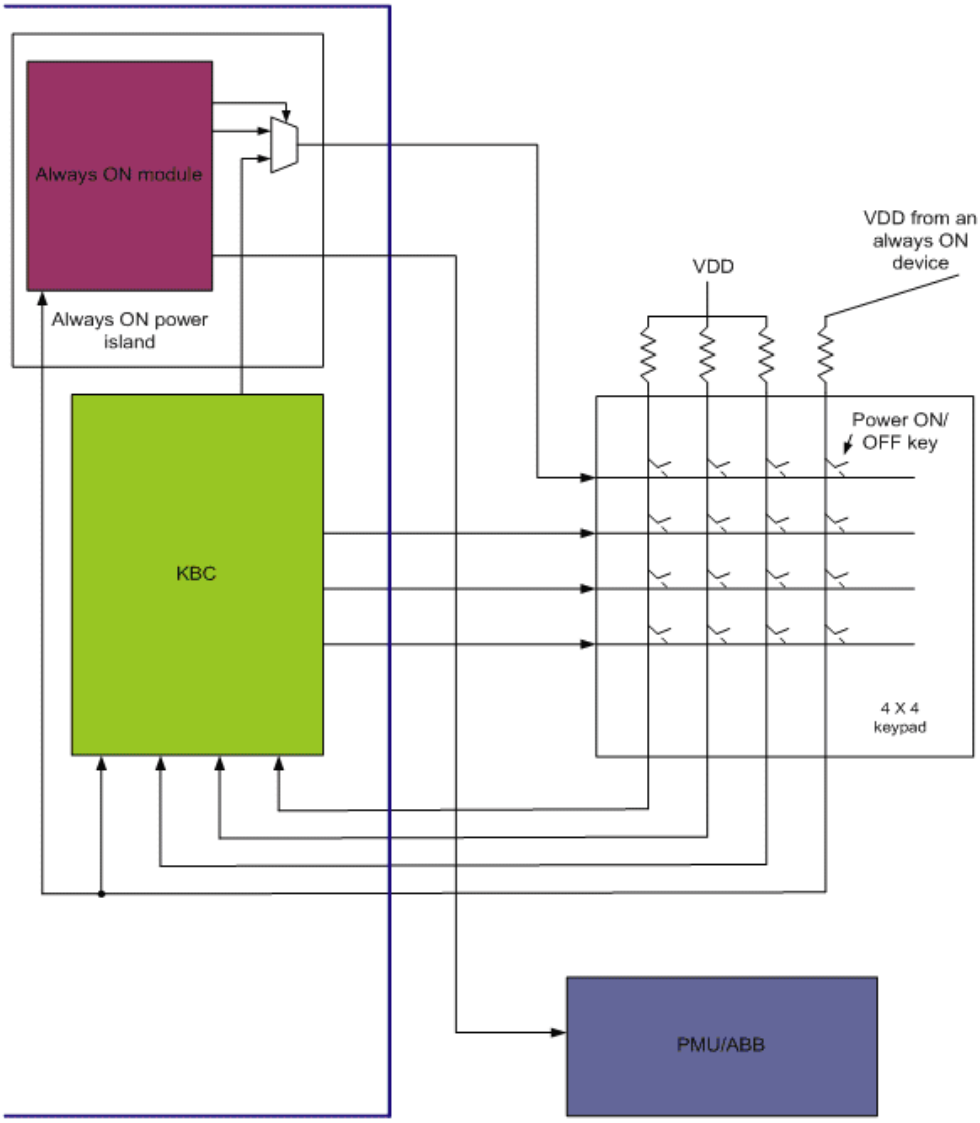
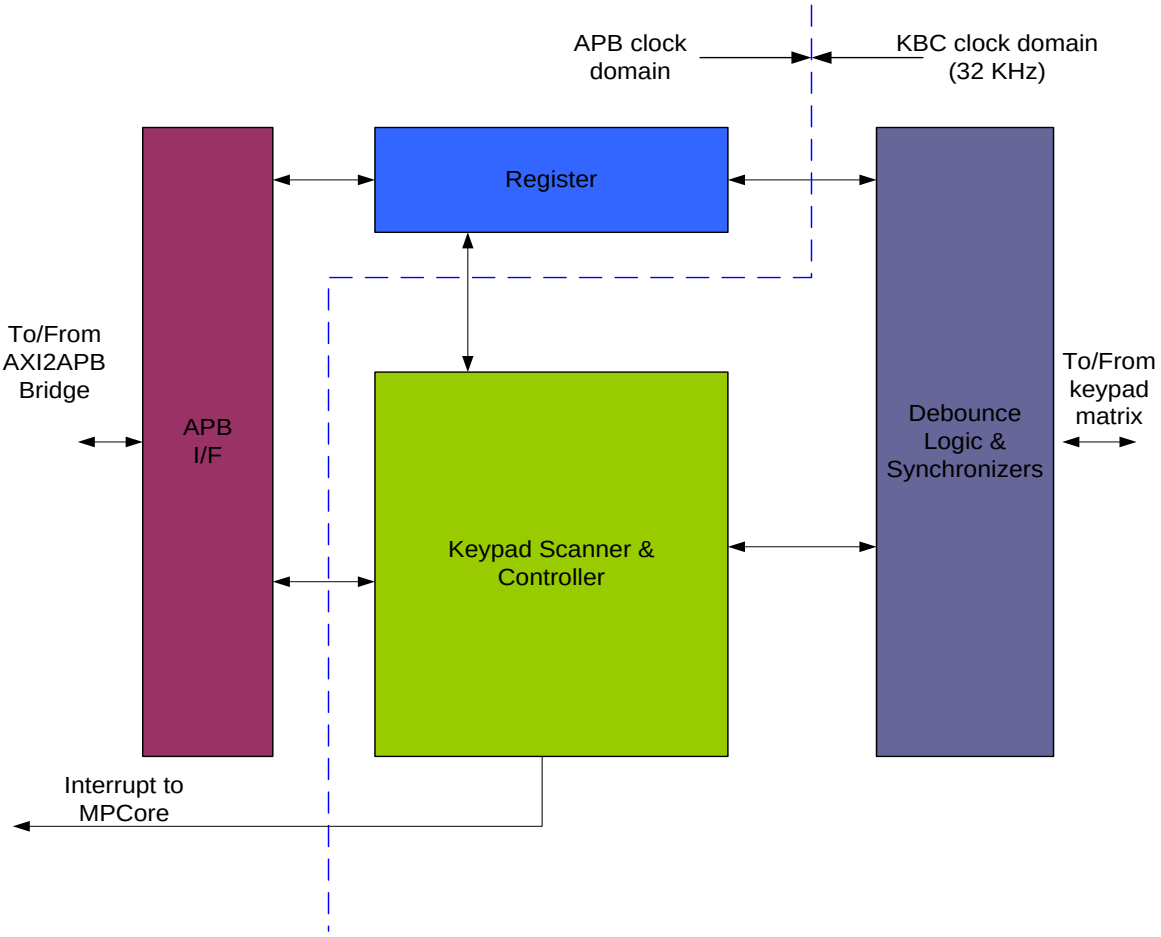


Clocking

- APB clock for APB interface and register sub-module
- KBC clock for keypad scanner and controller (32 KHz)

13.1 Functionality

Figure 21. KBC Functional Block Diagram



The keyboard controller is enabled when the enable bit is set and some pins are configured for interfacing with keypad matrix. The pins which are not interfaced to keypad matrix can be used as GPIO pins. To configure the KBC, the following registers should be programmed:

- APBDEV_KBC_ROW_CFG
- APBDEV_KBC_INT
- APBDEV_KBC_COL_CFG
- APBDEV_KBC_CONTROL

All the pins interfacing with keypad use de-bounce logic to detect a valid key press (filter out glitches).

Initially, the KBC is in wake-up state on key-press (WuKP). In this mode, it waits for any key-press. All rows are driven low to detect any key-press in this state. Once a key is pressed, KBC generates an optional key-press interrupt (KP_INT_STATUS in APBDEV_KBC_INT register), goes to continuous polling (CP) state and starts scanning after INIT_DLY_VAL (in APBDEV_KBC_INIT_DLY register) cycles.

In CP state, the delay between two consecutive full scans is RPT_DLY_VAL (in APBDEV_KBC_RPT_DLY register) cycles. In CP state, it scans all the rows one-by-one by driving one row low while other rows are configured as input so they are driven "Z". Then all the columns are sampled for each row scan.

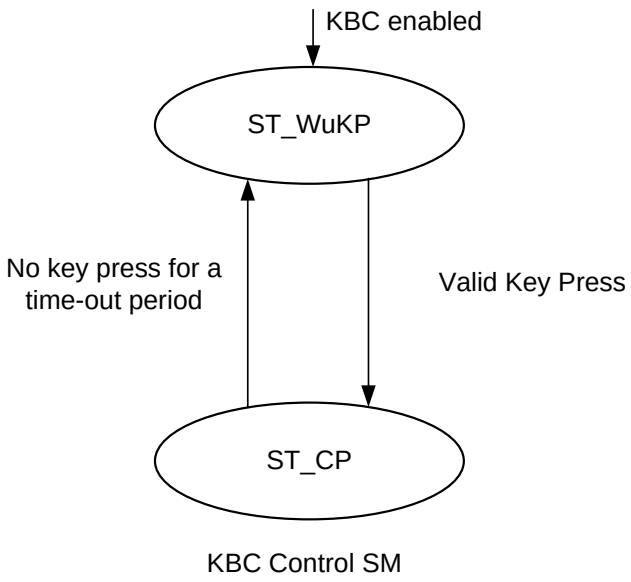
The driving of rows and sampling of columns is based on de-bounce cycle. The KBC cycle is 32 KHz (time period = 31.25 microseconds). So if de-bounce count is 4, one row scan takes 125 microseconds. One complete scan of all rows (16 max.) takes 2 milliseconds. In one second there can be 500 complete scans (if RPT_DLY_VAL = 0).

KBC supports up to eight simultaneous key-presses per complete scan. These eight key numbers are stored in the registers APBDEV_KBC_KP_ENT0 and APBDEV_KBC_KP_ENT1. The FIFO pointer increments on the second register entry register (APBDEV_KBC_KP_ENT1) read. Software should always read the two entry registers consecutively. It should first read APBDEV_KBC_KP_ENT0 and then read APBDEV_KBC_KP_ENT1.

To avoid any wrong key-press more than once, software should see the AV_FIFO_CNT value in APBDEV_KBC_INT register. The entry registers give new key press information only when AV_FIFO_CNT value is non-zero. A zero value indicates that there are no new key presses after the last read. To indicate whether an entry is valid or not, a valid bit is associated with every entry in the two entry registers.

Software should read the entry register fast enough in CP state to avoid overflow. To avoid an overflow in case of slow reads, the first level warning indicator can be programmed in FIFO_TH_CNT field of the APBDEV_KBC_CONTROL register. An optional interrupt (FIFO_CNT_INT_STATUS in APBDEV_KBC_INT register) can be generated when the FIFO occupancy count reaches this value. In case of overflow an optional interrupt (FIFO_OVF_INT_STATUS in APBDEV_KBC_INT register) is generated and software will have two options of treating the new entries. It can either drop them or overwrite them. This bit is FIFO_MODE in APBDEV_KBC_CONTROL register. Figure below shows KBC control the SM.

Figure 22 KBC Control Logic



13.2 Micro-Architecture

13.2.1 Keypad Matrix

The maximum supported keypad matrix size varies by the Tegra 3 package variation.

The KBC controller itself can support up to a 16x8 keypad matrix (16 rows and 8 columns). Up to eight simultaneous key presses can be stored per full scan (row scanning). Storage for key press events is as follows: an asynchronous FIFO stores 1 key press event, a synchronous FIFO stores eight events and a register stores 1 event.

A minimum of two rows must always be enabled.

13.2.2 Additional Interface Signals

kbc_interrrupt : An interrupt in the 32 KHz domain is sent to PMC and is used to wake up the system.

13.2.3 Pull-ups and pull-downs in pads

All the pads have pull-ups and pull-down bits which can be programmed by the software per your requirement(s). Contact your NVIDIA representative for details on the pullup/pulldown registers.

Rows are always output to the Tegra 3 and Columns are inputs. Row and Columns for the IO can be programmed by software as needed.

13.2.4 Ghost Key Detection

Ghost key detection is built-in to the way scanning interacts with keys that are simple switches. The solution is to have a diode in series with the key switch to avoid the ghost paths.

13.3 KBC Registers

13.3.1 APBDEV_KBC_CONTROL_0

This register is the main control register. It should be configured last after configuring all other settings.

KBC Control Register

Offset: 000h | Read/Write: R/W | Reset: 0b00100000000000000000

Bit	Reset	Description
18	0x0	FIFO_MODE: Selects the behavior in case of FIFO overflow 0 = Drop the new detected key-presses 1 = Overwrite the new detected key-presses
17:14	0x4	FIFO_TH_CNT: FIFO threshold count. Keeps the threshold FIFO occupancy count. If FIFO reaches/crosses that count an optional interrupt will be raised. Should not be programmed as 0 N = Threshold occupancy count is N
13:4	0x0	DBC_CNT: De-bounce count. This value sets the De-bounce FSM associated with each KBC input pin evaluate the input transitions 0 = No De-bounce N = N KBC clocks
3	0x0	FIFO_CNT_INT_EN: FIFO threshold count interrupt enable. Setting this bit will enable interrupt when FIFO occupancy reaches/crosses the value specified in FIFO_TH_CNT 0 Disable FIFO overflow interrupt 1 Enable FIFO overflow interrupt
2	0x0	FIFO_OVF_INT_EN: FIFO overflow interrupt enable. Setting this bit will enable interrupt on FIFO overflow
1	0x0	KP_INT_EN: Key-press interrupt enable. Setting this bit will enable interrupt on any key-press 0 = DISABLE 1 = ENABLE
0	0x0	EN: Keyboard controller enable. Setting this bit will override the pins settings done in GPIO 0 = DISABLE 1 = ENABLE

13.3.2 APBDEV_KBC_INT_0

KBC Interrupt Status and Clear Register

Offset: 004h | Read/Write: R/W | Reset: 0bxxxxx000

Bit	R/W	Reset	Description
7:4	RO	X	AV_FIFO_CNT: FIFO occupancy count. Shows the number of unread registers. Read only.
3	RO	X	KBC_ST_STATUS: KBC status. Read only. 0 = WuKP (Wake-up on key-press) interrupt mode 1 = CP (Continuous polling) mode
2	RW	0x0	FIFO_CNT_INT_STATUS: FIFO threshold count interrupt status. Writing '1' to this bit will clear the interrupt 0 FIFO threshold count interrupt de-asserted 1 FIFO threshold count interrupt asserted (read) 1 Clear FIFO overflow interrupt (write)
1	RW	0x0	FIFO_OVF_INT_STATUS: FIFO overflow interrupt status. Writing '1' to this bit will clear the interrupt 0 FIFO overflow interrupt de-asserted 1 FIFO overflow interrupt asserted (read) 1 Clear FIFO overflow interrupt (write)
0	RW	0x0	KP_INT_STATUS: Key-press interrupt status. Writing '1' to this bit will clear the interrupt 0 Key-press interrupt de-asserted 1 Key-press interrupt asserted (read) 1 Clear key-press interrupt (write)

13.3.3 APBDEV_KBC_ROW_CFG0_0

This register setting will take precedence in case same GPIO pin is configured in column register also. It does the mapping between GPIO pins and rows of keypad matrix. It configures for GPIO pin# 0 to 5.

First Row Configuration Register

Offset: 008h | Read/Write: R/W | Reset: 0b00000000000000000000000000000000

Bit	Reset	Description
29:26	0x0	GPIO_5_ROW_NUM: Mapping of GPIO pin# 5 to row number. Valid only if GPIO_5_ROW_EN is set. Indicates row number 0x0 = Row number 0 0xF = Row number 15
25	0x0	GPIO_5_ROW_EN: Indicates whether GPIO pin# 5 is mapped to any row of keypad matrix. This bit overrides any setting done for pin# 5 in column configuration 0 = NOT_MAPPED 1 = MAPPED
24:21	0x0	GPIO_4_ROW_NUM: Mapping of GPIO pin# 4 to row number. Valid only if GPIO_4_ROW_EN is set. Indicates row number 0x0 = Row number 0 0xF = Row number 15
20	0x0	GPIO_4_ROW_EN: Indicates whether GPIO pin# 4 is mapped to any row of keypad matrix. This bit overrides any setting done for pin# 4 in column configuration 0 = NOT_MAPPED 1 = MAPPED
19:16	0x0	GPIO_3_ROW_NUM: Mapping of GPIO pin# 3 to row number. Valid only if GPIO_3_ROW_EN is set. Indicates row number 0x0 = Row number 0 0xF = Row number 15
15	0x0	GPIO_3_ROW_EN: Indicates whether GPIO pin# 3 is mapped to any row of keypad matrix. This bit overrides any setting done for pin# 3 in column configuration 0 = NOT_MAPPED 1 = MAPPED

Bit	Reset	Description
14:11	0x0	GPIO_2_ROW_NUM: Mapping of GPIO pin# 2 to row number. Valid only if GPIO_2_ROW_EN is set. Indicates row number 0x0 = Row number 0 0xF = Row number 15
10	0x0	GPIO_2_ROW_EN: Indicates whether GPIO pin# 2 is mapped to any row of keypad matrix. This bit overrides any setting done for pin# 2 in column configuration 0 = NOT_MAPPED 1 = MAPPED
9:6	0x0	GPIO_1_ROW_NUM: Mapping of GPIO pin# 1 to row number. Valid only if GPIO_1_ROW_EN is set. Indicates row number 0x0 = Row number 0 0xF = Row number 15
5	0x0	GPIO_1_ROW_EN: Indicates whether GPIO pin# 1 is mapped to any row of keypad matrix. This bit overrides any setting done for pin# 1 in column configuration 0 = NOT_MAPPED 1 = MAPPED
4:1	0x0	GPIO_0_ROW_NUM: Mapping of GPIO pin# 0 to row number. Valid only if GPIO_0_ROW_EN is set. Indicates row number 0x0 = Row number 0 0xF = Row number 15
0	0x0	GPIO_0_ROW_EN: Indicates whether GPIO pin# 0 is mapped to any row of keypad matrix. This bit overrides any setting done for pin# 0 in column configuration 0 = NOT_MAPPED 1 = MAPPED

13.3.4 APBDEV_KBC_ROW_CFG1_0

This register setting takes precedence in case same GPIO pin is configured in column register also. It does the mapping between GPIO pins and rows of keypad matrix. It configures for GPIO pin# 6 to 11.

Second Row Configuration Register

Offset: 00ch | Read/Write: R/W | Reset: 0b00000000000000000000000000000000

Bit	Reset	Description
29:26	0x0	GPIO_11_ROW_NUM: Mapping of GPIO pin# 11 to row number. Valid only if GPIO_11_ROW_EN is set. Indicates row number 0x0 = Row number 0 0xF = Row number 15
25	0x0	GPIO_11_ROW_EN: Indicates whether GPIO pin# 11 is mapped to any row of keypad matrix. This bit overrides any setting done for pin# 11 in column configuration 0 = NOT_MAPPED 1 = MAPPED
24:21	0x0	GPIO_10_ROW_NUM: Mapping of GPIO pin# 10 to row number. Valid only if GPIO_10_ROW_EN is set. Indicates row number 0x0 = Row number 0 0xF = Row number 15
20	0x0	GPIO_10_ROW_EN: Indicates whether GPIO pin# 10 is mapped to any row of keypad matrix. This bit overrides any setting done for pin# 10 in column configuration 0 = NOT_MAPPED 1 = MAPPED
19:16	0x0	GPIO_9_ROW_NUM: Mapping of GPIO pin# 9 to row number. Valid only if GPIO_9_ROW_EN is set. Indicates row number 0x0 = Row number 0 0xF = Row number 15
15	0x0	GPIO_9_ROW_EN: Indicates whether GPIO pin# 9 is mapped to any row of keypad matrix. This bit overrides any setting done for pin# 9 in column configuration 0 = NOT_MAPPED

Bit	Reset	Description
		1 = MAPPED
14:11	0x0	GPIO_8_ROW_NUM: Mapping of GPIO pin# 8 to row number. Valid only if GPIO_8_ROW_EN is set. Indicates row number 0x0 = Row number 0 0xF = Row number 15
10	0x0	GPIO_8_ROW_EN: Indicates whether GPIO pin# 8 is mapped to any row of keypad matrix. This bit overrides any setting done for pin# 8 in column configuration 0 = NOT_MAPPED 1 = MAPPED
9:6	0x0	GPIO_7_ROW_NUM: Mapping of GPIO pin# 7 to row number. Valid only if GPIO_7_ROW_EN is set. Indicates row number 0x0 = Row number 0 0xF = Row number 15
5	0x0	GPIO_7_ROW_EN: Indicates whether GPIO pin# 7 is mapped to any row of keypad matrix. This bit overrides any setting done for pin# 7 in column configuration 0 = NOT_MAPPED 1 = MAPPED
4:1	0x0	GPIO_6_ROW_NUM: Mapping of GPIO pin# 6 to row number. Valid only if GPIO_6_ROW_EN is set. Indicates row number 0x0 = Row number 0 0xF = Row number 15
0	0x0	GPIO_6_ROW_EN: Indicates whether GPIO pin# 6 is mapped to any row of keypad matrix. This bit overrides any setting done for pin# 6 in column configuration 0 = NOT_MAPPED 1 = MAPPED

13.3.5 APBDEV_KBC_ROW_CFG2_0

This register setting takes precedence in case same GPIO pin is configured in column register also. It does the mapping between GPIO pins and rows of keypad matrix. It configures for GPIO pin# 12 to 17.

Third Row Configuration Register

Offset: 010h | Read/Write: R/W | Reset: 0b00000000000000000000000000000000

Bit	Reset	Description
29:26	0x0	GPIO_17_ROW_NUM: Mapping of GPIO pin# 17 to row number. Valid only if GPIO_17_ROW_EN is set. Indicates row number 0x0 = Row number 0 0xF = Row number 15
25	0x0	GPIO_17_ROW_EN: Indicates whether GPIO pin# 17 is mapped to any row of keypad matrix. This bit overrides any setting done for pin# 17 in column configuration 0 = NOT_MAPPED 1 = MAPPED
24:21	0x0	GPIO_16_ROW_NUM: Mapping of GPIO pin# 16 to row number. Valid only if GPIO_16_ROW_EN is set. Indicates row number 0x0 = Row number 0 0xF = Row number 15
20	0x0	GPIO_16_ROW_EN: Indicates whether GPIO pin# 16 is mapped to any row of keypad matrix. This bit overrides any setting done for pin# 16 in column configuration 0 = NOT_MAPPED 1 = MAPPED
19:16	0x0	GPIO_15_ROW_NUM: Mapping of GPIO pin# 15 to row number. Valid only if GPIO_15_ROW_EN is set. Indicates row number 0x0 = Row number 0 0xF = Row number 15
15	0x0	GPIO_15_ROW_EN: Indicates whether GPIO pin# 15 is mapped to any row of keypad

Bit	Reset	Description
		matrix. This bit overrides any setting done for pin# 15 in column configuration 0 = NOT_MAPPED 1 = MAPPED
14:11	0x0	GPIO_14_ROW_NUM: Mapping of GPIO pin# 14 to row number. Valid only if GPIO_14_ROW_EN is set. Indicates row number 0x0 = Row number 0 0xF = Row number 15
10	0x0	GPIO_14_ROW_EN: Indicates whether GPIO pin# 14 is mapped to any row of keypad matrix. This bit overrides any setting done for pin# 14 in column configuration 0 = NOT_MAPPED 1 = MAPPED
9:6	0x0	GPIO_13_ROW_NUM: Mapping of GPIO pin# 13 to row number. Valid only if GPIO_13_ROW_EN is set. Indicates row number 0x0 = Row number 0 0xF = Row number 15
5	0x0	GPIO_13_ROW_EN: Indicates whether GPIO pin# 13 is mapped to any row of keypad matrix. This bit overrides any setting done for pin# 13 in column configuration 0 = NOT_MAPPED 1 = MAPPED
4:1	0x0	GPIO_12_ROW_NUM: Mapping of GPIO pin# 12 to row number. Valid only if GPIO_12_ROW_EN is set. Indicates row number 0x0 = Row number 0 0xF = Row number 15
0	0x0	GPIO_12_ROW_EN: Indicates whether GPIO pin# 12 is mapped to any row of keypad matrix. This bit overrides any setting done for pin# 12 in column configuration 0 = NOT_MAPPED 1 = MAPPED

13.3.6 APBDEV_KBC_ROW_CFG3_0

This register setting takes precedence in case same GPIO pin is configured in column register also. It does the mapping between GPIO pins & rows of keypad matrix. It configures for GPIO pin# 18 to 23.

Fourth Row Configuration Register

Offset: 014h | Read/Write: R/W | Reset: 0b00000000000000000000000000000000

Bit	Reset	Description
29:26	0x0	GPIO_23_ROW_NUM: Mapping of GPIO pin# 23 to row number. Valid only if GPIO_21 is set. Indicates row number 0x0 = Row number 0 0xF = Row number 15
25	0x0	GPIO_23_ROW_EN: Indicates whether GPIO pin# 23 is mapped to any row of keypad matrix. This bit overrides any setting done for pin# 23 in column configuration 0 = NOT_MAPPED 1 = MAPPED
24:21	0x0	GPIO_22_ROW_NUM: Mapping of GPIO pin# 22 to row number. Valid only if GPIO_21 is set. Indicates row number 0x0 = Row number 0 0xF = Row number 15
20	0x0	GPIO_22_ROW_EN: Indicates whether GPIO pin# 22 is mapped to any row of keypad matrix. This bit overrides any setting done for pin# 22 in column configuration 0 = NOT_MAPPED 1 = MAPPED
19:16	0x0	GPIO_21_ROW_NUM: Mapping of GPIO pin# 21 to row number. Valid only if GPIO_21 is set. Indicates row number 0x0 = Row number 0 0xF = Row number 15
15	0x0	GPIO_21_ROW_EN: Indicates whether GPIO pin# 21 is mapped to any row of keypad matrix. This bit overrides any setting done for pin# 21 in column configuration

Bit	Reset	Description
		0 = NOT_MAPPED 1 = MAPPED
14:11	0x0	GPIO_20_ROW_NUM: Mapping of GPIO pin# 20 to row number. Valid only if GPIO_20 is set. Indicates row number 0x0 = Row number 0 0xF = Row number 15
10	0x0	GPIO_20_ROW_EN: Indicates whether GPIO pin# 20 is mapped to any row of keypad matrix. This bit overrides any setting done for pin# 20 in column configuration 0 = NOT_MAPPED 1 = MAPPED
9:6	0x0	GPIO_19_ROW_NUM: Mapping of GPIO pin# 19 to row number. Valid only if GPIO_19_ROW_EN is set. Indicates row number 0x0 = Row number 0 0xF = Row number 15
5	0x0	GPIO_19_ROW_EN: Indicates whether GPIO pin# 19 is mapped to any row of keypad matrix. This bit overrides any setting done for pin# 19 in column configuration 0 = NOT_MAPPED 1 = MAPPED
4:1	0x0	GPIO_18_ROW_NUM: Mapping of GPIO pin# 18 to row number. Valid only if GPIO_18_ROW_EN is set. Indicates row number 0x0 = Row number 0 0xF = Row number 15
0	0x0	GPIO_18_ROW_EN: Indicates whether GPIO pin# 18 is mapped to any row of keypad matrix. This bit overrides any setting done for pin# 18 in column configuration 0 = NOT_MAPPED 1 = MAPPED

13.3.7 APBDEV_KBC_COL_CFG0_0

This register does the mapping between GPIO pins & columns of keypad matrix. It configures for GPIO pin# 0 to 7.

First Column Configuration Register

Offset: 018h | Read/Write: R/W | Reset: 0b00000000000000000000000000000000

Bit	Reset	Description
31:29	0x0	GPIO_7_COL_NUM: Mapping of GPIO pin# 7 to column number. Valid only if GPIO_7_COL_EN is set. Indicates row number 0x0 = Column number 0 0x7 = Column number 7
28	0x0	GPIO_7_COL_EN: Indicates whether GPIO pin# 7 is mapped to any column of keypad matrix. This bit should be set to '1' only when GPIO_7_ROW_EN in ROW_CFG1 is set to 0. 0 = NOT_MAPPED 1 = MAPPED
27:25	0x0	GPIO_6_COL_NUM: Mapping of GPIO pin# 6 to column number. Valid only if GPIO_6_COL_EN is set. Indicates row number 0x0 = Column number 0 0x7 = Column number 7
24	0x0	GPIO_6_COL_EN: Indicates whether GPIO pin# 6 is mapped to any column of keypad matrix. This bit should be set to '1' only when GPIO_6_ROW_EN in ROW_CFG1 is set to 0. 0 = NOT_MAPPED 1 = MAPPED
23:21	0x0	GPIO_5_COL_NUM: Mapping of GPIO pin# 5 to column number. Valid only if GPIO_5_COL_EN is set. Indicates row number 0x0 = Column number 0 0x7 = Column number 7
20	0x0	GPIO_5_COL_EN: Indicates whether GPIO pin# 5 is mapped to any column of keypad matrix. This bit should be set to '1' only when GPIO_5_ROW_EN in ROW_CFG0 is set to 0.

Bit	Reset	Description
		0 = NOT_MAPPED 1 = MAPPED
19:17	0x0	GPIO_4_COL_NUM: Mapping of GPIO pin# 4 to column number. Valid only if GPIO_4_COL_EN is set. Indicates row number 0x0 = Column number 0 0x7 = Column number 7
16	0x0	GPIO_4_COL_EN: Indicates whether GPIO pin# 4 is mapped to any column of keypad matrix. This bit should be set to '1' only when GPIO_4_ROW_EN in ROW_CFG0 is set to 0. 0 = NOT_MAPPED 1 = MAPPED
15:13	0x0	GPIO_3_COL_NUM: Mapping of GPIO pin# 3 to column number. Valid only if GPIO_3_COL_EN is set. Indicates row number 0x0 = Column number 0 0x7 = Column number 7
12	0x0	GPIO_3_COL_EN: Indicates whether GPIO pin# 3 is mapped to any column of keypad matrix. This bit should be set to '1' only when GPIO_3_ROW_EN in ROW_CFG0 is set to 0. 0 = NOT_MAPPED 1 = MAPPED
11:9	0x0	GPIO_2_COL_NUM: Mapping of GPIO pin# 2 to column number. Valid only if GPIO_2_COL_EN is set. Indicates row number 0x0 = Column number 0 0x7 = Column number 7
8	0x0	GPIO_2_COL_EN: Indicates whether GPIO pin# 2 is mapped to any column of keypad matrix. This bit should be set to '1' only when GPIO_2_ROW_EN in ROW_CFG0 is set to 0. 0 = NOT_MAPPED 1 = MAPPED
7:5	0x0	GPIO_1_COL_NUM: Mapping of GPIO pin# 1 to column number. Valid only if GPIO_1_COL_EN is set. Indicates row number 0x0 = Column number 0 0x7 = Column number 7
4	0x0	GPIO_1_COL_EN: Indicates whether GPIO pin# 1 is mapped to any column of keypad matrix. This bit should be set to '1' only when GPIO_1_ROW_EN in ROW_CFG0 is set to 0. 0 = NOT_MAPPED 1 = MAPPED
3:1	0x0	GPIO_0_COL_NUM: Mapping of GPIO pin# 0 to column number. Valid only if GPIO_0_COL_EN is set. Indicates row number 0x0 = Column number 0 0x7 = Column number 7
0	0x0	GPIO_0_COL_EN: Indicates whether GPIO pin# 0 is mapped to any column of keypad matrix. This bit should be set to '1' only when GPIO_0_ROW_EN in ROW_CFG0 is set to 0. 0 = NOT_MAPPED 1 = MAPPED

13.3.8 APBDEV_KBC_COL_CFG1_0

It does the mapping between GPIO pins & columns of keypad matrix. It configures for GPIO pin# 8 to 15.

Second Column Configuration Register

Offset: 01ch | Read/Write: R/W | Reset: 0b00000000000000000000000000000000

Bit	Reset	Description
31:29	0x0	GPIO_15_COL_NUM: Mapping of GPIO pin# 15 to column number. Valid only if GPIO_15_COL_EN is set. Indicates row number 0x0 = Column number 0 0x7 = Column number 7
28	0x0	GPIO_15_COL_EN: Indicates whether GPIO pin# 15 is mapped to any column of keypad

Bit	Reset	Description
		matrix. This bit should be set to '1' only when GPIO_15_ROW_EN in ROW_CFG2 is set to 0. 0 = NOT_MAPPED 1 = MAPPED
27:25	0x0	GPIO_14_COL_NUM: Mapping of GPIO pin# 14 to column number. Valid only if GPIO_14_COL_EN is set. Indicates row number 0x0 = Column number 0 0x7 = Column number 7
24	0x0	GPIO_14_COL_EN: Indicates whether GPIO pin# 14 is mapped to any column of keypad matrix. This bit should be set to '1' only when GPIO_14_ROW_EN in ROW_CFG2 is set to 0. 0 = NOT_MAPPED 1 = MAPPED
23:21	0x0	GPIO_13_COL_NUM: Mapping of GPIO pin# 13 to column number. Valid only if GPIO_13_COL_EN is set. Indicates row number 0x0 = Column number 0 0x7 = Column number 7
20	0x0	GPIO_13_COL_EN: Indicates whether GPIO pin# 13 is mapped to any column of keypad matrix. This bit should be set to '1' only when GPIO_13_ROW_EN in ROW_CFG2 is set to 0. 0 = NOT_MAPPED 1 = MAPPED
19:17	0x0	GPIO_12_COL_NUM: Mapping of GPIO pin# 12 to column number. Valid only if GPIO_12_COL_EN is set. Indicates row number 0x0 = Column number 0 0x7 = Column number 7
16	0x0	GPIO_12_COL_EN: Indicates whether GPIO pin# 12 is mapped to any column of keypad matrix. This bit should be set to '1' only when GPIO_12_ROW_EN in ROW_CFG2 is set to 0. 0 = NOT_MAPPED 1 = MAPPED
15:13	0x0	GPIO_11_COL_NUM: Mapping of GPIO pin# 11 to column number. Valid only if GPIO_11_COL_EN is set. Indicates row number 0x0 = Column number 0 0x7 = Column number 7
12	0x0	GPIO_11_COL_EN: Indicates whether GPIO pin# 11 is mapped to any column of keypad matrix. This bit should be set to '1' only when GPIO_11_ROW_EN in ROW_CFG1 is set to 0. 0 = NOT_MAPPED 1 = MAPPED
11:9	0x0	GPIO_10_COL_NUM: Mapping of GPIO pin# 10 to column number. Valid only if GPIO_10_COL_EN is set. Indicates row number 0x0 = Column number 0 0x7 = Column number 7
8	0x0	GPIO_10_COL_EN: Indicates whether GPIO pin# 10 is mapped to any column of keypad matrix. This bit should be set to '1' only when GPIO_10_ROW_EN in ROW_CFG1 is set to 0. 0 = NOT_MAPPED 1 = MAPPED
7:5	0x0	GPIO_9_COL_NUM: Mapping of GPIO pin# 9 to column number. Valid only if GPIO_9_COL_EN is set. Indicates row number 0x0 = Column number 0 0x7 = Column number 7
4	0x0	GPIO_9_COL_EN: Indicates whether GPIO pin# 9 is mapped to any column of keypad matrix. This bit should be set to '1' only when GPIO_9_ROW_EN in ROW_CFG1 is set to 0. 0 = NOT_MAPPED 1 = MAPPED
3:1	0x0	GPIO_8_COL_NUM: Mapping of GPIO pin# 8 to column number. Valid only if

Bit	Reset	Description
		GPIO_8_COL_EN is set. Indicates row number 0x0 = Column number 0 0x7 = Column number 7
0	0x0	GPIO_8_COL_EN: Indicates whether GPIO pin# 8 is mapped to any column of keypad matrix. This bit should be set to '1' only when GPIO_8_ROW_EN in ROW_CFG1 is set to 0. 0 = NOT_MAPPED 1 = MAPPED

13.3.9 APBDEV_KBC_COL_CFG2_0

It does the mapping between GPIO pins & columns of keypad matrix. It configures for GPIO pin# 16 to 23.

Third Column Configuration Register

Offset: 020h | Read/Write: R/W | Reset: 0b00000000000000000000000000000000

Bit	Reset	Description
31:29	0x0	GPIO_23_COL_NUM: Mapping of GPIO pin# 23 to column number. Valid only if GPIO_23 is set. Indicates row number 0x0 = Column number 0 0x7 = Column number 7
28	0x0	GPIO_23_COL_EN: Indicates whether GPIO pin# 23 is mapped to any column of keypad matrix. This bit should be set to '1' only when GPIO_22 in ROW_CFG3 is set to 0. 0 = NOT_MAPPED 1 = MAPPED
27:25	0x0	GPIO_22_COL_NUM: Mapping of GPIO pin# 22 to column number. Valid only if GPIO_22 is set. Indicates row number 0x0 = Column number 0 0x7 = Column number 7
24	0x0	GPIO_22_COL_EN: Indicates whether GPIO pin# 22 is mapped to any column of keypad matrix. This bit should be set to '1' only when GPIO_22 in ROW_CFG3 is set to 0. 0 = NOT_MAPPED 1 = MAPPED
23:21	0x0	GPIO_21_COL_NUM: Mapping of GPIO pin# 21 to column number. Valid only if GPIO_21 is set. Indicates row number 0x0 = Column number 0 0x7 = Column number 7
20	0x0	GPIO_21_COL_EN: Indicates whether GPIO pin# 21 is mapped to any column of keypad matrix. This bit should be set to '1' only when GPIO_21 in ROW_CFG3 is set to 0. 0 = NOT_MAPPED 1 = MAPPED
19:17	0x0	GPIO_20_COL_NUM: Mapping of GPIO pin# 20 to column number. Valid only if GPIO_20 is set. Indicates row number 0x0 = Column number 0 0x7 = Column number 7
16	0x0	GPIO_20_COL_EN: Indicates whether GPIO pin# 20 is mapped to any column of keypad matrix. This bit should be set to '1' only when GPIO_20 in ROW_CFG3 is set to 0. 0 = NOT_MAPPED 1 = MAPPED
15:13	0x0	GPIO_19_COL_NUM: Mapping of GPIO pin# 19 to column number. Valid only if GPIO_19_COL_EN is set. Indicates row number 0x0 = Column number 0 0x7 = Column number 7
12	0x0	GPIO_19_COL_EN: Indicates whether GPIO pin# 19 is mapped to any column of keypad matrix. This bit should be set to '1' only when GPIO_19_ROW_EN in ROW_CFG3 is set to 0. 0 = NOT_MAPPED 1 = MAPPED
11:9	0x0	GPIO_18_COL_NUM: Mapping of GPIO pin# 18 to column number. Valid only if GPIO_18_COL_EN is set. Indicates row number 0x0 = Column number 0 0x7 = Column

Bit	Reset	Description
		number 7
8	0x0	GPIO_18_COL_EN: Indicates whether GPIO pin# 18 is mapped to any column of keypad matrix. This bit should be set to '1' only when GPIO_18_ROW_EN in ROW_CFG3 is set to 0. 0 = NOT_MAPPED 1 = MAPPED
7:5	0x0	GPIO_17_COL_NUM: Mapping of GPIO pin# 17 to column number. Valid only if GPIO_17_COL_EN is set. Indicates row number 0x0 = Column number 0 0x7 = Column number 7
4	0x0	GPIO_17_COL_EN: Indicates whether GPIO pin# 17 is mapped to any column of keypad matrix. This bit should be set to '1' only when GPIO_17_ROW_EN in ROW_CFG2 is set to 0. 0 = NOT_MAPPED 1 = MAPPED
3:1	0x0	GPIO_16_COL_NUM: Mapping of GPIO pin# 16 to column number. Valid only if GPIO_16_COL_EN is set. Indicates row number 0x0 = Column number 0 0x7 = Column number 7
0	0x0	GPIO_16_COL_EN: Indicates whether GPIO pin# 16 is mapped to any column of keypad matrix. This bit should be set to '1' only when GPIO_16_ROW_EN in ROW_CFG2 is set to 0. 0 = NOT_MAPPED 1 = MAPPED

13.3.10 APBDEV_KBC_TO_CNT_0

This register holds the time-out count value. In CP state, if the corresponding counter crosses this value KBC goes back to WuKP (Wake-up on Key-press state).

Continuous Polling (CP) State Time-out Count Register

Offset: 024h | Read/Write: R/W | Reset: 0b00100111000100000000

Bit	Reset	Description
19:0	0x27100	TO_CNT_VAL: Time-out count value. The default value is 5 seconds. The value should be calculated for a 32 KHz clock.

13.3.11 APBDEV_KBC_INIT_DLY_0

This register holds the initial delay for scan when KBC goes from WuKP mode to CP mode.

Offset: 028h | Read/Write: R/W | Reset: 0b00000000010000000000

Bit	Reset	Description
19:0	0x400	INIT_DLY_VAL: Initial delay value. The default value is 32.25 milliseconds. The value should be calculated for a 32 KHz clock.

13.3.12 APBDEV_KBC_RPT_DLY_0

This register holds the repeat scan delay. This is the delay between two successive scans in CP mode.

Offset: 02ch | Read/Write: R/W | Reset: 0b00000000010000000000

Bit	Reset	Description
19:0	0x400	RPT_DLY_VAL: delay value. The default value is 32.25 milliseconds. The value should be calculated for a 32 KHz clock.

13.3.13 APBDEV_KBC_KP_ENT0_0

This register holds the key numbers of the keys which have been pressed.

It holds the first four entries

NOTE: Both the entry registers should be read consecutively. A read of first register changes the FIFO read pointer

First Key-Press Entries Register

Offset: 030h | Read/Write: RO | Reset: 0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx

Bit	Reset	Description
31	X	KP_NEW_ENT3: Indicates whether fourth entry is valid or not 0x0 Entry not valid 0x1 Valid entry
30:27	X	KP_ROW_NUM_ENT3: Row number for fourth key. 0x0 = Row number 0, 0xF = Row number 15
26:24	X	KP_COL_NUM_ENT3: Column number for fourth key. 0x0 = Column number 0, 0x7 = Column number 7
23	X	KP_NEW_ENT2: Indicates whether third entry is valid or not 0x0. Entry not valid 0x1 Valid entry
22:19	X	KP_ROW_NUM_ENT2: Row number for third key. 0x0 = Row number 0. 0xF = Row number 15
18:16	X	KP_COL_NUM_ENT2: Column number for third key. 0x0 = Column number 0. 0x7 = Column number 7
15	X	KP_NEW_ENT1: Indicates whether second entry is valid or not 0x0. Entry not valid 0x1 Valid entry
14:11	X	KP_ROW_NUM_ENT1: Row number for second key. 0x0 = Row number 0. 0xF = Row number 15
10:8	X	KP_COL_NUM_ENT1: Column number for second key. 0x0 = Column number 0. 0x7 = Column number 7
7	X	KP_NEW_ENT0: Indicates whether first entry is valid or not. 0x0 Entry not valid. 0x1 Valid entry
6:3	X	KP_ROW_NUM_ENT0: Row number for first key. 0x0 = Row number 0. 0xF = Row number 15
2:0	X	KP_COL_NUM_ENT0: Column number for first key. 0x0 = Column number 0. 0x7 = Column number 7

13.3.14 APBDEV_KBC_KP_ENT1_0

This register holds the key numbers of the keys which have been pressed.

It holds the last four entries (out of eight entries)

NOTE: Both the entry registers should be read consecutively. A read of first register changes the FIFO read pointer

Second Key-press Entries Register

Offset: 034h | Read/Write: RO | Reset: 0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx

Bit	Reset	Description
31	X	KP_NEW_ENT7: Indicates whether eight entry is valid or not 0x0 Entry not valid 0x1 Valid entry

14.0 GPIO CONTROLLER

The Tegra® 3 devices provide a large number of potential general-purpose I/O (GPIO) pins. The actual number of available GPIO pins depends on the system pin-mux configuration. These pins are grouped as 31 8-bit ports. The ports are grouped into 8 GPIO controllers containing four 8-bit ports each. All these port pins are designed with multiplexing logic, so they can be used as either a dedicated Special Function I/O (SFIO) or a GPIO.

Features

- Multiplexed GPIO/SFIO functionality
- Protection against meta-stability for GPIO inputs (back-to-back D flip-flops)
- Interrupts are programmable on each individual GPIO pin
- Interrupt levels also programmable
- All pin configurations are independent of the other pins
- Masked-write registers

> **Note:** Some pin attributes that affect GPIO operation, including Tristate, Pullup/down, drive/schmidt control, are on Pin Group or Pin Config (group) granularity. These controls are outside the GPIO block.

Each port has a set of configuration registers, which are used for:

- GPIO/SFIO selection
- Enabling outputs
- Driving the output pin with a HIGH or LOW
- Receiving the input when in GPIO mode
- Enabling interrupts
- Checking status
- Clearing interrupts

14.1 Functionality

There are 244 pins that can function as either multiplexed Special Function I/O (SFIO) pins or General-Purpose I/O (GPIO) pins. In Special function mode, these pins are driven by the pinmux controller, where, each pin is driven by a special function controller selected based on the pinmux option (primary, alternate-1, alternate-2 and alternate-3).

This multiplexing architecture helps to support a much higher number of IOs on a minimal number of pads on the chip. There are additional pins too, that function as SFIOs only, without sharing the GPIO function. GPIO programmability gives more flexibility to the firmware. In addition to this, the GPIO architecture gives Firmware the flexibility of receiving any interrupt from an external requestor on any GPIO pin.

GPIO Pins

Each GPIO controller consists of 4 GPIO ports. Each port has a set of registers capable of controlling 8 GPIO pins. The ports for the first controller are named A, B, C, and D. The ports for the second controller are named E, F, G, and H. To find the offset of a particular register for a particular port, add the port offset from Table 29 to the register's offset. For example, the offset of GPIO Port R's GPIO_OUT register is 0x404 (Port Offset) + 0x20 (Register Offset) = 0x424.

Table 29: GPIO Controllers, Ports, and Pins

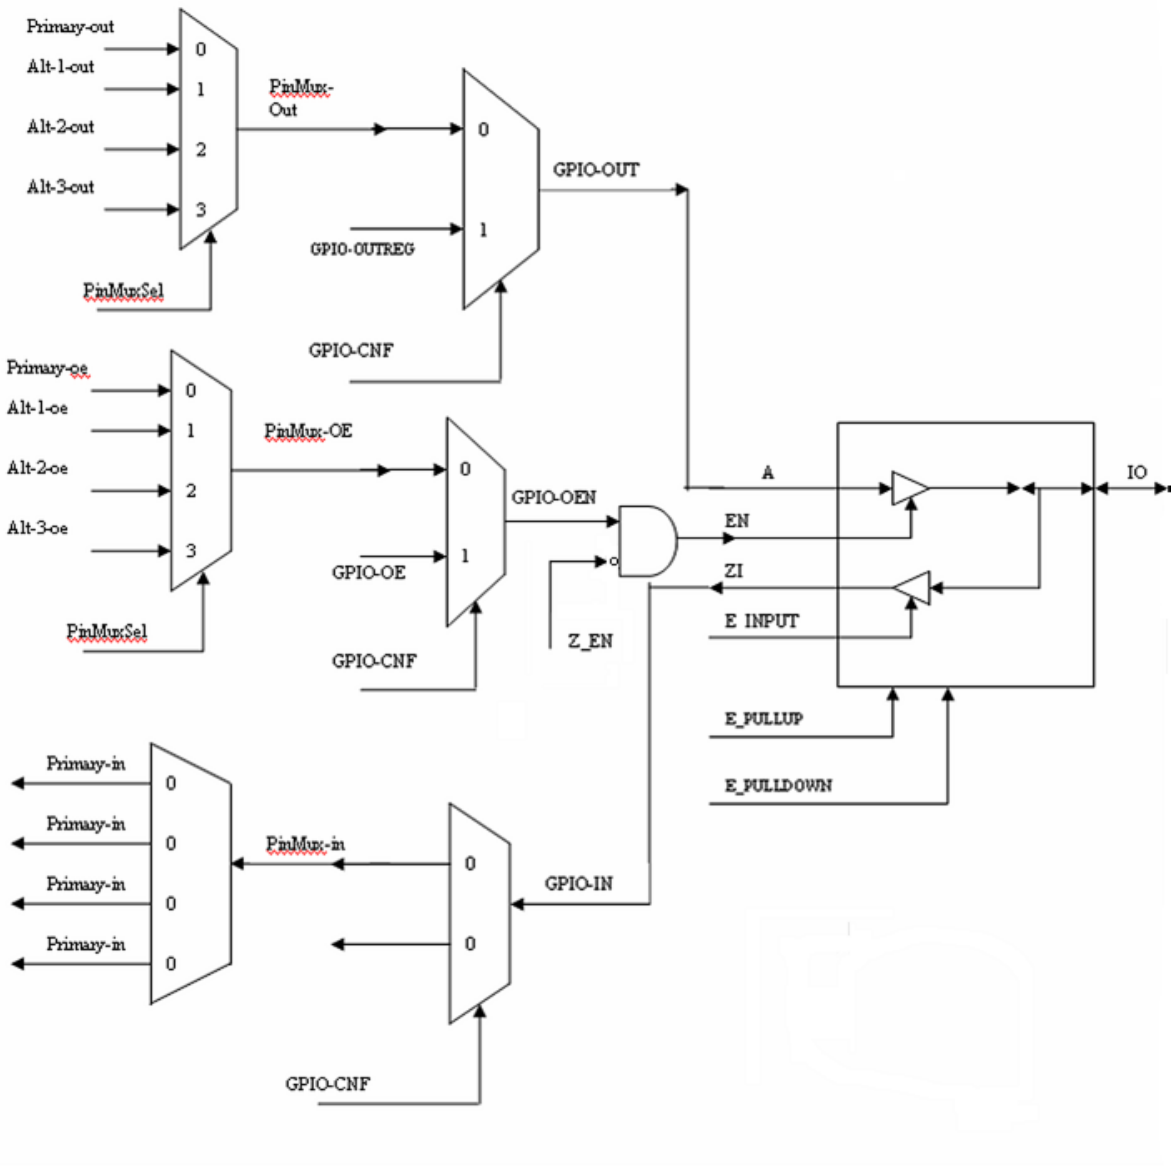
Controller	Port	Port Offset	Pins
GPIO1	Port A	0x000	GPIO_PA0 - GPIO_PA7
	Port B	0x004	GPIO_PB0 - GPIO_PB7
	Port C	0x008	GPIO_PC0 - GPIO_PC7
	Port D	0x00C	GPIO_PD0 - GPIO_PD7
GPIO2	Port E	0x100	GPIO_PE0 - GPIO_PE7
	Port F	0x104	GPIO_PF0 - GPIO_PF7
	Port G	0x108	GPIO_PG0 - GPIO_PG7
	Port H	0x10c	GPIO_PH0 - GPIO_PH7
GPIO3	Port I	0x200	GPIO_PI0 - GPIO_PI7
	Port J	0x204	GPIO_PJ0 - GPIO_PJ7
	Port K	0x208	GPIO_PK0 - GPIO_PK7
	Port L	0x20C	GPIO_PL0 - GPIO_PL7
GPIO4	Port M	0x300	GPIO_PM0 - GPIO_PM7
	Port N	0x304	GPIO_PN0 - GPIO_PN7
	Port O	0x308	GPIO_PO0 - GPIO_PO7
	Port P	0x30C	GPIO_PP0 - GPIO_PP7
GPIO5	Port Q	0x400	GPIO_PQ0 - GPIO_PQ7
	Port R	0x404	GPIO_PR0 - GPIO_PR7
	Port S	0x408	GPIO_PS0 - GPIO_PS7
	Port T	0x40c	GPIO_PT0 - GPIO_PT7
GPIO6	Port U	0x500	GPIO_PU0 - GPIO_PU7
	Port V	0x504	GPIO_PV0 - GPIO_PV7
	Port W	0x508	GPIO_PW0 - GPIO_PW7
	Port X	0x50C	GPIO_PX0 - GPIO_PX7
GPIO7	Port Y	0x600	GPIO_PY0 - GPIO_PY7
	Port Z	0x604	GPIO_PZ0 - GPIO_PZ7
	Port AA	0x608	GPIO_PAA0 - GPIO_PAA7
	Port BB	0x60C	GPIO_PBB0 - GPIO_PBB7
GPIO8	Port CC	0x700	GPIO_PCC0 - GPIO_PCC7
	Port DD	0x704	GPIO_PDD0 - GPIO_PDD7
	Port EE	0x708	GPIO_PEE0 - GPIO_PEE7

Use the appropriate GPIO_CNF register to designate a pin to act either as a GPIO as an SFIO. Setting a pin's CNF bit to 1 configures the pin to be used as a GPIO and prevents the pin from being used as for its Primary, Alternate 1, Alternate 2, or Alternate 3 SFIO function. Setting the CNF bit to 0 allows the port to be used as an SFIO.

For each pin designated to act as a GPIO, the corresponding bit in the appropriate GPIO_OE register controls the pin's output enable. When the OE bit is 1, the pin is driven LOW or HIGH according to the state of the corresponding OUT bit in the appropriate GPIO_OUT register. When the OE bit is 0, the output pin is tri-stated and can be used as an input.

Each IN bit in each GPIO_IN register contains the registered input value of a pin designated as a GPIO. The input goes through two D flip-flops to protect against meta-stability. The following figure shows how the pins are shared and multiplexed functionally.

Figure 23 SFIO/GPIO Pin Multiplexing Architecture



The SFIO output enable signals are generated automatically by the modules controlling the signals; they are not controlled through registers. However, the SFIO output enable mux does select which group of SFIO output enables signals to use based on the bits in the PIN_MUX_CTL registers.

These SFIO output enables are then sent to another mux that is controlled with the bits in the GPIO_CNF registers. Next, the selected output enables are ANDed with the bits in the TRI_STATE register. The ANDing function allows the output pins to be driven only if the TRI_STATE register bit is disabled.

In the input direction, the state of the input buffers is controlled with the DATAIN_EN signals. These signals are generated automatically by the modules controlling the signals; they are not controlled through registers. The first mux selects between the SFIO and GPIO input signals, and the last mux passes on the appropriate group of SFIO signals if so allowed.

14.2 GPIO Registers

Each port of each GPIO controller has several registers for the control and monitoring of the port's 8 GPIO pins. The registers provide per-pin control of the following features:

- GPIO_CNF_* / GPIO_MSK_CNF — Select SPIO or GPIO
- GPIO_OE_* / GPIO_MSK_OE_* — Output Enable
- GPIO_OUT_* / GPIO_MSK_OUT_* — GPIO Output Value
- GPIO_IN_* — GPIO Input Value (Read Only)
- GPIO_INT_STA_* / GPIO_MSK_INT_STA_* — GPIO Interrupt Status
- GPIO_INT_ENB_* / GPIO_MSK_INT_ENB_* — Interrupt Enable
- GPIO_INT_LVL_* / GPIO_MSK_INT_LVL_* — Interrupt Selection (Edge/Level)
- GPIO_INT_CLR_* — Interrupt Flag Set-to-Clear

Many of the control registers are accessible from two offsets. Accesses to the lower offsets affect all 8 pins for the GPIO port. Accesses to the upper offsets provide a per-pin mask capability allowing adjustments to a subset of the pins. Using the upper offsets can eliminate the need for Read-Modify-Write operations. For example, a write to GPIO_MSK_CNF can substitute for a Read-Modify-Write of GPIO_CNF.

Table 30 Tegra 3 GPIO Register Summary

Register Name	Offset (Lower: Read-Modify-Write)				Offset (Upper: Per-Pin Mask Write)			
GPIO Controller 1 – Port	**A**	**B**	**C**	**D**	**A**	**B**	**C**	**D**

2	0x0	BIT_2: GPIO mode (GPIO_CNF.x=1) must be true for this condition to be valid 0 = LOW 1 = HIGH
1	0x0	BIT_1: GPIO mode (GPIO_CNF.x=1) must be true for this condition to be valid 0 = LOW 1 = HIGH
0	0x0	BIT_0: GPIO mode (GPIO_CNF.x=1) must be true for this condition to be valid 0 = LOW 1 = HIGH

All GPIO inputs can be programmed to generate an interrupt request. This configuration is also independent of that of the other pins.

In addition, the individual trigger-level for interrupt on each input pin can be programmed as either active-on-high or active-on-low. For example, to program an active-on-high interrupt on the bit-3 of GPIO-PORT_C, write '1' into the bit-3 of

GPIO_INT.LVL.C register (this sets the interrupt to be active-on-high), and then write '1' into the bit-3 of GPIO_INT.ENB.C (this enables interrupt on the named bit).

The interrupt flag status can be read in the appropriate bit of the GPIO_INT.STA.C register. Once the programmed interrupt occurs, status should be cleared by writing into the appropriate bit of the GPIO_INT.CLR.C register. It has to be noted that the interrupt thus generated will be routed to the processor only if the corresponding bit for GPIO interrupts in the Secondary interrupt controller is enabled.

14.2.5 GPIO_INT_STA_0

GPIO mode (GPIO_CNF.x=1) and GPIO_INT.ENB.x=1 must be true for this condition to be valid. Every GPIO pin generates and Interrupt when switching from Low-High ot High-Low. Interrupt status for each port is saved in an Interrupt status registers.

This is an array of 4 identical register entries; the register fields below apply to each entry.

