TECHNICAL REFERENCE MANUAL

NVIDIA TEGRA 4
4-PLUS-1 Quad-Core Processors

NVIDIA® Tegra® Processors: T40SW, T40X, T40S, AP40

Abstract

The Technical Reference Manual focuses on the logical structure and control of Tegra 4 (“Wayne” series) processors. It provides information for those modules that interface to external devices, or those that control fundamental chip operations. The modules detailed in this document provide an overview, any necessary programming guidelines, and a register listing for that module. Internal functional units such as video and graphics hardware acceleration are controlled by NVIDIA provided software and not documented here.

Revision History

Version	Date	Description
v01p	SEP 6, 2013	Public Release to support Open Source Development. The following section is undergoing further review and should be considered preliminary: • MIPI-DSI (Display Serial Interface)

Table of Contents

[THIS PAGE INTENTIONALLY LEFT BLANK]

1.0 INTRODUCTION

The NVIDIA® Tegra® 4 series processor is a complete applications and digital media system built around several powerful hardware elements:

- CPU Complex: Quad Cortex™-A15 Symmetric Multi-Processing ARM® Cores in a 4-PLUS-1™ configuration with a quad-core fast CPU complex and a fifth Battery Saver Core. The Cortex-A15 core features triple instruction issue and both out-of-order and speculative execution. It has full cache coherency support for the quad symmetric processors. All processors have 32 KB Instruction and 32 KB Data Level 1 caches; and there is a 2 MB shared Level 2 cache for the quad-core complex and a 512 KB Level 2 cache for the fifth core. The NVIDIA 4-PLUS-1 architecture uses the fifth Battery Saver Core, which operates exclusively with the main CPU complex, for very low-power, low-leakage operation at the light CPU loads common to multimedia and lightly loaded use situations.
- Memory Controller: dual-channel (2x 32-bit) DRAM interface providing more than twice the available bandwidth of Tegra 3 devices. LP-DDR2, LP-DDR3 and DDR3 DRAM types are all supported.
- Graphics: Ultra Low-power, high-performance NVIDIA GeForce® Graphics Processing Unit (GPU). Handles 2D graphics rendering and 3D pixel and vertex shading. Quad pixel rendering pipes are capable of fully using the enhanced bandwidth from the dual channel memory controller.
- Audio/Video Decoder: the Audio-Video Processor (AVP) subsystem includes dedicated audio and video decode hardware acceleration, an ARM7 processor, and embedded RAM. This subsystem provides full motion playback of up to 1440P high-definition video and supports H.264 BP/MP/HP/MVC, VC-1, VP8, MPEG-2 and MPEG-4 video standards and multiple audio standards with dedicated hardware.
- Video Encoder: A high performance H.264 1440P capable hardware video encoder. This processor supports H.264 BP/MP/HP/MVC and VP8 encoding.
- Imaging: A high-quality hardware accelerated still-image and video capture path supporting Bayer and YUV format sensors.
- Display: Dual display controllers with MIPI-DSI output for LCD panels up to 2540x1600 and HDMI output for external display devices up to 4096x2160. Multiple line pixel storage allows more memory efficient scaling operations and pixel fetching. Hardware display surface rotation is also provided for bandwidth reduction.

In addition to these major elements, Tegra 4 series processors have a broad range of peripheral interfaces to enable communication with wireless baseband, other communications peripherals, audio codecs, power management, and mass storage. When combined with baseband and PMIC chips, the Tegra 4 series processor provides the functionality needed to build a range of low-power devices. Dedicated high-performance mass storage controllers, with their own DMA engines, free the CPU Complex from routine data management tasks.

1.1 The Role of the Technical Reference Manual

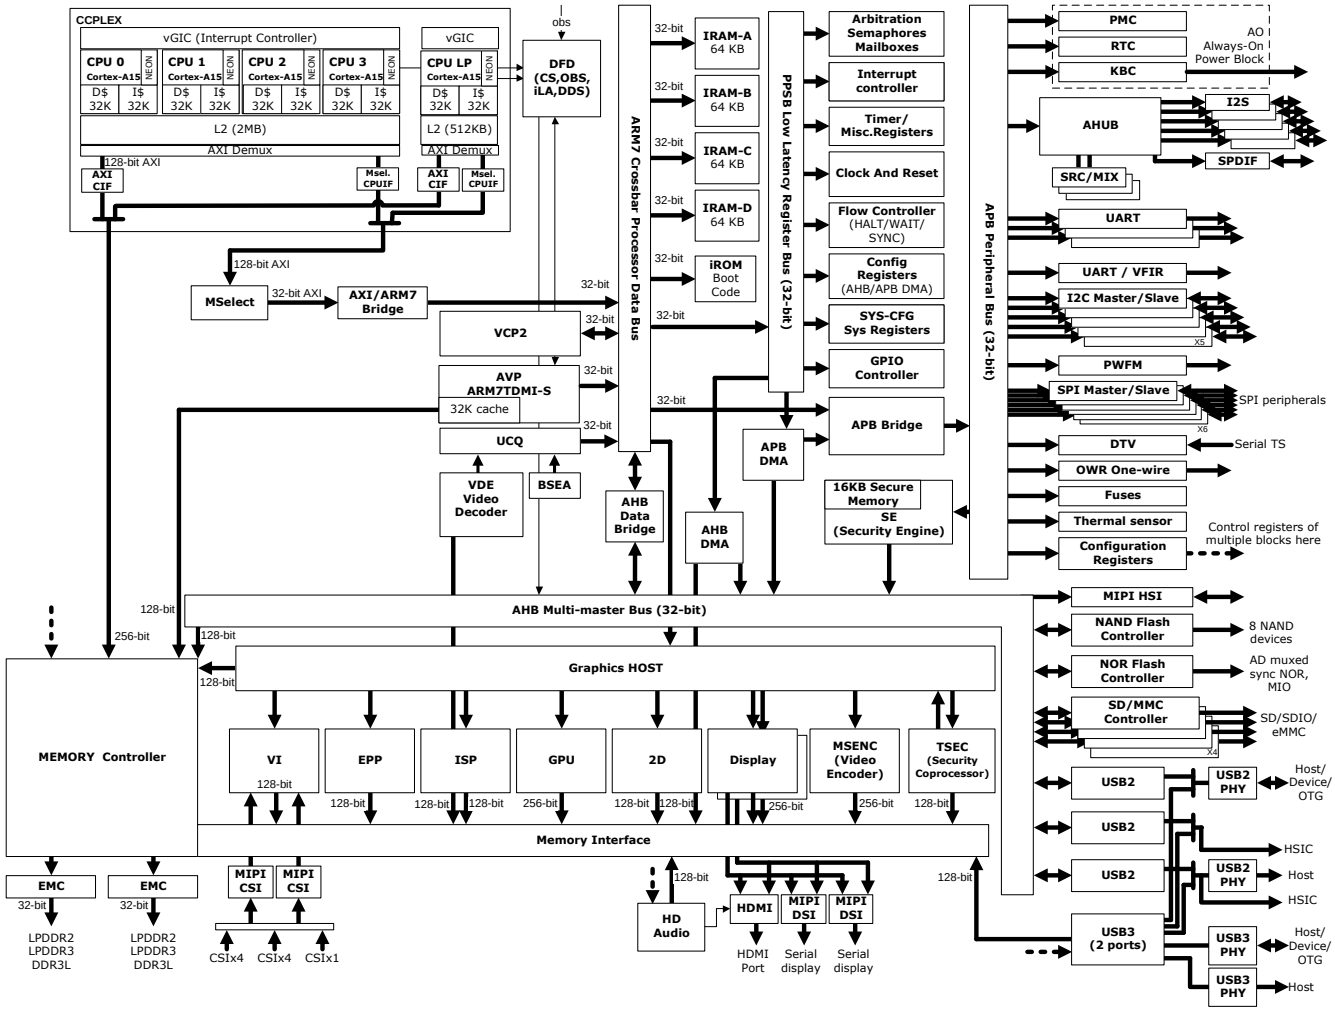
This document is intended to provide guidance to programmers writing code for Tegra 4 devices. It describes the register interfaces and hardware functionality, with the goal to aid anyone in understanding and potentially modifying the NVIDIA provided code.

Some hardware functions described here are not supported by NVIDIA; thus the description of a capability in this document does not necessarily imply software support for that function, nor does it imply that the function has been fully validated by NVIDIA.

1.2 Block Diagram

This diagram provides an overview of a Tegra 4 series processor.

Figure 1: Tegra 4 Series Processor Block Diagram



1.3 Memory Controller and Internal Bus Architecture

The Tegra 4 series processor has a highly optimized dual-channel memory controller, supporting low latency access for the CPU, optimized high bandwidth access for the graphics and video devices, and controlled latency for real time devices such as display.

There is a three-level hierarchy of memory clients:

1. Memory controller clients: The memory controller directly arbitrates between these using a complex algorithm optimizing DRAM efficiency. The highest bandwidth clients all fall into this class, and they communicate directly with the memory controller using a proprietary high-speed bus.
2. AHB devices: These generally have a built-in DMA engine, and share a single memory client using the AHB bus protocol.
3. APB devices: All APB devices are slaves, and are serviced by a shared multi-channel APB DMA controller which is also an APB device.

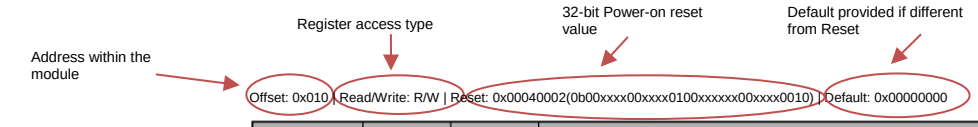
Special provisions are made for the CPU to bypass parts of the memory controller arbitration to help achieve a lower latency.

1.4 Reading Register Tables

Every register table has an address line followed by a table containing the bit descriptions for that register. The address line contains:

- **Offset:** the address of the register within the specific module. Refer to the system memory map for the start address of the module, and apply the offset at the top of the table to get the register address.
- **Read/Write:** the register access type. When a register table contains the R/W column, individual bits within the register will have different R/W properties. When there is no R/W column, all bits in that register have the same R/W property.
- **Reset:** gives the power-on reset value in 32-bit binary. A value of x implies that the register bit has an undefined value at reset. A hexadecimal value is listed for convenience, where appropriate.
- **Default:** only displayed if the default setting is different from the Reset value.

Unspecified bits may not appear in tables (see example below). Unspecified bits should be written with their Reset values, while reads return an unknown value.



Unspecified bits in this example register: 31:26, 23:20, 15:10, 7:4

In the Reset field above the table, most unspecified bits are shown as 'x' in binary format. In hex format, unspecified bits within nibbles are shown as 0 in the Reset field above the table.

At power-on reset, write only the provided reset value to unspecified bits for proper operation. For example, in the Reset field above the table, bits [31:30], which are not specified in the table, must be written as 0s.

Bit	R/W	Reset	Description
25:24	RW	N1	EMEM_NUMDEV 0 = N1 1 = N2
19:16	RO	D64MB	EMEM_DEVSIZE 0 = D4 MB 1 = D8 MB 2 = D16 MB 3 = D32 MB 4 = D64 MB 5 = D128 MB 6 = D256 MB 7 = D512 MB
9:8	RW	W2	EMEM_BANKWIDTH 1 = W1 2 = W2 3 = W3
3:0	RO	W9	EMEM_COLWIDTH 0 = W7 1 = W8 2 = W9 3 = W10 4 = W11

1.5 Glossary

This glossary is intended to cover the Tegra specific acronyms used in this document; along with some others related to the ARM SOC world. Many acronyms in this document are in broad engineering use and are not documented here; we assume you already know what USB and CPU are, for example.

Term	Definition
ADX	Audio Demultiplexer Block, part of the Audio Hub used to demultiplex multiple audio streams.
AHB	AMBA® High-Speed Bus, a multi-master high-speed (relative to APB) bus supporting arbitration and split transactions, defined as part of AMBA 2.
AHBSLVMEM	The AHB slave used for the main memory interface. Acts as an AHB slave and provides a path from there to main memory. Refer to the AHB section.
AMBA	Advanced Microcontroller Bus Architecture, a set of standard buses defined by ARM.
AMX	Audio Multiplexer Block, part of the Audio Hub used to multiplex multiple audio streams together.
APB	AMBA Peripheral Bus, a simple 32-bit single master bus for peripheral devices.
APBDMA	A multi-channel DMA controller for devices on the APB bus, performing DMA between APB and AHB.
ARM	Advanced RISC Machines, a company that licenses CPU IP to Tegra. Also: Architecture Reference Manual, so the ARM ARM defines the CPU architecture.
AVP	Audio-Video Processor, the term used both to describe the ARM7 processor in Tegra devices, and to describe the broader audio and video decode acceleration hardware and RAM associated with the ARM7. Note that the AVP is sometimes known as COP in legacy documentation and registers.
AXI	AMBA Advanced eXtensible Interface, a more advanced bus than AHB defined as part of AMBA 3.
BSEA	Bit Stream Engine for Audio applications
CAR	Clock and Reset module allows controlling clocks and resets to all the modules and subsystems in the Tegra processor.
CEC	Consumer Electronics Control, a part of the HDMI interface specification used for sending device control commands, often from a remote control.
COP	CO-Processor, an obsolete name for the AVP still present in legacy documentation and registers.
CSI	MIPI Camera Serial Interface, a standard high-speed serial interface for connecting cameras to the Tegra processor.
DAM	Digital Audio sample-rate conversion and Mixing block, a block within the Audio Hub that performs audio mixing and sample rate conversion
DSI	MIPI Display Serial Interface, a standard high-speed serial interface for connecting displays to the Tegra processor.
DTV	Digital TV input block, used to stream a serial TV transport stream of compressed data into Tegra, using an SPI like protocol.
DVC	Dynamic Voltage Controller module
EMC	External Memory Controller, a module that interfaces with external DDR/LPDDR devices.
EPP	The video Encoder Pre-Processor, on the Tegra processor capable of filtering, color-space conversion, rotation and pixel format conversion.
GART	Graphic Address Relocation Table, a now obsolete mechanism for mapping from virtual to physical addresses for devices. Remains in Tegra only as an aperture to memory that may be mapped though the SMMU, the replacement for the GART.
GPIO	General Purpose Input/Output, an I/O signal uncommitted to a specific role and controlled by software.
GR2D	2D graphics engine, capable of scaling, filtering and rotating pixel blocks.
HDMI	High-Definition Multimedia Interface, a digital connection carrying uncompressed video and audio at high speed over a single connector.

Term	Definition
HSI	MIPI High-Speed Synchronous Interface, a standard high-speed serial interface for bi-directional communications with baseband processors and other devices.
IDE	Integrated Drive Electronics (or Integrated Device Electronics)
ISP	Image Signal Processor, a hardware engine that is part of the camera processing pipeline.
KBC	Keyboard Controller module allows the Tegra processor to be connected to keyboard matrices of sizes up to 11x8.
MC	Memory Controller module handles requests from internal clients and arbitrates among them to allocate memory bandwidth.
MCCIF or MC-CIF	Memory Controller Client InterFace, the standard interface block between the memory controller sub-system fabric and the client device. Note that some modules may have multiple client interfaces.
MIPI	The Mobile Industry Processor Interface and industry alliance promoting a number of standard interfaces for mobile devices.
MPCore	Multi-processor CPU core, a generic term for a CPU capable of operating as part of an SMP group.
MPE	An older name for the Video Encoder in the Tegra processor capable of encoding raw video stream into MPEG. Now referred to as MSENC.
MSENC	Multi-Standard video Encoder engine.
NAND	A type of flash memory supporting high densities, and commonly used for non-volatile mass storage in portable devices. Accessed in sequential blocks to be generally treated as a file system.
NOR	A type of flash memory, with a direct bus interface that allows random access so code can be executed in place. Generally more costly and less dense than NAND flash memory.
OGL	Open Graphics Library, also known as OpenGL. An API supported on Tegra devices and accelerated in hardware by dedicated 3D and 2D engines.
PCIE	Peripheral Component Interconnect Express, a high-speed interface for external devices connected to the Tegra SOC.
PMC	Power Management Controller module controls the various power management features in the system.
PPSB	PortalPlayer System Bus, a proprietary register bus used for some blocks. Similar to APB. PortalPlayer is a company that was acquired by NVIDIA, and from where parts of Tegra are derived including this bus.
PWFM	Pulse Width Frequency Modulation module generates programmed pulse widths typically used to control backlight in display panels.
PVT	Process, Voltage & Temperature
RISC	Reduced Instruction Set Computer, the CPU architecture used by ARM CPUs.
SDMMC	SD and MMC controller. An I/O controller supporting
SLINK	Serial Link, a legacy and now obsolete name for the SPI controller
SMMU	System Memory Management Unit, a block within the memory controller used to map from a virtual address space to physical addresses for device DMA.
SMP	Symmetric Multi-Processing
SOC	System On a Chip, an integrated circuit containing a CPU, memory controller and the peripheral devices needed for a computing system.
S/PDIF	Sony/Philips Digital Interconnect Format
SPI	Serial Peripheral Interface Bus, a synchronous serial data link, that operates in full duplex mode.
TSEC	Tegra Security co-processor, an embedded security processor used mainly to manage the HDCP encryption and keys on the HDMI link.
TZ	Trust Zone, a secure operating environment of the ARM CPU and the related secure parts of the SOC backbone and devices
TZRAM	Trust Zone secured RAM on the SOC.
UCQ	Unified Command Queue – a sub module within Video Decoder Engine

Term	Definition
VCP2	Vector Co-Processor version 2, a hardware acceleration block for the signal processing parts of audio decode and filtering. Use to offload the ARM7 AVP during audio playback.
VDE	Video Decode Engine, a Tegra hardware acceleration block dedicated to decoding compressed video in various formats.
VI	Video Input block, the acronym used to describe the Tegra block used for camera and related input functions.

2.2 Available DRAM Address Ranges

Table 2 describes the various address regions that are available as DRAM in Tegra 4 devices.

The address map available varies by master, because MMIO is not available to any direct MC client except the processors. These other direct MC clients are therefore able to access all of the DRAM on 4GB systems, with the spaces reserved for MMIO on the processors available to them as DRAM. This may be used as a carve-out or for similar purposes.

Clients/Controllers are logically (static) grouped in different SWNAME/SWID. SMMU translation can be enabled/disabled for individual SWNAME. Table 3 gives the Client to SW Name mapping details.

Note: MMIO in Table 2 below refers to the MMIO target, register, or non-DRAM region. Not all of the MMIO regions actually have an MMIO target.
Physical/Virtual Address Range is available for Host1X clients for all apertures.

Table 2: DRAM Address Ranges

Aperture	Range	Size (MB)	H/W Config Option	Recommended Config Value	Physical DRAM Range			IOVA Range[1]
					2 GB	3GB	4 GB	
T35_IROM,HiVEC	FFF0_FFFF - FFFF_FFFF	1	Selectable	MMIO	No	No	No	No
DRAM	8000_0000 - FFEF_FFFF	2047	Always DRAM	N/A	Yes	Yes	Yes	Yes
AHB_A2_rsvd	7E00_0000 - 7FFF_FFFF	32	Selectable	DRAM	No	No	Yes	Yes
AHB_A2	7C00_0000 - 7DFF_FFFF	32	Always MMIO	N/A	No	No	No	No
AHB_A1_rsvd	7900_0000 - 7BFF_FFFF	48	Selectable	DRAM	No	No	Yes	Yes
AHB_A1	7800_0000 - 78FF_FFFF	16	Selectable	MMIO	No	No	No	No
APB_rsvd	7100_0000 - 77FF_FFFF	112	Selectable	DRAM	No	No	Yes	Yes
APB	7000_0000 - 70FF_FFFF	16	Always MMIO	N/A	No	No	No	No
ExtIO_rsvd	6900_0000 - 6FFF_FFFF	112	Selectable	DRAM	No	No	Yes	Yes
ExtIO	6800_0000 - 68FF_FFFF	16	Always MMIO	N/A	No	No	No	No
PPSB_rsvd	6100_0000 - 67FF_FFFF	112	Selectable	DRAM	No	No	Yes	Yes
PPSB	6000_0000 - 60FF_FFFF	16	Always MMIO	N/A	No	No	No	No
GART/GPU_GART	5700_0000 - 5FFF_FFFF	144	Selectable	DRAM	No	No	Yes	Yes
Graphics Host rsvd (HOST1X_DR_RSVD)	5500_0000 - 56FF_FFFF	32	Selectable	DRAM	No	No	Yes	Yes
Graphics Host (HOST1X_DR)	5400_0000 - 54FF_FFFF	16	Always MMIO	N/A	No	No	No	No
Verif Aper + Rsvd	5100_0000 - 53FF_FFFF	48	Selectable	DRAM	No	No	Yes	Yes
Host1x+PERIPH	5000_0000 - 50FF_FFFF	16	Always MMIO	N/A	No	No	No	No
NOR_A3	4B00_0000 - 4FFF_FFFF	80	Selectable	DRAM	No	No	Yes	Yes
NOR_A2	4900_0000 - 4AFF_FFFF	32	Selectable	DRAM	No	No	Yes	Yes
NOR_A1	4800_0000 - 48FF_FFFF	16	Selectable	DRAM	No	No	Yes	Yes
IRAM_rsvd	4100_0000 - 47FF_FFFF	112	Selectable	DRAM	No	No	Yes	Yes
IRAM	4000_0000 - 40FF_FFFF	16	Always MMIO	N/A	No	No	No	No
PCIE_A3	1000_0000 - 3FFF_FFFF	768	Selectable	DRAM	No	Yes	Yes	Yes
PCIE_A2	0200_0000 - 0FFF_FFFF	224	Selectable	DRAM	No	Yes	Yes	Yes
PCIE_A1	0100_0000 - 01FF_FFFF	16	Selectable	DRAM	No	Yes	Yes	Yes
T40_IROM,LoVEC	0000_0000 - 00FF_FFFF	16	Selectable	MMIO	No	No	No	No

Notes:

[1] The IOVA Range column is available for AVP or AHB clients that have SMMU translation enabled or PA address for AHB clients that have SMMU translation disabled.

Note: Requests from all clients (except main CPU) are allowed to use SMMU translation. Any request address range that can reach the MC can be translated by the SMMU.
SMMU is a sub-unit in the memory controller. Address ranges marked as "No" in table would not reach the memory controller.
All Host1x clients can see the full 4GB physical or IOVA range

Table 3: Client to SW Name Mapping

SW Group	Client	Description
AVPC	AVP Cache	ARM7 Audio-Video Processor (AVP)
DC	Display head 0	Display reads, head 0
DCB	Display head 1	Display reads, head 1
VDE	VDE	Video Decode Engine
MSENC	MSENC	Multi Standard Video Encoder
G2	GR2D	2D engine
HC	Host1x	Host interface
HDA	HDA	High-definition Audio engine
VI	VI	Video Input engine for CSI
ISP	ISPW	ISP
EPP	EPP	EPP Engine
MPCORE	AXICIF	Eagle CPU cores
MPCORELP	AXICIF_LP	Eagle Shadow CPU core
NV	3D engine	3D Engine
PPCS	AHBDMA, AHBSLV	Clients in the AHB cluster (ppcs2mc_swid=1'b0)
PPCS1	AHBDMA, AHBSLV	Same as PPCS, ppcs2mc_swid=1'b0)
PTC	MC (SMMU)	Misses from SMMU PTC
XUSB_HOST	USB3 Host	Although the same driver is expected to control both units, each has its own SWNAME
XUSB_DEV	USB3 device	
TSEC	TSEC	Tegra Security co-processor

Note: Requests from all clients (except main CPU) are allowed to use SMMU translation. Any request address range that can reach the MC can be translated by the SMMU.

The clients behind AHBSLV in the above table are:

- SDMMC
- USB1/2/3
- BSEA
- DDS
- SE
- BSEV
- NOR
- NAND
- AHBDMA
- ARC
- CORESIGHT
- VCP
- COP
- CPU

- APBDMA clients, which are also behind AHBSLVMEM (APBDMA_Ch{0-31})

Each client in the above list has a SWID register field which controls whether the client maps to PPCS or PPCS1 SWNAME.

2.3 Interrupt Mapping

The next five tables show the mapping of the interrupts from system devices to the bit fields in the interrupt controllers.

Interrupts to the CPU's embedded interrupt controller (GIC) are in this same order, but start at offset 32 as the first 32 are reserved for the CPU's internal interrupts. See the Interrupt Controller section of this document for more information on how interrupts are routed.

Table 4: Primary Interrupt Controller Mapping

Global Interrupt Number	Interrupt Target	Legacy Interrupt Controller (LIC) Name	LIC Interrupt Number	Interrupt Name	Source Block	Interrupt Description	Interrupt Order
31		PRI_ICTLR	31	SDMMC4	SDMMC	SDMMC4 Controller	0
30		PRI_ICTLR	30	OWR	OWR	OWR Interrupt	0
29	CPU	PRI_ICTLR	29	ARB_SEM_GNT_CPU	Semaphore	GNT.0 Arbitration Grant Status of CPU	0
28	COP	PRI_ICTLR	28	ARB_SEM_GNT_COP	Semaphore	GNT.1 Arbitration Grant Status of COP	0
27	CPU	PRI_ICTLR	27	AHB_DMA_CPU	APB_DMA	AHB DMA Controller (CPU)	0
26	CPU	PRI_ICTLR	26	APB_DMA_CPU	APB_DMA	APB Bridge DMA Controller (CPU)	0
25		PRI_ICTLR	25	VCP	VCP	VCP	0
24		PRI_ICTLR	24	NANDCTRL	NANDCTRL	NAND Flash Controller	0
23		PRI_ICTLR	23	SATA_CTL	SATA	SATA Controller Interrupt	0
22		PRI_ICTLR	22	Currently Unmapped		Currently Unassigned	0
21		PRI_ICTLR	21	USB2	USB	USB Device	0
20		PRI_ICTLR	20	USB	USB	USB Device	0
19		PRI_ICTLR	19	SDMMC3	SDMMC	SDMMC3 Controller	0
18		PRI_ICTLR	18	AVP_UCQ	AVP_UCQ	AVP UCQ Interrupt	0
17		PRI_ICTLR	17	VDE	VDE	VDE Interrupt	0
16		PRI_ICTLR	16	Currently Unmapped		Currently Unassigned	0
15		PRI_ICTLR	15	SDMMC2	SDMMC	SDMMC2 Controller	0
14		PRI_ICTLR	14	SDMMC1	SDMMC	SDMMC1 Controller	0
13		PRI_ICTLR	13	SATA_RX_STAT	SATA	SATA RX Wake-Up Interrupt	1
12		PRI_ICTLR	12	VDE_SXE	VDE	VDE SXE Interrupt	3
11		PRI_ICTLR	11	VDE_BSEA	VDE	AVP BSEA Interrupt	0
10		PRI_ICTLR	10	VDE_BSEV	VDE	VDE BSE-V Interrupt	1
9		PRI_ICTLR	9	VDE_SYNC_TOKEN	VDE	VDE Sync Token Interrupt	0
8		PRI_ICTLR	8	VDE_UCQ	VDE	VDE UCQ Error Interrupt	4
7	CPU	PRI_ICTLR	7	SHR_SEM_OUTBOX_ EMPTY	Semaphore	CPU Out Box Empty Interrupt	3
6	COP	PRI_ICTLR	6	SHR_SEM_OUTBOX_FULL	Semaphore	COP Out Box Full Interrupt	2
5	COP	PRI_ICTLR	5	SHR_SEM_INBOX_EMPTY	Semaphore	COP In Box Empty Interrupt	1
4	CPU	PRI_ICTLR	4	SHR_SEM_INBOX_FULL	Semaphore	CPU In Box Full Interrupt	0
3		PRI_ICTLR	3	CEC	CEC	CEC General Interrupt	0
2		PRI_ICTLR	2	RTC	RTC	RTC Interrupt	0
1		PRI_ICTLR	1	TMR2	Timer	TMR2 Interrupt	0
0		PRI_ICTLR	0	TMR1	Timer	TMR1 Interrupt	0

Table 5: Secondary Interrupt Controller Mapping

Global Interrupt Number	Interrupt Target	Legacy Interrupt Controller (LIC) Name	LIC Interrupt Number	Interrupt Name	Source Block	Interrupt Description	Interrupt Order
63		SEC_ICTLR	31	Currently Unmapped		Currently Unassigned	0
62		SEC_ICTLR	30	CLDVFS	CL-DVFS	Close Loop DVFS control logic	0

3.0 INTERRUPT CONTROLLER

This section describes the architecture for routing and handling of the Tegra® 4 family processor interrupts. It also describes semaphores, which provide a mechanism for the processors to arbitrate for the use of various resources.

From the perspective of interrupts: devices (GPU, Memory Controller, Video encode/decode engines, and various I/O devices) are the sources of interrupts; and processors are the target of interrupts. From sources, interrupts go to interrupt controllers which, based on configuration, prioritize and route them to appropriate target processor. There are two different types of interrupt controllers used in Tegra, the ARM® vGIC in the main CPU complex and the Legacy Interrupt Controller (LIC), which is used for the AVP and also to control wake events for the CPU.

Glossary and Acronyms

Acronym	Description
GIC	Generic Interrupt Controller (also known as GICv1, part of Cortex™-A15 MPCore™)
vGIC	Virtual GIC (also known as GICv2, part of Cortex-A15 MPCore)
LIC	Legacy Interrupt Controller (used for the ARM7 AVP)
WFI	Wait For Interrupt (an ARM instruction)
WFE	Wait For Event (an ARM instruction)
IRQ	Interrupt Request
FIQ	Fast Interrupt Request
IPI	Inter Processor Interrupt
SGI	Software Generated Interrupt
PPI	Private Peripheral Interrupts
SPI	Shared Peripheral Interrupts
SMP	Symmetric MultiProcessors
MSI	Message Signaled Interrupt
CPU	Unless specified otherwise, it refers to main (Cortex-A15) CPUs
COP	Refers to ARM7 AVP

3.1 Functional Description

3.1.1 Interrupt Handling Mechanism

There are two different types of interrupt controllers (vGIC, LIC) which receive interrupts from devices (i.e. hardware interrupts aka SPIs) or processors (i.e., software interrupts including IPI , also known as SGIs), arbitrate them and send them to appropriate target processor(s). From interrupts perspective, there are two different types of processors: CPUs (Cortex™A15), and COP (ARM7 AVP). The vGIC is the interrupt controller for the Cortex-A15 CPUs, and the LIC is for the ARM7 AVP. Any processor can initiate a software interrupt, targeted to any one or more processors (including self). However, IPIs can only be initiated by a Cortex-A15 CPU to any one or more Cortex-A15 CPUs (including self).

There are a total of 160 hardware interrupts in Tegra 4 devices. Interrupt sources are allocated one or more interrupt as required. The 160 interrupts are grouped into slices of 32, where each slice can be configured independently.

3.1.1.1 ARM Processors' IRQ and FIQ

ARM processors (Cortex-A15 and ARM7) have two input pins to receive two different types of interrupts. These interrupts are called IRQ (Interrupt Request) and FIQ (Fast Interrupt Request). The interrupts are implemented as active-low pins on the ARM processor input, thus processor pins are named nIRQ and nFIQ.

The ARM processor goes into the IRQ mode or the FIQ mode depending up on which interrupt is activated. Conventionally, FIQ is used as secure interrupt (although either IRQ or FIQ can be configured as secure interrupt). As a result, non-secure interrupts are normally IRQ only. FIQ is relatively low latency interrupt, so interrupts which require low latency, or are time critical, can potentially be configured as FIQ.

3.1.1.2 Interrupt Controllers

The interrupt controller receives interrupts from large number of sources. The interrupt sources can be assigned a target-processor, a type (IRQ vs FIQ), priority levels, et cetera, by configuring interrupt-controller registers. The interrupt controller arbitrates among different incoming interrupts and sends the interrupt to the nIRQ or nFIQ pin of targeted processor.

In general, any of incoming hardware interrupt can be routed to either nIRQ or nFIQ pin of any of the processor.

The LIC (Legacy Interrupt Controller) is primarily used for COP (ARM7). But it is also used for generating interrupt as wake events for CPUs when vGIC is powered off. All of the device hardware interrupt signals are sent to the LIC first, which routes them to COP as well as forwards them to other interrupt controllers. The LIC also provides a software set/clear mechanism for all of the interrupts.

The interrupt controller used for CPUs (Cortex-A15) is called vGIC (virtual generic interrupt controller). The vGIC is SMP interrupt controller. It receives interrupts targeted to any one or more of the CPUs in the SMP complex. Similar to Tegra 3 which had one GIC per CPU cluster, there is one vGIC per CPU cluster.

3.1.1.3 vGIC Interrupt Sources

The vGIC can support up to 256 interrupts. All interrupts are identified by a unique ID. There are three types of interrupt sources vGIC.

Software Generated Interrupts (SGIs)

These are software interrupts which are generated by writing to GIC (or vGIC) register. A maximum of 16 SGIs, with ID0-15, can be generated by software. These are also referred to as IPI (Inter Processor Interrupts).

Private Peripheral Interrupts (PPIs)

These are interrupts generated by a peripheral that is specific to a single processor.

There were five possible PPIs for each Cortex-A9 processor: global timer (ID27), legacy nFIQ (ID28), private timer interrupt (ID29), watchdog timer interrupt (ID30), and legacy nIRQ (ID31).

There are seven PPIs for each Cortex-A15 processor: virtual maintenance interrupt (ID25), hypervisor timer interrupt (ID26), virtual timer interrupt (ID27), legacy nFIQ (ID28), secure physical timer interrupt (ID29), non-secure physical timer interrupt (ID30), legacy nIRQ (ID31).

Tegra 4 devices do not use legacy nFIQ/nIRQ of vGIC or GIC.