GPIO Port Interrupt Status Registers

Offset: 040h..04fh | Read/Write: R/W | Reset: 0b00000000

Bit	Reset	Description
7	0x0	BIT_7: GPIO mode (GPIO_CNF.x=1) and GPIO_INT.ENB.x=1 must be true for this condition to be valid. 0 = IN_ACTIVE = ACTIVE
6	0x0	BIT_6: GPIO mode (GPIO_CNF.x=1) and GPIO_INT.ENB.x=1 must be true for this condition to be valid. 0 = IN_ACTIVE 1 = ACTIVE
5	0x0	BIT_5: GPIO mode (GPIO_CNF.x=1) and GPIO_INT.ENB.x=1 must be true for this condition to be valid. 0 = IN_ACTIVE 1 = ACTIVE
4	0x0	BIT_4: GPIO mode (GPIO_CNF.x=1) and GPIO_INT.ENB.x=1 must be true for this condition to be valid. 0 = IN_ACTIVE 1 = ACTIVE
3	0x0	BIT_3: GPIO mode (GPIO_CNF.x=1) and GPIO_INT.ENB.x=1 must be true for this condition to be valid. 0 = IN_ACTIVE 1 = ACTIVE
2	0x0	BIT_2: GPIO mode (GPIO_CNF.x=1) and GPIO_INT.ENB.x=1 must be true for this condition to be valid. 0 = IN_ACTIVE 1 = ACTIVE
1	0x0	BIT_1: GPIO mode (GPIO_CNF.x=1) and GPIO_INT.ENB.x=1 must be true for this condition to be valid. 0 = IN_ACTIVE 1 = ACTIVE
0	0x0	BIT_0: GPIO mode (GPIO_CNF.x=1) and GPIO_INT.ENB.x=1 must be true for this condition to be valid. 0 = IN_ACTIVE 1 = ACTIVE

14.2.6 GPIO_INT_ENB_0

Every bit of GPIO pin needs has an enable which when enabled routes the Interrupt to Interrupt controller. This is an array of 4 identical register entries; the register fields below apply to each entry.

GPIO Port Interrupt Enable Registers

Offset: 050h..05h | Read/Write: R/W | Reset: 0b00000000

Bit	Reset	Description
7	0x0	BIT_7: GPIO mode (GPIO_CNF.x=1) must be true for this condition to be valid. 0 = DISABLE 1 = ENABLE
6	0x0	BIT_6: GPIO mode (GPIO_CNF.x=1) must be true for this condition to be valid. 0 = DISABLE 1 = ENABLE
5	0x0	BIT_5: GPIO mode (GPIO_CNF.x=1) must be true for this condition to be valid. 0 = DISABLE 1 = ENABLE
4	0x0	BIT_4: GPIO mode (GPIO_CNF.x=1) must be true for this condition to be valid. 0 = DISABLE 1 = ENABLE
3	0x0	BIT_3: GPIO mode (GPIO_CNF.x=1) must be true for this condition to be valid. 0 = DISABLE 1 = ENABLE
2	0x0	BIT_2: GPIO mode (GPIO_CNF.x=1) must be true for this condition to be valid. 0 = DISABLE 1 = ENABLE
1	0x0	BIT_1: GPIO mode (GPIO_CNF.x=1) must be true for this condition to be valid. 0 = DISABLE 1 = ENABLE
0	0x0	BIT_0: GPIO mode (GPIO_CNF.x=1) must be true for this condition to be valid. 0 = DISABLE 1 = ENABLE

14.2.7 GPIO_INT_LVL_0

GPIO can detect interrupt for any edge /Trigger/Level signals. Following register bits [7:0] are set when Level signal toggles.

- Bits [15:8] toggles whenever an Edge changes High-Low.
- Bits [15:8] toggles whenever an Any Edge changes. High-Low or Low-High

This is an array of 4 identical register entries; the register fields below apply to each entry

GPIO Port Interrupt Activation Level Registers

Offset: 060h..06fh | Read/Write: R/W | Reset: 0b00000000000000000000000000

Bit	Reset	Description
23	0x0	DELTA_7: 1 means Trigger Interrupt on ANY change of input if EDGE is TRUE

Bit	Reset	Description
22	0x0	DELTA_6: 1 means Trigger Interrupt on ANY change of input if EDGE is TRUE
21	0x0	DELTA_5: 1 means Trigger Interrupt on ANY change of input if EDGE is TRUE
20	0x0	DELTA_4: 1 means Trigger Interrupt on ANY change of input if EDGE is TRUE
19	0x0	DELTA_3: 1 means Trigger Interrupt on ANY change of input if EDGE is TRUE
18	0x0	DELTA_2: 1 means Trigger Interrupt on ANY change of input if EDGE is TRUE
17	0x0	DELTA_1: 1 means Trigger Interrupt on ANY change of input if EDGE is TRUE
16	0x0	DELTA_0: 1 means Trigger Interrupt on ANY change of input if EDGE is TRUE
15	0x0	EDGE_7: 1 means Configure as Edge-Triggered Interrupt
14	0x0	EDGE_6: 1 means Configure as Edge-Triggered Interrupt
13	0x0	EDGE_5: 1 means Configure as Edge-Triggered Interrupt
12	0x0	EDGE_4: 1 means Configure as Edge-Triggered Interrupt
11	0x0	EDGE_3: 1 means Configure as Edge-Triggered Interrupt
10	0x0	EDGE_2: 1 means Configure as Edge-Triggered Interrupt
9	0x0	EDGE_1: 1 means Configure as Edge-Triggered Interrupt
8	0x0	EDGE_0: 1 means Configure as Edge-Triggered Interrupt
7	0x0	BIT_7: Interrupt Activation Level or Edge (HIGH for High level or Rising Edge) 0 = LOW 1 = HIGH
6	0x0	BIT_6: Interrupt Activation Level or Edge (HIGH for High level or Rising Edge) 0 = LOW 1 = HIGH
5	0x0	BIT_5: Interrupt Activation Level or Edge (HIGH for High level or Rising Edge) 0 = LOW 1 = HIGH
4	0x0	BIT_4: Interrupt Activation Level or Edge (HIGH for High level or Rising Edge) 0 = LOW 1 = HIGH
3	0x0	BIT_3: Interrupt Activation Level or Edge (HIGH for High level or Rising Edge) 0 = LOW 1 = HIGH
2	0x0	BIT_2: Interrupt Activation Level or Edge (HIGH for High level or Rising Edge) 0 = LOW 1 = HIGH
1	0x0	BIT_1: Interrupt Activation Level or Edge (HIGH for High level or Rising Edge) 0 = LOW 1 = HIGH
0	0x0	BIT_0: Interrupt Activation Level or Edge (HIGH for High level or Rising Edge) 0 = LOW 1 = HIGH

14.2.8 GPIO_INT_CLR_0

This register clears the Interrupts which are set. This is a Write-Only register. This is valid only in GPIO mode and GPIO_INT.ENB is set.

This is an array of 4 identical register entries; the register fields below apply to each entry.

GPIO Port Interrupt Flag Set-to-Clear Registers

Offset: 070h..07fh | Read/Write: R/W | Reset: 0b00000000

Bit	Reset	Description
7	0x0	BIT_7: GPIO mode (GPIO_CNF.x=1) and GPIO_INT.ENB.x=1 must be true for this condition to be valid. 0 = SET 1 = CLEAR
6	0x0	BIT_6: GPIO mode (GPIO_CNF.x=1) and GPIO_INT.ENB.x=1 must be true for this condition to be valid. 0 = SET 1 = CLEAR
5	0x0	BIT_5: GPIO mode (GPIO_CNF.x=1) and GPIO_INT.ENB.x=1 must be true for this condition to be valid. 0 = SET 1 = CLEAR
4	0x0	BIT_4: GPIO mode (GPIO_CNF.x=1) and GPIO_INT.ENB.x=1 must be true for this condition to be valid. 0 = SET 1 = CLEAR
3	0x0	BIT_3: GPIO mode (GPIO_CNF.x=1) and GPIO_INT.ENB.x=1 must be true for this condition to be valid. 0 = SET 1 = CLEAR
2	0x0	BIT_2: GPIO mode (GPIO_CNF.x=1) and GPIO_INT.ENB.x=1 must be true for this condition to be valid. 0 = SET 1 = CLEAR
1	0x0	BIT_1: GPIO mode (GPIO_CNF.x=1) and GPIO_INT.ENB.x=1 must be true for this condition to be valid. 0 = SET 1 = CLEAR
0	0x0	BIT_0: GPIO mode (GPIO_CNF.x=1) and GPIO_INT.ENB.x=1 must be true for this condition to be valid. 0 = SET 1 = CLEAR

14.2.9 GPIO_MSK_CNF_0

Each register is provided with an individual 16-bit version, for enabling Masked-Writes, to avoid a Read-Modify-Write operation by the firmware. The exception is for the interrupt clear register, whose functionality is combined in the interrupt status register. Individual pins only can be programmed by suitably enabling the write-masks in the upper byte of these 16-bit registers.

This is an array of 4 identical register entries; the register fields below apply to each entry.

MASKED PRIMARY GPIO/SFIO Config Registers (Masked Writes)

Offset: 080h..08fh | Read/Write: R/W | Reset: 0b0000000000000000

Bit	R/W	Reset	Description
15	WO	0x0	MSK7: 0=Disable bit for write 0 = DISABLE 1 = ENABLE
14	WO	0x0	MSK6: 0=Disable bit for write 0 = DISABLE 1 = ENABLE
13	WO	0x0	MSK5: 0=Disable bit for write 0 = DISABLE 1 = ENABLE

1	DISABLE	BIT_1: Lock access to each pin 0 = DISABLE 1 = ENABLE
0	DISABLE	BIT_0: Lock access to each pin 0 = DISABLE 1 = ENABLE

[THIS PAGE INTENTIONALLY LEFT BLANK]

15.0 CPU

The NVIDIA® Tegra® 3 CPU complex contains quad Cortex®-A9 CPUs and a PL310 L2 Cache controller. The L2 cache controller is described in another section under L2 Cache Controller.

The CPUs are quad ARM® Cortex-A9 MPCore™ processors, which is the SMP variant of the Cortex-A9 CPU (there is also a single core variant). These feature the NEON Media Processing Engine.

Tegra 3 devices implement the NVIDIA vSMP processor architecture, with a fifth Companion Core available for low power operation. In addition to the main quad core CPU complex, the Companion Core is an additional CPU complex replicating CPU 0 of the main complex, and implemented in a low-leakage technology. This provides efficient operation at low processor loads. These two CPU complexes operate exclusively to each other, meaning the hardware does not support simultaneous operation in any form. The L2 cache RAM is shared between the complexes allowing for fast transitions.

This section does not document the CPU itself; for that you will need the ARM documentation:

Cortex-A9 MPCore
Revision: r2p0
Technical Reference Manual

Published by ARM Limited, document number ARM DDI 0407D.

Cortex-A9 NEON Media Processing Engine
Revision: r2p0
Technical Reference Manual

Published by ARM Limited, document number ARM DDI 0409E.

Note:	Current version at this time. You should periodically look for updates and refer to the latest available version of this material.

Implementation Details

Many aspects of the Cortex-A9 processor may be configured for a specific implementation. The Tegra 3 implementation has the following features:

- r2p9 revision level
- 32 Kbyte I-cache per core
- 32 Kbyte D-cache per core
- 160 external interrupt inputs (SPIs)
- NEON Media Processing Engine, high performance vector floating point unit
- Trace supported (PTM)
- ACP present (but not used)

15.1 CPU Timers

The Cortex-A9 processor contains built in timers. These may be used by software, but are subject to some restrictions and warnings that the system timers external to the CPU complex are not.

These are:

- The timers are always clocked at the CPU clock speed divided by two. Therefore they will have to be re-programmed to maintain real time when the CPU clock frequency is changed.
- There is no hardware interaction between these timers and the flow controller, and the external interrupt unit, unlike the system timers. They are entirely internal to the Cortex-A9 processor.
- If the CPU is powered off, then they will stop counting and their contents will be lost unless saved and restored. They cannot be used to wake the CPU from a power down.

Refer to the Cortex-A9 documentation for further details of these timers.

16.0 LEVEL 2 CACHE CONTROLLER

The Tegra® 3 CPU complex contains quad ARM® Cortex®-A9 CPUs and a PL310 L2 Cache controller. This section describes the L2 cache controller. ARM also refers to this as the L2C-310 AMBA® Level 2 Cache Controller.

The L2 Cache Controller is an ARM PL310 L2 controller configured with 1 MByte of cache RAM.

This section does not document the PL310 itself; for that you will need the documentation that is available from ARM. At the time of writing the latest version is:

AMBA Level 2 Cache Controller (L2C-310)
Revision: r3p1
Technical Reference Manual

Published by ARM Limited, document number ARM DDI 0246E.

> **Note:** Current version at this time. You should periodically look for updates and refer to the latest available version of this material.

Implementation Details

Some aspects of the PL310 may be configured for a specific implementation. The Tegra 3 implementation has the following features:

- R3p1-50 revision level (RTL release 7)
- 8-way set-associative
- 1 Megabyte cache size
- Support for locking per master ID

[THIS PAGE INTENTIONALLY LEFT BLANK]

17.0 FLOW CONTROLLER

The flow controller provides a mechanism to halt processors conditionally or unconditionally:

- Conditional halt/resume is based on a variety of events, including timers, external trigger, and internal clocks.
- COP (AVP) is halted by extending a bus cycle.
- CPU is halted in one of two ways:
  - Software Interaction: Software issues the WFE instruction to stop the processor, the flow controller asserts the EVENT input of the CPU to restart it.
  - Stop the clock [Legacy]: Should never be done for application software.
- Clocks to the processors can be halted when halted through flow control.

17.1 Flow Controller Registers

The EVENTS register is replicated five times, once each for COP (AVP) and each of CPU0-3

The fields and enums have the following interpretation:

- MODE defines how the flow controller logic operates; the reset value is 0x0 (does nothing).
- Enumerated values for the field MODE are defined below.

Field Mode	Enumerated Value	Description
FLOW_MODE_NONE	0	No flow control
FLOW_MODE_RUN_AND_INT	1	Keep running but generate interrupt when event conditions met
FLOW_MODE_WAITEVENT	2	Stop running until event conditions met
FLOW_MODE_WAITEVENT_AND_INT	3	Same as FLOW_MODE_WAITEVENT but generate an interrupt when resumed
FLOW_MODE_STOP_UNTIL_IRQ	4	Stop until an interrupt controller interrupt occurs
FLOW_MODE_STOP_UNTIL_IRQ_AND_INT	5	Same as FLOW_MODE_STOP_UNTIL_INT but generate another interrupt when resumed
FLOW_MODE_STOP_UNTIL_EVENT_AND_IRQ	6	Stop until event conditions met AND an interrupt controller interrupt occurs

The rest of the fields define which conditions will be taken into account to restart a halted processor.

There are two types of events:

- Counted events: These decrement the field called ZERO. Flow controller resumes when this counter reaches 0
- Activity events: The flow controller resumes when the activity occurs, no counting

All conditions are disabled at reset:

- JTAG: Resume on JTAG activity
- SCLK: Resume on Nth SYSCLK cycle ticks
- X32K: Resume on Nth X32K clock input ticks
- uSEC: Resume on Nth uSEC clock ticks (uSEC = microsecond)
- mSEC: Resume on Nth mSEC clock ticks (mSEC = millisecond)
- SEC: Resume on Nth second RTC clock ticks
- X_RDY: Resume on Nth XIO.RDY Ext. IO Ready events
- SMP3[1,0]: Resume on Nth SMP.3[1,0] Semaphore set events
- XRQ_[D,C,B,A]: Resume on Nth XRQ.[D,C,B,A] External Trigger events
- [O,I]B[E,F]: Resume on Nth [O,I]B[E,F] [Outbox, Inbox] [Empty, Full] Events
- [IRQ,FIQ]_[1,0]: Resume on [IRQ,FIQ].[1,0] IRQ Valid, 1 is COP, 0 is CPU
- ZERO: Initialized then decremented

Note: If more than one event is enabled, the event counter will decrement based on an or condition of enabled events

uSEC, mSEC and SEC are based on free running clocks, so there is a -1 to 0 period possible difference between the programmed delay value and the really observed delay value.

17.1.1 FLOW_CTLR_HALT_CPU_EVENTS_0

17.1.3 FLOW_CTLR_CPU_CSR_0

The CPU_CSR registers are replicated for each CPU core. They define additional characteristics of the flow controller linked to CPU cores, especially the interaction of the flow controller with power management functions. The LP1 state is normally entered and exited via side effects of the flow controller operation.

All fields of the CPU_CSR register have an initial value of 0. The different fields are:

- PWR_STATE: Current state of the Power-Gate State Machine
- WAIT_EVENT: CPU is waiting, wake up is via an event
- HALT: CPU is halted
- P2F_ACK: pmc2flow_ack signal, this is the same signal for both CPU cores
- F2P_PWRUP: flow2pmc_pwrup, this is the same signal for both CPU cores
- F2P_REQ: flow2pmc_req valid, this is the same signal for both CPU cores
- F2C_MPCORE_RST: TRUE when requesting reset of the MPCore™
- PWR_OFF_STS: TRUE when CPU power-gated OFF by the flow controller
- INTR_FLAG: TRUE when Interrupt is Active -- Write-1-to-Clear
- EVENT_FLAG: TRUE when Event is Active -- Write-1-to Clear
- SWITCH_CLUSTER : If set, the active cluster is switched when all indicated CPUs reach STANDBY_WFI. This bit self-clears once the cluster switch sequence is completed
- WAIT_WFI_BITMAP : All cores indicated in the bitmap must be in STANDBY_WFI before switching Cluster
- WAIT_WFE_BITMAP: All cores indicated in bitmap must be in STANDBY_WFE before CPU Power-Gating
- EVENT_ENABLE: Generates an event when the flow controller exits the halted state
- ENABLE: Power-Gate Enable - Halt or Event-wait causes CPU Power-Gating

Directly writing the Active field will otherwise most probably result in serious errors as there are no interlock in HW as when the flow controller is used to control the switch together with the use of WFI on the currently inactive cluster 0 = G 1 = LP

[THIS PAGE INTENTIONALLY LEFT BLANK]

18.0 MEMORY CONTROLLER

The NVIDIA® Tegra® 3 memory controller is significantly enhanced from previous Tegra designs. Major features include:

- New arbiter design for higher memory efficiency.
- System Memory Management Unit (SMMU) for virtual to physical address mapping for any device.
- DDR3 and low voltage DDR3 support; as well as faster LP-DDR2 operation.

18.1 Memory Controller Architecture

The memory controller architecturally consists of the following parts:

- Arbitration Domains, which can handle a single request or response per clock from a group of clients. Typically, a system has a single Arbitration Domain, but an implementation may divide the client space into multiple Arbitration Domains to increase the effective system bandwidth.
- Protocol Arbiter, which manage a related pool of memory devices. A system may have a single Protocol Arbiter or multiple Protocol Arbiters.
- Memory Crossbar, which routes request and responses between Arbitration Domains and Protocol Arbiters. In the simplest version of the system, the Memory Crossbar is just a pass through between a single Arbitration Domain and a single Protocol Arbiter.
- Global Resources, which include things like configuration registers which are shared across the Memory Subsystem.

18.2 Hardware Features

18.2.1 DRAM Protocol Arbiter Features

- 1 channel, 32 bits of data bus, 16 MB to 2 GB attached DRAM
  - 2 chip selects, up to 2 GB attached DRAM per chip-select
  - 2 individually-controllable clock-enable
  - 2 individually-controllable ODT (for DDR3)
- Each chip select may support different geometries
  - 2 or 3 bank bits
  - DDR3: up to 15 bits of row address if using 2 chip-selects, up to 16 bits if using 1 chip-select
  - Support up to 11 column bits[1], i.e. up to 4KB page-size
- Per-byte data masks
- BL4 or BL8 for both DDR3 and LPDDR2. For DDR3, BC4_on_the_fly.
- POP LPDDR2 up to 400 MHz; discrete LPDDR2 up to 533 MHz
- Discrete DDR3 up to 667 MHz
- Support for low-power modes:
  - Software controllable entry/exit from: self-refresh, power down, deep power down
  - Hardware dynamic entry/exit from: power-down, self-refresh
  - Support for intermittent or disabled DLL

1 This includes C0, which is not pinned out on the DRAM, and C1, which will be zero for all burst-length four bursts.

- Disable unused address/command taps based on whether in POP or Discrete mode, and whether Discrete is in in DDR3 or LPDDR2 mode.
- Pads use DPD-mode during idle periods

- For Tegra 3, we can set/adjust trims per-byte AND per-chip-select. We can still use the PVT-compensated value and either add a PVT/frequency-compensated adjustment to it (1/16, 1/8, 3/16 of a cycle) or a non-PVT- offset to it. There is no HW training mechanism. Either SW or characterization would need to determine best settings.
- Support for x32, x16, or x8 chips attached to the channel
  - DQ/DQS swizzling: MRR_BYTESEL need to match byte swizzling.

18.2.2 Memory Crossbar

The Memory Crossbar (MXB) is in charge of adapting Arbitration Domains to Protocol Arbiters (PAs). In a simple system, the MXB is a direct connection. In a more complex system, the MXB does the following:

- Conflict arbitration for ingress of requests to a single PA from multiple ADs.
- Conflict arbitration for egress of responses to a single AD from multiple PAs, with skid buffering to handle backpressure.
- Clock-domain crossing FIFOs for requests and responses destined for PAs that run on an asynchronous clock.
- Fragmentation of wide requests from a wider AD into a narrower PA.
- Reassembly of wide responses from a narrower PA to a wider AD.

18.2.3 Global Resources

The Memory Subsystem also contains some global resources not owned by a particular AD or PA:

- SMMU
- Configuration registers and statistics counters

18.3 Software Features

The majority of software interaction with the memory subsystem involves:

- Initial configuration
- Power management
- Device management
- SMMU translation management
- Surface allocation
- Statistics and debugging

18.4 Initial Configuration

The details of configuring the Memory Subsystem (MSS) can be broken down into the following:

- Client configuration
- Protocol Arbiter configuration
- Arbitration Domain configuration
- Global Memory Subsystem configuration

> **Note:** This configuration must be performed as part of the chip-wide boot sequence

18.4.1 Client Configuration

The primary per-client configuration knob is the target latency. The target latency value is the expected latency hiding of the client. It is statically configured based on the clients request rate and request buffering capability. The value is used by the Memory Subsystem to track the maximum allowed request lifetime in the system.

As an example of client latency tolerance, consider a Display client which has a 32-atom FIFO. If that Display client is expected to handle a 74.25 megapixel per second HDMI interface and is outputting 32-bit RGBA data on that interface, the client's latency tolerance is 32 atoms × 16 bytes per atom ÷ 4 bytes per pixel ÷ 74.25 Mpixel per second = 1.72 µsec.

The latency configuration knobs for the system are calculated off a programmable divide-down of the DRAM clock. This divide-down can be changed whenever the DRAM clock is changed, so that the latency knobs always represent the same relative amount of time to the system. For example, at 533 MHz, the divide-down would be programmed to divide by 16 to give a 30 ns tick. If the DRAM speed dropped to 400 MHz, the divide-down would be changed to 12 to maintain the 30 ns tick.

For the above example, the latency timeout would be 1.72 µsec ÷ 30 ns = 57 ticks. However, the Memory System does not guarantee that the maximum latency will never be exceeded, so some amount of headroom should be added to this number. Even so, clients should be designed to gracefully handle excessively-delayed transactions; hard-isochronous clients like Display and VI should not require a reset if a pixel does not arrive in time.

In the above scenario, the latency tolerance is use-case dependent. If the Display was doing 16 bits per pixel instead of 32, it would have double the amount of latency. Software can choose to recalculate the latency tolerance, or it can just pick a worst-case value. In general, given an acceptable amount of client buffering, the latency tolerance need not be tuned on a per-use-case basis (but if software does choose to tune the latency, it need only be done within the context of a single driver, since the latency value neither depends on other clients nor on the Protocol Arbiter clock).

Modules like the CPU, which have no well-defined latency requirements (beyond "as fast as possible") can use the latency tolerance value as a tuning knob, trading off performance of the latency-sensitive client versus the overall performance of the memory system. Some tuning of these parameters may be necessary to maximize system performance.

Module designers should choose an appropriate conservative default value for their client's latency tolerance registers. Software should be able to use the default configuration and still meet system use-case targets.

18.4.2 Protocol Arbiter Configuration

Each Protocol Arbiter has its own requirements for initialization. Timing parameters specific to the Arbiter, the DRAM and the current operating clock speed have to be written into Protocol Arbiter configuration registers. The type and geometry of the attached DRAM also have to be programmed. Afterwards, the DRAM will require a set of initialization cycles to be issued.

18.4.2.1 Device Geometry

DRAM devices come in many sizes, widths, etc. The arbiter must be programmed to drive the correct combination of address bits, data bits, and protocol.

18.4.2.2 Device Timing and Arbiter Timing

A DRAM arbiter has configuration related to timing parameters specific to the attached device. The JEDEC timing specifications for the device has to be converted from nanoseconds to cycle-counts. The controller must also be programmed with the cycles per tick number for their particular clock-domain (see also the subsection on "Global Memory Subsystem Configuration" below).

18.4.2.3 Other Arbiter Parameters

Other parameters related to arbitration that need to be configured include:

- overall number of requests outstanding
- which clients are considered isochronous

- which clients participate in power-saving hysteresis operations

18.4.2.4 Device Initialization and Calibration Cycles

In particular, PAs will need to write registers in the DRAM devices via special cycles to initialize the DRAM. In general all special cycles to a device are done via a hardware/software handshake that looks like:

- Software writes information about the special cycle to an Arbiter-specific register
- The Controller does the special cycle out to the DRAM device(s) when timing requirements are met
- Software checks a status register to ensure the special cycle is complete; or for Mode Register Read operations, the Controller issues an interrupt to indicate that the special cycle has been consumed

Special cycles may be emitted during normal operation as well; the Arbiter will inject them into the data stream at appropriate places (typically along with refresh cycles).

During device initialization, software must ensure that no client can access the memory. This can be done with per-module flush-enable bits.

18.4.3 Arbitration Domain Configuration

Physical implementation decisions (such as the mapping of clients to partition clients) combined with the requirement for unequal bandwidth allocation (eg. display clients needing 80% of the bandwidth) might necessitate the addition of configuration options to the Arbitration Domains to ensure the desired bandwidth allocation occurs.

18.4.4 Global Memory Subsystem Configuration

Some parts of the Memory Subsystem must be configured before any transfers are allowed into the system. The address map must be configured to set which portions of the physical address map are allocated to which Protocol Arbiters, and what portions of it are protected by the physical address protection mechanisms. Hardware may enforce address-range-based protection to carve out memory that is only accessible via a Secure ARM® TrustZone™ transaction, or memory that is read-only (to protect OS code). This is in addition to the translations available via the SMMU.

The Arbitration Domains operate off of a unified arbitration clock. This clock is further divided-down to produce a clock-rate independent clock for counting latency intervals across the Memory System (aka “ticks”). This divide-down should be programmed to a constant interval at initialization (and any other clock-rate change). A 30 ns interval is suggested since it is an even divide-down of many common DRAM clocks, but any convenient granularity may be chosen.

There are also a few global memory system tuning options that tend to shape the memory performance. In general, the values of these should not need to be changed from the default value used by the MSS team, but they are mentioned here for reference:

- The *expiration* value, which is in latency-count units. This is the expected amount of time that the Memory Subsystem thinks it will need on average to “fast-path” a request through the system. A request becomes “hot” when the latency timer reaches the expiration value, and has expired once the latency timeout hits zero[2]. Increasing the expiration value reduces the number of requests that exceed the latency timeout, but at a cost of overall efficiency.
- The *priority inversion limit*, which limits how long a low-priority (non-expired) group of requests can keep a bank open before a high-priority (expired) group of requests will close the bank. The priority inversion limit is in atoms; if a lower-priority page has this many atoms or fewer to retire, it is allowed to keep the bank open and finish its request. If it has more, the bank is closed to allow the high-priority requests and the low-priority requests must re-open the bank later to finish the request group. The priority inversion limit parameter increases worst-case latency while increasing efficiency.

[2] In practice, the latency timeout doesn’t actually count down; rather hardware time-stamps the incoming request and computes a deadline value which is based on the current time + latency timeout – expiration. The request has expired when the current time passes the deadline.

- SMMU configuration. The SMMU will require software to set up and maintain page tables in memory, enable translation for clients, and assign clients to address space identifiers.

18.5 Power Management

The primary form of system power management involves transition to and from low-power DRAM states. The DRAM controller can be programmed to automatically enter a precharge power-down or self-refresh state after some amount of time without a request. The power-down state can be independently entered for each individual DRAM device – it is possible for one device to be in power-down while another is active. If software knows that the system will not be making further DRAM requests, it can cause an immediate transfer to the self-refresh state by writing an override register. If multiple chip-selects are available for the DRAM controller, both the hardware and software may choose to enter low-power states on a per-chip-select basis.

Once a request is queued to the controller for that DRAM the hardware will automatically wake from the low-power state if it entered that state via hardware control. This can take a relatively long amount of time since the controller may be required to issue a number of refresh cycles first. For software-initiated self-refresh, software must issue a register write to start the transition from self-refresh back to a fully-powered state.

Deep power-down must be explicitly requested by software, since it causes DRAM data to be lost. Software must disable new incoming requests to the MSS, wait for all outstanding in-flight requests to retire, and then write a register to transition to the deep power-down state. To exit the state, software must reinitialize the DRAM and controller before re-enabling transfers. Deep power-down mode may be enabled for each chip-select in a Protocol Arbiter independently and each Protocol Arbiter independently.

Normal active bank power optimization is managed principally by the Protocol Arbiter. The arbiter will arrange to close banks as soon as possible and to hold requests for as long as the latency timer will allow, with the intent of grouping same-page accesses into a coherent burst. One important case of active power management is the “OSIdle” use case where only Display is active. The Display client can be prone to “dribbling” – that is, sending isolated requests at infrequent intervals.

When doing the OSIdle use case, the Protocol Arbiter will not have enough traffic to keep the client dribble from becoming DRAM dribble (isolated requests that open and close the DRAM pages more often than necessary). To manage DRAM dribble, the controller adds the concept of the “*hysteresis holdoff”*, which is a per-controller state bit. When the holdoff is active, the controller is held off from issuing activate commands to open new DRAM pages. Incoming requests will back up in the Protocol Arbiter’s row sorter and store buffer until the holdoff is released.

The holdoff is enabled whenever an individual device goes idle due to lack of work. It is released automatically whenever a latency timer expires, or the Protocol Arbiter stalls due to fullness. The net effect of the holdoff is to group *all* requests for the DRAM into activity bursts.

The holdoff causes a delay in requests transitioning from a memory-idle state. This can affect some traffic in a negative manner – principally requests that are low-latency like the CPU. To keep the holdoff from impacting these requests, software has a per-module configuration bit that disables the holdoff for certain known-latency-sensitive clients. Whenever a request with the holdoff-disable bit set enters the Protocol Arbiter, the holdoff is released.

A final aspect of power management is scaling the Memory System clocks. Generally there are two sets of clocks that can be controlled:

- The overall Memory System “arbitration clock”, which is the clock used by the Arbitration Domains. Changing this clock reduces the overall bandwidth of the system and reduces the power required by the client interfaces and cross-chip Memory System routing.
- Individual Protocol Arbiter clocks. These reduce the bandwidth available to a particular memory pool and reduce the power consumed by the external pins and the external DRAM. Some Protocol Arbiters may be synchronous to the arbitration clock and not be explicitly controllable via a separate clock enable.

Both clocks may be changed as part of frequency scaling. Changing the arbitration clock rate affects the Arbitration Domain’s idea of the latency timeout. As described in the above section, software should change the divide-down register to keep the

scale of latency timeout “ticks” to a (relatively) constant time unit. Generally a tick time of 30 ns is used since it divides evenly into most of the common DRAM frequencies, but any value of tick granularity may be chosen.

Both the arbitration clock and memory clock have separate divide-downs.

Changing the Protocol Arbiter clock rate affects the relative memory timing parameters. The DRAM timing parameters are double-buffered to allow software to update the timing values for the next clock speed setting and then simultaneously switch to using the new values by writing a trigger.

The DRAM protocol itself may require further clock-change restrictions. For example, DDR3 requires a certain number of cycles in which to re-lock the on-DRAM DLL. To further facilitate the hardware/software handoff, and reduce latency for the clock-change operation, a hardware handshake exists between the clock controller module and the Protocol Arbiter.

The MSS maintains two copies of each configuration register that may need to change due to a clock-change, the “active” and “assembly” copies; this is also known as a “shadowed” register. The active copy is what the MSS is currently configured to use, and cannot be written to. The assembly copy can be written to at any time, and it can be copied onto the active via a trigger mechanism. The clock-change handshake includes a hardware-initiated trigger for this shadow update.

To assist in full-system power analysis using silicon, the Protocol Arbiter should include enough statistics about the DRAM bus cycles to be able to calculate the DRAM power consumed.

18.6 Surface Allocation

For linear buffers, software needs to allocate a range of virtual addresses for the buffer and map them to physical pages; the address mapping of bytes within the buffer corresponds to the buffer’s virtual address. For 2D surfaces there are multiple options for layout of the bytes in the surface.

Pitched surfaces are the most straightforward. Assuming 8-bit pixels, for a given pixel coordinate (x, y), the pixel’s byte address is:

$$\text{Address} = \text{Surface\_base} + y * \text{Surface\_pitch} + x$$

For larger pixels, “x” is first multiplied by the number of bytes per pixel.

The Surface_pitch value is the line-to-line stride in bytes of the surface. This may be equal to the surface’s width times the bytes-per-pixel value or it may be additionally padded to a larger stride. Pitched surfaces are conceptually straightforward to use, but they can be inefficient if accesses walk in a vertical or diagonal direction through the surface, since each line may be in a different DRAM row. Software can help on pathologically-sized surfaces (where vertical traversal causes a bank collision) by padding out the Surface_pitch value, but in general they are best used when the surface will only be traversed horizontally or as an interface to naive software that assumes a pitched arrangement.

Tiled surfaces attempt to improve performance for vertical and diagonal traversal by making the DRAM page map more square in the surface. Previous chips used a form of tiling that ordered bytes within the surface into 16x16 tiles:

$$\text{Address} = \text{Surface\_base} + (y / 16) * (\text{Surface\_pitch} * 16) + (x / 16) * 256 + (y \,\%\, 16) * 16 + (x \,\%\, 16)$$

The previous memory controller design put the DRAM bank bits at the 1 KB boundary, so a DRAM page ends up being a 64x16 arrangement of bytes. Clients that traverse horizontally get four 16-byte atoms in-page before moving to a new bank, and with a four-bank DRAM get 16 atoms before needing to cycle a bank for a given row, which was enough to ensure efficient access to the page.

Similarly, clients that accessed vertically got 16 atoms in-page before moving outside the tile. Software would still need to pitch-pad the surface to ensure that moving vertically didn’t cause a bank-collision – to do this it needed to make sure that Surface_pitch wasn’t a multiple of 1 KB.

18.7 Statistics and Debugging

Statistics are used for performance monitoring and for generating usage information for guiding dynamic voltage and frequency scaling. Hardware will provide a set of statistics counters that are used for DVFS, both for global MSS bandwidth and for individual PA bandwidth. A separate set of counters with additional filtering support will be available for performance monitoring and debugging.

The hardware blocks illegal transfers to memory. Some transfers are based on physical DRAM limitations (addressing outside of the address map), permissions (addressing “secure” physical memory from a non-secure client) and from the SMMU (accessing an unmapped page). All of these are reported via a fault interface which records the transfer information of the last faulting address, including the following data:

- Virtual address of fault
- Module and client ID of fault
- Fault type

Faulting transfers continue through the system, but faulting reads return all-ones and faulting writes discard the write data. Writing a fault triggers a (maskable) interrupt.

18.8 Coherency and Ordering

- The MSS does not guarantee the coherency between different clients.
- The MSS does guarantee that within a single write client, if a write is sent with a write-response tag, all previous writes from that client will complete before returning the write completion tag.
- The MSS also guarantees that within a single client, writes to the same address will complete in-order.

The combination of the three above rules can produce problems if a module accessing memory assumes PCI-like ordering rules; since write ordering is not guaranteed as seen by other clients in the system, it is possible for this scenario to occur:

- Client A is polling a flag location in memory to see that a packet arrives.
- Client B sends write request for packet data to a buffer in memory.
- B sends write request to flip the flag to “available”.
- B writes to the flag complete.
- A sees this and starts reading the packet data.
- B’s packet data writes complete.

Obviously in this scenario, A reads incorrect data. The recommended way to solve this problem is to avoid polling loops in software as they are inefficient in both performance and power, and instead architect synchronization points in the hardware so that B can directly interrupt A when it determines all work is complete.

If such modifications cannot be made to the clients, then the writing client must be restricted to one request outstanding. Individual Protocol Arbiters may provide further ordering guarantees. If only one PA exists, then the ordering rules for the MSS may be relaxed to match that of the PA.

For Tegra 3, SMMU implementation guarantees that the lower 10 bits of the virtual address are untranslated. The Protocol Arbiter implementation guarantees that writes from a single client made to a single page will complete in-order. The Protocol Arbiter also guarantees that the lower 10 bits of physical address are always column bits. Therefore, Tegra 3 can guarantee that writes within the same kilobyte-aligned kilobyte of address will complete in-order, regardless of whether the client is dealing in virtual or untranslated physical addresses.

18.9 Hardware / Software Partitioning

Software needs to be involved in the configuration, translation, and power management services as described above. The main CPUs will run their clients as untranslated by the SMMU, instead relying on the CPU's MMU to do translation. The system does not provide SMMU translation for the CPU clients. It is up to software to keep the CPU and SMMU page tables matched.

Surface allocation is straightforward; software allocates the surface out of the device's virtual space, and then backs the mappings with physical pages. Software should make sure to make the surface mappings not bank collide by pitch-padding surfaces to prevent vertical bank conflicts (generally, this means making sure the pitch for block-linear surfaces is not a multiple of 256 bytes). For surfaces that are accessed in tandem (YUV planar surfaces, Depth and Color for 3D, etc.) software should align the surfaces to start on different banks and use the BANKSWIZ surface kinds to remove page collisions.

18.10 Software Interfaces

The primary software interface for configuration is via the APB bus registers.

- Initial configuration
- Power management
- Device management
- SMMU translation management
- Surface allocation
- Statistics and debugging

The most important tool for configuration is **emc_reg_calc**, which is a tool to generate the DRAM timing and configuration sequences based on information from a vendor's datasheet.

18.10.1 Boot

The Tegra 3 device has a two-stage boot:

- The Boot ROM is responsible for getting the chip out of reset and to the point where driver-level software can take over.
- The Boot Loader or the OS-recovery code is the portion of the driver responsible for completing the boot process to the general-purpose OS.

The Boot ROM is an actual ROM built into the chip, and the Boot Loader and OS recovery section is externally loaded code. The Boot Loader is only used for Cold Boot; Warm Boot utilizes operating-system recovery code.

Tegra 3 devices can "boot" in two ways: "Warm Boot" or "Cold Boot". Cold Boot is defined as booting from a fully powered-off or fully reset state. Warm Boot is defined as recovery from the lowest-power state (LP0), where the external DRAM has been held in self-refresh mode while Tegra 3 core was powered off. Warm Boot use case occurs much more often; it is the use case hit whenever a SmartPhone wakes from Standby to answer a call.

18.10.1.1 Cold Boot

Before Memory Subsystem boot can begin, the Boot ROM must read the Boot Configuration Tables (BCTs) from flash memory (slow storage) into on-chip RAM. These tables include the configuration data for up to 4 initial DRAM configurations supported. The Boot ROM then reads the strap signals assigned to the SDRAM and begins to bring up the memory subsystem.

The Cold Boot Boot ROM sequence:

1. Configure PLL used by MC/EMC based on BCT values

2. Wait for PLLs to lock
3. Program necessary always-on static pad configurations in PMC
4. Configure memory clocks based on BCT values
5. Enable MC/EMC clocks
6. Release memory subsystem resets
7. Program other necessary pad/pad-macro configuration
8. Program initial configuration for MC/EMC based on BCT values
9. Perform the DRAM initialization sequence. This sequence is specific to the DRAM protocol used and varies depending on the requirements of a particular device. For example, a DDR3 sequence goes as follows:
    a. Apply power to the device
    b. Wait until voltage is stable
    c. Assert DRAM reset
    d. Wait 200µs
    e. Deassert DRAM reset
    f. Apply stable clocks
    g. Wait 500µs
    h. Assert and hold CKE high
    i. Precharge all banks
    j. Send 2 Auto refresh commands
    k. Write to Mode register 0, 1, 2, 3
    l. Issue ZQ Calibration command
    m. Wait for ZQ calibration and DRAM DLL lock time to complete
10. Enable power saving features such as clock stop, active power down, dynamic-self-refresh
11. Start periodical sequences such as auto refresh, ZQ calibration, auto-calibration
12. Release the memory-initialization hardware lock[3]

After this, the external DRAM and Memory Subsystem are ready for use.

18.10.1.2 Warm Boot

The Warm Boot sequence is very similar to the Cold Boot sequence, and many of the same steps are performed. One obvious difference is that instead of powering-on the DRAM, we are waking it out of SelfRefresh. Another difference is the configuration data for Boot ROM portion of MC/EMC initialization is stored in the Power Management Controller (PMC) Scratch Registers.

The PMC Scratch registers are in Always-On partition, and are powered during LP0. The power and area limitations of this implementation restricts the number of PMC Scratch registers available; there are a smaller number of PMC Scratch Registers than the number of bits needed to fully configure MC and EMC. The Scratch Registers are only used to store the minimum required configuration to get to working DRAM. The Boot ROM may not be able to Warm Boot to full POR speed using only the Scratch Register data; if this limitation is confirmed, the Boot Loader may be required to mimic DVFS software and reprogram the MC/EMC to full-speed operation using data stored in DRAM. It is up to the LP0 Entry software code to ensure the proper configuration gets written to the Scratch Registers.

[3] AHB_ARBITRATION_XBAR_CTRL.MEM_INIT_DONE

The Warm Boot code provided by the MSS includes algorithms for deriving the approximate MC arbiter performance parameters from the EMC timing parameters. The EMC has provided generation code for the packing/unpacking calls for the scratch registers to ease the software maintenance burden.

The Warm Boot Boot ROM sequence:

1. Configure memory PLLs and memory clocks based on Scratch values
2. Wait for PLLs to lock
3. Configure memory clocks based on scratch values
4. Enable MC/EMC clocks
5. Release memory subsystem resets. Program any necessary static pad configuration that was powered-off in LP0
6. Program initial configuration for MC/EMC based on Scratch values
7. Release the DRAM from software-controlled Self Refresh. This sequence is specific to the DRAM protocol used and may further vary depending on the requirements of a particular device. For example, a DDR3 sequence goes as follows:
    a. Apply stable clocks
    b. Assert and hold CKE high
    c. Issue ZQ Calibration command
    d. Wait for ZQ calibration and DRAM DLL lock time to complete
    e. Write to Mode registers if different from LP0 entry values
    f. Issue refreshes to ensure tREFI is satisfied
8. Enable power saving features such as clock stop, active power down, dynamic-self-refresh
9. Start periodical sequences such as auto refresh, ZQ calibration, auto-calibration
10. Release the memory-initialization hardware lock

After the Boot ROM sequence is complete, the operating system restore code may access DRAM and restore a different or higher-speed operation. The operating system may also restore translation or client configuration settings before allowing any user code to execute.

18.10.2 Security Apertures

To secure the MC registers, the Cortex® A9 processor's page table entries for the MC register space must be marked as secured. Then to access the registers securely, the Cortex A9 must be switched into secure mode. For more details about these Cortex A9 operations, please read the Cortex A9 architecture manual from ARM.

To secure a region of EMEM, the Cortex A9's page table entries for that region must be marked as secured. Then the MC registers must be configured for the secured region, using Cortex A9 in the secured mode:

```
RegWrite(MC_SECURITY_CFG0, security_aperture_base_address);
RegWrite(MC_SECURITY_CFG1, security_aperture_size_in_megabytes);
```

After the registers are updated, the Cortex-A9 must be in secure mode to access the described region of memory.

To protect a region of EMEM, the MC register must be configured for the protected region, using Cortex A9 in the secured mode:

```
RegWrite(MC_SECURITY_CFG2, carveout_base_address);
```

For more information on handling security violations, see subsection "MC Interrupts" below.

18.10.3 Virtual Addressing: Using the SMMU

For a discussion of the virtual-address translation features provided by the SMMU, please read subsection on “Virtual Addressing” below.

In Tegra 3, it is physically impossible to enable SMMU translation for the Cortex-A9 CPU.

There is no way to apply different ASIDs to requests that arrive at MC through the same MCCIF client. An example would be all three USB controllers access EMEM through the AHBSLV clients on Tegra 3; thus there is no way to assign those USB controllers to different ASIDs.

There is a need on the software side to distinguish between an invalid mapping (which has an invalid PA field) and a mapping that is valid, but has no access. The following pseudo-code describes the recommended conventions.

```
// page/section/address space permission types
//
// note that INVALID implies the PA field is unused.
// PA is valid for all others, including NO ACCESS.
enum Permission {
     INVALID           = NvU32(0),
     NO ACCESS         =                       NONSECURE,
     SECURE WRITE ONLY =            WRITABLE,
     WRITE ONLY        =            WRITABLE | NONSECURE,
     SECURE READ ONLY  = READABLE,
     READ ONLY         = READABLE |            NONSECURE,
     SECURE            = READABLE | WRITABLE,
     ANY               = READABLE | WRITABLE | NONSECURE
 };
```

For more information on handling SMMU faults, see subsection on “MC Interrupts” below.

18.10.3.1 SMMU Initialization

1. For each Virtual Address Space (VAS) to be used, set up the page-table in the DRAM. See subsection on “Virtual Addressing” below for details on the page-table formats supported.
2. For each ASID, set up the pointer to the page-table base and the ASID-wide protection bits. Since the PTB pointers are stored in a RAM, this uses an indirect access mechanism involving two register writes:
   a. Write MC_SMMU_PTB_ASID_0 with the ASID to be modified.
   b. Write MC_SMMU_PTB_DATA_0 with the information for this VAS:
      - Page Table Base pointer
      - Whether non-secure accesses are allowed
      - Whether reads are allowed
      - Whether writes are allowed
3. Assign hardware engines (SWNAMES) to the ASIDs and turn on translation for those engines. This involves writes to various MC_SMMU_<SWNAME>_ASID_0 registers.
4. If needed for HW Diagnostics purposes, disable or enable translation within a SWNAME on a per-client basis. This involves writes to various bits in MC_SMMU_TRANSLATION_ENABLE_*_0 registers.
5. If desired, secure the ASIDs, which prevent untrusted code from modifying the ASID PTB pointers by enabling a requirement for TrustZone security on register writes that modify the PTBs. This operation involves a write to MC_SMMU_ASID_SECURITY_0. Note that this register itself is secured by TrustZone to prevent it from being modified by untrusted sources, and in some situations writes to it must also be TrustZone secured for them to take effect. In particular, you cannot change a module’s ASID with a non-secure write if you are trying to change it to a secure ASID, or if it is already a secure ASID.

6. If desired, enable ASID promotion, which allows clients without security access to inherit the security status based on the page-table translation. This operation involves a write to MC_SMMU_ASID_SECURITY_0.
7. Write PTC_FLUSH_TYPE=ALL to MC_SMMU_PTC_FLUSH_0.
8. Write TLB_FLUSH_VA_MATCH=ALL to MC_SMMU_TLB_FLUSH_0.
9. Configure reserved bits found to be necessary during chip bring-up, if any. There are reserved bits in MC_SMMU_PTC_CONFIG_0 and MC_SMMU_TLB_CONFIG_0.
10. Enable the SMMU by writing SMMU_ENABLE=ENABLE to MC_SMMU_CONFIG_0. Note that this register is secured by TrustZone to prevent it from being modified by untrusted sources, and writes to it must also be TrustZone secured for them to take effect.

18.10.3.2 Page Table Modifications after Initialization

Modifications may be made to the page tables while the system is operating; however, care must be taken to avoid modifying an entry that is in active use. Modifying an entry in active use will result in undefined operation; the most likely failure is the use of an out-of-date cached translation. The general rules for safe modification are:

- If no client is using an ASID, then that ASID and its page table can be modified.
- If no client is using any PTE in a PDE, that PDE can be modified.
- If no client is using a PTE, that PTE can be modified.

It is up to software to ensure these rules are followed when virtual address translations need changed. Once software has updated the page-table or ASID mappings, the final step is to perform PTC and TLB flushes on the modified entries. Note that the granularity of flushing is at the PTE group, which is the number of PTEs that fit in a memory atom. Software can write:

- MC_SMMU_TLB_FLUSH_0 to flush a specific page group, 4MB section, entire ASID or the entire TLB.
- MC_SMMU_PTC_FLUSH_0 to flush a specific PTE or PDE from the PTC

18.10.3.3 Collecting Statistics on SMMU Performance

The TLB and PTC each have hit and miss statistics counters. To enable statistics collection, set MC_SMMU_*_CONFIG_0.*_STATS_ENABLE == ENABLE, where * stands for PTC or TLB. The counters will begin collecting information when enabled. To check the results, read the appropriate registers:

- MC_SMMU_STATS_TLB_HIT_COUNT_0
- MC_SMMU_STATS_TLB_MISS_COUNT_0
- MC_SMMU_STATS_PTC_HIT_COUNT_0
- MC_SMMU_STATS_PTC_MISS_COUNT_0

These counters do not saturate when full; instead they wrap from MAX_UINT to 0. There is no explicit reset for these counters; the only reset-like option is to force the counter bits to all 1’s using the MC_SMMU_*_CONFIG_0.*_STATS_TEST trigger bits. This is essentially like resetting the counters to -1.

18.10.4 DVFS Sequences

DVFS (Dynamic Voltage and Frequency Scaling) is a Software feature for controlling system power. A key Hardware feature for supporting that is changing SDRAM frequency on the fly with minimal impact on system performance. That suggests the following requirement:

- EMC timing parameters and their corresponding MC arbitration timing parameters need to be adjusted to the optimal performance for the new frequency. These parameters can usually be derived from DRAM datasheet and do not need characterization.
- All trimmer values need to be adjusted for the new frequency. These values need to be characterized across PVT (process, voltage, temperature) and frequencies.

- The pad configurations that can be turned off to save power at low frequencies should also change with frequency change, such as pad terminations and DQS-pulls.
- All registers involved in frequency change should be shadowed. That includes the reserved register fields that can possible be turned on only in a certain frequency range. Note that any HW Diagnostics feature that has power implications should be considered to be shadowed.
- No SW interference should be expected from SW after SW pulls the trigger to change frequency and before the clock change completes: SW runs on CPU from SDRAM. Once EMC blocks the requests to SDRAM, CPU may be frozen until the EMC finishes frequency change and unblocks the requests. Note that CPU can also possibly run out of the contents in cache during clock change, so we need to consider both scenarios.
- The delay caused by clock change should not cause functional failures or visible artifacts.

That results in a design as follows:

- CAR module handshakes with EMC on clock change. EMC handshakes with MC on shadow register latching. The whole process is done by hardware and transparent to SW.
- A rough estimation of clock change delay is 1-4us for lpddr2, 2-6us for DDR3.
- Supports two clock change mode: self-refresh clock change mode and power-down clock change mode. Both LPDDR2 and DDR3 support both modes. We recommend clock change power-down mode for LPDDR2 since it takes shorter time. We recommend self-refresh clock change mode for DDR3, since power-down clock change mode does not allow DLL to be turned off.
- For flexibility, EMC has a 16-deep FIFO to hold register programming and release them during or immediately after clock change. That enables us to send DRAM command or latch in unshadowed registers. Here are a few examples:
  - Self-refresh clock change mode requires programming EMC_SELF_REF to put DRAM in self-refresh during clock change.
  - DDR3 precharge-power-down mode requires programming EMC_PRE to close all banks before clock change.
  - Both DDR3 and LPDDR2 clock change requires writing mode registers after clock change.
  - To support DLL-ON/DLL-OFF mode switching on DDR3, program mode registers before or after clock change according to the DDR3 specification.

This is the summary of the frequency change process.

- SW turns off features like self-refresh or auto-calibration if necessary to minimize their interference with DVFS sequence
- SW programs MC/EMC shadow registers for the new frequency
- SW programs EMC clock change flow control registers, such as entering self-refresh before clock change and programming SDRAM mode registers after clock change
- SW programs MC/EMC clock source register to trigger the clock change
- CAR sends clock change request to EMC (clock divider and/or clock source)
- EMC stalls all DRAM commands including refreshes
- EMC handshakes with MC to stalls incoming transactions and waits until EMC pipe is flushed
  Within handshaking, EMC may enters power down state if it is in power-down clock change mode
- EMC executes pre-clock change sequence such as entering self-refresh and programming mode register to turn off DLL
- EMC latches in shadowed registers and requests MC to latch in shadow registers
- EMC acknowledges CAR to change clock
- CAR changes MC/EMC clock
- CAR desserts the clock change request to EMC indicating the clock change is done

- EMC executes post-clock-change sequence, such as exiting self-refresh and programming SDRAM mode registers
- EMC desserts the clock change acknowledgement to CAR
- EMC unstalls dram commands including refresh and resumes incoming MC transactions
- SW waits 1us before continuing,

SW programming sequence on Tegra 3 clock change sequence:

- Before any clock change, usually at boot time
  - Keep these register fields in reset values:
    CLKCHANGE_REQ_ENABLE = ENABLED
    CLKCHANGE_SR_ENABLE = DISABLED
  - CLKCHANGE_PD_ENABLE:
    ENABLED: power-down clock change mode (for LPDDR2)
    DISABLED: self-refresh clock change mode (for DDR3)
- At each clock change:
  - Clear clockchange_complete flag so we can poll it later for clock change completion:
    EMC_INTSTATUS.CLKCHANGE_COMPLETE_INT = SET
  - Disable DSR (dynamic-self-refresh) if it is currently enabled
    EMC_CFG. DYN_SELF_REF = DISABLE
  - If this clock change is going to switch from SCHMITT to VREF DQ mode, enable VREF DQ:
    EMC_XM2DQSPADCTRL2.EMC2TMC_CFG_XM2DQS_E_VREF_DQ = 1
  - If this clock change is going to switch from SCHMITT to VREF DQS mode, enable VREF DQS:
    EMC_XM2DQSPADCTRL3.EMC2PMACRO_CFG_XM2DQS_E_VREF_DQS = 1
  - If this clock change is going to turn on QUSE IVREF, enable it:
    EMC_XM2QUSEPADCTRL.EMC2TMC_CFG_XM2QUSE_E_IVREF = 1
  - Latch shadow registers:
    EMC_TIMING_CONTROL = 1
    Poll for latching completion: EMC_EMC_STATUS_TIMING_UPDATE_STALLED == 0
  - Wait 5us to allow all actions above have finished
  - If CFG_XM2COMP_VREF_CAL_EN mode needs to change with the clock change, turn off auto-calibration:
    EMC_AUTO_CAL_INTERVAL = 0
    Then poll for the possible on-going auto-cal to complete:
    EMC_AUTO_CAL_STATUS.AUTO_CAL_ACTIVE == 0
  - Program shadow registers for the new frequency, listed below:
    EMC_RC, EMC_RFC, EMC_RAS, EMC_RP, EMC_R2W, EMC_W2R, EMC_R2P, EMC_W2P, EMC_RD_RCD, EMC_WR_RCD, EMC_RRD, EMC_REXT, EMC_WEXT, EMC_WDV, EMC_QUSE, EMC_QRST, EMC_QSAFE, EMC_RDV, EMC_REFRESH, EMC_BURST_REFRESH_NUM, EMC_PRE_REFRESH_REQ_CNT, EMC_PDEX2WR, EMC_PDEX2RD, EMC_PCHG2PDEN, EMC_ACT2PDEN, EMC_AR2PDEN, EMC_RW2PDEN, EMC_TXSR, EMC_TXSRDLL, EMC_TCKE, EMC_TFAW, EMC_TRPAB, EMC_TCLKSTABLE, EMC_TCLKSTOP, EMC_TREFBW, EMC_QUSE_EXTRA, EMC_FBIO_CFG6, EMC_ODT_WRITE, EMC_ODT_READ, EMC_FBIO_CFG5, EMC_CFG_DIG_DLL, EMC_CFG_DIG_DLL_PERIOD, EMC_DLL_XFORM_DQS0, EMC_DLL_XFORM_DQS1, EMC_DLL_XFORM_DQS2, EMC_DLL_XFORM_DQS3, EMC_DLL_XFORM_DQS4, EMC_DLL_XFORM_DQS5, EMC_DLL_XFORM_DQS6, EMC_DLL_XFORM_DQS7, EMC_DLL_XFORM_QUSE0, EMC_DLL_XFORM_QUSE1, EMC_DLL_XFORM_QUSE2, EMC_DLL_XFORM_QUSE3, EMC_DLL_XFORM_QUSE4, EMC_DLL_XFORM_QUSE5, EMC_DLL_XFORM_QUSE6, EMC_DLL_XFORM_QUSE7, EMC_DLI_TRIM_TXDQS0, EMC_DLI_TRIM_TXDQS1, EMC_DLI_TRIM_TXDQS2, EMC_DLI_TRIM_TXDQS3, EMC_DLI_TRIM_TXDQS4,

EMC_DLI_TRIM_TXDQS5, EMC_DLI_TRIM_TXDQS6, EMC_DLI_TRIM_TXDQS7, EMC_DLL_XFORM_DQ0, EMC_DLL_XFORM_DQ1, EMC_DLL_XFORM_DQ2, EMC_DLL_XFORM_DQ3, EMC_XM2CMDPADCTRL, EMC_XM2DQSPADCTRL2, EMC_XM2DQPADCTRL2, EMC_XM2COMPPADCTRL, EMC_XM2VTTGENPADCTRL, EMC_XM2VTTGENPADCTRL2, EMC_XM2QUSEPADCTRL, EMC_XM2DQSPADCTRL3, EMC_CTT_TERM_CTRL, EMC_ZCAL_INTERVAL, EMC_ZCAL_WAIT_CNT, EMC_MRS_WAIT_CNT, EMC_AUTO_CAL_CONFIG, EMC_CTT, EMC_CTT_DURATION, EMC_DYN_SELF_REF_CONTROL, EMC_FBIO_SPARE, EMC_CFG_RSV, MC_EMEM_ARB_CFG, MC_EMEM_ARB_OUTSTANDING_REQ, MC_EMEM_ARB_TIMING_RCD, MC_EMEM_ARB_TIMING_RP, MC_EMEM_ARB_TIMING_RC, MC_EMEM_ARB_TIMING_RAS, MC_EMEM_ARB_TIMING_FAW, MC_EMEM_ARB_TIMING_RRD, MC_EMEM_ARB_TIMING_RAP2PRE, MC_EMEM_ARB_TIMING_WAP2PRE, MC_EMEM_ARB_TIMING_R2R, MC_EMEM_ARB_TIMING_W2W, MC_EMEM_ARB_TIMING_R2W, MC_EMEM_ARB_TIMING_W2R, MC_EMEM_ARB_DA_TURNS, MC_EMEM_ARB_DA_COVERS, MC_EMEM_ARB_MISC0, MC_EMEM_ARB_RING1_THROTTLE

- If this clock change is going to enable DDR3 DLL (and previous frequency disables it), program the time needed for DLL latching into MRS_LONG_WAIT_CNT. You can minus the time that DLL locking overlaps with other commands (such as ZQ-long calibration time, if it is inserted in post clock change sequence below) to reduce this latency.
  EMC_MRS_WAIT_CNT_MRS_LONG_WAIT_CNT = 512 – overlapping-clocks-with-other-commands
- Program STALL_THEN_EXE_BEFORE_CLKCHANGE = 1
  All following EMC register programming will happen after flushing DRAM requests and stalling further DRAM commands, including auto-refreshes.
  IMPORTANT NOTE: EMC register read still stop functioning from this point until the clock change completes: issuing an EMC register read in this duration will hang the system.
- (optional) Program unshadowed EMC registers that need to change with clock change. For example, if periodic_qrst needs to be enabled during clock change, it can be done here. If that register is shadowed, use WRITE_MUX = ACITVE before writing the register, then restore WRITE_MUX after writing the register.
- Disable auto-refresh to reduce the latency of clock change:
  EMC_REFCTRL.DEVICE_REFRESH_DISABLE = depending on DRAM configuration
  EMC_REFCTRL.REF_VALID = DISABLE
- (self-refresh clock change mode only, DLL-ON to DLL-OFF mode switching only, DDR3 only)
  Program EMC_MRS to disable DLL.
- (self-refresh clock change mode only) Program SELF_REF to enter self-refresh:
  SELF_REF.DISABLED = ENABLED
  SELF_REF.DEV_SELECTN = depending on DRAM configuration
- Program STALL_THEN_EXE_AFTER_CLKCHANGE = 1
  All following EMC register programming will happen after clock change but before unblocking DRAM requests
- (optional) Program other unshadowed registers that need to be programmed during self-refresh, such as EMC_XM2CLKPADCTRL register. If periodic_qrst is enabled in clock change but not meant for the new frequency, the value can be restored here.
- (self-refresh clock change mode only) Program SELF_REF to exit self-refresh
  EMC_SELF_REF.DISABLED = DISABLED
  EMC_SELF_REF.DEV_SELECTN = depending on DRAM configuration
- Program DRAM mode registers by MRS/EMRS (DDR3) or MRW (LPDDR2) to change CL/WL/TWR etc.
  On DLL-OFF to DLL-ON switch on DDR3, DLL is turned on with this step. Note that if a mode register has the same value at both the old and new frequencies, it does not have to be programmed.
- Issue ZQ calibration if the clock change is switching from a ZQ calibration disabled frequency to a ZQ calibration enabled frequency.

- Program UNSTALL_RW_AFTER_CLKCHANGE = 1
  Note that all following EMC register programming will happen after clock change, possible with on-going SDRAM access
- Read and discard an arbitrary MC register (Note: cannot use EMC register) to ensure the register writes are complete.
- Do clock change. Note that until this step, SDRAM access were still happening in the system
  Program CLK_SOURCE_EMC to change clock:
  EMC_2X_CLK_SRC: MC/EMC clock source
  USE_PLLM_UD: use low jitter clock
  MC_EMC_SAME_FREQ: drive EMC vs MC clock ration at 1:1, otherwise 2:1
  EMC_2X_CLK_DIVISOR: EMC clock divider
- Poll for clock change completion:
  EMC_INTSTATUS.CLKCHANGE_COMPLETE_INT == 1
- Re-enable auto-refresh
  EMC_REFCTRL.DEVICE_REFRESH_DISABLE = depending on DRAM configuration
  EMC_REFCTRL.REF_VALID = ENABLE
- Re-enable auto-calibration if it was previously enabled and then temporarily disabled during clock change:
  EMC_AUTO_CAL_INTERVAL = new value
- Re-enable DSR (dynamic-self-refresh) if it was previously enabled
  EMC_CFG. DYN_SELF_REF = ENABLE
- If EMC_ZCAL_WAIT_CNT was changed before clock change for issuing ZQ-long calibration command, restore the value:
  EMC_ZCAL_WAIT_CNT = new value
- Wait 2 us for the actions above to complete
- Update shadow registers
  EMC_TIMING_CONTROL = 1
  Poll for latching completion: EMC_EMC_STATUS_TIMING_UPDATE_STALLED == 0

18.10.5 ZQ Calibration Sequence

ZQ calibration is a feature of LPDDR2 and DDR3 to calibrate Ron (the output driver) across PVT (process, voltage, temperature), and also ODT values on DDR3. EMC supports periodically sending ZQ calibration commands to both DRAMs, requiring only the initial configuration after booting. EMC also supports one time calibration commands at booting.

For cold booting, Boot ROM does ZQ-init on LPDDR2 and ZQ-long on DDR3, and then enables periodical ZQ-short.

For warm booting, Boot ROM does ZQ-long on both LPDDR2 and DDR3, and then enables periodical ZQ-short.

One time calibration:

- LPDDR2, Write MC_MRW:
  - MRW_DEV_SELECTN: 2 for device 0, 1 for device 1. Or use 0 for both, though we don’t use it because SW must control the delays between commands in Boot ROM.
  - MRW_MA: 10
  - MRW_OP: 0xFF for ZQ-init. 0xAB for ZQ-long, 0x56 for ZQ-short
- DDR3: Write EMC_ZQ_CAL
  - ZQ_CAL_DEV_SELECTN: 2 for device 0, 1 for device 1. Or use 0 for both, though we don’t use it because SW must control the delays between commands in Boot ROM

- ZQ_CAL_LENGTH:
  SHORT: issue ZQ-short command
  LONG: issue ZQ-long command
- ZQ_CAL_CMD: 1

Periodical calibration:

- EMC_ZCAL_INTERVAL: number of microseconds to wait between periodical ZQ commands. Program this register to 0 to disable periodical ZQ calibration
- EMC_ZCAL_WAIT_CNT: number of clocks to wait after each ZQ command before other commands
- EMC_ZCAL_MRW_CMD:
  - ZQ_MRW_DEV_SELECTN
    2 for device 0 only, 1 for device 1 only, 0 for both devices
  - ZQ_MRW_MA
    LPDDR2: 10
    DDR3: 0 for ZQ-short, 1 for ZQ-long
  - ZQ_MRW_OP
    LPDDR2: 0x56 for ZQ-short; 0xAB for ZQ-long
    DDR3: 0

18.10.6 MRR Sequence

Mode Register Read (MRR) is desirable on LPDDR2 for reading manufacturer ID to identify DRAM vendors, or reading back from LPDDR2 temperature sensor.

Simple sequence:

- Before any MRR, such as at booting:
  - Set MRR_BYTESEL and MRR_BYTESEL_X16 corresponding to data byte sizzling if applied on board. The reason is that LPDDR2 always returns MRR at low byte of a data-strobe, which is the only case that EMC needs to know about swizzling.
- For each MRR
  - Check EMC_STATUS.MRR_DIVLD = 0. If not true, read EMC_MRR until it becomes true
  - Issue MRR:
    MRR_MA: the index of the mode register to read back
    MRR_DEV_SELECTN: 2 for device 0, 1 for device 1. 0 or 3 are illegal. If both devices are desired, repeat this sequence on each device.
  - Poll for EMC_STATUS.MRR_DIVLD = 1
  - Read EMC_MRR. Data is in the MRR.DATA field

18.10.7 Auto-cal Sequence

Auto-cal is for periodically calibrating the output driver of Tegra 3 pads. EMC supports periodic auto-calibration without SW interference, usually initiated at booting.

To enable auto-calibration:

- Program AUTO_CAL_INTERVAL: the number of microseconds between two auto-calibration
- Program EMC_AUTO_CAL_CONFIG:
  AUTO_CAL_START = 1
  AUTO_CAL_ENABLE = 1
  AUTO_CAL_OVERRIDE: 1 to enable override, 0 to use normal auto-calibration

AUTO_CAL_PD_OFFSET: override value
AUTO_CAL_PU_OFFSET: override value
AUTO_CAL_E_CAL_UPDATE: number of EMC clocks E_CAL_UPDATE is asserted
AUTO_CAL_STEP: number of micro seconds between each calibration steps

To disable auto-calibration:

- Program AUTO_CAL_INTERVAL to 0

To re-enable auto-calibration after disabling it

- Program AUTO_CAL_INTERVAL to the new value

18.10.8 LP0/LP1 Entry/Exit

LP0 and LP1 are both power saving modes with DRAM in self-refresh mode. The only difference is that MC and EMC are ON during LP1 but powered OFF during LP0.

LP0 and LP1 entry share the same sequence:

- Disable ZQ calibration: EMC_ZCAL_INTERVAL = 0
- Disable Auto calibration: EMC_AUTO_CAL_INTERVAL = 0
- Disable DSR (Dynamic self-refresh) EMC_CFG. DYN_SELF_REF = DISABLED
- Latch shadow registers:
  EMC_TIMING_CONTROL = 1
  Poll for latching completion: EMC_EMC_STATUS_TIMING_UPDATE_STALLED == 0
- Wait 5 us for worst case DSR exit time
- Program EMC_REQ_CTRL to stall all transactions
  STALL_ALL_WRITES = 1
  STALL_ALL_READS = 1
- Wait until EMC pipe is flushed
  poll EMC_EMC_STATUS.NO_OUTSTANDING_TRANSACTIONS == 1
- enter self-refresh
  EMC_SELF_REF.SELF_REF_CMD = 1
  EMC_SELF_REF.SREF_DEV_SELECTN: 2 for device 0 only, 1 for device 1 only, 0 for both
- Wait until the device is in self-refresh
  poll EMC_EMC_STATUS.DRAM_IN_SELF_REFRESH ==
  1: dev0 is in self-ref; 2: dev1 is in self-ref; 3: both devices are in self-ref
- Put VTTGEN in lowest power mode:
  EMC_XM2VTTGENPADCTRL.EMC2TMC_CFG_XM2VTTGEN_DRVUP = 0
  EMC_XM2VTTGENPADCTRL.EMC2TMC_CFG_XM2VTTGEN_DRVDN = 0
  EMC_XM2VTTGENPADCTRL2.EMC2TMC_CFG_XM2VTTGEN_E_NO_VTTGEN = 7
- Latch shadow registers:
  EMC_TIMING_CONTROL = 1
  Poll for latching completion: EMC_EMC_STATUS_TIMING_UPDATE_STALLED == 0
- Put pads in lowest power mode (must program in a single register write):
  APBDEV_PMC_IO_DPD_REQ.CODE = DPD_ON
  APBDEV_PMC_IO_DPD_REQ.POP_ADDR_CMD == ON
  APBDEV_PMC_IO_DPD_REQ.POP_CLK = ON
  APBDEV_PMC_IO_DPD_REQ.DDR_ADDR_CMD = ON
  APBDEV_PMC_IO_DPD_REQ.DISC_ADDR_CMD = ON

APBDEV_PMC_IO_DPD_REQ.DDR_DATA = ON
APBDEV_PMC_IO_DPD_REQ.COMP = 1

- Now it is safe to disable PLL, which will freeze EMC and DRAM clocks

LP0-exit is also called warm boot. Refer to “Warm Boot” subsection.

LP1-exit:

- Enable PLL and waits until clocks stabilize
- Restore pad power state to normal. Note that writing back the original value to this register does not guarantee restoring to the original state. Instead, read and save the value of APBDEV_PMC_IO_DPD_STATUS before LP1 entry (which has value 0 on the register fields representing the enabled pads), and in this step write the inverted value of it (so that it has 1 on register fields representing the same enabled pads) to APBDEV_PMC_IO_DPD_REQ with the field “CODE” set to “DPD_OFF” (meaning “turn it on”).
- Restore the registers to original values before LP1 entry. The register values need to be read and saved before LP1 entry and restored here.
  EMC_XM2VTTGENPADCTRL
  EMC_XM2VTTGENPADCTRL2
  EMC_AUTO_CAL_INTERVAL (this will re-enable auto-calibration)
- Relock DLL.
  Read and write back EMC_CFG_DIG_DLL with field DLL_RESET set to 1.
- Latch shadow registers:
  EMC_TIMING_CONTROL = 1
  Poll for latching completion: EMC_EMC_STATUS_TIMING_UPDATE_STALLED == 0
- Do a single auto-calibration:
  Read and write back EMC_AUTO_CAL_CONFIG with field AUTO_CAL_START set to 1
- Wait for the auto-calibration to complete:
  EMC_AUTO_CAL_STATUS.AUTO_CAL_ACTIVE == 0
- Exit self-refresh
  EMC_SELF_REF.SELF_REF_CMD = 0
  EMC_SELF_REF.SREF_DEV_SELECTN = 2 for device 0 only, 1 for device 1 only, 0 for both
- poll for self-refresh completes
  poll for EMC_EMC_STATUS.DRAM_IN_SELF_REFRESH == 0
- Issue a ZQ calibration:
  LPDDR2:
  1. Write EMC_MRW with
     MRW_DEV_SELECTN = 2
     MRW_MA = 10
     MRW_OP = 0xAB
  2. Wait 1us
  3. If this is a two rank configuration, repeat step 1 with MRW_DEV_SELECTN = 1, then repeat step 2

  DDR3:
  1. Write EMC_ZQ_CAL with
     ZQ_CAL_DEV_SELECTN = 2
     ZQ_CAL_LENGTH = LONG
     ZQ_CAL_CMD = 1
  2. Wait 10 us
  3. If this is a two rank configuration, repeat step 1 with ZQ_CAL_DEV_SELECTN = 1, then repeat step 2

- Program EMC_REQ_CTRL to unstall all transactions
  STALL_ALL_WRITES = 0
  STALL_ALL_READS = 0
- If ZQ calibration was enabled before LP1 entry, re-enable it.
  EMC_ZCAL_INTERVAL = saved value
- If DSR was enabled before LP1 entry, re-enable it:
  EMC_CFG. DYN_SELF_REF = ENABLED
  Latch in the shadow by EMC_TIMING_CONTROL.TIMING_UPDATE = 1
  The poll for latching completion: EMC_EMC_STATUS_TIMING_UPDATE_STALLED == 0

18.10.9 Performance Tuning

The Tegra MSS is architected in such a way that, other than the per-client LA setting, only minimal performance tuning is required.

> **Note:** The capitalization in the below sections refers to the actual register name of the associated setting.

18.10.9.1 Arbitration Knobs

The suggested configuration values produced by the emc_reg_calc program are the best-known values, the SW should use these values.

The Arbitration Domain provides a set of arbitration knobs that affect the entire MSS, particularly the fairness algorithm in the snap-arbitration. These knobs are:

- RING1_THROTTLE
- RING3_THROTTLE
- Per-partition SNAP_LEVELS

The Protocol Arbiter provides a set of arbitration knobs that affect the entire PA. These knobs are:

- MAX_OUTSTANDING count, and the related controls
- TURN and COVER costs for the Direction Arbiter
- PRIORITY_INVERSION thresholds
- BC2AA_HOLDOFF threshold
- EXPIRING_SOON threshold
- REFRESH_ACK threshold
- DEADLOCK_PREVENTION_SLACK threshold

It is *not* expected that software will need to shmoo these values for best performance; the emc_reg_calc script has been used in the performance verification effort.

18.10.9.2 Per Client Knobs

Each client of the MSS has some configuration knobs that affect the behavior of the request in the PA. These knobs are:

- ISOchronous
- HYSTeresis
- Latency ALLOWANCE

Most clients set their ISO and HYST bits based on the behavior profile of the client; which is static for all systems. The default programming should be acceptable for these bits. The Latency Allowance may need to be programmed on a per-usecase basis for some clients.

18.10.9.3 Activity indication for DVFS

The Tegra MSS does not maintain statistics information for the DVFS. However, it does send two signals to the centralized Statistics Monitor for that unit that maintains the threshold and interrupts that are used by DVFS. The number of atoms between toggles for these signals can be controlled by ATOMS_PER_DVFS_PULSE.

18.10.9.4 Statistics

Memory Subsystem statistics are for debugging/profiling only

There are two sets –

- MC statistics provide ability to view bandwidth/latency/per-client information.
- EMC statistics provide the ability to view DRAM commands, which you can then use to calculate approximate DRAM power consumption.

18.10.10 Errors (Interrupts)

Both the MC and the EMC implement a handful of interrupts to inform the software of completed events or error conditions encountered by the hardware. Both MC and EMC have implemented the same style of interrupt interface, so this section will use the MC as the example.

The interrupt interface for MC consists of two registers and a hardware output wire. The output signal is wired to the central interrupt handling module on Tegra 3; from there it can be routed to any of the CPU complexes. The first register, INTSTATUS, contains the interrupt vector for MC. Each bit in this register is set when the hardware detects an interrupt. Writing a 1 to the interrupt vector bit will clear the associated interrupt. The second register is the INTMASK, each bit in this register corresponds to a vector bit in INTSTATUS. If the MASK bit for an interrupt is *clear (MASKED)*, the corresponding interrupt will *not* forward the interrupt to the central interrupt handling module. If any of the UNMASKED interrupt vector bits are set, the MC will assert the interrupt to the central interrupt handling module.

18.10.10.1 MC Interrupts

The MC contains two classes of interrupt: address decode errors and performance warnings.

There is currently only one performance warning type interrupt: ARBITRATION_EMEM. It fires when the MC detects that a request has been pending in the Row Sorter long enough for to hit the DEADLOCK_PREVENTION_SLACK_THRESHOLD. In addition to true performance problems, this interrupt may fire in situations like clock-change where the EMC backpressures pending traffic for long periods of time. This interrupt is intended to help developers identify and debug performance issues and configuration issues.

There are three types of address decode errors implemented for Tegra 3, discussed below. All the decode errors share a single pair of information-capture registers that are intended to assist developers in debugging such errors (ERR_STATUS and ERR_ADR). The capture registers records information about error, including:

- the Virtual or Physical address of the error (depending on the type of fault)
- which type of fault the captured error corresponds to
- a read/write indicator
- the requesting client’s ID
- If the error was an INVALID_SMMU_PAGE, then information about the page's protection status is also captured:
  - whether the page was marked non secure in the page-table

- whether the page was marked readable in the page-table
- whether the page was marked writeable in the page-table
- Note that SMMU page protection bits are formed by ANDing the page protection bits from the Page Table Base, PDE and PTEs from all three stages of the page-walk. The ANDed protection bits and the type of the provoking transaction are both available in the status register.

Subsequent errors (of any type) will not change the status and address registers until the corresponding interrupt is cleared.

To prevent requests with address decode errors from modifying memory or accessing memory they do not have permission to, the MC “squashes” the requests. A write request that is “squashed” has had its byte-enables forced to all-zeros, this prevents the write data from being applied to DRAM. A read request that is “squashed” will have its read-return data forced to all-ones, this protects the data in DRAM from being read by non-secure sources.

The three types of address decode errors are:

- DECERR_EMEM: Decode Errors: there is no DRAM attached at the Physical Address.
- SECURITY_VIOLATION: Legacy Security Apertures: the Physical Address is in one of the Legacy Security Apertures, and the client permissions are not sufficient to allow access. There are two Legacy Security Apertures which decode as different ERR_STATUS.ERR_TYPE.

  Note: If a single request causes both a TrustZone and Protected security violation, the ERR_TYPE will report the Protected Aperture violation.

- SMMU_FAULT: The SMMU translation engine encountered either a security permission error, a read/write type error, or an invalid translation error during translation.

SMMU-translated requests and Physical Aperture Errors

All Virtual Addresses are translated through the SMMU, then run through the Physical Aperture checks. There are a number of confusing scenarios when debugging these interactions including:

- SMMU fault followed by any physical aperture error of any sort: because the SMMU translation occurs first, the data captured by the ERR_ADR and ERR_STATUS registers will always be the SMMU fault information. Both interrupt bits are set.
- Decode error on a successfully translated (ie no SMMU fault indicated) client request: the PA checks will throw a decode error; the data captured includes the Physical Address, not the Virtual Address. The client request is squashed. The decode-error interrupt bit is set.
- Decode error on a Page-Table fetch (PDE or PTE): the page-table fetch will throw a decode error; the data captured includes the Physical Address of the PDE or PTE, and the client ID corresponds to the PTC. In addition, the data returned to the PTC is modified to turn off all access permissions, marking the page INVALID. This forces the client request to also throw a SMMU fault when it is translated. Both the decode-error and SMMU-fault interrupt bits are set. The PDE or PTE are then cached with those modified access permissions, so any subsequent requests to that virtual page are also SMMU fault.
- TrustZone security violation on a translated client request: the PA checks throw a security error, the data captured includes the Physical Address, not the Virtual Address. The security violation interrupt bit is set. The client request is squashed. This behavior allows the Secure Aperture to stand as a “last line of defense” against SMMU page-table modification attacks.
- Protected-region security violation on a translated client request: the PA checks throw a security error, the data captured includes the Physical Address, not the Virtual Address. The security violation interrupt bit is set. However, the client request is not squashed. Due to this behavior, it is not recommended that the Protected Aperture be used in conjunction with SMMU translation.

18.10.11 Software Client Groupings

The Memory Subsystem inherently implements a hardware mapping of memory clients (“MCCIFs”) to super-clients, and super-clients to the hardware modules. Additionally, the MSS implements a system of mapping modules to “software groups” (aka SWGROUP or SWNAME). This is intended to allow a single point of control for all clients for that hardware “engine”. Often the list of clients in a SWGROUP is the same as the list of clients in the module that implements the hardware engine.

The mapping of SWGROUP to modules for Tegra 3 is listed here:

SWGROUP	Modules	Translatable?	Further Description
AFI	PCIE	Yes	PCI Express
AVPC	AVP Cache	Yes	Arm7 Audio-Video Processor (AVP)
DC	Display, 1st instance	Yes	Display reads
DCB	Display, 2nd instance	Yes	Display reads, instance b
EPP	EPP	Yes	Encoder Pre-Processor
G2	GR2D	Yes	2D engine
HC	Host1x	Yes	Host interface
HDA	HDA	Yes	High-definition Audio engine
ISP	ISP	Yes	Image Signal Processor
MPCORE	AXICIF	No	Cortex-A9
MPCORELP	AXICIF_LP	No	Cortex-A9
MPE	MPEA, MPEB, MPEC	Yes	MPEG4 Encoder
NV	TEX, IDX, FDC	Yes	3D engine, 1st instance
NV2	TEX, IDX, FDC	Yes	3D engine, 2nd instance
PPCS	AHBDMA, AHBSLV	Yes	Clients in the AHB cluster.
PTC	MC (SMMU)	N/A	Misses from SMMU PTC.
SATA	SATA	Yes	Serial ATA.
VDE	VDE	Yes	Video Decode Engine
VI	VI	Yes	Video Input engine.

18.11 Functionality

18.11.1 Addressing

The physical address space supported by MC is 4GB. Within this 4GB range, one physical aperture and two virtual apertures are defined. The physical aperture maps external memory. The security aperture allows software to define a region of external memory as secure so that only trusted clients[4] can access that region. The protected aperture allows software to define a region of external memory as carveout so that only certain clients can access that region.

For any particular chip, the size and locations of these apertures are fixed based on project specific definitions. For Tegra 3, these apertures are defined to be: 2GB maximum for external memory, up to 2GB secured region, up to 2GB protected region.

In addition to the physical address apertures and spaces, the MC supports a full virtual addressing scheme via the SMMU.

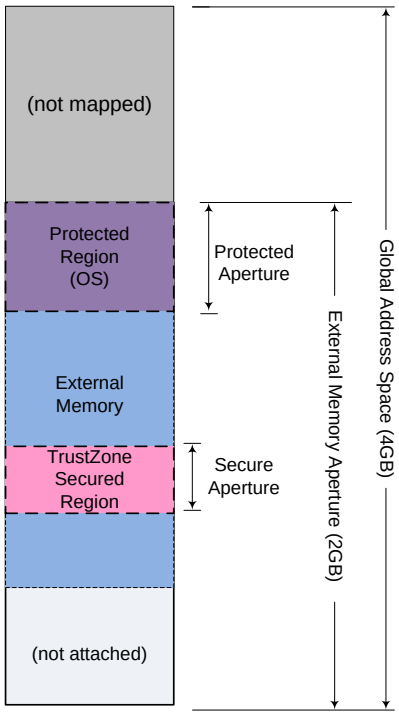
The MC receives a full 32 bit physical address and decodes it in the following way:

- The external memory is present in a fixed aperture of 2GB at a naturally aligned boundary defined by the system address map. The actual size of the external memory is defined by a programmable register; addresses outside the programmed range are treated as invalid. The offset in the external memory is given by the 31 LSBs of the address.
- A secured region of variable size can be defined in the external memory range.

[4] See subsection on TrustZone Security Region below for a discussion of security.

- A protected region of variable size can be defined in the external memory range, but always starts from offset 0x0.

Figure 24. Physical Address Map Example



Accesses that don't match one of the three address spaces are detected and an error logged. MC returns a predefined pattern[5] for reads to invalid addresses and acknowledges invalid write addresses, but otherwise EMC drops the write.

18.11.2 Granularity

The access granularity[6] inside MC is 128 bits (16 bytes) for external memory accesses. Byte access remains possible but involves a minimum granularity access. Write accesses can use byte enables to write a set of bytes (including a null set), read accesses always return a full word with potentially unneeded data (aka overfetch).

The granularity of external access is linked to the burst size programmed for DRAM access. Bursts into external memory always start at a 16-byte aligned boundary. For LPDDR2, this corresponds to a burst length of 4 data transfers (or 2 clock cycles at double data rate, known as BL4).

The DDR3 situation is complicated by the DRAM's minimum internal burst-length of 8; because the MSS works in 16-byte atoms, a naïve implementation using BL4 or BL8 setting would result in 50% efficiency loss. However, the DDR3 specification also includes a burst-chop on-the-fly mode that allows the controller to indicate for each CAS command whether it wants to transfer 4 or 8 data beats. The BL4 or BC4 accesses still consume a full 8 data beats, but some amount of power is saved by not transferring the data off-chip. The MC and EMC implement support for coalescing of 2 atoms into a 32-byte-aligned pair.

18.11.3 Virtual Addressing

The SMMU is a centralized virtual-to-physical translation for MSS. It allows the following:

[5] All data bits are forced to 1's.

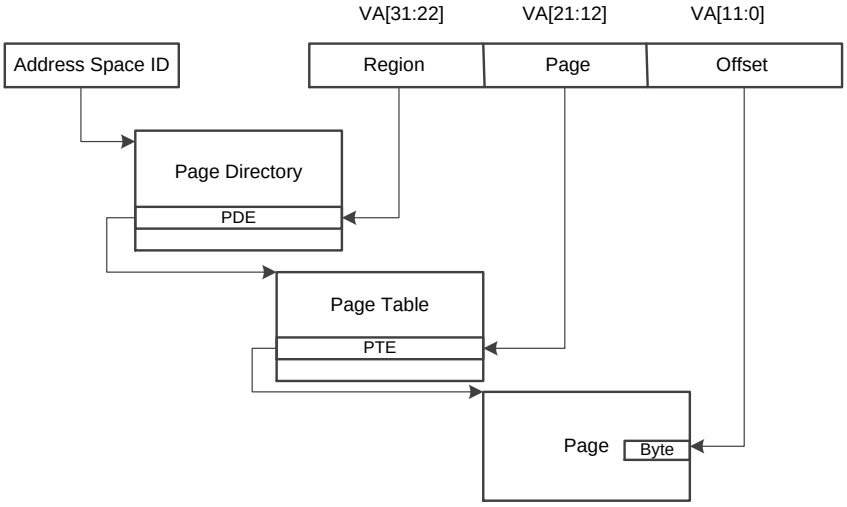
[6] A datum of 128-bit-granularity may be referred to as a "memory atom".

- Memory allocation for hardware pools (surfaces and buffers) could be made from non-contiguous page-sized chunks of memory
- Areas of the hardware memory map could be marked as protected, preventing access from hardware devices
- Hardware memory access can be controlled on a per-device or per-process basis

The virtual-to-physical translation is via a two-level page table that carves up the virtual address as follows:

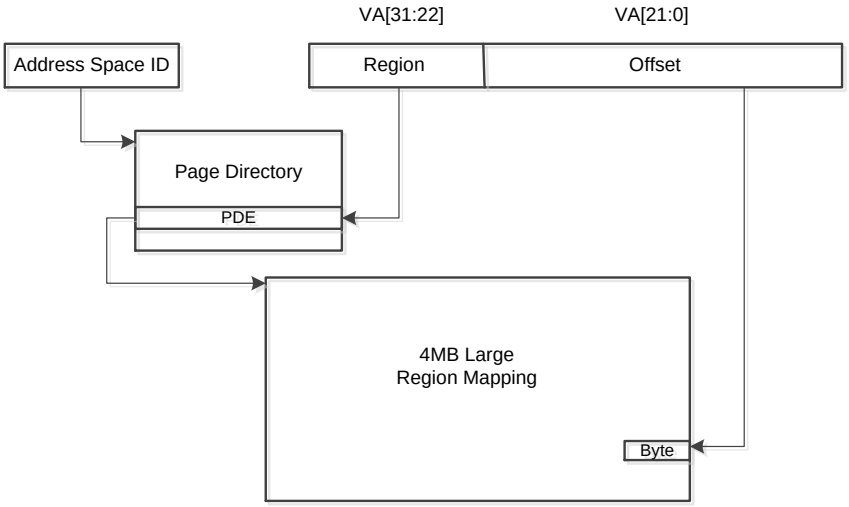
- Bits 31:22 choose a page directory entry (PDE). Each page directory has 1,024 PDEs, each mapping 4MB region.
- Bits 21:12 choose a page table entry (PTE) from a page table. Each page table has 1,024 PDEs, each mapping a 4kB page.
- Bits 11:0 choose a byte within a page

Figure 25. Page Table and Virtual Address



Each PTE or PDE consume 32-bits of memory, so that each page directory or page table consumes one 4kB memory page. In addition, the page directory lookup does an early-out either to map an entire 4MB region of the virtual space as invalid, or to map the region to a contiguous range of physical pages.

Figure 26. Large Region Mapping



Both the page and directory tables are stored in DRAM. A translation look-aside buffer (TLB) is used to cache recently-used translations. Translations that miss in the TLB incur potentially two additional round-trip DRAM delays, but the latency-scheduling features of the Protocol Arbiter is used to hide this latency behind the normal latency incurred by the DRAM reordering policy. The TLB is backed by a page-table cache (PTC) to reduce this memory traffic further.

In addition, the SMMU supports multiple address spaces, each tagged with an address space identifier (ASID). The ASID allows for multiple virtual mappings to exist at the same time. Typically, software uses these to assign different mappings to each process that directly uses the hardware drivers, allowing process isolation. The number of ASIDs provided by the implementation is a system parameter, but is expected to be a smallish number (Tegra 3 implements 4 ASIDs total). Software is responsible for managing the assignments between processes and ASIDs, flushing ASIDs out of the TLB as needed when they are remapped between processes.

ASIDs are assigned based on the SWNAME of the incoming request. An on-chip mapping between SWNAME and the ASID is maintained by the SMMU. For register-based devices, the driver is responsible for updating the mapping between the SWNAME and the ASID when a device in context is swapped between processes.

Untranslated modules are also supported. The SWNAME-to-ASID mapping has a translation-enable bit to allow translation on a per-SWNAME basis. There is also a per-client translation-enable bit for HW Diagnostics purposes.

Typically, only the CPU uses the untranslated mode, since it has its own MMU and can map any physical page into a process at will. Untranslated accesses for all clients are fast-pathed through the MC/SMMU system so that the latency of such accesses are not impacted more than necessary. To further improve CPU latency, the Tegra 3 CPU low-latency read paths bypass the SMMU altogether; the hardware also restricts the CPU write paths to untranslated-mode to prevent any configuration mishaps. In addition, a global “translation enable” bit disables all translation when cleared (cleared is the default out of reset).

18.11.3.1 Page Table Layout

The in-memory layout of a PTE looks like

- 20 bits of physical address (PA[31:12]) for the base of the page
- Protection bits which include
  - A “readable” bit which allows clients to read this page
  - A “writeable” bit which allows clients to write this
  - A “nonsecure” bit which (when unset) restricts access of this page to “secure” TrustZone clients

The remaining bits in the 32-bit word are reserved.

> **Note:** Wherever physical addresses are used in this document, it is assumed that the device can address 4GB of physical memory. The actual physical memory that can be attached to the device may be smaller or larger, and if so, any of the hardware structures that hold physical addresses shrink or grow accordingly. This means that, for example, in a 2GB system, the physical addresses in the PDE and PTEs have only a 19 bit field, and the TLB and PTC need only cache those 19 bits instead of the full 20.

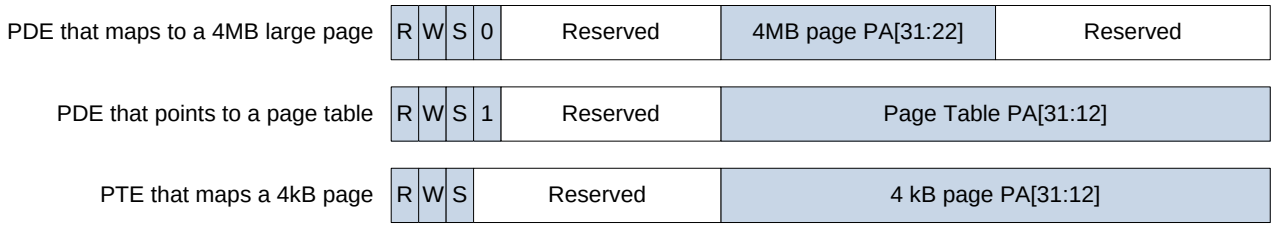
The in-memory layout of a PDE looks like:

- A “next level” bit which says if this PDE maps a single 4MB region, or if it points to a page containing a table of PTEs for the second level of translation
- If the “next level” bit is set, there are 20 bits of physical address (PA[31:12]) that point to a page containing the base of the PTE table for this PTE. If the “next level” bit is clear, we use 10 bits (PA[31:22]) to point to the base of an aligned 4MB physical region mapped directly by the PDE.
- The remaining bits set the permissions for the access. For 4MB large pages, these are used directly for the region. For PDEs that point to a second-level page table, these permissions are ANDed with those of the PTE to give the final permission

- A “readable” bit for the region
- A “writeable” bit for the region
- A “nonsecure” bit for the region

The remaining bits in both interpretations are reserved.

Figure 27. PDE and PTE Formats



The base address of the page directory for a particular ASID is stored on-chip in the ASID table. Changes to this table may require flushing the ASID in question from the TLB.

18.11.3.2 Faults

When an access violates the “readable”, “writable” or “nonsecure” bits for the region, it generates a fault. A fault can cause an interrupt to be generated if desired. In addition, information about the most recent fault is stored on chip, consisting of the following:

- VA[31:4] of the faulting access
- Access type (read/write, secure/non-secure)
- Client ID
- The page permissions at the time of fault (readable, writeable, nonsecure)

Only faults for translated requests use this mechanism. Untranslated requesters (including the SMMU itself) report other types of faults (address out of range, etc.) via the existing MC fault reporting mechanism.

18.11.3.3 Flushes and Page Table Updates

Changes to the page tables require the TLB to be flushed. A software interface for selectively flushing parts of the TLB is provided. The flush command can flush any TLB entries that match a particular subset of virtual addresses. Each address component may be included for matching:

- Match on the ASID, or not
- Match VA[31:24], or Match VA[31:14], or no VA match

Disabling all matches flushes the entire TLB. Note that the TLB is 4 entries wide, so when you match any particular VA you flush the entire line, which is why the VA matches are down to 24 and 14, rather than 22 and 12.

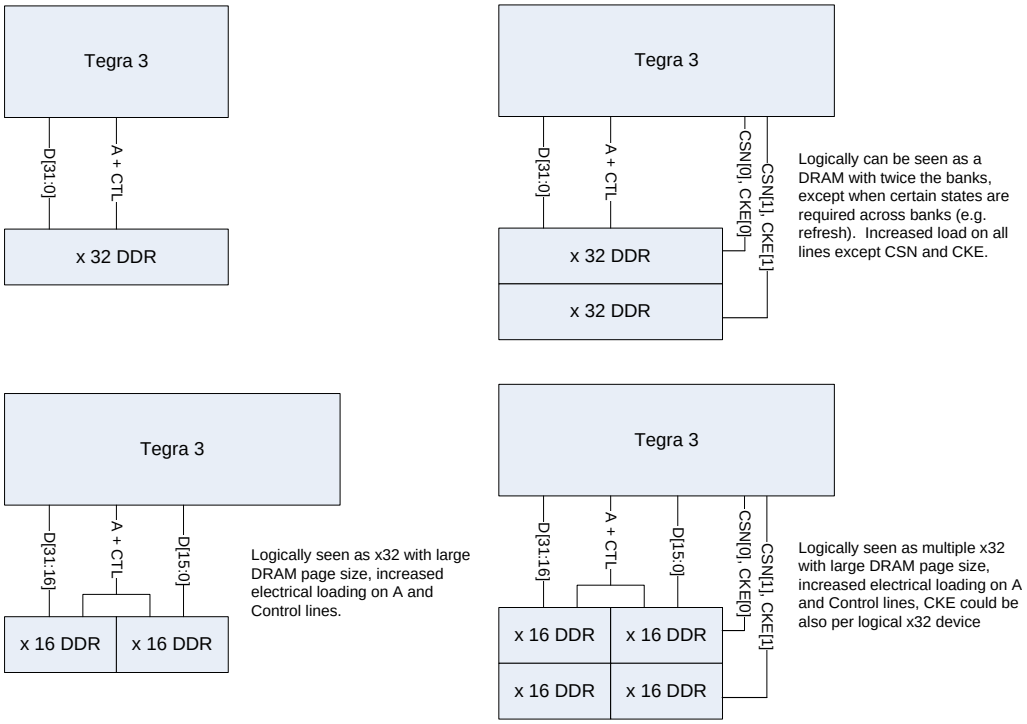
In addition to the TLB, page table updates require flushing stale entries out of the PTC. This needs to be done on a slot-by-slot basis by writing the PDE or PTE’s physical address (PA[31:4]) to the PTC flush command. Each flush flushes four aligned PTEs or PDEs (one DRAM atom’s worth) out of the cache.

Note that a page table update requires three writes – one to write the PTE to memory, one to flush the stale PTE out of the PTC and a third to flush the stale VA mapping out of the TLB. However, since a single PTC flush flushes four PTE or PDEs and a single TLB flush can flush the entire TLB, software can reduce the flush traffic by merging flushes from multiple updates.

18.11.4 DRAM device, bank and page mapping

This relates to the external memory devices, EMC supports multiple devices with datawidths of 8, 16, or 32 bits[7], all identical. Examples of configurations are shown in the next figure. The EMC controller uses specific bits in the address to identify the chip select associated with the address.

Figure 28. Multiple chip select signals (x8 cases not shown)



The POR specifies support for 2 CS and 2 CKE. Having the same number of CS as CKE is important to limit the operating power consumption of the external DRAM.

The two ways of supporting multiple external devices have the following consequences for the inside logic.

- Width extension, when two x16 (or four x8) DRAM chips are used as one x32 device
  - Results in the apparent page size of the apparent x32 devices to be twice the size of the external x16 device page size but the number of banks is unchanged.
  - The EMC only needs one state machine corresponding to the apparent x32 device.
  - Data-bit loading is unchanged but address/control-bit loading is doubled.
- Depth extension, when multiple x32 devices are used at different address offsets,
  - Results in an apparent page size equal to the external device page size but the apparent number of banks is multiplied by the number of devices
  - The EMC needs to maintain multiple bank and device state machines
  - Loading on all interface bits except CKE and CS are doubled.

Each DRAM device also exposes a bank and page structure that affects performance. For better performance, a stream of accesses to the DRAM should be such that

- Access to different banks are interleaved

[7] A x32 device may be a single x32 chip or two x16 chips in parallel.

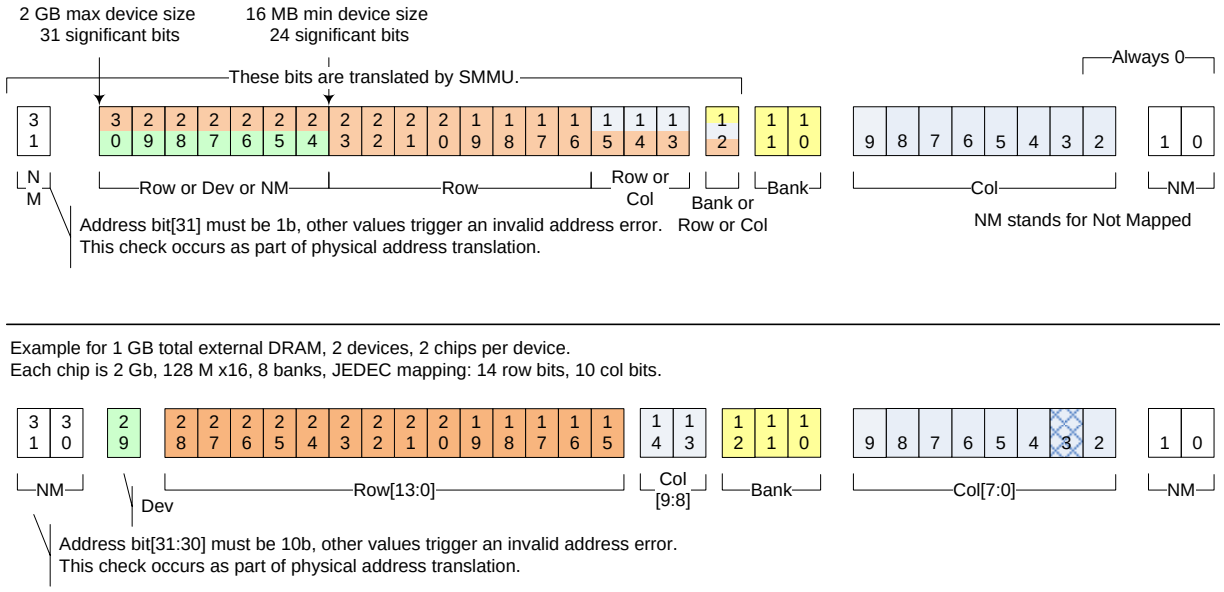
- Consecutive accesses to the same bank are for the same page in that bank

The external memory arbiter attempts to generate a request stream with such characteristics, but it is dependent on the requests it receives from the different clients. It is more important to ensure bank interleaving for robust performance, this is achieved by ensuring that banks are also interleaved with a small pitch in the address space, with a pitch small compared to the size of expected data structures in memory. However, the pitch should not be too small either to ensure that address locality in a client results in same page accesses.

The proposed bank pitch corresponds to 64 DRAM data bursts, each of 16 bytes, for a final pitch of 1024 bytes. The bit mapping between the internal linear address and the device, row, column and bank bits is performed like this:

- The 2 LSBs of the linear address are ignored as the address granularity of the DRAM is 32 bits/4 bytes
- Bits[9:2] of the linear address are mapped as column bits[7:0]
- Bits [11:10] are bank bits.
- Bit [12] is a bank bit if the device has more than two bank bits.
- The next bits of the linear address are mapped as column bits, as many as remaining after previous mapping
- The next bits of the linear address are mapped as row bits, as many as needed for the selected device
- The next bit is a device bit if device bits are needed

Figure 29. Address mapping example



The number of bank, column, row, and device bits is limited by the number of address pins available:

- Bank width: 2 or 3
- Column width: 8 to 11
- Row width, depends on if you're using DDR3 with 1 device:
  - Yes: up to 16 bits
  - No: up to 15 bits
- Logical Devices (aka chip-selects): 1 or 2

When two logical devices are used, the total memory mapped by the second device must be less than or equal to the first device. The second device also may have a different row, bank, column mapping from the first device.

18.11.5 TrustZone Security Region

The MC can secure a region in the physical address aperture from insecure software sources. The region can be defined on 1MB boundaries in the external memory region, in multiples 1MB. If a non-secure request is made to the secured region, MC throws an interrupt and logs the details of the request (address, client id). After the details are logged, write requests are dropped and read requests forced to return all 1's, thus protecting the secured region from corruption by the insecure source.

Only clients configured for security are able to make secure requests. In Tegra 3, the CPU is configured to allow secure requests (via the PL310 and AXICIF), as well as the AHB slave clients and the VDE bitstream decode engine (BSEV). The AXICIF follows the AXI protocol of using aprot[1]==0 as the "secure" indication. The AHB bus adds a secure-bit as a sideband to the request, and translates this bit to the MCCIF secure indication. The VDE BSEV connects directly to a secure MCCIF client.

The SMMU's memory client (PTCR, used for page-table misses) may also access secured memory if the SMMU is configured to allow secure accesses. See subsection on "Virtual Addressing" above for details.

In addition to securing the region in memory, register accesses that would modify the location of the secure region must also be secured. The two registers controlling security may only be modified by secure register requests.

18.11.6 OS-Protection Memory Region

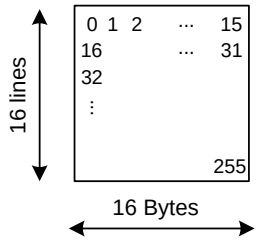
The MC can secure a region in memory from access and modification by the GPU hardware engines. The intended use of this section is to prevent modification of the OS image from untrusted software via the hardware engines. The protected region is defined to start at EMEM_BOM and can be extended in multiples of 1MB. The clients allowed to access the protected region are the CPU, the COP, the AHB, VDE's BSEV, and the PTC and anything translated through the SMMU. All other clients attempting to access this region will cause MC to throw and interrupt and log the details of the request (address, client id). After the details are logged, write requests will be dropped and read requests will be forced to return all 1's, thus protecting the region from corruption by the insecure source.

In addition to protecting the region in memory, register accesses that would modify the boundary of the protected region are also secured by TrustZone.

18.12 Memory Tiling

The memory tiling format was originally proposed to decrease the latency for vertical accesses and to improve overall bandwidth utilization. Each tile is 256 bytes; the width of a tile is 16 bytes and height is 16 lines. Each tile entirely fits in a single DRAM page, often more than one per DRAM page. For example, 4 tiles will fit in a 1KB page. The addressing with in a tile is shown below and aligns with a macro-block pattern. This tiling fits well for video decoder and encoder needs. For clients that are inherently linear, tiling should have no effect for DRAM interfaces working on a 16-byte atom.

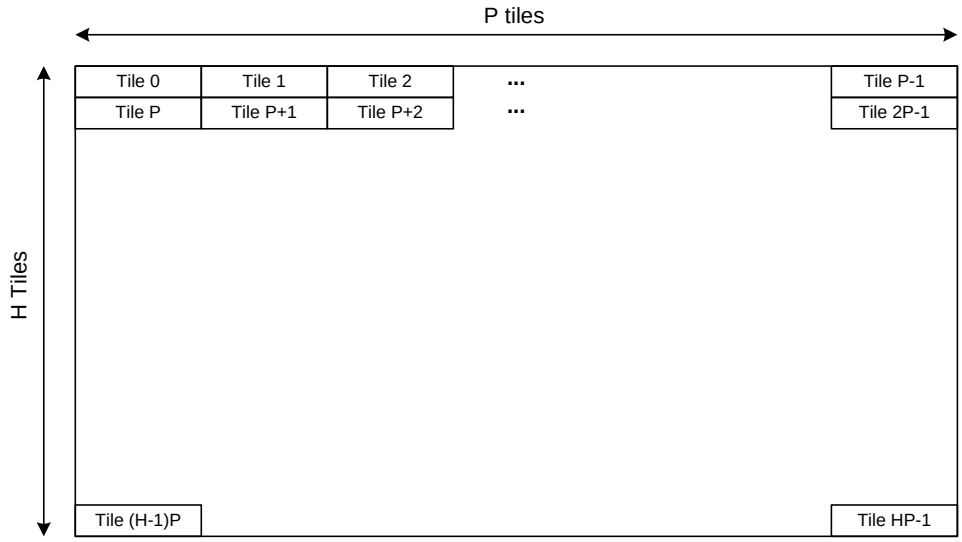
Figure 30. A Memory Tile



18.12.1 Tiling pattern and layout in memory

Memory tiles are scan line ordered within tiled surface. Since each tile width is 16-bytes, height is 16-lines and the surface needs to be rectangular with integral number of tiles, it puts a restriction on the surface stride to be multiple of 16-bytes and height to be multiple of 16-lines. The diagram below shows how a typical surface of (PxH) tiles look like.

Figure 31. Tile Layout in a Surface



18.12.1.1 Tiled address calculation

For addressing a location in a tiled surface, the client has to provide the surface parameters - base address, pitch and pixel coordinate (x, y). The tiled address is calculated using the equation,

tiled_addr = base + (y/16) * 16 * pitch + (x/16) * 256 + (y%16) * 16 + x%16

where *base* is the surface base address in bytes, *y* is the vertical top-to-bottom offset of the pixel data in lines, *x* is the horizontal left-to-right offset of the pixel data in bytes, *pitch* is the surface padded pitch in bytes, and *tiled_addr* is the memory byte address after tiling.

18.12.1.2 Linear to Tiled Address Translation

Certain clients in the system are not able to provide (x, y) coordinates without disruptive hardware changes. In these cases, the client may choose to implement a linear-to-tiled address conversion mechanism that has reduced flexibility. By restricting the pitch *p* to the form

$p = k * 2^{(n + 6)}$

where *k* is an odd natural number and *n* is a natural number, a linear address can be converted to a tiled address requiring only the additional information of the surface base address and the surface pitch. This method reduces the width of the division operator required, thus reducing the latency impact of this operation.

The supported values of k are [1,3,5,7,9,11,13,15]; the supported values of n are [0,1,2,3,4,5,6]. For most surfaces with pitches of the restricted form, the resulting tiled address is exactly the same as would be computed by the normal (x, y) equation; surfaces where

$(linear – base) > 2^{22}$

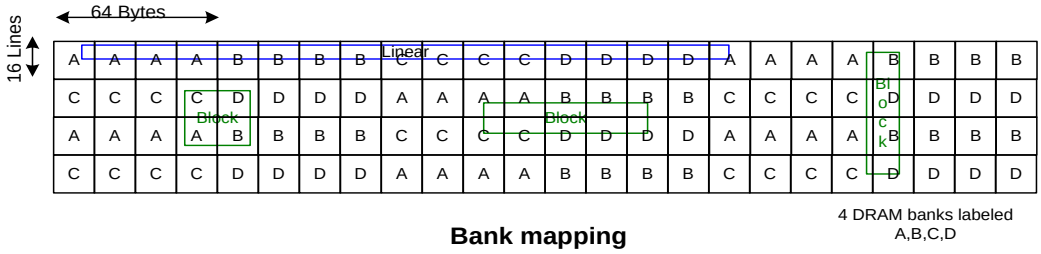
will result in incorrect tiled address. Certain surfaces that do not naturally align to a pitch of the form mentioned above will have wasted memory at the right and bottom edges of the surface.

18.12.2 Tiling Bank Layout

Even though tiling helps the block accesses to be in a single DRAM page, block accesses often fall in multiple tiles. For a typical DRAM, the penalty for closing the current page and opening a new page on the same bank is around 10 cycles; if the controller does not have to close the current page, this penalty drops to around 3 cycles. Penalty for closing and re-opening a page cannot be hidden in a single-client stream, so adjacent tiles should not be mapped to different row on the same bank. Penalty for opening a page on different bank can be hidden with the data transfer from different bank.

To balance the needs of linear clients and block clients, the bank interleaving must be chosen such that page-miss penalties are acceptable for both access patterns. The solution in Tegra 3 is to use byte address bits [11:10] as the bank bits to DRAM. For a typical 1KB-page DRAM, and assuming a 16-byte memory atom, this causes linear clients to switch banks every fourth access. The block clients also retain the benefits of page locality while still spreading their access patterns across enough banks to hide the page-open penalty.

Figure 32. Effects of Bank Address Mapping on Tile Layout



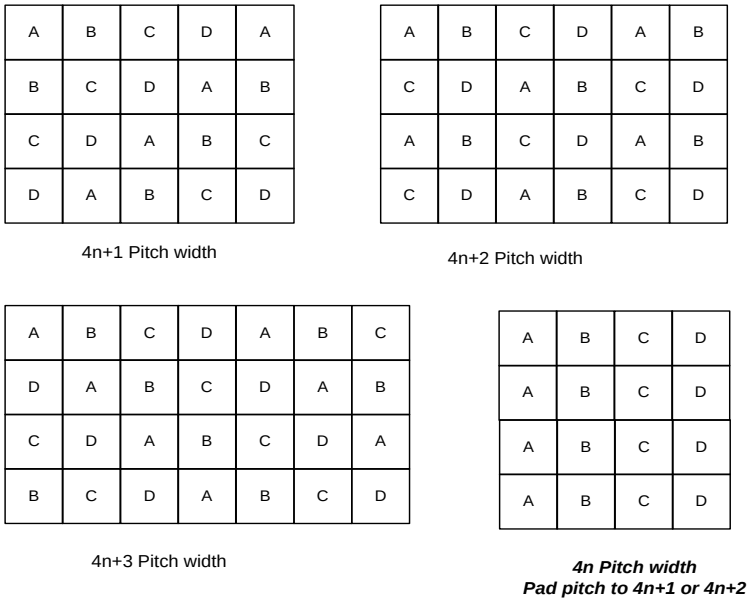
This bank mapping creates one problem, in that it reduces the inherent bank interleaving between different clients. The reordering aspects of the external memory arbiter should fairly handle contention between different clients; however, the basic resource conflict still limits the available performance of the system.

18.12.2.1 Tiling pitch values and padding

The figure below shows the bank ordering for different widths of surface. For pitch values which are in the form 4n+1, 4n+2, 4n+3, normal bank ordering provides bank interleaving for the vertical accesses. For 4n pitch, normal bank ordering is inefficient. To correct this, software should pad 4n pitch to 4n+1 or 4n+2 for better bank mapping for vertical accesses.

For 4n+1, 4n+3 mappings, even though banks in horizontal and vertical directions are different, the diagonals show inefficient bank orderings. Block accesses opening the same bank twice for these configurations will have some performance degradation. If this is not acceptable the surfaces should be padded to a 4n+2 format.

Figure 33. Surface Pitch and Padding Examples



Impact of DRAM Configurations on Surface Pitch Alignment

Having 8 physical banks with the third bank-bit mapped low doubles the interval before a page-collision occurs (eg ABCDEFGH pattern) when using physical addressing. However, most applications are expected to use the virtual addressing via the SMMU, which translates the third bank-bit. Software SMMU allocation should be aware of this issue and attempt to page-color and pad accordingly.

Having two devices does not have any impact on tiling since the device bit is mapped high, and is translated.

Padding for Multiple Surfaces

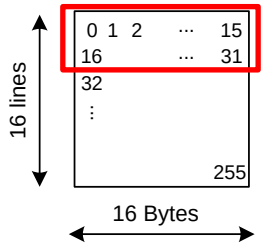
It is often the case that fetching from two surfaces which are tiled and switching buffers constantly. Good examples could be color and Z fetches, blending two surfaces, YUV surfaces, etc. In these cases it is quite possible that both the surfaces would keep accessing same bank and different rows, causing page-thrashing. This would create penalty in opening and closing the same bank multiple times. It must be noted that due to different consumption rates for different scenarios, it is impossible to avoid all page-thrashing. Efforts have been made to minimize page-thrashing in the MCCIF clients.

To reduce page-thrashing, software should program the base addresses of the surfaces staggered by the page size (usually 1KB), so that surfaces would start with a different bank. If the first surface is starting at address aligned to (4x) K bytes, the second surface should be aligned to (4x+1)K, (4x+2)K or (4x+3)K.

18.12.3 Tiling with DRAM Atoms Larger than MSS Atoms

For situations where the DRAM fetches a minimum of 32 bytes per CAS command (DDR3), this tiling format produces an inherent 50% overfetch. Each memory access returns two lines of data, as shown in the figure below. For clients that issue request in macroblock order (MPE), or are natively working in 32 bytes (CPU caches, 3D engine) the MSS can coalesce two requests together late in the pipestage to take advantage of the overfetch. For clients that issue requests in horizontal linear order (Display, VI), the overfetch issue cannot be solved by MSS. Software should consider the overfetch inherent in linear clients into consideration when computing the overall bandwidth consumed for those clients touching tiled surfaces.

Figure 34. DDR3 Tiled Fetch



18.13 Memory Controller Registers

18.13.1 MC Registers

USAGE NOTE: Many MC register fields are shadowed.

Writes to shadowed register fields update the shadow copy (this is default, assumes TIMING_CONTROL_DBG.WRITE_MUX==ASSEMBLY).

Reads to shadowed register fields return the currently-active copy (this is default, assumes TIMING_CONTROL_DBG.READ_MUX==ACTIVE).

This allows a new set of frequency-dependent timing parameters to be written to the shadow registers while memory traffic is ongoing, then when the parameters are completely written, the MC hardware can perform a timing-safe switch.

Such switches can be triggered via two methods: TIMING_CONTROL.TIMING_UPDATE (generally used during initialization), or the automatic CAR/EMC handshake on a clock-frequency or divider change (assuming TIMING_CONTROL_DBG.IGNORE_EMC_TRIGGERS==DISABLED).

Registers that are shadowed are marked by a comment:

“This register is shadowed: see usage note at top”

USAGE NOTE: Many MC registers should be programmed by the BootLoader as part of the warm boot (aka "wake from LP0") and cold boot (aka "power up") sequences. Suggested actions for the Boot ROM/Bootloader are noted in comments labeled "Boot requirements: ...".

USAGE NOTE: Some MC registers may only be accessed by TrustZone-secured register transactions. See the Cortex A9 documentation for information on how to handle security. Such registers are marked by a comment:

“Access to this register is restricted to TrustZone-secured requestors.”

USAGE NOTE: The MC register fields to be stored in PMC scratch registers for warm boot must have "[PMC]" in their comments. After adding and removing such PMC flag, the tool warmboot_code_gen must be rerun to generate new bootrom code.

18.13.1.1 MC_SMMU_CONFIG_0

Used for interrupt set/clear enums. When disabled, all transactions are untranslated. When enabled, transactions may be translated. See per-client and per-module enables in SMMU_* registers below.

This register can only be accessed by TrustZone-Secured accesses from the CPU.

Access to this register is restricted to TrustZone-secured requestors.