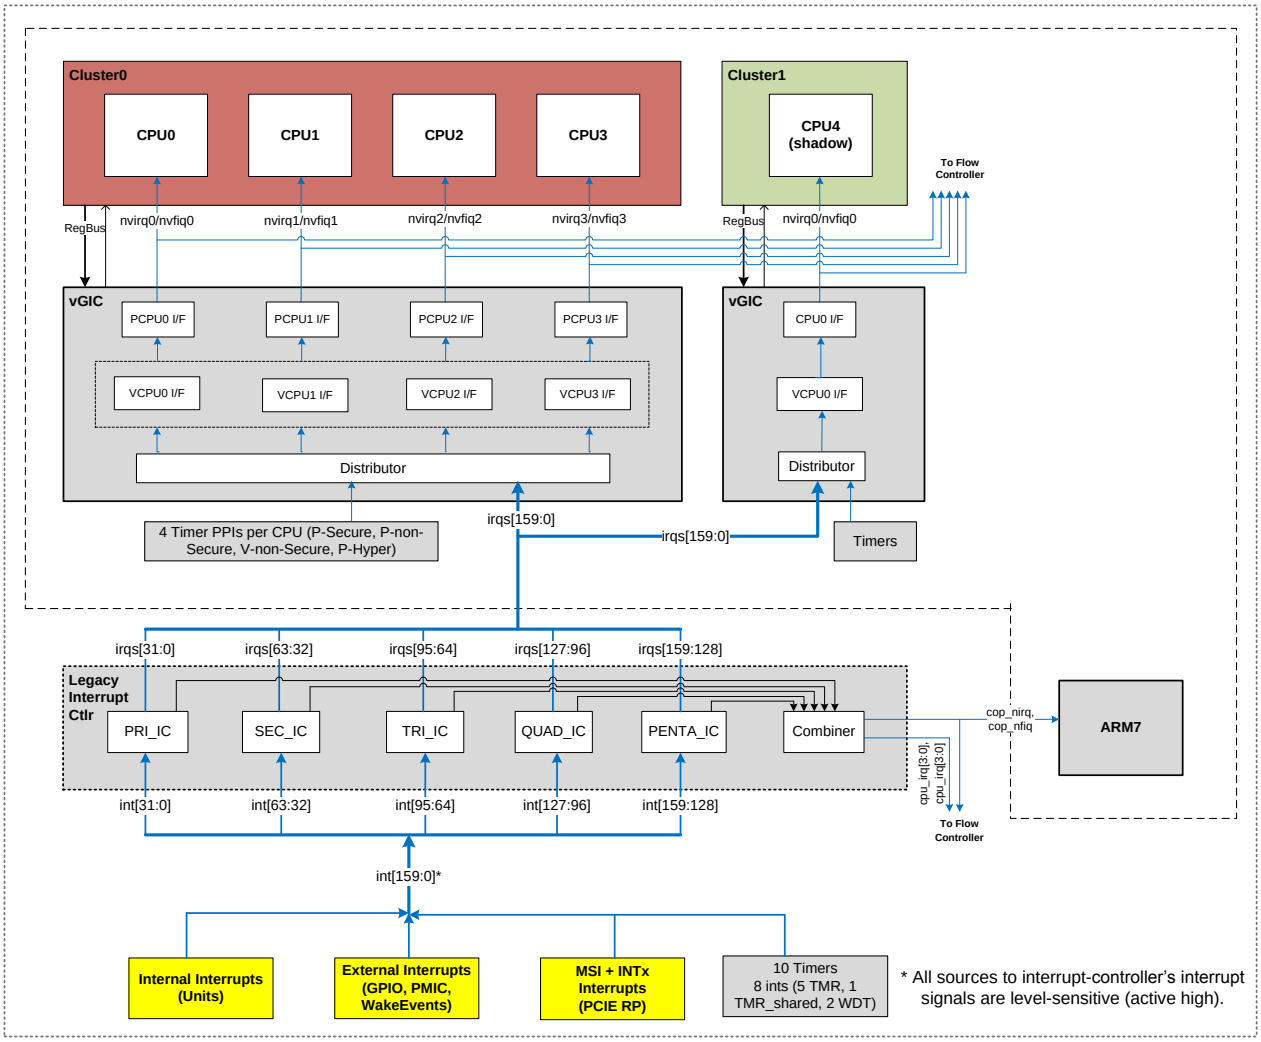
Shared Peripheral Interrupts (SPIs)

SPIs are external hardware interrupts which are generated by asserting signals on vGIC input pins (called IRQS). From Tegra hardware perspective, these are the interrupts which are generated by various units to be sent to interrupt controllers. There can be a maximum of 224 SPIs generated through IRQS[223:0] pins. However, Tegra 4 devices use only 160.

3.1.1.4 Interrupt Routing

Tegra hardware interrupts (also known as Shared Peripheral Interrupts) can be generated either by Internal SoC units, or external events (through GPIO, USB. etc.). All of these hardware interrupts are routed through sideband active-high level-sensitive signals to LIC. Devices which natively generate MSIs are converted by their bus wrappers to sideband interrupt signals.

Figure 2: Interrupt Routing (Top-Level View)



As shown in the figure above, hardware interrupts are routed to the interrupt controllers (called IC32) within LIC, where each IC32 handles 32 interrupts. The interrupt signals are synchronized within LIC to the system clock. The synchronized signals are combined with software set/clear bits per interrupt. This allows software to set or clear individual interrupts, provided the corresponding interrupt is not asserted by hardware. The resulting interrupt signals are broadcast to LIC, for further processing, and vGIC. Within LIC, and vGIC. per interrupt and per CPU enable-masks are configured to qualify the interrupts targeted for the corresponding processor. This mechanism allows any interrupt to be targeted to any one or more processors in Tegra 4 devices.

For the details of interrupt handling within LIC and vGIC, refer to the following sections.

3.1.1.5 Interrupt Handling with Targeted CPU and vGIC Powered Off

When a CPU and associated vGIC are powered off (e.g., CPU rail is powered off for cluster0), then the legacy-interrupt-controller is configured to act as a "proxy" interrupt controller to generate IRQ/FIQ for that CPU. Also, Tegra timers (instead of vGIC timers) will have to be set up if a timer interrupt is required. The flow-controller uses legacy interrupt controller IRQ/FIQ to power-up targeted CPU (and vGIC).

Following sequence describes the steps to follow to be able to handle interrupts when CPU and vGIC are powered off:

- [SW-CPU] Prepare CPU (including vGIC) for power off

    - Flush caches and save context
    - Setup Tegra timer (if required)
    - Configure corresponding legacy-interrupt controller
    - Configure flow-controller for interrupt (from flow-controller) wake-up event
    - Trigger power-off by WFI/WFE instruction
- [HW-Flow] Power off CPU with the help of PMC
- [HW-Flow] Wait for wake-up interrupt (from legacy-interrupt-controller)
- [HW-Flow] At interrupt assertion, power up CPU with the help of PMC
- [SW-CPU] Restore the context (including vGIC context)
- [SW-CPU] CPU receives the interrupt and jumps to interrupt handler

Since Tegra interrupts are level-triggered, the interrupt that triggered the wake-up is still asserted and is now visible to vGIC. vGIC will process the interrupt and send it to CPU.

3.1.1.6 Interrupt Handling with Targeted CPU Powered Off

Each CPU can be individually powered off while corresponding vGIC is powered on. In this case, the flow controller uses vGIC interrupts to wake up the CPU. Note, this allows vGIC timers, and IPI interrupts to be used as wake events.

Following sequence describes the steps to follow to be able to handle interrupts when targeted CPU is powered off:

- [SW-CPU] Prepare CPU for power off
    - Flush caches and save context
    - Configure flow-controller for interrupt (from vGIC) wake-up event
    - Trigger power-off by WFI/WFE instruction
- [HW-Flow] Power off CPU with the help of PMC
- [HW-Flow] Wait for wake-up interrupt (from vGIC)
- [HW-Flow] At interrupt assertion, power up CPU with the help of PMC
- [SW-CPU] Restore the context
- [SW-CPU] CPU receives the interrupt and jumps to interrupt handler

Note that since the vGIC IRQ/FIQ are level-triggered, the interrupt which triggered the wake-up is still asserted.

3.1.2 Virtual Generic Interrupt Controller (vGIC)

This section provides brief description of Cortex-A15 vGIC (also known as GICv2). Also, it assumes that you are aware of GIC also known as GICv1 (see previous section for Cortex-A9 GIC description). For more details of vGIC, refer to Cortex-A15 TRM (for vGIC implementation specific spec) and/or vGIC architectural spec.

Similar to GIC, vGIC consists of the physical CPU interface and the physical distributor. In addition, to support CPU virtualization it consists of an entirely new component (the virtual CPU Interface) to be configured by the Hypervisor and used by the VM (virtual machine).

By default, the vGIC is configured to behave as GIC. In systems without a hypervisor, vGIC functionality is not expected to be used beyond GIC.

3.1.2.1 Functional Description

IRQ and FIQ Bypass Disable

Prior to powering off a CPU (e.g., in LP2 entry), its IRQ/FIQ needs to be disabled at vGIC CPU-interface. At the same time, vGIC has to generate IRQ/FIQ equivalent interrupts for CPU wake purpose. In GICv1, IRQ/FIQ interrupt lines going to CPU are same lines which are also used for wake-interrupt. Therefore, we cannot disable the vGIC CPU interface if we need to use same IRQ/FIQ for CPU wake purposes. This effectively means that IRQ/FIQ to CPU cannot be disabled, which creates a race condition for CPU power off entry. Also, in GICv1, disabling GICv1 CPU-interface puts GICv1 into bypass mode such that incoming (from SoC to GICv1) legacy IRQ/FIQ interrupts are sent to CPU when GICv1 is disabled (also known as bypassed), which means disabling GIC CPU-interface doesn't really disable IRQ/FIQ to CPU.

To fix above race issue, vGIC (GICv2) provides a wake IRQ/FIQ (for wake-event purpose), which are not disabled by GIC CPU-interface disable. Also, vGIC supports disabling of the CPU from it respective IRQ/FIQ interrupt lines, while still providing GIC-generated IRQ and FIQ functionality as wakeup events to SoC (system power controller). This is done by adding a bypass override capability when the interrupts are disabled at the CPU Interface. To support this, four register control bits are added to the Physical CPU Interface Control Register (also known as GICC_CTLR in GICv2 and ICDDCR in GICv1). Since the VCPUIF is not involved in power-management, these bits do not exist in the VCPU interface.

Table 10: CPU Interface Control Register (GICC_CTLR) – Secure View

Bit Field Name	Bit	Description
EOImodeNS	10	Unrelated to bypass disable (used when interrupts are virtualized).
EOImode	9	Unrelated to bypass disable (used when interrupts are virtualized).
IRQBypDisNS	8	When the CPU Interface is disabled, prevents the legacy bypass IRQ signal being forwarded to the CPU (if IRQs are under Non-secure control).
FIQBypDisNS	7	When the CPU Interface is disabled, prevents the legacy bypass FIQ signal being forwarded to the CPU (if FIQs are under Non-secure control).
IRQBypDisable	6	When the CPU Interface is disabled, prevents the legacy bypass IRQ signal being forwarded to the CPU (if IRQs are under Secure control).
FIQBypDisable	5	When the CPU Interface is disabled, prevents the legacy bypass FIQ signal being forwarded to the CPU (if FIQs are under Secure control).
Various	4:2	Reserved. Same as GICv1.
Enable Non-secure	1	Same as GICv1 0 = disables all Non-secure interrupts control bits in the distributor from changing state because of any external stimulus change that occurs on the corresponding **SPI** or **PPI** signals 1 = enables the distributor to update register locations for Non-secure interrupts
Enable secure	0	Same as GICv1 0 = disables all Secure interrupt control bits in the distributor from changing state because of any external stimulus change that occurs on the corresponding **SPI** or **PPI** signals. 1 = enables the distributor to update register locations for Secure interrupts.

In GICv1 (i.e., in Tegra 3), GIC CPU Interface Control Register is programmed to 0x0 (secure view) to disable the GIC CPU interface. In GICv2, GIC CPU Interface Control Register needs to be programmed to 0x1E0 (secure view) to disable GIC CPU-interface. Depending upon FIQ/IRQ being secure or non-secure, this programming can be different.

Note: Non-secure banked version of above register does not have bits<8:7>. For more details, refer to "IRQ and FIQ bypass disable functionality" in the vGIC specification.

Split EOI Functionality

Within GICv1, every interrupt has a priority, and any interrupt being active will prevent another interrupt of equal (or lower) priority being asserted to the CPU. This causes problems for virtualization where there is not necessarily any well-defined priority for interrupts between the various VMs. To address this problem the functionality associated with EOI is divided into two distinct functions – "Priority Drop" to be used after the interrupt is acknowledged to drop the running priority of the CPU

back down but leave the interrupt in the ACTIVE state, and “Deactivate Interrupt” to be used when the interrupt handling is truly completed by the VM, causing the interrupt to transition from ACTIVE to INACTIVE in the physical Distributor. To avoid Hypervisor intervention being necessary when a Guest OS completes interrupt processing, the virtual CPU Interface is able to directly trigger a Deactivate Interrupt event on the interrupt distributor.

Virtual CPU Interface

The Virtual CPU Interface is a new block of hardware (vs. GIC) which is added to support CPU virtualization. Its only connection to the existing GIC is via the interrupt deactivation interface described above section.

The Virtual CPU Interface provides two sets of registers for each CPU in the system. The “front end” registers are intended to be mapped into the VM’s IPA space where the Guest OS’ CPU Interface registers are expected to reside. The “back end” registers are intended to be accessed by the Hypervisor only. The front and back end registers are mapped into separate 4KB address space. The “back end” registers primarily comprise a list of active and pending interrupts for the current Virtual CPU. These registers are updated by the Hypervisor when new interrupts occur, and by the VCPUIF itself in response to accesses to the “front end” from the VM.

The “front end” registers have exactly the same format as the existing GIC CPU Interface, but reflect the status of interrupts stored in the list registers rather than physical interrupts reported by the distributor.

Security and Virtual FIQ

In ARM virtualization, Hypervisor and all VMs run in TrustZone™ Non-Secure domains. Therefore, all vGIC features are available to Non-Secure accesses. Protection of the physical GIC components and the Hypervisor view of the Virtual CPU Interface is achieved using MMU protection. However, some operating systems running as Guests might require the security features of the GIC architecture to allow interrupts to be divided into IRQ and FIQ. To support this, the Hypervisor and Virtual CPU Interface provide a view compatible with the Secure view of the physical GIC, even though the software is running in the Non-Secure domain. This means that the vGIC interface includes various “security” related bits which have no relationship to TrustZone but exist purely to support this model.

Life of an Interrupt in vGIC

Physical Interrupt Asserted

The physical interrupt is routed to the vGIC, which generates an interrupt which is taken by the Hypervisor. The Hypervisor reads INTACK on the physical vGIC to determine the interrupt number. Determining that the interrupt is destined for a virtual machine, the EOI register is written to prevent further interrupts being masked by the vGIC.

Hypervisor locates an empty list register (in the target VM’s virtual CPU interface) and writes a new value indicating that this is a Valid interrupt in PENDING state, with the physical and virtual interrupt numbers and its priority as assigned by the VM.

Virtual Interrupt Asserted

Upon the write to the list register, the VCPU interface will re-evaluate whether to assert the Virtual IRQ signal, based on the priority of the interrupt, any currently active interrupts and the current setting of the Priority Mask register. Assuming these conditions are met the Virtual Interrupt signal will be asserted. When the CPU returns to the virtual machine, (with the CPSR.I bit clear), the Virtual Interrupt will be taken triggering a jump to the normal IRQ vector.

Virtual Interrupt Acknowledged

The Guest OS’s interrupt handler will access the VCPU Interface’s INTACK register. In response to this, the VCPU interface determines the highest priority PENDING interrupt stored in the list. Its priority is checked against the Active Priorities register and the Priority Mask register. Assuming that the pending interrupt’s priority is higher, its virtual interrupt number is returned, its status in the list register changed to ACTIVE and the corresponding bit in the Active Priorities register is set. Otherwise, the spurious interrupt value is returned. Once the Guest OS has received the virtual interrupt number it is able to execute interrupt processing exactly as it would if it were running on bare hardware with a real GIC.

Virtual Interrupt EOI

Once interrupt processing is complete, the Guest OS writes to the EOI register on the VCPU interface to indicate this. In response to this, the VCPU interface determines the highest priority ACTIVE interrupt from the list registers, and the highest priority set bit in the Active Priorities register. This highest priority set bit is cleared. Assuming a highest priority ACTIVE interrupt was found, a Deactivate Interrupt signal is sent to the Interrupt Distributor specifying the physical interrupt number from the list register. The list register is updated to indicate that the entry is now empty (INVALID).

Timers

The Cortex-A15 processor provides a set of four timers for each processor in the cluster.

- Physical Timer for use in Secure and Non-secure PL1 modes. The registers for the Physical Timer are banked to provide Secure and Non-secure copies
- Virtual Timer for use in Non-secure PL1 modes.
- Physical Timer for use in Hypervisor mode.

The counter value is distributed to the processor with a synchronous binary encoded 64-bit bus, **CNTVALUEB[63:0]**. Within each processor, a set of Timer registers are allocated to the CP15 coprocessor space.

3.1.2.2 vGIC Clock Frequency

The vGIC can operate at any integer multiple that is slower than the main Cortex-A15 CPU clock (CLK) using the PERIPHCLKEN signal. For example, the CLK to internal vGIC clock frequency ratio can be 2:1 or 3:1. PERIPHCLKEN asserts one CLK cycle prior to the rising edge of the internal IC clock. The CLK to internal vGIC clock frequency ratio can be changed dynamically using PERIPHCLKEN.

Both CPU clusters (cluster0 and cluster1) incorporate their own vGIC. The vGIC will be running at half the CPU CLK frequency of the cluster it is in.

3.1.2.3 vGIC Context Save/Restore

The vGIC (and Timers) is part of Cortex-A15 MPCore non-CPU (including L2 Cache) logic. The cluster0 vGIC would be powered by CPU rail, and cluster1 is powered by SoC rail. Also, if non-CPU is power gated then vGIC would be power gated as part of non-CPU partition.

In general, vGIC context need to be saved/restored in following cases.

- When CPU(s) is individually power gated (i.e., LP2 power state), then vGIC is still powered, so vGIC context doesn't have to be saved/restored. Therefore, CPUs can be individually powered-off (i.e., put into LP2 state) and powered-on without saving/restoring their vGIC context.
- When non-CPU partition is power-gated or the CPU rail is powered off, then the context of corresponding vGIC needs to be saved.
- When one cluster is migrated to other cluster, then VGIC context need to be migrated from source cluster to destination cluster.
- When SoC rail is powered off (i.e., LP0 power state), then vGIC will be powered off. So vGIC has to be configured/restored at LP0 exit (also known as warm boot)
- When using virtualization extension of vGIC, then for switching from one VM to another Hypervisor will save the contents of all the "back end" registers (i.e., VM view of VCPU Interface registers) from the outgoing VM and load them in the registers for the incoming VM. This restores the VCPU interface to the correct state for the incoming VM.

When a VCPU is migrated (context switched) to another physical CPU, the software has to save the contents of all the "back end" registers (i.e. VM view of VCPU Interface registers) associated with the outgoing CPU, and load them to the corresponding registers of the incoming CPU.

3.1.3 Arbitration Semaphores

Arbitration semaphores provide a mechanism by which the two processors can arbitrate for the use of various resources. These semaphores provide a hardware locking mechanism, so that when a processor is already using a resource, the second processor is not granted that resource. There are 32 bits of Arbitration semaphores provided in the system. The hardware does not enforce any resource association to these bits. It is left to the software to assign and use these bits. Any processor that needs to access a particular resource will request for the corresponding bit in the Arbitration semaphores by writing a one to that bit in the Arbitration Semaphore Request register (SMP_GET register). Software will then check the corresponding bit in the Semaphore Granted Status register (SMP_GNT_ST register)

If the requesting processor has been granted the resource, then the status returned will be a one. Alternately, the processor can configure the interrupt controller to generate an interrupt when the resource becomes available.

When the processor has finished using the resource, it releases the resource by writing a one to the corresponding bit in the Arbitration Semaphore Put Request register (SMP_PUT register). Additionally, pending request status is provided through the Arbitration Request Pending Status register (SMP_REQ_ST register).

The Primary Interrupt Controller (PRI_ICTLR) supports Arbitration Grant Interrupts. When a processor is granted access to a resource, the Arbitration semaphore module can be programmed to send a Grant signal to the interrupt controller. The interrupt controller can then interrupt the processor to indicate that it has been granted exclusive access to a particular resource. The individual ARB_GNT bits are OR'ed together and presented to the Primary Interrupt controller as interrupt number 29.

The Arbitration/Grant interrupts mechanism registers are described in the Semaphores section of this document.

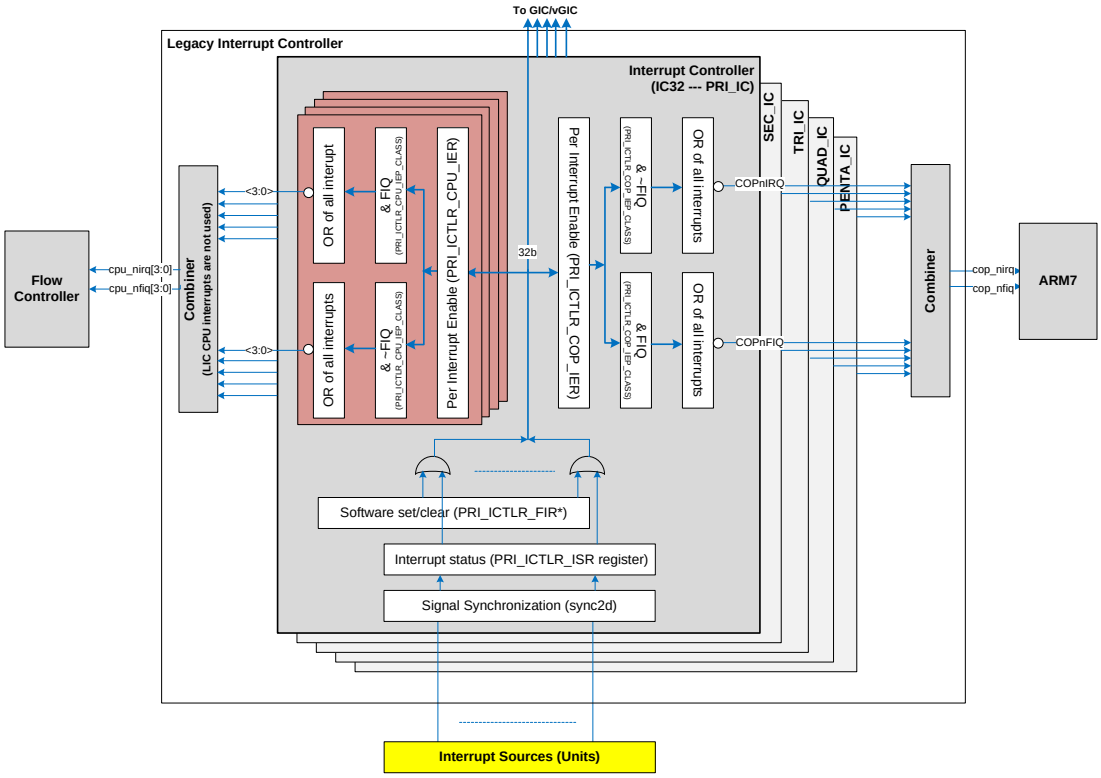
3.1.4 Interrupts Used for Processor Power Ups

The interrupt signals (nIRQ and nFIQ per processor), which are routed to each processor, are also routed to the Flow Controller unit. Based on configuration, the Flow Controller uses them to power up corresponding CPU. Refer to the Flow Controller section in this TRM for the details of processor wake-up.

3.2 Legacy Interrupt Controller (LIC)

Interrupts from various Tegra 4 units are routed to the LIC. The LIC consists of five interrupt controllers (called IC32), where each IC32 handles 32 interrupts (so a total of 160 interrupts). Each IC32 generates five sets of IRQ/FIQ interrupts, one for COP (ARM7), and other one for CPU<3:0>. The interrupts for CPU<3:0> are used by flow controller only for the purpose of wake events.

Figure 3: Legacy Interrupt Controller Block Diagram



The following text discusses interrupts as they relate to the COP IRQ/FIQ, but unless specified otherwise, this also applies to the CPU<3:0> IRQ/FIQ interrupts.

3.2.1.1 LIC Functional Description

Each of IC32 in the LIC handles 32 interrupts. As shown in above figure, the IC32 synchronizes the incoming hardware interrupt requests and combines (bitwise OR) them with software interrupts (FIR). The software interrupt can set be set/clear by FIR register. The combined software/hardware interrupts signal are broadcast to GIC, vGIC, and are used by IC32 for targeting interrupts to COP. This allows any interrupt to be routed to any one or more processors (Cortex-A15/ARM7) in Tegra system. Note, routing can be changed dynamically. In addition, any of these interrupts can be mapped to either IRQ or FIQ.

The interrupt routing (to COP) is achieved by configuring the Interrupt Enable Register (IER) and the Interrupt Class Registers (IEP_CLASS). Each IC32 has a set of IER and IEP Class registers. The COP registers are called COP_IER and COP_IEP_CLASS. Similarly the CPU IER/IEP Class Registers are called CPU_IER and CPU_IEP_CLASS.

When a 1 is set in the proper bit position in the COP_IER register, that particular source is capable of interrupting the COP. Also, the class is set in the proper bit position of COP_IEP_CLASS for the corresponding interrupt to be routed as IRQ or FIQ.

The interrupt status register (ISR) allows the processor to view the state of the pending hardware interrupt requests regardless of the bit enables programmed in COP_IER. The forced interrupt status register (FIR) allows the software to selectively force set/clear specific interrupts. The read-only VIRQ/VFIQ allows the COP to determine the source of the interrupt request(s) causing the processor to enter the interrupt service routine.

The nIRQ signals generated by five IC32 controllers are combined (logical AND) in the combiner to generate final nIRQ (called nirq1 in above diagram) which is routed to COP. Similarly nFIQ signals are combined (logical AND) in the combiner to generate nFIQ which is routed to COP.

3.2.1.2 LIC Registers Description

The LIC consists of five interrupt controllers (called IC32), where each IC32 handles 32 interrupts (so a total of 160 interrupts). Each IC32 defines two sets of registers: one set for COP (ARM7) and other set for CPU (unused).

Each IC32 has 16 32-bit registers. The COP and CPU<n> interrupt enable registers (COP_IER/CPU_IER) indicate the interrupts enabled for the COP and CPU<3:0> respectively. These registers have their respective SET and CLR registers that allow setting or clearing individual bits of these registers without the need of a Read-Modify-Write cycle.

The COP/CPU Interrupt Class Register (COP_IEP_CLASS/CPU_IEP_CLASS) controls whether the interrupt will be routed to the IRQ or the FIQ interrupt of the respective processor.

The Forced Interrupt Status Register (FIR) allows the software to force the set and clear of individual interrupts. This could be used for debugging/testing purposes or could be actually used in the working system. Note, software cannot force set/clear an interrupt which is already asserted by hardware source. The FIR has its corresponding SET and CLR registers.

The Valid Interrupt Status Register (VIRQ_COP/VIRQ_CPU) and Valid FIQ Interrupt Status Register (VFIQ_COP/VFIQ_CPU) indicate the currently active interrupts that are valid on the respective pins (nIRQ or nFIQ).

The difference between ISR and VFIQ/VIRQ registers are:

- The VFIQ/VIRQ registers indicate the interrupt which is sent to the processor (i.e. these registers indicate interrupts outgoing from interrupt controller). On the other hand, ISR indicates hardware interrupt incoming into interrupt controller.
  - The VFIQ/VIRQ registers indicate the interrupts whether set by hardware or by the software. The ISR register will indicate registers set by only the hardware.
  - Also the VFIQ/VIRQ registers will only show the enabled interrupts. ISR will show the interrupt status irrespective of whether the interrupt is enabled or not.
  - Also the ISR will show the interrupt to be active whether it is routed to the FIQ pin or to the IRQ pin. The VFIQ/VIRQ registers contain only the routed interrupts.

The VIRQ_COP and VIRQ_CPU registers are calculated as follows.

VIRQ_COP = (ISR **|** FIR) **&** IER_COP **&** (**~**COP_IEP_CLASS)

VIRQ_CPU<n> = (ISR **|** FIR) **&** IER_CPU<n> **&** (**~**CPU_IEP_CLASS)

Similarly the VFIQ_COP and VFIQ_CPU<n> registers are generated as follows.

VIRQ_COP = (ISR **|** FIR) **&** IER_COP **&** COP_IEP_CLASS

VIRQ_CPU<n> = (ISR **|** FIR) **&** IER_CPU<n> **&** CPU<n>_IEP_CLASS

3.2.1.3 Hierarchical Interrupts Grouping

To reduce the number of interrupts (as seen by interrupt controllers also known as IRQS), interrupt sources which are non-critical or used in pre-production systems only are grouped together. The hierarchical interrupt group (HIER_GROUPx) groups 32 interrupts into two interrupts: one for CPU (called HIER_GROUPx_CPU) and other one for COP (called HIER_GROUPx_COP). There is a software configurable enable register (HIER_GROUPx_{CPU,COP}_ENABLE) for each of the two interrupts which can be independently programmed to select interrupts for that destination. Also, there is a status register (HIER_GROUPx_{CPU,COP}_STATUS) for each of the two interrupts which provides the status of interrupt which are qualified by enable register. Note, incoming interrupt signals are active-high level signals, so interrupts have to cleared (by software) at the source unit. The interrupts are grouped as follows.

```
HIER_GROUP1_CPU_STATUS[31:0] = HIER_GROUP1_CPU_ENABLE[31:0] & source_INT[31:0]
HIER_GROUP1_CPU = | HIER_GROUP1_CPU_STATUS[31:0]     //OR-ing of all bits

HIER_GROUP1_COP_STATUS[31:0] = HIER_GROUP1_COP_ENABLE[31:0] & source_INT[31:0]
HIER_GROUP1_COP = | HIER_GROUP1_COP_STATUS[31:0]    //OR-ing of all bits
```

The Address Interrupt section of this document lists the interrupt sources which are in the hierarchical interrupts group(s).

3.2.2 Primary Interrupt Controller Registers

Refer to “Reading Register Tables” in the Introduction section for the register table protocol as well as recommendations for accessing registers.

3.2.2.1 PRI_ICTLR_VIRQ_CPU_0

Valid Interrupt Request Status for CPU Register

Offset: 0x0 | Read/Write: RO | Reset: 0xXXXXXXXX (0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx)

Bit	Reset	Description

3.2.3 Arb_gnt Specific Interrupt Controller Registers

Arbitration semaphores provide a mechanism by which the two processors can arbitrate for the use of various resources. These semaphores provide a hardware locking mechanism, so that when a processor is already using a resource, the second processor is not granted that resource. There are 32 bits of Arbitration semaphores provided in the system.

The hardware does not enforce any resource association to these bits. It is left to the firmware to assign and use these bits.

The Arbitration Semaphores can also generate an interrupt when a hardware resource becomes available. The registers in this module configure these interrupts. When a 1 is set in the corresponding bit position of the Arbitration Semaphore Interrupt

Source Register (CPU_enable or COP_enable), an interrupt will be generated when the processor achieves Grant Status for that resource.

The current Grant status can be viewed in the CPU_STATUS or COP_STATUS registers.

3.2.3.1 PRI_ICTLR_ARBGNT_CPU_STATUS_0

CPU Arbitration Semaphore Interrupt Status Register

Offset: 0x40 | Read/Write: RO | Reset: 0xXXXXXXXX (0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx)

Bit	Reset	Description
31:0	X	GNT31_GNG0: Each bit is set by hardware when the corresponding arbitration semaphore ownership is granted to the CPU. Interrupt is cleared when the CPU writes the ARB_SMP.PUT register with the corresponding bit set.

3.2.3.2 PRI_ICTLR_ARBGNT_CPU_ENABLE_0

CPU Arbitration Semaphore Interrupt Enable Register

Offset: 0x44 | Read/Write: R/W | Reset: 0x00000000 (0b00000000000000000000000000000000)

Bit	Reset	Description
31:0	0x0	GER31_GER0: Writing a 1 in any bit position will enable the corresponding arbitration semaphore interrupt.

3.2.3.3 PRI_ICTLR_ARBGNT_COP_STATUS_0

COP Arbitration Semaphore Interrupt Status Register

Offset: 0x48 | Read/Write: RO | Reset: 0xXXXXXXXX (0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx)

Bit	Reset	Description
31:0	X	GNT31_GNG0: Each bit is set by hardware when the corresponding arbitration semaphore ownership is granted to the COP. Interrupt is cleared when the COP writes the ARB_SMP.PUT register with the corresponding bit set.

3.2.3.4 PRI_ICTLR_ARBGNT_COP_ENABLE_0

COP Arbitration Semaphore Interrupt Enable Register

Offset: 0x4c | Read/Write: R/W | Reset: 0x00000000 (0b00000000000000000000000000000000)

Bit	Reset	Description
31:0	0x0	GER31_GER0: Writing a 1 in any bit position will enable the corresponding arbitration semaphore interrupt.

3.2.4 Second Interrupt Controller Registers

3.2.8.7 HIER_GROUP_FIR_CLEAR_0

FIR Clear for Hier Group

Offset: 0x818 | Read/Write: WO | Reset: 0x00000000 (0b00000000000000000000000000000000)

Bit	Reset	Description
31:0	0x0	FIR_CLEAR: FIR clear for hier group

4.0 ARBITRATION SEMAPHORES

4.1 Overview

Arbitration semaphores provide a mechanism by which the two processors can arbitrate for the use of various resources.

These semaphores provide a hardware locking mechanism to ensure that when a processor is already using a resource, the second processor is not granted that resource. There are 32 bits of arbitration semaphores provided in the system. The hardware does not enforce any resource association to these bits and it is left to the user to assign and use these bits.

Any processor that needs to access a particular resource will request for the corresponding bit in the arbitration semaphores by writing a one to that bit in the Arbitration Semaphore Request register (SMP_GET register). Firmware will then check the corresponding bit in the Semaphore Granted Status register (SMP_GNT_ST register). If the requesting processor has been granted the resource, then the status returned will be a one.

Alternately, the processor can configure the interrupt controller to generate an interrupt when the resource becomes available. When the processor has finished using the resource, it releases the resource by writing a one to the corresponding bit in the Arbitration Semaphore Put Request register (SMP_PUT register). Additionally, pending request status is provided through the Arbitration Request Pending Status register (SMP_REQ_ST register).

(Note that an alternative mechanism to this exists in the Atomics block. Please refer to the corresponding section of this document for further details. At the time of this writing, NVIDIA software does not make use of the Atomics block.)

4.2 Semaphore Registers

Refer to “Reading Register Tables” in the Introduction section for the register table protocol as well as recommendations for accessing registers.

4.2.1 ARB_SEMA_SMP_GNT_ST_0

Semaphore Granted Status Register

Offset: 0x0 | Read/Write: RO | Reset: 0x00000000 (0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx)

Bit	Reset	Description
31:0	X	ARB_31_ARB_0: A one in any bit indicates that the processor reading this register as granted status for that bit. A zero indicates semaphore not granted.