Boot requirements: This register should be saved to SDRAM registers and restored by the OS during warm boot.

SMMU Enable Register

Offset: 010h | Read/Write: R/W | Secure: Trust Zone Protected | Reset: 0b0

Bit	Reset	Description
0	DISABLE	SMMU_ENABLE: 0 = DISABLE 1 = ENABLE

18.13.1.2 MC_SMMU_TLB_CONFIG_0

Translation Lookaside Buffer Config Register

Controls usage of the TLB.

Boot requirements: This register should be saved to SDRAM registers and restored by the OS during warm boot.

Offset: 014h | Read/Write: R/W | Reset: 0b001xxxxxxxxxxxxxxxxxxxxxxxx10000

Bit	Reset	Description
31	DISABLE	TLB_STATS_ENABLE: Enable TLB Hit and Miss counters 0 = DISABLE 1 = ENABLE
30	DISABLE	TLB_STATS_TEST: Set stats registers to all "1s" 0 = DISABLE 1 = ENABLE
29	ENABLE	TLB_HIT_UNDER_MISS: Allow hits to pass misses in the TLB. This value may not be changed on the the fly. Ideally this should be set before enabling the SMMU. At the very least, the TLB needs to be flushed and traffic through the SMMU stopped before changing this value. 0 = DISABLE 1 = ENABLE
4:0	0x10	TLB_ACTIVE_LINES: Set the number of active lines. Allows the TLB to be made "virtually smaller" to save power. "Inactive" lines will never hit and never hold data.

18.13.1.3 MC_SMMU_PTC_CONFIG_0

Controls usage of the PTC

Boot requirements: This register should be saved to SDRAM registers and restored by the OS during warm boot.

Page Table Cache Config Register

Offset: 018h | Read/Write: R/W | Reset: 0b001xxxxxxxxxxxxxxxxxxxxxxx111111

Bit	Reset	Description
31	DISABLE	PTC_STATS_ENABLE: Enable PTC Hit and Miss counters 0 = DISABLE 1 = ENABLE
30	DISABLE	PTC_STATS_TEST: Set stats regs to all "1s" 0 = DISABLE 1 = ENABLE
29	ENABLE	PTC_CACHE_ENABLE: Enable the PTC cache. 0 = DISABLE 1 = ENABLE
5:0	0x3f	PTC_INDEX_MAP: XOR pattern for tag generation

18.13.1.4 MC_SMMU_PTB_ASID_0

Page Table Bases (PTBs)

These pointers point to a 4KB-page aligned table of PDEs for each ASID. They also contain initial permission bits that are ANDed with those in the PDE and PTEs to determine the final permissions of accesses through this ASID.

The PTBs are stored in a RAM that is accessed indirectly though the SMMU_PTB_ASID and SMMU_PTB_DATA registers.

Boot requirements: This RAM should be saved to SDRAM and restored by the OS during warm boot.

Page Table Base ASID Register

This register selects which PTB is modified by the SMMU_PTB_DATA register.

Offset: 01ch | Read/Write: R/W | Reset: 0bxx

Bit	Reset	Description
1:0	X	CURRENT_ASID: ASID used to address SMMU_PTB register

18.13.1.5 MC_SMMU_PTB_DATA_0

Writes or reads to this register write or read the Page Table Base pointer for the ASID defined in the SMMU_PTB_ASID register.

This register is not TrustZone secure, but only a TrustZone secure access may alter the PTB for a secure ASID.

Secure ASIDs have additional privilege over other non-secure ASIDs - they may fetch page tables from secure memory and they can allow clients translated through them to make secure accesses if programmed to do so.

Attempts to write a secure ASID with a non-secure access will be ignored, and non-secure reads will return garbage.

Page Table Base Data Register

Offset: 020h | Read/Write: R/W | Reset: 0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx

Bit	Reset	Description
31	X	ASID_READABLE: if set, reads are allowed for this ASID
30	X	ASID_WRITABLE: if set, writes are allowed for this ASID
29	X	ASID_NONSECURE: if set, non-secure accesses are allowed for this ASID
19:0	X	ASID_PDE_BASE: Pointer to page of PDEs, bits [31:12] for this ASID

18.13.1.6 MC_SMMU_TLB_FLUSH_0

Software can write this register to flush a specific page group, 4MB section, entire ASID or the entire TLB. There is independent control over matching part or all of the VA and/or matching the ASID.

Note: The granularity of VA mapping here is at a page group, which is the number of PTEs that fit in a memory atom.

Translation Lookaside Buffer Flush Register

Offset: 030h | Read/Write: R/W | Reset: 0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx

Bit	Reset	Description
31	X	TLB_FLUSH_ASID_MATCH: If ENABLED, Only entries matching TLB_FLUSH_ASID are flushed. 0 = DISABLE 1 = ENABLE
30:29	X	TLB_FLUSH_ASID: ASID to match when TLB_FLUSH_ASID_MATCH is ENABLED
19:2	X	TLB_FLUSH_VA_GROUP: Virtual address to match for group flushes, VA[31:14]
1:0	X	TLB_FLUSH_VA_MATCH: Controls flushing based on VA, one of ALL: Flush entire TLB SECTION: Flush all entries with a VA[31:22] that match TLB_FLUSH_VA_SECTION GROUP: Flush all entries with a VA[31:14] that match TLB_FLUSH_VA_GROUP 0 = ALL 2 = SECTION 3 = GROUP

18.13.1.7 MC_SMMU_PTC_FLUSH_0

Software can use this register to flush a specific PTE or PDE from the Page Table Cache (PTC) by writing the atom-aligned physical address of the PTE group. It can also flush the entire PTC via this register.

> **Note:** The granularity of flushing is at the PTE group, which is the number of PTEs that fit in a memory atom.

Page Table Cache Flush Register

Offset: 034h | Read/Write: R/W | Reset: 0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx

Bit	Reset	Description
31:4	X	PTC_FLUSH_ADR: Physical address of PTE group to match for address flushes, PA[31:4]
0	X	PTC_FLUSH_TYPE: Controls flushing, one of ALL: Flush entire PTC ADR: Flush PTEs that are addressed by PTC_FLUSH_ADR 0 = ALL 1 = ADR

18.13.1.8 MC_SMMU_ASID_SECURITY_0

This register controls which ASIDs are considered "secure". Secure ASIDs cannot have their PTBs read or written by a non-secure access, nor can they be assigned as a module's ASID by a non-secure write.

ASIDs may also be enabled as "promoting", which allows modules mapped through them to inherit their secure status. If a secure ASID has its promotion bit enabled, modules mapped to this ASID may access the secure physical memory region.

> **Note:** All ASIDs, regardless of security, may access TrustZone-secure physical memory for page table accesses.

This register can only be accessed by TrustZone-Secured accesses from the CPU.

Boot requirements: This register should be saved to SDRAM and restored by the OS during warm boot.

ASID Security Register

Offset: 038h | Read/Write: R/W | Secure: Trust Zone Protected | Reset: 0b0000xxxxxxxxxxxx0000

Bit	Reset	Description
19:16	0x0	PROMOTING_ASIDS: If bit N in this field is set, clients that are mapped to ASID N may access the TrustZone-secure area of memory if ASID N is also marked as "secure".
3:0	0x0	SECURE_ASIDS: If bit N in this field is set, the PTB of ASID N cannot be read or written by a non-secure access, nor can this ASID be mapped to a module by a non-secure write.

18.13.1.9 MC_EMEM_CFG_0

Boot requirements:

- This register should be parameterized in the BCT and written by the Boot ROM during cold boot.
- This register should be saved in the scratch registers and restored by the Boot ROM during warm boot.
- During warm boot, this register may be derived from EMEM_ADR_CFG* register values.

External Memory Aperture Configuration

Offset: 050h | Read/Write: R/W | Reset: 0b011111111111

Bit	Reset	Description
11:0	0x7ff	EMEM_SIZE_MB: Specify the external memory aperture size in megabytes. This field must be set to less than or equal to the available physical memory for proper operation. This value is used to check for decode errors; requests to addresses greater than or equal to EMEM_BOM+EMEM_SIZE_MB will result in an EMEM decode error.

18.13.1.10 MC_EMEM_ADR_CFG_0

The EMEM_ADR_CFG* registers are used to specify the DRAM density and geometry parameters. MC will use these parameters to derive device, row, bank, column addressing values to EMC.

> **Note:** The maximum size externally supported is dependent on pinout and address-map aperture limitations, and that it may be possible to configure the device/row/bank/column addresses in ways that exceed these limitations.

For each device attached [1..NUMDEV], the associated per-device address configuration must also be programmed, in the associated register EMEM_ADR_CFG_DEV{N-1}.

The maximum number of row bits carried internally is defined by NV_MC_EMEM_ROW_WIDTH.

The maximum number of address pins is defined by NV_MC_EMEM_ROWPIN_WIDTH.

If not being used to address a device, the chip-select pins may be re-used as row address pins for DDR3.

> **Note:** LPDDR2 only supports up to 15 row bits.

Valid settings for EMEM_ADR_CFG_DEV* regs should ensure device address width <= bank width + column width + NV_MC_EMEM_ROW_WIDTH

Boot requirements:

- This register should be parameterized in the BCT and written by the Boot ROM during cold boot.
- This register should be saved in the scratch registers and restored by the Boot ROM during warm boot.

External Memory Address Configuration, System

Offset: 054h | Read/Write: R/W | Reset: 0b0

Bit	Reset	Description
0	N1	EMEM_NUMDEV: [PMC] number of populated DRAM devices. 0 = N1 1 = N2

18.13.1.11 MC_EMEM_ADR_CFG_DEV0_0

Configures the density and geometry of the first attached device.

Boot requirements:

- This register should be parameterized in the BCT and written by the Boot ROM during cold boot.
- This register should be saved in the scratch registers and restored by the Boot ROM during warm boot.

External Memory Address Configuration, Device 0

Offset: 058h | Read/Write: R/W | Reset: 0b0100xxxxxx10xxxxx010

Bit	Reset	Description
19:16	D64MB	EMEM_DEV0_DEVSIZE: [PMC] density of the first attached DRAM device, used to generate width of row address. 2 = D16MB 3 = D32MB 4 = D64MB 5 = D128MB 6 = D256MB 7 = D512MB 8 = D1024MB 8 = D1GB 9 = D2048MB 9 = D2GB
9:8	W2	EMEM_DEV0_BANKWIDTH: [PMC] width of bank address of the first attached DRAM device. 2 = W2 3 = W3
2:0	W9	EMEM_DEV0_COLWIDTH: [PMC] width of column address of the first attached DRAM device. W8 maps to 1KB page size, W9 to 2KB, W10 to 4KB, etc. 1 = W8 2 = W9 3 = W10 4 = W11

18.13.1.12 MC_EMEM_ADR_CFG_DEV1_0

Configures the density and geometry of the second attached device, if a second device is populated.

To allow for 2 devices with different colwidth/bankwidth to be used without creating holes in the system-level address map, the DEVSIZE setting of the second device may be smaller than the others to allow for non-powers-of-2 attached memory sizes.

Boot requirements:

- This register should be parameterized in the BCT and written by the Boot ROM during cold boot.
- This register should be saved in the scratch registers and restored by the Boot ROM during warm boot.

External Memory Address Configuration, Device 1

Offset: 05ch | Read/Write: R/W | Reset: 0b0100xxxxxx10xxxxx010

Bit	Reset	Description
19:16	D64MB	EMEM_DEV1_DEVSIZE: [PMC] density of the second attached DRAM device, used to generate width of row address. 2 = D16MB 3 = D32MB 4 = D64MB 5 = D128MB 6 = D256MB 7 = D512MB 8 = D1024MB 8 = D1GB 9 = D2048MB 9 = D2GB
9:8	W2	EMEM_DEV1_BANKWIDTH: [PMC] width of bank address of the second attached DRAM device. 2 = W2 3 = W3
2:0	W9	EMEM_DEV1_COLWIDTH: [PMC] width of column address of the second attached DRAM device. W8 maps to 1KB page size, W9 to 2KB, W10 to 4KB, etc. 1 = W8 2 = W9 3 = W10 4 = W11

18.13.1.13 MC_SECURITY_CFG0_0

Security aperture: can be only accessed by TrustZone-secured accesses from the secure clients. Access to this register is restricted to TrustZone-secured requestors.

Boot requirements: This security configuration register should be saved to SDRAM and restored by the OS during warm boot.

Generated from mc_clientsecurity.spec

The global memory client IDs with TrustZone-level security are as follows:

CLIENT	ID	ID(hex)	SWGROUP	MODULE	PARTITION	DESCRIPTION
csr_ppcsahbslvr	30	(0x1e)	ppcs	ppcs	ahb	AHB bus reads
csr_vdebsevr	34	(0x22)	vde	vde2x	vd	Video Decode (VDE) video bitstream engine reads
csr_mpcorelpr	38	(0x26)	mpcorelp	mpcorelp	a9lp	Reads from Cortex-A9 Shadow CPU core via the L2 cache
csr_mpcorer	39	(0x27)	mpcore	mpcore	pi	Reads from Cortex-A9 4 CPU cores via the L2 cache
csw_mpcorelpw	56	(0x38)	mpcorelp	mpcorelp	a9lp	Writes from Cortex-A9 Shadow CPU core via the L2 cache
csw_mpcorew	57	(0x39)	mpcore	mpcore	pi	Writes from Cortex-A9 4 CPU cores via the L2 cache
csw_ppcsahbslvw	60	(0x3c)	ppcs	ppcs	ahb	AHB bus writes
csw_vdebsevw	62	(0x3e)	vde	vde2x	vd	Video Decode (VDE) video bitstream engine writes

Secure Region Configuration: Base

Offset: 070h | Read/Write: R/W | Secure: Trust Zone Protected | Reset: 0b100000000000

Bit	Reset	Description
31:20	0x800	SECURITY_BOM: SECURITY_BOM is the base of the secured region, limited to MB granularity. This must point to a region of the physical address map allocated to EMEM for it to be effective; MC cannot secure address space it does not own. (In other words, this is an absolute address, not an offset.) Above is the list of clients with the TrustZone-security access. Note that AXICIF clients will adhere to the standard AXI protocol "aprot[1]==0" indication for secure requests.

18.13.1.14 MC_SECURITY_CFG1_0

Access to this register is restricted to TrustZone-secured requestors.

Boot requirements: This security configuration register should be saved to SDRAM and restored by the OS during warm boot.

Secure Region Configuration: Bound

Offset: 074h | Read/Write: R/W | Secure: Trust Zone Protected | Reset: 0b000000000000

Bit	Reset	Description
11:0	0x0	SECURITY_SIZE_MB: SECURITY_SIZE_MB is the size, in megabytes, of the secured region. If set to 0, the security check in MC is disabled.

18.13.1.15 MC_SECURITY_CFG2_0

Protected/Carveout apertures: If enabled, certain memory clients are restricted to using SMMU-translated pages or the carveout aperture, they cannot access the protected aperture.

The protected region can be used to prevent hardware engines from accessing the operating system.

The protected region is always [EMEM_BOM..CARVEOUT_BOM).

The carveout region is always [CARVEOUT_BOM..EMEM_TOM].

Access to this register is restricted to TrustZone-secured requestors.

Boot requirements: This security configuration register should be saved to SDRAM and restored by the OS during warm boot.

The global memory client IDs allowed access to the protected region are as follows:

CLIENT	ID	ID(hex)	SWGROUP	MODULE	PARTITION	DESCRIPTION
csr_ptcr	0	(0x00)	ptc			Misses from System Memory Management Unit (SMMU) Page Table Cache (PTC)
csr_avpcarm7r	15	(0x0f)	avpc	avpc	avp	Arm7 Audio-Video Processor (AVP) reads via the avp_cache
csr_ppcsahbslvr	30	(0x1e)	ppcs	ppcs	ahb	AHB bus reads
csr_vdebsevr	34	(0x22)	vde	vde2x	vd	Video Decode (VDE) video bitstream engine reads
csr_mpcorelpr	38	(0x26)	mpcorelp	mpcorelp	a9lp	Reads from Cortex-A9 Shadow CPU core via the L2 cache
csr_mpcorer	39	(0x27)	mpcore	mpcore	pi	Reads from Cortex-A9 4 CPU cores via the L2 cache
csw_avpcarm7w	50	(0x32)	avpc	avpc	avp	Arm7 Audio-Video Processor (AVP) writes via the avp_cache
csw_mpcorelpw	56	(0x38)	mpcorelp	mpcorelp	a9lp	Writes from Cortex-A9 Shadow CPU core via the L2 cache
csw_mpcorew	57	(0x39)	mpcore	mpcore	pi	Writes from Cortex-A9 4 CPU cores via the L2 cache
csw_ppcsahbslvw	60	(0x3c)	ppcs	ppcs	ahb	AHB bus writes
csw_vdebsevw	62	(0x3e)	vde	vde2x	vd	Video Decode (VDE) video bitstream engine writes

Protected Region Configuration: Bound

Offset: 078h | Read/Write: R/W | Secure: Trust Zone Protected | Reset: 0b100000000000

Bit	Reset	Description
31:20	0x800	CARVEOUT_BOM: CARVEOUT_BOM is the megabyte-aligned starting address of the carveout region. (In other words, this is an absolute address, not an offset.) If CARVEOUT_BOM is set to <=NV_ADDRESS_MAP_EMEM_BASE, this security check in MC is disabled.

18.13.1.16 MC_EMEM_ARB_CFG_0

General configuration of the External Memory Arbiter.

Boot requirements:

- This register should be parameterized in the BCT and written by the Boot ROM during cold boot.
- This arbitration configuration register should be saved to SDRAM and restored by the OS during warm boot.

- During Boot ROM warm boot, this register may be derived from the emcclk and a standard tick-value.

This register is shadowed: see usage note at top.

External Memory Arbitration Configuration

Offset: 090h | Read/Write: R/W | Reset: 0b00000xxxxxxx000001000

Bit	Reset	Description
20:16	0x0	EXTRA_TICKS_PER_UPDATE: The number of extra ticks to add every deadline timer update. Used to keep cycles-per-tick constant when the mcclk period is less than the chosen wall-clock granularity for the deadline counter. If =0, then every tick increments the deadline counter by 1; if =1, then every tick increments the deadline counter by 2, etc. Assuming a target of 30ns-per-tick, some example programming (assumes DIV=2): 10MHz emcclk => 5MHz mcclk => would need to increment deadline counter by 6.67 if using 1 cycle-per-tick => or update by 20 every 3 cycles => 3 cycles-per-tick and 19 extra-ticks-per-update. Since performance is not critical at such slow speeds, rounding errors may be deemed acceptable, so the previous example may be simpler to program as 1 cycle-per-tick and 5 extra-ticks-per-update. Another example, the slowest supported clock speed using a 30ns tick that doesn't distort the tick is: 1.04MHz mcclk => with 31 extra-ticks-per-update and updating every cycle.
8:0	0x8	CYCLES_PER_UPDATE: The number of mcclk cycles per deadline timer update. The target wall-clock granularity (aka "tick") for the deadline counter should be fixed for the design, then the CYCLES_PER_UPDATE should be used to convert the wall-time value into mcclk cycles. All client latency allowances are also expressed in units of "ticks". Of all deadline-related controls, only the CYCLES_PER_UPDATE and EXTRA_TICKS_PER_UPDATE values need to be updated on a clock-change event. Assuming a target of 30ns-per-tick, some example programming (assumes DIV=2): 667MHz emcclk => 333MHz mcclk => 10 cycles-per-tick; 400MHz emcclk => 200MHz mcclk => 6 cycles-per-tick. Note that value 0x0 is illegal.

18.13.1.17 MC_EMEM_ARB_OUTSTANDING_REQ_0

This register can be used to limit the number of outstanding requests in the arbiter and monitor the count.

If outstanding transaction is > max, requests are throttled based on MC_EMEM_ARB_RING1_THROTTLE_0 register

Boot requirements:

- This register should be parameterized in the BCT and written by the Boot ROM during cold boot.
- This arbitration configuration register should be saved to SDRAM and restored by the OS during warm boot.
- During Boot ROM section of warm boot, this register may be derived from other MC settings.

This register is shadowed: see usage note at top.

External Memory Arbitration Configuration: Outstanding Request Limiter

Offset: 094h | Read/Write: R/W | Reset: 0b10xxxxxxxxxxxxxxxxxxxxx010000000

Bit	R/W	Reset	Description
31	RW	ENABLE	LIMIT_OUTSTANDING: when ENABLED, the total number of requests in the arbiter is limited to the value in ARB_MAX_OUTSTANDING 0 = DISABLE 1 = ENABLE
30	RW	DISABLE	LIMIT_DURING_HOLDOFF_OVERRIDE: when DISABLED, override the limiting of transactions during holdoff to let requests flow freely 0 = DISABLE 1 = ENABLE
24:16	RO	X	ARB_OUTSTANDING_COUNT: Current number of outstanding requests
8:0	RW	0x80	ARB_MAX_OUTSTANDING: The maximum number of requests allowed in the arbiter when LIMIT_OUTSTANDING is set to ENABLE.

18.13.1.18 MC_EMEM_ARB_TIMING_RCD_0

Boot requirements:

- This register should be parameterized in the BCT and written by the Boot ROM during cold boot.
- This arbitration configuration register should be saved to SDRAM and restored by the OS during warm boot.
- During Boot ROM section of warm boot, this register may be derived from EMC settings using the given equations.

This register is shadowed: see usage note at top.

External Memory Arbitration Configuration: DRAM Timing : tRCD

Offset: 098h | Read/Write: R/W | Reset: 0b111111

Bit	Reset	Description
5:0	0x3f	RCD: The minimum number of cycles between activate commands to the same bank. Program to max (1,ceil(max(EMC.WR_RCD,EMC.RD_RCD)/DIV)-1-1). Note that value 0x0 is illegal.

18.13.1.19 MC_EMEM_ARB_TIMING_RP_0

Boot requirements:

- This register should be parameterized in the BCT and written by the Boot ROM during cold boot.
- This arbitration configuration register should be saved to SDRAM and restored by the OS during warm boot.
- During Boot ROM section of warm boot, this register may be derived from EMC settings using the given equations.

This register is shadowed: see usage note at top.

External Memory Arbitration Configuration: DRAM Timing : tRP

Offset: 09ch | Read/Write: R/W | Reset: 0b1111111

Bit	Reset	Description
6:0	0x7f	RP: The minimum number of cycles between an internal precharge command and an activate command to the same bank. Program to ceil (EMC.RP/DIV)-1+SFA. Note that: the combined value of RAP2PRE+RP 0x0 is illegal; the combined value of WAP2PRE+RP 0x0 is illegal.

18.13.1.20 MC_EMEM_ARB_TIMING_RC_0

Boot requirements

- This register should be parameterized in the BCT and written by the Boot ROM during cold boot.
- This arbitration configuration register should be saved to SDRAM and restored by the OS during warm boot.
- During Boot ROM section of warm boot, this register may be derived from EMC settings using the given equations.

This register is shadowed: see usage note at top.

External Memory Arbitration Configuration: DRAM Timing : tRC

Offset: 0a0h | Read/Write: R/W | Reset: 0b1111111

Bit	Reset	Description
6:0	0x7f	RC: This is the minimum number of cycles between activate commands to the same bank. Program to ceil (max(EMC.RC,(EMC.RAS+EMC.RP))/DIV)-1.

18.13.1.21 MC_EMEM_ARB_TIMING_RAS_0

Boot requirements:

- This register should be parameterized in the BCT and written by the Boot ROM during cold boot.
- This arbitration configuration register should be saved to SDRAM and restored by the OS during warm boot.
- During Boot ROM section of warm boot, this register may be derived from EMC settings using the given equations.

This register is shadowed: see usage note at top.

External Memory Arbitration Configuration: DRAM Timing: tRAS

Offset: 0a4h | Read/Write: R/W | Reset: 0b111111

Bit	Reset	Description
5:0	0x3f	RAS: This is the minimum number of cycles between an activate command and a precharge command to the same bank. Program to ceil (EMC.RAS/DIV)-1-1.

18.13.1.22 MC_EMEM_ARB_TIMING_FAW_0

Boot requirements:

- This register should be parameterized in the BCT and written by the Boot ROM during cold boot.
- This arbitration configuration register should be saved to SDRAM and restored by the OS during warm boot.
- During Boot ROM section of warm boot, this register may be derived from EMC settings using the given equations.

This register is shadowed: see usage note at top.

External Memory Arbitration Configuration: DRAM Timing: tFAW

Offset: 0a8h | Read/Write: R/W | Reset: 0b111111

Bit	Reset	Description
5:0	0x3f	FAW: For 8-bank devices: Only 4 activates may occur within this rolling window. Program to ceil (EMC.TFAW/DIV)-1. Programming this to 0x0 or not programming a device to 4-banks will turn off this check.

18.13.1.23 MC_EMEM_ARB_TIMING_RRD_0

Boot requirements:

- This register should be parameterized in the BCT and written by the Boot ROM during cold boot.
- This arbitration configuration register should be saved to SDRAM and restored by the OS during warm boot.
- During Boot ROM section of warm boot, this register may be derived from EMC settings using the given equations.

This register is shadowed: see usage note at top of spec file.

External Memory Arbitration Configuration: DRAM Timing: tRRD

Offset: 0ach | Read/Write: R/W | Reset: 0b1111

Bit	Reset	Description
3:0	0xf	RRD: The minimum number of cycles between a activate command and an activate command to a different bank. Program to ceil (EMC.RRD/DIV)-1.

18.13.1.24 MC_EMEM_ARB_TIMING_RAP2PRE_0

Boot requirements:

- This register should be parameterized in the BCT and written by the Boot ROM during cold boot.
- This arbitration configuration register should be saved to SDRAM and restored by the OS during warm boot.
- During Boot ROM section of warm boot, this register may be derived from EMC settings using the given equations.

This register is shadowed: see usage note at top.

External Memory Arbitration Configuration: DRAM Timing : tRAP2PRE

Offset: 0b0h | Read/Write: R/W | Reset: 0b111111

Bit	Reset	Description
5:0	0x3f	RAP2PRE: The number of cycles between a read command with auto-precharge and the internal precharge command generated by the DRAM. Program to ceil (EMC_R2P/DIV). Note that: the combined value of RAP2PRE+RP 0x0 is illegal.

18.13.1.25 MC_EMEM_ARB_TIMING_WAP2PRE_0

Boot requirements:

- This register should be parameterized in the BCT and written by the Boot ROM during cold boot.
- This arbitration configuration register should be saved to SDRAM and restored by the OS during warm boot.
- During Boot ROM section of warm boot, this register may be derived from EMC settings using the given equations.

This register is shadowed: see usage note at top.

External Memory Arbitration Configuration: DRAM Timing: tWAP2PRE

Offset: 0b4h | Read/Write: R/W | Reset: 0b1111111

Bit	Reset	Description
6:0	0x7f	WAP2PRE: The number of cycles between a write command with auto-precharge and the internal precharge command generated by the DRAM. Program to ceil (EMC_W2P/DIV). Note that: the combined value of WAP2PRE+RP 0x0 is illegal.

18.13.1.26 MC_EMEM_ARB_TIMING_R2R_0

Boot requirements:

- This register should be parameterized in the BCT and written by the Boot ROM during cold boot.
- This arbitration configuration register should be saved to SDRAM and restored by the OS during warm boot.
- During Boot ROM section of warm boot, this register may be derived from EMC settings using the given equations.

This register is shadowed: see usage note at top.

External Memory Arbitration Configuration: DRAM Timing: tR2R

Offset: 0b8h | Read/Write: R/W | Reset: 0b11111

Bit	Reset	Description
4:0	0x1f	R2R: The number of cycles between consecutive read commands to different devices (aka, different chip-selects). Program to ceil (EMC.REXT/DIV)-1+OTFA+SFA.

18.13.1.27 MC_EMEM_ARB_TIMING_W2W_0

Boot requirements:

- This register should be parameterized in the BCT and written by the Boot ROM during cold boot.
- This arbitration configuration register should be saved to SDRAM and restored by the OS during warm boot.
- During Boot ROM section of warm boot, this register may be derived from EMC settings using the given equations.

This register is shadowed: see usage note at top.

External Memory Arbitration Configuration: DRAM Timing: tW2W

Offset: 0bch | Read/Write: R/W | Reset: 0b11111

Bit	Reset	Description
4:0	0x1f	W2W: The number of cycles between consecutive write commands to different devices (aka, different chip-selects). Program to ceil (EMC.WEXT/DIV)-1+SFA.

18.13.1.28 MC_EMEM_ARB_TIMING_R2W_0

Boot requirements:

- This register should be parameterized in the BCT and written by the Boot ROM during cold boot.
- This arbitration configuration register should be saved to SDRAM and restored by the OS during warm boot.
- During Boot ROM section of warm boot, this register may be derived from EMC settings using the given equations.

This register is shadowed: see usage note at top.

External Memory Arbitration Configuration: DRAM Timing: tR2W

Offset: 0c0h | Read/Write: R/W | Reset: 0b111111

Bit	Reset	Description
5:0	0x3f	R2W: The number of cycles to turn the bus from reads to writes. Program to ceil (EMC.R2W/DIV)-1+OTFA+SFA.

18.13.1.29 MC_EMEM_ARB_TIMING_W2R_0

Boot requirements:

- This register should be parameterized in the BCT and written by the Boot ROM during cold boot.
- This arbitration configuration register should be saved to SDRAM and restored by the OS during warm boot.
- During Boot ROM section of warm boot, this register may be derived from EMC settings using the given equations.

This register is shadowed: see usage note at top.

External Memory Arbitration Configuration: DRAM Timing: tW2R

Offset: 0c4h | Read/Write: R/W | Reset: 0b111111

Bit	Reset	Description
5:0	0x3f	W2R: The number of cycles to turn the bus from reads to writes. Program to ceil (EMC.W2R/DIV)-1+SFA.

18.13.1.30 MC_EMEM_ARB_DA_TURNS_0

The direction arbiter attempts to choose the highest efficiency (i.e. lowest bubbles) direction to open pages next. While programming this register incorrectly may lower performance, it should never cause chip-hangs since the EMC always controls the final DRAM timing decisions. This register should be reprogrammed after clock-change events to bring the computed values back in alignment with EMC's register values. These turn costs are deliberately not computed in hardware to provide better flexibility to tweak arbiter performance.

The configuration registers for turns for DA are separate from the timing registers to allow for flexibility in the programming.

Boot requirements:

- This arbitration configuration register should be saved to SDRAM and restored by the OS during warm boot.
- During Boot ROM section of warm boot, this register may be derived from MC settings using the given equations.

This register is shadowed: see usage note at top.

External Memory Arbitration Configuration: Direction Arbiter: Turns

Offset: 0d0h | Read/Write: R/W | Reset: 0b00001111000011110000001000000101

Bit	Reset	Description
31:24	0xf	W2R_TURN: Bubbles produced by a write to read bus turn. Approx MC_EMEM_ARB_TIMING_W2R.
23:16	0xf	R2W_TURN: Bubbles produced by a read to write bus turn. Approx MC_EMEM_ARB_TIMING_R2W.
15:8	0x2	W2W_TURN: Bubbles produced by a write to write (other device) bus turn. Approx MC_EMEM_ARB_TIMING_W2W.
7:0	0x5	R2R_TURN: Bubbles produced by a read to read (other device) bus turn. Approx MC_EMEM_ARB_TIMING_R2R.

18.13.1.31 MC_EMEM_ARB_DA_COVERS_0

The direction arbiter attempts to choose the highest efficiency (i.e. lowest bubbles) direction to open pages next. While programming this register incorrectly may lower performance, it should never cause chip-hangs since the EMC always controls the final DRAM timing decisions. This register should be reprogrammed after clock-change events to bring the computed values back in alignment with EMC's register values. These cover costs are deliberately not computed in hardware to provide better flexibility to tweak arbiter performance.

Boot requirements:

- This arbitration configuration register should be saved to SDRAM and restored by the OS during warm boot.
- During Boot ROM section of warm boot, this register may be derived from MC settings using the given equations.

This register is shadowed: see usage note at top.

External Memory Arbitration Configuration: Direction Arbiter: Covers

Offset: 0d4h | Read/Write: R/W | Reset: 0b00001111000011110000011111

Bit	Reset	Description
23:16	0xf	RCD_W_COVER: Cost to cover the activate-to-write delay. Approx ceil ((EMC.RTP + EMC.RP + EMC.RD_RCD)/DIV)-1.
15:8	0xf	RCD_R_COVER: Cost to cover the activate-to-read delay. Approx ceil ((EMC.WTP + EMC.RP + EMC.WR_RCD)/DIV)-1.

Bit	Reset	Description
7:0	0xf	RC_COVER: Cost to cover the activate-to-activate delay. Approx MC_EMEM_ARB_TIMING_RC.

18.13.1.32 MC_EMEM_ARB_MISC0_0

BC2AA_HOLDOFF: In the case where the currently-open pages have more work pending than the time it would take to open another page, it is better to holdoff opening that page until it is truly needed. The Best-bank Cache computes the pending work and compares it to this threshold and advises the Activation Arbiter to holdoff.

Priority Inversion: In general, if the arbiter is working on a lower-priority request that blocks a higher-priority request, these thresholds are used to limit the number of low-priority requests we will service before the arbiter will interrupt the lower-priority traffic to start servicing the higher-priority traffic.

The priority classes are (in increasing priority order): Low (! expired), High (expired), HighIso.

There are three ways priority can be inverted: Bank Activation, Bus Direction, and Refresh:

Bank Activation: If an unexpired request to bank A, row R currently holds the page open, and a request to bank A, row S expires, the Transaction Arbiter must make a decision whether to finish out the work for row R or to interrupt that transfer to immediately service row S. The TA makes this decision based on the remaining work for row R and whether row S is for an isochronous client, and the two PRIORITY_INVERSION thresholds.

Bus Direction: If the Transaction Arbiter is currently working on expired requests in direction P, and requests are also expired (or expired-iso) in direction Q, the Transaction Arbiter must make a decision whether to continue working in direction P or switch the bus to direction Q. The Transaction Arbiter will service at maximum PRIORITY_INVERSION_THRESHOLD (or _INVERSION_ISO_THRESHOLD) requests in direction P before switching to direction Q.

Refresh: If the Transaction Arbiter is currently working on requests, and EMC asks to inject a refresh, the Transaction Arbiter must decide whether it is more efficient (overall) to close the pages immediately or to finish the pages and then close them. Depending on the setting of the REFRESH_ACK_THRESHOLD_USAGE configuration bit (in EMEM_ARB_MISC1 register, below), the Transaction Arbiter will either choose to close the page immediately (NONE), close the page immediately if its length is over the iso threshold (ISO), or close the page immediately if its length is over the normal threshold (NORMAL). If the length is less than the chosen threshold, the Transaction Arbiter will service all remaining requests to the page before acknowledging the EMC refresh request.

When in DDR3 coalesce-for-performance mode, the arbiters will monitor the traffic patterns and may halve the priority inversion thresholds if they detect the current traffic is not coalescing efficiently. When in MC_EMC_SAME_FREQ mode, the priority inversion thresholds should be set to half of their non-same-frequency values.

Boot requirements:

- This register should be parameterized in the BCT and written by the Boot ROM during cold boot.
- The MC_EMC_SAME_FREQ field should be saved to scratch registers and restored by the Boot ROM during warm boot.
- The other fields of this register should be saved to SDRAM and restored by the OS during warm boot.
- During Boot ROM section of warm boot, this register may be derived from other settings.

This register is shadowed: see usage note at top.

External Memory Arbitration Configuration: Miscellaneous Thresholds (0)

Offset: 0d8h | Read/Write: R/W | Reset: 0b111001000001010x100000000010000

Bit	Reset	Description
30:28	0x7	ATOMS_PER_DVFS_PULSE: The MC will toggle the sys_stats_mon outputs for every

Bit	Reset	Description
		2^(atoms_per_dvfs_pulse+1) atoms of traffic, where an atom is defined as NV_MC_EMEM_WD=16 bytes. The maximum atoms_per_dvfs_pulse setting supported is the reset value, aka NV_MC_EMEM_DVFS_CNTR_CFG_RESET.
27	DISABLE	MC_EMC_SAME_FREQ: [PMC] Used in conjunction with EMEM_ARB_MISC1.COALESCE_FOR_PERFORMANCE to configure how often MC can send EMC a data request, should be configured to mirror CAR's CLK_SOURCE_EMC.MC_EMC_SAME_FREQ. If configured to DIV=2 BL=4, then MC can send a data request every cycle. If configured to DIV=1 BL=4, then MC can send a data request every other cycle. If configured to DIV=2 BL!=4, then MC can send a data request every other cycle. If configured to DIV=1 BL!=4, then MC can send a data request once every four cycles. 0 = MC is 1/2 the frequency of EMC (aka DIV=2). 1 = MC is the same frequency of EMC (aka DIV=1). 0 = DISABLE 1 = ENABLE
26:21	0x10	EXPIRING_SOON_SLACK_THRESHOLD: Slack threshold below which a isochronous request is considered to be expiring "soon". Used to de-assert mc2emc_idle signal early to wake EMC out of power-down or self-refresh. If using EMC's Dynamic Self Refresh features, set this to the ticks needed to cover exit self-refresh delay; otherwise, if using EMC's ACPD feature, set to the ticks needed to cover exit power-down delay; if neither power-saving feature is being used, the programming of this threshold should have no effect.
20:16	0xa	PRIORITY_INVERSION_ISO_THRESHOLD: Bank Activation: maximum number of unexpired or expired-but-not-isochronous requests that can be serviced before switching to expired isochronous traffic. Bus Direction: maximum number of requests in direction P that can be serviced before switching to expired-isochronous traffic in direction Q. Refresh: maximum number of requests that can be serviced before refresh is sent. Values <= 0x2 disable the feature. Values < 0x6 should be avoided if coalescing for performance.
14:8	0x40	PRIORITY_INVERSION_THRESHOLD: Bank Activation: maximum number of unexpired requests that can be serviced before switching to expired traffic. Bus Direction: maximum number of requests in direction P that can be serviced before switching to expired traffic in direction Q. Refresh: maximum number of requests that can be serviced before refresh is sent. Values <= 0x2 disable the feature. Values < 0x6 should be avoided if coalescing for performance.
7:0	0x10	BC2AA_HOLDOFF_THRESHOLD: If the pending work is greater than this value, hold off on activations. Generally should be set to match the page-opening cost: MC_EMEM_ARB_TIMING_RC+1.

18.13.1.33 MC_EMEM_ARB_MISC1_0

Boot requirements:

- This register should be parameterized in the BCT and written by the Boot ROM during cold boot.
- The COALESCE_FOR_PERFORMANCE field should be saved to scratch registers and restored by the Boot ROM during warm boot. It may also be derived from EMC settings.
- The other fields of this register should be saved to SDRAM and restored by the OS during warm boot.

External Memory Arbitration Configuration: Miscellaneous Thresholds (1)

Offset: 0dch | Read/Write: R/W | Reset: 0b10000x00

Bit	Reset	Description
31:28	0x8	DEADLOCK_PREVENTION_SLACK_THRESHOLD: If the slack at the head of any bank-queue, or any of the slacks in the hit-under-miss FIFO is less than -(2^threshold), backpressure the input to the arbiter until the violating slack values have been arbitrated. This is intended to: (a) avoid deadline-wrapping in heavily-backpressured corner-cases and (b) quickly get such cases back into high-efficiency arbitration. Value of 0x0 disables the feature. The reset value is NV_MC_EMEM_DL_WIDTH-1. Behavior with values >= NV_MC_EMEM_DL_WIDTH is UNDEFINED. If the threshold is reached, ARBITRATION_EMEM_INT will fire.
27	DISABLE	COALESCE_FOR_PERFORMANCE: If EMC has BL=8 or BL=4_or_8_on_the_fly, tell the

Bit	Reset	Description
		arbiter to coalesce for performance reasons. While MC/EMC will functionally work without this bit, performance will be significantly better if MC knows it should coalesce. 0 = DISABLE 1 = ENABLE
25:24	NORMAL	REFRESH_ACK_THRESHOLD_USAGE: Determines which thresholds (if any) the refresh-acknowledge signal will use to determine how to close all pages after EMC has requested a refresh. 0 = NORMAL : Use priority-inversion threshold 1 = ISO : Use priority-inversion-ISO threshold 2 = NONE : Force a precharge immediately to close the page

18.13.1.34 MC_EMEM_ARB_RING1_THROTTLE_0

Ring1 Snap Arbiter Throttle - Inserts some number of stall cycles at Ring1 after every request.

Throttle cycle count varies whether outstanding_request count is below (LOW) or above (HIGH) the max_outstanding threshold.

Boot requirements: During Boot ROM section of warm boot, this register may be derived from other settings.

This register is shadowed: see usage note at top.

External Memory Arbitration Configuration: Snap Arbiter Throttle

Offset: 0e0h | Read/Write: R/W | Reset: 0b11111xxxxxxxxxxx00000

Bit	Reset	Description
20:16	0x1f	RING1_THROTTLE_CYCLES_HIGH: Cycles of throttle after each request when outstanding transaction count is greater than or equal to threshold.
4:0	0x0	RING1_THROTTLE_CYCLES_LOW: Cycles of throttle after each request when outstanding transaction count is below threshold. Suggested programming: (DIV==1)? 1 : 0.

18.13.1.35 MC_EMEM_ARB_RING3_THROTTLE_0

Ring3 Snap Arbiter Throttle - Inserts some number of stall cycles at Ring3 after every request

Boot requirements: This register should be saved in the SDRAM and restored by the OS during warm boot.

This register is shadowed: see usage note at top.

External Memory Arbitration Configuration: Snap Arbiter Throttle

Offset: 0e4h | Read/Write: R/W | Reset: 0b00000

Bit	Reset	Description
4:0	0x0	RING3_THROTTLE_CYCLES: Cycles of throttle after each request.

18.13.1.36 MC_CLIENT_HOTRESET_CTRL_0

Writing FLUSH_ENABLE to a bit in this register causes a flush to be. Performed on all of the clients for the selected swname. The status of the flush (done/in progress) can be monitored in the CLIENT_HOTRESET_STATUS register.

A proper client reset sequence is as follows:

1. Set the appropriate FLUSH_ENABLE bit in the CLIENT_HOTRESET_CTRL register to block further access by the client, and start the flush process.
2. Poll the CLIENT_HOTRESET_STATUS register until the appropriate bit returns FLUSH_DONE.

3. Clear module bit in the CLK_RST_CONTROLLER_RST_DEVICES_* register to reset the module.
4. Set module bit in the CLK_RST_CONTROLLER_RST_DEVICES_* register to release the module reset.
5. Clear the appropriate FLUSH_ENABLE bit in the CLIENT_HOTRESET_CTRL register to allow transactions to flow.

Memory Client Hot Reset Control Register

Offset: 200h | Read/Write: R/W | Reset: 0b000000000000000000

18.13.1.38 MC_EMEM_ARB_ISOCHRONOUS_0_0

Controls whether a client is considered to be an isochronous client for EMEM arbitration. If a client is configured to be isochronous, the arbiter will favor expired isochronous requests over requests of any other type. This applies to arbitration for: best-bank arbiter (BA), activation arbiter (AA), direction arbiter (DA), and transaction arbiter (TA).

Per-client isochronous settings

Offset: 208h | Read/Write: R/W | Reset: 0b00000000000000011001000011111111

18.13.1.71 MC_PI_EXTRA_SNAP_LEVELS_0

Each additional level provides an extra request to the snap arbiter. For n requesters, each will get 1/n of the bandwidth. Adding a second level for one client will give that client 2/n+1 of the bandwidth.

Note that a value of 0 means no 'additional' requests, the client still has 1 request.

Additional snap arbiter levels for partition client pi

18.13.2 EMC Registers

Note: Please use EMC_WINCR definition to specify incr1/incr4 based on the project defines.

USAGE NOTE: Many EMC register fields are shadowed.

- Writes to shadowed register fields update the shadow copy (this is default, assumes DBG.WRITE_MUX==ASSEMBLY).
- Reads to shadowed register fields return the currently-active copy (this is default, assumes DBG.READ_MUX==ACTIVE).

This allows a new set frequency-dependent timing parameters to be written to the shadow registers while memory traffic is ongoing, then when the parameters are completely written, the EMC hardware can perform a timing-safe switch.

Such switches can be triggered via two methods: TIMING_CONTROL.TIMING_UPDATE (generally used during initialization), or the automatic CAR/EMC handshake on a clock-frequency or divider change (assuming CFG_2.CLKCHANGE_REQ_ENABLE==ENABLED).

Registers that are shadowed are marked by a comment:

```
// This register is shadowed: see usage note at top.
```

Occasionally, only certain fields in the register will be shadowed, if so they are noted after the above comment.

USAGE NOTE: Many EMC registers play crucial roles in warm boot (aka "wake from LP0") and cold boot (aka "power up") sequences. Suggested actions for the Boot ROM/Boot Loader are noted in comments labelled "Boot requirements: ...".

USAGE NOTE: The EMC register fields to be stored in PMC must have "[PMC]", "[PMC2]", or "[PMC3]"... in their comments. ([PMC2] registers are packed/unpacked after [PMC] register group in SW code. [PMC3] is even later.) Internal note: After adding and removing such PMC flag, the tool warmboot_code_gen must be rerun to generate new boot ROM code.

18.13.2.1 EMC_INTSTATUS_0

Interrupt Status Register

Clear on 1-write. Init value is clear.

Offset: 000h | Read/Write: R/W | Reset: 0b00000

Bit	Reset	Description
7	CLEAR	DLL_ALARM_INT: indicate DLL alarm has been set 0 = CLEAR 1 = SET
6	CLEAR	ACCESS_TO_SR_DPD_DEV_INT: indicate system attempt to access a self-refresh/deep-powered-down device. 0 = CLEAR 1 = SET
5	CLEAR	MRR_DIVLD_INT: LPDDR2 MRR data is available to be read. 0 = CLEAR 1 = SET
4	CLEAR	CLKCHANGE_COMPLETE_INT: CAR/EMC clock-change handshake complete. 0 = CLEAR 1 = SET
3	CLEAR	REFRESH_OVERFLOW_INT: Refresh request overflow timeout. 0 = CLEAR 1 = SET

18.13.2.2 EMC_INTMASK_0

Interrupt Mask Register

Init value is masked.

Offset: 004h | Read/Write: R/W | Reset: 0b00000

Bit	Reset	Description
7	MASKED	DLL_ALARM_INTMASK: Mask for DLL alarm 0 = MASKED 1 = UNMASKED
6	MASKED	ACCESS_TO_SR_DPD_DEV_INTMASK: Mask for access a self-refresh/deep-powered-down device interrupt. 0 = MASKED 1 = UNMASKED
5	MASKED	MRR_DIVLD_INTMASK: Mask for MRR data available. 0 = MASKED 1 = UNMASKED
4	MASKED	CLKCHANGE_COMPLETE_INTMASK: Mask for CAR/EMC clock-change handshake complete. 0 = MASKED 1 = UNMASKED
3	MASKED	REFRESH_OVERFLOW_INTMASK: Mask for refresh request overflow timeout. 0 = MASKED 1 = UNMASKED

18.13.2.3 EMC_DBG_0

Debug Register

The DBG register is used to reconfigure the EMC during debug or chip testing.

Boot requirements

- This register should be parameterized in the BCT and written by the Boot ROM during cold boot.
- This register should be saved in the scratch registers and restored by the Boot ROM during warm boot.

Offset: 008h | Read/Write: R/W | Reset: 0b1xxxxxxxxxx00x10xxxxx0000

Bit	Reset	Description
24	ENABLED	CFG_PRIORITY: determines the priority of cfg accesses to the DRAM. Setting this register to ENABLED gives DRAM config cycles (refresh, mrs, emrs, etc.) higher priority over real time requestors. The DISABLED setting gives the real time requestors higher priority than DRAM config cycles. Do not program to DISABLED unless for debugging. 0 = DISABLED 1 = ENABLED
13	DISABLED	SUPPRESS_WRITE_CMD: suppress write command sent to DRAM 0 = DISABLED 1 = ENABLED
12	DISABLED	SUPPRESS_READ_CMD: suppress read command sent to DRAM 0 = DISABLED 1 = ENABLED
10	ENABLED	AP_REQ_BUSY_CTRL: determines whether the busy signal from the auto-precharge cancellation (APC) fifo is allowed to stall requests to the EMC. This field should usually be set to ENABLED 0 = DISABLED 1 = ENABLED

Bit	Reset	Description
9	MANAGED	READ_DQM_CTRL: If set to MANAGED, EMC only turns them on when necessary. If set to ALWAYS_ON, the dqm signals are enabled during non-write operation. This field should usually be set to MANAGED 0 = MANAGED 1 = ALWAYS_ON
2	DISABLED	FORCE_UPDATE: causes the active state to get updated with the assembly state immediately upon writing the TIMING_CONTROL register. 0 = DISABLED 1 = ENABLED
1	ASSEMBLY	WRITE_MUX: controls whether writes to the configuration registers are done from the assembly or active state. 0 = ASSEMBLY 1 = ACTIVE
0	ACTIVE	READ_MUX: controls whether reads to the configuration registers are done from the assembly or active state. 0 = ACTIVE 1 = ASSEMBLY

18.13.2.4 EMC_CFG_0

Configuration Register

The CFG register is used to configure the external memory interface.

Boot requirements

- This register should be parameterized in the BCT and written by the Boot ROM during cold boot.
- This register should be saved in the scratch registers and restored by the Boot ROM during warm boot.

Offset: 00ch | Read/Write: R/W | Reset: 0b0000xx11110

Bit	Reset	Description
31	DISABLED	DRAM_CLKSTOP_PD: clockstop only allowed to happen if DRAM is in active/precharge powerdown (for all CKE bits associated with clock) 0 = DISABLED 1 = ENABLED
30	DISABLED	DRAM_CLKSTOP_SR: clockstop only allowed to happen if DRAM is in self-refresh (for all CKE bits associated with clock) 0 = DISABLED 1 = ENABLED
29	NO_POWERDOWN	DRAM_ACPD: allows the DRAM controller to perform opportunistic active powerdown control using the CKE pin on the DRAM. The behavior of the powerdown control logic is controlled by the PDEX2* and *2PDEN registers. The value of DRAM_ACPD should only be changed when CKE is low, e.g., during software-controlled self-refresh or before DRAM initialization. 0 = NO_POWERDOWN 1 = ACTIVE_POWERDOWN
28	DISABLED	DYN_SELF_REF: 0 = DISABLED 1 = ENABLED
25	ENABLED	AUTO_PRE_WR: enable using MC auto-precharge indication for writes. This bits, when set to DISABLE, will override the settings in the MC register (EMC ignore the auto-precharge indication from MC). Otherwise, they permit clients to make either auto or explicit precharge requests depend on the state of MAN_PRE_WR. 0 = DISABLED 1 = ENABLED
24	ENABLED	AUTO_PRE_RD: enable using MC auto-precharge indication for reads. This bits, when set to DISABLE, will override the settings in the MC register (EMC ignores the

Bit	Reset	Description
		auto-precharge indication from MC). Otherwise, they permit clients to make either auto or explicit precharge requests depend on the state of MAN_PRE_RD. 0 = DISABLED 1 = ENABLED
23	ENABLED	MAN_PRE_WR: [PMC3] enable explicit-precharge in the EMC for writes. When this bit is enabled (and AUTO_PRE_WR=enable), EMC will issue an explicit precharge command after the memory write command. If this bit is disabled (and AUTO_PRE_WR=enable), EMC will issue an auto-precharge with the memory write command. 0 = DISABLED 1 = ENABLED
22	ENABLED	MAN_PRE_RD: [PMC3] enable explicit-precharge in the EMC for reads. When this bit is enabled (and AUTO_PRE_RD=enable), EMC will issue an explicit precharge command after the memory read command. If this bit is disabled (and AUTO_PRE_RD=enable), EMC will issue an auto-precharge with the memory read command. 0 = DISABLED 1 = ENABLED
21	DISABLED	PERIODIC_QRST: [PMC] specifies whether or not to periodic reset the FBIO read-data fifo during normal operation. The periodic resets can be used for graceful recovery from an intermittent failure condition; only the initial reset is absolutely required. 0 = DISABLED 1 = ENABLED

18.13.2.5 EMC_ADR_CFG_0

External Memory Address Configuration, System

The ADR_CFG register is used to specify the number of DRAM devices. DRAM density and geometry parameters are specified by the EMEM_ADR_CFG* registers in MC.

Boot requirements:

- This register should be parameterized in the BCT and written by the Boot ROM during cold boot.
- This register should be saved in the scratch registers and restored by the Boot ROM during warm boot.

Offset: 010h | Read/Write: R/W | Reset: 0b0xxxxxx0

Bit	Reset	Description
7	DISABLED	EMEM_ROW_MSB_ON_CS1: [PMC] drive CS1 pin with address bit 15 0 = DISABLED 1 = ENABLED
0	N1	EMEM_NUMDEV: number of populated DRAM devices. 0 = N1 1 = N2

18.13.2.6 EMC_REFCTRL_0

Refresh Control Register

The REFCTRL register allows SW to enable or disable the refresh controller.

REF_VALID should be enabled after the initialization sequence is completed.

Boot requirements

- If per-device DPD is used, the DEVICE_REFRESH_DISABLE field should be parameterized in the BCT and written by the Boot ROM during cold boot.

- If per-device DPD is used, the DEVICE_REFRESH_DISABLE field should be parameterized the scratch registers registers and restored by the Boot ROM during warm boot.
- REF_VALID field should always be set to ENABLED for normal use, no need to parameterize in BCT/scratch.

Offset: 020h | Read/Write: R/W | Reset: 0b0xxxxxxxxxxxxxxxxxxxxxxxxxxxxxx00

Bit	Reset	Description
31	DISABLED	REF_VALID: enable refresh controller. 0 = DISABLED 1 = ENABLED
1:0	0x0	DEVICE_REFRESH_DISABLE: disables refresh to individual attached device (1 bit per dram chip-select).

18.13.2.7 EMC_PIN_0

Controls state of selected DRAM pins

The PIN register allows SW to control the state of the selected external DRAM pins.

Boot requirements

- Both fields in this register should be set to NORMAL during cold boot.
- Both fields in this register should be set to NORMAL during warm boot.

Offset: 024h | Read/Write: R/W | Reset: 0b1xxx0xxx0

Bit	Reset	Description
8	INACTIVE	PIN_RESET: selects the level of the DDR3 RESET# pin. 0 = ACTIVE 1 = INACTIVE
4	NORMAL	PIN_DQM: is used to always mask DRAM writes. This pin should only be used for initialization. Certain DRAM vendors require the DQM to be high during initialization. The register value should be set to NORMAL after the initialization sequence. 0 = NORMAL 1 = INACTIVE
0	POWERDOWN	PIN_CKE: selects the level of the CKE pin. This can be used to place the DRAM in power down state. PIN_CKE value is applied all CKE pins. 0 = POWERDOWN 1 = NORMAL

18.13.2.8 EMC_TIMING_CONTROL_0

Triggers an update of the timing-related registers

The TIMING_CONTROL register is used by SW to trigger parameter updates for timing parameter registers, rdqs/quse delay controls, and some DLL controls. Writing the TIMING_UPDATE field updates the active state of these registers with the programmed assembly state. The active state is updated during a safe interval determined by the EMC. If CLKCHANGE_REQ_ENABLE is enabled, the active value will automatically be updated on completion of the clock change.

> **Note:** Programming of this register does not trigger the shadow register update event immediately. To prevent shadow register programming issued after programming this register from being latched accidentally, always poll for TIMING_UPDATE_STALLED==0 after programming this register.

Boot requirements

- Writing this register with 0x1 will trigger a timing update event, which should be used in both warm boot and cold boot sequences.

Offset: 028h | Read/Write: R/W | Reset: 0bx

Bit	Reset	Description
0	X	TIMING_UPDATE

18.13.2.9 EMC_RC_0

DRAM timing parameter

This register is shadowed: see usage note at top.

Boot requirements

- This register should be parameterized in the BCT and written by the Boot ROM during cold boot.
- This register should be saved in the scratch registers and restored by the Boot ROM during warm boot.

Offset: 02ch | Read/Write: R/W | Reset: 0b1111111

Bit	Reset	Description
6:0	0x7f	RC: [PMC] specifies the row cycle time. This is the minimum number of cycles between activate commands to the same bank. DDR3: max(0, ceil(tRC/tCK) - (CMD_2T_TIMING == 1 ? 2 : 1)) LPDDR2: ceil((tRASmin+tRPpb)/tCK) - 1

18.13.2.10 EMC_RFC_0

DRAM timing parameter

This register is shadowed: see usage note at top.

Boot requirements

- This register should be parameterized in the BCT and written by the Boot ROM during cold boot.
- This register should be saved in the scratch registers and restored by the Boot ROM during warm boot.

Offset: 030h | Read/Write: R/W | Reset: 0b000111111

Bit	Reset	Description
8:0	0x3f	RFC: [PMC] specifies the auto refresh cycle time. This is the minimum number of cycles between an auto refresh command and a subsequent auto refresh or activate command. DDR3: max(0, ceil(tRFC/tCK) - (CMD_2T_TIMING == 1 ? 2 : 1)) LPDDR2: ceil(tRFCab/tCK) - 1

18.13.2.11 EMC_RAS_0

DRAM timing parameter

This register is shadowed: see usage note at top.

Boot requirements

- This register should be parameterized in the BCT and written by the Boot ROM during cold boot.
- This register should be saved in the scratch registers and restored by the Boot ROM during warm boot.

Offset: 034h | Read/Write: R/W | Reset: 0b111111

Bit	Reset	Description
5:0	0x3f	RAS: [PMC] specifies the row active time. This is the minimum number of cycles between an activate command and a precharge command to the same bank. DDR3: max(0,

Bit	Reset	Description
		ceil(tRASmin/tCK) - (CMD_2T_TIMING == 1 ? 2 : 1)) LPDDR2: max(3, ceil(tRASmin/tCK)) - 1

18.13.2.12 EMC_RP_0

DRAM timing parameter

This register is shadowed: see usage note at top.

Boot requirements

- This register should be parameterized in the BCT and written by the Boot ROM during cold boot.
- This register should be saved in the scratch registers and restored by the Boot ROM during warm boot.

Offset: 038h | Read/Write: R/W | Reset: 0b111111

Bit	Reset	Description
5:0	0x3f	RP: [PMC] specifies the row precharge time. This is the minimum number of cycles between a precharge command and an activate command to the same bank. DDR3: max(0, ceil(tRP/tCK) - (CMD_2T_TIMING == 1 ? 2 : 1)) LPDDR2: max(3, ceil(tRP/tCK)) - 1

R2something and W2something registers are independent of burst length, and are relative to the last virtual CAS_ of a command. We start counting from the last data transfer as related to where CAS_ would be if BL = 4.

18.13.2.13 EMC_R2W_0

DRAM timing parameter

This register is shadowed: see usage note at top.

Boot requirements

This register should be parameterized in the BCT and written by the Boot ROM during cold boot.

Boot requirements

- This register should be saved in the scratch registers and restored by the Boot ROM during warm boot.

Offset: 03ch | Read/Write: R/W | Reset: 0b11111

Bit	Reset	Description
4:0	0x1f	R2W: [PMC] specifies the minimum number of cycles from any read command to any write command, irrespective of bank. This parameter guarantees the read->write turn-around time on the bus. DDR3: RL - WL + 2 - (CMD_2T_TIMING == 1 ? 1 : 0) + (CTT_TERMINATION == 1 ? max(0, CTT + CTT_DURATION - RDV - 2) : (EMC2PMACRO_CFG_XM2DQS_E_STRPULL_DQS ? 1 : 0)) + (EMC2PMACRO_CFG_QUSE_MODE == ALWAYS_ON ? 1 : 0) LPDDR2: RL - WL + 1 + ceil(tDQSCKmax/tCK) + (EMC2PMACRO_CFG_XM2DQS_E_STRPULL_DQS ? 1 : 0) + (EMC2PMACRO_CFG_QUSE_MODE == ALWAYS_ON ? 1 : 0) Largest programming value is 29

18.13.2.14 EMC_W2R_0

DRAM timing parameter

This register is shadowed: see usage note at top.

Boot requirements

- This register should be parameterized in the BCT and written by the Boot ROM during cold boot.

- This register should be saved in the scratch registers and restored by the Boot ROM during warm boot.

Offset: 040h | Read/Write: R/W | Reset: 0b11111

Bit	Reset	Description
4:0	0x1f	W2R: [PMC] specifies the minimum number of cycles from a write command to a read command, irrespective of bank. DDR3 : WL + max(4, ceil(tWTR/tCK)) - (CMD_2T_TIMING == 1 ? 1 : 0) LPDDR2 : WL + 1 + ceil(tWTR/tCK) Largest programming value is 29

18.13.2.15 EMC_R2P_0

DRAM timing parameter

This register is shadowed: see usage note at top.

Boot requirements

- This register should be parameterized in the BCT and written by the Boot ROM during cold boot.
- This register should be saved in the scratch registers and restored by the Boot ROM during warm boot.

Offset: 044h | Read/Write: R/W | Reset: 0b11111

Bit	Reset	Description
4:0	0x1f	R2P: [PMC] specifies the minimum number of cycles from a read command to a precharge command for the same bank. DDR3 : max(4, ceil(tRTP/tCK)) - (CMD_2T_TIMING == 1 ? 2 : 1) LPDDR2 : BL/2 + max(2, ceil(tRTP/tCK)) - 1 - (is-lpddr2-s2 ? 1 : 2). Here is-lpddr2-s2 is 1 if the LPDDR2 is S2, otherwise (S4) it's 0

18.13.2.16 EMC_W2P_0

DRAM timing parameter

This register is shadowed: see usage note at top.

Boot requirements

- This register should be parameterized in the BCT and written by the Boot ROM during cold boot.
- This register should be saved in the scratch registers and restored by the Boot ROM during warm boot.

Offset: 048h | Read/Write: R/W | Reset: 0b111111

Bit	Reset	Description
5:0	0x3f	W2P: [PMC] specifies the minimum number of cycles from a write command to a precharge command for the same bank. DDR3 : WL + max(2, ceil(tWR/tCK)) - (CMD_2T_TIMING == 1 ? 1 : 0) LPDDR2: WL + max(3, TWR)

18.13.2.17 EMC_RD_RCD_0

DRAM timing parameter

This register is shadowed: see usage note at top.

Boot requirements

- This register should be parameterized in the BCT and written by the Boot ROM during cold boot.
- This register should be saved in the scratch registers and restored by the Boot ROM during warm boot.

Offset: 04ch | Read/Write: R/W | Reset: 0b011111

Bit	Reset	Description
5:0	0x1f	RD_RCD: [PMC] specifies the ras to cas delay. RD_RCD is the minimum number of cycles between an activate command and a read command to the same bank. DDR3 : ceil(tRCD/tCK) - (CMD_2T_TIMING == 1 ? 2 : 1) LPDDR2: max(3, ceil(tRCD/tCK)) - 1

18.13.2.18 EMC_WR_RCD_0

DRAM timing parameter

This register is shadowed: see usage note at top.

Boot requirements

- This register should be parameterized in the BCT and written by the Boot ROM during cold boot.
- This register should be saved in the scratch registers and restored by the Boot ROM during warm boot.

Offset: 050h | Read/Write: R/W | Reset: 0b011111

Bit	Reset	Description
5:0	0x1f	WR_RCD: [PMC] minimum number of cycles between an activate command and a write command to the same bank. DDR3 : ceil(tRCD/tCK) - (CMD_2T_TIMING == 1 ? 2 : 1) LPDDR2: max(3, ceil(tRCD/tCK)) - 1

18.13.2.19 EMC_RRD_0

DRAM timing parameter

This register is shadowed: see usage note at top.

Boot requirements

- This register should be parameterized in the BCT and written by the Boot ROM during cold boot.
- This register should be saved in the scratch registers and restored by the Boot ROM during warm boot.

Offset: 054h | Read/Write: R/W | Reset: 0b1111

Bit	Reset	Description
3:0	0xf	RRD: [PMC] specifies the Bank X Act to Bank Y Act command delay. DDR3 : max(4, ceil(tRRD/tCK)) - (CMD_2T_TIMING == 1 ? 2 : 1) LPDDR2: max(2, ceil(tRRD/tCK)) - 1

18.13.2.20 EMC_REXT_0

DRAM timing parameter

This register is shadowed: see usage note at top.

Boot requirements

- This register should be parameterized in the BCT and written by the Boot ROM during cold boot.
- This register should be saved in the scratch registers and restored by the Boot ROM during warm boot.

Offset: 058h | Read/Write: R/W | Reset: 0b0001

Bit	Reset	Description
3:0	0x1	REXT: [PMC] specifies the read to read delay for reads when multiple physical devices are present. DDR3: USE_PER_DEVICE_DLY_TRIM_IB == 1 ? 2 : 1 LPDDR2: ceil(3/tCK + 0.5) + USE_PER_DEVICE_DLY_TRIM_IB ? 1 : 0

18.13.2.21 EMC_WDV_0

DRAM timing parameter

This register is shadowed: see usage note at top.

Boot requirements

- This register should be parameterized in the BCT and written by the Boot ROM during cold boot.
- This register should be saved in the scratch registers and restored by the Boot ROM during warm boot.

Offset: 05ch | Read/Write: R/W | Reset: 0b0000

Bit	Reset	Description
3:0	0x0	WDV: [PMC] the number of cycles to post (delay) write data from being asserted to the rams. DDR3 : WL - 1 LPDDR2 : WL 15 = MAX

18.13.2.22 EMC_QUSE_0

DRAM timing parameter

The QRST,QUSE,RDV fields specify the delays from read to internal timing signals. These fields should be set as follows:

QUSE = CAS_LATENCY - 1 non-mobile SDRAM
= CAS_LATENCY - 2 for mobile SDRAM
QRST = CAS_LATENCY - 2
QSAFE >= RDV - QRST
RDV = CAS_LATENCY + 5

Because SDRAM uses a tristating clock (the DQS) a method is needed to deal with the ambiguity of when DQS is tristate. Only one such method is supported: QUSE.

This register is shadowed: see usage note at top.

Boot requirements

- This register should be parameterized in the BCT and written by the Boot ROM during cold boot.
- This register should be saved in the scratch registers and restored by the Boot ROM during warm boot.

Offset: 060h | Read/Write: R/W | Reset: 0b00010

Bit	Reset	Description
4:0	0x2	QUSE: [PMC] tells the chip when to look for read return data. LPDDR2/DDR3: obtained from characterization

18.13.2.23 EMC_QRST_0

DRAM timing parameter

This register is shadowed: see usage note at top.

Boot requirements

- This register should be parameterized in the BCT and written by the Boot ROM during cold boot.
- This register should be saved in the scratch registers and restored by the Boot ROM during warm boot.

Offset: 064h | Read/Write: R/W | Reset: 0b00001

Bit	Reset	Description
4:0	0x1	QRST: [PMC] time from expiration of QSAFE until reset is issued. DDR3 : CL - 2 LPDDR2 : RL - 2

18.13.2.24 EMC_QSAFE_0

DRAM timing parameter

When PERIODIC_QRST is enabled, the QSAFE parameter is intended to guarantee that the QRSTs will not interfere with pending reads (e.g. the queue is empty). This field must be set to at least (RDV - QRST).

This register is shadowed: see usage note at top.

Boot requirements

- This register should be parameterized in the BCT and written by the Boot ROM during cold boot.
- This register should be saved in the scratch registers and restored by the Boot ROM during warm boot.

Offset: 068h | Read/Write: R/W | Reset: 0b0111

Bit	Reset	Description
3:0	0x7	QSAFE: [PMC] time from a read command to when it is safe to issue a QRST (delayed by the QRST parameter). LPDDR2/DDR3 QSAFE >= RDV - QRST

18.13.2.25 EMC_RDV_0

DRAM timing parameter

RDV is the read latency register. This register value is not negotiable, it will work with the right value and will not with the wrong value. It is sequential timing, not combinational (i.e., maybe the silicon is fast enough type) timing.

This register is shadowed: see usage note at top.

Boot requirements

- This register should be parameterized in the BCT and written by the Boot ROM during cold boot.
- This register should be saved in the scratch registers and restored by the Boot ROM during warm boot.

Offset: 06ch | Read/Write: R/W | Reset: 0b01000

Bit	Reset	Description
4:0	0x8	RDV: [PMC] time from read command to latching the read data from the pad macros. DDR3 : RL + 6 + f_ceil(fly-by-time/tCK) - (dram-dll-is-off ? 1 : 0) LPDDR2: RL + 6 + ceil((tDQSCKmax + fly-by-time)/tCK) fly-by-time is board routing dependent, which usually should be less than 1.5ns dram-dll-is-off is true below 150MHz where DRAM DLL has to be turned off 20 = MAX

18.13.2.26 EMC_REFRESH_0

DRAM timing parameter

The value of REFRESH is calculated using the following formula:

```
{REFRESH, REFRESH_LO} = max[(tREF/#_of_rows) / (emc_clk_period) - 64,
                            (tREF/#_of_rows) / (emc_clk_period) * 97%]
```

For example, if the clock frequency is 133MHz, and the refresh requirement is 64ms per 4096 rows. The programming value is 0x7e3.

This register is shadowed: see usage note at top.

Boot requirements

- This register should be parameterized in the BCT and written by the Boot ROM during cold boot.
- This register should be saved in the scratch registers and restored by the Boot ROM during warm boot.

Offset: 070h | Read/Write: R/W | Reset: 0b0000000000011111

Bit	Reset	Description
15:6	0x0	REFRESH: [PMC] specifies the interval between refresh requests.
5:0	0x1f	REFRESH_LO

18.13.2.27 EMC_BURST_REFRESH_NUM_0

DRAM timing parameter

BURST_REFRESH_NUM is used to specify the refresh burst count. The refresh controller will wait until BURST_REFRESH_NUM refreshes have been scheduled, then issue them all at once. This can result in a performance improvement in many cases.

Note: If tRAS(max) is less than the refresh interval (tREF/#_of_rows), tRAS(max) must be used instead of the refresh interval in the formula above. This is because refresh is used to satisfy tRAS(max) timing. Accordingly, BURST_REFRESH_NUM must be programmed in such a way that queuing up multiple refreshes does not violate tRAS(max) timing. Burst length = 2^BURST_REFRESH_NUM. Refreshes will be throttled to meet TREFBW limitation (8/window) if TREFBW > 0.

Note: Do not program this register to value non-zero unless for testing.

This register is shadowed: see usage note at top.

Boot requirements

- This register should be parameterized in the BCT and written by the Boot ROM during cold boot.
- This register should be saved in the scratch registers and restored by the Boot ROM during warm boot.

Offset: 074h | Read/Write: R/W | Reset: 0b0000

Bit	Reset	Description
3:0	BR1	BURST_REFRESH_NUM: specify the refresh burst count. 0 = BR1 1 = BR2 2 = BR4 3 = BR8 4 = BR16 5 = BR32 6 = BR64 7 = BR128 8 = BR256 9 = BR512 9 = MAX

18.13.2.28 EMC_PDEX2WR_0

DRAM timing parameter

This register is shadowed: see usage note at top.

Boot requirements

- This register should be parameterized in the BCT and written by the Boot ROM during cold boot.
- This register should be saved in the scratch registers and restored by the Boot ROM during warm boot.

Offset: 078h | Read/Write: R/W | Reset: 0b111110

Bit	Reset	Description
5:0	0x3e	PDEX2WR: specify the timing delay from exit of powerdown mode to a write command. DDR3 : max(3, ceil(tXP/tCK)) - (CMD_2T_TIMING == 1 ? 2 : 1) LPDDR2 : ceil(tXP/tCK) - 1 Note: on DDR3, if slow power down exit mode is used and ODT is enabled, use max(10, ceil(tXPDLL/tCK)) instead of max(3, ceil(tXP/tCK)) in the formula Largest allowed value is 62

18.13.2.29 EMC_PDEX2RD_0

DRAM timing parameter

This register is shadowed: see usage note at top.

Boot requirements

- This register should be parameterized in the BCT and written by the Boot ROM during cold boot.
- This register should be saved in the scratch registers and restored by the Boot ROM during warm boot.

Offset: 07ch | Read/Write: R/W | Reset: 0b111110

Bit	Reset	Description
5:0	0x3e	PDEX2RD: specify the timing delay from exit of powerdown mode to a read command. DDR3 : (use-slow-pd-exit-mode ? max(10, ceil(tXPDLL/tCK)) : max(3, ceil(tXP/tCK))) - (CMD_2T_TIMING == 1 ? 2 : 1) LPDDR2 : ceil(tXP/tCK) - 1 use-slow-pd-exit-mode is 1 if slow power down exit mode is used (MR0 bit 12 is 0) Largest allowed value is 62

18.13.2.30 EMC_PCHG2PDEN_0

DRAM timing parameter

This register is shadowed: see usage note at top.

Boot requirements

- This register should be parameterized in the BCT and written by the Boot ROM during cold boot.
- This register should be saved in the scratch registers and restored by the Boot ROM during warm boot.

Offset: 080h | Read/Write: R/W | Reset: 0b011111

Bit	Reset	Description
5:0	0x1f	PCHG2PDEN: [PMC3] specify the timing delay from a precharge command to powerdown entry. DDR3 : 1 LPDDR2 : f_ceil(tRP]/tCK) - (CMD_2T_TIMING == 1 ? 1 : 0)

18.13.2.31 EMC_ACT2PDEN_0

[PMC3] DRAM timing parameter

This register is shadowed: see usage note at top.

Boot requirements

- This register should be parameterized in the BCT and written by the Boot ROM during cold boot.

- This register should be saved in the scratch registers and restored by the Boot ROM during warm boot.

Offset: 084h | Read/Write: R/W | Reset: 0b011111

Bit	Reset	Description
5:0	0x1f	ACT2PDEN: specify the timing delay from an activate, mrs or emrs command to powerdown entry. DDR3/LPDDR2: 0

18.13.2.32 EMC_AR2PDEN_0

DRAM timing parameter

This register is shadowed: see usage note at top.

Boot requirements

- This register should be parameterized in the BCT and written by the Boot ROM during cold boot.
- This register should be saved in the scratch registers and restored by the Boot ROM during warm boot.

Offset: 088h | Read/Write: R/W | Reset: 0b000011111

Bit	Reset	Description
8:0	0x1f	AR2PDEN: [PMC3] specify the timing delay from an autorefresh command to powerdown entry. DDR3 : max(7, ceil((tXPDLL - tXP)/tCK)) LPDDR2 : 1

18.13.2.33 EMC_RW2PDEN_0

DRAM timing parameter

This register is shadowed: see usage note at top.

Boot requirements

- This register should be parameterized in the BCT and written by the Boot ROM during cold boot.
- This register should be saved in the scratch registers and restored by the Boot ROM during warm boot.

Offset: 08ch | Read/Write: R/W | Reset: 0b011111

Bit	Reset	Description
5:0	0x1f	RW2PDEN: [PMC3] specify the timing delay from a read/write command to powerdown entry. Auto-precharge timing must be taken into account when programming this field DDR3: max(RL+5, WL+4+TWR) - 1 LPDDR2: max(RL+BL/2+ceil((tDQSCKmax+1)/tCK)+1, WL+BL/2+1+ceil((tWR+1)/tCCK)) - 1

18.13.2.34 EMC_TXSR_0

DRAM timing parameter

This register is shadowed: see usage note at top.

Boot requirements

- This register should be parameterized in the BCT and written by the Boot ROM during cold boot.
- This register should be saved in the scratch registers and restored by the Boot ROM during warm boot.

Offset: 090h | Read/Write: R/W | Reset: 0b1111111110

Bit	Reset	Description
9:0	0x3fe	TXSR: cycles between self-refresh exit & first DRAM command that doesn't require a locked DLL. Largest allowed value is 0x3fe DDR3: max(5, ceil(tXSR/tCK)) LPDDR2: max(2, ceil(tXSR/tCK))

18.13.2.35 EMC_TCKE_0

DRAM timing parameter

This register is shadowed: see usage note at top.

Boot requirements

- This register should be parameterized in the BCT and written by the Boot ROM during cold boot.
- This register should be saved in the scratch registers and restored by the Boot ROM during warm boot.

Offset: 094h | Read/Write: R/W | Reset: 0b111110

Bit	Reset	Description
5:0	0x3e	TCKE: specify minimum CKE pulse width. DDR3: use-slow-pd-exit-mode ? max(10, ceil(max(tCKESR, uXPDLL)/tCK)) : max(4, ceil(max(tXP,tXP)/tCK)) LPDDR2: max(3, tCKE, ceil(tXP/tCK)) use-slow-pd-exit-mode is 1 if slow power down exit mode is used (MR0 bit 12 is 0

18.13.2.36 EMC_TFAW_0

DRAM timing parameter

This register is shadowed: see usage note at top.

Boot requirements

- This register should be parameterized in the BCT and written by the Boot ROM during cold boot.
- This register should be saved in the scratch registers and restored by the Boot ROM during warm boot.

Offset: 098h | Read/Write: R/W | Reset: 0b000000

Bit	Reset	Description
5:0	0x0	TFAW: [PMC] specify the width of the FAW (four-activate window) for 8-bank devices. Set to 0 to disable this timing check. Only 4 activates may occur within the rolling window. . DDR3/LPDDR2: ceil(tFAW/tCK)

18.13.2.37 EMC_TRPAB_0

DRAM timing parameter

This register is shadowed: see usage note at top.

Boot requirements

- This register should be parameterized in the BCT and written by the Boot ROM during cold boot.
- This register should be saved in the scratch registers and restored by the Boot ROM during warm boot.

Offset: 09ch | Read/Write: R/W | Reset: 0b000000

Bit	Reset	Description
5:0	0x0	TRPAB: [PMC] specify precharge-all tRP allowance for 8-bank devices. Setting this field to 0 will cause EMC to use TRP.TRP for precharge-all. DDR3 : ceil(tRP/tCK) + 1 LPDDR2: max(3, ceil((tRPpb+3)/tCK

18.13.2.38 EMC_TCLKSTABLE_0

DRAM timing parameter

This register is shadowed: see usage note at top.

Boot requirements

- This register should be parameterized in the BCT and written by the Boot ROM during cold boot.
- This register should be saved in the scratch registers and restored by the Boot ROM during warm boot.

Offset: 0a0h | Read/Write: R/W | Reset: 0b01111

Bit	Reset	Description
4:0	0xf	TCLKSTABLE: specify minimum number of cycles of a stable clock period prior to exiting powerdown or self-refresh modes. DDR3 : max(5, ceil(tCKSRX/tCK)) - 1 LPDDR2: 2

18.13.2.39 EMC_TCLKSTOP_0

DRAM timing parameter

This register is shadowed: see usage note at top.

Boot requirements

- This register should be parameterized in the BCT and written by the Boot ROM during cold boot.
- This register should be saved in the scratch registers and restored by the Boot ROM during warm boot.

Offset: 0a4h | Read/Write: R/W | Reset: 0b01111

Bit	Reset	Description
4:0	0xf	TCLKSTOP: delay from last command to stopping the external clock to DRAM devices. DDR3 : max(5, ceil(tCKSRE/tCK)) - 1 LPDDR2

18.13.2.40 EMC_TREFBW_0

DRAM timing parameter

This register is shadowed: see usage note at top.

Boot requirements

- This register should be parameterized in the BCT and written by the Boot ROM during cold boot.
- This register should be saved in the scratch registers and restored by the Boot ROM during warm boot.

Offset: 0a8h | Read/Write: R/W | Reset: 0b00000000000000

Bit	Reset	Description
13:0	0x0	TREFBW: [PMC] specify the width of the burst-refresh window. If set to a non-zero value, only 8 refreshes will occur in this rolling window. Set to 0 to disable this timing check. DDR3: ceil(tREFI/tCK) LPDDR2: ceil(tREFBW/tCK)

18.13.2.41 EMC_QUSE_EXTRA_0

QUSE_EXTRA is combined with quse to add extra cycles to data return window. This is for use with dqs pulldowns in LPDDR2 where start of read preamble could vary by more than 1 cycle.

Example: To extend end of QUSE window by 1 cycle, set QUSE_EXTRA = QUSE + 1. To start QUSE window earlier by 1 cycle, set QUSE_EXTRA = QUSE - 1. Disabled if QUSE_EXTRA = 0.

This register is shadowed: see usage note at top.

Boot requirements

- This register should be parameterized in the BCT and written by the Boot ROM during cold boot.
- This register should be saved in the scratch registers and restored by the Boot ROM during warm boot.

Offset: 0ach | Read/Write: R/W | Reset: 0b0000

Bit	Reset	Description
3:0	0x0	QUSE_EXTRA: [PMC2] DDR3/LPDDR2: (EMC2TMC_CFG_XM2DQS_E_SCHMT == 1) ? (QUSE + 1) : 0

18.13.2.42 EMC_ODT_WRITE_0

For DDR3, ODT may be enabled during writes and disabled during reads via control of ODT pin.

This register is shadowed: see usage note at top.

Boot requirements

- This register should be parameterized in the BCT and written by the Boot ROM during cold boot.
- This register should be saved in the scratch registers and restored by the Boot ROM during warm boot.

Offset: 0b0h | Read/Write: R/W | Reset: 0b00xxxxxxxxxxxxxxxxxxxxxxxxxx0x000

Bit	Reset	Description
31	0x0	ENABLE_ODT_DURING_WRITE: enables ODT to be turned on prior to issuing write to DRAM. [PMC] If ENABLE_ODT_DURING_WRITE = 1 and DISABLE_ODT_DURING_READ = 0, ODT will always be enabled after 1st write.
30	0x0	ODT_B4_WRITE: [PMC] If this field == 1, ODT is turned on ODT_WR_DELAY cycles prior to dram WRITE command. If this field == 0, ODT is turned on ODT_WR_DELAY cycles after dram WRITE command. Set ODT_B4_WRITE to 1 if (WL - ceiling(tAOND) - 2) < 0. This field is not used for DDR3.
4	0x0	DRIVE_BOTH_ODT: [PMC] If this field = 0, only the ODT for the requested device will be asserted during write. If this field = 1, ODTs for both devices will be asserted during write.
2:0	0x0	ODT_WR_DELAY: [PMC] Set this field = ABS (WL - ceiling(tAOND) - 2). The valid programming range is 0 <= ODT_WR_DELAY <= 2 if ODT_B4_WRITE=0, 0 <= ODT_WR_DELAY <= 1 if ODT_B4_WRITE=1 For DDR3, this field = (WL - 3).

18.13.2.43 EMC_ODT_READ_0

This register is not used. Please keep it in reset value.

This register is shadowed: see usage note at top.

Boot requirements

- This register should be parameterized in the BCT and written by the Boot ROM during cold boot.
- This register should be saved in the scratch registers and restored by the Boot ROM during warm boot.

Offset: 0b4h | Read/Write: R/W | Reset: 0b00xxxxxxxxxxxxxxxxxxxxxxxxxx000

Bit	Reset	Description
31	0x0	DISABLE_ODT_DURING_READ: enables ODT to be turned off prior to issuing read to DRAM. If this field == 0, ODT state will not be changed for reads. If this field == 1, Turn off ODT prior to READ command (has no effect if ODT ENABLE_ODT_DURING_WRITE == 0, as ODT will always be disabled). This field is not used for DDR3.
30	0x0	ODT_B4_READ: If this field == 1, ODT is turned off ODT_RD_DELAY cycles prior to dram READ command. If this field == 0, ODT is turned off ODT_RD_DELAY cycles after dram READ command. Set ODT_B4_READ to 1 if (RL - ceiling(tAOFD) - 2) < 0. This field is not used for DDR3.
2:0	0x0	ODT_RD_DELAY: Set this field = ABS (RL - ceiling(tAOFD) - 2). The valid programming range is 0 <= ODT_RD_DELAY <= 2 if ODT_B4_READ=0, 0 <= ODT_RD_DELAY <= 1 if ODT_B4_READ=1 This field is not used for DDR3.

18.13.2.44 EMC_WEXT_0

DRAM timing parameter

This register is shadowed: see usage note at top.

Boot requirements

- This register should be parameterized in the BCT and written by the Boot ROM during cold boot.
- This register should be saved in the scratch registers and restored by the Boot ROM during warm boot.

Offset: 0b8h | Read/Write: R/W | Reset: 0b0000

Bit	Reset	Description
3:0	0x0	WEXT: [PMC] specifies the write to write delay for writes when multiple physical devices are present. DDR3: max(0, (USE_PER_DEVICE_DLY_TRIM_OB == 1 ? 5 : 0) - (CMD_2T_TIMING == 1 ? 1 : 0)) LPDDR2: USE_PER_DEVICE_DLY_TRIM_OB == 1 ? 5 : 0

18.13.2.45 EMC_CTT_0

DRAM timing parameter

CTT controls timing of internal read terminations. Based on read latency (CTT must frame read data). Adding non-RDV linked timing control for flexibility. Has no effect unless CTT_TERMINATION = ENABLED It is sequential timing, not combinational (i.e., maybe the silicon is fast enough type) timing.

This register is shadowed: see usage note at top.

Boot requirements

- This register should be parameterized in the BCT and written by the Boot ROM during cold boot.

Offset: 0bch | Read/Write: R/W | Reset: 0b01000

Bit	Reset	Description
4:0	0x8	CTT: [PMC] time from read command to CTT turn-on on DDR3 ? CTT_TERMINATION == 1 ? CL + 6 : 0 LPDDR2: 0 20 = MAX

18.13.2.46 EMC_MRS_WAIT_CNT_0

This register allows the delay between a MRS command and the following DRAM command

Boot requirements

- This register should be parameterized in the BCT and written by the Boot ROM during cold boot.

Offset: 0c8h | Read/Write: R/W | Reset: 0b1000001000xxxxxx0000001111

Bit	Reset	Description
25:16	0x208	MRS_LONG_WAIT_CNT: Number of EMC clocks to wait before issuing any commands after sending MRS long command.
9:0	0xf	MRS_SHORT_WAIT_CNT: Number of EMC clocks to wait before issuing any commands after sending MRS short command.

18.13.2.47 EMC_MRS_0

Command trigger: MRS

The MRS register allows SW to issue an MRS command.

BA0, BA1 are used to address MRS or EMRS registers in DRAM. Although this register can also program EMRS, use the EMRS register so that the HW registers can shadow what is in the DRAM.

Boot requirements

- This register should be parameterized in the BCT and written by the Boot ROM during cold boot.

Offset: 0cch | Read/Write: R/W | Reset: 0b00xxx0xxxx00xxxxxx00000000000000

Bit	Reset	Description
31:30	0x0	MRS_DEV_SELECTN: active low chip-select, 0x0 applies command to both devices, 0x2 to for only dev0, 0x1 for only dev1.
26	SHORT	USE_MRS_LONG_CNT: Indicate to use long or short MRS wait count. 0 = SHORT 1 = LONG
21:20	0x0	MRS_BA: Set to 0x0 for MRS.
13:0	0x0	MRS_ADR: mode-register data to be written.

18.13.2.48 EMC_EMRS_0

Command trigger: EMRS

The EMRS register allows SW to issue an EMRS command.

Boot requirements

- This register should be parameterized in the BCT and written by the Boot ROM during cold boot.

Offset: 0d0h | Read/Write: R/W | Reset: 0b00xxx0xxxx00xxxxxx00000000000000

Bit	Reset	Description
31:30	0x0	EMRS_DEV_SELECTN: active low chip-select, 0x0 applies command to both devices, 0x2 to for only dev0, 0x1 for only dev1.
26	SHORT	USE_EMRS_LONG_CNT: Indicate to use long or short MRS wait count. 0 = SHORT 1 = LONG
21:20	0x0	EMRS_BA: Set to 0x1 for EMRS (and where applicable, 0x2 for EMRS2, and 0x3 for EMRS3).
13:0	0x0	EMRS_ADR: mode-register data to be written.

18.13.2.49 EMC_REF_0

Command trigger: Refresh

The REF register allows SW to issue refresh commands. This is done to ensure proper DRAM initialization.

Boot requirements

- This register triggers a refresh command. REF_CMD should be written with 0x1 during cold boot to trigger refresh commands during DRAM initialization.

Offset: 0d4h | Read/Write: R/W | Reset: 0b00xxxxxxxxxxxxxx00000000xxxxxx00

Bit	Reset	Description
31:30	0x0	REF_DEV_SELECTN: active low chip-select, 0x0 applies command to both devices, 0x2 to for only dev0, 0x1 for only dev1.
15:8	0x0	REF_NUM: perform (REF_NUM + 1) refresh cycles.
1	0x0	REF_NORMAL: 0 = execute first refresh immediately (this is use during DRAM initialization). 1 = execute refresh through normal refresh mechanism (this should be used in normal operation).
0	0x0	REF_CMD: causes the hardware to perform a REFRESH to all DRAM banks.

18.13.2.50 EMC_PRE_0

Command trigger: Precharge-All

The PRE register allows SW to issue a precharge all command. This command may be used to ensure proper DRAM initialization.

Boot requirements

- This register triggers a precharge-all command. PRE_CMD should be written with 0x1 during cold boot to trigger refresh commands during DRAM initialization.
- If per-device DPD is used, the PRE_DEV_SELECTN field should be parameterized in the BCT and written by the Boot ROM during cold boot.

Offset: 0d8h | Read/Write: R/W | Reset: 0b00xxxxxxxxxxxxxxxxxxxxxxxxxxxxxx0

Bit	Reset	Description
31:30	0x0	PRE_DEV_SELECTN: active low chip-select, 0x0 applies command to both devices, 0x2 to for only dev0, 0x1 for only dev1.
0	0x0	PRE_CMD: causes the hardware to perform a PRECHARGE to all DRAM banks.

18.13.2.51 EMC_NOP_0

Command trigger: NOP

The NOP register allows SW to issue an explicit nop command. This command may be used to ensure proper DRAM initialization.

Boot requirements

- This register triggers a no-operation command. NOP_CMD should be written with 0x1 during cold boot to trigger no-op commands during DRAM initialization.

Offset: 0dch | Read/Write: R/W | Reset: 0b00xxxxxxxxxxxxxxxxxxxxxxxxxxxxx0

Bit	Reset	Description
31:30	0x0	NOP_DEV_SELECTN: active low chip-select, 0x0 applies command to both devices, 0x2 to for only dev0, 0x1 for only dev1.
0	0x0	NOP_CMD: causes the hardware to perform a NOP to all DRAM banks.

18.13.2.52 EMC_SELF_REF_0

Command trigger: SELF REFRESH

The SELF_REF register allows SW to issue self-refresh commands.

Do not program this register when a clock change sequence is on-going: check CLKCHANGE_COMPLETE_INT value if not sure.

Offset: 0e0h | Read/Write: R/W | Reset: 0b00xxxxxxxxxxxxxxxxxxxxxxxxxxxxx0

Bit	Reset	Description
31:30	0x0	SREF_DEV_SELECTN: active low chip-select, 0x0 applies command to both devices, 0x2 to for only dev0, 0x1 for only dev1, 0x3 for neither device.
0	DISABLED	SELF_REF_CMD: causes the hardware to issue a SELF_REFRESH command. While CMD:ENABLED, the CKE pin is held deasserted. The CMD:ENABLED state will override the PIN:CKE setting. The DRAM will ignore all accesses until CMD:DISABLED. 0 = DISABLED 1 = ENABLED

18.13.2.53 EMC_DPD_0

Command trigger: Deep Power Down

The DPD register allows SW to issue a deep power down command.

Offset: 0e4h | Read/Write: R/W | Reset: 0b00xxxxxxxxxxxxxxxxxxxxxxxxxxxxx0

Bit	Reset	Description
31:30	0x0	DPD_DEV_SELECTN: active low chip-select, 0x0 applies command to both devices, 0x2 to for only dev0, 0x1 for only dev1.
0	DISABLED	DPD_CMD: causes the hardware to issue the deep power down command (Burst Terminate with CKE low). While in DPD mode, the DRAM will not maintain data integrity. While CMD:ENABLED, the CKE pin is held deasserted. The CMD:ENABLED state will override the PIN:CKE setting. The DRAM will ignore all accesses until CMD:DISABLED. 0 = DISABLED 1 = ENABLED

18.13.2.54 EMC_MRW_0

Command trigger: MRW

Mode Register Write: LPDDR2-only version of MRS/EMRS

Boot requirements

- This register triggers a mode register write command. Multiple mode-register writes may be required by the cold boot sequence. Such commands should be parameterized in the BCT and written by the Boot ROM during cold boot.

Offset: 0e8h | Read/Write: WO | Reset: 0b00xxxxxx00000000xxxxxxxx00000000

Bit	Reset	Description
31:30	0x0	MRW_DEV_SELECTN: active-low chip-select, 0x0 applies command to both devices, 0x2 to for only dev0, 0x1 for dev1.
23:16	0x0	MRW_MA: register address
7:0	0x0	MRW_OP: data to be written

18.13.2.55 EMC_MRR_0

Command trigger: MRR

Mode Register Read: LPDDR2 only

Sequence

1. Read MRR until EMC_STATUS.MRR_DIVLD=0 (ok to skip if it is sure there is no pending MRR reads)

2. Write this register with the desired addr (MA) and device (DEV_SELECTN), device needs to be either DEV0 or DEV1: writing to both is illegal

3. Poll EMC_STATUS.MRR_DIVLD=1, or if using interrupt, wait for MRR_DIVLD_INT

4. Read back MRR. The value is in MRR_DATA field.

Note: It is ok to issue new MRR requests while there are on-going requests. e.g. to issue 3 MRR, follow these steps: 1,2,2,2,3,4,3,4,3,4. Data read back in step 4 are in the same order requested in step 2.

To make sure EMC is available for new MRR requests, poll for EMC_STATUS.MRR_FIFO_SPACE > 0 before step 2.

If using 2 x16 DRAM, MRR_DATA[15:8] can be used to store MRR from 2nd DRAM on same CS (configured via CFG_2.MRR_BYTESEL_X16)

Offset: 0ech | Read/Write: R/W | Reset: 0b00xxxxxx00000000xxxxxxxxxxxxxxxx

Bit	Reset	Description
31:30	0x0	MRR_DEV_SELECTN: active-low chip-select, choose which device to send the command to. (enum for safety). 0 = ILLEGAL 1 = DEV1 2 = DEV0 3 = RESERVED
23:16	0x0	MRR_MA: register address
15:0	X	MRR_DATA: data returned

18.13.2.56 EMC_XM2DQSPADCTRL3_0

Offset: 0f8h | Read/Write: R/W | Reset: 0b1000xxxxxxxxxxxxxxxxx0xxxxx

Bit	Reset	Description
27:24	0x8	EMC2PMACRO_CFG_XM2DQS_VREF_DQS: [PMC]
5	0x0	EMC2PMACRO_CFG_XM2DQS_E_VREF_DQS: [PMC]
0	X	EMC2PMACRO_CFG_XM2DQS_E_STRPULL_DQS: [PMC]

18.13.2.57 EMC_FBIO_CFG5_0

FBIO configuration Register

The FBIO_DQSIB_DLY registers have been removed.

The trimmer value may be overridden by setting using MULT==0 and OFFS = val <<4

The FBIO_CFG5 register controls the FBIO I/O cells.

The following fields are shadowed: DIFFERENTIAL_DQS, CTT_TERMINATION, DQS_PULLD, CMD_2T_TIMING.

Writes to these fields will not take effect until the active value is updated via TIMING_UPDATE or (if enabled) CLKCHANGE_REQ.

Boot requirements

- This register (except for field DISABLE_CONCURRENT_AUTOPRE) should be parameterized in the BCT and written by the Boot ROM during cold boot.
- This register (except for field DISABLE_CONCURRENT_AUTOPRE) should be saved in the scratch registers and restored by the Boot ROM during warm boot.

Offset: 104h | Read/Write: R/W | Reset: 0b0000x0000xxx0001

Bit	Reset	Description
15:13	NORMAL	EMC2PMACRO_CFG_QUSE_MODE: [PMC] Select quse mode (NORMAL = off-chip) (ALWAYS_ON = requires DQS PULL) (INTERNAL_LPBK selects on-chip loopback) 0 = NORMAL 1 = ALWAYS_ON 2 = INTERNAL_LPBK 3 = PULSE_INT 4 = PULSE_EXT 5 = RESERVED
12	DISABLED	CMD_2T_TIMING: [PMC] enable 2T command timing (RAS/CAS/WE/ROW/A/BA). 0 = DISABLED 1 = ENABLED
10	DISABLED	DISABLE_CONCURRENT_AUTOPRE: disables reads/writes to a device until the precharge command has been issued by the dram internally. 0 = DISABLED 1 = ENABLED
9	DISABLED	DQS_PULLD: [PMC] enables pulldowns on dqs lines (and pullups on DQS_N if DIFFERENTIAL_DQS). 0 = DISABLED 1 = ENABLED
8	DISABLED	CTT_TERMINATION: [PMC] enables CTT_TERMINATION mode in pads (ddr2 support) 0 = DISABLED 1 = ENABLED
7	DISABLED	DIFFERENTIAL_DQS: [PMC] enables differential signalling on dqs strobes (lpddr2/ddr2 options) 0 = DISABLED 1 = ENABLED
3:2	BURST4	DRAM_BURST: [PMC] specifies the burst length to use for the attached device(s). ON_THE_FLY BC4/BL8 is only use for DDR3. 0 = BURST4 1 = BURST8 2 = ON_THE_FLY 3 = RESERVED

Bit	Reset	Description
1:0	DDR1	DRAM_TYPE: [PMC] specifies which DRAM protocol to use for the attached device(s). 0 = DDR3 1 = DDR1 2 = LPDDR2 3 = DDR2

18.13.2.58 EMC_FBIO_CFG6_0

FBIO configuration register

QUSE_LATE determines how much added delay fbio should add to the QUSE path. QUSE needs to align (approximately) with the incoming DQS in order to qualify it, since the incoming DQS/feedback clock is not always valid.

DRAMC can position QUSE with m2clk granularity (2 bit times). QUSE_LATE provides finer granularity of 1/2 an m2clk cycle (1/2 bit time). The amount of delay added is primarily a function of the round trip wire delay to/from the DRAM. Other portions of the delay (driver and receiver delay) are compensated for by delay through a non-bonded QUSE pad cell.

Additional delay can be added to QUSE vi XFORM_QUSEx_MULT and XFORM_QUSEx_OFFS (applied to DLL offset).

Boot requirements

- This register should be parameterized in the BCT and written by the Boot ROM during cold boot.
- This register should be saved in the scratch registers and restored by the Boot ROM during warm boot.

Offset: 114h | Read/Write: R/W | Reset: 0b010

Bit	Reset	Description
2:0	0x2	CFG_QUSE_LATE: [PMC]

18.13.2.59 EMC_AUTO_CAL_CONFIG_0

Auto-calibration settings for EMC pads

Boot requirements

- This register (except for AUTOCAL_SLW_OVERRIDE and AUTO_CAL_START(trigger)) should be parameterized in the BCT and written by the Boot ROM during cold boot.
- This register (except for AUTOCAL_SLW_OVERRIDE and AUTO_CAL_START(trigger)) should be saved in the scratch registers and restored by the Boot ROM during warm boot.

Offset: 2a4h | Read/Write: R/W | Reset: 0b0000xx001111x001xxx00000xxx00000

Bit	R/W	Reset	Description
31	RO	0x0	AUTO_CAL_START: Writing a one to this bit starts the calibration state machine. This bit must be set even if the override is set in order to latch in the override value.
30	RW	0x0	AUTO_CAL_OVERRIDE: [PMC] 0 (normal operation): use AUTO_CAL_PU/PD_OFFSET as an offset to the calibration state machine setting 1 (override) : use AUTO_CAL_PU/PD_OFFSET register values directly
29	RW	DISABLED	AUTO_CAL_ENABLE: 1 (normal operation): use EMC generated pullup/dn (override or autocal) 0 (disabled): use emc2tmc_cfg* register settings for pullup/dn 0 = DISABLED 1 = ENABLED
28	RW	0x0	AUTOCAL_SLW_OVERRIDE: 0 (Normal operation) pad DRVDN/UP_SLWR/F tied to AUTO_CAL output DRDVDN/UP_SLWR/F[3:0] = AUTO_CAL_PULLDOWN/UP[4:1] 1 (override) use EMC2TMC_CFG*_DRVDN/UP_SLWR/F pins to control pad slew inputs

Bit	R/W	Reset	Description
25:20	RW	0xf	AUTO_CAL_E_CAL_UPDATE: number of EMC clocks E_CAL_UPDATE is asserted
18:16	RW	0x1	AUTO_CAL_STEP: calibration step interval (in microseconds)
12:8	RW	0x0	AUTO_CAL_PD_OFFSET: [PMC] 2's complement offset for pull-down value
4:0	RW	0x0	AUTO_CAL_PU_OFFSET: [PMC] 2's complement offset for pull-up value

18.13.2.60 EMC_AUTO_CAL_INTERVAL_0

EMC pad calibration interval

Boot requirements

- This register should be parameterized in the BCT and written by the Boot ROM during cold boot.
- This register should be saved in the scratch registers and restored by the Boot ROM during warm boot.

Offset: 2a8h | Read/Write: R/W | Reset: 0b00000000000000000000

Bit	Reset	Description
20:0	0x0	AUTO_CAL_INTERVAL: 0: do calibration once Otherwise, auto-calibration occurs at intervals equivalent to the programmed number of microseconds.

18.13.2.61 EMC_AUTO_CAL_STATUS_0

EMC pad calibration status

Offset: 2ach | Read/Write: RO | Reset: 0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx

Bit	Reset	Description
31	X	AUTO_CAL_ACTIVE: One when auto calibrate is active - valid only after auto calibrate sequence has completed (EMC_CAL_ACTIVE == 0)
28:24	X	AUTO_CAL_PULLDOWN_ADJ: Pulldown code sent to pads
20:16	X	AUTO_CAL_PULLUP_ADJ: Pullup code sent to pads
12:8	X	AUTO_CAL_PULLDOWN: Pulldown code generated by auto-calibration
4:0	X	AUTO_CAL_PULLUP: Pullup code generated by auto-calibration

18.13.2.62 EMC_REQ_CTRL_0

Request status/control

When either STALL_ALL_READS and/or STALL_ALL_WRITES is asserted, the stalling of read and/or write requests will not take effect until the status bit from EMC_STATUS register's NO_OUTSTANDING_TRANSACTIONS field is asserted.

Offset: 2b0h | Read/Write: R/W | Reset: 0b00

Bit	Reset	Description
1	0x0	STALL_ALL_WRITES: Stall incoming write transactions
0	0x0	STALL_ALL_READS: Stall incoming read transactions

18.13.2.63 EMC_EMC_STATUS_0

EMC state-machine status

DRAM_IN_POWERDOWN, DRAM_IN_SELF_REFRESH, DRAM_IN_DPD: active high signal indicating current DRAM status for each of these modes, with 1 status bit per device, bit[0] = dev0 status, bit[1] = dev1 status.

Example: DRAM_IN_SELF_REFRESH = 0x3, both devices are in self-refresh, DRAM_IN_DPD= 0x2 would indicate only dev1 is in deep-power-down mode.

> **Note:** If EMC is reset or powered down, the actual DRAM state could be different than indicated by these status bits. These bits do not reflect manually entered/exited powerdown or self-refresh (via use of PIN_CKE).

Offset: 2b4h | Read/Write: RO | Reset: 0bxxxxxxxxxxxxxxxxxxxxxxxxxx

Bit	Reset	Description
23	X	TIMING_UPDATE_STALLED: indicate timing update triggered by TIMING_CONTROL.TIMING_UPDATE is not yet completed.
20	X	MRR_DIVLD: mrr data available for reading
19:16	X	MRR_FIFO_SPACE: mrr fifospace available
13:12	X	DRAM_IN_DPD: dev[n] has been put into deep powerdown state
9:8	X	DRAM_IN_SELF_REFRESH: dev[n] has been put into self-refresh (will remain until SR exit cmd).
5:4	X	DRAM_IN_POWERDOWN: dev[n] has entered powerdown state (incoming req's will awaken if not stalled)
2	X	NO_OUTSTANDING_TRANSACTIONS: All non-stalled requests have completed
0	X	EMC_REQ_FIFO_EMPTY: Request fifo is empty

18.13.2.64 EMC_CFG_2_0

EMC Configuration

Clock change sequencing: Once the divider is reprogrammed, CAR signals to EMC that a clock change is pending. If enabled, EMC stalls incoming requests, drains outstanding requests, and, if CLKCHANGE_(PD|SR)_ENABLE is enabled, puts DRAM into powerdown (or self-refresh) before signalling to CAR that it is idle and ready for the change to happen. CAR will then change the divider/pll reprogramming. Once complete, EMC updates its shadow registers (assuming they may have been reprogrammed for new clock setting), unstalls requests, and resumes operation with new clock setttings.

Boot requirements

- This register (except for fields DRAMC_PRE_B4_ACT, MRR_BYTESEL_X16, MRR_BYTESEL) should be parameterized in the BCT and written by the Boot ROM during cold boot.
- This register (except for fields DRAMC_PRE_B4_ACT, MRR_BYTESEL_X16, MRR_BYTESEL) should be saved in the scratch registers and restored by the Boot ROM during warm boot.
- If the OS needs the MRR_BYTESEL* fields set to non-default values to perform a mode-register read, it needs to correctly program these values before performing the MRR.

Offset: 2b8h | Read/Write: R/W | Reset: 0b00000000x0000000x00000000xx00011

Bit	Reset	Description
31	DISABLED	DRAMC_PRE_B4_ACT: Reserved bit, gives priority to activates over precharges, determining which (precharge/activate) is processed first if both are pending and unblocked. 0 = DISABLED 1 = ENABLED

Bit	Reset	Description
22	0x0	ISSUE_PCHGALL_AFTER_REF: [PMC] Reserved bit. 1 = always generate precharge all bank after refresh.
21:20	0x0	MRR_BYTESEL_X16: [PMC3] If using 2 X16 DRAM on a single CS to form 32-bit wide data, indicates which byte lane 2nd DRAM's byte 0 is connected to.
19	0x0	BYPASS_POP_PIPE2_STAGE: For testing only [PMC] Reserved bit. 1 = bypass LPDDR2 adr/cmd pipeline stage2.
18	0x0	BYPASS_POP_PIPE1_STAGE: For testing only [PMC] Reserved bit. 1 = bypass LPDDR2 adr/cmd pipeline stage1.
17:16	0x0	MRR_BYTESEL: [PMC3] Indicates which AP byte lane is connected to DRAM byte 0 (over which MRR data is returned).
13	DISABLED	USE_PER_DEVICE_DLY_TRIM_OB: [PMC] Reserved bit. Allow using different outbound delay trim values per device. When enable, WDV must be program to >= 2, WEXT >=5. 0 = DISABLED 1 = ENABLED
12	DISABLED	USE_PER_DEVICE_DLY_TRIM_IB: [PMC] Reserved bit. Allow using different inbound delay trim values per device. When enable, REXT/RDV/QUSE must be program to >= 2. 0 = DISABLED 1 = ENABLED
9:8	LPDDR2	PIN_CONFIG: [PMC] Remaps address/command pins for LPDDR2_POP ball-out otherwise uses standard LPDDR2 pin configuration. 0 = LPDDR2 1 = LPDDR2_POP 2 = RESERVED
7	0x0	EARLY_TRFC_8_CLK: [PMC] Reserved bit. 1 = 8 clocks early, 0 = 16 clocks early.
4	0x0	DIS_POP_PIPE2_STAGE_CLK: For testing only, must always be set to 1.
3	0x0	DIS_POP_PIPE1_STAGE_CLK: For testing only, must always be set to 1.
2	DISABLED	CLKCHANGE_SR_ENABLE: Forces DRAM into self-refresh during CLKCHANGE. Takes precedent over CLKCHANGE_PD_ENABLE if both are set. **Note**: 1. If the new clock change scheme is use, this bit must be disabled. 2. If this bit is enabled, DONT_USE_REF_REQACK_IFC must be set to 1. 3. If this big is enabled, DYN_SELF_REF must be set to DISABLED 0 = DISABLED 1 = ENABLED
1	ENABLED	CLKCHANGE_PD_ENABLE: Forces DRAM into power-down during CLKCHANGE. 0 = DISABLED 1 = ENABLED
0	ENABLED	CLKCHANGE_REQ_ENABLE: allows EMC and CAR to handshake on PLL divider/source changes. 0 = DISABLED 1 = ENABLED

18.13.2.65 EMC_CFG_DIG_DLL_0

Configure Digital DLL

Controls for digital DLL's, which used to measure and maintain 1/4 cycle phase adjustment for RDQS strobes.

This register is shadowed: see usage note at top.

Boot requirements

- This register (except for field CFG_DLL_ALARM_DISABLE and DLL_RESET(trigger) and CFG_DLL_USE_OVERRIDE_UNTIL_LOCK(trigger)) should be parameterized in the BCT and written by the Boot ROM during cold boot.

- This register (except for field CFG_DLL_ALARM_DISABLE and DLL_RESET(trigger) and CFG_DLL_USE_OVERRIDE_UNTIL_LOCK(trigger)) should be saved in the scratch registers and restored by the Boot ROM during warm boot.

Offset: 2bch | Read/Write: R/W | Reset: 0bx0000x00000000000000000010xx1x1

Bit	R/W	Reset	Description
31	RO	X	CFG_DLL_USE_OVERRIDE_UNTIL_LOCK: Writing 1 to this register causes override_val to be used in place of DLL output until DLL_LOCK/DLL_LOCK_TIMEOUT is obtained. Takes effect on next shadow update.
30	RO	0x0	DLL_RESET: Writing 1 to this register will send reset pulse to DLL's on next shadow update. Must reset DLL's when changing clock frequency by factor >= 2
29:28	RW	0x0	CFG_DLL_LOCK_LIMIT: [PMC] Reserved in case DLL has problems locking. DLL will be treated as locked after LIMIT uSec. Counter is reset with DLL_RESET (from above) or with each periodic update (if using RUN_PERIODIC). Settings are: 00: LIMIT = 16uS 01: LIMIT = 64uS 10: LIMIT = 128uS 11: LIMIT = 512uS
27	RW	0x0	CFG_DLL_ALARM_DISABLE: [PMC] Reserved bit -- disable override of DLL logic when DLL_ALM is set (otherwise overrides DLI to 0x3FF).
25:16	RW	0x0	CFG_DLL_OVERRIDE_VAL: [PMC] Value to use in place of DLI output if CFG_DLL_OVERRIDE_EN is set or prior to lock in RUN_TIL_LOCK mode.
15	RW	0x0	CFG_DLL_TESTEN: Enable DLL test mode
14	RW	0x0	CFG_DLL_QUSE_TESTOUT: Enable DLL TESTOUT on QUSE pads
13:12	RW	0x0	CFG_DLL_TESTSEL: Select DLL test output
11:8	RW	0x0	CFG_DLL_UDSET: [PMC] DLL Loop filter control (2^(udset+3)).
7:6	RW	RUN_TIL_LOCK	CFG_DLL_MODE: [PMC] Controls how frequently DLL runs, as follows 0 = RUN_CONTINUOUS : DLL will run continuously. This option will consume the most power. Once LOCK/TIMEOUT occurs, trimmers will be updated at REFRESH or shadow update. 1 = RUN_TIL_LOCK : after DLL_RESET is set, DLL will run until it has locked/timed out, then be disabled. Trimmers updated at following REFRESH/shadow update. 2 = RUN_PERIODIC : after DLL_LOCK/TIMEOUT, DLL will be disabled and re-enabled after CFG_DLL_RUN_PERIOD uSec to track delay changes (temp/voltage). 3 = RESERVED
5	RW	0x0	CFG_DLL_LOWSPEED: [PMC] Enable DLL for use with low-speed EMCCLK operation (<200MHz).
4	RO	X	CFG_DLL_STALL_RW_UNTIL_LOCK: [PMC] Writing 1 to this register will cause emc to stall all RW traffic until DLL locks. Takes effect on next shadow update.
2	RW	ENABLED	CFG_DLL_OVERRIDE_EN: [PMC] Override DLL's DLI output with OVERRIDE_VAL (still uses mult/offset). 0 = DISABLED 1 = ENABLED
0	RW	ENABLED	CFG_DLL_EN: [PMC] Enable digital DLL 0 = DISABLED 1 = ENABLED

18.13.2.66 EMC_CFG_DIG_DLL_PERIOD_0

This register is shadowed: see usage note at top.

Offset: 2c0h | Read/Write: R/W | Reset: 0b1000000000000000

Bit	Reset	Description
15:0	0x8000	CFG_DLL_RUN_PERIOD: If CFG_DLL_MODE == RUN_PERIODIC, this specifies interval between runs in uSec

18.13.2.67 EMC_DIG_DLL_STATUS_0

Digital DLL Status

Digital DLL Status bits directly from DLL

Offset: 2c8h | Read/Write: RO | Reset: 0bxxxxxxxxxxxxxxxx

Bit	Reset	Description
15	X	DLL_LOCK
14	X	DLL_ALARM
13	X	DLL_LOCK_TIMEOUT
9:0	X	DLL_OUT

18.13.2.68 EMC_CTT_DURATION_0

DRAM timing parameter

CTT_DURATION controls how long CTT remains enabled. If CTT + CTT_DURATION - RDV - 2 > 0, R2W must be increased by that amount.

Offset: 2d8h | Read/Write: R/W | Reset: 0b011

Bit	Reset	Description
2:0	0x3	CTT_DURATION: determines how long CTT remains enabled during reads. CTT determines when it will be enabled. DDR3: CTT_TERMINATION == 1 ? 3 : 0 LPDDR2: 0

18.13.2.69 EMC_CTT_TERM_CTRL_0

Configure CTT termination output drive strength

If CTT_TERMINATION is enabled this controls the strength of the output drivers.

TERM_OVERRIDE forces use of EMC2TMC_CFG*_DRVDN_TERM, EMC2TMC_CFG*_DRVUP_TERM instead of using of AUTO_CAL DRVDN/DRVUP values with the following equation applied:

```
TERM_DRDN = (AUTO_CAL_DRVDN * TERM_SLOPE) / 4 + TERM_OFFSET
TERM_DRUP = (AUTO_CAL_DRVUP * TERM_SLOPE) / 4 + TERM_OFFSET
```

Recommended values for SLOPE/OFFSET

100ohm CTT: TERM_SLOPE = 0x1, TERM_OFFSET = 0x4

50ohm CTT: TERM_SLOPE = 0x2, TERM_OFFSET = 0x8

Note: setting slope = 0 allows TERM_DRDN/DRVUP = TERM_OFFSET

setting slope > 2 is not supported

Boot requirements

- This register (except for fields TERM_DRVDN and TERM_DRVUP) should be parameterized in the BCT and written by the Boot ROM during cold boot.
- This register (except for fields TERM_DRVDN and TERM_DRVUP) should be saved in the scratch registers and restored by the Boot ROM during warm boot.

Offset: 2dch | Read/Write: R/W | Reset: 0b0xxxxxxxxxxxxxxxxxx01000xxxxx010

Bit	R/W	Reset	Description
31	RW	DISABLED	TERM_OVERRIDE: 0 = DISABLED 1 = ENABLED
28:24	RO	X	TERM_DRVUP
19:15	RO	X	TERM_DRVDN
12:8	RW	0x8	TERM_OFFSET:
2:0	RW	0x2	TERM_SLOPE:

ZQ Calibration Registers -- LPDDR2/DDR3

1. Periodic mode

Allows an ZQ calibration command to be sent periodically to dram. After ZCAL_INTERVAL, ZCAL_MRW_CMD will be sent to each DRAM, 1 at a time, followed by ZCAL_WAIT_CNT interval in which no other commands will be allowed to be sent to either dram. So if ZQ_MRW_DEV_SELECTN == 2'b00, it would send the MRW cmd to dev0, wait ZCAL_WAIT_CNT, send cmd to dev1, wait ZCAL_WAIT_CNT, resume normal operation. It will then wait ZCAL_INTERVAL microseconds before repeating the procedure. ZQ calibration command will not be sent to devices that are 1)unpopulated 2)either in or about to enter either self-refresh or dpd.

To enable periodic ZQ calibration, program ZCAL_INTERVAL and ZCAL_WAIT_CNT to be non-zero, as well as ZCAL_MRW_CMD to contain the command and device selection, followed by TIMING_CONTROL to latch those three registers.

Note that ZCAL_WAIT_CNT will be used instead of MRS_WAIT_CNT for delaying the subsequent dram commands after the ZQ calibration commands, even though in lpddr2 a ZQ calibration command is also a MRW command.

Disable this feature by setting ZCAL_INTERVAL.ZCAL_REF_INTERVAL = 0, followed by TIMING_CONTROL to latch it.

2. Oneshot mode

Allows ZQ calibration command to be sent to dram.