4.2.2 ARB_SEMA_SMP_GET_0

Request Arbitration Semaphore Register

Offset: 0x4 | Read/Write: WO | Reset: 0x00000000 (0b00000000000000000000000000000000)

Bit	Reset	Description
31:0	0x0	GET_31_GET_0: Writing a one in any bit is a request for that semaphore bit by the processor performing the register write.

4.2.3 ARB_SEMA_SMP_PUT_0

Arbitration Semaphore Put Request Register

Offset: 0x8 | Read/Write: R/W | Reset: 0x00000000 (0b00000000000000000000000000000000)

Bit	Reset	Description
31:0	0x0	PUT_31_PUT_0: Writing a one in any bit will clear the corresponding semaphore bit by the processor performing the register write.

4.2.4 ARB_SEMA_SMP_REQ_ST_0

Arbitration Request Pending Status Register

Offset: 0xc | Read/Write: RO | Reset: 0x00000000 (0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx)

Bit	Reset	Description
31:0	X	REQ_31_REQ_0: A one in any bit indicates a request pending status. The corresponding bits are set when the request for the individual resource is pending. The read by CPU of this register shows the pending status for CPU and a read of this register by AVP (COP) shows the pending status for AVP.

5.0 ATOMICS

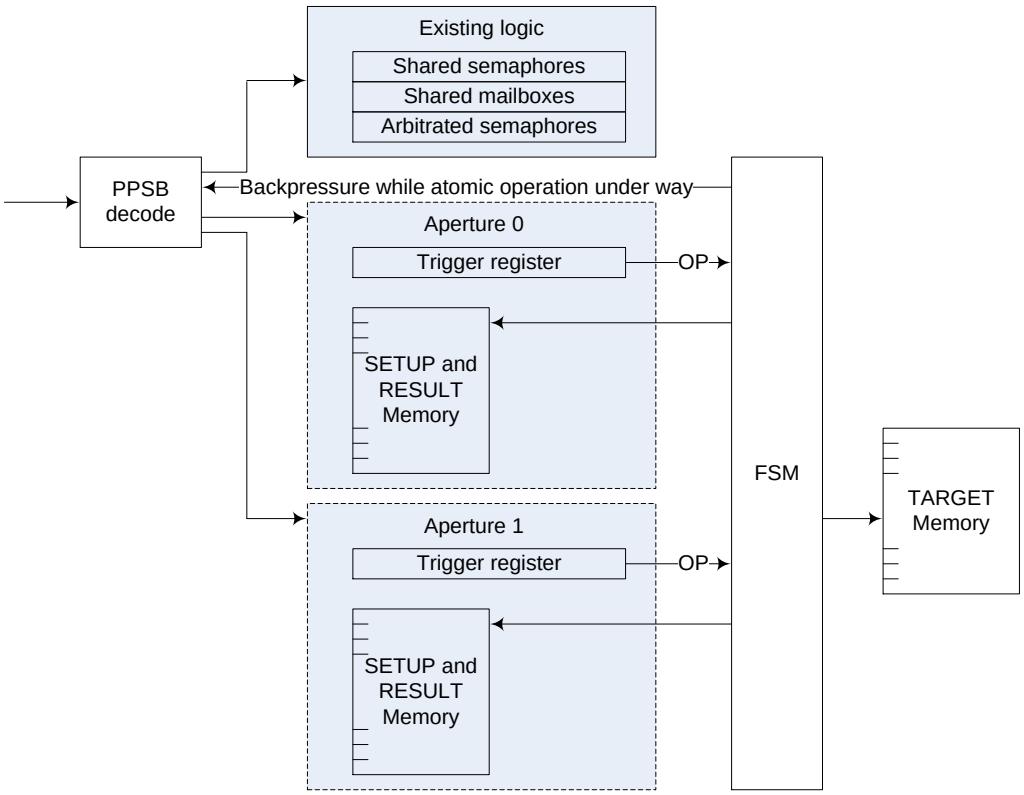
5.1 Introduction

The Atomics block assists software tasks with maintaining synchronization. It is parallel to the existing Semaphores block, and extends that block's functionality with new capabilities.

5.2 Functionality

The figure below shows a reference decomposition of the hardware synchronization elements in functional blocks.

Figure 4: Reference Block Diagram



5.3 Synchronization Elements

The synchronization elements are atomic primitives. Their main advantage is to allow some specific algorithms that access shared resources to be performed lock free, for better performance.

In general, the atomic primitives below have results equivalent to atomic RMW operations on a target register. The cycle is made atomic without using locked bus accesses as explained below.

5.3.1 General Principles

Atomic primitives maintain atomicity by splitting the whole operation in three phases:

- A setup phase where parameters are prepared in registers. There are as many sets of setup registers as there are apertures.

- A trigger register that starts a specific operation. The trigger register fits in one 32-bit word to ensure atomic issue of the operation. There is one trigger register per aperture. The trigger register specifies:
  - The primitive operation to be performed.
  - The index of the target register for the primitive operation.
- A result phase where the results of the operation are made available. There are as many sets of result registers as there are sets of setup registers. The operation, once triggered, is executed atomically.

The setup, result, and trigger registers are duplicated in separate apertures, one aperture per client of the block. There are two such apertures in Tegra® 4 processors, normally one used by CPU, the other by AVP, but this is not enforced by hardware as it is for the arbitrated semaphores.

Setup, target, and result registers are 32 bits each with no further structure imposed by hardware. The trigger register is 32 bits, structured in command and target fields.

The description of the different operations is based on pseudo code that uses the following conventions:

- ATOMIC_OP identifies the exact operation and index ID identifies a given target register. Both ATOMIC_OP and ID are duplicated per aperture
- Index A identifies the aperture from which the operation is executed.
- The setup registers in a set are stored in arrays v and c. The result registers are stored in array old[1]. All of these are duplicated per aperture.
- The target registers are not duplicated per aperture and are stored in an array T.
- The semantic of assignment is like C. All assignments are assumed to take place instantaneously. Intermediate values are used to get the equivalent of clocked operations of the hardware. Typically, the hardware implementation has no intermediate values if operations are performed in one clock cycle.
- Arithmetic operations are performed as signed 32-bit operation modulo 2^{32} using 2's complement coding.

5.3.2 Atomic Exchange

In an atomic exchange, its only purpose is to be able to read a value and replace it with another value in an atomic fashion.

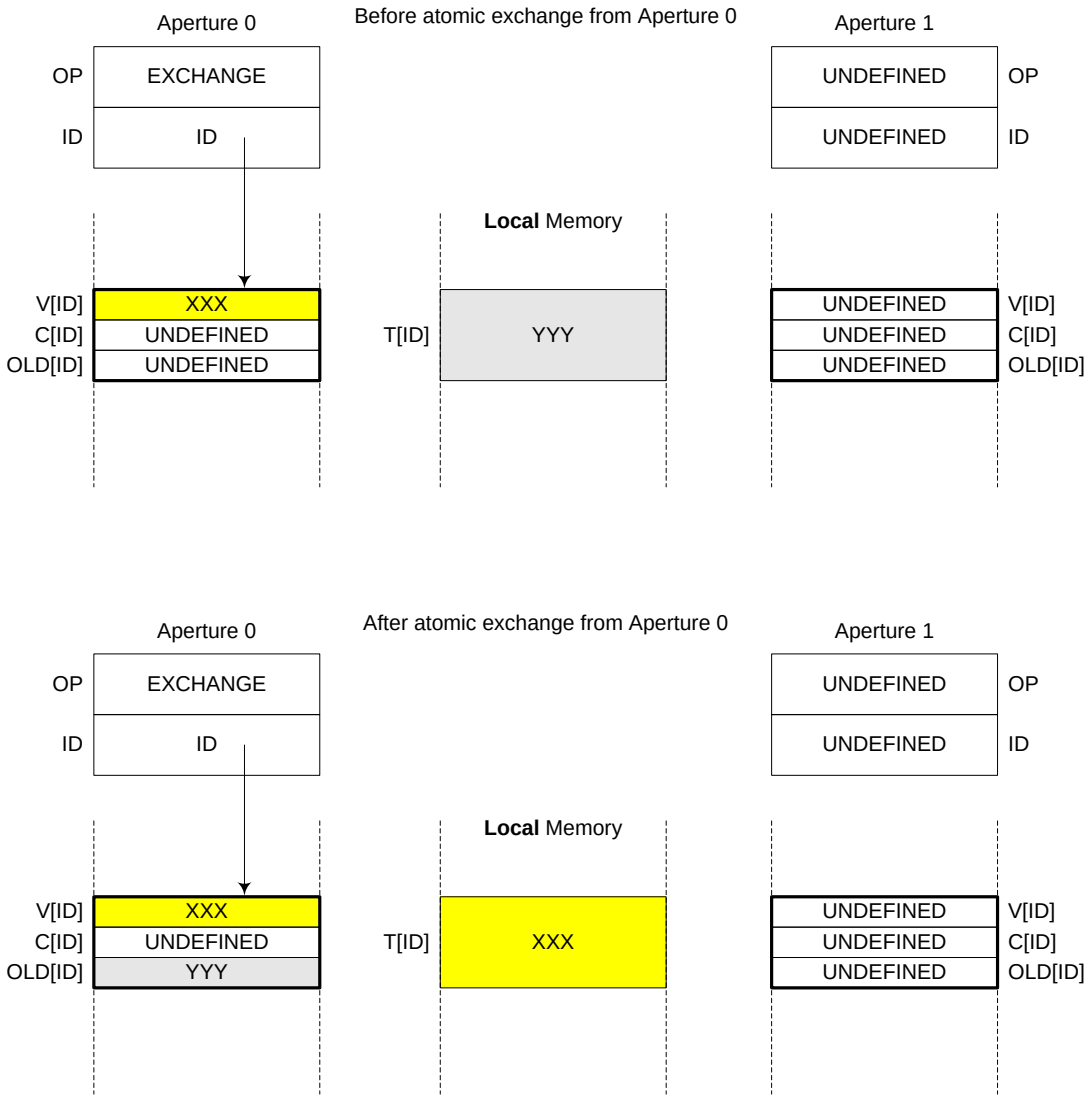
The corresponding pseudo code is

```
if (ATOMIC_OP[A] == EXCHANGE) {
  old[A][ID[A]] = T[ID[A]] ;
  T[ID[A]] = v[A][ID[A]]
```

The figure below illustrates an atomic exchange performed using aperture 0.

[1] The result register always contains the old value of the target register, i.e. the value before applying the atomic operation. This is true even for PUT, so that PUT and EXCHANGE are semantically equivalent with the current definition.

Figure 5: Atomic Exchange Operation



5.3.3 Atomic Compare and Exchange

This is a variant of atomic exchange where the exchange only takes place if the old value matches the second setup register.

```
if (ATOMIC OP[A] == COMPARE AND EXCHANGE) && (T[ID[A]] == c[A][ID[A}]) {
  old[A][ID[A]] = T[ID[A]]
  T[ID[A]] = v[A][ID[A]]
}
```

5.3.4 Atomic Increment

The atomic increment simply ensures that different processors can increment a shared value without losing any increment. The operation is labeled INCREMENT, but, for 32-bit operations, incrementing by 2^{32} – k is equivalent to decrementing by k.

```
if (ATOMIC_OP[A] == INCREMENT) {
  old[A][ID[A]] = Target[ID[A]]
  T[ID[A]] += v[A][ID[A]]
}
```

The variant DECREMENT_WITH_ZERO_SATURATE is similar, adding a saturation to zero when going down. This may be used to manage shared resources that are present in finite numbers.

```
if (ATOMIC_OP[A] == DECREMENT_WITH_ZERO_SATURATE) {
  old[A][ID[A]] = T[ID[A]]
  T[ID[A]] -= v[A][ID[A]]
  if MSB(T[ID[A]]) == 1b && MSB(r[A][ID[A]]) == 0b { T[ID[A]] = 0 ; }
}
```

5.3.5 Atomic Get and Put

These are trivial for hardware if there is only one access port, in which case they act as normal register operations. They are nevertheless defined to allow more complex future implementations where the atomic operation blocks could present multiple hardware interfaces to the rest of the system.

```
if (ATOMIC OP[A] == GET) {
  old[A][ID[A]] = T[ID[A]]
}

if (ATOMIC OP[A] == PUT) {
  old[A][ID[A]] = T[ID[A]]
  T[ID[A]] = v[A][ID[A]]
}
```

5.3.6 Atomic Test and Set, Test and Clear, Test and Invert

These are simple extensions of previous cases, where the operation is either a bit set, bit clear, or bit invert.

```
if (ATOMIC_OP[A] == TEST_AND_SET) {
  old[A][ID[A]] = T[ID[A]]
  T[ID[A]] |= v[A][ID[A]]
}

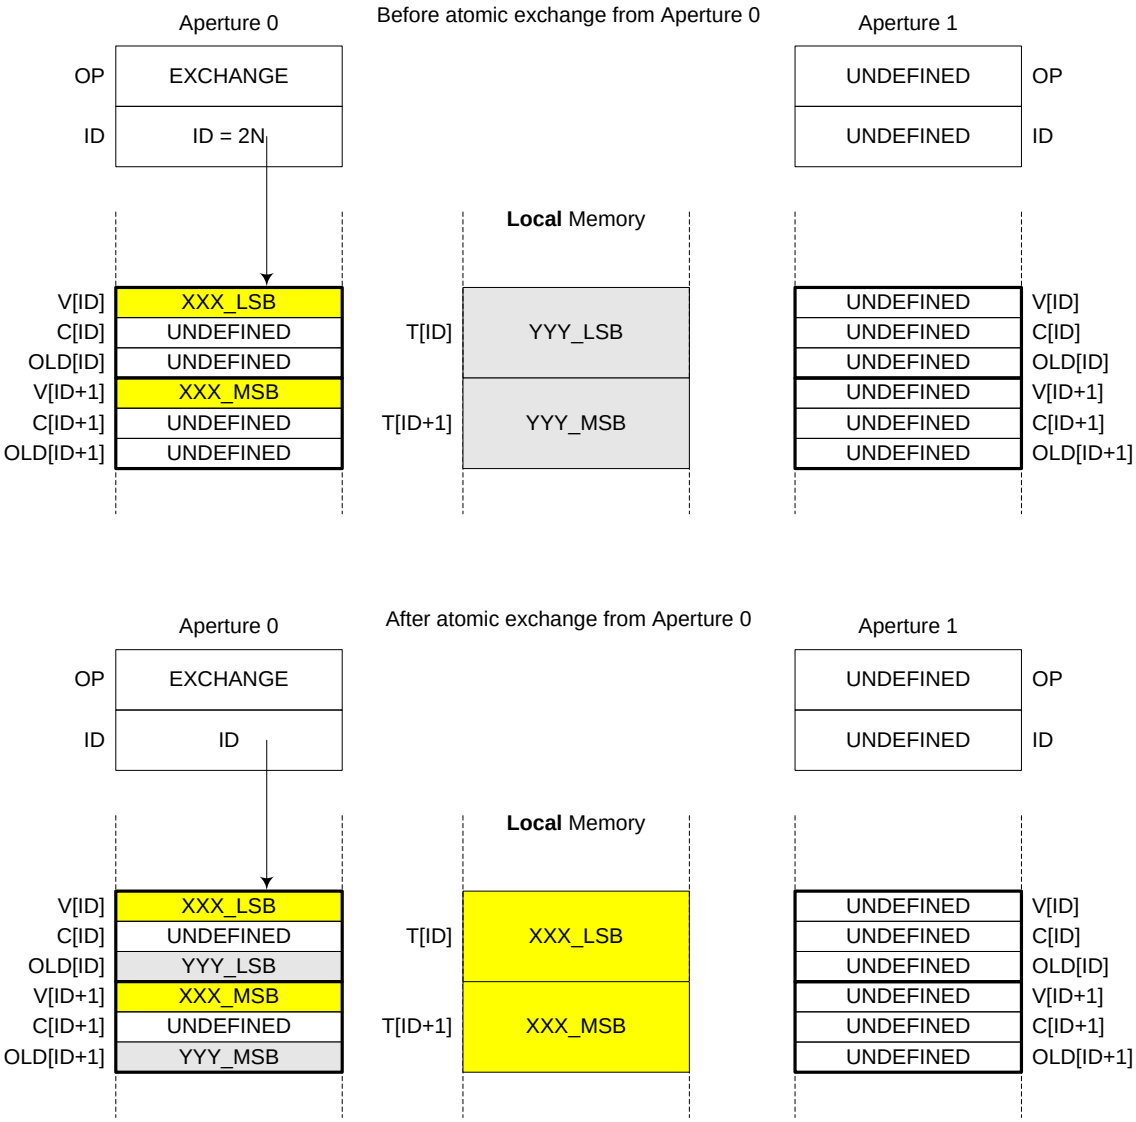
if (ATOMIC_OP[A] == TEST_AND_CLEAR) {
  old[A][ID[A]] = T[ID[A]]
  T[ID[A]] &= ~v[A][ID[A]]
}

if (ATOMIC_OP[A] == TEST_AND_INVERT) {
  old[A][ID[A]] = T[ID[A]]
  T[ID[A]] ^= v[A][ID[A]]
}
```

5.3.7 Width of Operations

All operations can operate on 32 bits or 64 bits. 64-bit operations use an even/odd pair of address, with the MSB at the odd address. The next figure shows how a 64-bit exchange operates. Other operations behave similarly. In the case of atomic increment and decrement operations, the carry will correctly propagate from the LSB to the MSB.

Figure 6: 64-bit Atomic Exchange Operation



5.4 Atomics Registers

Refer to “Reading Register Tables” in the Introduction section for the register table protocol as well as recommendations for accessing registers.

5.4.1 ATOMICS_AP0_TRIGGER_0

Trigger Registers

[THIS PAGE INTENTIONALLY LEFT BLANK]

6.0 CLOCK AND RESET CONTROLLER

The Clock and Reset (CAR) block contains all the logic needed to control most of the clocks and resets to the Tegra® 4 device. The CAR block provides the registers to program the PLLs and controls most of the clock source programming, and most of the clock dividers.

Power on reset (SYS_RESET_N_) is the primary reset for the Tegra 4 chip and is provided by the external PMC.

6.1 Hardware Features

6.1.1 External Clock Sources

The CAR block takes two external clock sources as input:

- A single external 32.768 kHz clock, normally provided by the Power Manager Integrated Circuit (PMIC)
- An oscillator clock at 12, 13, 16.8, 19.2, 26, 38.4, or 48 MHz, provided by an external crystal. Not all these frequencies may be supported by software.

6.1.2 Clock Sources and PLLs

Clock sources are provided by 12 PLLs in the Tegra 4 clock system:

- PLLM: Clock source for EMC 2x clock
- PLLX: Clock source for the fast CPU cluster and the shadow CPU
- PLLC: Clock source for general use
- PLLC2 and PLLC3: Clock source for engine scaling
- PLLP: Clock source for most peripherals
- PLLA: Audio clock sources:
  - 11.2896 MHz
  - 12.288 MHz
  - 24.576 MHz
- PLLU: Clock source for USB PHY, provides 12/60/480 MHz
- PLLD and PLLD2: Clock sources for the DSI and display subsystem
- refPLLe and PLLE generate the 100 MHz reference clock for USB 3.0 and can generate a spread-spectrum clock

There are two clock inputs to the Tegra 4 device:

- OSC: Source from external crystal
- CLK_32K_IN: 32-kHz clock provided by the PMC

6.1.3 Clock Dividers / Skippers / Multipliers

There are a number of clock skippers, clock dividers, and clock multipliers in use in the Tegra 4 devices.

- Clock skippers:
  - An M/N clock-skipping divider that is used to generate the CPU clock and also the Tegra 4 "system clock" (sclk).
  - Clock skippers that are used to generate the "AHB clock" (hclk) and "APB clock" (pclk). One that divides down by a 2-bit unsigned value (U2).
- Clock dividers:
  - An unsigned 16-bit divider (U16) that is the divider for the I2C and UART devices.

- An unsigned 8-bit divider that provides 7 bits of mantissa and 1 bit of fraction (U7.1). Tegra 4 devices have reduced the number of divider types and in particular this U7.1 divider is the default divider for most all blocks in Tegra 4 devices.

  Note: The clock-skipping divider and the U7.1 divider when programmed with the 1b fraction do not create 50/50 duty-cycle clock waveforms and may not be suitable for all modules under all circumstances.

- Clock multiplier:
  - A times-two multiplier used to double the external reference frequency by delaying and XORing the input clock with a 4-bit programmable delayed reference clock. Care must be exercised when using this dual-frequency and widely varying duty-cycle clock.

6.1.4 Power Gating and Partitions

Power gating is used to reduce leakage of idle units. For example, if a power rail is shared by unit A and unit B, then that rail (thus units) can only be powered off when both units are idle and can accept the rail power on/off latency. However, with the help of on-die power gates, each of the units can be powered off independently without powering off the rail. This is also useful to reduce latency of powering up the unit (because rail power up latency is 1000x times that of power gates).

Tegra 4 devices use the header power-gate implementation because of its power efficiency. A power-gated partition has two VDD rails. The first one is called the real power (VDD), and the second one is called the virtual power (VVDD). There are hundreds of sleep transistors (also known as power gates) that sit between the two power rails such that VVDD can be powered on/off by controlling power gates. The logic in the power-gated partition is powered by the VVDD rail.

The Tegra 4 device uses three core power rails: VDD_CPU, VDD_SoC, and VDD_AO (always-on). The VDD_CPU power rail is used for high-performance CPUs (fast CPUs), VDD_AO is used for the PMC and some of the other always-on logic. VDD_SoC is used for the rest of the core logic (including the shadow CPU) in Tegra 4 devices.

Within each power rail, some of the partitions may be power gated (referred to as PG partitions or PG domains), and others may not be power gated (referred to as NPG or non-PG domains).

In addition to three core power rails, the Tegra 4 device uses several I/O power rails which are not described in this document.

6.1.4.1 CPU Power Rail

The CPU power rail is used to power a fast CPU cluster (cluster0). Each of the four CPUs in cluster0 is independently power-gated as a separate partition. The cluster0 non-CPU (including L2) is power gated as a separate fifth partition.

To be able to power-gate cluster0 non-CPU partition, all of the CPU partitions have to be power gated first. Also, the cluster0 L2 cache has to be flushed out to DRAM before non-CPU power-gating. The L2 flushing is a long latency event. So instead of power-gating a non-CPU, the CPU rail is powered off, which is better from leakage saving perspective but costly from a power-up latency perspective (rail power-up is much longer than power-ungating).

Tegra 4 Partition	Description
CE0	Cluster0 CPU0
CE1	Cluster0 CPU1
CE2	Cluster0 CPU2
CE3	Cluster0 CPU3
C0NC	Cluster0 Non-CPU (L2 Ctrl + L2 Data (2MB) + L2 Tags + Debug, GIC/Timers, AXD, AXICIF) also known as (FL2 and FTOP)

6.1.4.2 SoC Power Rail

The SoC power rail is used to power all of the SoC logic. The following table lists the power-gated and unpower-gated domains in the VDD_SoC power rail.

PG Domain	Description
CELP	Cluster1 CPU (Shadow CPU)
C1NC	Cluster1 Non-CPU (L2 Ctrl + L2 Data (512KB) + L2 Tags + Debug, GIC/Timers, AXD, AXICIF) also known as (SL2 and STOP)
DISP	DisplayA
DISPB	DisplayB
HEG	GR2D, GSHIM, EPP
MPE	MSENC (Video Encoder)
TD (TDA,TDB, TDC,TDD, TDE,TDF)	GPU (3D)
VDE	Video Decoder Engine
VE	VI(Video Input), CSI, ISP
XUSBA	XUSB (USB3): SuperSpeed (USB3)
XUSBB	XUSB (USB3): Device Mode (USB2/1)
XUSBC	XUSB (USB3): Host Mode
NPG	AHB Cluster, TZRAM, SE, SDMMC, NAND, CoreSight APB Cluster, Audio Cluster, Fuse AVP Cluster CAR, Host1x MCA, MCB USX (USB2,USB1) Mselect, APC

6.1.4.3 AO Power Rail (VDD_AO)

The VDD_AO power rail runs the logic that needs to be active during deep sleep (LP0). The following functions are in the VDD_AO power rail:

- KBC (KeyBoard Controller)
- PMC (Power Management Controller)
- RTC (Real-Time Clock)
- Some of the pads

6.2 Clocking Architecture

Tegra 4 clocks are classified into two categories: core clocks and I/O clocks. Core clocks drive the non-I/O modules on the Tegra 4 chip. I/O clocks are custom designed for each I/O module. Only core clocks are described here.

6.2.1 Core Clocks

The core clock structure consists of:

- Sources
- Switches

- Distribution and skew balancing
- Second-level non-functional clock gates.

Core clocks originate from external clock sources which are used by on-chip PLLs to generate a set of primary clock sources. Secondary clock sources are created by dividing down various PLL outputs. This group of external, PLL, and divided PLL clocks constitutes the clock sources.

These sources feed the clock switches. Each module has its own switch. A clock switch consists of one or more clock sources selected through a Clock Source Selection Mux and driving a clock divider. Multiple clock source options are available to the module divider to allow software to choose a clock frequency based on the unit's performance requirements and overall SOC power. Switching a clock source away from a PLL when it is locking after being reprogrammed to a new frequency may also be required. There are three types of dividers: fixed divide value, fractional divider, or clock skipping (pulse eating) divider.

6.2.2 Main Clock Sources

There are three types of clock sources:

- External clock sources
- PLLs
- Derived clock sources

Table 11: External Clocks to Tegra 4 Devices

Clock Name	Description
dbg_oscout:	This clock runs at 12MHz, 13 MHz, 19.2 MHz, 26 MHz, 16.8 MHz, 38.4 MHz, or 48 MHz.
ck32khz_IB:	This clock runs at 32.768 kHz.

Table 12: Primary Clock Sources in Tegra 4 Devices

Clock Name	Description
osc_div_clk:	This clock runs at 12 MHz, 13 MHz, 16.8 MHz, 19.2 MHz, or 26MHz.
clk_m:	This clock (with DFT control) runs at 12 MHz, 13 MHz, 16.8 MHz, 19.2 MHz, 26 MHz, 38.4 MHz, or 48 MHz.
ck32khz_IB	This clock runs at 32.768 kHz.
car_clk_m:	CAR's clock tree balanced version of clk_m.
dfllCPU_out:	This is the dfllCPU's output clock. FCPU voltage following clock.
pllX_out_g:	This is the PLLX's output clock. FCPU clock.
pllC_out:	This is the PLLC's output clock. GP clock source.
pllC2_out:	This is the PLLC2's output clock. GP clock source.
pllC3_out:	This is the PLLC3's output clock. GP clock source.
pllM_out:	This is the PLLM's output clock. EMC/MC Memory clock.
pllD_out:	This is the PLLD's output clock. Display 1 clock.
pllD2_out:	This is the PLLD2's output clock. Display 2 clocks.
pllU:	This is the PLLU's output clock. USB2 I/O.
refPLLE_out:	This is the refPLLE's output clock. Low jitter reference clock for pllE, USB.
pllE_out0:	This is the PLLE's output clock. USB3 I/O.
pllP_out:	This is the PLLP's output clock. Fixed frequency GP clock source.
clk_s:	This clock (with DFT control) runs at 32.768 kHz.
car_clk_s:	CAR's clock tree balanced version of clk_s.

Table 13: Derived Clock Sources in Tegra 4 Devices

Clock Name	Description
pllxlp:	Simple div1/div2 output clocked by “pllX_out_g”. SCPU clock.
pllC_out1:	This is the U7.1 divider output clocked by “pllC_out”. GP clock source.
pllM_out1:	This is the U7.1divider output clocked by “pllM_out”. Alternate sys_clk source.
pllD_out0:	This is the divided-by-2 from PLLD’s output clock. Display 1 clock.
pllD2_out0:	This is the divided-by-2 from PLLD2’s output clock. Display 2 clock.
pllP_out1:	This is the U7.1 divider output clocked by “pllP_out”. PLLA reference clock.
pllP_out2:	This is the U7.1 divider output clocked by “pllP_out”. GP clock source.
pllP_out3:	This is the U7.1 divider output clocked by “pllP_out”. GP clock source.
pllP_out4:	This is the U7.1 divider output clocked by “pllP_out”. GP clock source.
pllA_out0:	This is the U7.1 divider output clocked by “int_pllA_out”. Audio and GP clock.
audio_sync_clk:	This clock is muxed from 9 possible audio clock inputs.
audio_2x_sync_clk:	This is the clock doubled from audio_sync_clk.

The table below lists which clock source they are derived from and their divider size.

Table 14: Clock Sources for the Derived Clocks

	dbg_oscout	pllC_out	ck32khz_lB	pllM_out	pllM_2x_out	pllP_out	int_pllA_out	spdif_in_recovered_bclk	i2s0_sclk_in	i2s1_sclk_in	i2s2_sclk_in	i2s3_sclk_in	i2s4_sclk_in	pllA_out0	vimclk_pri_in	Have super clock divider ? (# of bits)	Have U7.1 divider? (# of bits)
pllC_out1		x															8
pllM_out1				x													8
pllP_out1						x											8
pllP_out2						x											8
pllP_out3						x											8
pllP_out4						x											8
pllA_out0							x										8
audio_2x_sync_clk								0	1	2	3	4	5	6	7	-	-

These clock sources are shown in the following two figures.

Figure 7: Clocking Sources (1 of 2)

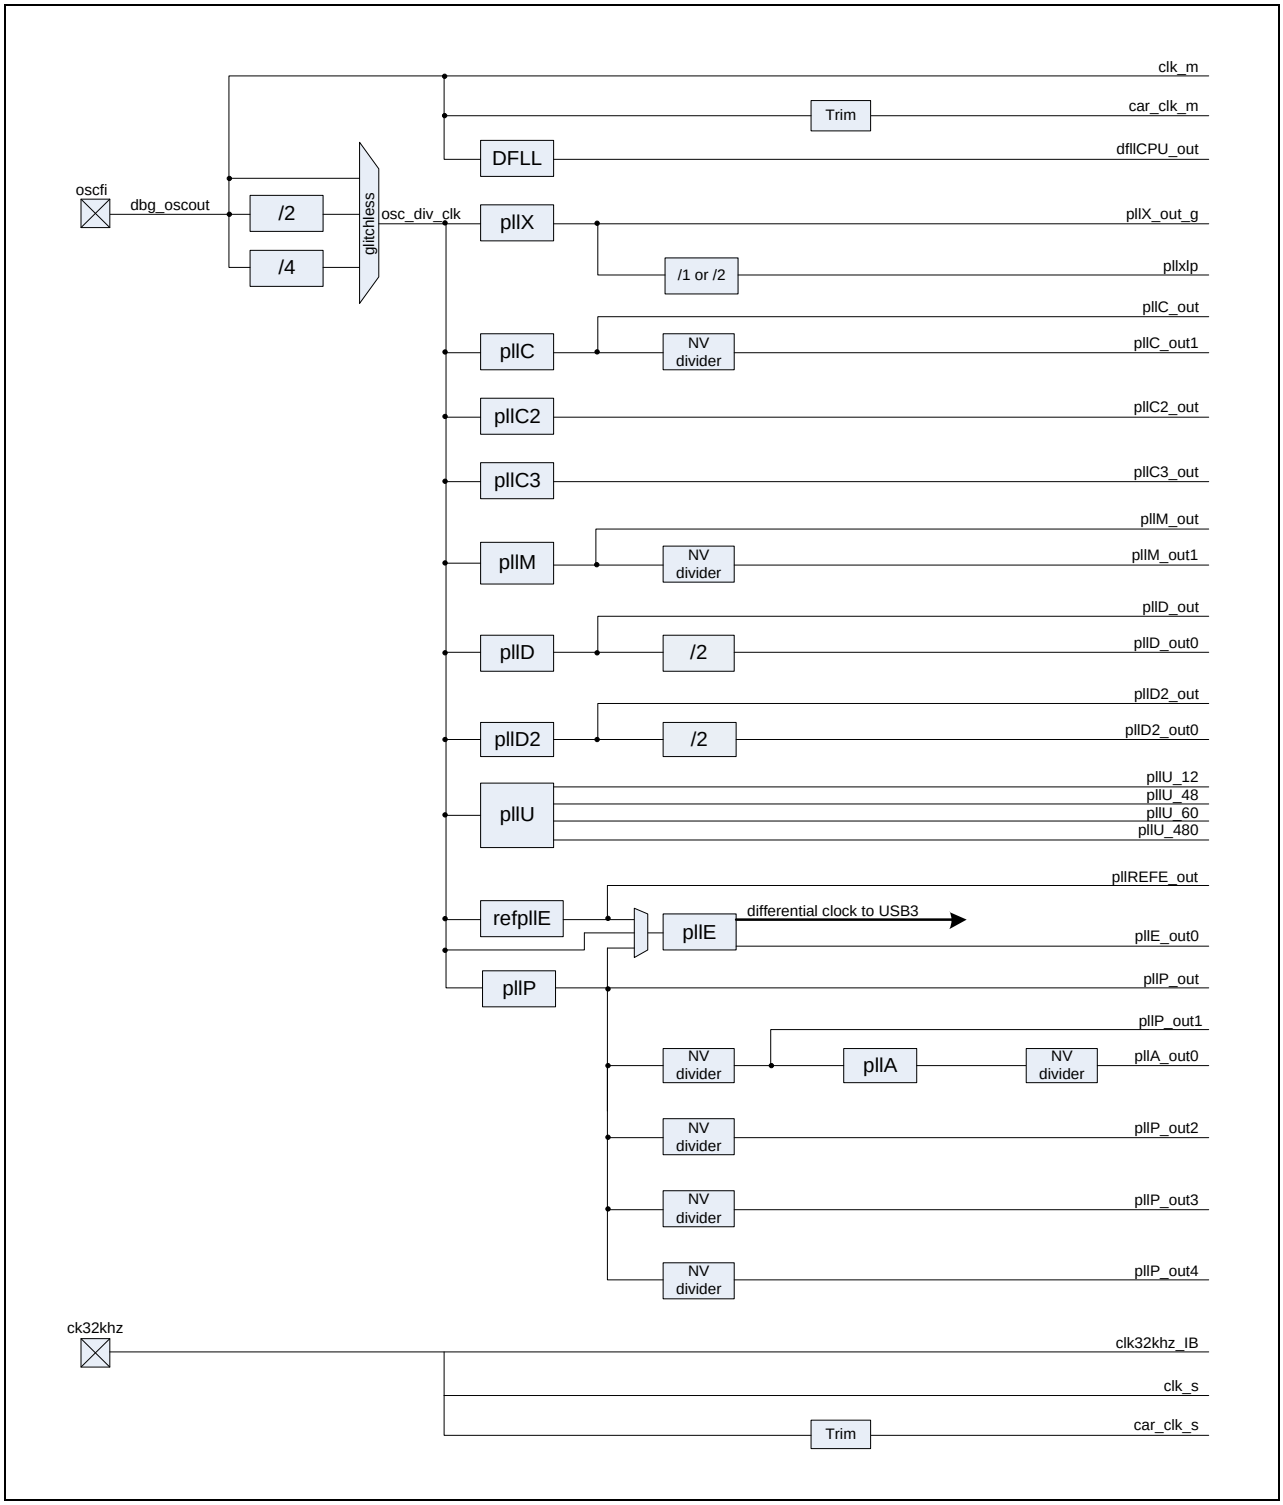

Figure 8: Clock Sources (2 of 2)

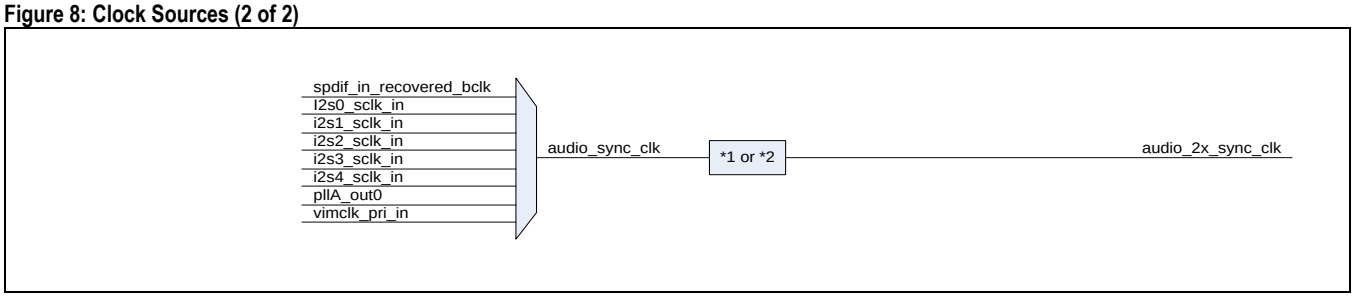

The table below gives a quick overview of the root clock generators. It includes the clock sources and the divider type and size. For example, the ACTMON root clock has 6 clock sources (000=pllP_out, 001=pllC2_out, 010=pllC_out, 011=pllC3_out, 100=ck32khz_IB, 110=dbg_oscout) and has an 8-bit wide U7.1 fractional divider. The default reset value is shown as an underlined value such as 6.