To send a one-shot command, keep ZCAL_INTERVAL and ZCAL_WAIT_CNT zero, program ZCAL_MRW_CMD with only one device selected, then program TIMING_CONTROL to latch in those registers, and finally program ZCAL_ONE_SHOT to 1 to trigger the one-shot command. If more than one devices need to be calibrated, wait the ZQ calibration time and repeat the steps above with the other device selection bit enabled in ZCAL_MRW_CMD.

Do not send oneshot ZQ calibration command when periodic mode is enabled.

18.13.2.70 EMC_ZCAL_INTERVAL_0

Configure ZQ Calibration

This register is shadowed: see usage note at top.

Boot requirements

- This register should be parameterized in the BCT and written by the Boot ROM during cold boot.
- This register should be saved in the scratch registers and restored by the Boot ROM during warm boot.

Offset: 2e0h | Read/Write: R/W | Reset: 0b00000000000000000000000000

Bit	Reset	Description
23:10	0x0	ZCAL_INTERVAL_HI: [PMC] Combined with ZCAL_INTERVAL_LO specifies the number of microseconds to wait between issuance of ZCAL_MRW_CMD. If 0, ZCAL is disabled and internal counter will be reset.
9:0	0x0	ZCAL_INTERVAL_LO

18.13.2.71 EMC_ZCAL_WAIT_CNT_0

Configure ZQ Calibration

This register is shadowed: see usage note at top.

Boot requirements

- This register should be parameterized in the BCT and written by the Boot ROM during cold boot.
- This register should be saved in the scratch registers and restored by the Boot ROM during warm boot.

Offset: 2e4h | Read/Write: R/W | Reset: 0b0000000000

Bit	Reset	Description
9:0	0x0	ZCAL_WAIT_CNT: [PMC] Number of emc clocks to wait before issuing any commands after sending ZCAL_MRW_CMD.

18.13.2.72 EMC_ZCAL_MRW_CMD_0

Configure ZQ Calibration

This register is shadowed: see usage note at top.

(However, it does not obey READ_MUX/WRITE_MUX non-default values.)

Boot requirements

- This register should be parameterized in the BCT and written by the Boot ROM during cold boot.
- This register should be saved in the scratch registers and restored by the Boot ROM during warm boot.

Offset: 2e8h | Read/Write: WO | Reset: 0b00xxxxxx00000000xxxxxxxx00000000

Bit	Reset	Description
31:30	0x0	ZQ_MRW_DEV_SELECTN: active-low chip-select, 0x0 applies command to both devices (will happen 1 at a time), 0x2 to for only dev0, 0x1 for dev1.
23:16	0x0	ZQ_MRW_MA: [PMC] MRW MA field to be sent after ZCAL_INTERVAL
7:0	0x0	ZQ_MRW_OP: [PMC] MRW OP field to be sent after ZCAL_INTERVAL

18.13.2.73 EMC_ZQ_CAL_0

Trigger a single ZQ Calibration

This register issues a ZQ calibration command for DDR3.

Offset: 2ech | Read/Write: R/W | Reset: 0b00xxxxxxxxxxxxxxxxxxxxxxxxx1xxx0

Bit	Reset	Description
31:30	0x0	ZQ_CAL_DEV_SELECTN: active low chip-select, 0x0 applies command to both devices, 0x2

Bit	Reset	Description
		to for only dev0, 0x1 for only dev1, 0x3 for neither device (0x0, for both devices, is not allowed if the ZQ resister is shared between devices).
4	LONG	ZQ_CAL_LENGTH: Indicate short or long ZQ calibration. 0 = SHORT 1 = LONG
0	0x0	ZQ_CAL_CMD: Issues a ZQ calibration command (DDR3 only).

18.13.2.74 EMC_XM2CMDPADCTRL_0

Pad configuration registers from APB_MISC:

XM2CMD Pad control register

Boot requirements

- This register should be parameterized in the BCT and written by the Boot ROM during cold boot.
- This register should be saved in the scratch registers and restored by the Boot ROM during warm boot.

18.13.2.86 EMC_SCRATCH0_0

This is a scratch register for general use.

Offset: 324h | Read/Write: R/W | Reset: 0b00000000000000000000000000000000

Bit	Reset	Description
31:0	0x0	SCRATCH:

18.13.2.87 EMC_DLL_XFORM_DQS0_0

Configure Digital DLL

XFORM_DQSx_MULT and XFORM_DQSx_OFFS are a multiplier and offset, respectively that can be used to modify the DLL output. Final products may be read out in DQS_TRIMMER_RD register. Default is multiply by 1, to keep DLL's 1/4 cycle delay. Integer + fractional formats for multiplier & offset:

OFFS is 2's complement format, with bit [4] representing integer

The output of the XFORM is xform_out = (xform_in * MULT + OFFS)/ 16

Largest allowed MULT = 0x17

In the case of overflow, output is clamped according to these rules:

out >= 0x600, xform_out = 0x000

0x600 > out >= 0x400, xform_out = 0x3ff

That means clamping works within 50% above the maximum (0x3ff) dll output or 50% below the minimum (0) dll output.

To make sure that is always satisfied, conservatively program OFFS so that 0x6000 < OFFS < (0x5fff - MULT * 0x3ff) DLL output is effectively overridden by setting XFORM_*_MULT to 0 and programming XFORM_*_OFFS[12:5] to override value

This register is shadowed: see usage note at top.

Boot requirements

- This register should be parameterized in the BCT and written by the Boot ROM during cold boot.
- This register should be saved in the scratch registers and restored by the Boot ROM during warm boot.

The DQS_CURRENT_TRIM_VAL_BYTE_x registers provide a way to observe the values being used by the trimmers

18.13.2.127 EMC_STALL_THEN_EXE_BEFORE_CLKCHANGE_0

Scheme to change controller timing parameters only

1. Program the EMC controller timing registers (shadowed)
2. Program CAR to change either clock source and/or clock divider

> **Note:** This scheme is not capable of changing read/write latency or enabling/disabling DLL. DONT_USE_REF_REQACK_IFC must be set to 1 in this scheme

Scheme to change controller timing parameters + SDRAM mode timing atomically.

1. Program the EMC controller timing registers (shadowed).
2. Pre-program SDRAM mode registers.
   a. Write 1 to STALL_THEN_EXE_BEFORE_CLKCHANGE field which will prevent further cfg execution until clock change request has been detected.

      Note: After this step, no register read should happen on EMC before the clock change (C) happens, otherwise system will hang. Disable EMC interrupt before this step if the interrupt handler reads EMC registers.

   b. write to whatever EMC registers you want to be execute after clock change request has been detected but before the actual clock change happens. For example, if you want to disable DLL in DDR3 mode, you can,
   - Issue a write to SDRAM's MR1 register via EMC MRS register to disable DLL.
   - Issue a Self-refresh entry via EMC SELF_REF register.

      Note: If there's no need to execute any register access before clock change, simply skip step (b); step (a) is still required.

   c. write 1 to STALL_THEN_EXE_AFTER_CLKCHANGE field which will prevent further cfg execution until after the actual clock change has happened.
   d. write to whatever EMC registers you want to be execute after clock change happened. Using the same example as (b), you will,
   - Issue a Self-refresh exit via EMC SELF_REF register.
   - Issue writes to SDRAM's MRx register(s) to change read/write latencies and/or enable DLL
   - Issue burst refreshs via EMC REF register.

      Note: If there's no need to execute any register access after clock change, simply skip step (d); step (c) is still required.

   e. write 1 to UNSTALL_RW_AFTER_CLKCHANGE field which will restore normal memory read/write accesses.
3. Program CAR to change either clock source and/or clock divider.

   Note: When using this clock change scheme, CLKCHANGE_SR_ENABLE field must be disabled.

   Note: In both sequences above, DYN_SELF_REF must be disabled off before the first step, then can be restored after the last step.

   The interval between two clock change sequences are recommended to be at least 20us apart

Write to this register will stall the register read/write path until a clock change request is detected. Once detected, whatever register access follows this register write will be executed until a STALL_THEN_EXE_AFTER_CKLCHANGE is encountered. At that point, EMC timing registers will be updated and clock change request will be acknowledge.

Offset: 3c8h | Read/Write: RO | Reset: 0b0

Bit	Reset	Description
0	0x0	STALL_THEN_EXE_BEFORE_CLKCHANGE: Writing a one to this bit will stall subsequent register access.

18.13.2.128 EMC_STALL_THEN_EXE_AFTER_CLKCHANGE_0

Write to this register will stall the register read/write path until after EMC timing registers are updated and that clock change has been completed. Once that happen, whatever register access follows this register write will be executed until UNSTALL_RW_AFTER_CLKCHANGE is encountered. At that point, normal memory read/write will be allowed to resume.

Offset: 3cch | Read/Write: RO | Reset: 0b0

Bit	Reset	Description
0	0x0	STALL_THEN_EXE_AFTER_CLKCHANGE: Writing a one to this bit will stall subsequent register access.

18.13.2.129 EMC_UNSTALL_RW_AFTER_CLKCHANGE_0

Writing to this register will un-stall memory read/write after clock change, use in conjunction with STALL_THEN_EXE_AFTER_CLKCHANGE.

Offset: 3d0h | Read/Write: RO | Reset: 0b0

Bit	Reset	Description
0	0x0	UNSTALL_RW_AFTER_CLKCHANGE: Writing a one to this bit will unstall memory read/write after clock change.

18.13.2.132 EMC_PRE_REFRESH_REQ_CNT_0

Offset: 3dch | Read/Write: R/W | Reset: 0b0000000000000000

Bit	Reset	Description
15:0	0x0	PRE_REF_REQ_CNT: When the refresh counter reach this pre-refresh request count just before a burst refresh will be issued when it reach the {REFRESH,REFRESH_LO}, a pre-refresh request will be asserted to MC to close the banks/pages and flush its pipeline. A 0 value will disable this feature.

18.13.2.133 EMC_DYN_SELF_REF_CONTROL_0

Threshold for dynamic self-refresh entry

This register controls how dynamic self-refresh entry/exit is handled.

If ODT is enabled, the DSR_PER_DEVICE field must be set to DISABLED.

It is recommended to change the values of ODT_WRITE and DSR_PER_DEVICE with a clock change

To do it outside of a clock change sequence, one has to be aware that DSR enable/disable takes time to take effect. This is the sequence for disabling DSR_PER_DEVICE and enabling ODT outside of clock change:

1. DYN_SELF_REF <= DISABLED (DSR exit)
2. TIMING_UPDATE <= 1 (latch in the shadow value)
3. read back and discard any EMC register such as INTSTATUS (ensure 1 and 2 have gone through)
4. wait 2 us for the last possible self-refresh entry
5. Poll for SDRAM_IN_SELF_REFRESH == 0 (ensure that self-refresh exits)
6. ODT_WRITE <= new value to turn on ODT

   DSR_PER_DEVICE <= DISABLED (turn off per-device DSR)

   DYN_SELF_REF <= EABLED (re-enable DSR)
7. TIMING_UPDATE <= 1 (latch in the shadow values)

Offset: 3e0h | Read/Write: R/W | Reset: 0b0xxxxxxxxxxxxxxx0000000000000000

Bit	Reset	Description
31	DISABLED	DSR_PER_DEVICE: controls whether dynamic self-refresh is done on a per-device basis. 0 = DISABLED 1 = ENABLED
15:0	0x0	DSR_THRESHOLD: number of idle cycles to wait before allowing dynamic self-refresh entry

18.13.2.134 EMC_TXSRDLL_0

DRAM timing parameter

This register is shadowed: see usage note at top.

Boot requirements

- This register should be parameterized in the BCT and written by the Boot ROM during cold boot.
- This register should be saved in the scratch registers and restored by the Boot ROM during warm boot.

Note: If operating in non-DLL mode, this register needs to be updated with the non-DLL timing requirement.

Offset: 3e4h | Read/Write: R/W | Reset: 0b011111111111

Bit	Reset	Description
11:0	0x7ff	TXSRDLL: cycles between self-refresh exit & first DRAM command requiring a locked DLL DDR3: READ (and RAP) and synchronous ODT commands LPDDR2: NA Largest allowed value is 0xffe

[THIS PAGE INTENTIONALLY LEFT BLANK]

19.0 AHB

19.1 AHB Bus

The AHB Bus conforms to the ARM® *AMBA® Specification (Rev 2.0) Advanced High-performance Bus (AHB)* architecture as published by ARM Limited.

AHB is a 32-bit multi-master bus. Despite the nomenclature, it is considered a second tier bus in the Tegra® 3 device, slower and less flexible than the AXI bus used by the CPU, or the memory client interface used by the high-speed devices.

AHB clients in Tegra 3 devices include:

- The AHB DMA controller master
- The AHB memory controller slave
- The AVP crossbar, both as a master and as a slave
- The APB DMA controller
- The USB-OTG controllers
- The NAND flash controller
- The NOR/MIO controller
- The SDMMC controllers
- The SE (security engine), both as a master and as a slave
- BSEA and BSEV bit-stream engines
- The CoreSight™ debug controller

AHB in Tegra 3 devices supports secure access to memory, using the same secure bit mechanism used by the ARM® Cortex®-A9 TrustZone™ security mechanism. This is only supported by the SE, which can make secure accesses to memory.

19.2 AHB Bus Arbiter

The AHB Arbiter controls AHB bus master arbitration. This effectively forms a second level of arbitration for access to the memory controller through the AHB Slave Memory device, although AHB masters in some circumstances can use other AHB slaves, in particular access IRAM.

The controls presented here are largely for diagnostic purposes only. For suspect AHB performance problems, try disabling the other masters for the device with performance issues. In normal operation bus parking is usually enable, and all the masters are enabled.

Also see the AHB slave interface registers, where the AHB pre-fetch logic can be configured to enhance performance for devices doing sequential access.

Each AHB master is assigned to either the high or low priority bin.

19.2.1 Arbitration Scheme

In every AHB Arbitration Cycle, it is first decided whether a request from the high or low priority bin will be served. If there are only requests active for one of the bins, then that bin is served. When there are active requests from both bins, then the value from the AHB_PRIORITY_WEIGHT field is considered. There is a counter that is loaded with the AHB_PRIORITY_WEIGHT whenever the current count is 0 and someone wins an AHB arbitration. This counter is decremented anytime the count is nonzero and the winner of AHB arbitration was from the high-priority-bin. Whenever this counter is nonzero, then a high-priority bin request will win over any low-priority bin request. In a system where both high- and low- priority bin requests are constantly active, the AHB_PRIORITY_WEIGHT says how many high-priority requests will be served for every one low-priority request.

Within each bin, the arbitration algorithm is round robin. For example, after AHB Master 2 wins an arbitration, then Master 3 has precedence for winning the next (followed by Master 4, etc. while Master 2 is last). AHB Master ID's can be seen in the enumeration of AHB_MEM_PREFETCH_CFG* registers' "AHB_MST_ID" field.

19.2.2 AHB Arbiter Registers

19.2.2.1 AHB_ARBITRATION_DISABLE_0

The AHB arbitration control register allows user to tweak arbitration behavior of the AHB arbiter.

- Enable bus parking. This keeps the last serviced AHB master on the bus granted so that it can start another transaction faster. If bus parking is disabled, no AHB master will be able to start a new transaction until the arbitration is done and the master is granted the bus.
- Allows the user to specifically disable an AHB master from arbitrating on the AHB bus.

AHB Arbitration Controller

Offset: 004h | Read/Write: R/W | Reset: 0b0xxxxxxxxxx00000x000000x000x0000

Bit	Reset	Description

3	0x0	CSITE: 1 = disable CoreSight from arbitration. 0 = ENABLE 1 = DISABLE

Bit	Reset	Description
2	0x0	VCP: 1 = disable VCP from arbitration. 0 = ENABLE 1 = DISABLE
1	0x0	COP: 1 = disable COP from arbitration. 0 = ENABLE 1 = DISABLE
0	0x0	CPU: 1 = disable CPU from arbitration. 0 = ENABLE 1 = DISABLE

19.2.2.2 AHB_ARBITRATION_PRIORITY_CTRL_0

The AHB arbiter implements a 2-level priority scheme. In the 1st level, arbitration is determined between the high and low priority group according to the priority weight; the higher the weight, the higher the winning rate of the high priority group.

In the 2nd level, within each of the high/low priority group, arbitration is determined in a round-robin fashion.

AHB Arbitration Priority Control Register

Offset: 008h | Read/Write: R/W | Reset: 0b00000000000000000000000000000000

Bit	Reset	Description

19.3 AHB “Gizmo”

AHB master/slave gizmos are essentially hardware layers used by many of the master/slave logic which need to connect to the AHB bus.

These hardware layers handle all the AHB bus protocols and convert the more complex AHB protocol into a much simpler IP interface/handshake.

Because the AHB master/slave gizmos interface with many IP logic with different characteristics varying in speed, latency, etc., the gizmos accept a number of static configuration bits. Depending on system speed, latency requirement, transfer direction, burst characteristic, etc., these static configuration bits can be pre-configured to give extra performance or improve bus efficiency.

19.3.1 AHB Gizmo Registers

19.3.1.1 AHB_GIZMO_AHB_MEM_0

AHB Master/Slave Gizmo Register

Given below is a description of each configuration field, what they are used for and the pros and cons of using them.

> **Note:** If the gizmo configuration bits are changed while the particular gizmo is transferring data, behavior of the system is non-deterministic.

AHB gizmo configuration bit definition:

(1) AHB Master Gizmo

1. MAX_AHB_BURSTSIZE: Controls the maximum burst size that this gizmo can generate on the AHB bus. For the current system, this field should be set to burst-of-8.
2. IMMEDIATE: Controls how quickly an AHB write request on the bus can start.
   - If 1, gizmo will start an AHB write request once the IP side provides one beat of data of a burst. For IP that can provide quick continuous burst data, this setting provides parallelism between AHB request and IP data transfer. However, for IP that cannot provide quick burst data, this setting will force this gizmo to hold the AHB bus longer, reducing bus efficiency.
   - If 0, gizmo will wait until all beats of data of a burst are provided before starting an AHB write request. With this setting, AHB bus efficiency is realized but IP latency and efficiency may be reduced.
3. RD_DATA: Controls how read data will be returned from the gizmo to the IP side.
   - If 1, all beats of data of a burst have to be available before it indicates to the IP logic that read data is ready. This setting ensures there's no wait-state (bubble) between read data burst, but it will increase latency.

- If 0, each beat of data of a burst will be sent from gizmo to the IP logic immediately. This setting will reduce latency, but can create non-consecutive data burst or bubble between data.

4. REQ_NEG_CNT: Provides a way to limit (in terms of number of AHB bus clock) how fast/often this master can request the AHB bus. The bigger the number, the slower the rate of AHB request.

(2) AHB Slave Gizmo

1. ENABLE_SPLIT: Controls enabling the split feature of the AHB bus.
   - If 1, gizmo will always generate split response for a read. If ' DON'T_SPLIT_AHB_WR' is set to 0, gizmo also generates split response if it cannot accept write request from the AHB master anymore. This setting can increase AHB bus utilization since it allows other AHB masters to talk to other AHB slaves while this original AHB slave is fetching read data. However, the flip side is that it takes longer time for the original AHB master to get the read data, because the original AHB master has to re-arbitrate for the AHB bus again in order to get to the data it asked for.
   - If 0, gizmo will not generate split response. Instead, it will hold on to the AHB bus until all the requested read data is returned back to the AHB master. This setting will reduce read latency to the master, but decrease AHB bus utilization.
2. FORCE_TO_AHB_SINGLE: Controls how the gizmo treats the AHB master's burst request.
   - If 1, gizmo will break up the burst request internally into individual single word requests.
   - If 0, gizmo will burst request internally as burst request.
3. ENB_FAST_REARBITRATE: Controls when the gizmo can allow the original read requested AHB master to re-arbitrate for the AHB bus again so the AHB master can retrieve the originally requested read data.
   - If 1, once first read data of a burst is in the slave gizmo's FIFO, it will allow the original AHB master to re-arbitrate, thus, allowing arbitration to happen in parallel with subsequent read data of a burst. However, if the data burst has wait-states or bubbles, then this setting will decrease AHB bus utilization because the slave gizmo will hold on to the AHB bus longer.
   - If 0, all read data of a burst must be in the slave gizmo's FIFO before it allows the original AHB master to re-arbitrate to retrieve the read data. This increases read data latency, and also increase AHB bus utilization.
4. IP_WR_REQ_IMMEDIATE: Controls when gizmo will start write data request to the IP logic.
   - If 1, gizmo will start write request to the IP logic once it gets one write data of a burst from the AHB side. This setting will create non-consecutive/bubbles in a write data burst.
   - If 0, gizmo will start write request to the IP logic only when it gets all write data of a burst from the AHB side. This setting will create consecutive data burst (no bubbles or wait-states).
5. MAX_IP_BURSTSIZE: Controls the maximum burst size that this gizmo can generate to the IP logic.
6. ACCEPT_AHB_WR_ALWAYS: Controls how the slave gizmo will treat AHB write request.
   - If 1, gizmo will always accept a write request without checking whether it's FIFOs can accept the write or not. This setting can reduce bus utilization, but can reduce the rate of AHB retry.
   - If 0, gizmo will check its FIFOs to make sure they have room before accepting the AHB write request. This setting increase bus utilization, but can create a lot of AHB retry.
7. DON'T_SPLIT_AHB_WR: Controls whether to split AHB write request when the slave gizmo determines it cannot accept the write request.
   - If 1 and when ENABLE_SPLIT=1, gizmo will generate split for write if its FIFOs are not ready to accept the AHB write request or data. This setting can improve AHB bus utilization as there are no continuous AHB master retries on the bus.
   - If 0, gizmo will generate retry response for write if its FIFOs are not ready to accept the AHB write request. Software should leave this bit at 0 since this feature has not been proven.

AHB Gizmo AHB-DMA/Memory Control Register

Offset: 010h | Read/Write: R/W | Reset: 0b00000000xxxxx010xxxxxxx010xxx001

Bit	Reset	Description
31:24	0x0	REQ_NEG_CNT: AHB master request negate count. This is an 8-bit counter used to indicate the minimum number of clk count between requests from this AHB master.
18	0x0	IMMEDIATE: AHB master gizmo (AHB-DMA) – Start AHB write request immediately 1 = start the AHB write request immediately as soon as the device has put one write data in the AHB gizmos queue. 0 = start the AHB write request only when all the write data has transferred from the device to the AHB gizmos queue. 0 = DISABLE 1 = ENABLE
17:16	0x2	MAX_AHB_BURSTSIZE: AHB master gizmo (AHB-DMA) – Maximum allowed AHB burst size. 00 = single transfer. 01 = burst-of-4. 10 = burst-of-8 11 = burst-of-16. 0 = DMA_BURST_1WORDS 1 = DMA_BURST_4WORDS 2 = DMA_BURST_8WORDS 3 = DMA_BURST_16WORDS
8	0x0	WR_WAIT_COMMIT_ON_1K: writes to ahbslv will only be issued to MC when all prior writes in different 1kB pages have reached the point of coherency. This is needed because MC allows re-ordering of transactions. If this is not set, an entity which polls memory for a descriptor or flag to indicate some other memory has been written may be think something is available in memory when it is in fact not. 0 = DISABLE 1 = ENABLE
7	0x1	DON'T_SPLIT_AHB_WR: AHB slave gizmo (memory controller) - don't split AHB write transaction 1 = don't split AHB write transaction ever. 0 (and enable_split=1) = allow AHB write transaction to be split. 0 = ENABLE 1 = DISABLE
6	0x0	ACCEPT_AHB_WR_ALWAYS: AHB slave gizmo (memory controller) - Accept AHB write request always. 1= always accept AHB write request without checking whether there is room in the queue to store the write data. Bypass Memory Controller AHB slave gizmo write queue. 0 = accept AHB write request only when there's enough room in the queue to store all the write data. Memory controller AHB slave gizmos write queue is used in this case. 0 = ACCEPT_ON_CHECK 1 = ACCEPT_ON_NOCHECK
2	0x0	ENB_FAST_REARBITRATE: AHB slave gizmo - Enable fast re-arbitration. 1 = allow AHB master re-arbitration as soon as the device returns one read data into the gizmos queue. 0 = allow AHB master re-arbitration only when the device returns all read data into the gizmos queue. 0 = DISABLE 1 = ENABLE
1	0x0	FORCE_TO_AHB_SINGLE: AHB slave gizmo (memory controller) - Force all AHB transaction to single data request transaction 1 = force to single data transaction always. 0 = don't force to single data transaction. 0 = NOT_SINGLE_DATA 1 = SINGLE_DATA
0	0x1	ENABLE_SPLIT: AHB slave gizmo (memory controller) - Enable splitting AHB transaction. 1 = enable 0 = disable. 0 = DISABLE 1 = ENABLE

19.3.1.2 AHB_GIZMO_APB_DMA_0

AHB Gizmo APB-DMA Control Register

Offset: 014h | Read/Write: R/W | Reset: 0b00000000xxxx1010

Bit	Reset	Description
31:24	0x0	REQ_NEG_CNT: AHB master request negate count. This is an 8-bit counter used to indicate the minimum number of clk count between requests from this AHB master.
19	0x1	RD_DATA: AHB master gizmo - Pack all AHB read data. 1 = wait for all requested read data to be in the AHB gizmos queue before returning the data back to the IP. 0 = transfer each read data from the AHB to the IP immediately. 0 = NO_WAIT 1 = WAIT

19.4 AHB Memory Controller Slave

The AHB memory controller slave is the path used by AHB bus masters to access the Memory Controller. It provides access to DRAM from the AHB bus, and can pre-fetch data.

19.4.1 AHB Memory Pre-Fetcher

The AHB memory controller slave contains a pre-fetcher block. This is intended to improve performance for AHB masters performing sequential reads from DRAM. Performance can be a problem because the AHB bus protocol only allows a single outstanding read request from a master, so the round trip latency limits bandwidth. As there are two level of arbitration, firstly on AHB and secondly within the memory controller, this latency can become large on a busy system.

There are four such pre-fetchers, allowing this function to be active for up to four AHB masters.

When the pre-fetcher is enabled, the first read request initiates a speculative read of up to 128 bytes, and subsequent linear reads will return the data directly to the AHB master without going through the memory controller to DRAM.

19.4.1.1 Pre-Fetch Invalidate

The pre-fetch buffer's contents are invalidated under any of the following conditions, in all cases a read refers to a DRAM read by the assigned HB master:

- The programmed time-out value is reached since the last read
- A read occurs which is not sequential with the previous read
- A read occurs, which is not the same size as the previous read, unless the corresponding DISABLE_CHECK_SIZE_MASTERx bit is set.
- A read occurs which is past the end of the pre-fetch buffer (this will trigger a new fill of the buffer).
- The pre-fetcher is disabled. A momentary disable and then re-enable can be used to invalidate the buffer.

19.4.1.2 Pre-Fetch Buffer Coherency

As the pre-fetch buffer contains a copy of data in DRAM, there is an inherent coherency risk if the DRAM data is updated. The hardware invalidation mechanisms provide some protection here, but there remains risk of subtle problems arising from this hardware. If an AHB master shows errors that appear to arise from stale data then a reasonable experiment is to disable the pre-fetcher to see if that cures the problem. If so, the following guidelines may help.

Problems have been seen for control structures such as USB Transfer Descriptors.

Two approaches can resolve this problem:

1. Pad the data

As the pre-fetcher invalidates the buffer for any non-sequential read, placing some padding will prevent pre-fetch issues. A problem can be triggered by using something like this:

```
struct dtd { unsigned HW_descriptor[K] ; } ; struct dtd dtd_array[N] ;
```

This makes the HW descriptors structures as read by the USB DMA sequential, and so pre-fetchable.
If the definition is modified as:

```
struct dtd { unsigned HW_descriptor[K] ; unsigned Padding ; } ; struct dtd dtd_array[N] ;
```

Then reads by USB DMA of consecutive HW descriptors become **not** sequential and so there is no coherency issue as the pre-fetch buffer will be invalidated.

2. Invalidate the pre-fetch buffer

After updating a memory structure, the pre-fetch buffer can be invalidated by disabling the pre-fetcher and then immediately re-enabling it.

19.4.2 AHB Memory Controller Slave Registers

19.4.2.1 AHB_AHB_MEM_PREFETCH_CFG_X_0

If DISABLE_CHECK_SIZE is 0, then only read requests that have the exact same size as the original read request that kick-started the prefetch process will cause a "hit". In addition, the address must be the exact next one in the sequence.

For instance, if the first request on a prefetch-enabled AHB Master arrives with SIZE=ONE_BYTE and ADDR[31:0]=0x3, then the next access must have SIZE=ONE_BYTE and ADDR[31:0]=0x4 in order to be considered a hit.

If DISABLE_CHECK_SIZE is 1, then a read request will hit as long as the incoming ADDR[31:4]matches the expected_ADDR[31:4]. expected_ADDR[31:4] is always either "last ADDR[31:4]" or "last ADDR[31:4] + 1", where last ADDR is the prior read request actually issued by the AHB Master(as opposed to the last request to the CIF, which could have been a speculative read).

expected_ADDR[31:4] is always "last ADDR[31:4]" unless "SIZE" field in the last request uses the last byte in the 16-byte CIF word.

19.4.2.18 AHB_AXICIF_FASTSYNC_CTRL_0

These registers control the Fast Synchronizer Logic in FIFOs between the CPU clock domain and the Memory Controller clock domain in the CPU AXICIF's MCCIF. This fast synchronizer will reduce latency, but is subject to certain restrictions stated below. These registers are nothing to do with the AHB bus, but are implemented here for convenience.

FASTSYNC_MODE

If ENABLE, the fastsync logic may be controlling the fifo's cross-clock synchronization. To enable this mode, the CLK_RST_CONTROLLER_LVL2_CLK_GATE_OVRC.MPCORE_MCCLK_OVR_ON must also be enabled to ensure 2nd-level clocks are always running.

When enabling fastsync:

- First set CLK_RST_CONTROLLER_LVL2_CLK_GATE_OVRC_0.MPCORE_MCCLK_OVR_ON == 1
- Then AHB_AXICIF_FASTSYNC_CTRL_0.FASTSYNC_MODE == 1

When disabling fastsync:

- first set AHB_AXICIF_FASTSYNC_CTRL_0.FASTSYNC_MODE == 0
- then if desired CLK_RST_CONTROLLER_LVL2_CLK_GATE_OVRC_0.MPCORE_MCCLK_OVR_ON == 0

While ENABLED, the following AXICIF_FASTSYNC(0|1|2)_* registers should not be written. The hardware will ignore writes to these registers while ENABLED.

To change the fastsync configuration:

- software must first set MODE=DISABLE
- readback MODE=DISABLE (to give it plenty of time to propagate)
- Update the configuration
- then set MODE=ENABLE.

FASTSYNC_EN_STATUS

Indication whether CAR is telling AXICIF it is safe to enable fast-mode. Note that these indicators lag the actual locking by a few cycles, so this should only be used to confirm that a software request to turn off fastsync has taken effect.

FASTSYNC_*CLK_TO_*CLK_STATUS

Indicates whether the fastsync logic is locked in fast-mode for the named clock-crossing. Note that these indicators lag the actual locking by a few cycles, so this should only be used to confirm that a software request to turn off fastsync has taken effect.

Offset: 130h | Read/Write: R/W | Reset: 0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx0

Bit	R/W	Reset	Description
31	RO	X	FASTSYNC_MCCLK_TO_CPUCLK_STATUS: 0 = SLOW 1 = FAST
30	RO	X	FASTSYNC_CPUCLK_TO_MCCLK_STATUS: 0 = SLOW 1 = FAST
29	RO	X	FASTSYNC_EN_STATUS: 0 = DISABLE 0 = DISABLED 1 = ENABLE 1 = ENABLED
0	RW	DISABLE	FASTSYNC_MODE: 0 = DISABLE 1 = ENABLE

19.4.2.19 AHB_AXICIF_FASTSYNC_STATISTICS_0

Fastsync Performance Statistics

Allows the user to gather data about percentage of time fastsync logic is in fast synchronization mode. This statistics samples once a microsecond, (assuming that sys_clk period is greater than a microsecond).

FASTSYNC_STATS_GATHER –

The GATHER bits are master control bits to turn collection on and off. The stats controls can be enabled/disabled at will.

The RST state for GATHER zeros out any counters. Once entered, GATHER stays in the RST state until software changes it.

The DISABLE state causes all statistics counters to freeze at their current value. If the GATHER state goes back to ENABLE, the counters keep incrementing from their previous value.

The ENABLE state is when the statistics counters increment.

FASTSYNC_STATS_FAST_COUNT --

A count of microsecond samples where FASTSYNC_CPUCLK_TO_MCCLK_STATUS == FAST. If this counter hits its maximum value, both counters will stop counting and hold their value until cleared with GATHER=RST.

FASTSYNC_STATS_SLOW_COUNT --

A count of microsecond samples where FASTSYNC_CPUCLK_TO_MCCLK_STATUS == SLOW. If this counter hits its maximum value, both counters will stop counting and hold their value until cleared with GATHER=RST.

Note that these statistics use CPUCLK_TO_MCCLK because MCCLK is generally run slower than CPUCLK and thus there's more latency benefit when synchronization is fast in that direction.

Offset: 134h | Read/Write: R/W | Reset: 0b10xxxxxxxxxxxxxxxxxxxxxxxxxxxxxx

Bit	R/W	Reset	Description
31:30	RW	DISABLE	FASTSYNC_MCCLK_TO_CPUCLK_STATUS: 0 = SLOW 1 = FAST
29:15	RO	X	FASTSYNC_STATS_FAST_COUNT
14:0	RO	X	FASTSYNC_STATS_SLOW_COUNT

19.4.2.20 AHB_AXICIF_FASTSYNC0_CPUCLK_TO_MCCLK_0

Fastsync Per-direction controls:

ENABLE : If 1, allows fast synchronization (default: 0).

Note: can still get disabled temporarily while CAR is changing cpuclk or mcclk frequencies.

FREQ_FRAC_OVERRIDE: If 1, override frequency ratio fraction using FREQ_FREQ (default: 0, which means to use frequency estimator). Do not change value while FASTSYNC_CTRL.FASTSYNC_MODE==ENABLE.

PRED_INIT_FRAC: If not 0, overrides the up/lo bound initialization fraction used in the phase predictor (default: 0, which means compute fraction from max_delay parameter used for the phase detector). Do not change value while FASTSYNC_CTRL.FASTSYNC_MODE==ENABLE.

PRED_BOUND_FRAC: If not 0, overrides the up_bound comparison fraction used in the phase predictor (default: 0, which means compute fraction from min_delay parameter used for the phase detector). Do not change value while FASTSYNC_CTRL.FASTSYNC_MODE==ENABLE.

PLESIO_BOUND_FRAC: If not 0, overrides the plesio bound fraction used in the phase predictor when plesio mode is in effect; Note that this value is the upper 8 bits of the 17-bit fraction; (default: 0, which means to use a fraction which is 10% more than 2*max_delay param). Do not change value while FASTSYNC_CTRL.FASTSYNC_MODE==ENABLE.

PRED_INC_FRAC: If not 0, overrides the value subtracted-from/added-to low/high bounds each cycle until the next phase detect. It's essentially 2x the amount by which the prediction window widens each cycle before the next phase detect. (default: 0)

Do not change value while FASTSYNC_CTRL.FASTSYNC_MODE==ENABLE.

SPARE: 21 spare diagnostic workaround bits each direction (default: 0)

Do not change value while FASTSYNC_CTRL.FASTSYNC_MODE==ENABLE.

19.5 AHB DMA Controller

The AHB DMA is a master placed between the AHB Bus and the Memory Controller (MC). It is used to accomplish block data transfers between external memory (DRAM) and internal memory (IRAM). It can also be used to move data from one section of external memory to another. It has four channels which can transfer data concurrently.

AHB DMA is used to transfer data from a source location to a destination location. Transfers can be from DRAM to DRAM, or between DRAM and IRAM in either direction. DMA transfers are done without any processor intervention other than the register writes to program the parameters for a particular transfer and handling interrupts.

AHB DMA is a “legacy” block, and is deprecated. Its performance is less than alternative memory to memory copy mechanisms such as program transfer (memcpy), or using the 2D engine. It may be useful as a means of DRAM to IRAM transfer but should not be used otherwise.

Features

- DMA master for transfers between external memory and AHB
- Data can be transferred from DRAM to DRAM, DRAM to IRAM or IRAM to DRAM
- Two modes of data transfer: single transfer (once) or continuous
- Programmable burst sizes of 1, 4, or 8 words
- Maximum transfer size of 64 KB per channel
- Minimum transfer size is 4B per channel
- Separate source and destination address pointers
- Per channel trigger and flow control mechanism
- Channel to channel trigger support i.e. ability to start transfer from one channel upon completion of transfer of another channel
- Interrupts per channel can be routed to CPU or AVP
- Ability to hold processor until transfer is done
- Address strides and wrap modes supported in once mode
- Double-buffering mode which allows transfer of data to two sequential destination addresses
- Round robin arbitration among channels at burst granularity
- Runs on system clock

19.5.1 Functionality

There are 4 channels in AHB DMA. An AHB DMA channel can transfer specified portions of data from an AHB address space (basically used for IRAM) to an MC address space, or transfer data between two different locations of MC address space.MC and XMB are used interchangeably. AHB DMA follows a simple round robin arbitration scheme.

Each channel can have independent burst transfer sizes programmed to one word, four words, or eight words.

Each DMA channel supports:

- Enable bit (note that there is another enable bit known as global enable bit).
- Direction bit to determine the direction of transfer: AHB to MC or MC to AHB.
- Interrupt Enable at the end of transfer with ability to mask or route to desired processor.
- Ability to hold off a Processor. Processor which writes into this bit will be held until transfer is completed.
- Trigger and Flow selects. These are additional control bits on which the transfer depends; Trigger bit is used to start a channel on some event to start the transfer and Flow bit is used to proceed with the transfer on every burst. This

again depends upon events from the system or AHB DMA itself. i.e., transfers can be started automatically, or under software control or under hardware control.

- Stride feature allows transfer of blocks of data where the transfer size and skip size are programmed.
- Wrap feature wraps the address on every burst transfer.
- Double Buffering Mode will make the AHB DMA Burst Address to reset to AHB Base Address after every even (2nd, 4th, 6th, etc) numbered transfer. Double buffering mode can be enabled with continuous transfer mode only.
- Separate registers for specifying AHB start address and MC start address.
- Ability to reduce the burst rate by delaying each burst by a programmable number of clock cycles.

19.5.2 Programming Guidelines

All the registers of a channel should be programmed before the channel enable bit is set.

Clearing the Global Enable bit causes the transfers that are in progress to be paused and setting the Global Enable resumes the transfers. If channel is disabled while transfer is in progress, transfer ends after completing any burst sequence that is in progress.

For best performance, MC source and destination addresses should be aligned to the burst size. For example, if Burst size is programmed to 4, the address needs to be aligned to 4-word boundary to achieve best throughput. If the MC address is not aligned to a 4-word boundary, 1-word transfers are initiated at the start and end of transfer as needed. Busy bit gets set as soon as a channel is enabled and gets cleared after transfer completes.

Interrupts are write-1-to-clear i.e., interrupt bit is cleared when the value of write data corresponding the bit position of the interrupt bit is 1.

19.5.3 AHB DMA Registers

19.5.3.1 AHBDMA_CMD_0

AHB-DMA Command Register

The Global Enable bit in the command register enables the AHB DMA. Clearing this bit causes active DMA transfers to be paused.

Pending bus transactions (ongoing burst) are completed and no new transactions are generated. Set this bit again to resume transfers.

Offset: 000h | Read/Write: R/W | Reset: 0b0

Bit	Reset	Description
31	0x0	GEN: 0 = Disable AHB-DMA. 0 = DISABLE 1 = ENABLE

19.5.3.2 AHBDMA_STA_0

AHB-DMA Status Register

Busy bits in the status register indicate which (if any) of the AHB DMA channels have active pending AHB DMA transfers.

AHB DMA transfers that are started in continuous (repetitive) mode have their busy bits active until the enable bit for the AHB DMA channel is cleared to 0.

Offset: 004h | Read/Write: RO | Reset: 0bxxxx

Bit	Reset	Description

19.5.4 AHBDMACHANNEL_REGISTERS

The description given for AHB-DMA-CHANNEL-0 applies to all the corresponding registers for the remaining channels AHB-DMA-CHANNEL-1 to AHB-DMA-CHANNEL-3

19.5.4.1 AHBDMACHAN_CHANNEL_0_CSR_0

AHB-DMA-CHANNEL-0 Control Register

Writing a 1 to bit [31] of an AHB DMA Channel Control Register will initiate the AHB DMA Transfer. Because this action will depend on some values programmed in the other registers, it is recommended that the registers in the address space in the required AHB DMA channel be programmed before writing into control register.

In "Once" mode, the channel is disabled after the AHB DMA Transfer has completed. When the channel's Transfer completes, an interrupt will be sent if the IE.EOC bit is set

If the transfer requires a trigger or flow, then the corresponding trigger selected by the "TRIG_SEL" or "REQ_SEL" field must become active respectively before the channel can starts its transfer. If both Trigger and Flow bits are set, both conditions must be met before the channel starts each DMA Burst.

Offset: 000h | Read/Write: R/W | Reset: 0b00000000000000000000000000000000

Bit	Reset	Description

19.5.4.3 AHBDMACHAN_CHANNEL_0_AHB_PTR_0

AHB-DMA-CHANNEL-0 AHB Starting Address Pointer Register

If stride is enabled, the AHB address should be aligned to burst size.

Offset: 010h | Read/Write: R/W | Reset: 0b00000000000000000000000000000000

Bit	Reset	Description
31:2	0x0	AHB_BASE: AHB-DMA starting address for internal AHB Bus

19.5.4.4 AHBDMACHAN_CHANNEL_0_AHB_SEQ_0

AHB-DMA-CHANNEL-0 AHB Address Sequencer Register

An AHB DMA stride is a sub-section of an AHB DMA transfer, can be used in once mode, and is composed of one or more AHB DMA bursts. When stride is enabled, wrap should not be enabled. The size of a stride is programmable, but is always an integer multiple of 4 words.

The size of the AHB DMA stride must always be an integer multiple of the AHB DMA burst size. The size of the AHB DMA transfer count (total words in the transfer) must also be a multiple of both the burst size and the stride size.

If stride is enabled, the AHB_STRIDE should be aligned to burst size.

7:4	X	RAM_CODE: read at power-on reset time from gmi_ad[7:4] strap pads In emulation (HIDREV_MAJORREV==0), this field indicates the RAM type connected. For QT (HIDREV_MINORREV==0): 0=SIM, 1=DDR, 2=DDR2, 3=LPDDR2 For FPGA (HIDREV_MINORREV==1): 0=SIM, 1=DDR, 2=DDR2, 3=LPDDR2
0	RSVD1	NOR_WIDTH: 0 = RSVD1 1 = RSVD2

20.1.2 JTAG Configuration Register

20.1.2.1 APB_MISC_PP_CONFIG_CTL_0

Configuration Control Register

The use of the SO bits below has been deprecated. Keep these bits disabled at all times.

Offset: 024h | Read/Write: R/W | Reset: 0b01xxxx00

Bit	Reset	Description
7	DISABLE	TBE: 0 = Disable ; 1 = Enable RTCK Daisychaining 0 = DISABLE 1 = ENABLE
6	ENABLE	JTAG: 0 = Disable Debug ; 1 = Enable JTAG DBGEN 0 = DISABLE 1 = ENABLE
1	DISABLE	XBAR_SO_DEFAULT: deprecated -- keep disabled -- default SO bit for non-CPU XBAR clients 0 = DISABLE 1 = ENABLE
0	DISABLE	CPU_XBAR_SO_ENABLE: deprecated -- keep disabled --Enable CPU SO bit to propagate to XBAR 0 = DISABLE 1 = ENABLE

20.1.3 PULL_UP/PULL_DOWN Control Register

Controls the pull_up/pull_down inputs of the pads. Used to eliminate external components on interfaces that need pullup/pulldown. Those are weak internal pullup/pulldowns

- NORMAL setting means pad is neither pulled up (driving weak 1) or pulled down (driving weak 0)
- PULL_DOWN selection means pad is driving weak 0
- PULL_UP selection means pad is driving weak 1

> **WARNING!** Driving internal pull-up when pad has external pull down and vice versa will cause significant increase in power consumption.

Table 31. Cross reference of fields with real ball names

Field Name	Controls Balls
XM2D_PU_PD	DDR_DQ0,DDR_DQ1,...,DDR_DQ31
XM2C_PU_PD	MIO_IORDY,DDR_DM0,..,DDR_DM3,DDR_DQS0,...,DDR_DQS3,DDR_A0,..,DDR_A13,DDR_BA0,DDR_BA1,DDR_CS0_,DDR_CS1_,DDR_CKE,DDR_RAS_,DDR_CAS_,DDR_WE_,
DDRC_PU_PD	DDR_COMP_PU, DDR_COMP_PD

20.1.3.1 APB_MISC_PP_PULLUPDOWN_REG_C_0

Offset: 0a8h | Read/Write: R/W | Reset: 0b000000

Bit	Reset	Description
31:30	NORMAL	XM2C_PU_PD: 0 = NORMAL 1 = PULL_DOWN 2 = PULL_UP 3 = RSVD

Bit	Reset	Description
29:28	NORMAL	XM2D_PU_PD: 0 = NORMAL 1 = PULL_DOWN 2 = PULL_UP 3 = RSVD
27:26	NORMAL	DDRC_PU_PD: 0 = NORMAL 1 = PULL_DOWN 2 = PULL_UP 3 = RSVD

20.1.3.2 APB_MISC_SC1X_PADS_VIP_VCLKCTRL_0

Enable VCLK pad to get external clock for VI.

VCLK Control Register

Offset: 428h | Read/Write: R/W | Reset: 0b00

Bit	Reset	Description
1	0x0	INVERSION: VCLK invert enable 0 = DISABLE 1 = ENABLE
0	0x0	IE: VCLK input enable 0 = DISABLE 1 = ENABLE

20.1.3.3 APB_MISC_SC1X_PADS_TVDAC_VHSYNCCTRL_0

In VGA mode of operation, there are separate HSYNC and VSYNC sync outputs to go with the R/G/B analog output signals.

TVDAC_HSYNCDLY and TVDAC_VSYNCDLY specify additional signal delay to be applied to HSYNC and VSYNC outputs. Values {0, 1, 2, 3} correspond to the added delay in {0-, 1-, 2-, 3-} pixel periods.

TVDAC HSYNC & VSYNC delay control

Offset: 438h | Read/Write: R/W | Reset: 0b0000

Bit	Reset	Description
3:2	0x0	TVDAC_VSYNCDLY
1:0	0x0	TVDAC_HSYNCDLY

20.1.3.4 APB_MISC_SC1X_PADS_TVDAC_CONTROL_0

- DAC_IDDQ, DAC_POWERDOWN, and DAC_DETECT_EN are power down control to all 3 DACs.
- DAC_SLEEPR, DAC_SLEEPG, and DAC_SLEEPB are individual power down controls.
- DAC_COMP_TH[1:0] is to choose threshold voltage of the internal comparator for load detection.
  {0, 1, 2, 3} for {0.24 V, 0.30 V, 0.48 V, 0.60 V}
- DAC_BGAP_AVG_ON is to enable bandgap averaging (default is 0).
- DAC_BGAP_CURVE[2:0] is to adjust temperature coefficient (default is 0x4).
- DAC_BGAP_CNTL[3:0] is to set up clock frequency in ATE calibration mode.

- DAC_ATEST[2:0] is for testing. To select various internal analog outputs to be sent to the VREF pin.
- DAC_CNTL[4:0] is to adjust bias current and bias resistance.
- DAC_COMPR_EN, DAC_COMPG_EN, and DAC_COMPB_EN are to enable comparator outputs.
- DAC_PLUG_OK is to indicate the load status. 0/1 for unloaded/loaded.

TV DAC control

Offset: 43ch | Read/Write: R/W | Reset: 0b0000x00000000000100000111011

Bit	Reset	Description
28	0x0	DAC_PLUG_OK: Indicate load status 0 = UNLOADED 1 = LOADED
27	0x0	DAC_COMPB_EN: Enable COMPOUTB output 0 = DISABLE 1 = ENABLE
26	0x0	DAC_COMPG_EN: Enable COMPOUTG output 0 = DISABLE 1 = ENABLE
25	0x0	DAC_COMPR_EN: Enable COMPOUTR output 0 = DISABLE 1 = ENABLE
23:19	0x0	DAC_CNTL: Reserved for additional control
18:16	0x0	DAC_ATEST: For debugging. Selects internal analog output to be sent out of VREF pin
15:12	0x0	DAC_BGAP_CNTL: Control bits for bandgap
11:9	0x4	DAC_BGAP_CURVE: To adjust temp coeff
8	0x0	DAC_BGAP_AVG_ON: Turn bandgap averaging on/off 0 = DISABLE 1 = ENABLE
7:6	0x0	DAC_COMP_TH: Adjust threshold voltage of comparator inside DAC
5	0x1	DAC_SLEEPB: Low power (sleep) mode. Shut down OUTB output 0 = DISABLE 1 = ENABLE
4	0x1	DAC_SLEEPG: Low power (sleep) mode. Shut down OUTG output 0 = DISABLE 1 = ENABLE
3	0x1	DAC_SLEEPR: Low power (sleep) mode. Shut down OUTR output 0 = DISABLE 1 = ENABLE
2	0x0	DAC_DETECT_EN: Power down everything including the band-gap 0 = DISABLE 1 = ENABLE
1	0x1	DAC_POWERDOWN: Power down everything except the band-gap 0 = DISABLE 1 = ENABLE
0	0x1	DAC_IDDQ: Power down everything including the band-gap 0 = DISABLE 1 = ENABLE

20.1.3.5 APB_MISC_SC1X_PADS_TVDAC_STATUS_0

Output signals from internal comparators

TV DAC status

Offset: 440h | Read/Write: RO | Reset: 0bxxx

Bit	Reset	Description
2	X	DAC_COMPOUTB: Channel B comparator output for auto-detect 0 = COMPINB > threshold 1 = COMPINB < threshold, or when POWERDOWN==1 comparison threshold = 0.325V
1	X	DAC_COMPOUTG: Channel G comparator output for auto-detect 0 = COMPING > threshold 1 = COMPING < threshold, or when POWERDOWN==1 comparison threshold = 0.325V
0	X	DAC_COMPOUTR: Channel R comparator output for auto-detect 0 = COMPINR > threshold 1 = COMPINR < threshold, or when POWERDOWN==1 comparison threshold = 0.325V

20.1.3.6 APB_MISC_SC1X_PADS_TVDAC_DINCONFIG_0

- DAC_FIFO_TH[2:0] is to specify number of pixels kept in the input FIFO.
- DAC_SOURCE[1:0] is to specify input signal sources to the TVDAC.

  The sources are TVO, DISPLAY, and DISPLAYB.
- DAC_DIN_ORIDE_EN is to enable DAC_DIN_ORIDE to override the input signal.
- DAC_DIN_ORIDE[9:0] is to override regular input signals for testing.
- DAC_AMPIN[7:0] is to set DAC output amplitude.

There are 3 ways that DAC's output amplitude range is calibrated. They are,

- SDTV mode (VREF=1.4V)
- CRT (VGA) mode (VREF=0.7V)
- HDTV mode (VREF=1.0V)

Corresponding calibration values for DAC_AMPIN are provided from FUSE module. They are,

- DAC_SDTV_CALIB[7:0]
- DAC_CRT_CALIB[7:0]
- DAC_HDTV_CALIB[7:0]

Corresponding to the DAC_SOURCE selection, those calibration values shall be selectively loaded to DAC_AMPIN.

DAC_SOURCE	DAC_AMPIN
0 (TVDAC_OFF)	(dont_care)
1 (TVO)	DAC_SDTV_CALIB[7:0]
2 (DISPLAY)	DAC_CRT_CALIB[7:0]
3 (DISPLAYB)	DAC_CRT_CALIB[7:0]

TV DAC FIFO config

Offset: 444h | Read/Write: R/W | Reset: 0b00000000000000000x0xx00x010

Bit	Reset	Description
27:20	0x0	DAC_AMPIN: AMPIN

Bit	Reset	Description
19:10	0x0	DAC_DIN_ORIDE: DIN override
8	0x0	DAC_DIN_ORIDE_EN: Override DAC DIN inputs 0 = DISABLE 1 = ENABLE
5:4	0x0	DAC_SOURCE: INPUT source for TVDAC 0 = TVDAC_OFF 1 = TVO 2 = DISPLAY 3 = DISPLAYB
2:0	0x2	DAC_FIFO_TH: Data Input FIFO threshold

20.1.3.7 APB_MISC_GP_HIDREV_0

Chip ID revision register

Offset: 804h | Read/Write: RO | Reset: 0bxxxxxxxxxxxxxxxxxxxx

Bit	Reset	Description
19:16	X	MINORREV: Chip ID minor revision (IF MAJORREV==0(Emulation) THEN 0: QT, 1:E388 FPGA)
15:8	X	CHIPID: Chip ID
7:4	X	MAJORREV: Chip ID major revision (0: Emulation, 1-15: Silicon) 0 = EMULATION 1 = A01
3:0	X	HIDFAM: Chip ID family register. 0 = GPU 1 = HANDHELD 2 = BR_CHIPS 3 = CRUSH 4 = MCP 5 = CK 6 = VAIO 7 = HANDHELD_SOC

20.1.4 Pad Control Registers

The registers below control pad behavior. For each digital pad, the following controls can be used to tune pad performance, functionality, and power consumption. The pads controlled by each pad group register can be found in the PinMux section of this document.

- **HSM_EN** - High speed mode - active high, enables high speed mode for driver and receiver for better matching of the rise/fall delay in outbound and inbound paths. Use it for clocks and the high speed signaling where the matching timings are of importance.
- **SCHMT_EN** - Schmitt enable - active high, enables the Schmitt Trigger Type of I/P receiver. Default is Inverter Type of receiver.
- **LPMD** - Low power mode - select low power modes (different impedance and current value). The table depicts the function of low power mode

Table 32. Low Power Mode Functions

LPMD1	LPMD0	Power Mode Selected
0	0	X/8 Current Setting. Lowest Power or Current (8*Z ohms)
0	1	X/4 Current Setting (4*Z ohms)
1	0	X/2 Current Setting (2*Z ohms)
1	1	X Current Setting (Z ohm = 50 ohms). Highest Power or Current.

- CAL_DRVDN - drive down (falling edge) - Driver Output Pull-Down drive strength code.
- CAL_DRVUP - drive up (rising edge) - Driver Output Pull-Up drive strength code. Works with combination of LMPD bits. For lower power modes, higher drive strength are masked. See table below:

LPMD1	LPMD0	CAL_DRV*4	CAL_DRV*3	CAL_DRV*2	CAL_DRV*1	CAL_DRV*0
0	0	Masked to 0	Masked to 0	Masked to 0	Pass Code	Pass Code
0	1	Masked to 0	Masked to 0	Pass Code	Pass Code	Pass Code
1	0	Masked to 0	Pass Code	Pass Code	Pass Code	Pass Code
1	1	Pass Code	Pass Code	Pass Code	Pass Code	Pass Code

- DRVDN_SLWR - Driver Output Rising Edge Slew 2-bit control code.
  Code 11 is least slewing of signal, code 00 is highest slewing of the signal.
- DRVUP_SLWF -Driver Output Falling Edge Slew 2-bit control code.
  Code 11 is least slewing of signal, code 00 is highest slewing of the signal.

20.1.4.1 APB_MISC_GP_AOCFG1PADCTRL_0

20.1.5 SATA AUX Registers

20.1.5.1 SATA_AUX_MISC_CNTL_1_0

MISC_CNTL_1 register

Offset: 1108h | Read/Write: R/W | Reset: 0bxx00xx00000

Bit	R/W	Reset	Description
10:9	RO	X	SATA2IPSM_ST: Indicate whether the Sata link is in partial/slumber modes. Used for debug purpose.
8	RW	0x0	NVA2SATA_OOB_ON_SCONTROL_SPD_WR: If OOB_ON_SCONTROL_SPD_WR is set to 1 then sata controller will do OOB and go through speed negotiation with the drive whenever its SCONTROL_SPD register is written. 0 = NO 1 = YES
7	RW	0x0	NVA2SATA_OOB_ON_POR: Controls whether SATA controllers do OOB sequence automatically when they come out of reset or not. 0 = NO 1 = YES
6:5	RO	X	L0_RX_IDLE_T_SAX: l0_rx_idle_t value from Sata controller When SAX partition is power-gated, this field will show clamped value 0 = NORMAL
4:3	RW	0x0	L0_RX_IDLE_T_NPG: set l0_rx_idle_t value for Sata phy from apb_misc(non-power-gated logic) Before SAX partition is power-gated, SATA_l0_rx_idle_t_npg needs to have the same value as SATA_l0_rx_idle_t_sax then set SATA_l0_rx_idle_t_mux to '1'. This is to make sure Sata PHY is still receiving correct threadhold setting for OOB detection when SAX is power-gated. After SAX power is restored, same value will be restored back to l0_rx_idle_t register in Sata controller then SATA_l0_rx_idle_t_mux can be set back to '0'. 0 = NORMAL
2	RW	0x0	L0_RX_IDLE_T_MUX: select l0_rx_idle_t driving source for sata phy 0 : from sata controller 1 : from apb_misc 0 = FROM_SATA 1 = FROM_APB_MISC
1	RW	0x0	PMU2SATA_ACCLMTR_TRIG: This config bit is used inside SATA to select between the two accelerometer triggers, between External trigger & PMU's trigger. 0 : external trigger disable 1 : external trigger enable 0 = DISABLE 1 = ENABLE
0	RW	0x0	DEVICE_DIS_SATA0: Serial ATA Interface 0 Disable 1 = Internal Serial ATA Interface 0 Disabled (Not seen as part of PCI space) 0 = Internal Serial ATA Interface 0 Enabled. 0 = ENABLE 1 = DISABLE

20.1.5.2 SATA_AUX_RX_STAT_INT_0

RX_STAT_INT register

Offset: 110ch | Read/Write: RO | Reset: 0bxx

Bit	Reset	Description
1	X	SATA_L0_RX_STAT_IDLE: Sata pad L0 rx_stat_idle status 1 : rx path is idle 0 : rx path is active 0 = NO 1 = YES

Bit	Reset	Description
0	X	SATA_RX_STAT_INT_STATUS: Sata rx_stat interrupt status from sata pad 1 = rx_stat interrupt is pending 0 = rx_stat interrupt is not pending 0 = NONE 1 = PENDING

20.1.5.3 SATA_AUX_RX_STAT_SET_0

RX_STAT_SET register

Offset: 1110h | Read/Write: R/W | Reset: 0b0

Bit	Reset	Description
0	0x0	SATA_RX_STAT_INT_SET: Sata rx_stat interrupt is set (this bit is auto-cleared) set interrupt status bit to '1' when register is written read back value is always '0'

20.1.5.4 SATA_AUX_RX_STAT_CLR_0

RX_STAT_CLR register

Offset: 1114h | Read/Write: R/W | Reset: 0b0

Bit	Reset	Description
0	0x0	SATA_RX_STAT_INT_CLR: Sata rx_stat interrupt is cleared (this bit is auto-cleared) clear interrupt status bit to '0' when register is written read back value is always '0'

List of input pins to be tied off:

- bst_bond_sata2 - tie to '1'
- storage_feature - tie to '0'
- dfa2fpci_cmd_compat - tie to '0', ipfs doesn't have this output
- dfa2fpci_cmd_passpw - tie to '0', ipfs doesn't have this output
- ufa2fpci_arb_block_coherent_np - tie to '0', ipfs doesn't have this output
- ufa2fpci_arb_block_coherent_pw - tie to '0', ipfs doesn't have this output
- pri_page_offset_endpoint_cfg - tie to 32'h50100000
- leg2dev_devnum_sata0 - tie to 5'h0A

Register bits that are not needed:

- 1b sata2pmu_wake R
- 4b fpci2pmu_core_act_sts_sata0 R
- 1b fpci2pmu_core_act_tog_sata0 R
- 16b sata2sm_pg_info R
- 1b sata2sm_pll_powerdown R
- 1b sata2smi_bohc_ooc_change R

20.1.6 Pin Mux Selects

This section defines the Pin mux selects, Pullup Pulldn and E_input programmability for each Pin/Ball in Tegra 3. Every register has 7 bits defined which are used for Functional Pin Select. The rest are specific to few pads like OD, IO_RESET.

1:0 PM --> Functional Pin Select.

3:2 PUPD --> Pullup / PullDn control.

4:4 Tristate --> Tristate Enable / Disable.

5:5 E_INPUT --> Input Receiver Enable/Disable.

7:7 LOCK --> Locks access to all configurable bits for pins, including itself.

--> 1 = Enable (preferably done during boot)

--> 0 = Disable (can only be done by full system reset)

8:8 IO_RESET --> Forces output drivers disabled (PU/PD control only). Required to guarantee pin state on *LPDDR2* pads during POR.

--> IO_RESET_N will override the enable signal of main driver. After power-up, core controls should be enabled first

--> to drive the pad with the same value as programmed by E_PULL. Then IO_RESET_N / E_PULL can be de-asserted.

--> If IO_RESET_N is de-asserted before core controls come up, there could be unknown outputs or glitches.

Optional bits

6:6 OD --> Open Drain Enable / Disable. Specifically for I2C pads.

20.1.6.1 PINMUX_AUX_ULPI_DATA0_0

Offset: 3000h | Read/Write: R/W | Reset: 0b0x111000

20.2 APB DMA Controller

The APB DMA Controller is placed between the AHB Bus and the APB Bus and is a master on both buses.

The APB DMA is used for block data transfer from a source location to the destination location. The source may be DRAM or IRAM, and the destination location could be devices placed on APB Bus; or *vice versa*. DMA transfers are done without any processor intervention other than register writes to program the parameters for a particular transfer and accesses needed to handle any interrupts.

It has 32 fully programmable channels, which can transfer data concurrently.

Hardware Features

- DMA master for transfers between external/internal memory and peripheral devices on the APB Bus
- Two modes of operation: single transfer (once) or continuous
- Programmable burst sizes of 1, 4, or 8 words
- Maximum transfer size is 64KB per channel, with the minimum size being one word
- Programmable APB Bus widths of 8, 16, and 32 bits
- Separate AHB and APB start addresses
- Per channel trigger and flow control mechanism support
- Channel to channel trigger support, i.e., ability to link up channels to start at the end of another channel's transfer, allowing scattering/gathering of physical memory.
- Interrupt generation at the completion of channel transfer
- Interrupts per channel can be routed to CPU or AVP
- Ability to hold processor until transfer is done
- Wrap mode supported for all channels in Once mode
- Ping-Pong feature supported in continuous mode
- Round robin arbitration among channels at burst granularity
- Runs on APB clock. APB Clock generally runs at 1:2:2 or 1:2:3 clock ratios (sclk : hclk : pclk).

Software Features

- The AHB burst size and the FIFO trigger levels (in the modules) should be programmed such that they do not lead to an overflow/underflow of the FIFO.
- SW should program all the registers of channel, ensuring that the channel enable bit is disabled. Channel enable bit should be set last.
- Disable the Global enable bit to halt transfer for some time, and set it when it is all right to resume the transfer. This halts transfers from all channels.
- If channel is disabled while transfer is in progress, the transfer ends after ongoing burst is completed and an interrupt is generated if enabled.
- Busy bit is set as soon as DMA channel is enabled and gets cleared after transfer is completed.
- Interrupts are "write 1 to clear".
- Interrupt is generated when the last data is placed on the AHB bus while writing and once the last data is placed on APB bus while reading from AHB bus.
- The AHB wrap around should be programmed keeping in mind the address that is programmed in the AHB start address and the burst size.

- If, for example, AHB wrap around is 4 words, the AHB start address is 0x4000 0000 and the AHB burst size is NOT 1, then address would change to:

  0x4000 0000 ' 0x4000 0004 ' 0x4000 0008 ' 0x4000 000C ' 0x4000 0000

- For the above condition if the AHB start address is programmed to

  0x0000 0004….

- Then the address would change as

  0x0000 0004 ' 0x0000 0008 ' 0x0000 000C ' 0x0000 0010

  Note that the address did not wrap around! Wrap around is NOT possible in between bursts.

- If this burst size is given to the AHB bus it increments the address 4 times as it does not see "AHB current address" but the initial address that was given to it with a request.
- If the start address has to be specified as 0x0000 0004 with wrap around as needed above, the solution is to give a burst size of 1.

- The default wrap around on the APB side is wrapping on 1 word. It prevents unnecessary address switching on the APB.
- The parameters of the channel should be programmed first (for e.g., base addr, wrap-around). The control register of that channel should then be programmed. If the control register is programmed first, the current parameters of the DMA would be considered as the programmed values.
- If a burst of 8 is requested with the address that is not aligned to a 8-word boundary (addr [4:2] not zeros), the DMA does a single burst till it aligns itself to the 8-word boundary and then starts issuing burst requests (on AHB address).
- If a burst of 8 is requested and at any point of time the transfer size goes below 8 (less than 8 words left to transfer), the DMA completes the remaining transfers with a burst of 4 or 1, whichever is possible.
- If a burst of 4 is requested with the address that is not aligned to a 4-word boundary (addr [3:2] not zeros), the DMA does a single burst till it aligns itself to the 4-word boundary.
- If a burst of 4 is requested and at any point of time the transfer size goes below 4 (less than 4 words left to transfer), the DMA completes the remaining transfers with a burst of 1.

20.2.1 Functionality

There are 32 channels in APB DMA. An APB DMA channel can transfer specified portions of data from an AHB address space (can be iRAMs or DRAMs on the MC) to an APB address space. APB DMA follows a simple round robin arbitration scheme, starting with ch-0.

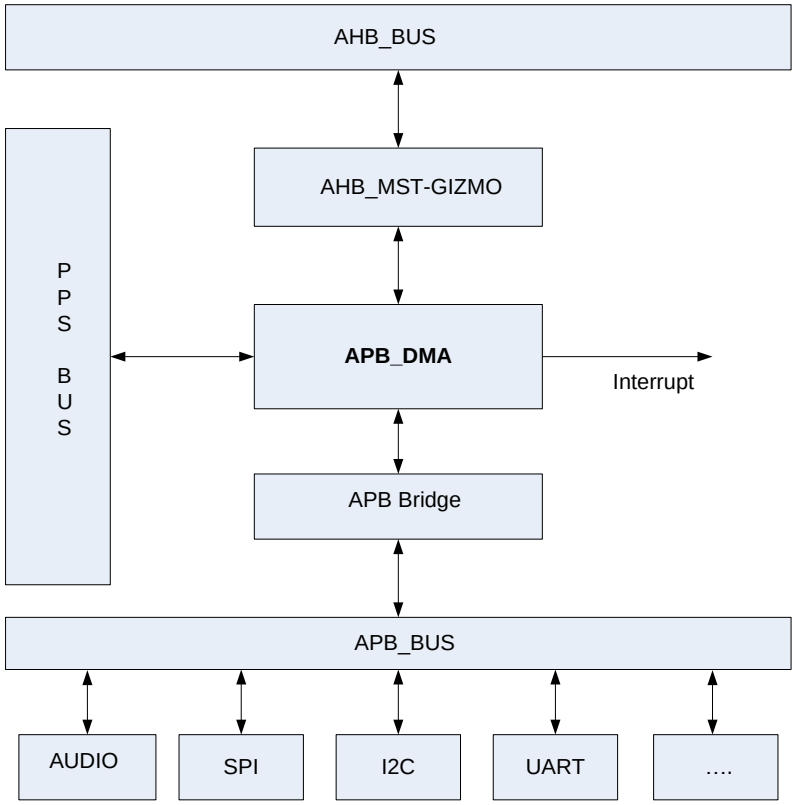
Each channel can have independent burst transfer sizes programmed to one word, four words, or eight words.

Each DMA channel supports:

- Enable Bit one for each channel and one global enable bit.
- Interrupt Enable at the end of transfer with ability to mask or route to desired processor.
- Ability to hold off a Processor. Processor which writes into this bit will be held until transfer is completed.
- Direction bit to determine the direction of transfer--AHB to APB or APB to AHB.
- Trigger and Flow selects. These are addition controls apart from channel enable, on which the transfer depends. Trigger is used to start a channel on some event to start the transfer and flow is used to proceed with every new burst transfer. These events are under either Software or Hardware control.

- Wrap feature enables you to wrap back the LSB nibble to 0000 instead of incrementing to next address if the burst starts from an unaligned address boundary. For example, if address starts at 0x4 with a burst of 4 words, then the address would increment as 0x4, 0x8, 0xC, 0x0. If disabled, it would be 0x4, 0x8, 0xC, 0x10.
- APB bus width is configurable whereas the AHB bus width is fixed to 32 bits. The APB bus can have values 8, 16 and 32. For an APB burst of 8 (burst is always with regard to words) and APB bus size of 16, you have: 8 words transferred to the APB side, or rather 16 "half words" transferred.
- Double Buffering Mode makes the APB DMA Burst Address reset to AHB Base Address after every even (2nd, 4th, 6th, etc) APB DMA Transfer. This mode is used only along with continuous mode (once bit 0).
- Separate AHB start address and APB start address.
- Ability to delay the burst rate with the help of a global counter which can be programmed to desired value, which equals number of clocks delay required between each burst.

Figure 35. APB-DMA Block Diagram



20.2.2 Programming Guidelines

Follow these guidelines when programming the APB DMA Controller:

1. All the registers of a channel should be programmed before the Channel Enable bit is set. To program each register:
   a. Program the AHB Starting Address and APB Starting address in *AHB_PTR and *APB_PTR Registers.
   b. Program the required AHB BURST size, WRAP word window size and AHB_DATA_SWAP (byte swapping) option in *AHB_SWQ Register. The AHB BUS WIDTH is fixed to 32 bit Bus.
   c. Program the required APB_BUS_WIDTH (as the peripheral), APB_DATA_SWAP (byte swapping) option and WRAP word window size in *APB_SEQ Register.

d. Program the Interrupt option, Hold Processor option, DMA transfer direction, Transfer Mode, Trigger/Flow Enable and DMA Count value in CHANNEL_*_CSR Register.
e. Program the Global Enable bit in APB_DMA Command Register.
f. Whenever the Channel ENB bit is Enabled, the DMA starts the Data transfer.
g. Each channel status is observed by polling or interrupt status using APB_DMA Status Register.
h. The Tx/Rx Flow/Trigger requestors are programmed in APB-DMA Requestor Assignments Registers.

2. Clearing the Global Enable bit causes the transfers that are in progress to be paused. Setting the Global Enable resumes the transfers.
3. If channel ENB is disabled independently while a transfer is in progress, the transfer ends after completing any burst sequence that is in progress.
4. Busy bit gets set as soon as a channel is enabled and is cleared after transfer is completed.
5. Interrupts are write-1-to-clear i.e., interrupt bit is cleared when the value of write data corresponding to the bit position of the interrupt bit is 1.
6. The AHB burst size and the FIFO trigger levels (in the modules) need to be programmed such that they do not lead to an overflow/underflow of the FIFO.
7. The AHB wrap around needs to be programmed keeping in mind the address that is programmed in the AHB start address and the burst size.
8. If a burst of 8 is requested with the address that is not aligned to a 8-word boundary, the DMA would do a single burst till it aligns itself to the 8-word boundary and then starts issuing burst requests.
9. If a burst of 8 is requested and at any point of time the transfer size goes below 8, the DMA completes the remaining transfers with a burst of 4 or 1, whichever is possible.
10. If a burst of 4 is requested with the address that is not aligned to a 4-word boundary, the DMA does a single burst till it aligns itself to the 4-word boundary.
11. If a burst of 4 is requested and at any time the transfer size goes below 4, the DMA completes the remaining transfers with a burst of 1.

20.2.3 APB DMA Registers

20.2.3.1 APBDMA_COMMAND_0

The Global Enable bit in the command register enables the APB DMA. Clearing this bit causes active DMA transfers to be paused. Pending bus transactions (ongoing burst) will be completed and no new transactions will be initiated. Setting this bit again resumes the transfers.

Note that the power on reset value for the APB DMA Global Enable is 0. This bit must be written to 1 before any APB DMA transactions can begin.

APB-DMA Command Register

Offset: 000h | Read/Write: R/W | Reset: 0b0

Bit	Reset	Description
31	0x0	GEN: Enables Global APB-DMA 0 = DISABLE 1 = ENABLE

20.2.3.2 APBDMA_STATUS_0

The Busy bits in the Status Register indicate which (if any) of the APB DMA channels have active pending APB DMA transfers. Note that APB DMA transfers that are started in continuous (repetitive) mode will have their busy bits active until the enable bit for the APB DMA channel is cleared to 0 (by the software).

Read-only Flags set/cleared by HW.

20.2.3.3 APBDMA_REQUESTORS_TX_0

The Tx Requestors are values used as triggers or flow controls for APB DMA transfers.

The Tx requestor register is read only. This register is provided only to give the software the ability to see the state of signals that may affect (trigger-start or flow-control-inhibit) APB DMA processes.

Bit[0] in the Tx Requestor channel is a signal generated from the programmable APB DMA Counter. This bit is active whenever the APB DMA Counter value is 0. When Tx request is active, DMA transmits data to peripheral.

20.2.3.5 APBDMA_CNTRL_REG_0

The APB DMA Counter is used to slow down the request rates on some APB DMA channels.

The APB DMA Channel Counter Enable register stores bits that configure which (if any) channel(s) should be throttled (bits [31:0] of channel counter enable register) correspond to APB DMA 32 channels.

The APB DMA Counter initial/reload count value is programmed in the APB DMA Counter Register (bits[15:0]).The APB DMA Counter is loaded with this initial/reload count value whenever the APB DMA Counter Register is written, and is re-loaded to this saved initial count value on a burst complete (programmable).

The APB DMA Counter value will decrement whenever an APB DMA burst complete, and the current count value is non-zero, and any of the bits [31:16] are set.

APB-DMA Counter Register

20.2.4 APB DMA Channel Registers

20.2.4.1 APBDMACHAN_CHANNEL_0_CSR_0

Writing a 1 to bit [31] of an APB DMA Channel Control Register will initiate the APB DMA Transfer. Because this action will depend on some values programmed in the other registers, it is recommended that the registers in the address space in the required APB DMA channel be programmed before writing into control register.

In "Once" mode, the channel is disabled after the APB DMA Transfer has completed. When the channel's transfer completes, an interrupt will be sent if the IE.EOC bit is set. If the transfer requires a trigger or flow, then the corresponding trigger selected by the "TRIG_SEL" or "REQ_SEL" field must become active respectively before the channel can starts its transfer. If both Trigger and Flow bits are set, both conditions must be met before the channel starts each DMA Burst.

APB-DMA-0 Control Register

21.0 USB COMPLEX

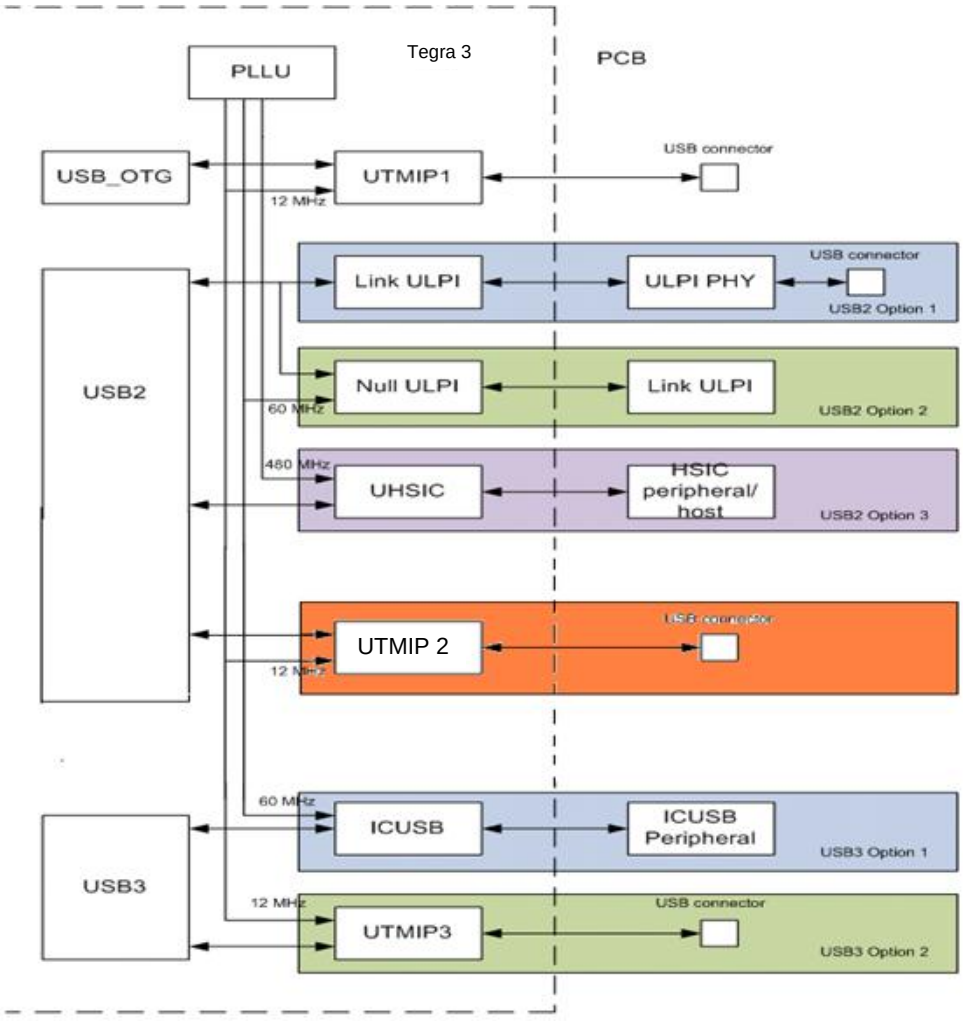
The USB complex in Tegra® 3 devices provides a mechanism to communicate with a PC and/or a peripheral such as a USB keyboard, mouse, camera, etc. using regular USB ports and to an on-board baseband controller using either USB/ULPI/HSIC/ICUSB interfaces. It consists of 3 USB controllers and 7 USB interfaces: UTMIP1, Link ULPI, Null ULPI, HSIC, UTMIP2, ICUSB and UTMIP3. Figure 36 shows the relationship between different USB controllers and interfaces.

Tegra 3 devices implement VBUS and ID sensors required for device/host functionality and associated interrupt mechanisms; software uses these for the device/host state machine in software. Battery charger detection is implemented as specified in USB Battery charger specification version 1.1; software needs to implement the charger sequence.

The USB controllers implement transaction level processing of control requests. Software decodes the type of control request and programs the packets appropriately. Suspend/resume functionality saves power at times when USB functionality is not required; there are automatic wake-up events and interrupts that software can program.

21.1 USB Controllers and Interfaces

Figure 36. Tegra 3 USB Controllers and Interfaces



USB Device/Host and UTMIP1 (USB1 Port)

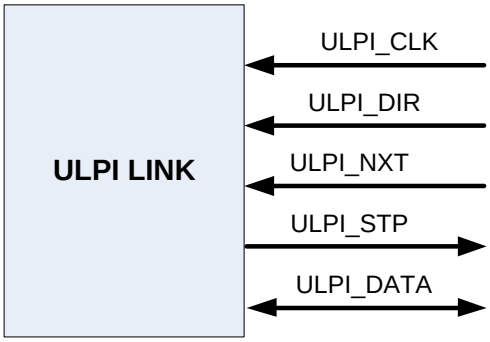
This is the primary USB port on Tegra 3 devices. It supports USB device and USB host modes. USB recovery is supported on this interface only. Wake-up from deep sleep mode is also supported on VBUS and accessory detect (ACCx_DETECT) pins. Power and Ground pins for USB1 and USB3 are shared.

USB2 and Link ULPI

This interface supports connecting an on-board external ULPI PHY to use as additional USB port. Depending on ULPI PHY capabilities, it can support USB Host and USB Peripheral modes of operation.

Link ULPI interface shares the pins with Null ULPI and other interfaces of Tegra 3 devices. It is required that the pin-mux be programmed prior to using the Link ULPI interface.

Link ULPI is a slave on the ULPI bus, in that the 60 MHz ULPI interface clock is driven from the external ULPI PHY on the ULPI_CLK pin. Note the change of direction in the pins ULPI_DIR, ULPI_NXT and ULPI_STP with respect to Null ULPI interface.

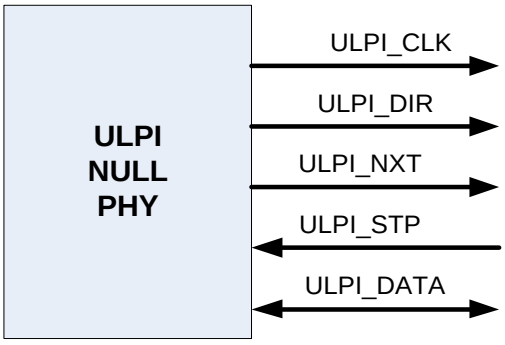


USB2 and Null ULPI

This interface allows Tegra 3 devices to behave like a ULPI PHY so that an external Link ULPI controller can be connected to it. This is used to support baseband controllers that use ULPI interface.

Null ULPI interface shares the pins with Link ULPI and other interfaces of Tegra 3 devices. It is required that the pin-mux be programmed prior to using the Null ULPI interface.

Null ULPI is a master on the ULPI bus, in that the 60 MHz ULPI interface clock is driven by Tegra 3 devices to the external Link on the ULPI_CLK pin. Note the change of direction in the pins ULPI_DIR, ULPI_NXT and ULPI_STP with respect to Link ULPI interface.



USB2 and UHSIC

This interface allows connection of an on-board HSIC Peripheral/Host to the Tegra 3 devices. This is used to support baseband controllers that use HSIC interface.

UHSIC supports both Host and Peripheral modes. It does not support switching between Host and Peripheral modes. Since the external HSIC Peripheral/Host is always on-board, the role of Peripheral and Host is expected to be fixed at board design time.

USB2 and UTMIP2

This interface allows an additional USB port. It can support native Host functionality only

USB3 and ICUSB

This interface allows connection of an on-board ICUSB Peripheral to the Tegra 3 devices. This is used to support baseband controllers that use ICUSB interface.

The ICUSB interface on Tegra 3 devices supports two power-supply voltages: 1.8V and 3.0V. Software needs to perform proper power sequencing as described in the ICUSB specification.

USB3 and UTMIP3 (USB3 port)

This is the third USB port on Tegra 3 devices. It supports Host a mode of operation only.

Power and Ground pins for USB1, USB2 and USB3 are shared.

21.1.1 Interface Restrictions

Link ULPI, Null ULPI and UHSIC are all exclusive interfaces on USB2 controller, and only one of the interfaces can be used in a given board design. Similarly, ICUSB and UTMIP3 are exclusive interfaces on USB3 controller, only one of the interfaces can be used in a given board design.

On power-on-reset, USB2 defaults to UTMIP mode, and USB3 defaults to ICUSB mode.

21.2 Controller

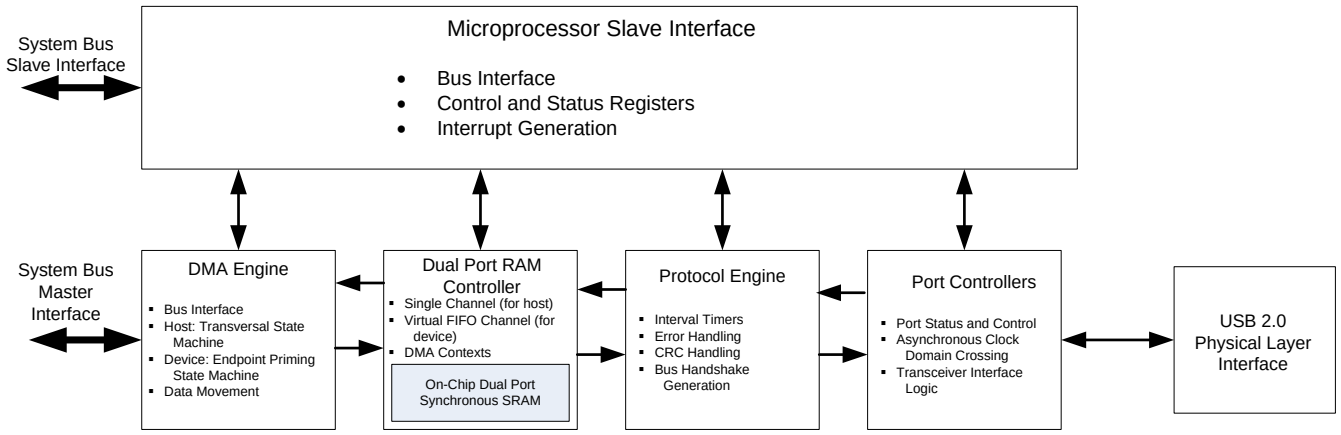
All three USB controllers offer the same functionality, although the interface may restrict any one to a subset of the possible functions.

The USB Controller can be either a USB host or device. It has a USB 2.0 High Speed dual role USB Host controller or USB Device controller.

- Device controller registers and data structures are implemented as extensions to the EHCI programmers interface.
- Supports USB legacy (USB 1.1) Full and Low speed devices without a companion USB 1.1 host controller or host controller driver software using EHCI standard data structures.

The block diagram of USB is shown in the figure below.

Figure 37. USB Controller Block Diagram



21.2.1 Endpoint Capabilities

All controllers support 16 bi-directional endpoints in device mode. Endpoint 0 is always a bi-directional control endpoint. All other endpoints can be programmed as one of Bulk, Interrupt, Isochronous or Control type in either direction. Control endpoints are always bi-directional and hence to program an endpoint as control type, both IN and OUT directions need to be programmed to control type. Conversely, if an endpoint has either IN or OUT direction programmed to be non-control type, the other direction also needs to be programmed to be non-control type.

The max packet size supported on any endpoint is 512 bytes in high-speed mode, for both device and host modes.

21.2.2 AHB Interface

All USB controllers use an AHB interface as master and slave for communicating with other parts of Tegra 3 devices. Table 33 lists the AHB interface numbers for each controller.

Table 33: AHB Master and Slave Numbers

Controller	AHB Master Number	AHB Slave Number
USB1	6	6
USB2	18	9
USB3	17	11

21.3 USB Programming Guidelines

21.3.1 USB Device/Host Programming

Clock Initialization

After power-on-reset, the USB clocks are disabled. Software can enable the USB clocks by setting CLK_ENB_USBD in CLK_OUT_ENB_L register to ENABLE.

Also, USB stays in reset and software should bring it out of reset by first setting SWR_USBD_RST in RST_DEVICES_L register to ENABLE and then set it to DISABLE.

There are some parameters in UTMIP that need to be programmed before bringing the UTMIP out of reset. Those need to be programmed every time USB is reset. The reset includes SWR_USBD_RST in RST_DEVICES_L register and RST in USB2D_USBCMD register.

After UTMIP is reset, PHY clock takes some time to come up, so software must wait until USB_PHY_CLK_VALID bit in USB_SUSP_CTRL register becomes valid. This bit, if set to 1, also generates an interrupt if RSM_IE is set in USB_SUSP_CTRL register.

21.3.1.1 ID and VBUS Connection

With Tegra 3 devices, you can use ACCx_DETECT supported by the UTMIP/USB hardware, or use a GPIO for ID functions. If using a GPIO as the ID, the GPIO can be sampled to detect the presence of a micro-A or micro-B plug and the sampled value can be written to SW_ID bit in **PHY_VBUS_WAKEUP_ID_0** register. It is recommended that board design connects ACCx_DETECT pin on the Tegra 3 devices to the ID pin on the micro-AB connector even if the ID is connected to a GPIO.

Tegra 3 devices have a VBUS pin connected to UTMIP and VBUS pin from the connector should be connected to this pin even though VBUS from the connector is connected to a GPIO. It is not required that VBUS from the connector is directly connected to Tegra 3' VBUS pin. It is required that its voltage is above 3V when VBUS is on.

Both VBUS and ACCx_DETECT are available as a wake-up event during DPD/LP0 state. USB bus D+/D- line wake events are also available in DPD/LP0 state. Please consult PMC programming guidelines for further recommendations.

21.3.1.2 Detection of USB Cable Insertion

The USB cable insertion event can be detected by a change in the ID or VBUS pin on the micro-AB connector. Initially, when the cable is not attached, the ID pin on the micro-AB connector is floating and is detected as 1 by the Tegra 3 devices because of the weak pull-up on this pin. This makes the Tegra 3 devices start-up as a B-device, even though a cable is not connected (When the ID pin is seen as a 1 by Tegra 3 devices, there can be no-cable or micro-B connected).

When a user attaches the USB cable, one of the following two events occur:

- User connects micro-A end of the cable to Tegra 3 devices. This changes the ID pin to 0. Hence the software can detect the ID change and go to A-device mode. Software can then supply power to the USB and places the Tegra 3 devices in host mode.
- User connects micro-B (or mini-B) end of the cable to Tegra 3 devices. The other end of the cable can be either micro-A or standard-A and will be connected to a standard host, respectively. For both cases, the Host will start driving power on VBUS and software can detect the cable insertion event by checking the voltage on VBUS has gone above A_Sess_Vld level by reading the A_VBUS_VLD_STS bit in USB_PHY_VBUS_SENSORS register. Once this is seen, it can place the Tegra 3 devices in the device mode.

> **Note:** ID change can be detected by enabling the GPIO interrupt.
> VBUS change can be detected by enabling the interrupt A_VBUS_VLD_INT_EN in USB_PHY_VBUS_SENSORS register.
> USB controller and PHY clocks need not be turned on for this detection.
> To detect these events during DPD/LP0 modes, use VBUS/ID wakeup events in PMC.

21.3.1.3 PHY Clock Control

The PHY clock can be turned off using the bit SUSP_SET in USB_SUSP_CTRL register. This bit must be pulsed by first writing a 1 and then writing a 0 to the bit.

To turn on the PHY clock, software should write to SUSP_CLR in USB_SUSP_CTRL register. This bit must be pulsed by first writing a 1 and then writing a 0 to the bit.

The current suspend status of the PHY can be checked by reading the bit SUSPENDED in USB_SUSP_CTRL register. If the PHY is placed in suspend, then this bit will be set to 1, else it will be set to 0. Also, if this bit is 1, PHY clock will be turned off

and USB_PHY_CLK_VALID in USB_SUSP_CTRL register will be set to 0. If this bit is 0, USB_PHY_CLK_VALID bit can indicate whether the PHY clock is turned on or not.

The PHY clock can be turned on automatically on the events mentioned below. Set only the required wakeup enable bits based on the state of the USB as mentioned below. Don't set unnecessary wakeup enable bits. When the PHY clock wakes up under any such event, make sure that the wakeup enable bits are turned off as soon as possible.

There is an interrupt generated whenever PHY clock is turned on which can be checked by checking the value of USB_PHY_CLK_VALID in USB_SUSP_CTRL register to be 1. The interrupt can be enabled/disabled by setting the bit RSM_IE in USB_SUSP_CTRL to 1/0.

Note:	The PLLU_ENABLE bit in PLLU_BASE register should be always set to ENABLE. All the parameters for PLLU in PLLU_BASE and PLLU_MISC register should be set according to the oscillator frequency used. Not doing that will put the USB PHY PLL in a free-running mode, and can result in undesirable side-effects. When the USB PHY is suspended, the PCLK should not be stopped. It can be reduced to 32 KHz, however. If the system clock is stopped, then it may not be possible to bring up the system on a wakeup event described below.

There are two cases to consider for controlling the PHY clocks.

Device Mode

The PHY clock can be turned off in two cases:

- When USB cable is not connected
- When the USB Host puts the USB bus in suspend mode

When USB cable isn't connected, the VBUS signal is 0. In this case, the software needs to turn on the PHY clock on cable insertion. Follow the procedure described above in the section on Detection of cable insertion.

When USB cable is connected, the PHY clock can only be turned off when the bit SLI in USB2D_USBSTS register is set to 1 when the USB Host puts the USB bus in suspend mode. This bit can be used to generate an interrupt if the bit SLE in USB2D_USBINTR register if set to 1. In this case, software needs to set two bits in the USB_SUSP_CTRL register to turn on the PHY clock on a USB resume or a USB reset event from USB Host: WAKE_ON_DISCON_EN: Wake on Disconnect enable, and WK_RSM_EN - Wake on Resume enable.

If WK_RSM_EN (bit 8) in USB_SUSP_CTRL register is set to 1, the PHY clock can be turned on automatically on receiving USB resume event from USB Host. If WAKE_ON_DISCON_EN in USB_SUSP_CTRL register is set to 1, the PHY clock can be turned on automatically on receiving USB reset event from USB Host or if the USB cable is disconnected. These bits should only be turned on after the PHY clock is turned off. The method described above can be used to interrupt the processor when the PHY clock is turned on. Also, turn off these bits when coming out of suspend.

Host Mode

When a device is not connected, software can set the WKCN bit in USB2D_PORTSC1 register. Make sure that VBUS is also turned on. After this, it can stop the PHY clock by using the method described above. The PHY clock will resume automatically when a device is connected. The method described above can be used to interrupt the processor when the PHY clock is turned on.

With a device connected, software needs to put the USB system under suspend by setting the bit SUSP in USB2D_PORTSC1 register. It needs to wait until this bit is set to 1 by the controller to make sure that the USB system actually went into suspend. It can enable the bits WK_RSM_EN in USB_SUSP_CTRL register and WK_DS in USB2D_PORTSC1 register. Then it can stop the PHY clock as described above. The PHY clock will be turned on automatically if the USB device disconnects or it does a remote wakeup signaling. There will be an interrupt associated with this as described above.

If the software wants to wakeup USB system, then it needs to turn on the PHY clock as described above.

21.3.1.4 Charger Detection 1 (Non-compliant Chargers)

There are 4 conditions for the different kind of non-compliant chargers: SE1, FS-PU, LS-PU, SE0. We can have some hooks in SW to support any kind of non-compliant charger by following the generic procedure below:

1. VBUS detection (by whatever means SW does it)
2. Enable USB controller and PHY power and clocks
3. Wait until PHY_CLKVALID = 1.
4. Wait for 10 microseconds more. This gives time for any filtering to pass through so SW doesn't read wrong values.
5. Read the LS bits [11:10] in PORTSC register.
    - Case 1: LS = 2'b11: connected to charger_1.
    - Case 2: LS = 2'b01: connected to charger_2.
    - Case 3: LS = 2'b10: connected to charger_3.
    - Case 4: LS = 2'b00: connected to either charger_4 or a PC host.
6. If case 1, 2, or 3, enable charging current as per that charger requirement. This could be different for every implementation.
7. If case 4, either we are connected to PC host or a charger_4 (which could be USB compliant charger as well). Go to step 10.
8. We can set the USB circuit on Tegra 3 devices to low-power mode now. Make sure the charger circuit doesn't change state.
9. VBUS disconnect. Go back to step 1.
10. Check if connected to a USB compliant charger by doing the charger detection from VBAT register. If yes, go back to step 8. If no, go to next step.
11. Try to set USB controller to device mode and enable by setting it to RUN mode. Wait for SOF.
12. If SOF is not seen after timeout, then we are connected to charger_4. Set current limit as required for that charger. Go to Step 7.

21.3.1.5 Charger Detection 2 (Compliant Chargers)

This substitutes step 10 from previous section.

1. Make sure UTMIP_PD_CHRG in UTMIP_BAT_CHRG_CFG0 register is set to 0, so that charger detection circuit is on.
2. Set the other register bits in UTMIP_BAT_CHRG_CFG0 register to the following value:
    - UTMIP_OP_I_SRC_EN = 1
3. Wait for about 10 microseconds to allow the battery charger detector to settle.
4. Now check the following bits in the register USB_PHY_VBUS_WAKEUP_ID.
    - VDCD_DET_CHG_DET bit is set, and VDCD_DET_STS indicates 1. Then we are connected to a USB compliant charger.
5. Set the registers bits in UTMIP_BAT_CHRG_CFG0 register to the following values:
    - UTMIP_OP_I_SRC_EN = 0
6. Set the other register bits in UTMIP_BAT_CHRG_CFG0_0 register to the following values:
    - UTMIP_OP_SRC_EN = 1
    - UTMIP_ON_SINK_EN = 1
    - UTMIP_OP_SINK_EN = 0
    - UTMIP_ON_SRC_EN = 0
7. Wait for about 10 microseconds to allow the battery charger detector to settle.

8. Now check the following bits in the register USB_PHY_VBUS_WAKEUP_ID.
    - VDAT_DET_CHG_DET bit is set, and VDAT_DET_STS indicates 1. Then we are connected to a USB compliant charger.
    - If it isn't set, then we are connected to a PC host.
9. Set the registers bits in UTMIP_BAT_CHRG_CFG0_0 register to the following values:
    - UTMIP_OP_SRC_EN = 0
    - UTMIP_ON_SINK_EN = 0
    - UTMIP_OP_SINK_EN = 0
    - UTMIP_ON_SRC_EN = 0
10. Now normal USB operation can continue if connected to PC host.

21.3.2 USB2 Programming Sequence

USB2 controller supports Link ULPI, Null ULPI and UHSIC interfaces. All of these interfaces are directly controlled through USB2 register space.

21.3.2.1 Clock Initialization

After power-on-reset, USB2 clocks are disabled. Software can enable USB2 clocks by setting CLK_ENB_USB2 in CLK_RST_CLK_OUT_ENB_H register to ENABLE.

Also, USB2 stays in reset at power-on and software should bring it out of reset by first setting SWR_USB2_RST in RST_DEVICES_H register to ENABLE and then set it to DISABLE.

After the clocks for USB2 are up, SW can program any registers for USB2 required for proper configuration.

PLLU outputs a 60 MHz clock FO_ICUSB for Null ULPI interface and a 480 MHz clock FO_UHSIC for UHSIC interface. If using any of these interfaces, PLLU should be programmed appropriately.

Any time after USB2 is reset, or ULPI/UHSIC PHY comes out of suspend, software needs to wait until ULPI/UHSIC PHY clock comes up. It can do that by checking for USB_PHY_CLK_VALID bit in USB2_IF_USB_SUSP_CTRL register. If this bit is 1, PHY clocks are up, else they aren't. There are interrupts associated with this bit: if USB_PHY_CLK_VALID_INT_ENB is set to ENABLE, USB_PHY_CLK_VALID_INT_STS will be set to SET whenever PHY clock becomes valid. Software can write a 1 to USB_PHY_CLK_VALID_INT_STS to clear the interrupt status.

Before doing anything useful on USB2, one of its interfaces needs to be selected and configured.

21.3.2.2 Selection of Link ULPI interface

If using Link or Null ULPI interface, software can hold UHSIC in reset by setting UHSIC_RESET in USB2_IF_USB_SUSP_CTRL register to 1. Similarly hold UTMIP in reset by setting UTMIP_RESET IN USB2_IF_USB_SUSP_CTRL register to 1.

1. Disable pull-ups on ULPI data pins by setting PULL_UP fields in **PINMUX_AUX_ULPI_DATA*_0** to NORMAL (2'b00)
2. Enable ULPI interface by writing 1 to ULPI_PHY_ENB bit in USB2_IF_USB_SUSP_CTRL register.
3. Bypass the pin-mux on ULPI outputs by writing 1 to ULPI_OUTPUT_PINMUX_BYP and ULPI_CLKOUT_PINMUX_BYP fields in USB2_IF_ULPI_TIMING_CTRL_0 register.
4. Remove the tri-state on ULPI pins by setting TRISTATE field in **PINMUX_AUX_ULPI_*_0** registers NORMAL (1'b0).

21.3.2.3 Selection of Null ULPI interface

If using Link or Null ULPI interface, software can hold UHSIC in reset by setting UHSIC_RESET in USB2_IF_USB_SUSP_CTRL register to 1.

1. Program the PLLU parameters.
2. Disable pull-ups on ULPI pins by setting PULL_UP field in **PINMUX_AUX_ULPI_*_0 registers** to NORMAL (2'b00).
3. Enable ULPI interface by writing 1 to ULPI_PHY_ENB bit in USB2_IF_USB_SUSP_CTRL register.
4. Set the ULPI pin-mux settings by writing 1 to the fields ULPI_OUTPUT_PINMUX_BYP, ULPI_CLKOUT_PINMUX_BYP, ULPI_CLK_OUT_ENA, ULPI_CLK_PADOUT_ENA, ULPI_SHADOW_CLK_SEL, and ULPI_CORE_CLK_SEL in USB2_IF_ULPI_TIMING_CTRL_0 register.
5. Enable PLLU 60 MHz output by writing 1 to ULPIS2S_PLLU_MASTER_BLASTER60 field in USB2_IF_USB_ULPIS2S_CTRL register.
6. Remove the tri-state on ULPI pins by setting TRISTATE field in **PINMUX_AUX_ULPI_*_0** registers to NORMAL (1'b0).

21.3.2.4 Selection of UHSIC interface

UHSIC IO pad is in power-down state at power-on. Bring it out of power-down mode by writing PD_BG, PD_TX, PD_TRK, PD_RX, PD_ZI and RPD_DATA, RPD_STROBE fields in UHSIC_PADS_CFG1 register to 0.

1. Hold UHSIC In reset by writing 1 to UHSIC_RESET field in USB2_IF_USB_SUSP_CTRL register.
2. Program the PLLU parameters to enable UHSIC PLLU clock.
3. Select UHSIC interface by writing 1 to UHSIC_PHY_ENB field in USB2_IF_USB_SUSP_CTRL register.
4. Program the configuration parameters for UHSIC.
5. Release reset to UHSIC by writing 0 to UHSIC_RESET field in USB2_IF_USB_SUSP_CTRL register.
6. Set CM field in USB2D_USBMODE register to HOST mode.
7. Program the USB2 controller to use UHSIC PHY by writing 0 to PTS field in USB2_CONTROLLER_1_USB2D_HOSTPC1_DEVLC register.
8. Program the UHSIC_HS_POSTAMBLE_OUTPUT_ENABLE field in the UHSIC_TX_CFG0 register to "1".
9. Wait until PHY clock comes up by checking for USB_PHY_CLK_VALID bit in USB2_IF_USB_SUSP_CTRL register. Interrupt can be generated as explained above.

There is no VBUS or ID detection required for this interface as these pins don't exist for UHSIC.

21.3.2.5 Selection of UTMIP Interface

UTMIP IO pads are in power-down state at power-on. Bring them out of power-down mode by writing the following fields to 0:

1. FORCE_PD_POWERDOWN, FORCE_PD2_POWERDOWN, FORCE_PDZI_POWERDOWN fields in UTMIP_XCVR_CFG0 register.
2. OTGPD and BIASPD fields in UTMIP_BIAS_CFG0 register.
3. FORCE_PDDISC_POWERDOWEN , FORCE_PDCHRP_POWERDOWN, FORCE_PDDR_POWERDOWN field in UTMIP_XCVR_CFG1 register.
4. Hold UTMIP PHY in reset by writing UTMIP_RESET bit in USB2_IF_USB_SUSP_CTRL register to 1.
5. Program the PLLU parameters to enable UTMIP PLLU clock.
6. Bring the corresponding data sampler B out of power down (see CLK_RST_CONTROLLER_UTMIP_PLL_CFG2_0 register below)
7. Enable UTMIP interface by setting UTMIP_PHY_ENB in USB2_IF_USB_SUSP_CTRL register to 1.
8. Program the configuration parameters for UTMIP.

9. Release reset to UTMIP by writing 0 to UTMIP_RESET field in USB2_IF_USB_SUSP_CTRL register.
10. Wait until PHY clock comes up by checking for USB_PHY_CLK_VALID bit in USB2_IF_USB_SUSP_CTRL register. Interrupt can be generated as explained above.
11. Program the USB controller to use UTMIP PHY by setting the PTS field in USB2_CONTROLLER_1_USB2D_HOSTPC1_DEVLC register to UTMIP (2'b00).

21.3.2.6 ID and VBUS detection in Link ULPI mode

For external ULPI PHY, the ID and VBUS can be connected to the USB connector as per the guidelines given by ULPI PHY vendor. The detection for ID and VBUS can be done in two ways:

- USB2 controller registers USB2_CONTROLLER_USB2D_OTGSC can be used to enable ID_PU (ID pull-up), and read status on VBUS and ID sensors.
- Use the USB2D_ULPI_VIEWPORT register for USB2 to perform writes/reads to the external ULPI PHY.

Setting the PP bit in USB2D_PORTSC1 register would enable the VBUS going out to the USB connector when USB2 is configured in Host mode. The board designer needs to connect appropriate signals from the ULPI PHY in order to make correct use of this feature.

Alternately, software can write appropriate register in ULPI PHY according to the datasheet of the particular PHY using the USB2D_ULPI_VIEWPORT register.

Note that USB2 is disabled during DPD (LP0) mode. If system designer wants to wake up the system on a cable connection for USB2, then ID and VBUS should be brought to PMU and PMU can be programmed to wake up the Tegra 3 devices on an event on these pins. Alternately, these can be driven to GPIOs and those GPIOs can be used in PMC as wakeup sources.

For details on USB2D_ULPI_VIEWPORT, please see the description for that register in the register section.

21.3.2.7 Detection of USB Cable Insertion in Link ULPI mode

The USB cable insertion event can be detected by a change in the ID or VBUS pin on the micro-AB connector connected to ULPI PHY. Initially, when the cable is not attached, the ID pin on the micro-AB connector is floating and is detected as 1 by Tegra 3 devices because of the weak pull-up on this pin. This makes the Tegra 3 devices USB2 start-up as a B-device, even though a cable is not connected (When the ID pin is seen as a 1 by Tegra 3 devices, there can be no-cable or micro-B connected).

When a user attaches the USB cable to the ULPI PHY port, one of the following two events occur:

- User connects micro-A end of the cable to Tegra 3 devices. This changes the ID pin to 0. Hence the software can detect the ID change by reading the USB2D_OTGSC register and go to A-device mode. Software can then supply power to VBUS on ULPI PHY port and place the Tegra 3 device USB2 in host mode.
- User connects micro-B (or mini-B) end of the cable to Tegra 3 devices. The other end of the cable can be either micro-A or standard-A, and will be connected to a standard host, respectively.

For both cases, the Host will start driving power on VBUS and software can detect the cable insertion event by checking the voltage on VBUS has gone above A_Vbus_Vld level using the USB2D_OTGSC register. Once this is seen, it can place the Tegra 3 device USB2 in the device mode.

21.3.2.8 PHY Clock control

The PHY clock can be turned off by writing 1 to the bit PHCD in USB2D_PORTSC1 register.

> **Note:** There is no need to pulse this bit as opposed to USB1 controller.

To turn on the PHY clock, software should write to USB_SUSP_CLR in USB2_IF_USB_SUSP_CTRL register. This bit must be pulsed by first writing a 1 and then writing a 0 to the bit.

Whenever the PHY is placed in suspend, PHY clock will be turned off and USB_PHY_CLK_VALID in USB2_IF_USB_SUSP_CTRL register will be set to 0. Software should make sure that PHY clock shuts down by polling this bit whenever it places the PHY into suspend. Software should make sure that PHY clock shuts down by polling this bit whenever it places the PHY into suspend.

The PHY clock can be turned on automatically on the events mentioned below. Set only the required wakeup enable bits based on the state of the USB as mentioned below. Don't set unnecessary wakeup enable bits. When the PHY clock wakes up under any such event, make sure that the wakeup enable bits are turned off as soon as possible.

To prevent the PHY clock from waking up on unnecessary glitches on the USB pins, software can set the USB_WAKEUP_DEBOUNCE_COUNT field in USB_SUSP_CTRL register to a non-zero value (between 1-7). This will allow the wakeup event to be debounced by the equivalent number of HCLK cycles.

There is an interrupt generated whenever PHY is woken up from suspend which can be checked by checking the value of USB_WAKEUP_INT_STS in USB_SUSP_CTRL register to be 1. The interrupt can be enabled/disabled by setting the bit USB_WAKEUP_INT_ENB in USB_SUSP_CTRL to 1/0.

There is an interrupt generated whenever PHY clock is turned on which can be checked by checking the value of USB_PHY_CLK_VALID_INT_STS in USB_SUSP_CTRL register to be 1. The interrupt can be enabled/disabled by setting the bit USB_PHY_CLK_VALID_INT_ENB in USB_SUSP_CTRL to 1/0.

To clear the interrupts USB_WAKEUP_INT_STS and USB_PHY_CLK_VALID_INT_STS, software can write a 1 to corresponding bits.

Generally, whenever PHY is waked up from suspend, first wakeup event is generated (USB_WAKEUP_INT_STS = 1) followed by PHY clock valid interrupt (USB_PHY_CLK_VALID_INT_STS = 1) when PHY clock starts up.

Note:

- This suspend is not supported in null ULPI mode.
- When doing this suspend for link ULPI mode,

a. USB2 clock should be enabled (CLK_ENB_USBD in ARCLK_RST_CLK_OUT_ENB_L register should be set to ENABLE).

b. USB2 reset should be disabled (SWR_USB2_RST in RST_DEVICES_H register should be set to DISABLE).

Not doing this could lead to undesirable side-effects.

- When USB2 is in suspend, AHB clocks to USB2 controller is turned off, and hence there should be no register access to USB2_CONTROLLER_1_* registers. All registers marked as ARUSB2_IF_* are accessible, and can be used to resume the ULPI PHY clocks.

There are two cases to consider for controlling the ULPI PHY clocks.

Device Mode

The PHY clock can be turned off in two cases:

- When USB cable isn't connected
- When the USB Host puts the USB bus in suspend mode

When USB cable isn't connected, the VBUS signal is 0. In this case, the software needs to turn on the PHY clock on cable insertion. Follow the procedure described above in the section on Detection of cable insertion.

When USB cable is connected, the PHY clock can only be turned off when the bit SLI in USB2D_USBSTS register is set to 1 when the USB Host puts the USB bus in suspend mode. This bit can be used to generate an interrupt if the bit SLE in USB2D_USBINTR register if set to 1. In this case, software needs to set two bits in the USB2_IF_USB_SUSP_CTRL register to turn on the PHY clock on a USB resume or a USB reset event from USB Host: USB_WAKE_ON_DISCON_EN_DEV: Wake on Disconnect enable in device mode, and USB_WAKE_ON_RESUME_EN - Wake on Resume enable.

If USB_WAKE_ON_RESUME_EN in USB2_IF_USB_SUSP_CTRL register is set to 1, the PHY clock can be turned on automatically on receiving USB resume event from USB Host. If USB_WAKE_ON_DISCON_EN_DEV in USB2_IF_USB_SUSP_CTRL register is set to 1, the PHY clock can be turned on automatically on receiving USB reset event from USB Host or if the USB cable is disconnected. These bits should only be turned on after the PHY clock is turned off. The method described above can be used to interrupt the processor when the PHY clock is turned on.

Also, turn off these bits when coming out of suspend.

Host Mode

When a device is not connected, software can set the WKCN bit in USB2D_PORTSC1 register. Make sure that VBUS is also turned on. After this, it can stop the PHY clock by using the method described above. The PHY clock will resume automatically when a device is connected. The method described above can be used to interrupt the processor when the PHY clock is turned on.

With a device connected, software needs to put the USB system under suspend by setting the bit SUSP in USB2D_PORTSC1 register. It needs to wait until this bit is set to 1 by the controller to make sure that the USB system actually went into suspend. It can enable the bits USB_WAKE_ON_RESUME_EN in USB2_IF_USB_SUSP_CTRL register and WK_DS in USB2D_PORTSC1 register. Then it can stop the PHY clock as described above. The PHY clock will be turned on automatically if the USB device disconnects or it does a remote wakeup signaling. There will be an interrupt associated with this as described above.

If the software wants to wakeup USB system, then it needs to turn on the PHY clock as described above.

Separate resets added for Slv0, Slv1, line, pads. Default resets on these need to be removed. ULPIS2S resets to be used as follows:

- assert ULPIS2S_SLV0_CLAMP_XMIT to ensure that the signals between SLV0 and the line simulator are clean.
- assert ULPIS2S_SLV0_RESET
- do a functional asynchronous reset of the controller
- deassert ULPIS2S_SLV0_RESET
- deassert ULPIS2S_SLV0_CLAMP_XMIT

NULPI_SLV1_RESET should be used in the same way if there is some explicit way to reset the external ULPI controller (which is not necessarily the case. There is usually no reason to assert ULPIS2S_LINE_RESET

21.3.2.9 Bus Signaling Procedure changes for UHSIC interface

To support the UHSIC interface, some changes are required in the bus signaling procedure for USB2 controller (connect and bus reset sequences). These are described in the sections below:

Host Mode - Bus Connect Sequence

The normal connect sequence assumes that port power has been enabled on a downstream port and the device has signaled a “Connect” on the bus. This will generate a port change interrupt and the software takes action from here:

1. Check if “LineState” (field LS in USB2D_PORTSC1 register) is DPlus – Make sure the HSIC bus is IDLE before starting the connect;
2. Program the XCVR to detect SHORT connect by writing “1” to DETECT_SHORT_CONNECT field in the UHSIC_MISC_CFG0 register.
3. Program the FORCE_XCVR_MODE field in UHSIC_MISC_CFG0 register to “1”.
4. Poll until “Device Connect” is received by polling until the UHSIC_CONNECT_DETECT field in the UHSIC_STAT_CFG0 register becomes “1”.

5. Check “PortSpeed” (field PSPD in USB2D_PORTSC1 register) – The ultimate check is to verify the bus connection speed as reported by the USB2 controller. It should match the HSIC native speed (High Speed).
6. The HSIC state machine does not detect a CONNECT if PHY clock is disabled. So SW should take care of this design limitation and should **NOT**
   - Either turn off PHY clock to detect the connect event. Or,
   - Expect a connect event if PHY clock in OFF.
7. The HSIC controller FSM detects CONNECT even before the actual CONNECT happens on the HSIC interface. This is due to the fact that FSM assumes CONNECT as soon as PHY type is selected to HSIC. From a controller perspective this makes sense as HSIC device only get connected once per power up event and there is no disconnect. Based on this the controller assumes that HSIC device is always connected. Since HSIC connect event doesn’t easily translate into linestate, this reduces dependency on third-party HSIC PHY designs.

Host Mode: Bus Reset Sequence

This is not the standard connect but rather a re-connect procedure without physically detaching the USB cable. This operation is demanded by software whenever it is necessary as it is the case when an unrecoverable anomaly takes place. It would then bring the bus, the port and the device into a well-known state.

1. Check if PortReset (PR bit in USB2D_PORTSC1 register) is NOT active – If by any means a bus reset is already taking place it must be stopped before proceeding. This is done by clearing the bit and polling until it goes LOW;
2. Enable the “PortReset” bit - Start the HSIC bus reset on a downstream port by activating the PR bit of the USB2D_PORTSC1 register;
3. Wait until the end of the reset – This wait time is defined by USB 2.0 spec and has the effect of holding the reset signaling on the HSIC bus;
4. Clear the PR bit – Stop the reset signaling by clearing the respective port reset bit;
5. Poll until the reset bit goes LOW – It is advised to guarantee that the reset bit is effectively cleared;
6. Poll until LineState is DPlus – This confirms that the reset signaling has really finished on the HSIC bus and that the USB2 controller is ready to connect again;
7. Proceed with step 2 of the “HOST Bus Connect Sequence” as described above. From here on, the procedure is the same as with an initial connect, instructing the USB2 controller to enter HS directly, skipping speed negotiation.
8. Standard EHCI reset interrupt can be used in Tegra 3 HSIC as native HSIC support in-built.

Device Mode: Bus Connect Sequence

Generally (assuming all initial procures have already been run), a connect will occur when both the RUNSTOP bit in USB2D_USBCMD register has been enabled and the Host has enabled the port power on its side. There is no physical connection event when dealing with a HSIC bus and this signaling mechanism guarantees a successful connect whichever component reaches the respective connection point first.

In a standard connection, software would wait for a “bus reset” System Interrupt to start the speed negotiation procedure. With a HSIC bus instead, reset does not take place and software must drive the USB2 controller into the “HS Connected Idle” state:

1. Enable the RUNSTOP bit in register USB2D_USBCMD – The HSIC PHY will detect this and wait for a bus IDLE meaning the bus has connected. When that happens, it will show LineState as DPlus and place the bus in the CONNECT state for at least two strobe periods;
2. Poll LineState until it reaches DPlus – This is needed because the Host may not be ready when the device starts the connect. We can only proceed to the “HS Connected Idle” state when the HOST has seen the connect;
3. Follow the exact instructions from step 3 of the Host “Bus Connect Sequence”.
4. Enable the Port Force Full Speed Connect (field PFSC in USB2D_PORTSC1 register) – This is necessary if system implementation is to account for bus resets during operation. Mostly this will be the case therefore the feature is

mandatory. Otherwise a bus reset would drive the device USB2 controller into speed negotiation which is not allowed for an HSIC bus.