Table 15: Root Clock Sources

Note:

a. For clock source pllX_out, this is an output of a mux that can select between the pllX_out clock and a predivide-by-2 pllX_out clock. For clock source dfllCPU_out, this is an output of a mux that can select between the dfllCPU_out clock and a predivide-by-2 dfllCPU_out.

b. When EMC clock source = 4, the U7.1 divider will be bypassed/ignored. This setting will give a very short low jitter clock path from pllM_out to EMC clock.

c. When clock source = 8 or 9, in addition to being selected into the glitch-less switching logic in CAR, the selected clock will also bypass the U7.1 divider creating a short low jitter clock path to the output clock.

d. The Clock Skipper is controlled by SOC Therm hardware.

6.2.3 Generic Clock Core Structure

Root clock generation is typically a clock source selection mux followed by a U7.1 fractional divider. The clock source selection mux is made glitch-less by the addition of a state machine that gates off the clocks that might be impacted by the glitch, switching the clock source, and then ungating the clock.

Changing the fractional divider ratio is also glitch-less and will use one of two mechanisms. When used in a switch with a clock source selection mux, the switching state-machine described above is used. When used without a clock source selection mux such as in the pllP_out1,2,3,4 dividers, the divider is not stopped and seamlessly switches to the new frequency at the end of a clock period. In this latter scheme, no dead cycles exist– between the original frequency and then the newly requested frequency.

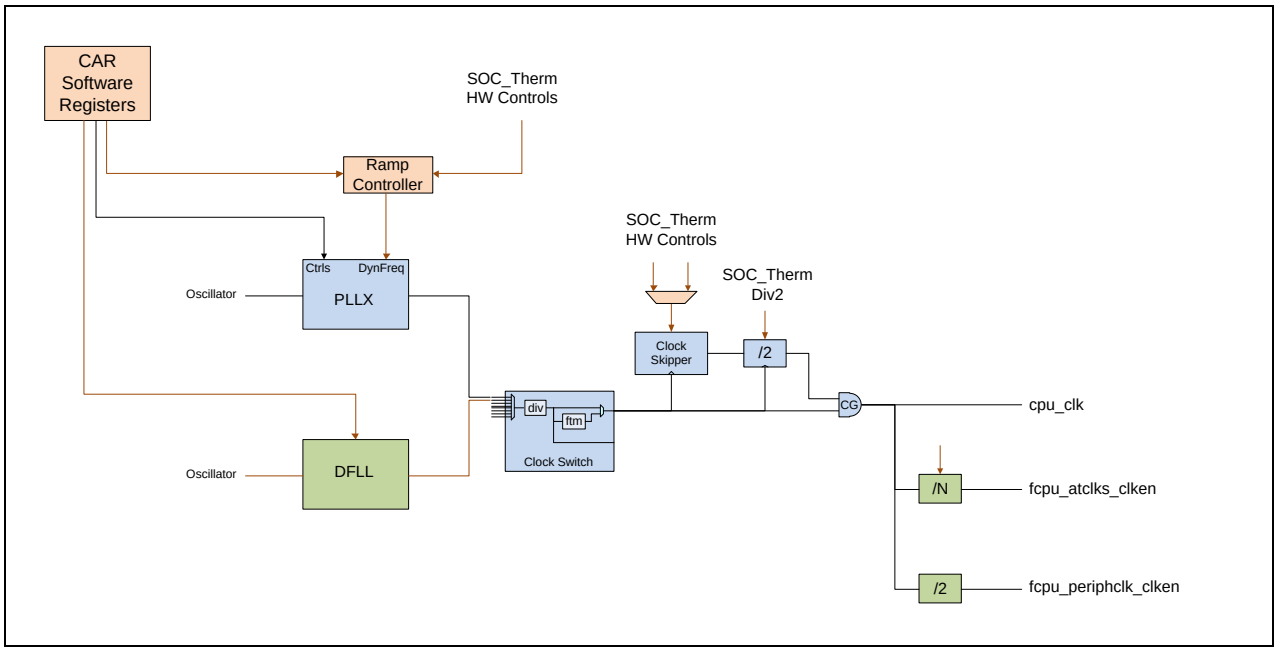
In all structures above, when the clock is gated off, it occurs at the end of the clock period so that 1) there are no runt pulses, and 2) the output clock will be stopped low.

6.2.4 Custom Core Clocks

6.2.4.1 FCPU Clock

The following figure shows a block diagram of the components of the Fast CPU (FCPU) clocking.

Figure 9: FCPU Clock Generation



DFLL

The primary clock source for the FCPU is the DFLL. The DFLL is based around a ring oscillator with supporting structures for di/dt management and frequency control.

PLLX

PLLX is one of two possible primary clock sources for the FCPU. It contains two dynamic frequency mechanisms: a fast one that could overshoot and a slower one with no overshoot.

Clock Skipper

An M/N clock skipper that is managed by the SOC Thermal module.

SOC Therm Div 2

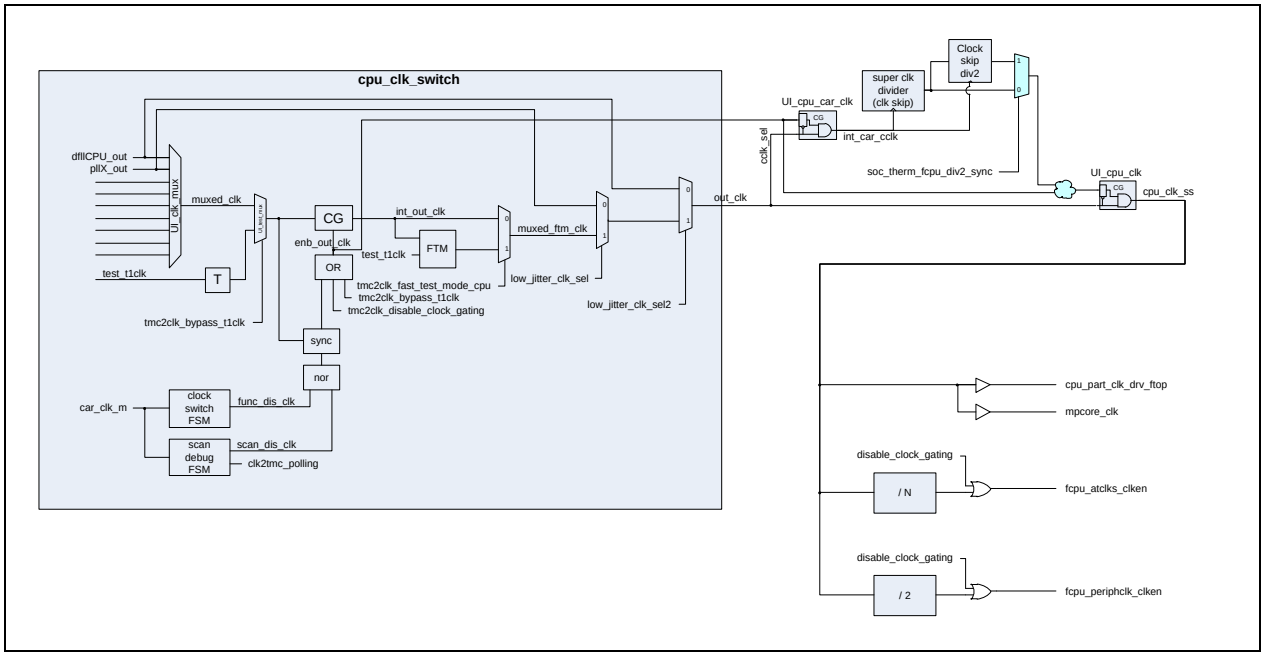
This logic will slow the CPU clock to manage thermal runaway.

Clock Switch

The clock switch consists of a clock source selection mux that can switch glitch-lessly between a number of clock sources including the PLLX and DFLL. This is followed by a programmable U7.1 divider. For low jitter when the divider is not required, a direct bypass path from PLLX or DFLL inputs to the output is also provided.

The following figure shows the details of the clock switch, clock skipper, SOC Therm Div 2, and root clock generation. The clock sources to the clock source selection mux are described in the table entitled “Root Clock Clock Sources” in the “Main Clock Sources” section.

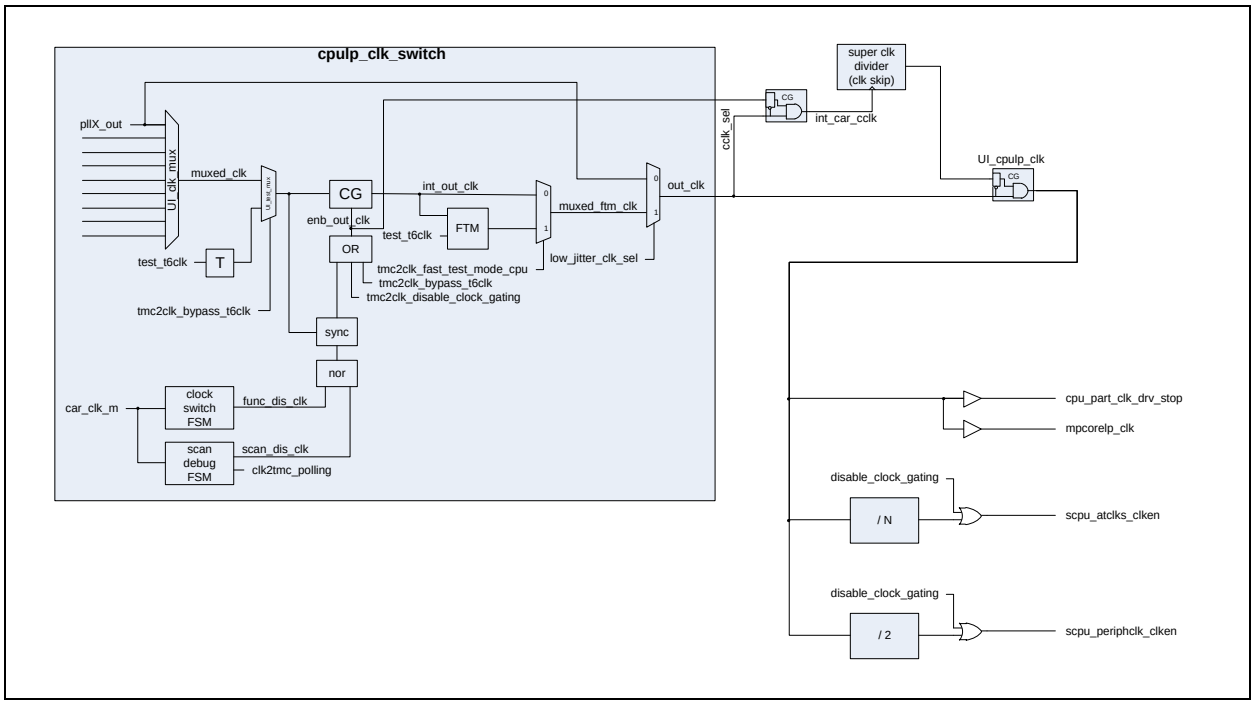
Figure 10: FCPU Clock Details



6.2.4.2 SCPU Clock

The following figure shows the details of the Clock Switch, Clock Skipper, and root clock generation for the Slow CPU (SCPU). The clock sources to the clock source selection mux are described in the table entitled “Root Clock Clock Sources” in the “Main Clock Sources” section.

Figure 11: SCPU Clock Details



6.2.4.3 GR3D Clock Switch

The hardware-controllable M/N clock skipper on the GR3D clock is managed by the SOC Therm module hardware. The clock sources to the clock source selection mux are described in the table entitled “Root Clock Clock Sources” in the “Main Clock Sources” section.

6.2.4.4 EMC/MC Clock

The PLLM’s primary purpose is to clock the MC and EMC. The EMC/MC clocking structure is complicated due to the need to support high speed DRAMs, avoid clock switching when DRAMs are being accessed, and conserve power.

When changing the EMC frequency, internal logic sequencing handles the requirement that the DRAMs must be placed into self-refresh before the clock frequency is changed. Certain register fields when written do not get immediately applied but rather are applied at the correct time during the sequencing. These registers are referred to as "shadowed". Other register fields initiate the sequencing state-machine and therefore should be written last. At the end of the sequencing, the DRAMs are restored to being operational.

The reprogramming sequence is:

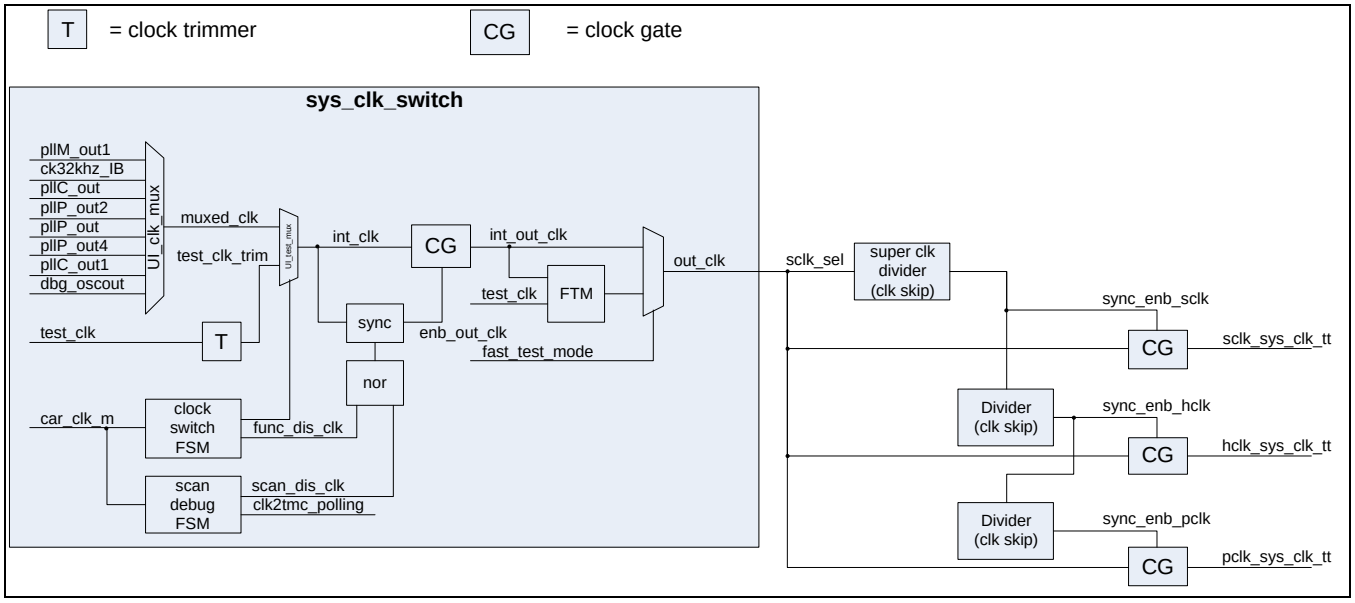
1. Program the MC/EMC shadow registers corresponding to the new frequency. These registers are “shadowed”, as noted in their descriptions, and will not impact the hardware until later during the clock change sequence.
2. Program the EMC clock change FIFO (CCFIFO) with the pre-/post-clock change sequence.
3. Program CAR CLK_SOURCE_EMC register to trigger a clock change. At this point hardware takes the following actions:
   - The CAR block asserts the clock change request to the EMC.
   - The EMC stops MC transactions, flushes its internal outstanding requests, executes MRSs/enter self-refresh, and then updates the timing to copy the EMC shadow
   - Register contents (including CDB phase select) to EMC current register.
   - The EMC asserts clock change acknowledge to the CAR block.
   - The CAR stops the clock to PLLM/CDB, updates to the new clock source, and passes the EMC CDB phase select control to the CDB.
   - The CAR re-enables the clock to PLLM/CDB.
   - The CAR deasserts the clock change request to the EMC (telling it the clock change is done).
   - The EMC unblocks MC transactions, deasserts clock change acknowledge.
   - The EMC executes the post clock change sequence (self-refresh exit, MRSs).
   - Normal memory access resumes.

Software monitors the clock change complete interrupt status from the EMC register to know when the clock change is done.

6.2.4.5 SYS Clock Generation (SCLK, HCLK, PCLK)

The system clock sclk is used by the AVP sub-system (COP), hclk is the AHB bus clock, and pclk is the APB bus clock.

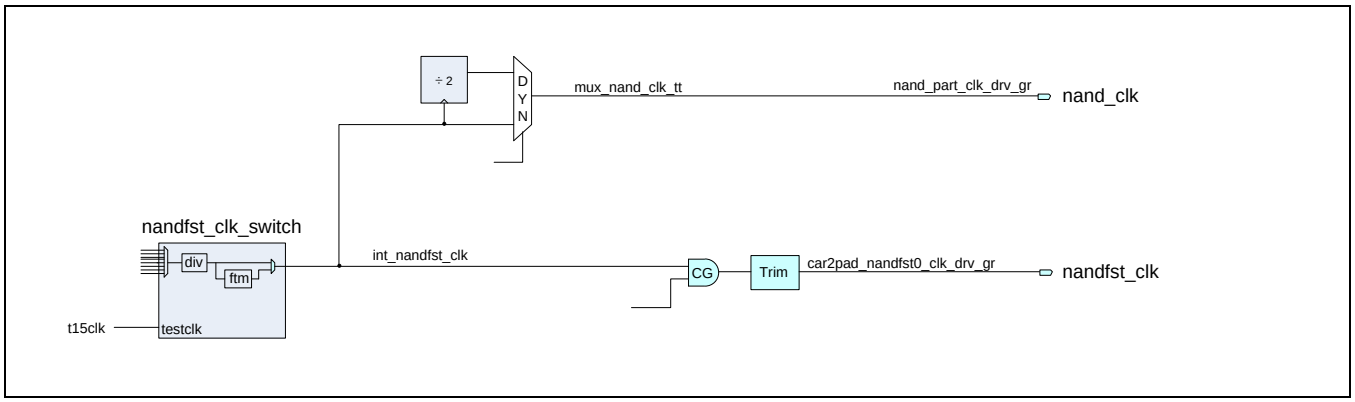
Figure 12: SCLK Clock Generation



6.2.4.6 NAND/NANDFST Clock

The NANDFST clock can be either the same or twice the frequency of the NAND clock as shown in the figure below.

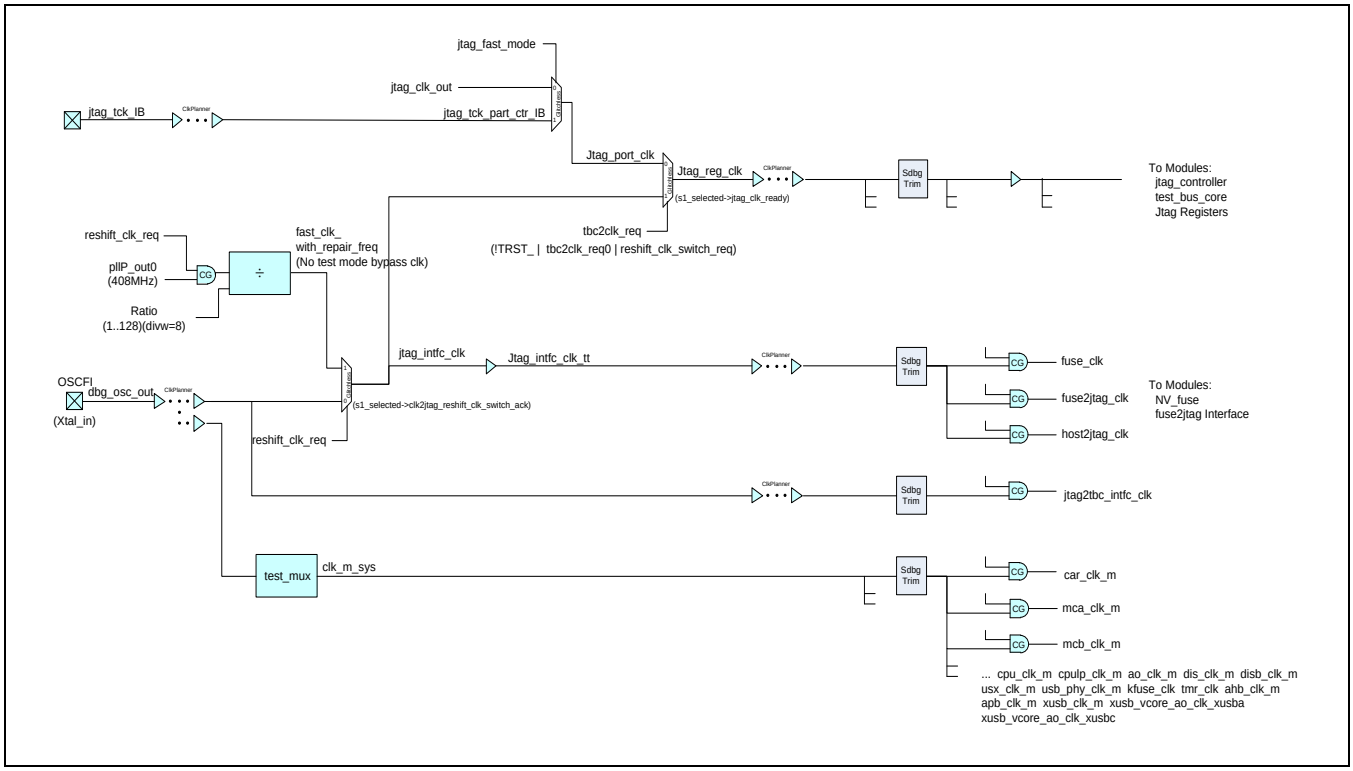
Figure 13: NAND/NANDFST Clock Generation



6.2.4.7 Jtag_ref_clk and fuse_clk

The RAMs in the Fast CPU need to support RAM repair. Since the power rail to the FCPU will be shut down in modes such as LP1, the RAM repair information will be lost. When power is returned, the RAM repair information needs to be reprogrammed. A faster clock is needed to avoid delays in bringing the FCPU online. Additionally, a synchronous clock relationship is temporarily needed between the fuse and the re-repair logic running on the JTAG clock.

Figure 14: Jtag_ref_clk and fuse_clk Clock Generation



6.3 PLLs

6.3.1 DFLLCPU

DFLLCPU is a dedicated clock source for the Fast CPU. The DFLL is based on a ring oscillator and translates voltage changes into frequency compensation changes needed to prevent the CPU from failing.

6.3.2 PLLX

Tegra 4 devices require an alternative clock source in addition to DFLLCPU. Additionally, for EDP management and to avoid creating di/dt problems, this PLL needs a dynamic frequency changing mechanism.

Similar to prior Mobile products, PLLX is dedicated for this purpose. This PLL will feed to both the Fast CPU Cluster and Shadow CPU. This PLL cannot be easily used opportunistically for other units.

6.3.3 refPLLE, PLLE, USB3 Brick PLLs

USB 3.0 requires a spread spectrum (SS) clock. It also has stringent jitter requirements to be met. A spread-spectrum PLL with high VCO frequency (for low jitter) meets these requirements. A dedicated PLL (PLLE) is used for this purpose.

In addition to PLLE, to ensure that oscillator clock jitter gets filtered out prior to feeding it to PLLE, a reference PLL (refPLLE) is required. There are additional PLL(s) in the pad brick used for physical layer signaling for USB 3.0. For cases where spread spectrum might not be required and jitter may not be an issue, an option is kept to bypass PLLE to save power. This option requires that the crystal be 12 MHz or 48 MHz to be able to create the required PLLE output frequency of 100 MHz.

6.3.4 PLLU and UTMI PLL

USB 2.0 mode requires 8 phase data sampling logic per USB 2.0 port to capture data. This requires a dedicated PLL (UTMI_PLL) with 2 data sampling logic ports. The dedicated PLL (PLLU) is used to generate the low jitter reference clock for UTMI_PLL. There is a provision to bypass PLLU for cases where a slightly higher jitter is acceptable for UTMI PLL reference clock.

6.3.5 PLLM

The DDR interface in Tegra 4 devices is required to operate at 1600 MT/s. This means that the EMC should work at 800 MHz and the MC should work at 400 MHz. The memory subsystem (DDR, EMC, and MC) is required to support a number of discrete frequencies like DDR 1600, DDR 1333, DDR 1066, DDR 800 as well as slower frequencies to conserve power. A dedicated PLL (PLLM) is used for memory clocks.

DDR interface signaling also needs a DLL to support ¼ clock shift to reliably capture/drive DQ. In addition, a CDB (clock distribution buffer) is required to get a low jitter/skew clock for each byte/command group.

6.3.6 PLLA and PLLP

All audio clocks are a multiple of the sampling frequency which can be 32 KHz, 44.1 KHz or 48 KHz. A frequency of 56.448 MHz or 73.728 MHz can be used to generate any of these sampling rates. It's not possible to generate both of these frequencies from the osc_freq by just using PLLA so a cascade of 2 PLLs, PLLP to PLLA, is required to generate the audio clocks.

PLLP is fixed at generating 408 MHz, and PLLA takes in 9.6 MHz (PLLP / 42.5) to generate the two required audio frequencies.

Because PLLP generates a fixed frequency clock for audio, it can also be divided down and used for other modules which might need a fixed frequency clock.

Most audio codecs have their own PLL, which turns out to be more power efficient, so it is possible that PLLA does not get used in a typical system for audio. In such a case PLLA can be used as a general purpose PLL.

6.3.7 Display Clocks and PLLs (PLLD and PLLD2)

Tegra 4 displays support the same 2 heads as in Tegra 3 displays. Following are the different display clocking requirements:

- Each display head requires an independent pixel clock which in worst case would need a dedicated PLL to generate the required frequency as there are too many precise clock frequencies that are required for pixel clock.
- DSI/HDMI interfaces require a differential clock to be sent out. So a dedicated PLL that can generate differential clocks is required for each one. In addition, DSI requires some PHY specific functionality to be present in the PLL.

PLLD and PLLD2 are two dedicated PLLs (with differential clock outputs and some DSI specific functionality) which should be used for DSI0 and DSI1. These PLLs can be configured to generate the pixel clock from any oscillator frequency. These PLLs consume high power (estimated at 4 times a regular general purpose PLL) and should be used only if DSI is required. For HDMI, the pad brick has PLLs which are used for interface signaling. These PLLs expect a pixel clock as an input.

6.3.8 PLLC2 and PLLC3

The A7-AVP (300MHz), MSENC (333 MHz), imaging (VI/ISP – 300 MHz), VDE (366 MHz) and various other high frequency peripherals have different maximum frequency requirements. PLLC2 and PLLC3, can go up to 600 MHz, are used for these modules.

6.3.9 PLLC

PLLC is a General-Purpose PLL. PLLC has dynamic frequency switching support, 300 MHz to 700 MHz, without overshoot. PLLC is available to most of the same modules as PLLC2 and PLLC3.

6.4 Reset Architecture

The external PMC provides the primary power-on reset (SYS_RESET_N_). Apart from POR, some other events can also result in a system reset. These are:

1. Reset due to an indication from a thermal sensor. The thermal sensor module would assert a reset signal tsensor2pmc_reset, which would in turn generate a reset for the whole chip and in the process deassert tsensor2pmc_reset itself.
2. Expiry of watchdog timer. The watchdog timer has a counter which is loaded with an initial value and ticks on periodic intervals. Once the counter expires, it reloads itself with the initial value, increments an expiry count, and generates an event for software. If software acknowledges the event, the expiry count is cleared and the counter is loaded back with initial value. This process continues indefinitely. Depending on the current expiry count, the event generated for software could be different. There are 2 types of watchdog timers in Tegra 4 systems depending on how they generate the reset:
   - Deadman timer (referred as WDT in reset code): This is the legacy implementation in which:

     1st expiry an interrupt is issued

     2nd expiry a reset is issued. This reset, however, resets only a subset of units.
   - Watchdog timer (referred as WDT2 in reset code):

     1st expiry – interrupt is issued

     2nd expiry – FIQ is issued

     3rd expiry – CPU reset is issued

     4th expiry – full system reset – This is the relevant reset for this section
3. Software reset. This reset is controlled by a configuration bit in the PMC address space (main_swrst). Once asserted, this result in a reset generation for the whole chip and in the process deasserts itself.
4. LP0 wakeup reset. This is controlled by the logic within the PMC.

The POR (SYS_RESET_N_) is deasserted by the external PMC after the power sequencing is done and after the RTC clock (clk_32KHz) and crystal clock is already running. For the other sources, the reset is originated within the Tegra 4 hardware.

6.5 Power Gating and Ungating

6.5.1 Clamp/Reset/Clock/PG-Enable Sequencing

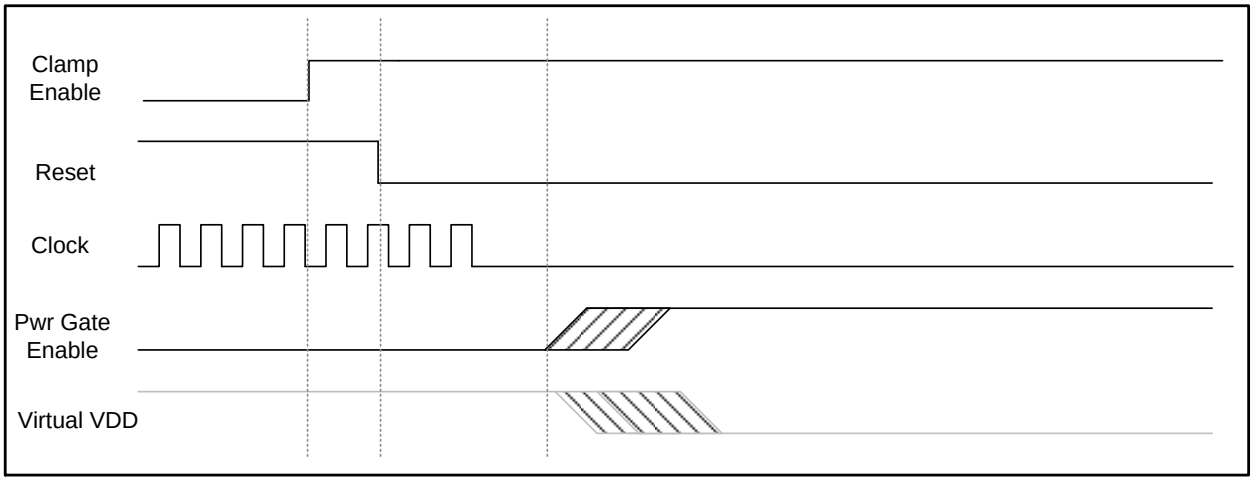
6.5.1.1 Power Gating

For power-gating (powering off) a partition, the clamp, reset, clocks, and PG-enable (also known as sleep-enable) controls must be sequenced as shown in following diagram. For CCPLEX PG partitions, this sequencing is ensured by hardware (when power-gating is done via flow-controller). For SoC (non-CCPLEX) PG partitions, this sequencing needs to be ensured by software.

In general, clamp-enable should be asserted before reset (as shown in the diagram). This works with synchronous or asynchronous clamping. However, if a unit can guarantee that its output signals will have the same clamp values as their pre-clamp values (idle values) as well as their reset values, then clamp and reset ordering is not critical. Note it is non-trivial to verify the above guarantee.

Also, it is recommended to have synchronous clamps. However, if a unit can guarantee that its output signals will have the same clamp value as their pre-clamp values (idle values) as well as their reset values, then asynchronous clamping can be used. It is non-trivial to verify the above guarantee.

Figure 15: Power-Gating Timing Sequence for Clamp/Reset/Clock/PG-Enable

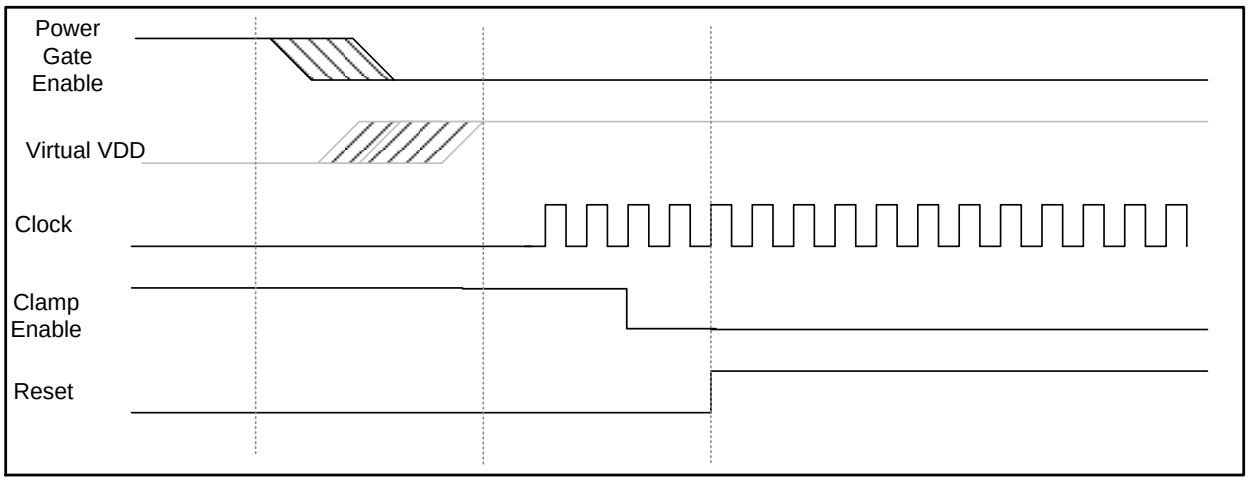


6.5.1.2 Power Ungating

For power-ungating (powering on) a partition, we have to ensure that clamp, reset, clocks, and PG-enable (sleep-enable) controls are sequenced as shown in the following diagram. For CCPLEX PG partitions, this sequencing is ensured by hardware (when power-gating is done via the flow controller). For SoC (non-CCPLEX) PG partitions, this sequencing needs to be ensured by software.

In general, the clamp enable should be deasserted before reset (as shown in the diagram). This works with synchronous or asynchronous clamping. However, if a unit can guarantee that its output signals will have same clamp values as its post-clamp values (idle values), then clamp and reset ordering is not critical for power ungating. Note it is non-trivial to verify the above guarantee.

Figure 16: Power-Ungating Timing Sequence for Clamp/Reset/Clock/PG-Enable



6.5.2 Power-Gating Controller

The PMC provides power-gating controllers as programmable sequencers. When the power gating/ungating in is triggered, the controller sequences PG-enable signals with a programmable delay (measured in APB clock cycles) between consecutive “zones” PG-enable controls. There are two types of power-gating controllers: CPU and SOC power-gating controllers. The following sections describe both types of controllers.

6.5.2.1 SOC Power-Gating Controller

The SOC power-gating controller is used to sequence power gating of SOC (including shadow CPU cluster) power partitions. It uses 8 zones and shares the same programming register for inter-zone delays. The zones are powered up in one order and powered down in reverse order, using the same inter-zone timings. So only one set of delays are used for both powering down and up.

For all non-CPU SOC partitions, power-gating can only be turned on/off by direct register write. For CPU (shadow) SOC partitions, power-gating can be turned on/off via flow-controller. Refer to “SOC Power Gating Controllers” in the PMC section.

GPU Power Gating

GPU power gating is an exception to power-gating of other SoC partitions. In Tegra 4 devices, the GPU (also known as TD) will have 6 partitions, which should be seen as one ELPG (Engine Level PG) by software. They should be powered on/off sequentially due to power restrictions. The PMC would sequence each of the TD partitions using the SOC power-gating controller, and would have a programmable inter-partition delay. The operation would be transparent for software. The PMC would also have an option of sequencing all 6 partitions in parallel to shorten power-gating latency.

Each of the GPU partitions would have its separate reset (from the CAR) and clamp (from the PMC). All of the GPU partitions can be clamped at the same time (and similarly reset at the same time). In other words, software should be able to treat the GPU as one engine for sequencing clamp/reset/clock/power-enable as described in previous sections.

6.5.2.2 Fast CPU Power-Gating Controller

The fast CPU power-gating controller is used to sequence power-gating of fast CPU partitions. All CPU partitions (CE0/1/2/3 and C0NC) share the same programming register for inter-zone delays, which are different from inter-zone delays in SoC partitions. The zones are powered up in one order and powered down in reverse order, using the same inter-zone timings. So only one set of delays are used for both powering down and up. For fast CPU partitions, power gating can be turned on/off via the flow controller. Refer to “CPU-G Power Gating Controllers” in the PMC section.

6.6 SRAM Power Gating

Tegra 4 devices contain two distinct types of RAMs: Custom RAMs (FCMs) in the VDD_CPU power domain and compiled RAMs in the VDD_SOC and VDD_AO domains.

6.6.1 Custom RAMs (FCMs) in CCPLEX

All custom RAMs (FCMs) can be power-gated. The following table lists the FCMs in the Tegra 4 VDD_CPU domain (all FCMs are in fast CCPLEX only).

SRAM	Partition	Tiles/ Inst	# Inst	# Cores
eag_l2_data_ram	FL2	4	16	1
eag_l2_tag_ram	FL2	1	32	1
eag_l2_tlb_ram	FL2	1	4	4
eag_l2_dirty_ram	FL2	4	1	4
eag_l2_psq_ram	FL2	1	1	4
eag_l2_snp_tag_ram	FL2	1	4	4
eag_ls_data_ram	FCPU	2	4	4
eag_ls_tag_ram	FCPU	2	4	4
eag_if_data_ram	FCPU	1	16	4

SRAM	Partition	Tiles/ Inst	# Inst	# Cores
eag_if_tag_ram	FCPU	1	2	4
eag_if_btb_ram	FCPU	1	4	4
eag_if_ghb_ram	FCPU	1	6	4
eag_if_ip_ram	FCPU	1	1	4

6.6.2 RAMs in SOC

The RAMs in the following table support power gating.

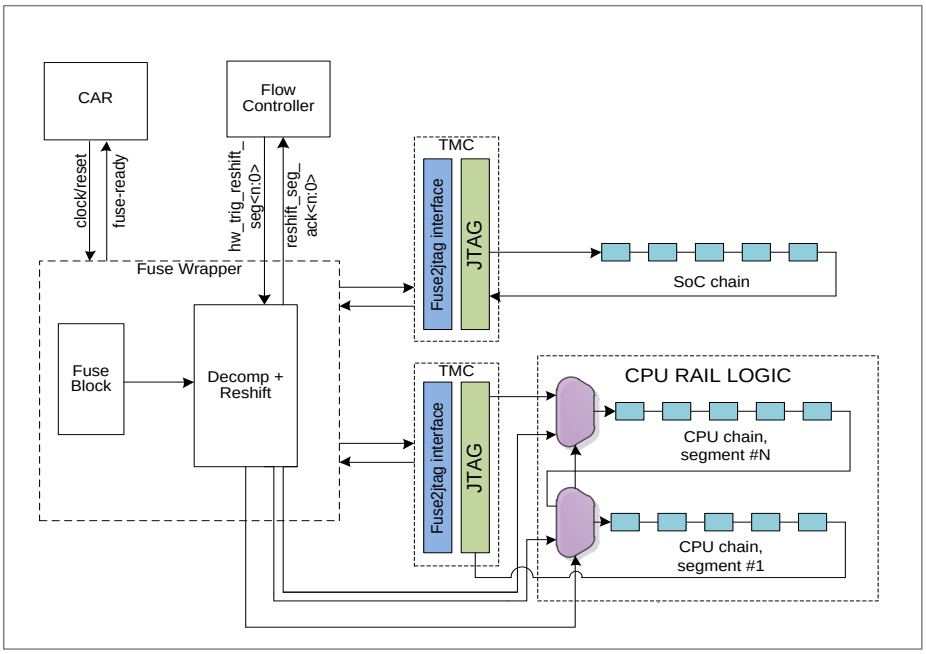
RAM	Partition	Count
RAMSP_2048X32_ABE8GR_M8_B1	SL2 (Companion core L2 Data)	64
RAMSP_2048X32_ABGPR_M8_B1	MSENC (TEB)	28
RAMSP_2048x541_BGPR_M4_B1	DISP	1
RAMSP_832x541_BGPR_M4_B2	DISP	1
RAMSP_768x541_BGPR_M4_B3	DISP	1

6.7 SRAM Repair and Re-repair

To repair faulty SRAMs, a set of repair flops are used in SRAMs to hold repair mux controls. At initial power up, these flops are programmed by fuse-value shifted into “repair chains”.

Tegra 4 devices use PAGO cells for repair flops, which hold repair information when an SRAM is power-gated. However, when the corresponding rail is powered off, PGAO repair flops are powered off.

Figure 17: SRAM Repair and Re-repair Block View



6.7.1 Number of Repair Chains and Segments

Tegra 4 devices have two repair chains:

- Repair chain for SoC-rail RAMs (including RAMs in shadow CPU cluster), referred to as the SoC chain
- Repair chain for CPU-rail RAMs, referred to as the CPU chain

To speed up the CPU RAMs repair, the CPU repair chain is segmented into 8 segments. The segments of a repair chain can be shifted-in one (or more) segments at a time.

6.7.2 Repair

At SoC rail power-up, the CAR block deasserts reset to the fuse, repair, and reshift logic (referred to as fuse wrapper) while holding reset for other SoC and CPU blocks (especially for boot blocks). At the deassertion of reset, the fuse wrapper reads fuses and shifts repair values into SoC and CPU repair chains, one chain at a time.

At this stage in the boot, the SoC rail is powered on, but the CPU rail is powered off. So repair to the CPU chain fails (at boot time).

The SoC repair chain needs to be repaired only at boot (cold or warm, also known as LP0). But the CPU rail is powered off, so the CPU repair chain needs to be re-repaired every time the CPU rail is powered up.

6.7.3 Re-repair

At boot-time, repair fails because the CPU rail is powered off. However, the “reshift” block snoops the fuse values (being shifted into the CPU chain), and stores them in an SRAM. Subsequently, the CPU chain is re-repaired by triggering the reshift block, which uses repair values from this SRAM.

The CPU chain is re-repaired every time the CPU rail is powered up (including the first time during boot). The following steps describe the sequence of CPU rail powering up:

- CPU rail is powered up
- CPU repair chain is re-repaired
- CPU reset and clamps are deasserted

When the CPU rail is powered up the first time (during boot), software triggers the CPU chain re-repair by programming the flow-controller register. Subsequently, flow-controller hardware triggers CPU chain re-repair. In either case, the flow controller requests the “reshift” block to perform re-repair.

6.7.3.1 Re-repair Programming Guide

Re-repair is required every time the CPU rail is powered up. However, re-repair needs to be explicitly triggered by software during cold or warm (LP0 exit) boot as described in the following sequence. The re-repair required during cluster-switch (from cluster1 to cluster0) or LP2 exit with CPU rail power-up is automatically done by hardware.

The re-repair frequency can be programmed (upfront) by writing to the CAR CLK_RST_CONTROLLER_PLLP_RESHIFT register. Software programs this value at cold/warm boot, and it does not change after that.

If need be, software can configure the re-repair frequency to be different for cluster-switch and/or LP2-exit by programming the appropriate value in the CAR CLK_RST_CONTROLLER_PLLP_RESHIFT register before cluster-switch or before going into LP2. As a result, when hardware triggers re-repair, it would use the frequency configured earlier by software.

Software CPU-Rail-Power-Up Sequence including RAM Re-repair

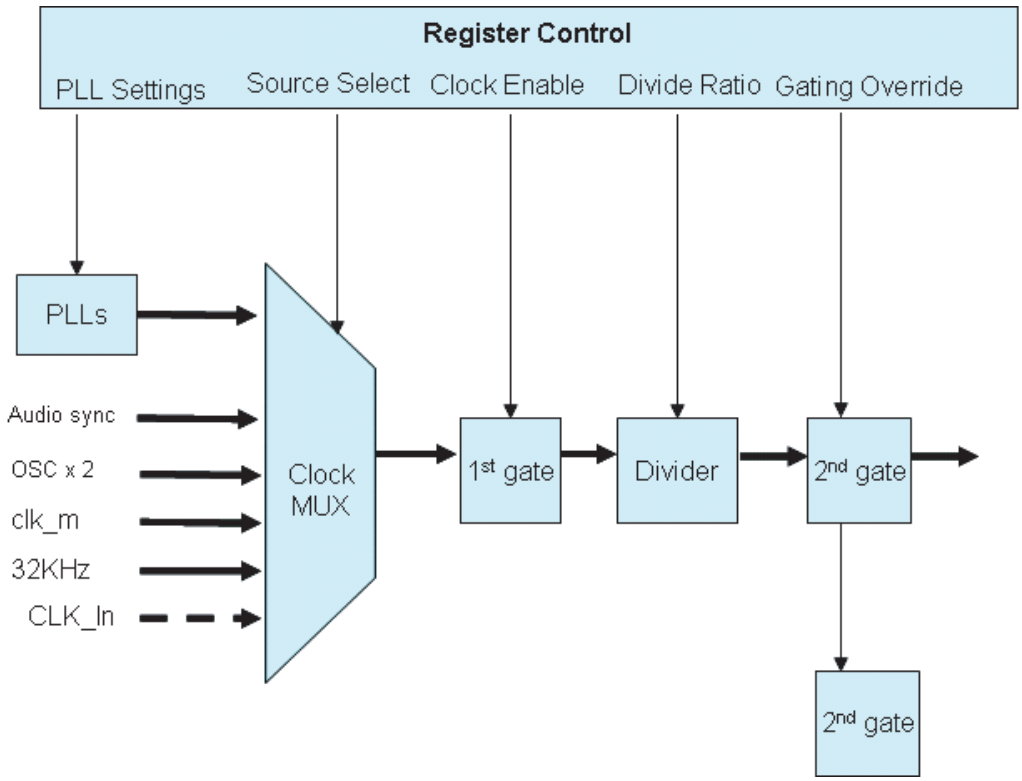
- Power-up CPU rail by direct register write or via PMIC I2C
- Wait for CPU rail power up (by reading PMC_PWRGATE_STATUS[CARIL] status)
- Trigger RAM repair (by writing FLOW_CTLR_RAM_REPAIR[REQ])
- Wait for RAM repair to be done (by reading FLOW_CTLR_RAM_REPAIR[STS])
- Continue the rest of power-up sequence as without re-repair, that is, clamp removal and reset deassertion).

6.8 Software Features and Programming Model

6.8.1 Clock Control

The figure below illustrates the software clock control model.

Figure 18: Clock Control



6.8.2 PLL Programming

PLL output frequencies are programmed by setting their N, M, and P values. The governing equations are:

VCO = (Fi / M) * N,

Fo = VCO / (2 ^ P)

where *Fo* is the output frequency from the PLL.

> **Note:** Not all PLLs have the simple mapping for the P value listed above. Contact your NVIDIA representative for assistance.

There are three requirements for each PLL that must be complied with:

- Each PLL has a legal input frequency (*Fi*) range.
- Each PLL has a legal comparison frequency (*CF*) range, where *CF = Fi / M*
- Each PLL has a legal *VCO* frequency range, where *VCO = CF * N*.

To change a PLL, do the following:

- Ensure that no enabled module is using the PLL that will change.
- Program the new PLL settings
- Wait for PLL stabilization
- Change the divider values for each clock that will use the PLL to divide-down to the target frequency, and change the module clock sources for all modules that will use the new PLL settings.

6.8.3 Clock Division Control

The ratio as defined by the *1/divisor* for an 8-bit fractional divider, of 7 bits of *d* and 1 bit of *h* is:

divisor = (ddddddd + 1) + (h * 0.5)

The divisor for UART 16b integer divider it is:

divisor = (dddddddddddddddd)

The divisor for the I2C 16b integer divider it is:

divisor = (ddddddddddddddd + 1)

6.8.4 Changing Clock Sources and Clock Dividers

Changing a clock source (except the clock sources to the audio_sync_clk) to a running module is "glitch free". The clock source and divide ratio can be set concurrently without creating spurious frequencies. For the audio_sync_clk, the clock source select needs to be set up before changing the device clock source to use that audio clock or to enable the device which uses that audio clock.

The glitch-free clock divider to a running module can also be changed. All modules support changing the clock divider ratio without disabling the clock; write the new divider to the appropriate register See the section on Power below.

To change the clock source and divider (either after system reset or for any other reason), follow this sequence:

Sequence 1 to change clock source and divider:

1. Assert reset to the module if it is not already asserted
2. Enable clock to the module if the clock is not already enabled
3. Change the clock divider and/or the clock source to the module
4. Wait 2 µs for the clock to flush through the pipe / logic.
5. Deassert reset to the module.

6.8.5 Clock Gating (Override)

Please refer to the register definition section for more information.

6.8.5.1 Power

The following guidelines should be followed in pursuit of the lowest use-case power consumption:

- Target the least number of PLLs running at their lowest allowable frequencies for the given use-case.
- For each module, use the source with the lowest frequency that provides adequate performance for the use case.
- Turn off all clocks not required for the given use-case - employ maximum clock-gating.
- Use hardware dynamic clock bursting whenever possible. Turn on the desired frequency, burst to completion, and then disable the input frequency (allowing PLLs to be turned off or their output frequencies to be lowered)
- Use the CPU and COP/system super clock divider for lower CPU frequency where possible.
- Disable the oscillator input and/or clock outputs when they are not in use.

6.8.6 Use-Case Restrictions

6.8.6.1 Use of PLLC for Display

Other than PLLD, there is no dedicated PLL for either display controller. PLLD is required when one of the display controllers outputs to DSI, but should be otherwise avoided due to its higher power. When DSI is not one of the output devices, or in dual-display use cases, the additional PLLs PLLC and PLLP must be used. The matrix of choices is shown in the table below.

Table 16: PLL Sources for Display Based on Use-Case

Primary Head	PLL Choices	Secondary Head	PLL Choices
Parallel	P, C, D	--	--
DSI	D	--	--
Parallel	P, C	Sub	P
DSI	D	Sub	P
Parallel	P, C	DSI	D
Parallel	P, C, D	Parallel	P, C, D
Parallel	P, C, D	TVO	P
Parallel	P, C, D	HDMI	P (480p), C, D (720p)
Parallel	P, C, D	CRT	C, D
DSI	D	TVO	P
DSI	D	HDMI	P (480p), C, D (720p)
DSI	D	CRT	C, D

If possible, the first choice should use the fixed PLLP as the Display source clock (divided-down to the required frequency). However, many display resolutions and/or output devices cannot be driven within the required tolerance by a divided-down PLLP.

Second choice is to use either PLLD or PLLC, depending on the acceptable trade-off. If PLLD is used, power consumption is 5x higher than that for PLLC. If PLLC is used, it may compromise other use cases since the Display source PLL must be programmed to a precise frequency to achieve the required Display error tolerance.

Since PLLC is a possible source clock for the AVP, the high-speed serial devices (SFlash and SPI), for the video encoder (MPE), and for 2D and 3D, these devices may not achieve their target (maximum) frequencies when the Display must constrain PLLC directly. An example of this is shown in the table below for a case where external memory is 166 MHz DDR (EMC 2x clock = 333 MHz).

Table 17: Example of Device Frequencies Possible when PLLC Frequency is Constrained for Use by Display

PLLC	PLLP	AVP	HS serial	MPE	2D / 3D
600.0	408.0	150.0	200.0	200.0	216.0
590.0	408.0	147.5	196.7	196.7	216.0
580.0	408.0	145.0	193.3	193.3	216.0
570.0	408.0	144.0	190.0	190.0	216.0
560.0	408.0	144.0	186.7	186.7	216.0
550.0	408.0	144.0	183.3	183.3	275.0
540.0	408.0	144.0	180.0	180.0	270.0
530.0	408.0	144.0	176.7	176.7	265.0
520.0	408.0	144.0	173.3	173.3	260.0
510.0	408.0	144.0	170.0	170.0	255.0
500.0	408.0	144.0	166.7	166.7	250.0

6.8.7 Programming Guide for Power Gating and Ungating

This section covers the software procedures for power gating and ungating of SOC power domains. Power gating and ungating of CPU power domains is not covered here because it is handled through the Flow Controller.

6.8.7.1 Procedure Summary

The general procedure for power gating an SOC power domain is as follows:

1. Write MC register to flush and block MC clients
2. Write CAR register to assert unit resets
3. Write CAR register to disable clocks
4. Write PMC register to gate power domain

The general procedure for power ungating an SOC power domain is as follows:

1. Write PMC register to ungate power domain
2. Write CAR register to enable clocks
3. Write CAR register to deassert resets
4. Write MC register to enable MC clients

In some cases, partitions require specific deviations from the general procedure. Deviations are covered in the domain-specific sections below.

This table summarizes the respective clock and reset bits and MC clients in each SOC power domain.

Table 18: MC Clients for Clocks and Resets per Domain

Domain	Unit Clocks and Resets	MC Clients
VE	VI, CSI, ISP	VI, ISP
TD	3D	NV
VDE	VDE	VDE
MPE	MSENC	MSENC
HEG	2D, EPP	G2, EPP
DIS	DISP1, DSI, DSIB, CSICIL, MIPICAL	DC
DISB	DISP2, HDMI	DCB
XUSBA	XUSB_SS	None
XUSBB	XUSB_DEV	XUSB_DEV
XUSBC	XUSB_HOST	XUSB_HOST

6.8.7.2 Procedures for VE Power Domain

VE Power Gating

1. Flush MC clients VI and ISP by setting the following bits:
   - MC_CLIENT_HOTRESET_CTRL_0.VI_FLUSH_ENABLE
   - MC_CLIENT_HOTRESET_CTRL_0.ISP_FLUSH_ENABLE
2. Poll MC_CLIENT_HOTRESET_STATUS_0 until the following bits are set:
   - VI_HOTRESET_STATUS
   - ISP_HOTRESET_STATUS
3. Set the following bits to assert reset to VI, ISP, and CSI:
   - CLK_RST_CONTROLLER_RST_DEVICES_L_0.SWR_VI_RST
   - CLK_RST_CONTROLLER_RST_DEVICES_L_0.SWR_ISP_RST
   - CLK_RST_CONTROLLER_RST_DEVICES_H_0.SWR_CSI_RST
4. Clear the following bits to disable clocks to VI, ISP, and CSI:
   - CLK_RST_CONTROLLER_CLK_OUT_ENB_L_0.CLK_ENB_VI
   - CLK_RST_CONTROLLER_CLK_OUT_ENB_L_0.CLK_ENB_ISP
   - CLK_RST_CONTROLLER_CLK_OUT_ENB_H_0.CLK_ENB_CSI
5. Write to these APBDEV_PMC_PWRGATE_TOGGLE_0 fields with the following settings:
   - PARTID = VE

START = ENABLE

6. Poll APBDEV_PMC_PWRGATE_STATUS_0 until bit VE is set

VE Power Ungating

1. Write to these APBDEV_PMC_PWRGATE_TOGGLE_0 fields with the following settings:
   PARTID = VE
   START = ENABLE
2. Poll APBDEV_PMC_PWRGATE_STATUS_0 until the VE bit is cleared
3. Set the following bits to enable clocks to VI and ISP:
   CLK_RST_CONTROLLER_CLK_OUT_ENB_L_0.CLK_ENB_VI
   CLK_RST_CONTROLLER_CLK_OUT_ENB_L_0.CLK_ENB_ISP
4. If the DIS domain is powered up, enable clocks to the CSI by setting the following bit:
   CLK_RST_CONTROLLER_CLK_OUT_ENB_H_0.CLK_ENB_CSI
5. Remove power-gating clamps by writing a 1 to the following bit:
   APBDEV_PMC_REMOVE_CLAMPING_CMD_0.VE
6. Poll APBDEV_PMC_REMOVE_CLAMPING_CMD_0 until the VE bit is cleared
7. Clear the following bits to deassert the reset to VI and ISP:
   CLK_RST_CONTROLLER_RST_DEVICES_L_0.SWR_VI_RST
   CLK_RST_CONTROLLER_RST_DEVICES_L_0.SWR_ISP_RST
8. If the DIS domain is powered up, deassert the reset to the CSI by clearing the following bit:
   CLK_RST_CONTROLLER_RST_DEVICES_H_0.SWR_CSI_RST
9. Enable MC clients VI and ISP by clearing the following bits:
   MC_CLIENT_HOTRESET_CTRL_0.VI_FLUSH_ENABLE
   MC_CLIENT_HOTRESET_CTRL_0.ISP_FLUSH_ENABLE

6.8.7.3 Procedures for TD Power Domain

TD Power Gating

1. Flush the NV MC client by setting the following bit:
   MC_CLIENT_HOTRESET_CTRL_0.NV_FLUSH_ENABLE
2. Poll MC_CLIENT_HOTRESET_STATUS_0 until the following bit is set:
   NV_HOTRESET_STATUS
3. Set the following bit to assert the reset to 3D:
   CLK_RST_CONTROLLER_RST_DEVICES_L_0.SWR_3D_RST
4. Clear the following bit to disable clocks to 3D:
   CLK_RST_CONTROLLER_CLK_OUT_ENB_L_0.CLK_ENB_3D
5. Write to these APBDEV_PMC_PWRGATE_TOGGLE_0 fields with the following settings:
   PARTID = TD
   START = ENABLE
6. Poll APBDEV_PMC_PWRGATE_STATUS_0 until the TD bit is set

TD Power Ungating

1. Write to these APBDEV_PMC_PWRGATE_TOGGLE_0 fields with the following settings:
   - PARTID = TD
   - START = ENABLE
2. Poll APBDEV_PMC_PWRGATE_STATUS_0 until the TD bit is cleared.
3. Set the following bit to enable clocks to 3D:
   - CLK_RST_CONTROLLER_CLK_OUT_ENB_L_0.CLK_ENB_3D
4. Remove power-gating clamps by writing a 1 to the following bit:
   - APBDEV_PMC_REMOVE_CLAMPING_CMD_0.TD
5. Poll APBDEV_PMC_REMOVE_CLAMPING_CMD_0 until the TD bit is cleared.
6. Clear the following bit to deassert the reset to 3D:
   - CLK_RST_CONTROLLER_RST_DEVICES_L_0.SWR_3D_RST
7. Enable the NV MC client by clearing the following bit:
   - MC_CLIENT_HOTRESET_CTRL_0.NV_FLUSH_ENABLE

6.8.7.4 Procedures for VDE Power Domain

VDE Power Gating

1. Flush the VDE MC client by setting the following bit:
   - MC_CLIENT_HOTRESET_CTRL_0.VDE_FLUSH_ENABLE
2. Poll MC_CLIENT_HOTRESET_STATUS_0 until the following bit is set:
   - VDE_HOTRESET_STATUS
3. Set the following bit to assert the reset to the VDE:
   - CLK_RST_CONTROLLER_RST_DEVICES_H_0.SWR_VDE_RST
4. Clear the following bit to disable clocks to the VDE:
   - CLK_RST_CONTROLLER_CLK_OUT_ENB_H_0.CLK_ENB_VDE
5. Write to these APBDEV_PMC_PWRGATE_TOGGLE_0 fields with the following settings:
   - PARTID = VDE
   - START = ENABLE
6. Poll APBDEV_PMC_PWRGATE_STATUS_0 until the VDE bit is set

VDE Power Ungating

1. Write to these APBDEV_PMC_PWRGATE_TOGGLE_0 fields with the following settings:
   - PARTID = VDE
   - START = ENABLE
2. Poll APBDEV_PMC_PWRGATE_STATUS_0 until the VDE bit is cleared
3. Set the following bit to enable clocks to the VDE:
   - CLK_RST_CONTROLLER_CLK_OUT_ENB_H_0.CLK_ENB_VDE
4. Remove power-gating clamps by writing a 1 to the following bit:
   - APBDEV_PMC_REMOVE_CLAMPING_CMD_0.VDE
5. Poll APBDEV_PMC_REMOVE_CLAMPING_CMD_0 until the VDE bit is cleared
6. Clear the following bit to deassert the reset to the VDE:

[redacted]CLK_RST_CONTROLLER_RST_DEVICES_H_0.SWR_VDE_RST

7. Enable the VDE MC client by clearing the following bit:

   [redacted]MC_CLIENT_HOTRESET_CTRL_0.VDE_FLUSH_ENABLE

6.8.7.5 Procedures for MPE Power Domain

MPE Power Gating

1. Flush the MSENC MC client by setting the following bit:

   [redacted]MC_CLIENT_HOTRESET_CTRL_0.MSENC_FLUSH_ENABLE

2. Poll MC_CLIENT_HOTRESET_STATUS_0 until the following bit are set:

   [redacted]MSENC_HOTRESET_STATUS

3. Set the following bit to assert the reset to the MSENC:

   [redacted]CLK_RST_CONTROLLER_RST_DEVICES_U_0.SWR_MSENC_RST

4. Clear the following bit to disable clocks to the MSENC:

   [redacted]CLK_RST_CONTROLLER_CLK_OUT_ENB_U_0.CLK_ENB_MSENC

5. Write to these APBDEV_PMC_PWRGATE_TOGGLE_0 fields with the following settings:

   [redacted]PARTID = MPE

   [redacted]START = ENABLE

6. Poll APBDEV_PMC_PWRGATE_STATUS_0 until the MPE bit is set

MPE Power Ungating

1. Write to these APBDEV_PMC_PWRGATE_TOGGLE_0 fields with the following settings:

   [redacted]PARTID = MPE

   [redacted]START = ENABLE

2. Poll APBDEV_PMC_PWRGATE_STATUS_0 until the MPE bit is cleared
3. Set the following bits to enable clocks to the MSENC:

   [redacted]CLK_RST_CONTROLLER_CLK_OUT_ENB_U_0.CLK_ENB_MSENC

4. Remove power-gating clamps by writing a 1 to the following bit:

   [redacted]APBDEV_PMC_REMOVE_CLAMPING_CMD_0.MPE

5. Poll APBDEV_PMC_REMOVE_CLAMPING_CMD_0 until the MPE bit is cleared
6. Clear the following bits to deassert the reset to the MSENC:

   [redacted]CLK_RST_CONTROLLER_RST_DEVICES_U_0.SWR_MSENC_RST

7. Enable the MSENC MC client by clearing the following bit:

   [redacted]MC_CLIENT_HOTRESET_CTRL_0.MSENC_FLUSH_ENABLE

6.8.7.6 Procedures for HEG Power Domain

HEG Power Gating

1. Flush the G2 and EPP MC clients by setting the following bits:

   [redacted]MC_CLIENT_HOTRESET_CTRL_0.G2_FLUSH_ENABLE

   [redacted]MC_CLIENT_HOTRESET_CTRL_0.EPP_FLUSH_ENABLE

2. Poll MC_CLIENT_HOTRESET_STATUS_0 until the following bits are set:

   [redacted]G2_HOTRESET_STATUS

[redacted]EPP_HOTRESET_STATUS

3. Set the following bits to assert the reset to 2D and EPP:
   [redacted]CLK_RST_CONTROLLER_RST_DEVICES_L_0.SWR_2D_RST
   [redacted]CLK_RST_CONTROLLER_RST_DEVICES_L_0.SWR_EPP_RST
4. Clear the following bits to disable clocks to 2D and EPP:
   [redacted]CLK_RST_CONTROLLER_CLK_OUT_ENB_L_0.CLK_ENB_2D
   [redacted]CLK_RST_CONTROLLER_CLK_OUT_ENB_L_0.CLK_ENB_EPP
5. Write to these APBDEV_PMC_PWRGATE_TOGGLE_0 fields with the following settings:
   [redacted]PARTID = HEG
   [redacted]START = ENABLE
6. Poll APBDEV_PMC_PWRGATE_STATUS_0 until the HEG bit is set

HEG Power Ungating

1. Write to these APBDEV_PMC_PWRGATE_TOGGLE_0 fields with the following settings:
   [redacted]PARTID = HEG
   [redacted]START = ENABLE
2. Poll APBDEV_PMC_PWRGATE_STATUS_0 until the HEG bit is cleared
3. Set the following bits to enable clocks to 2D and EPP:
   [redacted]CLK_RST_CONTROLLER_CLK_OUT_ENB_L_0.CLK_ENB_2D
   [redacted]CLK_RST_CONTROLLER_CLK_OUT_ENB_L_0.CLK_ENB_EPP
4. Remove power-gating clamps by writing a 1 to the following bit:
   [redacted]APBDEV_PMC_REMOVE_CLAMPING_CMD_0.HEG
5. Poll APBDEV_PMC_REMOVE_CLAMPING_CMD_0 until the HEG bit is cleared
6. Clear the following bits to deassert the reset to 2D and HEG:
   [redacted]CLK_RST_CONTROLLER_RST_DEVICES_L_0.SWR_2D_RST
   [redacted]CLK_RST_CONTROLLER_RST_DEVICES_L_0.SWR_EPP_RST
7. Enable the G2 and EPP MC clients by clearing the following bits:
   [redacted]MC_CLIENT_HOTRESET_CTRL_0.G2_FLUSH_ENABLE
   [redacted]MC_CLIENT_HOTRESET_CTRL_0.EPP_FLUSH_ENABLE

6.8.7.7 Procedures for DIS Power Domain

DIS Power Gating

1. The VE and DISB power domains have to be gated before the DIS can be gated.
2. Flush the DC MC client by setting the following bit:
   [redacted]MC_CLIENT_HOTRESET_CTRL_0.DC_FLUSH_ENABLE
3. Poll MC_CLIENT_HOTRESET_STATUS_0 until the following bit is set:
   [redacted]DC_HOTRESET_STATUS
4. Set the following bits to assert the reset to DISP1, DSI, DSIB, and MIPI_CAL:
   [redacted]CLK_RST_CONTROLLER_RST_DEVICES_L_0.SWR_DISP1_RST
   [redacted]CLK_RST_CONTROLLER_RST_DEVICES_H_0.SWR_DSI_RST
   [redacted]CLK_RST_CONTROLLER_RST_DEVICES_H_0.SWR_MIPI_CAL_RST

- CLK_RST_CONTROLLER_RST_DEVICES_U_0.SWR_DSIB_RST

5. Clear the following bits to disable clocks to DISP1, DIS, DISB, and MIPI_CAL:
   - CLK_RST_CONTROLLER_CLK_OUT_ENB_L_0.CLK_ENB_DISP1
   - CLK_RST_CONTROLLER_CLK_OUT_ENB_H_0.CLK_ENB_DSI
   - CLK_RST_CONTROLLER_CLK_OUT_ENB_H_0.CLK_ENB_MIPI_CAL
   - CLK_RST_CONTROLLER_CLK_OUT_ENB_U_0.CLK_ENB_DSIB
6. Disable PLLD and PLLD2 by clearing the following bits:
   - CLK_RST_CONTROLLER_PLLD_BASE_0_PLLD_ENABLE
   - CLK_RST_CONTROLLER_PLLD2_BASE_0_PLLD2_ENABLE
7. Write to these APBDEV_PMC_PWRGATE_TOGGLE_0 fields with the following settings:
   - PARTID = DIS
   - START = ENABLE
8. Poll APBDEV_PMC_PWRGATE_STATUS_0 until the DIS bit is set