Device Mode: Bus Reset Sequence

A bus reset is always started by a Host. When this happens the USB2 controller Device will detect the reset and issue a system interrupt. Both the fields PR in USB2D_PORTSC1 register and URI in USB2D_USBSTS register are set and after the typical setup operations, in order to connect, software must also do:

1. Check if LineState is SE0 – If the Host has actually started to drive reset signaling on the bus, then the LineState should be SE0, otherwise the reset condition is false;
2. Poll until LineState is DPlus – This will make software execution synchronized with the end of the bus reset. After the bus reset and because of the “Force Full Speed” feature, the USB2 controller will be in “Full Speed Idle” state;
3. Follow step 3 of the Device “Bus Connect Sequence” – The procedure to follow is the same as above. Software must also enable the “Force Full Speed” feature at the end (as with step 4).

Note: During the above described port connection procedures, due to the direct driving of the USB2 controller through a few of its internal states, some hardware interrupts will be skipped (this is why some steps involve polling cycles). Because of this, and depending on the programmer's choice, software may simulate/ignore some system interrupts (making interrupt routines to be called/attended from within the same execution thread) to maintain compatibility with the rest of the stack. This may apply for example to port change interrupts at the end of the bus reset for both Host/Device modes.

21.3.3 USB3 Programming Sequence

USB3 controller supports ICUSB and UTMIP3 interfaces. All of these interfaces are directly controlled through USB3 register space.

21.3.3.1 Clock Initialization

After power-on-reset, USB3 clocks are disabled. Software can enable USB3 clocks by setting CLK_ENB_USB3 in ARCLK_RST_CLK_OUT_ENB_H register to ENABLE.

Also, USB3 stays in reset at power-on and software should bring it out of reset by first setting SWR_USB3_RST in RST_DEVICES_H register to ENABLE and then set it to DISABLE.

After the clocks for USB3 are up, SW can program any registers for USB3 required for proper configuration.

PLLU outputs a 60 MHz clock FO_ICUSB for ICUSB interface and a 12 MHz clock FO_USB for UTMIP3 interface. If using any of these interfaces, PLLU should be programmed appropriately.

After anytime USB3 is reset, or ICUSB/UTMIP3 PHY comes out of suspend, software needs to wait until ICUSB/UTMIP3 PHY clock comes up. It can do that by checking for USB_PHY_CLK_VALID bit in USB3_IF_USB_SUSP_CTRL register. If this bit is 1, PHY clocks are up, else they aren't. There are interrupts associated with this bit: if USB_PHY_CLK_VALID_INT_ENB is set to ENABLE, USB_PHY_CLK_VALID_INT_STS will be set to SET whenever PHY clock becomes valid. Software can write a 1 to USB_PHY_CLK_VALID_INT_STS to clear the interrupt status.

Before doing anything useful on USB2, one of its interfaces needs to be selected and configured.

21.3.3.2 Selection of ICUSB Interface

If using ICUSB interface, software can hold UTMIP3 in reset by setting UTMIP3_RESET in USB3_IF_USB_SUSP_CTRL register to 1.

ICUSB interface only supports host mode of operation – a peripheral can be connected to Tegra 3 device’s ICUSB port. Peripheral mode of operation isn’t supported on ICUSB interface.

ICUSB IO pad is in power-down state at power-on. Bring it out of power-down mode by writing PD_ZI, PD_DR, PD_TX and IDDQ fields in ICUSB_XCVR_CFG register to 0.

1. Program slew rate to 0x2e by writing ICUSB_SLEW field into ICUSB_XCVR_CFG register which works across all PVT.
2. Program the PLLU parameters to enable ICUSB PLLU clock.
3. Select ICUSB interface by writing 1 to ICUSB_PHY_ENB field in USB3_IF_USB_SUSP_CTRL register.
4. Enable ICUSB module clock by writing 1 to ICUSB_MOD_CLK_ENB field in USB3_IF_USB_SUSP_CTRL register.
5. Wait until PHY clock comes up by checking for USB_PHY_CLK_VALID bit in USB2_IF_USB_SUSP_CTRL register. Interrupt can be generated as explained above.
6. Set CM field in USB2D_USBMODE register to HOST mode.
7. Change USB3 controller to ICUSB mode by writing iCUSB_SER to PTS field in USB2_CONTROLLER_2_USB2D_HOSTPC1_DEVLC register.
8. Enable appropriate voltage for ICUSB_VDD (1.8V or 3.0V) from PMU. Consult with the PMU vendor/datasheet about the programming required for this.
9. Enable ICUSB port in USB3 controller by writing 1 to IC_ENB1 field and appropriate ICUSB_VDD voltage in IC_VDD1 field of USB2D_ICUSB_CTRL register. For ICUSB_VDD of 1.8V, program 4 to IC_VDD1 and for ICUSB_VDD of 3.0V, program 5 to IC_VDD1. The value programmed in IC_VDD1 must match the voltage programmed in PMU for ICUSB_VDD.

Once initialization is done, standard USB drivers can be used to support ICUSB interface.

21.3.3.3 Selection of UTMIP3 interface

1. UTMIP3 IO pads are in power-down state at power-on. Bring them out of power-down mode by writing the following fields to 0:
   - FORCE_PD_POWERDOWN, FORCE_PD2_POWERDOWN, FORCE_PDZI_POWERDOWN fields in UTMIP_XCVR_CFG0 register.
   - OTGPD and BIASPD fields in UTMIP_BIAS_CFG0 register.
   - FORCE_PDDISC_POWERDOWEN , FORCE_PDCHRP_POWERDOWN, FORCE_PDDR_POWERDOWN field in UTMIP_XCVR_CFG1 register.
2. Hold UTMIP3 PHY in reset by writing UTMIP_RESET bit in USB3_IF_USB_SUSP_CTRL register to 1.
3. Program the PLLU parameters to enable UTMIP3 PLLU clock.
4. Enable UTMIP3 interface by setting UTMIP_PHY_ENB in USB3_IF_USB_SUSP_CTRL register to 1.
5. Program the configuration parameters for UTMIP3.
6. Bring the corresponding data sampler C out of power down (see CLK_RST_CONTROLLER_UTMIP_PLL_CFG2_0 register below)
7. Release reset to UTMIP3 by writing 0 to UTMIP_RESET field in USB3_IF_USB_SUSP_CTRL register.
8. Wait until PHY clock comes up by checking for USB_PHY_CLK_VALID bit in USB3_IF_USB_SUSP_CTRL register. Interrupt can be generated as explained above.
9. Set CM field in USB2D_USBMODE register to HOST mode.
10. Program the USB3 controller to use UTMIP3 PHY by setting the PTS field in USB2_CONTROLLER_2_USB2D_HOSTPC1_DEVLC register to UTMIP (2’b00).

21.3.3.4 ID and VBUS Connection

UTMIP3 is primarily meant to support additional USB Host functionality on Tegra 3 devices. Hence for UTMIP3, ID and VBUS pins are not supported. GPIOs could be used in applications that need these pins. In such cases, software would set

appropriate *_SW_VALUE and *_SW_EN bits for each VBUS and ID sensors depending on the value detected from the GPIOs.

Both VBUS and ID are available as a wake-up event during DPD/LP0 state. Please consult PMC programming guidelines for this.

21.3.3.5 Detection of USB Cable Insertion

The USB cable insertion event can be detected by a change in the ID or VBUS pin on the micro-AB connector. Initially, when the cable is not attached, the ID pin on the micro-AB connector is floating and is detected as 1 by Tegra 3 devices because of the weak pull-up on this pin. This makes Tegra 3 devices start-up as a B-device, even though a cable is not connected (When the ID pin is seen as a 1 by Tegra 3 devices, there can be no-cable or micro-B connected).

When a user attaches the USB cable, one of the following two events occur:

- User connects micro-A end of the cable to Tegra 3 devices. This changes the ID pin to 0. Hence the software can detect the ID change and go to A-device mode. Software can then supply power to the USB and place the Tegra 3 device in host mode.
- User connects micro-B (or mini-B) end of the cable to Tegra 3 devices. The other end of the cable can be either micro-A or standard-A and will be connected to a standard host, respectively.

For both cases, the Host will start driving power on VBUS and software can detect the cable insertion event by checking the VBUS status on corresponding GPIO. Once this is seen, it can place the Tegra 3 devices in the device mode.

Note:	Both ID and VBUS change can be detected by enabling the corresponding GPIO interrupts. USB controller/PHY clocks do not need to be turned on for this detection as this is done using GPIOs. To detect these events during DPD/LP0 modes, use VBUS/ID wakeup events in PMC.

21.3.3.6 PHY Clock Control

The PHY clock can be turned off by writing 1 to the bit PHCD in USB2D_PORTSC1 register.

Note:	There is no need to pulse this bit as opposed to USB1 controller.

To turn on the PHY clock, software should write to SUSP_CLR in USB3_IF_USB_SUSP_CTRL register. This bit must be pulsed by first writing a 1 and then writing a 0 to the bit.

The current suspend status of the PHY and thereby whether the PHY clock is running can be checked by reading the bit USB_PHY_CLK_VALID in USB_SUSP_CTRL register. If the PHY is placed in suspend, then this bit will be set to 0, else it will be set to 1. Software should make sure that PHY clock shuts down by polling this bit whenever it places the PHY into suspend.

The PHY clock can be turned on automatically on the events mentioned below. Set only the required wakeup enable bits based on the state of the USB as mentioned below. Don't set unnecessary wakeup enable bits. When the PHY clock wakes up under any such event, make sure that the wakeup enable bits are turned off as soon as possible.

To prevent the PHY clock from waking up on unnecessary glitches on the USB pins, software can set the USB_WAKEUP_DEBOUNCE_COUNT field in USB_SUSP_CTRL register to a non-zero value (between 1-7). This will allow the wakeup event to be debounced by the equivalent number of HCLK cycles.

There is an interrupt generated whenever PHY is waked up from suspend which can be checked by checking the value of USB_WAKEUP_INT_STS in USB_SUSP_CTRL register to be 1. The interrupt can be enabled/disabled by setting the bit USB_WAKEUP_INT_ENB in USB_SUSP_CTRL to 1/0.

There is an interrupt generated whenever PHY clock is turned on which can be checked by checking the value of USB_PHY_CLK_VALID_INT_STS in USB_SUSP_CTRL register to be 1. The interrupt can be enabled/disabled by setting the bit USB_PHY_CLK_VALID_INT_ENB in USB_SUSP_CTRL to 1/0.

To clear the interrupts USB_WAKEUP_INT_STS and USB_PHY_CLK_VALID_INT_STS, software can write a 1 to corresponding bits.

Generally, whenever PHY is waked up from suspend, first wakeup event is generated (USB_WAKEUP_INT_STS = 1) followed by PHY clock valid interrupt (USB_PHY_CLK_VALID_INT_STS = 1) when PHY clock starts up.

Note:	The PLLU_ENABLE bit in PLLU_BASE register should be always set to ENABLE. All the parameters for PLLU in PLLU_BASE and PLLU_MISC register should be set according to the oscillator frequency used. Not doing that will put the USB PHY PLL in a free-running mode, and can result in undesirable side-effects. When the USB PHY is suspended, the USB3 clock should not be stopped. It can be reduced to 32 KHz, however. If the system clock is stopped, then it may not be possible to bring up the system on a wakeup event described below. When USB3 is in suspend, AHB clocks to USB3 controller is turned off, and hence there should be no register access to USB2_CONTROLLER_2_* registers. All registers marked as ARUSB3_IF_* are accessible, and can be used to resume the UTMIP3 PHY clocks.

There are two cases to consider for controlling the PHY clocks.

Device Mode

The PHY clock can be turned off in two cases:

- When USB cable isn't connected
- When the USB Host puts the USB bus in suspend mode

When USB cable isn't connected, the VBUS signal is 0. In this case, the software needs to turn on the PHY clock on cable insertion. Follow the procedure described above in the section on Detection of cable insertion.

When USB cable is connected, the PHY clock can only be turned off when the bit SLI in USB2D_USBSTS register is set to 1 when the USB Host puts the USB bus in suspend mode. This bit can be used to generate an interrupt if the bit SLE in USB2D_USBINTR register if set to 1.

In this case, software needs to set two bits in the USB_SUSP_CTRL register to turn on the PHY clock on a USB resume or a USB reset event from USB Host: WAKE_ON_DISCON_EN_DEV: Wake on Disconnect enable during device mode, and USB_WAKE_ON_RESUME_EN - Wake on Resume enable.

If USB_WAKE_ON_RESUME_EN bit in USB_SUSP_CTRL register is set to 1, the PHY clock can be turned on automatically on receiving USB resume event from USB Host. If WAKE_ON_DISCON_EN_DEV bit in USB_SUSP_CTRL register is set to 1, the PHY clock can be turned on automatically on receiving USB reset event from USB Host or if the USB cable is disconnected. These bits should only be turned on after the PHY clock is turned off. The method described above can be used to interrupt the processor when the PHY clock is turned on. Also, turn off these bits when coming out of suspend.

Host Mode

When a device is not connected, software can set the WKCN bit in USB2D_PORTSC1 register. Make sure that VBUS is also turned on. After this, it can stop the PHY clock by using the method described above. The PHY clock will resume automatically when a device is connected. The method described above can be used to interrupt the processor when the PHY clock is turned on.

With a device connected, software needs to put the USB system under suspend by setting the bit SUSP in USB2D_PORTSC1 register. It needs to wait until this bit is set to 1 by the controller to make sure that the USB system actually went into suspend. It can enable the bits USB_WAKE_ON_RESUME_EN in USB_SUSP_CTRL register and WK_DS in USB2D_PORTSC1

register. Then it can stop the PHY clock as described above. The PHY clock will be turned on automatically if the USB device disconnects or it does a remote wakeup signaling. There will be an interrupt associated with this as described above.

If the software wants to wakeup USB system, then it needs to turn on the PHY clock as described above.

21.3.4 Initialization and Shutdown Procedure for USB

1. Bring up USB3 clocks by writing 1 to CLK_ENB_USB3 in ARCLK_RST_CLK_OUT_ENB_H register.
2. Assert and de-assert SWR_USB3_RST in RST_DEVICES_H register to bring the USB block out of reset.
3. Set UTMIP_RESET bit in USB_SUSP_CTRL register to 1 to keep UTMIP3 PHY in reset.
4. Program UTMIP and PLLU parameters.
   - Set register UTMIP_MISC_CFG0 UTMIP_SUSPEND_EXIT_ON_EDGE (bit 22) to 0.
   - Set the PLLU_ENABLE to 1, and never ever de-assert it.
5. Set UTMIP_RESET bit in USB_SUSP_CTRL register to 0 to bring UTMIP3 out of reset.
   - Wait until PHY_CLKVALID is set to 1.
6. Set USB controller and PHY to suspend by writing 1 to PHCD in USB2D_PORTSC1 register. This will reduce the power consumption on USB3 controller and UTMIP3 PHY.
   - Wait until PHY_CLKVALID is set to 0.
7. Set all PD bits required to bring USB pads to low power mode.
   - UTMIP_OTGPD in UTMIP_BIAS_CFG0 is needed for VBUS detection, and so it should be set to 0.
   - If using VBUS_WAKEUP for VBUS detection, then UTMIP_BIASPD in UTMIP_BIAS_CFG0 can be set to 1 to save power. But if using A_SESS_VLD or any other VBUS sensor for VBUS detection, then this bit should be set to 0.
   - ID_PU in USB_PHY_VBUS_WAKEUP_ID should be set to 1 to enable ID detection.
   - UTMIP_IDPD_SEL in UTMIP_BIAS_CFG0 should be set to 0.
8. To interrupt the processor on VBUS or ID detection, software can set the following:
   - Enable appropriate VBUS interrupt enable, for example, I using A_SESS_VLD sensor for VBUS detection, set A_SESS_VLD_INT_EN in USB_PHY_VBUS_SENSORS register to 1.
   - Enable ID detection interrupt by setting ID_INT_EN in USB_PHY_VBUS_WAKEUP_ID register.
9. When (VBUS=1) or (ID=0) is detected, do the following:
   - Bring USB3 controller and PHY out of suspend by pulsing SUSP_CLR in USB_SUSP_CTRL register by first writing 1 and then writing 0.
   - Wait until PHY_CLKVALID is set to 1.
   - Clear the PD bits that are required for the normal operation.
10. From this on, driver can run the normal operations.
    - UTMIP should only be suspended by writing 1 to PHCD in USB2D_PORTSC1 register when USB cable is connected and only after USB bus is in suspend, for both device and host modes.
11. If a cable disconnect is detected (VBUS = 0) or (ID = 1), then go back to step 4.

21.3.5 Recommended PHY Settings

- Set UTMIP_XCVR_SETUP to 0x5 and UTMIP_XCVR_SETUP_MSB to 0x3 of UTMIP_XCVR_CFG0_0 register. This helps in eye diagram.
- Set UTMIP_TERM_RANGE_ADJ to 0x7 of UTMIP_XCVR_CFG1 register. This helps in eye diagram.
- Set UTMIP_XCVR_HSSLEW_MSB to 0x8. This helps in eye diagram.

- Set disconnect level to 0x5. This can be done by setting UTMIP_HSDISCON_LEVEL to 0x1 and UTMIP_HSDISCON_LEVEL_MSB to 0x1 of UTMIP_BIAS_CFG0_0 register.
- Set squelch level to 0x2. This can be done by setting UTMIP_HSSQUELCH_LEVEL to 2'b10 UTMIP_BIAS_CFG0_0 register.
- Set HS SLEW to 2.92pf. This can be done by setting UTMIP_XCVR_HSSLEW_MSB to 7'h8, UTMIP_XCVR_HSSLEW to 2'b0 of UTMIP_XCVR_CFG0 register.

21.3.6 BOOTROM Initialization Sequence for USB Recovery

1. Program PLL_U.
   - Setting the PLLU_BASE register fields, PLLU_DIVM, PLLU_DIVN, PLLU_VCO_FREQ, PLLU_BYPASS and PLLU_ENABLE fields as described in the document.
2. Configuring USB
   - Bring up USB1 clocks by writing 1 to CLK_ENB_USBD in CLK_OUT_ENB_L register.
   - Assert and de-assert master USBD reset in CAR (SWR_USBD_RST in RST_DEVICES_L register) to bring USB1 out of reset.
   - Stop crystal clock by setting UTMIP_PHY_XTAL_CLOCKEN in UTMIP_MISC_CFG1 register to 0. This only stops the crystal clocks in the UTMIP units.
   - Default value of the USB1_UTMIP_PHY_XTAL_CLOCKEN is 1, now changing to 0.
   - To Use the A Session Valid for cable detection logic, set USB1_VBUS_SENSE_CTL field in USB1_LEGACY_CTRL register to A_SESS_VLD (2'b11).
   - Programming automatic PLL start times.
   - Setting USB1_IF_UTMIP_PLLU_ENABLE_DLY_COUNT, UTMIP_PLLU_STABLE_COUNT, UTMIP_PLL_ACTIVE_DLY_COUNT and UTMIP_XTAL_FREQ_COUNT as per the values given in the document.
   - Programming the tracking duration.
   - Setting USB1_IF_UTMIP_BIAS_CFG1.UTMIP_BIAS_PDTRK_COUNT as per the values given in the document.
   - Program the debouncer length times.
   - Setting UTMIP_DEBOUNCE_CFG0.UTMIP_BIAS_DEBOUNCE_A field.
   - Program various static parameters of the USB UTMIP1.
   - Set UTMIP_TX_CFG0.UTMIP_FS_PREAMBLE_J to 0x1.
   - Set UTMIP_BAT_CHRG_CFG0.UTMIP_PD_CHRG to 1.
   - Set UTMIP_XCVR_CFG0.UTMIP_XCVR_LSBIAS_SEL to 0.
   - Set 3rd bit of UTMIP_SPARE_CFG0 to 1. i.e UTMIP_SPARE_CFG0 [3] to 1.
   - Set UTMIP_HSRX_CFG0. UTMIP_IDLE_WAIT as per the values given in doc.
   - Set UTMIP_HSRX_CFG0.UTMIP_ELASTIC_LIMIT to 16.
   - Set UTMIP_HSRX_CFG1.UTMIP_HS_SYNC_START_DLY to 9
   - Resuscitate the crystal clock by setting UTMIP_PHY_XTAL_CLOCKEN in UTMIP_MISC_CFG1 register to 1 for USB.
3. Waiting for cable connect on USB UTMIP1 port. When cable is connected on USB UTMIP1 port,
4. Bring UTMIP1 out of reset by writing 0 to UTMIP_RESET bit of USB1_IF_SUSP_CTRL register.
5. Wait until USB1_IF_USB_SUSP_CTRL.PHY_CLK_VALID is set to 1.
6. Then perform USB controller initialization.
   - Do Bus reset.

- Wait until bus come out of reset.
- Set the controller in device mode.
- USB operations.

21.3.7 Performance Settings for USB Controllers

To meet USB's strict bandwidth/latency requirements, some AHB programming needs to be done. The following gives a guideline on the programming requirements to achieve maximum performance from USB:

- The burst size for USB controller should be programmed to 8 in the register USB2D_BURSTSIZE. Both TXPBURST and RXPBURST fields should be programmed to the same value of 8.
- The field ENB_FAST_REARBITRATE for AHB_MEM gizmo should be set to 1 in the register AHB_GIZMO_AHB_MEM.
- The field IMMEDIATE for USB gizmos should be set to 1 in the register AHB_GIZMO_USB, AHB_GIZMO_USB2 or AHB_GIZMO_USB3 depending on the controller in use.
- USB controllers should be set as high-priority masters on AHB by setting the bits corresponding to each USB controller to 1 in AHB_PRIORITY_SELECT field in the register AHB_ARBITRATION_PRIORITY_CTRL and setting the priority weight to 7 by setting the field AHB_PRIORITY_WEIGHT in the same register. USB master numbers are 6 for USB1, 18 for USB2 and 17 for USB3. The priority weight could be relaxed depending on requirements from other AHB masters in the system as required for different use cases.
- Prefetch engine needs to be setup correctly to enable prefetching of transmit data packets for USB masters. Each USB master needs one channel on the prefetch engine. There are 4 channels on the prefetch engine. If all 3 USB masters enable one channel at the same time, it would leave one more channel for another AHB master. Each prefetch channel is controlled by the register AHB_AHB_MEM_PREFETCH_CFG[NO] where NO=1,2,3,4. To enable prefetch for a USB controller on a channel, program AHB_MST_ID_USB, AHB_MST_ID_USB2 or AHB_MST_ID_USB3 in the field AHB_MST_ID for the register AHB_AHB_MEM_PREFETCH_CFG[NO]. The field ADDR_BNDRY should be set to log2 (buffer size) according to the buffer size required for the corresponding USB master. The field SPEC_THROTTLE should be set to 0, and the field INACTIVITY_TIMEOUT should be set to 0x800.
- When a particular USB controller is in Host mode, the field TXFIFOTHRES in the register USB2D_TXFILLTUNING (offset 0x154) should be set to 0x10.

All these programming need to be done before setting RS bit in USB2D_USBCMD to RUN (1) for the corresponding USB controller.

21.4 UTMIP Programming Guidelines

Tegra 3 devices have a total of 3 UTMI+ interfaces. This results in three cabled USB ports. These ports are not part of a multiport host configuration. They are completely independent ports and can be configured in any combination of device or host. All UTMI+ PHY interfaces are identical instances of the same design. All three controllers use latest edition of USB core controller.

21.4.1 Holding USB in Reset

It is important that most static configuration of the UTMIP (and USB) be done while the unit is held in reset. For example, holding reset ensures that PLL_U is disabled and can be reconfigured. It also ensures that transactions are not occurring on the USB interface. Holding reset in both a controller and its corresponding PHY can be achieved by using the RST bit of the USB2D_USBCMD register.

21.4.2 PLL_U Programming

The USB ports use a cascaded PLL scheme to guarantee a high clock quality. First there is a PLL_U, which is the source clock for both the USB PLLs that are dedicated to ports. PLL_U (of type CLKPLL960_USB) produces reference clocks for all forms of USB (ULPI (null mode), IC USB, UTMIP, UHSIC). Table 34 describes the parameter settings that are dependent on the crystal clock reference frequency. The parameters are specified in decimal notation.

Table 34 480MHz PLL_U Output Frequency Fo = (Fi·N)÷(M· 2) With VCO_FREQ=0

Fi (MHz)	12.0MHz	13.0MHz	16.8MHz	19.2MHz	26.0MHz	38.4 MHz	48.0MHz
N (PLLU_DIVN)	960	960	400	200	960	200	960
M (PLLU_DIVM)	12	13	7	4	26	4	12

These parameters can be found in the PLLU_BASE register. The PLLU_OVERRIDE bit should be set to 0. Please also note that PLLU_VCO_FREQ parameter must be set to 0.

> **Note:** PLL_U must be properly configured in the Boot ROM. DO NOT change the parameters of PLL_U while the unit is running. The same applies to the USB_PHY_PLL.

21.4.3 PLL_U and USB_PHY_PLL automatic startup times

The PLL_U and USB_PHY_PLL automatic startup times are used in reset and suspend modes to kick start the PLLs. Software should not manually force the PLL up and down as it cannot do so rapidly enough to meet the protocol.

Table 35 PLL Automated Start Times (Must be setup in the Boot ROM)

CRYSTAL FREQ.	12.0 MHz	13.0 MHz	16.8 MHZ	19.2 MHz	26.0 MHz	38.4 MHz	48.0 MHz
PLLU_ENALBLE_DELAY_COUNT	2	2	3	3	4	5	6
PLLU_STABLE_COUNT	47	51	66	75	102	150	188
PLL_ACTIVE_DLY_COUNT	8	9	11	12	9	24	31
XTAL_FREQ_COUNT	118	127	165	188	254	375	469

The PLLU_ENABLE_DLY_COUNT should be for at least 1 microsecond, the PLLU_STABLE_COUNT should be for at least 1ms, the PLL_ACTIVE_DLY_COUNT for at least 10 microseconds, and the XTAL_FREQ_COUNT for about 2.5ms.

21.4.4 Fuse Programming

Tegra 3 incorporates fuses to account for process variation in high speed data eye swing. The high speed data eye is controlled through the SETUP[6:0] transceiver pad parameter of the USB control registers. To set this parameter via the fuses, set the UTMIP_SPARE_CFG0[3] bit on all USB ports. This must be done in the Boot ROM. The default is to maintain backward compatibility; which implies no fuses are used by default. The objective is to get the data eye swing as close as possible to 400mV without falling below the mark under typical operating conditions.

21.4.5 Powering down a USB port outside of Deep Power Down (DPD)

When a port is known to be disabled, there needs to be a mechanism to stop its power consumption for situations outside of DPD. This section addresses disabling a port while powered up.

Powering down of USB at times other than deep power down should be done by setting all specialized PLL and pad power down pins instead of using the global E_DPD pins of the USB analog components. It has been determined that it is safer to power down the cells through the traditional power down pins when the 3.3V and 1.2V supplies might still be on. This is achieved by setting the following pad controls from UTMIP register space. Before setting the power down bits; save previous registers values so that they may be restored. This type of power down should not be done in the Boot ROM.

Table 36 UTMIP Pad Controls

Pad Control	Analog Cell	Register Bit Settings
PD	Transceiver	UTMIP_FORCE_PD_POWER_DOWN=1
PD2	Transceiver	UTMIP_FORCE_PD2_POWER_DOWN=1
PD_ZI	Transceiver	UTMIP_FORCE_PDZI_POWER_DOWN=1
PD_DR	Transceiver	UTMIP_FORCE_PDDR_POWER_DOWN=1
PD_CHRP	Transceiver	UTMIP_FORCE_PDCHRP_POWER_DOWN=1
PD_DISC	Transceiver	UTMIP_FORCE_PDDISC_POWER_DOWN=1
PD_CHG	Transceiver	UTMIP_PD_CHG=1
PD	Bias	UTMIP_BIASPD=1
PD_TRK	Bias	UTMIP_FORCE_PDTRK_POWER_DOWN=1
OTG_PD[X]	Bias	UTMIP_OTGPD=1
ID_PD[X]	Bias	UTMIP_IDPD_SEL=1, UTMIP_IDPD_VAL=1
VBUS_WAKEUP_PD[X]	Bias	UTMIP_VBUS_WAKEUP_POWER_DOWN=1
ENABLE	PHY PLL	UTMIP_FORCE_PLL_ENABLE_POWERDOWN=1
ACTIVE	PHY PLL	UTMIP_FORCE_PLL_ACTIVE_POWERDOWN=1
PD_SAMP_X	PHY_PLL	UTMIP_FORCE_PD_SAMP_X_POWERDOWN=1
ENABLE	PLL U	UTMIP_FORCE_PLLU_POWERDOWN=1
UTMIP	PHY	UTMIP_PHY_XTAL_CLOCKEN=0

The set of bits exists for both ports X, where X is 0, 1 or 2. Three of the power downs are explicitly labeled with a port index because they belong to the bias cell and happen to have a per port control. Otherwise the same register bits exist in both controllers.

21.4.6 UTMIP BIAS PAD Configurations

UTMIP BIAS pad is shared across all 3 USB controllers and below common bias pad settings need to be configured from USB1 controller only.

USB1_UTMIP_BIAS_CFG0_0:

- UTMIP_BIASPD
- UTMIP_HSCHIRP_LEVEL
- UTMIP_HSSQUELCH_LEVEL
- UTMIP_HSDISCON_LEVEL_MSB
- UTMIP_HSDISCON_LEVEL
- UTMIP_ACTIVE_TERM_OFFSET
- UTMIP_ACTIVE_PULLUP_OFFSET
- UTMIP_VBUS_LEVEL_LEVEL
- UTMIP_SESS_LEVEL_LEVEL

USB1_UTMIP_BIAS_CFG1_0:

- UTMIP_FORCE_PDTRK_POWERUP
- UTMIP_FORCE_PDTRK_POWERDOWN

The sequence to configure the above parameters of the BIAS pad:

1. Enable clock to USB1 controller
2. Set any of above parameters as required.
3. Disable clock to USB1 controller if it is not used.

21.4.7 Extending Debouncer Period Length

USB debouncers provide a programmable debounce to alleviate the software burden. This is done with the UTMIP_DEBOUNCE_TIME_SCALE parameter located at UTMIP_BIAS_CFG1[13:8]. The default implies a timescale factor of 1. The timescale should not be programmed at Boot ROM time. The timescale register field incremented by 1 multiplies the debounce duration for all debouncers.

21.4.8 Deep Power Down Behavior

Tegra 3 devices deep power down behavior for USB wake-up events is controlled in the PMC via registers USB_DEBOUNCE_DLY, USB_AO and the WAKE_MASK (USB_EVENT field) of the PMC unit. These control the wake-up events, their debounce duration and their debounce length while powered down. Each USB port has a possible event on ID or VBUS detection. These can be configured at startup time. These registers take over from the UTMIP registers when the chip is powered down. The programming depends on the context of the chip. For example, if both USB ports are dedicated host ports then the VBUS wake-up event should be kept powered down. Conversely a dedicated device mode port may not want to wake-up on the detection of an ID connector and can chose to power down ID.

21.4.9 PHY Resets

Additional controls have been provided to stop the USB PHY (and its clocks) by issuing a reset to the PHY only (as opposed to a reset encompassing the controller and the PHY). This is akin to the Reset found in the UTMI+ standard. This is done in both controllers.

21.4.10 Static Boot ROM configuration for UTMIP

The boot ROM configuration for UTMIP should be done while the unit is held in Reset. There is a change in the PowerDown control of the various units, so it is a **MUST** that these are removed appropriately to see correct behavior. The following is the sequence for this:

1. Reset is applied to USB controller (and UTMIP).
2. Crystal clock is running for approximately 5 microseconds while UTMIP in reset.
3. Stop crystal clock by setting UTMIP_PHY_XTAL_CLOCKEN low. This only stops the crystal clocks in the UTMIP units.
4. Program PLL_U as described in the PLL_U programming section (section 3).
5. Program automatic PLL start times as described in section PLL_U and USB_PHY_PLL automatic startup times.
6. Remove power downs from USB_PHY_PLL ACTIVE/ENABLE/PD_SAMP_A and PLL_U.
7. Program the tracking duration as described in section Programming the Tracking Length Time. Remove the power downs from PD (Bias) and disable PD_TRK. After 25us (tracking time), enable PD_TRK, by writing 0 into UTMIP_FORCE_PDTRK_POWER_DOWN.
8. Once PD (Bias) is disabled, disable OTG_PD[X] after 1us.
9. Remove powerdowns from ID_PD[X] and VBUS_WAKEUP_PD[X]. It can be removed earlier too, as it has no timing or sequential relation with other signals.
10. Once the PLL_U, USB_PHY_PLL and Bias pad are ready, remove PD (Transceiver). After 400ns the USB pad is ready for HS/FS/LS operation.
11. There are other powerdowns which can be removed if needed (as such not needed for Boot Rom). These are PD / PD_ZI / PD_DR / PD_CHRP / PD_DISC / PD_CHG.

12. Program the debouncer length time as described in the section Extending Debouncer Period Length.
13. Program various static parameters of the UTMIP as described in the section Miscellaneous Boot ROM fields.
14. Resuscitate the crystal clock by setting UTMIP_PHY_XTAL_CLOCKEN.
15. Resume any previous USB programming work that falls outside of UTMIP and release reset (from the UTMIP perspective it does not matter when reset is released, as long as it is after step 8. It will take about 3.5 ms before the 60 MHz clock appears once reset is released).

From a UTMIP perspective, ensure that all the cabled USB port PHYs are configured similarly in the Boot ROM.

21.4.11 EHCI Deviations

- Embedded Transaction Translator – Allows direct attachment of FS and LS devices in host mode without the need for a companion controller.
- Embedded design interface – This core does not have a PCI Interface and therefore the PCI configuration registers described in the EHCI specification are not applicable.

Programmable Physical Interface Behavior

This design supports multiple Physical interfaces which can operate in differing modes when the core is configured with software programmable Physical Interface Modes. Software programmability allows the selection of the Physical interface part during the board design phase instead of during the chip design phase. The control bits for selecting the Physical Interface operating mode have been added to the HOSTPCx register providing a capability that is not defined by EHCI.

Port Reset

The port connect methods specified by EHCI require setting the port reset bit in the PORTSCx register for a minimum duration of 10ms. Due to the complexity required to support the attachment of devices that are not high speed, there are counter already present in the design that can count the 10ms reset pulse to alleviate the requirement of the software to measure this duration. The basic connection is then summarized as the following:

- [Port Change Interrupt] Port connect change occurs to notify the host controller driver that a device has attached.
- Software shall write a ‘1’ to the reset the device.
- Software shall write a ‘0’ to the reset the device after 10ms.
- Driver needs to wait until port change interrupt is asserted and port reset is cleared

> **Note:** Should the EHCI host controller driver attempt to write a ‘0’ to the reset bit while a reset is in progress the write will be ignored and the reset will continue until completion.

- [Port Change Interrupt] Port enable change occurs to notify the host controller that the device is now operational and at this point the port speed has been determined.

Port Speed Detection

After the port change interrupt indicates that a port is enabled, the EHCI stack should determine the port speed. Unlike the EHCI implementation which will re-assign the port owner for any device that does not connect at High-Speed, this host controller supports direct attach of non High-Speed devices. Therefore, the following differences are important regarding port speed detection:

- Port Owner is read-only and always reads 0.
- A 2-bit Port Speed indicator (PSPD) has been added to HOSTPCx to provide the current operating speed of the port to the host controller driver.

Port Reset duration is 55 msec instead of 50 msec.

Port Suspend (PORTSC.Suspend) bit is set immediately after setting the bit. As per EHCI a 4msec delay is expected for this bit to be set.

Tegra 3 also has following areas that are not directly compliant to EHCI :

- USB controller/PHY interface initialization
- PHY Clock shutdown/wakeup procedure during suspend/resume/connect/disconnect
- For HSIC, connect process and bus reset process is not EHCI compliant – particularly no interrupts for connect.
- PMC logic use for special low power modes during suspend/LP0

21.5 USB Registers

21.5.1 USB 1 Controller Registers

21.5.1.1 USB2_CONTROLLER_USB2D_ID_0

USB2D Identification Register

Offset: 000h | Read/Write: RO |Reset: 0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx

Bit	Reset	Description
31:29	X	CIVERSION: Identifies the CI version
28:25	X	VERSION: Identifies the version of the core
24:21	X	REVISION: Revision number of the USB controller. This is set to 0x0.
20:16	X	TAG: Identifies the tag of the core
15:8	X	NID: Ones complement version of ID. This field is set to 0xF9.
7:0	X	ID: Configuration number. This field is set to 0x06

21.5.1.2 USB2_CONTROLLER_USB2D_HW_HOST_0

USB2D Hardware Host Register

Offset: 008h | Read/Write: RO | Reset: 0bxxxx

Bit	Reset	Description
3:1	X	NPORT: VUSB_HS_NUM_PORT-1: This host controller has only 1 port. So this field will always be 0.
0	X	HC: VUSB_HS_HOST: Indicates support for host mode. Set to 1.

21.5.1.3 USB2_CONTROLLER_USB2D_HW_DEVICE_0

USB2D Hardware Device Register

Offset: 00ch | Read/Write: RO | Reset: 0bxxxxxx

Bit	Reset	Description
5:1	X	DEVEP: VUSB_HS_DV_EP: No. of endpoints supported by this device controller. Set to 16. This includes control endpoint 0.

Bit	Reset	Description
0	X	DC: Device capable: Set to 1 indicating support for device mode.

21.5.1.4 USB2_CONTROLLER_USB2D_HW_TXBUF_0

USB2D Hardware TX Buffer Register

Offset: 010h | Read/Write: RO | Reset: 0bxxxxxxxxxxxxxxxxxxxxxxxxxx

Bit	Reset	Description
23:16	X	TXCHANADD: VUSB_HS_TX_CHAN_ADD: Total no. of address bits for the transmit buffer of each transmit endpoint. Set to 7. Each transmit buffer is 128 words deep.
15:8	X	TXADD: VUSB_HS_TX_ADD: Total no. of address bits for the transmit buffer. Set to 11. The total depth of the transmit buffer is 2048 words.
7:0	X	TCBURST: VUSB_HS_TX_BURST: Maximum burst size supported by the transmit endpoints for data transfers. Set to 8.

21.5.1.5 USB2_CONTROLLER_USB2D_HW_RXBUF_0

USB2D RX Buffer HW Parameters Register

Offset: 014h | Read/Write: RO | Reset: 0bxxxxxxxxxxxxxxxx

Bit	Reset	Description
15:8	X	RXADD: VUSB_HS_RX_ADD: Total no. of address bits for the receive buffer. Set to 7. The total depth of the receive buffer is 128 words
7:0	X	RXBURST: VUSB_HS_RX_BURST: Maximum burst size supported by the receive endpoints for data transfers. Set to 8.

21.5.1.6 USB2_CONTROLLER_USB2D_CAPLENGTH_0

USB2D Capability Register Length Register

Offset: 100h | Read/Write: RO | Reset: 0bxxxxxxxx

Bit	Reset	Description
7:0	X	CAPLENGTH: Indicates which offset to add to the register base address at the beginning of the Operational Register. Set to 0x40.

21.5.1.7 USB2_CONTROLLER_USB2D_HCIVERSON_0

USB2D Host Interface Version Number Register

Offset: 102h | Read/Write: RO | Reset: 0bxxxxxxxxxxxxxxxx

Bit	Reset	Description
15:0	X	HCIVERSION: Contains a BCD encoding of the EHCI revision number supported by this host controller. The most significant byte of this register represents a major revision and the least significant byte is the minor revision. This host controller supports EHCI revision 1.00.

21.5.1.8 USB2_CONTROLLER_USB2D_HCSPARAMS_0

USB2D Host Control Structural Parameters Register

Offset: 104h | Read/Write: RO | Reset: 0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx

Bit	Reset	Description
27:24	X	N_TT: Number of Transaction Translators: indicates the number of embedded transaction translators associated with the USB2.0 host controller. This field is always set to 1 indicating only 1 embedded TT is implemented in this implementation. This is a non-EHCI field to support embedded TT.
23:20	X	N_PTT: Number of Ports per Transaction Translator: indicates the number of ports assigned to each transaction translator within the USB2.0 host controller. Field always equals N_PORTS. This is a non-EHCI field to support embedded TT.
15:12	X	N_CC: Number of Companion Controller: indicates the number of companion controllers. This field is set to 0.
11:8	X	N_PCC: Number of Ports per Companion Controller: indicates the number of ports supported per internal companion controller. This field is set to 0.
4	X	PPC: Port Power Control: indicates whether the host controller implementation includes port power control. 1 = Ports have port power switches 0= Ports do not have port power switches. This field affects the functionality of the port Power field in each port status and control register. This field is set to 1.
3:0	X	N_PORTS: Number of downstream ports. This field specifies the number of physical downstream ports implemented on this host controller. This field is fixed to 1, since this host controller only supports 1 port.

21.5.1.9 USB2_CONTROLLER_USB2D_HCCPARAMS_0

USB2D Host Control Capability Parameters Register

Offset: 108h | Read/Write: RO | Reset: 0bxxxxxxxxxxxxxxxxxx

Bit	Reset	Description
18	X	PPC: Per-Port Change Event Capability - RO. Default = 1b. This field indicates the support for per-port change events. This field is related with USBCMD PPE field, USBSTS PPCI field and USBINTR PPCE field.
17	X	LEN: Link Power Management Capability - RO. Default = 1b. This field indicates the support for LPM L1 state. This field is related with USBCMD HIRD field, POSTSCx SSTS and DA fields and HOSTPCx LEN, BA, and EPLPM fields.
15:8	X	EECP: EHCI Extended Capabilities Pointer: indicates a capabilities list exists. A value of 00h indicates no extended capabilities are implemented. For this implementation this field is always "0".
7:4	X	IST: Isochronous Scheduling Threshold. This field indicates, relative to the current position of the executing host controller, where software can reliably update the isochronous schedule. When bit [7] is zero, the value of the least significant 3 bits indicates the number of micro-frames a host controller can hold a set of isochronous data structures (one or more) before flushing the state. When bit [7] is a one, then host software assumes the host controller may cache an isochronous data structure for an entire frame. This field will always be "0".
2	X	ASP: Asynchronous Schedule Park Capability. 1 = (Default) the host controller supports the park feature for high-speed queue heads in the Asynchronous Schedule. The feature can be disabled or enabled and set to a specific level by using the Asynchronous Schedule Park Mode Enable and Asynchronous Schedule Park Mode Count fields in the USBCMD register. This field is always 1.
1	X	PFL: Programmable Frame List Flag. 0 = System software must use a frame list length of 1024 elements with this host controller. The USBCMD register Frame List Size field is a read-only register and must be set to zero. 1 = System software can specify and use a smaller frame list and configure the host controller via the USBCMD register Frame List Size field. The frame list must always be aligned on a 4K-page boundary. This requirement ensures that the frame list is always physically contiguous. This field will always be "1".

21.5.1.10 USB2_CONTROLLER_USB2D_DCIVERSION_0

USB2D Device Interface Version Number Register

Offset: 120h | Read/Write: RO | Reset: 0bxxxxxxxxxxxxxxxx

Bit	Reset	Description
15:0	X	DCIVERSION: The device controller interface conforms to the two-byte BCD encoding of the interface version number contained in this register.

21.5.1.11 USB2_CONTROLLER_USB2D_DCCPARAMS_0

USB2D Device Control Capabilities Register

Offset: 124h | Read/Write: RO | Reset: 0bxxxxxxxxx

Bit	Reset	Description
8	X	HC: Host Capable: 1 = This controller is capable of operating as an EHCI compatible USB 2 0 host controller operating as an EHCI compatible USB 2.0 host controller. This field is set to 1.
7	X	DC: Device Capable: 1 = Controller is capable of operating as USB 2.0 device. This field is set to 1
5	X	LEN: Link Power Management Capability - RO. Default = 1b. This field indicates the support for LPM L1 state. This field is related with DEVLCx ASUS, STL,BA and NYT fields.
4:0	X	DEN: Device Endpoint Number: Number of endpoints built into the device controller. This is set to 16.

21.5.1.12 USB2_CONTROLLER_USB2D_EXTSTS_0

USB2D EXTSTS Register

Offset: 128h | Read/Write: R/W | Reset: 0b0000x

Bit	R/W	Reset	Description
4	RW	0x0	TI1: General Purpose Timer Interrupt 1 - RWC. Default = 0b. This bit is set when the counter in the GPTIMER1CTRL register transitions to zero. Writing a one to this bit will clear it.
3	RW	0x0	TI0: General Purpose Timer Interrupt 0 - RWC. Default = 0b. This bit is set when the counter in the GPTIMER1CTRL register transitions to zero. Writing a one to this bit will clear it.
2	RW	0x0	UPA: USB Host Periodic Interrupt (USBHSTPERINT) R/WC. This bit is set by the Host Controller when the cause of an interrupt is a completion of a USB transaction where the Transfer Descriptor (TD) has an interrupt on complete (IOC) bit set and the TD was from the periodic schedule. This bit is also set by the Host Controller when a short packet is detected AND the packet is on the periodic schedule. A short packet is when the actual number of bytes received was less than the expected number of bytes. This bit is not used by the device controller and will always be zero. 0 = DISABLE 1 = ENABLE
1	RW	0x0	UAI: USB Host Asynchronous Interrupt (USBHSTASYNCINT) R/WC. This bit is set by the Host Controller when the cause of an interrupt is a completion of a USB transaction where the Transfer Descriptor (TD) has an interrupt on complete (IOC) bit set AND the TD was from the asynchronous schedule. This bit is also set by the Host when a short packet is detected AND the packet is on the asynchronous schedule. A short packet is when the actual number of bytes received was less than the expected number of bytes. This bit is not used by the device controller and will always be zero. 0 = DISABLE 1 = ENABLE
0	RO	X	NAKI: NAK Interrupt Bit Read Only. This bit is read only. It is set by hardware when for a particular endpoint both the TX/RX Endpoint NAK bit and the corresponding TX/RX Endpoint NAK Enable bit are set. This bit is automatically cleared by hardware when the all the enabled TX/RX Endpoint NAK bits are cleared.

Bit	R/W	Reset	Description
			0 = DISABLE 1 = ENABLE

21.5.1.13 USB2_CONTROLLER_USB2D_USBEXTINTR_0

USB2D EXTINTR Register

Offset: 12ch | Read/Write: R/W | Reset: 0b00000

Bit	Reset	Description
4	0x0	TIE1: General Purpose Timer Interrupt Enable 1 - RWC. Default = 0b. When this bit is a one, and the TI1 bit in the EXTSTS register is a one, the controller will issue an interrupt. The interrupt is acknowledged by software clearing the TI1 bit.
3	0x0	TIE0: General Purpose Timer Interrupt Enable 0 - RWC. Default = 0b. When this bit is a one, and the TI1 bit in the EXTSTS register is a one, the controller will issue an interrupt. The interrupt is acknowledged by software clearing the TI1 bit.
2	0x0	UPIE: UPIE Interrupt Enable. 1 = USB controller issues an interrupt if UPA bit in USBSTS register transitions. 0 = DISABLE 1 = ENABLE
1	0x0	UAIE: UAIE Interrupt Enable. 1 = USB controller issues an interrupt if UAI bit in USBSTS register transitions. 0 = DISABLE 1 = ENABLE
0	0x0	NAKE: NAK Interrupt Enable. 1 = USB controller issues an interrupt if NAKI bit in USBSTS register transitions. 0 = DISABLE 1 = ENABLE

21.5.1.14 USB2_CONTROLLER_USB2D_USBCMD_0

USB2D USB Command Register

Offset: 130h | Read/Write: R/W | Reset: 0b000000001000000x1x11x0000000

Bit	R/W	Reset	Description
27:24	RW	0x0	HIRD: Host Initiated Resume Duration RW. Default = 0000b. This has the same behavior as bits 7:4 of BA field of HOSTPCx register. When writing to this field all BA[7:4] fields of all HOSTPCx registers will be set to this value. This field is used by system software to specify the minimum amount of time the host controller will drive the K-state during a host-initiated resume from a LPM state (e.g. L1), and is conveyed to each LPM-enabled device (via the HIRD bits within an LPM Tokens bmAttributes field) upon entry into a low-power state. Note the host controller is required to drive resume signaling for at least the amount of time specified in the HIRD value conveyed to the device during any proceeding host-initiated resume. Also note that the host controller is not required to observe this requirement during device-initiated resumes. Encoding for this field is identical to the definition for the similarly named HIRD field within an LPM Token, specifically: a value 0000b equals 50µs and each additional increment adds 75µs. For example, the value 0001b equals 125µs, and a value 1111b equals 1,175µs (~1.2ms).
23:16	RW	0x8	ITC: Interrupt Threshold Control .Read/Write. Default 08h. The system software uses this field to set the maximum rate at which the host/device controller will issue interrupts. ITC contains the maximum interrupt interval measured in micro-frames. Valid values are shown below. Value Maximum Interrupt Interval 00h Immediate (no threshold) 01h 1 micro-frame 02h 2 micro-frames 04h 4 micro-frames 08h 8 micro-frames 10h 16 micro-frames 20h 32 micro-frames 40h 64 micro-frames 0 = IMMEDIATE 2 = ONE_MF 4 = TWO_MF

Bit	R/W	Reset	Description
			8 = EIGHT_MF 16 = SIXTEEN_MF 32 = THIRTY_TWO_MF 64 = SIXTY_FOUR_MF
15	RW	0x0	FS2: Bit 2 of Frame List Size.
14	RW	0x0	ATDTW: Add DTD Tripwire. This bit is used as a semaphore when a dTD is added to an active (primed) endpoint. This bit is set and cleared by software and will be cleared by hardware when a hazard exists such that adding a dTD to a primed endpoint may go unnoticed. 0 = CLEAR 1 = SET
13	RW	0x0	SUTW: Setup Tripwire. This bit is used as a semaphore when the 8 bytes of setup data read extracted by the firmware. If the setup lockout mode is off, then there exists a hazard when new setup data arrives and firmware is copying setup data from the QH for a previous setup packet. This bit is set and cleared by software and will be cleared by hardware when a hazard exists. 0 = CLEAR 1 = SET
11	RW	0x1	ASPE: Asynchronous Schedule Park mode Enable. Software uses this bit to enable or disable Park mode. When this bit is one, Park mode is enabled. When this bit is a zero, Park mode is disabled. This field is set to "1" in this implementation. 0 = DISABLE 1 = ENABLE
9:8	RW	0x3	ASP1_ASP0: Asynchronous Schedule Park Mode Count (OPTIONAL) Read/Write. If the Asynchronous Park Capability bit in the HCCPARAMS register is a one, then this field defaults to 3h and is R/W. Otherwise it defaults to zero and is RO. It contains a count of the number of successive transactions the host controller is allowed to execute from a high-speed queue head on the Asynchronous schedule before continuing traversal of the Asynchronous schedule. Valid values are 1h to 3h. Software must not write a zero to this bit when Park Mode Enable is a one as this will result in undefined behavior. This field is set to 3h in this implementation and is Read/Write capable.
7	RO	X	LR: Light Host/Device Controller Reset (OPTIONAL) . Read Only. Not Implemented. This field will always be "0".
6	RW	0x0	IAA: Interrupt on Async Advance Doorbell. When the host controller has evicted all appropriate cached schedule states, it sets the Interrupt on Async Advance status bit in the USBSTS register. If the Interrupt on Sync Advance Enable bit in the USBINTR register is one, then the host controller will assert an interrupt at the next interrupt threshold. The host controller sets this bit to zero after it has set the Interrupt on Sync Advance status bit in the USBSTS register to one. Software should not write a one to this bit when the asynchronous schedule is inactive. Doing so will yield undefined results. This bit is only used in host mode. Writing a one to this bit when device mode is selected will have undefined results. 0 = CLEAR 1 = SET
5	RW	0x0	ASE: Asynchronous Schedule Enable. This bit controls whether the host controller skips processing the Asynchronous Schedule. 0 = Do not process the Asynchronous Schedule. 1 = Use the ASYNCLISTADDR register to access the Asynchronous Schedule. Only the host controller uses this bit. 0 = DISABLE 1 = ENABLE
4	RW	0x0	PSE: Periodic Schedule Enable.This bit controls whether the host controller skips processing the Periodic Schedule. 0 = Do not process the Periodic Schedule 1 = Use the PERIODICLISTBASE register to access the Periodic Schedule. Only the host controller uses this bit. 0 = DISABLE 1 = ENABLE
3:2	RW	0x0	FS1_FS0: Frame List Size . (Read/Write). 000 = Default This field is Read/Write only if Programmable Frame List Flag in the HCCPARAMS registers is set to one. Hence this field is Read/Write for this implementation. This field specifies the size of the frame list that controls which bits in the Frame Index Register should be used for the Frame List Current index. Note that this field is made up from USBCMD bits 15, 3 and 2. 000 = 1024 elements (4096 bytes) Default value 001 = 512 elements (2048 bytes) 010 = 256 elements (1024 bytes) 011 = 128 elements

Bit	R/W	Reset	Description
			(512 bytes) 100 = 64 elements (256 bytes) 101 = 32 elements (128 bytes) 110 = 16 elements (64 bytes) 111 = 8 elements (32 bytes) Only the host controller uses this field.
1	RW	0x0	RST: Controller Reset. Software uses this bit to reset the controller. This bit is set to zero by the Host/Device Controller when the reset process is complete. Software cannot terminate the reset process early by writing a zero to this register. Host Controller: When software writes a one to this bit, the Host Controller resets its internal pipelines, timers, counters, state machines etc. to their initial value. Any transaction currently in progress on USB is immediately terminated. A USB reset is not driven on downstream ports. Software should not set this bit to a one when the HCHalted bit in the USBSTS register is a zero. Attempting to reset an actively running host controller results in undefined behavior. Device Controller: When software writes a one to this bit, the Device Controller resets its internal pipelines, timers, counters, state machines etc. to their initial value. Any transaction currently in progress on USB is immediately terminated. Writing a one to this bit in device mode is not recommended. 0 = CLEAR 1 = SET
0	RW	0x0	RS: Run/Stop: Host Controller: When set to a 1, the Host Controller proceeds with the execution of the schedule. The Host Controller continues execution as long as this bit is set to a one. When this bit is set to 0, the Host Controller completes the current transaction on the USB and then halts. The HCHalted bit in the status register indicates when the Host Controller has finished the transaction and has entered the stopped state. Software should not write a one to this field unless the host controller is in the Halted state (i.e. HCHalted in the USBSTS register is a one). Device Controller: Writing a one to this bit will cause the device controller to enable a pull-up on D+ and initiate an attach event. This control bit is not directly connected to the pull-up enable, as the pull-up will become disabled upon transitioning into high-speed mode. Software should use this bit to prevent an attach event before the device controller has been properly initialized. Writing a 0 to this will cause a detach event. 0 = STOP 1 = RUN

21.5.1.15 USB2_CONTROLLER_USB2D_USBSTS_0

USB2D USB Status Register

Offset: 134h | Read/Write: R/W | Reset: 0b00000000000000000x1x0x0000x0000

Bit	R/W	Reset	Description
31:16	RW	0x0	PPCI: Port-n Change Detect - RW. Default = 0000h. The definition for each bit is identical to the Port Change Detect field (bit 2 of this register) except these bits are specific to a given port, where bit 16 = Port 1, 17 = Port 2, etc. For example, if bit 17 is set to a one then a port change event was detected on Port 2. The N_PORTS field in HCSPARAMS specifies how many ports are exposed by the host controller and thus how many bits in this field are valid.
15	RW	0x0	AS: Asynchronous Schedule Status. This bit reports the current real status of the Asynchronous Schedule. When set to zero the asynchronous schedule status is disabled and if set to one the status is enabled. The Host Controller is not required to immediately disable or enable the Asynchronous Schedule when software transitions the Asynchronous Schedule Enable bit in the USBCMD register. If AS = ASE: 1= Enable Asynchronous Schedule 0= Disable Asynchronous Schedule Only used by the host controller. 0 = DISABLE 1 = ENABLE
14	RW	0x0	PS: Periodic Schedule Status. This bit reports the current real status of the Periodic Schedule. When set to zero the periodic schedule is disabled, and if set to one the status is enabled. The Host Controller is not required to immediately disable or enable the Periodic Schedule when software transitions the Periodic Schedule Enable bit in the USBCMD register. If PS = PSE then: 1 = Periodic Schedule is enabled or 0 = Periodic Schedule is disabled Only used by the host controller. 0 = DISABLE 1 = ENABLE
13	RO	X	RCL: Reclamation. This is a read-only status bit used to detect an empty asynchronous schedule. Only used by the host controller. 0 = DISABLE

Bit	R/W	Reset	Description
			1 = ENABLE
12	RW	0x1	HCH: HCHalted. 1 = Default. This bit is a zero whenever the Run/Stop bit is a one. The Host Controller sets this bit to one after it has stopped executing because of the Run/Stop bit being set to 0, either by software or by the Host Controller hardware (e.g. internal error). Only used by the host controller. 0 = UNHALTED 1 = HALTED
10	RW	0x0	ULPI_INT: ULPI Interrupt. This bit is set whenever an interrupt is received from ULPI PHY. Software writes 1 to clear it. 0 = NOT_ULPI_INT 1 = ULPI_INT
8	RW	0x0	SLI: DCSuspend. When a device controller enters a suspend state from an active state, this bit will be set to a 1. The device controller clears the bit upon exiting from a suspend state. Only used by the device controller. 0 = NOTSUSPEND 1 = SUSPENDED
7	RW	0x0	SRI: SOF Received. When the device controller detects a Start Of (micro) Frame, this bit will be set to a one. When a SOF is extremely late, the device controller will automatically set this bit to indicate that an SOF was expected. Therefore, this bit will be set roughly every 1ms in device FS mode and every 125us in HS mode and will be synchronized to the actual SOF that is received. Since device controller is initialized to FS before connect, this bit Will be set at an interval of 1ms during the prelude to the connect and chirp. In host mode, this bit will be set every 125us and can be used by host controller driver as a time base. Software writes a 1 to this bit to clear it. This is a non-EHCI status bit. 0 = SOF_NOT_RCVD 1 = SOF_RCVD