DIS Power Ungating

1. Write to APBDEV_PMC_PWRGATE_TOGGLE_0 with the following fields:
   - PARTID = DIS
   - START = ENABLE
2. Poll APBDEV_PMC_PWRGATE_STATUS_0 until the DIS bit is cleared
3. If PLLD was enabled before power-gating, enable it by setting the following bit:
   - CLK_RST_CONTROLLER_PLLD_BASE_0_PLLD_ENABLE
4. If PLLD2 was enabled before power-gating, enable it by setting the following bit:
   - CLK_RST_CONTROLLER_PLLD2_BASE_0_PLLD2_ENABLE
5. If either PLLD or PLLD2 was enabled, wait 1 ms for the PLL to lock
6. Set the following bits to enable clocks to DISP1, DSI, DSIB, and MIPI_CAL:
   - CLK_RST_CONTROLLER_CLK_OUT_ENB_L_0.CLK_ENB_DISP1
   - CLK_RST_CONTROLLER_CLK_OUT_ENB_H_0.CLK_ENB_DSI
   - CLK_RST_CONTROLLER_CLK_OUT_ENB_H_0.CLK_ENB_MIPI_CAL
   - CLK_RST_CONTROLLER_CLK_OUT_ENB_U_0.CLK_ENB_DSIB
7. If the VE domain is powered up, enable clocks to the CSI by setting the following bit:
   - CLK_RST_CONTROLLER_CLK_OUT_ENB_H_0.CLK_ENB_CSI
8. Remove power-gating clamps by writing a 1 to the following bit:
   - APBDEV_PMC_REMOVE_CLAMPING_CMD_0.DIS
9. Poll APBDEV_PMC_REMOVE_CLAMPING_CMD_0 until the DIS bit is cleared
10. Write default values to the following registers to clear out any invalid values that might show up after power is ungated:
    - MIPI_CAL_MIPI_CAL_CTRL_0
    - MIPI_CAL_CILA_MIPI_CAL_CONFIG_0
    - MIPI_CAL_CILB_MIPI_CAL_CONFIG_0
    - MIPI_CAL_CILC_MIPI_CAL_CONFIG_0
    - MIPI_CAL_CILD_MIPI_CAL_CONFIG_0
    - MIPI_CAL_CILE_MIPI_CAL_CONFIG_0

- MIPI_CAL_DSIA_MIPI_CAL_CONFIG_0
- MIPI_CAL_DSIB_MIPI_CAL_CONFIG_0
- MIPI_CAL_DSIC_MIPI_CAL_CONFIG_0
- MIPI_CAL_DSID_MIPI_CAL_CONFIG_0

11. Write 1 to the following bits to clear any pending status:
    - MIPI_CAL_CIL_MIPI_CAL_STATUS_0.MIPI_AUTO_CAL_DONE
    - MIPI_CAL_CIL_MIPI_CAL_STATUS_0.MIPI_AUTO_CAL_DONE_CSIA
    - MIPI_CAL_CIL_MIPI_CAL_STATUS_0.MIPI_AUTO_CAL_DONE_CSIB
    - MIPI_CAL_CIL_MIPI_CAL_STATUS_0.MIPI_AUTO_CAL_DONE_CSIC
    - MIPI_CAL_CIL_MIPI_CAL_STATUS_0.MIPI_AUTO_CAL_DONE_CSID
    - MIPI_CAL_CIL_MIPI_CAL_STATUS_0.MIPI_AUTO_CAL_DONE_CSIE
    - MIPI_CAL_CIL_MIPI_CAL_STATUS_0.MIPI_AUTO_CAL_DONE_DSIA
    - MIPI_CAL_CIL_MIPI_CAL_STATUS_0.MIPI_AUTO_CAL_DONE_DSIB
    - MIPI_CAL_CIL_MIPI_CAL_STATUS_0.MIPI_AUTO_CAL_DONE_DSIC
    - MIPI_CAL_CIL_MIPI_CAL_STATUS_0.MIPI_AUTO_CAL_DONE_DSID
12. Read-back MIPI_CAL_CIL_MIPI_CAL_STATUS_0 to push all writes through to the unit.
13. Clear the following bits to deassert the reset to DISP1, DSI, DSIB, and MIPI_CAL:
    - CLK_RST_CONTROLLER_RST_DEVICES_L_0.SWR_DISP1_RST
    - CLK_RST_CONTROLLER_RST_DEVICES_H_0.SWR_DSI_RST
    - CLK_RST_CONTROLLER_RST_DEVICES_H_0.SWR_MIPI_CAL_RST
    - CLK_RST_CONTROLLER_RST_DEVICES_U_0.SWR_DSIB_RST
14. If the VE domain is powered up, deassert the reset to the CSI by clearing the following bit:
    - CLK_RST_CONTROLLER_RST_DEVICES_H_0.SWR_CSI_RST
15. Enable the DC MC client by clearing the following bit:
    - MC_CLIENT_HOTRESET_CTRL_0.DC_FLUSH_ENABLE

6.8.7.8 Procedures for DISB Power Domain

DISB Power Gating

1. Flush the DCB MC client by setting the following bit:
   - MC_CLIENT_HOTRESET_CTRL_0.DCB_FLUSH_ENABLE
2. Poll MC_CLIENT_HOTRESET_STATUS_0 until the following bit is set:
   - DCB_HOTRESET_STATUS
3. Set the following bits to assert the reset to DISP2 and HDMI:
   - CLK_RST_CONTROLLER_RST_DEVICES_L_0.SWR_DISP2_RST
   - CLK_RST_CONTROLLER_RST_DEVICES_H_0.SWR_HDMI_RST
4. Clear the following bits to disable clocks to DISP2 and HDMI:
   - CLK_RST_CONTROLLER_CLK_OUT_ENB_L_0.CLK_ENB_DISP2
   - CLK_RST_CONTROLLER_CLK_OUT_ENB_H_0.CLK_ENB_HDMI
5. Write to these APBDEV_PMC_PWRGATE_TOGGLE_0 fields with the following settings:
   - PARTID = DISB
   - START = ENABLE
6. Poll APBDEV_PMC_PWRGATE_STATUS_0 until the DISB bit is set

DISB Power Ungating

1. The DIS power domain has to be ungated before the DISB can be ungated.
2. Write to APBDEV_PMC_PWRGATE_TOGGLE_0 with the following fields:
   - PARTID = DISB
   - START = ENABLE
3. Poll APBDEV_PMC_PWRGATE_STATUS_0 until bit DISB is clear
4. Set the following bits to enable clocks to DISP2 and HDMI:
   - CLK_RST_CONTROLLER_CLK_OUT_ENB_L_0.CLK_ENB_DISP2
   - CLK_RST_CONTROLLER_CLK_OUT_ENB_H_0.CLK_ENB_HDMI
5. Remove power-gating clamps by writing a 1 to the following bit:
   - APBDEV_PMC_REMOVE_CLAMPING_CMD_0.DISB
6. Poll APBDEV_PMC_REMOVE_CLAMPING_CMD_0 until the DISB bit is clear
7. Clear the following bits to deassert reset to DISP2 and HDMI:
   - CLK_RST_CONTROLLER_RST_DEVICES_L_0.SWR_DISP2_RST
   - CLK_RST_CONTROLLER_RST_DEVICES_H_0.SWR_HDMI_RST
8. Enable the DCB MC client by clearing the following bit:
   - MC_CLIENT_HOTRESET_CTRL_0.DCB_FLUSH_ENABLE

6.8.7.9 Procedures for XUSBA Power Domain

XUSBA Power Gating

1. Set the following bit to assert the reset to XUSB_SS:
   - CLK_RST_CONTROLLER_RST_DEVICES_W_0.SWR_XUSB_SS_RST

2. Clear the following bit to disable clocks to XUSB_SS:

   CLK_RST_CONTROLLER_CLK_OUT_ENB_W_0.CLK_ENB_XUSB_SS
3. Write to these APBDEV_PMC_PWRGATE_TOGGLE_0 fields with the following settings:

   PARTID = XUSBA

   START = ENABLE
4. Poll APBDEV_PMC_PWRGATE_STATUS_0 until the XUSBA bit is set

XUSBA Power Ungating

1. Write to these APBDEV_PMC_PWRGATE_TOGGLE_0 fields with the following settings:

   PARTID = XUSBA

   START = ENABLE
2. Poll APBDEV_PMC_PWRGATE_STATUS_0 until the XUSBA bit is cleared
3. Set the following bit to enable clocks to XUSB_SS:

   CLK_RST_CONTROLLER_CLK_OUT_ENB_W_0.CLK_ENB_XUSB_SS
4. Remove power-gating clamps by writing a 1 to the following bit:

   APBDEV_PMC_REMOVE_CLAMPING_CMD_0.XUSBA
5. Poll APBDEV_PMC_REMOVE_CLAMPING_CMD_0 until the XUSBA bit is cleared
6. Clear the following bit to deassert the reset to XUSB_SS:

   CLK_RST_CONTROLLER_RST_DEVICES_W_0.SWR_XUSB_SS_RST

6.8.7.10 Procedures for XUSBB Power Domain

XUSBB Power Gating

1. Flush XUSB_DEV MC client by setting the following bit:

   MC_CLIENT_HOTRESET_CTRL_0.XUSB_DEV_FLUSH_ENABLE
2. Poll MC_CLIENT_HOTRESET_STATUS_0 until the following bit is set:

   XUSB_DEV_HOTRESET_STATUS
3. Set the following bits to assert reset to XUSB_DEV:

   CLK_RST_CONTROLLER_RST_DEVICES_U_0.SWR_XUSB_DEV_RST
4. Clear the following bits to disable clocks to XUSB_DEV:

   CLK_RST_CONTROLLER_CLK_OUT_ENB_U_0.CLK_ENB_XUSB_DEV
5. Write to these APBDEV_PMC_PWRGATE_TOGGLE_0 fields with the following settings:

   PARTID = XUSBB

   START = ENABLE
6. Poll APBDEV_PMC_PWRGATE_STATUS_0 until the XUSBB bit is set

XUSBB Power Ungating

1. Write to these APBDEV_PMC_PWRGATE_TOGGLE_0 fields with the following settings:

   PARTID = XUSBB

   START = ENABLE
2. Poll APBDEV_PMC_PWRGATE_STATUS_0 until the XUSBB bit is clear
3. Set the following bit to enable clocks to XUSB_DEV:

[redacted]CLK_RST_CONTROLLER_CLK_OUT_ENB_U_0.CLK_ENB_XUSB_DEV

4. Remove power-gating clamps by writing a 1 to the following bit:

   [redacted]APBDEV_PMC_REMOVE_CLAMPING_CMD_0.XUSBB

5. Poll APBDEV_PMC_REMOVE_CLAMPING_CMD_0 until the XUSBB bit is cleared
6. Clear the following bit to deassert the reset to XUSB_DEV:

   [redacted]CLK_RST_CONTROLLER_RST_DEVICES_U_0.SWR_XUSB_DEV_RST

7. Enable the XUSB_DEV MC client by clearing the following bit:

   [redacted]MC_CLIENT_HOTRESET_CTRL_0.XUSB_DEV_FLUSH_ENABLE

6.8.7.11 Procedures for XUSBC Power Domain

XUSBC Power Gating

1. Flush the XUSB_HOST MC client by setting the following bit:

   [redacted]MC_CLIENT_HOTRESET_CTRL_0.XUSB_HOST_FLUSH_ENABLE

2. Poll MC_CLIENT_HOTRESET_STATUS_0 until the following bit is set:

   [redacted]XUSB_HOST_HOTRESET_STATUS

3. Set the following bits to assert the reset to XUSB_HOST:

   [redacted]CLK_RST_CONTROLLER_RST_DEVICES_U_0.SWR_XUSB_HOST_RST

4. Clear the following bits to disable clocks to XUSB_HOST:

   [redacted]CLK_RST_CONTROLLER_CLK_OUT_ENB_U_0.CLK_ENB_XUSB_HOST

5. Write to these APBDEV_PMC_PWRGATE_TOGGLE_0 fields with the following settings:

   [redacted]PARTID = XUSBC

   [redacted]START = ENABLE

6. Poll APBDEV_PMC_PWRGATE_STATUS_0 until the XUSBC bit is set

XUSBC Power Ungating

1. Write to APBDEV_PMC_PWRGATE_TOGGLE_0 with the following fields:

   [redacted]PARTID = XUSBC

   [redacted]START = ENABLE

2. Poll APBDEV_PMC_PWRGATE_STATUS_0 until the XUSBC bit is cleared
3. Set the following bit to enable clocks to XUSB_HOST:

   [redacted]CLK_RST_CONTROLLER_CLK_OUT_ENB_U_0.CLK_ENB_XUSB_HOST

4. Remove power-gating clamps by writing a 1 to the following bit:

   [redacted]APBDEV_PMC_REMOVE_CLAMPING_CMD_0.XUSBC

5. Poll APBDEV_PMC_REMOVE_CLAMPING_CMD_0 until the XUSBC bit is cleared
6. Clear the following bit to deassert the reset to XUSB_HOST:

   [redacted]CLK_RST_CONTROLLER_RST_DEVICES_U_0.SWR_XUSB_HOST_RST

7. Enable the XUSB_HOST MC client by clearing the following bit:

   [redacted]MC_CLIENT_HOTRESET_CTRL_0.XUSB_HOST_FLUSH_ENABLE

6.9 Clock and Reset Controller Registers

Refer to “Reading Register Tables” in the Introduction section for the register table protocol as well as recommendations for accessing registers.

Because this chip is the system controller, resets are generated in hardware automatically as part of the power-on (POR) or system (either hardware or software) reset sequence.

In POR, all blocks will be held in reset (with clocks disabled) except the minimal set of modules that are needed for system boot-up. At POR, the appropriate bits in RST_DEVICES_L/H/U/V/W registers are set automatically by hardware. A "1" in the bit position signifies that block will be held at reset after POR. A "0" in the bit position signifies that block will have its reset de-asserted after POR.

Similarly for clocks, the appropriate bits in CLK_OUT_ENB_L/H/U/V/W registers are set automatically by hardware. A "1" in the bit position signifies that block will have clock running during and after POR. A "0" in the bit position signifies that block will not have clock running during or after POR.

The blocks necessary for boot (known as boot blocks) include:

- ARM7 (COP) and its L1 cache
- All system buses (PPSB, AHB, APB, etc.)
- Timer
- RTC
- NOR Flash controller
- eFUSE
- GPIO
- CoreSight
- Entropy

Each of the boot block devices will have their reset deasserted at the end of the POR period (as well as their clocks enabled and use the Oscillator clock for their clock source). Boot blocks clock dividers are all set to divided-by-one.

During POR or system reset, the reset controller will deassert reset to the boot blocks first and extend the resets to the MPCore™/ARM7 for another 511 oscillator clock periods. This will prevent either processor from talking to a boot device while it is still in the reset state.

Releasing a non-boot block/device from reset to bring into operation will require software to initiate a carefully controlled sequence with clock and reset control registers. This sequence must be implemented by software precisely to ensure correct operation of the hardware.

6.9.1 Precautions

- Unless noted elsewhere, all modules support changing the clock divider ratio without disabling the clock.
- Unless noted elsewhere, all modules' clock switching is glitch-free except "audio_sync_clk".
- For "audio_sync_clk", the clock source select needs to be set up before changing the device clock source to use that audio clock or to enable the device which use that audio clock.
- Before stopping the clock (via CLK_OUT_ENB_L/H/U/V/W registers) and/or asserting reset (via RST_DEVICES_L/H/U/V/W registers) to a module, first check the module to make sure it is not active. Stopping clock/asserting reset while the module is still busy can cause relatively minor problem such as incorrect data read/written, or catastrophic problem such as system hang. To ensure a module is not active, (a) disable the module by programming its disable bit if not already done so, and (b) wait until the module is not active by checking for its busy bit, done bit, count, or similar mechanism.

To set up a non-boot device for operation (only apply if a device has a CLK_SOURCE_ register)

1. Make sure the device's reset is asserted (via RST_DEVICES_L/H/U/V/W registers).
2. Enable clock to the device (via CLK_OUT_ENB_L/H/U/V/W registers).
3. Change the clock source and/or clock divisor to the device (via CLK_SOURCE_ register).
4. Wait 2 µs to make sure clock source/device logic is stabilized.
5. Deassert the device's reset (via RST_DEVICES_L/H/U/V/W registers).

To change a device's clock divider and/or source after boot-up (only apply if a device has a CLK_SOURCE_ register):

(A) Method 1 -- (using reset).

1. Make sure the device is disabled (via the device's register).
2. Assert device's reset (via RST_DEVICES_L/H/U/V/W registers).
3. Make sure clock to the device is enabled (via CLK_OUT_ENB_L/H/U/V/W registers).
4. Change the clock source and/or clock divisor to the device (via CLK_SOURCE_<mod> register).
5. Wait 2 µs to make sure clock source/device logic is stabilized.
6. Deassert the device's reset (via RST_DEVICES_L/H/U/V/W registers).

(B) Method 2 -- (not using reset).

1. Make sure the clock to the device is enabled (via CLK_OUT_ENB_L/H/U/V/W registers).
2. Change the clock source and/or the clock divisor to the device (via CLK_SOURCE_<mod> register).
3. Wait 2 µs to make sure the device logic is stabilized.

To reset a device (without need to change clock) after boot-up:

1. Make sure the device's reset is asserted (via RST_DEVICES_L/H/U/V/W registers).
2. Wait 2 µs to make sure the device logic is stabilized.
3. Deassert the device's reset (via RST_DEVICES_L/H/U/V/W registers).

Possible Method to wait for 2 µs.

1. To use one of the four timers, refer to the Timers section of this document. Program the TMR_PTV register's TMR_PTV field with the desired microsecond count.
2. Program the TMR_PTV register's EN field to enable the timer.
3. Poll the TMR_PCR register's TMR_PCV field until it reaches 0 to indicate the microsecond count has been reached.
4. Program the TMR_PTV register's EN field to disable the timer.

Fractional Divide Ratios

Many of the dividers support not only integer divide ratios but also N.5 fractional divide ratios. Special care needs to be exercised when using a fractional divide because the duty cycle of the clock will not be 50/50, which can place a special timing requirement on the logic. From a dynamic voltage scaling (DVS) standpoint, the slightly faster N.0 ratio should be used to determine how low one can lower the voltage.

Invert Duty-Cycle Distortion Control

Some dividers have a feature to help mitigate clock duty-cycle distortion -- the distortion of the positive edge of a clock can be swapped with the distortion of the negative edge. This ability may prove useful to counteract some of the inherent distortion

that occurs in clock generation logic and distribution. For example, a divider with a ratio of 1.0 having a 51%/49% duty cycle could be made to have a 49%/51% duty cycle, if the duty-cycle inversion control is activated.

- **Frequency Change Caution**:

  An INVERT_DCD field can be changed while the clock is running. In circumstances described in item 3 below, this may temporarily have a negative impact on the divided clock frequency, causing the module to fail if the frequency to the module is not temporarily adjusted first.

  1. Asserting INVERT_DCD adds 1/2 clock period (divider input clock) to the low pulse of a single divided output clock period during the change. This causes the divided output clock frequency to be lowered for one clock period.
  2. For ratios other than 1.0, deasserting INVERT_DCD removes 1/2 clock period (divider input clock) from the low pulse of a single divided output clock period during the change. Because this effectively speeds up the divided output clock frequency for one clock period, which can cause a module to fail, the module clock frequency may need to be changed to a lower frequency before deasserting INVERT_DCD.
  3. Deasserting INVERT_DCD with a ratio of 1.0 is unique in that removing 1/2 clock period (divider input clock) from the low pulse effectively removes the low pulse altogether. The resulting combination of the high pulses on either side will effectively look like 1/2 clock period was added to the high pulse instead. Thus there occurs a lower frequency for one clock period rather than an increased frequency like all other divide ratios.

- **Latency**:

  Once the INVERT_DCD signal gets to the divider logic, there will be a maximum delay of 6 divider input clocks + 1 divider output clock before the change will complete.

Main clock sources used by the system:

(A) Primary clocks.

- "osc" or "clk_m" which can be either 12 MHz, 13 MHz, 19.2 MHz 26 MHz, 16.8 MHz, 38.4 MHz, or 48 MHz.
- "clk_s" which is 32 kHz.

(B) PLL clocks.

- "PLLC" is general purpose and its output is called "pllC_out".
- "PLLC2" is general purpose and its output is called "pllC2_out".
- "PLLC3" is general purpose and its output is called "pllC3_out".
- "PLLM" (memory) is primarily used for memory and its output is called "pllM_out".
- "PLLP" (peripheral) has a fixed frequency and its output is called "pllP_out0".
- "PLLA" (audio) is cascaded from PLLP and is used for audio purposes.
- "PLLU" (USB) has fixed outputs at 12 MHz, 48 MHz, 60 MHz, and 480 MHz.
- "PLLD"(DSI) is primarily used for the display and its output (after a /2 fix) is called "pllD_out0".
- "PLLD2"(DSI) is primarily used for the display and its output (after a /2 fix) is called "pllD2_out0".
- "PLLX" has extra high frequency used primarily by the fast CPU and is called "pllX_out0".
- "refPLLE" is only used by PLLE.
- "PLLE" is only used by PCIe, SATA, USB3 (if they are present)

(D) PLL divided down clocks (each divider has 7 integer bits and 1 fractional bit).

- "pllC_out1" is divided-down from "pllC_out0".
- "pllM_out1" is divided-down from "pllM_out0".
- "pllP_out1" is divided-down from "pllP_out0".

- "pllP_out2" is divided-down from "pllP_out0".
- "pllP_out3" is divided-down from "pllP_out0".
- "pllP_out4" is divided-down from "pllP_out0".
- "pllA_out0" is divided-down from the "pllA" output.

Note: With the exception of PLLA and PLLE, the other PLLs all use "osc_div_clk" as the reference clock. This is the same frequency as "osc" with the exception of the following crystals:

38.4 MHz - Needs to be divided by 2 providing 19.2 MHz to the PLLs.

48.0 MHz - Needs to be divided by 4 providing 12.0 MHz to the PLLs

Note: In this document, CPULP, SCPU, and Slow CPU are synonymous. CPUG, FCPU, and Fast CPU are also synonymous.

6.9.2 Multi-Address Tagging

A register or bit marked with a [* Multi-Address] tag indicates multiple addresses can access the same register/bit. The two types of Multi-Address tags are described below.

[CCLK Multi-Address] Tags

These tags apply to legacy, CPUG, and CPULP multiple address registers and bits. For CCLK (CPU_CLK) related registers values:

- Three sets of addresses are provided to support single cluster legacy, CPUG, and CPULP clusters.
- Two sets of hardware flops are used to store programmed values for G and LP CPU clusters. Legacy single cluster registers are aliased to one of these based on the active cluster at the time the register is referenced.
- In some cases, only the CPU bit in an otherwise single access register is multi-address accessible, for example, CLK_ENB_CPU.

[FUSE Multi-Address] Tags

These tags apply to Fuse and CAR multiple address registers:

- A bond_out_* register can be programmed via fuse or CAR CLK_RST_CONTROLLER_BOND_OUT_L_0 register or fuse FUSE_SKU_BOND_OUT_L_0 register.
- Fuse bond_out writes are updated on fuse2all_fuse_outputs_valid rising edge
- CAR bond_out writes are updated on register writes

6.9.3 CLK_RST_CONTROLLER_RST_SOURCE_0

WatchDog (Deadman) Timer

The watchdog timer is used to recover from hang/lockup condition by resetting the system and/or COP (ARM7) and/or CPU (MPCore). Either timer1 or timer2 can be used as watchdog timer. Refer to the Timer section of this document for more information on watchdog timer usage.

6.9.10 CLK_RST_CONTROLLER_CCLK_BURST_POLICY_0

CPU (CCLK) and COP/System (SCLK) Clock Control

In this section, MPCore is referred to as CPU while ARM7 is referred to as COP. In this context, CPU refers to the active CPULP or CPUG cluster. Each CCLK and SCLK clock domain can have 5 states: SUSP (suspend) where the clock source is 32 kHz, and normal states (IDLE, RUN, IRQ, FIQ).

Each of the normal states can be selected by software from 8 different clock sources. Furthermore, if any of the CPU/COP FIQ/IRQ bit is enabled, a hardware auto trigger feature will be enabled such that hardware will jump from any state to IRQ or to FIQ automatically. Of course, if the source is from a PLL, software needs to guarantee that the PLL clock is running and stable before changing clock sources.

There are many usage models that can be derived from this mechanism: For example:

- Software can simply keep changing the clock source to one state (i.e., just CWAKEUP_IDLE_SOURCE) without changing the CPU_STATE field.
- Software can have the concept of multiple states by first setting up CWAKEUP__SOURCE and then changing the CPU_STATE field.
- Software can enable hardware auto detect of IRQ/FIQ to jump to the IRQ or FIQ state.

Note: Whenever the clock source is switched, the clock is stopped for approximately 400-600 ns.

CCLK and SCLK Super Clock Divider Control

The super clock divider allows a very fine tune of clock frequency going to CPU and COP/system using clock skipping technique. It is different from a traditional divider (1/n) in that both the numerator and denominator are programmable (m/n). Both the numerator and denominator are 8 bits each. Thus, "effective" frequency = source frequency * (m/n). Furthermore, if any of the CPU/COP FIQ/IRQ bits is enabled, hardware will auto disable the super clock divider functionality.

There are many usage models that can be derived from this mechanism. For example:

- There is no clock source switching penalty. Software can just pick a PLL output as a maximum frequency source via CCLK/SCLK_BURST_POLICY and just keep changing SUPER_CCLK/SCLK_DIVIDER to yield the desired lower "effective" frequency.
- For applications where the "osc" frequency is more than sufficient to do the job, PLLs can be turned off to save power and the super clock divider can further divide down the "osc" clock to yield even more power saving.
- If auto IRQ/FIQ feature is enabled, CCLK/SCLK will automatically jump back to full frequency to handle high priority interrupt routines.

Note: From a dynamic voltage scaling (DVS) standpoint, the full clock frequency source (not the output frequency of the super clock divider) going into the super clock divider should be used to determine how low one can lower the voltage.

If m > n, the resulting super clock divider output frequency will be the same as the input frequency. In other words, there will be no clock skip or divide down.

6.9.14 CLK_RST_CONTROLLER_CLK_SYSTEM_RATE_0

Audio Sync Clock

The audio sync clock synchronizes communication between 2 audio devices to prevent a FIFO overrun/underrun condition in either of the audio devices. For example, one can receive data from SPDIFIN and transmit the same data back out to an I2S speaker. But if the SPDIFIN stream is 43.9 kHz while transmitting a 44.1 kHz sample rate to I2S, the SPDIFIN receive FIFO can get overrun while the I2S transmit FIFO can get underrun.

> **Note:** There is no clock switching protection for the audio sync clock so one needs to set up the desired clock source before enabling the audio transmit/receive device.

HCLK/PCLK

SCLK is the main system clock which can run up to 275 MHz.

HCLK is the AHB clock which can run at 1, 1/2, 1/3, or 1/4 of SCLK.

PCLK is the APB clock which can run at 1, 1/2, 1/3, or 1/4 of HCLK.

1:0	0x0	APB_RATE: 1/(n+1) of HCLK.

6.9.15 CLK_RST_CONTROLLER_COP_CLK_SKIP_POLICY_0

COP Clock Skip

The COP uses the same clock as the system (SCLK). The COP_CLK_SKIP_POLICY register provides a mechanism to slow down the COP without slowing down the system clock. This is done by deferring/delaying the ready signal back to the COP. Again, hardware can auto detect CPU/COP IRQ/FIQ and change the skip rate as programmed by software.

6.9.19 CLK_RST_CONTROLLER_OSC_CTRL_0

Oscillator Control

"osc" can have any of the hardware-supported frequencies (12, 13, 19.2, 26, 16.8, 38.4, 48 MHz) . The OSC_FREQ field provides a way for software to inform hardware what the incoming clock frequency is. This information is used by hardware to auto setup the parameters (DIVN, DIVM, DIVP, CPCON, LFCON, VCOCON, DCCON, OUT1_RATIO, OUT2_RATIO, OUT3_RATIO, and OUT4_RATIO) to PLLP and its dividers. There is a way to override the hardware auto-generated PLLP parameters, if necessary.

6.9.21 CLK_RST_CONTROLLER_OSC_FREQ_DET_0

Oscillator Frequency Detect

The oscillator can have any one of the seven supported crystal frequencies (12, 13, 19.2, 26, 16.8, 38.4, 48 MHz). Hardware provides the following mechanism to detect the frequency of the oscillator. To determine the oscillator frequency, create an oscillator clock period counting window. The window is defined by programming the number of 32.768 kHz clock periods. Once the counting process is done, the count value can be used to determine the oscillator frequency.

OSC Frequency (MHz)	Approximate OSC_FREQ_DET_CNT (using two 32.768 kHz periods as window)
12.00	732 (0x02DC)
13.00	794 (0x031A)
16.80	1025 (0x0401)
19.20	1172 (0x0494)
26.00	1587 (0x0633)
38.40	2344 (0x0928)
48.00	2930 (0x0B72)

6.9.22 CLK_RST_CONTROLLER_OSC_FREQ_DET_STATUS_0

Offset: 0x5c │ Read/Write: RO │ Reset: 0x00000000 (0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx)

Bit	Reset	Description
31	X	OSC_FREQ_DET_BUSY: 0 = not busy, 1 = busy.
15:0	X	OSC_FREQ_DET_CNT: Indicates the number of osc counts within the 32.768 kHz clock reference window.

6.9.23 CLK_RST_CONTROLLER_PLLC_BASE_0

PLL Configuration

Unless noted otherwise, PLLs are programmed by:

- Setting configuration values.
- Enabling the PLL. It is recommended that the reference clock to the PLL be stable.
- Waiting for the PLL to lock by polling the lock register.

For any PLL specific programming information that may follow, there is an assumption that the default values noted for the register field are already programmed into the registers. Only the changes from these default values are mentioned.

Tegra 4 devices have 12 PLLs controllable by clock control. Consult the PLL specifications for electrical requirements. Below are the PLL cells used for each PLL referenced in this TRM:

- PLLC is of type PLL14G_DYN_ESD.
- PLLC2 and PLLC3 are of type PLL12G_DIG_E1.
- PLLM is of type PLL800_4PH_ESD_C1.

- PLLP and PLLA are of type CLKPLL700_LP_C1.
- PLLU is of type CLKPLL960_USB_B.
- PLLD and PLLD2 are of type CLKPLL10G_MIPI_C.
- PLLX is of type PLL18G_DYN_PRB_ESD.
- refPLLE is of type PLL600_ESD_D1.
- PLLE is of type PLL24G_SSA_33VCML_ESD_C1.

In general, there are 3 requirements for each PLL with which software needs to comply:

- Input frequency range (REF).
- Comparison frequency range (CF). CF = REF/DIVM, where DIVM is the input divider control.
- VCO frequency range (VCO). VCO = CF * DIVN, where DIVN is the feedback divider control.

Note: The final PLL output frequency (FO) = VCO / DIVP, where DIVP is the post divide control.

Crystals 38.4 MHz and 48 MHz require pre-divider PLL_REF_DIV settings of 2 and 4, respectively, to meet the input frequency requirements of all PLLs that use "osc_div_clk" as a reference. All other supported crystals are used by the PLLs directly, without any pre-divider.

Unless noted otherwise, writing to the PLL bypass fields can cause clock glitches and a strategy is required to contain these glitches.

Contact your NVIDIA representative for more details on the PLLs.

PLL Post Dividers pll*_out*

These are U7.1 fractional dividers as described earlier. To avoid clock frequencies that the dividers cannot support, they should be placed in reset while the PLL is configured and locking. Only when the PLL clock has locked and is stable should the reset to a divider be deasserted.

The configuration of the divide ratio is glitch-less and can be done at any time. However, if done while the divider in enabled, care should be exercised that driven logic can tolerate both the frequency before the change and the frequency after the change.

PLLP Configuration Information

PLLP is configured as a fixed frequency PLL. The code in the Boot ROM configures PLLP at a fixed 216 MHz. Later on, software (typically the boot loader) may change this to another "fixed" frequency.

For Tegra 4 devices, software changes this frequency from 216 MHz to 408 MHz. Boot ROM configuration values for 216 MHz are listed below.

Table 19: Boot ROM Configuration to 216 MHz

Reference Frequency	13.0 MHz	19.2 MHz	12.0 MHz	26.0 MHz	16.8MHz	38.4MHz	48.0MHz	Resulting Frequency
DIVN	216 (0d8h)	180 (0b4h)	216 (0d8h)	216 (0d8h)	180 (0b4h)	180 (0b4h)	216 (0d8h)	-

12	9	306	0	1.33	408	408
12	10	340	0	1.20	408	408
12	12	408	0	1.00	408	408

Special Consideration when Using PLLX as a Clock Source for the CPU

PLLX is shared between G and LP CPU clusters. To save power, the proper PLLX_FO_LP_DISABLE or PLLX_FO_G_DISABLE bit should only be deasserted when the output is being used.

PLLX source to cpulp (PLLX_OUT0) is DIV2 by default. DIV2 is controlled by PLLX_DIV2_BYPASS_LP bit.

The startup sequence noted in the PLLX datasheet (PLL18G_DYN_PRB_ESD rev 1.6), section 3.4 "PLL Startup sequence" can be simplified to (default register values: PLLX_IDDQ=0, PLLX_ENABLE=0):

1. Program PLL registers (PLLX_ENABLE must be 0 or PLLX_IDDQ must be 1).
2. PLLX_IDDQ 1->0 (if not already 0).
3. Wait 2 µs.
4. PLLX_ENABLE 0->1 (clockin must be running before asserting PLLX_ENABLE). Use PLLX_ENABLE to stop/start the PLL.

6.9.48 CLK_RST_CONTROLLER_CLK_SOURCE_I2S1_0

Clock Configuration for Each Peripheral

In general, each block or module has a dedicated CLK_SOURCE_ register that provides clock source and clock divider control to that device. The clock source select is typically 2 bits long to select one of the four clock sources. The divider is typically 8 bits long, consisting of a 7-bit integer and a 1-bit fraction. Furthermore, depending on the specific module, the CLOCK_SOURCE_ register may contain additional control bits.

Note: The 16-bit UARTA/UARTB/UARTC clock divider control is provided by the UART register set and not by the CLK_SOURCE_ registers.
To switch from one clock source to the next, both clock sources must be active/running.

Special PLL Clock Usage by Certain Peripherals

As mentioned previously, each peripheral has a clock source select in its corresponding CLK_SOURCE_ register. There are a number of modules that take in an additional fixed PLL clock source for portion of their logic.

Listed below are the modules/logic and the fixed PLL clock source they use.

Module/Logic	Fix PLL Clock Source Used
LFSR	pllM_out0
UARTA	pllP_out3
UARTB	pllP_out3
UARTC	pllP_out3
UARTD	pllP_out3
MIPI_CAL	pllP_out3
MIPI_IOBIST	pllP_out3

More information about clock sources and divider widths can be found under “Hardware Features” in this section.

6.9.65 CLK_RST_CONTROLLER_CLK_SOURCE_NDFLASH_0

The Tegra NAND module uses a combination of 3 clocks: nandfst_clk, nand_clk, and nand_speed_clk

- nandfst_clk and nand_clk are controlled by the CLK_SOURCE_NDFLASH register
- nand_speed_clk is controlled by the CLK_SOURCE_NAND_SPEED register

The output of the clock switch is nandfst_clk at full rate.

An additional nand_clk is programmable to full or div2 rate of nandfst_clk.

6.9.76 CLK_RST_CONTROLLER_CLK_SOURCE_EMC_0

When changing the EMC frequency, internal logic sequencing handles the requirement that the DRAMs must be placed into self-refresh before its clock frequency is changed.

To support this, certain register fields when written do not get immediately applied but rather are applied at the correct time during the sequencing. These registers are referred to as "shadowed".

Other register fields initiate the sequencing state machine and therefore should be written last. Note that the value of the field must change to start the state machine - simply writing the same value to the field is insufficient.

At the end of the sequencing, the DRAMs are restored to being operational. The programming sequence then is:

1. Program the MC/EMC shadow registers corresponding to the new frequency. These registers are "shadowed", as noted in their descriptions, and will not impact the hardware until later during the clock change sequence.
2. Program the EMC clock change FIFO (CCFIFO) with the pre-/post-clk change sequence.

3. Program CAR CLK_SOURCE_EMC register to trigger a clock change. At this point hardware takes over to perform the clock changing sequence.
4. Monitor the clock change complete interrupt status from EMC register to know when clock change is done.

As an alternative to writing one of the sequencing initiating fields, the FORCE_CC_TRIGGER is provided to force the state machine to run. This is not the recommended method as internal restrictions must be met to maintain DRAM contents.

There are EMC/MC configuration registers that are shadowed or can initiate a clock change sequence are described below:

- Initiates sequencing (value must change):
  - CLK_SOURCE_EMC.EMC_2X_CLK_SRC
    - EMC_2X_CLK_DIVISOR
    - MC_EMC_SAME_FREQ
    - FORCE_CC_TRIGGER
- Shadowed (will be applied during sequencing):
  - CLK_SOURCE_EMC.EMC_2X_CLK_SRC
    - EMC_2X_CLK_DIVISOR
    - MC_EMC_SAME_FREQ
- Not shadowed:
  - CLK_SOURCE_EMC.EMC_INVERT_DCD (must be set during initial configuration and before the EMC clock is started)

6.9.100 CLK_RST_CONTROLLER_RST_DEV_L_SET_0

The RST_DEV_(L,H,U, V, W)_(SET,CLR) and CLK_ENB_(L,H,U, V, W)_(SET,CLR) registers are provided as an alternate method of programming the same registers found in RST_DEVICES_(L,H,U, V, W) and CLK_OUT_ENB_(L,H,U, V, W) registers, respectively.

Therefore, using either methods will change the same underlying peripherals reset, and clock enable control for writes. For reads, you can use either method to retrieve the reset/clock-enable state of each peripheral.

6.9.127 CLK_RST_CONTROLLER_CPU_SOFTRST_CTRL_0

Earlier Tegra chips had a single state-machine that took care of sequencing reset (delaying reset deassertion based on a timer value) in case of a flow-controller request or a WatchDog Timer (WDT) expiry request. This has changed in Tegra 4 devices because flow-controller initiated requests do more. The timer control of reset deassertion for WDT initiated requests is in the same place while the new controls have been added to the new registers.

Offset: 0x380 │ Read/Write: R/W │ Reset: 0x00000010 (0bxxxxxxxxxxxxxxxxxxxxxxxx00010000)

6.9.172 CLK_RST_CONTROLLER_UTMIP_PLL_CFG0_0

The data sampling frequency relies on a 960 MHz clock, so the goal of the PLL is to have:
In_Frequency * (PLL_VCOMULTBY2+1) * (PLL_NDIV/PLL_MDIV) = 960 MHz. With a 12 MHz input from PLL_U, the default setting of PLL_VCOMULTBY2 = 1, PLL_NDIV = 40, and PLL_MDIV = 1 results in a correct output.

This register is used to configure the PHY PLL contained in the UTMIP module.

UTMIP PLL Configuration Register 0

Offset: 0x480 │ Read/Write: R/W │ Reset: 0x00500100 (0bx00000001010000000000001xxxxx000)

Bit	Reset	Description
30:29	0x0	UTMIP_PLL_VREG_BG_CTRL: Voltage regulator and band-gap probe mux control. VREG_BG_CTRL = 0 => VREG_BG_PRB = 0. VREG_BG_CTRL = 1 => VREG_BG_PRB = bandgap. VREG_BG_CTRL = 2 => VREG_BG_PRB = Vregulator. See cell specification.
28:27	0x0	UTMIP_PLL_VREG_CTRL: Voltage regulator voltage level control. See cell specification.

Bit	Reset	Description
26:25	0x0	UTMIP_PLL_KCP: KCP of the UTMIP PHY PLL. Charge Pump Gain control. Default value is zero. See cell specification.
23:16	0x50	UTMIP_PLL_NDIV: NDIV[7:0] input of UTMIP PLL. This is the feedback divider on the VCO feedback. 0x0 is not allowed. See cell specification.
15:8	0x1	UTMIP_PLL_MDIV: MDIV[7:0] input of the UTMIP PLL. This is the predivide on the PLL. 0x0 is not allowed. See cell specification.
2	0x0	UTMIP_PLL_LOCK_OVR: LOCK_OVERRIDE control of the UTMIP PLL. Forces PLL_LOCK to 1. See cell specification.
1	0x0	UTMIP_PLL_EN_FSTLCK: EN_FSTLCK input of UTMIP PLL. Reserving pin for PLL fast lock circuitry. See cell specification.
0	0x0	UTMIP_PLL_ENB_LCKDET: ENB_LCKDET input of UTMIP PLL. When set to 1, powers down the lock detect. Setting ENB_LCKDET=X, LOCK_OVERRIDE=1, PLL_LOCK=1, and PLL_FREQLOCK=1 also powers down lock detect. 0 0 0->1(after lock) 0->1 (after lock) 1 0 0 0 lock detect power down. See cell specification.

6.9.173 CLK_RST_CONTROLLER_UTMIP_PLL_CFG1_0

UTMIP PLL Configuration and Parameters

In normal operation, the following clock generators are in play for USB:

Crystal (Xtal) clock -> enters PLL_U to generate 12 MHz clock -> enters USB_PHY PLL to generate 480/60 MHz clock.

The following parameters control the bring-up of the PLLs (coming out of reset or suspend):

- PllUOnState: start pllu_enable_count and pll_lock_count
  - Wait ~1 µs to enable the PLL_U (pllu_enable_count == ClkXtal * PLLU_ENABLE_DLY_COUNT * 8)
  - Wait ~1 ms until PLL_U is stable (pll_lock_count == ClkXtal * PLLU_STABLE_COUNT * 256) => USB_PHY PLL_ENABLE
  - pll_active_count = 0
    - Wait 5 µs to enable pll_active: pll_active_count == ClkXtal * PLL_ACTIVE_DLY_COUNT * 16 => USB_PHY PLL_ACTIVE
  - Wait ~2.5 ms until USB_PHY is stable (pll_lock_count == ClkXtal * XTAL_FREQ_COUNT * 256) => USB_PHY

Sample values for a 12 MHz Xtal clock are:

- PLLU_ENABLE_DLY_COUNT[4:0] = 1 * 12 / 8 = 1.5 = 0x02
- PLLU_STABLE_COUNT[11:0] = 1000 * 12 / 256 = 46.9 = 0x2f
- PLL_ACTIVE_DLY_COUNT[4:0] = 10 * 12 / 16 = 7.5 = 0x08
- XTAL_FREQ_COUNT[11:0] = 2500 * 12 / 256 = 117.2 = 0x76

2	RW	OSC_DIV	PLLE_REF_SRC: PLLE input reference clock source select. 0=OSC_DIV (options: mux (PLLs, ext_osc), /2, /4), 1=PLLP_OUT0 (use pre-divM=18 for 12 MHz reference) 0 = OSC_DIV 1 = PLLP_OUT0

6.9.176 CLK_RST_CONTROLLER_SATA_PLL_CFG0_0

SATA Power Sequencer Input Software Control Program Guide

The software control input can be used for test coverage or diving the power sequencer SM via software. The SATA power sequencer is driven by 3 primary reset and power-down input signals: reset, lane_pd, and padpll_pd. The normal power-up sequence deasserts in this order: padpll_pd > lane_pd > reset. The normal power-down sequence asserts in this order: reset > lane_pd > padpll_pd.

It is acceptable to assert all three signals at the same time. It is also acceptable for reset or lane_pd to return to the power-up state in the middle of a power-down sequence.

6.9.179 CLK_RST_CONTROLLER_PROG_AUDIO_DLY_CLK_0

- Clock doubler with 1x/2x select for: I2S0 through I2S4 and S/PDIF.
- Clock doublers with 1x/2x select use by the clock controller for each I2S0 through I2S4 and S/PDIF sync clock.
- Clock doubler enable controlled by CLK_ENB_I2S[0..4]_DOUBLE and CLK_ENB_SPDIF_DOUBLE bits in CLK_OUT_ENB_V register. CLK_ENB_*_DOUBLE bit must be enabled for either SYNC_1X_CLK or SYNC_2X_CLK to operate.
- PROG_DLY_CLK provides programmable delay for the clock doublers. An individual clock doubler is provided for each audio sync clock: I2S0..4, S/PDIF.

Audio Sync Clock Source Mux Options

SPDIFIN, I2S0, I2S1, I2S2, I2S3, I2S4, PLLA_OUT0, EXT_VIMCLK

Enable Sync Clocks

There are 3 related clock enables/selects:

- CG_1. AUDIO_SYNC_CLK_I2S0-SYNC_CLK_DIS: disable output of sync_clk mux
- CG_2. CLK_OUT_ENB_V-CLK_ENB_I2S0_DOUBLER: disable input to doubler
- SEL_3. PROG_AUDIO_DLY_CLK-I2S0_1X_SEL: Select 1x sync clock. 0=2x 1=1x

Flow of Clock Logic

sync_clk mux (CG_1)-> (CG_2) (SEL_3) doubler -> clk switch

Suggested Programming for Sync Clock Enable:

- Leave CG_2 as default enabled.
- Use CG_1 to disable or enable (default) sync clock.
- Use SEL_3 to select 1x or 2x sync clock.

SYNC_CLK_DIS	CLK_ENB_I2S0_DOUBLER	I2S0_1X_SEL	SYNC_CLK
0	1	0	2x (Default)
0	1	1	1x
1	1	X	0 (off, recommended)
1	X	X	0 (off)
X	0	X	0 (off)

15:0	RW	0x0	PLLREFE_SETUP

CPU Trimmer Registers

Bit	Name	Direction	Default Value	Description
7	byp	Read/Write	0	When asserted, the trimmer is bypassed.
6	select	Read/Write	0	When asserted, rise'rise clock propagation delay will be specified by {dr,r} fields. Otherwise, hardwired default delay will be applied. Similarly, fall'fall clock propagation delay will be specified by {df, f} fields when select is asserted.
5	dr	Read/Write	0	0: Minimal rise'rise clock propagation delay 1: Use one of the four delay steps specified by the {r} field.
4:3	r	Read/Write	0	00,01,10,11: Increment rise'rise clock delay by 1, 2, 3, or 4 steps
2	df	Read/Write	0	0: Minimal fall'fall clock propagation delay 1: Use one of the four delay steps specified by {f} field.
1:0	f	Read/Write	0	00, 01, 10, 11: Increment fall'fall clock delay by 1, 2, 3, or 4 steps

These registers control the delay through the programmable trimmers (CORE_CLOCKS_shaper) inside the Cortex™-A15 partitions.

- CPU_FINETRIM_BYP
- CPU_FINETRIM_SELECT
- CPU_FINETRIM_DR
- CPU_FINETRIM_DF
- CPU_FINETRIM_F
- CPU_FINETRIM_R

The naming convention of the fields of these registers is:

- FCPU_n : partition n in fast CPU cluster
- SCPU_n : partition n in slow CPU cluster

The partitions related to these registers are as follows:

- FCPU_1: fcpu0 partition
- FCPU_2: fcpu1 partition
- FCPU_3: fcpu2 partition
- FCPU_4: fcpu3 partition
- FCPU_5: fl2 partition
- FCPU_6: ftop partition
- SCPU_7: not used

- SCPU_8: not used
- SCPU_9: not used

6.9.196 CLK_RST_CONTROLLER_PLLC2_BASE_0

There are special startup and programming considerations for this digital PLL. Consult the datasheet for details

Some field descriptions will have a LATCHED or a DIRECT keyword:

- LATCHED: The writes to this field are latched by the PLLC2 STROBE. Once one or more of the "LATCHED" fields are written, PLLC2_STROBE must be toggled by software for the value to be latched into the PLL and become effective. See 'Dynamic Frequency Change' section in the datasheet. If the sequence is not completed correctly, readback of value by software may not be the value used by PLL.
- DIRECT: It is a DIRECT read/write field. The writes to this field are not latched by STROBE. So, readback will always tell the correct state.

The digital PLL, PLL12G_DIG_B1, has an update rate limit of 19.2 MHz. The osc_div_clk that drives the CLOCKIN pin of these PLLs can have values of 12 MHz, 13 MHz, 19.2 MHz, 16.8 MHz, or 26 MHz. The 26 MHz crystal is faster than the allowed update rate. This can be resolved by programming the SDIV of the PLLs to internally divide the clock by 2, giving 13 MHz.

Offset: 0x4e8 │ Read/Write: R/W │ Reset: 0x0X000101 (0b000xxxxxx000xxxx00000001xxxxxx01)

6.9.209 CLK_RST_CONTROLLER_XUSBIO_PLL_CFG0_0

XUSB I/O PLL Power Sequencer Input Software Control Program Guide

The software control input can be used for test coverage or driving power sequencer SM via software.

The XUSB power sequencer is driven by a primary reset input signal: reset. Reset is expected to be held static until the power-up or power-down sequence is complete.

Offset: 0x51c │ Read/Write: R/W │ Reset: 0x0X00000d (0bxxxxxx10xxxxxxxxxxxxxxxxx0001101)

7.0 CL-DVFS

The CL_DVFS module contains control logic that provides a hardware mechanism for controlling the clock rate and power supply voltage of the fast CPU complex.

This section describes the closed-loop dynamic voltage and frequency scaling (CL-DVFS) registers. It is not intended to be a programming guide to CL-DVFS, as it is expected that NVIDIA supplied drivers will always be used with it. However, the register interface is documented to aid with understanding those drivers.

7.1 CL-DVFS Registers

Refer to “Reading Register Tables” in the Introduction section for the register table protocol as well as recommendations for accessing registers.

7.1.1 CL_DVFS_CTRL_0

Offset: 0x0 | Read/Write: R/W | Reset: 0x00000000 (0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx00)

Bit	Reset	Description
1:0	0x0	DFLL_CTRL_MODE: DFFL Control Mode. 0 = DISABLE: Disabled. The ring oscillator does not run. 1 = ENABLE_OPEN_LOOP: In Enable Open Loop mode, the ring oscillator will run, but the control loop will remain inactive. 2 = ENABLE_CLOSED_LOOP: In Enable Closed Loop mode, the control loop is enabled and the I2C interface will continuously update the control output in order to maintain the desired frequency set in the DFLL_FREQ_REQ_xxxx fields.

7.1.2 CL_DVFS_CONFIG_0

Offset: 0x4 | Read/Write: R/W | Reset: 0x00000006 (0bxxxxxxxxxxxxxxxxxxxxxxxx00000110)

Bit	Reset	Description
7:0	0x6	DFLL_CONFIG_DIV_S: Refclk divider for setting DFLL control loop sample rate. Refclk is divided by 32x the value in this field

7.1.3 CL_DVFS_PARAMS_0

Offset: 0x8 | Read/Write: R/W | Reset: 0x000000f0 (0bxxxxxxx000000000xxxxx00011110000)

Bit	Reset	Description
24	0x0	DFLL_PARAMS_CG_SCALE: If set to 1, reduces the overall loop gain by a factor of 8.
23:22	0x0	DFLL_PARAMS_FORCE_MODE: 0 = DISABLE : Disabled. The I2C control value is never forced during a frequency change. 1 = FIXED : In Fixed Delay mode, the I2C control value is forced for a fixed number of sample periods. 2 = AUTO: In Auto mode, the I2C control value is forced for a calculated number of sample periods.
21:16	0x0	DFLL_PARAMS_CF_PARAM: Length of time that a forced I2C control value will be applied after a frequency change if forcing was requested for that change. In Fixed Delay mode, it provides the number of sample periods to force the I2C control value. In Auto mode, the force time is equal to I2C control output delta * cf_param / 16
10:8	0x0	DFLL_PARAMS_CI_PARAM: Integral term gain in the control loop controls how a cycle deficit/surfeit after a frequency change is cleared. It temporarily raises or lowers the core voltage to allow the total clock cycle count to converge with the ideal number of cycles that should have been produced since the last frequency change request. 0 = DISABLE 1 = DIV2 2 = DIV4 : 3 = DIV8 4 = DIV16

Bit	Reset	Description
		5 = DIV32 : 6 = DIV64 7 = DIV128
7:0	0xf0	DFLL_PARAMS_CG_PARAM: Overall loop gain control (SIGNED value), controls the overall response time of the control loop

7.1.4 CL_DVFS_TUNE0_0

Offset: 0xc | Read/Write: R/W | Reset: 0x00000000 (0bxxxxxxxx00000000000000000000000)

Bit	Reset	Description
23:16	0x0	DFLL_TUNE0_DLY_STK: Input bits to both coarse (4) and fine (4) tune the delay
15:8	0x0	DFLL_TUNE0_DLY_SRAM: Input bits to both coarse (3) and fine (5) tune the delay of the SRAM path.
7:0	0x0	DFLL_TUNE0_DLY_INV: Input bits to both coarse (3) and fine (5) tune the delay of the inverter path

7.1.5 CL_DVFS_TUNE1_0

Offset: 0x10 | Read/Write: R/W | Reset: 0x00000000 (0bxxxxxxxxxxxx00000000000000000000)

Bit	Reset	Description
19:11	0x0	DFLL_TUNE1_DLY_FINE: Input bits to tune the two phases of the clock. 8 bits to tune, and 1 bit to choose high vs. low
10:0	0x0	DFLL_TUNE1_DLY_WIRE: Input bits to both coarse (2) and fine (9) tune the delay of wire dominated path

7.1.6 CL_DVFS_FREQ_REQ_0

Offset: 0x14 | Read/Write: R/W | Reset: 0x0000ff40 (0bxxx00000000000011111111101000000)

Bit	Reset	Description
28	0x0	DFLL_FREQ_REQ_FORCE_EN: Set to '1' to force I2C control output to initial value specified by the 'force_val' field
27:16	0x0	DFLL_FREQ_REQ_FORCE_VAL: Value forced onto the integrator during a frequency transition, only used if the 'force_en' field below is '1' AND the global 'force_mode' field of the dfll_params register is not set to 'disable'. The best value is (desired I2C control value - safe I2C control value) x 128) / Cg.
15:8	0xff	DFLL_FREQ_REQ_SCALE: Proportion of output clock cycles (+1) to *not* skip over a period of 256 cycles
7	0x0	DFLL_FREQ_REQ_VALID: Set to '1' to indicate that the frequency configuration is valid and should be used. If this bit is '0', the control loop will revert to 'open loop' mode, and the I2C control interface value will be determined by the 'safe' value.
6:0	0x40	DFLL_FREQ_REQ_MULT: Primary frequency multiplication factor 'F'. The ring oscillator output frequency will be (REF_CLK/2) x F.

7.1.7 CL_DVFS_SCALE_RAMP_0

Offset: 0x18 | Read/Write: R/W | Reset: 0x00000000 (0bxxxxxxxxxxxxxxxxxxxxxxxxxxxx0000)

Bit	Reset	Description
3:0	0x0	DFLL_OUTPUT_RAMP_RATE: The ramp up/ramp down rate of the control signal to the output scaler. Determines the number of cycles (+1) to wait for each counter step.

7.1.8 CL_DVFS_DROOP_CTRL_0

Offset: 0x1c | Read/Write: R/W | Reset: 0x00000810 (0bxxxxxxxx00000000xxxx100000010000)

Bit	Reset	Description
23:16	0x0	DFLL_DROOP_CTRL_MIN_FREQ: The minimum allowed ring oscillator frequency before the 'droop' clock skipper is enabled. The value written determines the minimum number of cycles that are allowed in 4 REF_CLK cycles' Fmin = droop_ctrl.min_freq * (REF_CLK / 4)
11:8	0x8	DFLL_DROOP_CTRL_CUT: CPU clock is scaled by (cut+1)/16 immediately after reaching the minimum ring oscillator frequency
7:0	0x10	DFLL_DROOP_CTRL_RATE: Controls the rate at which clock cycles are re-introduced to the droop skipper after it has been ramped down to compensate for a frequency droop. It is the number of cycles (+1) to wait for each counter step

7.1.9 CL_DVFS_OUTPUT_CFG_0

Offset: 0x20 | Read/Write: R/W | Reset: 0x50200000 (0bx1010000xx100000xx00000000000000)

Bit	Reset	Description
30	0x1	DFLL_OUTPUT_CONFIG_I2C_ENABLE: Master enable control for I2C control value updates. If this field is '0', then I2C control messages are inhibited, regardless of the DFLL mode.
29:24	0x10	DFLL_OUTPUT_CONFIG_SAFE: 'Safe' value for the OUTPUT control interface. This value will be output whenever OUTPUT is enabled but the DFLL is disabled, or in open loop mode.
21:16	0x20	DFLL_OUTPUT_CONFIG_MAX: Maximum allowed value on the OUTPUT control interface.
13:8	0x0	DFLL_OUTPUT_CONFIG_MIN: Minimum allowed value on the OUTPUT control interface.
7	0x0	DFLL_OUTPUT_CONFIG_DELTA_EN: 1: In conjunction with 'clk_en'=1, causes the PWM clock/data output to only become active (for 32 cycles) whenever a change in the PWM value occurs. 0: The PWM data/clock outputs run continuously when enabled.
6	0x0	DFLL_OUTPUT_CONFIG_CLK_EN: Enables the PMIC control clock output for digitally controlled PMICs.
5:0	0x0	DFLL_OUTPUT_CONFIG_DIV_D: Divider setting for PWM PMIC control output (divides the SOC clock).

7.1.10 CL_DVFS_OUTPUT_FORCE_0

Offset: 0x24 | Read/Write: R/W | Reset: 0x000000XX (0bxxxxxxxxxxxxxxxxxxxxxxxxxxx0xxxxxx)

Bit	Reset	Description
6	0x0	DFLL_OUTPUT_FORCE_ENABLE: Enable the force value onto the OUTPUT control output
5:0	X	DFLL_OUTPUT_FORCE_VALUE: Value to force OUTPUT control output whenever the i2c_ctrl_force_enable field is set to 1.

7.1.11 CL_DVFS_MONITOR_CTRL_0

Offset: 0x28 | Read/Write: R/W | Reset: 0x0000000X (0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx)

Bit	Reset	Description
2:0	X	DFLL_MONITOR_CTRL_SELECT: Selects a control loop data source for monitoring 0 = DISABLE 1 = CYCLE_INT 2 = PRO_TERM 3 = INT_TERM 4 = OUTPUT_INT 5 = OUTPUT_VALUE 6 = FREQ

7.1.12 CL_DVFS_MONITOR_DATA_0

Offset: 0x2c | Read/Write: RO | Reset: 0x000XXXXX (0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx)

Bit	Reset	Description
16	X	DFLL_MONITOR_DATA_NEW: Set to '1' whenever a new sample is generated. Cleared on reads.
15:0	X	DFLL_MONITOR_DATA_VAL: Read data monitor source selected by dfll_monitor_ctrl_select. If monitoring is enabled, this field is updated every sample period.

7.1.13 CL_DVFS_I2C_CFG_0

Offset: 0x40 | Read/Write: R/W | Reset: 0x0010fXXX (0bxxxxxxxxxxxx1x0001111xxxxxxxxxxx)

Bit	Reset	Description
20	0x1	I2C_BUS_ARB: Enables arbitration for bus
18:16	0x0	I2C_MASTER_CODE: Master code for high-speed transfers
15	0x1	I2C_PACKET_MODE: Enables Packet mode for high-speed transfers
14:12	0x7	I2C_SIZE: Size of voltage values from 1 to 7
10	X	I2C_ADDR_7BIT_10BIT: 0: Selects 7-bit addressing 1: Select 10-bit addressing
9:0	X	I2C_SLAVE_ID: External slave ID address

7.1.14 CL_DVFS_I2C_VDD_REG_ADDR_0

Offset: 0x44 | Read/Write: R/W | Reset: 0x0000XXXX (0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx)

Bit	Reset	Description
15:8	X	I2C_DEFAULT_DATA: Default data
7:0	X	I2C_ADDR_DATA: Address for voltage sel

7.1.15 CL_DVFS_I2C_STS_0

Offset: 0x48 | Read/Write: RO | Reset: 0x000000XX (0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx)

Bit	Reset	Description
6:1	X	I2C_LAST_VALUE: Output value from the DFLL of last I2C request that was completed successfully
0	X	I2C_REQ_PENDING: Indicates there is an outstanding I2C request

7.1.16 CL_DVFS_INTR_STS_0

Offset: 0x5c | Read/Write: RO | Reset: 0x0000000X (0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx)

Bit	Reset	Description
1	X	MAX_VDD_LIMIT_INTR: Interrupt to indicate the DFLL has hit the VDD ceiling as programmed in DFLL_OUTPUT_CONFIG_MAX
0	X	MIN_VDD_LIMIT_INTR: Interrupt to indicate the DFLL has hit the VDD floor as programmed in DFLL_OUTPUT_CONFIG_MIN

7.1.17 CL_DVFS_INTR_EN_0

Offset: 0x60 | Read/Write: R/W | Reset: 0x0000000X (0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx)

Bit	Reset	Description
1	X	MAX_VDD_LIMIT_INTR_EN: Enable for interrupt to indicate the DFLL has hit the VDD ceiling as programmed in DFLL_OUTPUT_CONFIG_MAX
0	X	MIN_VDD_LIMIT_INTR_EN: Enable for interrupt to indicate the DFLL has hit the VDD floor as programmed in DFLL_OUTPUT_CONFIG_MIN

7.1.18 CL_DVFS_I2C_CLK_DIVISOR_REGISTER_0

The divisor values (N) must be programmed so that:

- SCL frequency (Std/Fast mode) = ClkSourceFreq/(8*(N+1))
- SCL frequency (HS mode) = ClkSourceFreq/(12*(N+1))

Offset: 0x16c | Read/Write: R/W | Reset: 0x00190001 (0b00000000000110010000000000000001)

Bit	Reset	Description
31:16	0x19	I2C_CLK_DIVISOR_STD_FAST_MODE:N = Divide by n+1
15:0	0x1	I2C_CLK_DIVISOR_HSMODE:N = Divide by n+1

7.1.19 CL_DVFS_OUTPUT_LUT_0

This lookup table (LUT) contains voltage LUT values stored in a 33-deep by 8 bit wide RAM. To program the LUT, simply sequentially address the RAM, using the base offset address of 10’b10xxxxxxx. Addresses are DWORD aligned, not BYTE aligned. PMIC values must be programmed to span the entire desired operating range, and be monotonically increasing. The logic assumes that the middle entry (16th) corresponds to the ‘safe’ initial voltage, as specified in the dfll_output_config.safe field.

[THIS PAGE INTENTIONALLY LEFT BLANK]

8.0 TIMERS

This section documents the various timers available to software in a Tegra® 4 series system. The following table summarizes these timers.

Table 22: List of Timers

Name	Primary Use	Related Interrupt	Secure	Freq.	Notes
RTC	Wall Clock Timer	RTC	Pseudo	32kHz	See the Real-Time Clock section in this TRM for detailed information.
TMR	NVIDIA® Generic Timers	TMR9-0	Cfg	1MHz	Configurable to be secure
WDT	TMR timers used as Watchdog	WDT_<>	Cfg	1MHz	Configurable to be secure
TSC	Reference for GIT	N/A	Yes	OSC	Counter value can only be updated in secure mode.
GIT	ARM CPU Generic Timers	PPIs*	Yes	TSC	These timers use TSC as reference.

*PPIs are per CPU Private Peripheral Interrupts

8.1 ARM CPU Generic Timers (GITs)

The ARM® Generic Timer architecture defines generic CPU timer requirements. The architecture requires that the SoC supply a timestamp counter reference that is independent of the CPU clock frequency.

The Cortex™-A15 Generic Timer includes:

- A physical counter that contains the count value of the system counter.
- A virtual counter that indicates virtual time. The virtual counter contains the value of the physical counter minus a 64-bit virtual offset.
- A set of four timers per CPU.

The four timers are the following:

- Secure Physical Timer
- Non-Secure Physical Timer
- Hypervisor Timer
- Virtual Timer

Refer to the ARM Architecture Reference Manual v7 for generic timer specifications.

8.2 Generic Timer System Counter (TSC)

The ARM Generic Timer Specification requires a system time-stamp counter (TSC) supplied by the SoC.

The TSC is implemented as part of the Tegra 4 Power Management Controller (PMC). It is a 56-bit counter which runs at the crystal oscillator clock frequency. Refer to the Power Management Controller section in this TRM for additional TSC information.

8.3 NVIDIA Timers (TMR)

The programmable timer block contains ten 29-bit programmable timer counters and one 32-bit timestamp counter.

Timer interval, one-shot, or periodic interrupts are configured in the Timer Present Value register (PTV). When enabled, the timer loads the Timer Present Value count and begins decrementing every one microsecond. The timer generates a timer request when the count reaches zero.

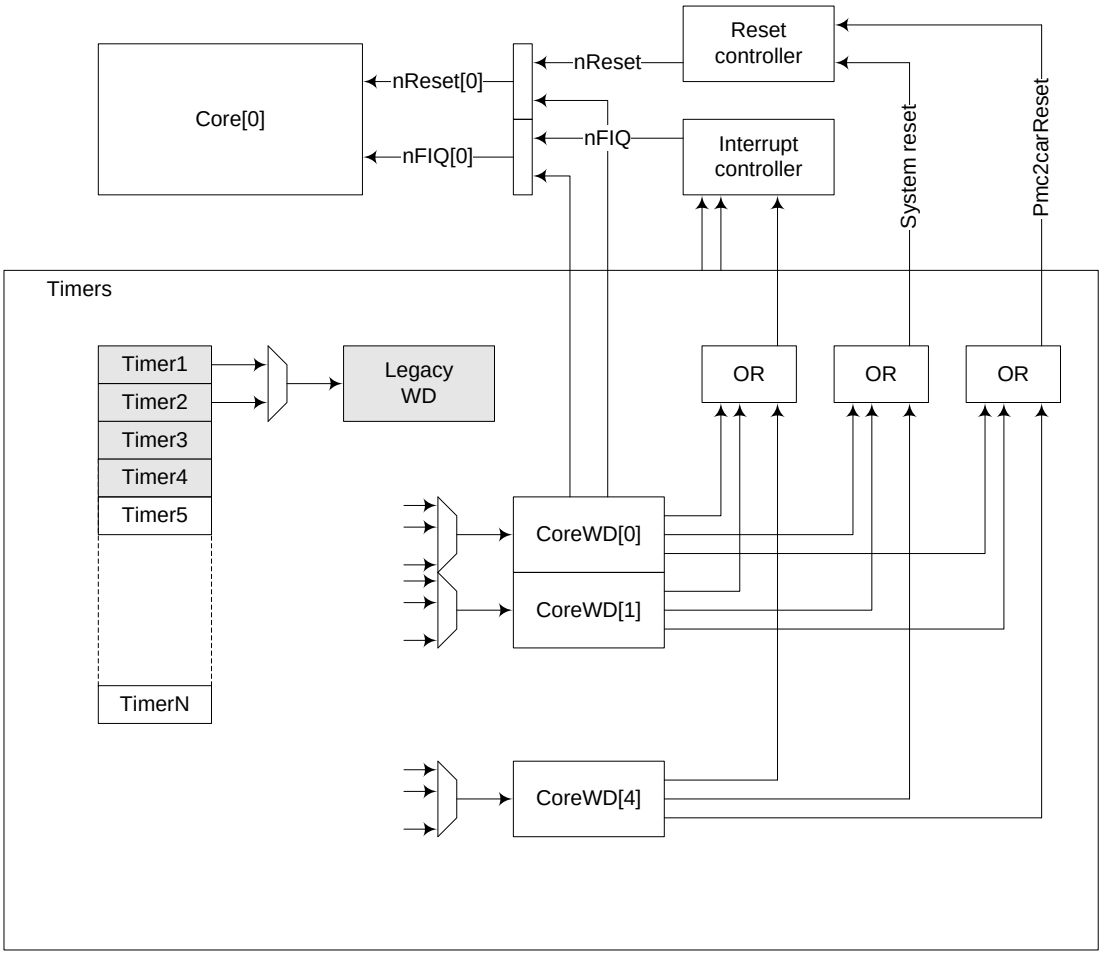
If the PTV periodic control bit is set, the timer reloads the PTV interval and continues decrementing the timer.

The timer count is 29 bits wide, supporting timer intervals of 16.384 ms maximum or 1 µs minimum. Bit 30 of the periodic Timer Value (PTV) is the enable bit for the timer. Reading the PTV Register clears any pending timer interrupt.

A read-only Preset count register (PCR) allows the processor to inspect the current value of the timer decrement counter. The timestamp counter (32 bits wide) is cleared to zero on reset, and counts upwards every 1 µs.

The figure below shows a reference decomposition of the timers in functional blocks.

Figure 19: Timer Functional Block Diagram



- The timers are numbered 0 to 9
- Timers 1 to 5 have a dedicated interrupt bit
- Timers 0, 6, 7, 8, and 9 share a common interrupt called SharedTimerInterrupt.
- Timer interrupts are assigned as follows:
  - Timer 1 = primary interrupt controller bit 0

- Timer 2 = primary interrupt controller bit 1
- Timer 3 = secondary interrupt controller bit 9
- Timer 4 = secondary interrupt controller bit 10

8.4 Watchdog Timers (WDTs)

A watchdog timer facilitates recovery from system lockup conditions. The watchdog timer can interrupt the processor when the selected timer counter expires. Under normal operation, this interrupt is serviced by reading the timer status register (TIMER_WDTx_STATUS). Any timer in the Tegra 4 timer block may be configured as a watchdog timer.

- The Tegra 4 series processor provides five WatchDog Timers, one each for main CPUs and one for COP (AVP): WDT0 is allocated to CPU0 of cluster0 or the shadow CPU of cluster1
- WDT1 is allocated to CPU1
- WDT2 is allocated to CPU2
- WDT3 is allocated to CPU3
- WDT4 is allocated to COP (AVP)

The 5 watchdog timers are directly associated with a processor core, i.e., 4 CPU cores[1] and the COP:

- The watchdog is reset by the corresponding core reset signal
- WD timers 0 to 3 are associated with CPU 0 to 3, WD 4 is associated with COP

There are no dedicated timers for the WDTs. Each WDT can be configured to use any one of the TMRs as its timer source.

Based on the configuration of the TIMER_WDTx_CONFIG register, a WDT works as follows:

- When the timer decrements to zero the first time, a WDT interrupt can be generated
- When the timer consecutively decrements down to zero a third time, without the processor reading the interrupt status register (TIMER_TMRx_TMR_PCR), a per CPU reset can be generated.
- When the timer consecutively decrements down to zero a fourth time, a system reset can be generated. The cause of this system reset can be read by reading PMC_RST_STATUS[RST_SOURCE] (see the Power Management Controller section for more information).

8.5 Secure TMRs and Secure WDTs

The Tegra 4 series processor TMRs and/or WDTs can be configured to be secure timers. As described in TIMER_SECURE_CFG register table later in this section, a secure register TIMER_SECURE_CFG -- which itself can only be written by secure writes – can be configured such that each of the TMRs and WDTs can be independently configured to be secure. By default all of TMRs and WDTs are non-secure and backward compatible.

8.6 Watchdog Timer Programming Guide

The watchdog timer can be programmed to reset just the CPU, just the AVP, or the entire system.

If only the CPU is reset, then AVP will just continue running as-is. The CPU reset vector should be programmed in advance so that it skips the iROM boot code and jumps directly into its own CPU boot routine (which can be anywhere.)

If only the AVP is reset, the same is true. The CPU keeps running as-is. If the AVP reset vector is set to default, it runs the normal boot code. It is up to the boot loader to decide if it needs to restart the CPU as well.

[1] CPU Core 0 is treated in a specific manner so that the watchdog process is transparent to software migration from the G to the LP process.

The watchdog timer can be programmed to the maximum timeout value of 0x3fffffff. At 1 µs/count, this is more than one thousand seconds.

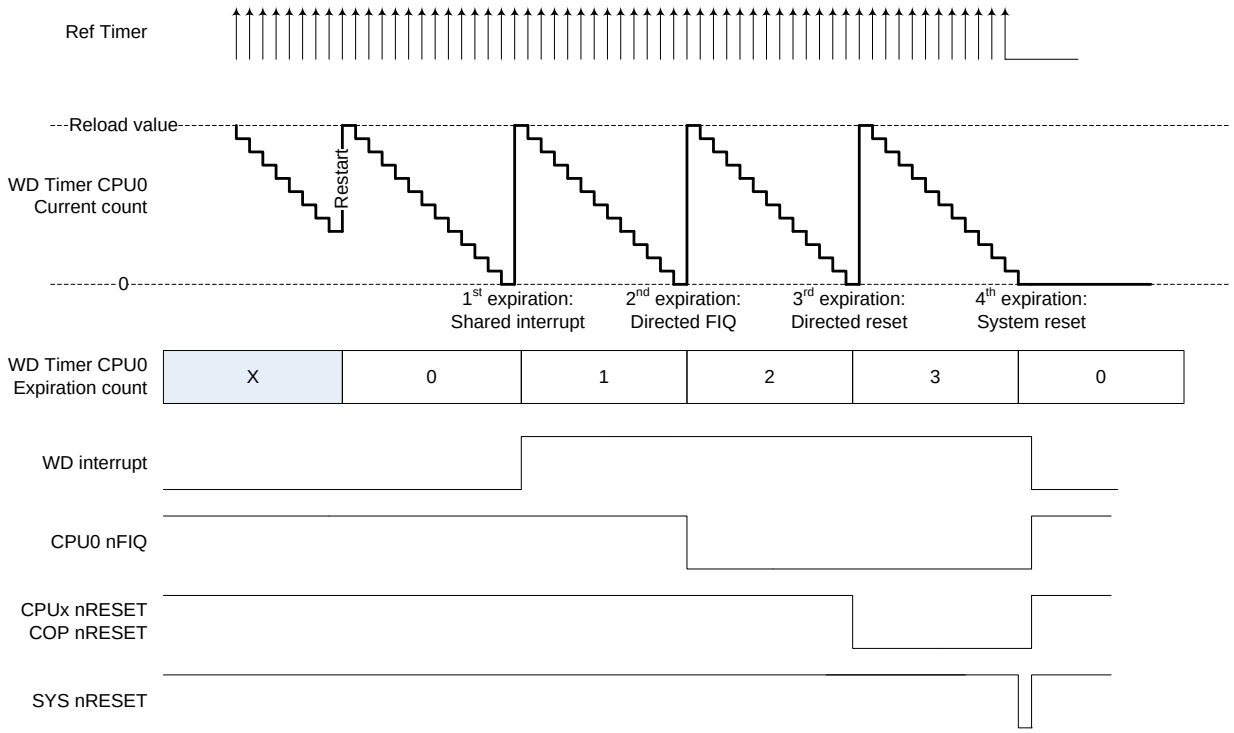
It is operated as follows:

1. Watchdog generates an Interrupt based on the Timer
    a. TMR1 or TMR2 can be selected as source
    b. Timer should be programmed as Periodic with Interrupt.
    c. CAR.RST_SOURCE.WDT_EN = 1
    d. CAR.RST_SOURCE.WDT_SEL selects TMR2/TMR1
2. Reset can be for the AVP, CPU, or full system
    a. CAR.RST_SOURCE.WDT_***_RST_EN = 1
3. Upon reboot, CAR.RST_SOURCE.WDT_*_RST_STA indicates the cause of the reset

The five watchdog timers operate as follows:

- Select any one of the general-purpose timers as timing reference
- Standard down counter with programmable period, that also counts expirations, specific action are taken at the counter expiration
    - If the expiration count is 0, a normal interrupt may be generated (probably pooled)
    - If the expiration count is 1, the FIQ for the corresponding processor may be asserted, this operation bypasses the normal interrupt controller
    - If the expiration count is 2, the reset for a programmable set of processors is asserted, this may be the null set
    - If the expiration count is 3, a system wide reset may be asserted (two variants, standard system or closer to external hardware reset)

Figure 20: Watchdog Example Timing Diagram

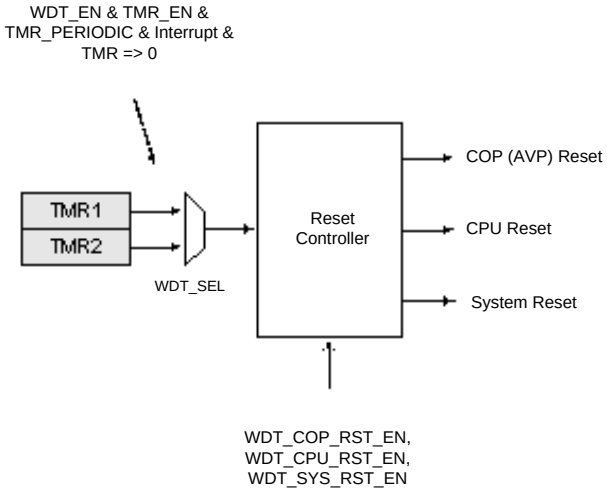


Any operation that targets CPU0 is done in the following way:

- Any output is broadcast to both instances of CPU0, in CPU cluster 0 (G) and 1 (LP). This applies to the reset and FIQ signals.
- Resetting any of the CPU0 results in resetting the WD associated with CPU 0

Although the timing diagram implies that you need to restart the timer when you service the interrupt, this is not necessary as long as you can always service the interrupt (clear the TMR interrupt) before the next timeout occurs. The reset only happens if a new timeout occurs when the TMR interrupt is still active.

Figure 21: Watchdog Block Diagram



8.7 Timers Registers

Refer to “Reading Register Tables” in the Introduction section for the register table protocol as well as recommendations for accessing registers.

8.7.1 TIMER_TMR1_TMR_PTV_0

Before programming the timer:

- Input oscillator frequency must be specified in the TIMERUS_USEC_CFG register.
- Program the number of 1 µs timer counts per "tick" in the PTV (Present Trigger Value) register.
- Set the PTV EN (enable bit) to start counting down.
- When the count reaches zero, an interrupt is generated.
- To auto-reload the timer counter, set the PTV PER (periodic) bit. Otherwise, leave it clear for a one-shot.

Timer Present Trigger Value (Set) Register

Offset: 0x0 │ Read/Write: R/W │ Reset: 0x00000000 (0b00x00000000000000000000000000000)

30	RW	0x0	INTR_CLR: 1 = clears the interrupt, 0 = no effect. Write-1-to-Clear
28:0	RO	X	TMR_PCV: Counter value: decrements from PTV.

8.8 Timer USEC CFG

Refer to “Reading Register Tables” in the Introduction section for the register table protocol as well as recommendations for accessing registers.

The purpose of the USEC_CFG/CNTR_1US registers is to provide a fixed time base (in microseconds) to be used by the rest of the system regardless of the oscillator frequency (i.e., 12 MHz, 13 MHz, 19.2 MHz, 26 MHz, or other frequencies).

8.8.1 USEC_CFG Register

Software should first configure this register by telling what fraction of 1 microsecond each oscillator clock represents. For example, if the oscillator clock is running at 12 MHz, then each oscillator clock represents 1/12 of a microsecond. "USEC_DIVIDEND" and "USEC_DIVISOR" are used to indicate what fraction of 1 microsecond each oscillator clock represents.

Table 23: Oscillator Clock Frequency Indicator for USEC

Oscillator Clock Frequency	Dividend/Divisor	USEC_DIVIDEND/USEC_DIVISOR
12 MHz	1/12	0x00 / 0x0b
13 MHz	1/13	0x00 / 0x0c
19.2 MHz	5/96	0x04 / 0x5f
26 MHz	1/26	0x00 / 0x19
16.8 MHz	5/84	0x04 / 0x53
38.4 MHz	5/192	0x04 / 0xbf
48 MHz	1/48	0x00 / 0x2f

8.9 CNTR_1US Register

Refer to “Reading Register Tables” in the Introduction section for the register table protocol as well as recommendations for accessing registers.

This free-running read-only register/counter changes once every microsecond and is used mainly by hardware (can also be used by software). It starts counting from 0 once it is out of system reset and will continue counting forever, unless the oscillator clock is stopped or during a system reset.

(A) Software Use

Although there's no interrupt mechanism for this register, software can read the content of this register multiple times to determine the amount of time that has elapsed.

(B) Hardware Use

- Used by the 4 timers to determine whether the programmed timer value has been reached; these 4 timers can trigger interrupts.
- To provide a periodic USEC pulse to be used by the flow controller to count the programmable number of microseconds before a flow control condition is triggered.
- Used by secure boot logic.

8.9.1 TIMERUS_CNTR_1US_0

Offset: 0x0 | Read/Write: RO | Reset: 0xXXXXXXXX (0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx)

Bit	Reset	Description
31:16	x	HIGH_VALUE: Elapsed time in microseconds
15:0	x	LOW_VALUE: Elapsed time in microseconds

8.9.2 TIMERUS_USEC_CFG_0

Offset: 0x4 | Read/Write: R/W | Reset: 0x0000000c (0bxxxxxxxxxxxxxxxx0000000000001100)

Bit	Reset	Description
15:8	0x0	USEC_DIVIDEND: microsecond dividend. (n+1)
7:0	0xc	USEC_DIVISOR: microsecond divisor. (n+1)

8.9.3 TIMERUS_CNTR_FREEZE_0

Offset: 0x3c | Read/Write: R/W | Reset: 0x00000000 (0bxxxxxxxxxxxxxxxxxxxxxxxxxxx00000)

Bit	Reset	Description
4	0x0	DBG_FREEZE_COP: 1 = freeze timers when COP is in debug state, 0 = no freeze.
3	0x0	DBG_FREEZE_CPU3: 1 = freeze timers when CPU3 is in debug state, 0 = no freeze.
2	0x0	DBG_FREEZE_CPU2: 1 = freeze timers when CPU2 is in debug state, 0 = no freeze.
1	0x0	DBG_FREEZE_CPU1: 1 = freeze timers when CPU1 is in debug state, 0 = no freeze.
0	0x0	DBG_FREEZE_CPU0: 1 = freeze timers when CPU0 is in debug state, 0 = no freeze.

8.10 Watchdog Timers

Refer to “Reading Register Tables” in the Introduction section for the register table protocol as well as recommendations for accessing registers.

The following register offsets are relative to the TMR block base.

Each Watchdog timer has the following:

- CoreWatchdog Configuration Register
- Timer sources are numbered 1 through 10 (0 is not used and results in undefined behavior)
- Period of 0 results in MAX period
- The generated interrupt is dependent on the WD index.
- WD0 to 3 generate a CPU_WD_Interrupt,
- WD4 generates a COP_WD_Interrupt
- CPU0 settings apply to both clusters
- Core numbering: 0-3 applies to CPU0-CPU3, 4 applies to COP

8.10.1 TIMER_WDT0_CONFIG_0

Core Watchdog Configuration Register

Offset: 0x100 | Read/Write: R/W | Reset: 0x00000000 (0bxxxxxxxxxxxx00000000000000000000)

Bit	Reset	Description
20:16	0x0	CoreResetBitmapEn: Enable reset of a set of cores at third expiration counter (one bit per proc) same level the signal from PMC asserted in case of external reset.
15	0x0	Pmc2CarResetEn: Enable Full system reset at fourth expiration of the counter 0 = DISABLE 1 = ENABLE
14	0x0	SystemResetEnable: Enable system reset at fourth expiration of the counter, at same level as existing watchdog interrupt 0 = DISABLE 1 = ENABLE
13	0x0	FIQEnable: Enable FIQ assertion at second expiration of the counter 0 = DISABLE 1 = ENABLE
12	0x0	InterruptEnable: Enable interrupt at first expiration of the counter 0 = DISABLE 1 = ENABLE
11:4	0x0	Period: Measured in periods of selected timer, this is reload value
3:0	0x0	TimerSource: Select the timer used as reference (1..10) 0 = TMR0 1 = TMR1 2 = TMR2 3 = TMR3 4 = TMR4 5 = TMR5 6 = TMR6 7 = TMR7 8 = TMR8 9 = TMR9

8.10.2 TIMER_WDT0_STATUS_0

Core Watchdog Status

Offset: 0x104 | Read/Write: RO | Reset: 0x0000XXXX (0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx)

Bit	Reset	Description
13:12	X	CurrentExpirationCount: Current count of expiration since the last start of expiration
11:4	X	CurrentCount: Current value of the counter
2	X	FiqStatus: Current status of FIQ, cleared by start
1	X	InterruptStatus: Current status of interrupt, cleared by start
0	X	Enabled: 1 when counter is active. When true, writes to corresponding config reg are ignored

8.10.3 TIMER_WDT0_COMMAND_0

The StartCounter bit enables watchdog counter operation, loads the watchdog counter, starts the watchdog timer to count down, resets the expiration count to 0, and clears all flags. Also used as restart.

The counter can be disabled by setting the DisableCounter bit, but only if the unlock register has been programmed before with the correct pattern. Writing to the command register always clears the disable unlock register. When set while StartCounter is 0 and the unlock register contains the unlock pattern the Watchdog transitions back to disabled.

The register fields are Write to set only.

CoreWatchdogCommand Register

Offset: 0x108 | Read/Write: R/W | Reset: 0x00000000 (0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx00)

Bit	Reset	Description
1	0x0	DisableCounter: Write 1 to disable WDT counter if unlocked
0	0x0	StartCounter: Write 1 to enable WDT counter

8.10.4 TIMER_WDT0_UNLOCK_PATTERN_0

CoreWatchdogDisableUnlock Register

Offset: 0x10c | Read/Write: R/W | Reset: 0x00000000 (0bxxxxxxxxxxxxxxxx0000000000000000)

Bit	Reset	Description
15:0	0x0	UnlockPattern: Must be written with value 0xC45A to allow write to DisableCounter to take effect. The pattern is reset at each write to Command Reg.

8.10.5 TIMER_WDT1_CONFIG_0

Offset: 0x120 | Read/Write: R/W | Reset: 0x00000000 (0bxxxxxxxxxxx00000000000000000000)

Bit	Reset	Description
20:16	0x0	CoreResetBitmapEn: Enable reset of a set of cores at the third expiration counter (one bit per proc) same level the signal from PMC asserted in case of external reset.

Bit	Reset	Description
15	0x0	Pmc2CarResetEn: Enable Full system reset at the fourth expiration of the counter, at 0 = DISABLE 1 = ENABLE
14	0x0	SystemResetEnable: Enable system reset at the fourth expiration of the counter, at same level as existing watchdog interrupt 0 = DISABLE 1 = ENABLE
13	0x0	FIQEnable: Enable FIQ assertion at the second expiration of the counter 0 = DISABLE 1 = ENABLE
12	0x0	InterruptEnable: Enable interrupt at the first expiration of the counter 0 = DISABLE 1 = ENABLE
11:4	0x0	Period: Measured in periods of selected timer, this is the reload value
3:0	0x0	TimerSource: Select the timer used as reference (1..10) 0 = TMR0 1 = TMR1 2 = TMR2 3 = TMR3 4 = TMR4 5 = TMR5 6 = TMR6 7 = TMR7 8 = TMR8 9 = TMR9

8.10.6 TIMER_WDT1_STATUS_0

CoreWatchdogStatus

Offset: 0x124 | Read/Write: RO | Reset: 0x0000XXXX (0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx)

Bit	Reset	Description
13:12	X	CurrentExpirationCount: Current count of expiration since the last start of expiration
11:4	X	CurrentCount: Current value of the counter
2	X	FiqStatus: Current status of FIQ, cleared by start
1	X	InterruptStatus: Current status of interrupt, cleared by start
0	X	Enabled: 1 when counter is active. When true, writes to corresponding config reg are ignored

8.10.7 TIMER_WDT1_COMMAND_0

CoreWatchdogCommand Register

Offset: 0x128 | Read/Write: R/W | Reset: 0x00000000 (0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx00)

Bit	Reset	Description
1	0x0	DisableCounter: Write 1 to disable WDT counter if unlocked
0	0x0	StartCounter: Write 1 to enable WDT counter

8.10.8 TIMER_WDT1_UNLOCK_PATTERN_0

CoreWatchdogDisableUnlock Register

Offset: 0x12c | Read/Write: R/W | Reset: 0x00000000 (0bxxxxxxxxxxxxxxxx0000000000000000)

Bit	Reset	Description
15:0	0x0	UnlockPattern: Must be written with value 0xC45A to allow write to DisableCounter to take effect. The pattern is reset at each write to Command Reg.

8.10.9 TIMER_WDT2_CONFIG_0

Offset: 0x140 | Read/Write: R/W | Reset: 0x00000000 (0bxxxxxxxxxxx00000000000000000000)

Bit	Reset	Description
20:16	0x0	CoreResetBitmapEn: Enable reset of a set of cores at the third expiration counter (one bit per proc) same level the signal from PMC asserted in case of external reset.
15	0x0	Pmc2CarResetEn: Enable Full system reset at the fourth expiration of the counter, at 0 = DISABLE 1 = ENABLE
14	0x0	SystemResetEnable: Enable system reset at the fourth expiration of the counter, at same level as existing watchdog interrupt 0 = DISABLE 1 = ENABLE

8.10.16 TIMER_WDT3_UNLOCK_PATTERN_0

CoreWatchdogDisableUnlock Register

Offset: 0x16c | Read/Write: R/W | Reset: 0x00000000 (0bxxxxxxxxxxxxxxxx0000000000000000)

Bit	Reset	Description
15:0	0x0	UnlockPattern: Must be written with value 0xC45A to allow write to DisableCounter to take effect. The pattern is reset at each write to the Command Register.

8.10.17 TIMER_WDT4_CONFIG_0

Offset: 0x180 | Read/Write: R/W | Reset: 0x00000000 (0bxxxxxxxxxxx00000000000000000000)

Bit	Reset	Description
20:16	0x0	CoreResetBitmapEn: Enable reset of a set of cores at third expiration counter (one bit per proc), same level the signal from PMC asserted in case of external reset.
15	0x0	Pmc2CarResetEn: Enable Full system reset at fourth expiration of the counter, at 0 = DISABLE 1 = ENABLE
14	0x0	SystemResetEnable: Enable system reset at fourth expiration of the counter, at same level as existing watchdog interrupt 0 = DISABLE 1 = ENABLE
13	0x0	FIQEnable: Enable FIQ assertion at second expiration of the counter 0 = DISABLE 1 = ENABLE
12	0x0	InterruptEnable: Enable interrupt at first expiration of the counter 0 = DISABLE 1 = ENABLE
11:4	0x0	Period: Measured in periods of selected timer, this is reload value
3:0	0x0	TimerSource: Select the timer used as reference (1..10) 0 = TMR0 1 = TMR1 2 = TMR2 3 = TMR3 4 = TMR4 5 = TMR5 6 = TMR6 7 = TMR7 8 = TMR8 9 = TMR9

8.10.18 TIMER_WDT4_STATUS_0

CoreWatchdogStatus

Offset: 10x84 | Read/Write: RO | Reset: 0x0000XXXX (0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx)

Bit	Reset	Description
13:12	X	CurrentExpirationCount: Current count of expiration since the last start of expiration
11:4	X	CurrentCount: Current value of the counter
2	X	FiqStatus: Current status of FIQ, cleared by start
1	X	InterruptStatus: Current status of interrupt, cleared by start
0	X	Enabled: 1 when counter is active. When true, writes to corresponding configuration register are ignored

8.10.19 TIMER_WDT4_COMMAND_0

CoreWatchdogCommand Register

Offset: 0x188 | Read/Write: R/W | Reset: 0x00000000 (0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx00)

Bit	Reset	Description
1	0x0	DisableCounter: Write 1 to disable WDT counter if unlocked
0	0x0	StartCounter: Write 1 to enable WDT counter

8.10.20 TIMER_WDT4_UNLOCK_PATTERN_0

CoreWatchdogDisableUnlock Register

Offset: 0x18c | Read/Write: R/W | Reset: 0x00000000 (0bxxxxxxxxxxxxxxxx0000000000000000)

Bit	Reset	Description
15:0	0x0	UnlockPattern: Must be written with value 0xC45A to allow write to DisableCounter to take effect. The pattern is reset at each write to the Command Register.

8.11 Timer Shared Interrupt Status

Refer to “Reading Register Tables” in the Introduction section for the register table protocol as well as recommendations for accessing registers.

TimerSrcBitmap is used for Timers 6 through 10 which share a common interrupt line to the controller. Bit b is set if timer 6+b generated an interrupt. The corresponding bit is cleared by writing INTR_CLR bit of the TMR_PCR register.

WatchdogSrcBitmap is used for the 5 watchdog timers. This is the set of Interrupt Status bits from the corresponding CoreWatchdogStatus, but as a bitmap.

8.11.1 SHARED_INTR_STATUS_0

Offset: 0x0 | Read/Write: RO | Reset: 0x00000XXX (0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx)

Bit	Reset	Description
10:6	X	TimerSrcBitmap: Timer[0,9:6] interrupt status in bitmap form
4:0	X	WatchdogSrcBitmap: WDT[4:0] interrupt status in bitmap form

8.11.2 SHARED_TIMER_SECURE_CFG_0

Offset: 0x4 | Read/Write: R/W | Reset: 0x00000000 (0bxxxxxxxxxxxx0xxx00000xx0000000000)

Bit	Reset	Description
20	0x0	USEC: TIMERUS_USEC_CFG secure mode config. If this bit is set (=1) then TIMERUS_USEC_CFG register can only be written by secure writes. If this bit is cleared then TIMERUS_USEC_CFG register can be written by secure or non-secure writes. This register can always be read by secure or non-secure reads. Note: this bit should be set if any one of the TMR is enabled to be secure. 1: ENABLE 0: DISABLE

Bit	Reset	Description
16	0x0	WDT4: WDT4 secure mode config. See the WDT0 bit description. This bit is reserved since WDT4 belongs to COP and it has no notion of Secure or Non-Secure transactions
15	0x0	WDT3: WDT3 secure mode config. See the WDT0 bit description.
14	0x0	WDT2: WDT2 secure mode config. See the WDT0 bit description.
13	0x0	WDT1: WDT1 secure mode config. See the WDT0 bit description.
12	0x0	WDT0: WDT0 secure mode config. If this bit is set (=1) then WDT0 registers (i.e. TIMER_WDT0_{CONFIG,COMMAND,UNLOCK_PATTERN}) can only be written by secure writes. A non-secure read will not trigger read-side-effect, but would return proper read value. If this bit is cleared then WDT0 registers can be written by secure or non-secure writes. WDT0 registers can always be read by secure or non-secure reads. Note: if this bit set, then TMR used for this WDT0 should be enabled to be secure. 1: ENABLE 0: DISABLE
9	0x0	TMR9: Timer9 secure mode config. See the TMR0 bit description.
8	0x0	TMR8: Timer8 secure mode config. See the TMR0 bit description.
7	0x0	TMR7: Timer7 secure mode config. See the TMR0 bit description.
6	0x0	TMR6: Timer6 secure mode config. See the TMR0 bit description.
5	0x0	TMR5: Timer5 secure mode config. See the TMR0 bit description.
4	0x0	TMR4: Timer4 secure mode config. See the TMR0 bit description.
3	0x0	TMR3: Timer3 secure mode config. See the TMR0 bit description.
2	0x0	TMR2: Timer2 secure mode config. See the TMR0 bit description.
1	0x0	TMR1: Timer1 secure mode config. See the TMR0 bit description.
0	0x0	TMR0: Timer0 secure mode config. If this bit is set (=1) then TMR0 registers (i.e., TIMER_TMR0_TMR_{PTV,PCR}) can only be written by secure writes. A non-secure read will not trigger read-side-effect, but would return proper read value. If this bit is cleared then TMR0 registers can be written by secure or non-secure writes. TMR0 registers can always be read by secure or non-secure reads. 0: DISABLE 1: ENABLE

9.0 MULTI-PURPOSE I/O PINS AND PIN MULTIPLEXING (PINMUXING)

9.1 Overview

Tegra® 4 devices can be configured with different I/O functions on particular pins to allow use in a variety of different configurations. This section discusses how this is controlled and how the pins themselves are set up.

Many of the pins on Tegra 4 devices are connected to multi-purpose I/O (MPIO) pads. An MPIO can operate in two modes: either acting as a signal for a particular I/O controller, referred to as a Special-Function I/O (SFIO); or as a software-controlled general-purpose I/O function, referred to as GPIO. Each MPIO has up to four SFIO functions as well as being a GPIO.

Though each MPIO has up to 5 functions (a GPIO function and up to 4 SFIO functions), a given MPIO can only act as a single function at a given point in time. The Pinmux controller in Tegra 4 devices includes the logic and registers to select a particular function for each MPIO.

This section describes the following features of MPIOs, the Pinmux controller, and the GPIO controller:

- Basic capabilities of the MPIO pads
- Differences between the variety of MPIO pads
- Mapping of MPIO pads to I/O controllers (i.e., pinmuxing)
- Behavior of the MPIO pads during power-up
- Behavior of the MPIO pads before, during, and after deep sleep
- Recommendations for software programming related to the MPIO pads.

This section covers the Multi-Purpose digital I/O pads. It does not address the special-purpose I/O pads, such as those used for USB, IC_USB, SATA, PCIE, TVO/DAC, MIPI DSI, MIPI CSI, the oscillator, or DRAM interfaces.

9.2 Terms and Acronyms

Some common terms used with Tegra 4 processor pinmuxing are as follows:

- MPIO = Multi-Purpose I/O
- GPIO = General-Purpose I/O
- SFIO = Special-Function I/O
- ST = Standard MPIO pads
- DD = Dual-driver MPIO pads
- OD = Open-drain MPIO pads
- CZ = Controlled-output impedance MPIO pads
- LV = Low-voltage MPIO pads
- Deep sleep

9.3 MPIO Pad Description

Each MPIO pad consists of:

- An output driver with:
  - Tristate capability
  - Drive strength controls AND
  - Push-pull mode, open-drain mode, or both

- An input receiver with:
  - Schmitt mode, CMOS mode, or both
- A weak pull-up and a weak pull-down

Tegra 4 devices include five types of MPIO pads, which all share a common structure. The following table summarizes the differences between the five MPIO pad types.

Table 24: MPIO Pad Types

Pad Type	I/O Rail Voltage	Input Buffer	Output Buffer	I/O Voltage Tolerance	Nominal Pull Strength	"Slew Rate" Control	Drive Strength Control
ST	1.8, 2.8-3.3	Schmitt & CMOS	push-pull	VDDIO	100 kΩ	2 bits, up & down	5 bits, up & down. LPMD
CZ	1.8, 2.8-3.3	Schmitt & CMOS	push-pull	VDDIO	15 kΩ	2 bits, up & down	7 bits, up & down.
DD	1.8, 2.8-3.3	Schmitt & CMOS	push-pull & open-drain	3.3V for open-drain, VDDIO otherwise	50 kΩ	2 bits, up & down	5 bits, up & down. LPMD
LV	1.2, 1.8	CMOS	push-pull	VDDIO	15 kΩ	2 bits, up & down	5 bits, up & down.
OD	1.8, 2.8-3.3	Schmitt & CMOS	open-drain	5V	100 kΩ -- down only	2 bits, down only	5 bits, up. LPMD

The ST (standard) MPIO pads are the most common pads on the chip.

The DD (dual-driver) MPIO pads are similar to the ST pads with the addition of a 3.3V tolerant true open-drain mode. A DD pad can tolerate its I/O pin being pulled up to 3.3V (regardless of supply voltage) as long as the pad's output-driver is set to open-drain mode. There are special power-sequencing considerations when using this functionality.

Note: Refer to Power Sequencing, in *NVIDIA Tegra 4 Series 4-PLUS-1 Quad-Core Processors Data Sheet* (DS-06217-001) for a complete description of the power-up sequencing requirements for Tegra 4 processors.

The OD (open drain) MPIO pads are optimized to tolerate 5V on the I/O pin regardless of the supply voltage. They are similar to ST pads except for an improved I/O voltage tolerance, the absence of a weak pull-up, and the absence of a push-pull output driver.

The CZ (controlled output impedance) MPIO pads are optimized for use in applications requiring a tightly controlled output impedance. They are similar to the ST pads except for changes in the drive strength circuitry and in the weak pull-ups/pull-downs. Tegra 4 processors include CZ pads on the VDDIO_SDMMC1 and VDDIO_SDDMC3 power rails. Each of those rails also includes a pair of CZ_COMP pads. Circuitry within the Tegra 4 device continually matches the output impedance of the CZ pads to the on-board pull-up/-down resistors attached to the CZ_COMP pads.

The LV (low voltage) MPIO pads are optimized for use with a 1.2V supply voltage (and signaling level). They support a 1.8V supply voltage (and signaling level) as a secondary mode. The Tegra 4 processors include LV pads on VDDIO_SDMMC4. The SDMMC4 interface also has a pair of COMP pads, i.e., LV_COMP pads, to generate impedance code.

Note: Refer to Multi-Purpose I/O Pads, in *NVIDIA Tegra 4 Series 4-PLUS-1 Quad-Core Processors Data Sheet* (DS-06217-001) for the list of the pad type, the nominal pull-up/-down strength, and the I/O power rail information associated with each MPIO. See the columns labeled "Pad Type", "Pull Strength", and "Power Rail."

9.4 Pad Controls

The Tegra 4 devices include many controls for each MPIO pad. Some of these controls can be set on a per-pin basis. Other controls are shared across multiple pins.

9.4.1 Per Pad Options

The following controls can be independently configured on a per-pad basis:

PUPD	Internal Pull-up/down option: Option to enable internal Pull-up, Pull-down resistors or neither
TRISTATE	Tristate (high-z) option: Disables or enables the pad's output driver. This setting overrides any other functional setting and also whether pad is selected for SFIO or GPIO. Can be used when the pad direction changes or the pad is assigned to different SFIO to avoid glitches.
E_INPUT	Input Receiver (Enable/Disable): Enables or disables input receiver.
OD	Open Drain option: (Applies to DD pads only) Selects between an open-drain output driver and a push-pull driver.
IO_RESET	Not used.
RCV_SEL	(Applies to OD pads only). Selects between "High VIL/VIH" and "Normal VIL/VIH" receivers. RCV_SEL=1: "High VIL/VIH" RCV_SEL=0: "Normal VIL/VIH"

During normal operation, these per-pad controls are driven by the pinmux controller registers. See the section called "Pinmuxing" below for more information.

During deep sleep, the PMC bypasses and then resets the pinmux controller registers. Software should reprogram these registers as necessary after returning from deep sleep. See the section called "Deep Sleep Behaviors" for more information on the interaction of PMC, software, and the pinmux controller following deep sleep.

9.4.2 Per Pad Control Group

The MPIO pads are partitioned into 35 "pad control groups". The following controls can be configured independently for each pad control group. Pad control groups are associated with a group of pads that share similar functionality for example, GMI, SDMMC.

HSM	High Speed Mode (Enable/Disable)
SCHMT	Schmitt Trigger (Enable/Disable)
LPMD	Low Power Mode. Select Low Power Modes (different impedance/current values)
DRVDN / UP	Drive Down / Up. Driver Output Pull-Up/Pull-Down drive strength code. Normally, the code is 5 bits but for CZ type pads, it is 7 bits.
SLWR/ SLWF	Slew Falling / Rising. Driver Output Pull-Up/Pull-Down slew control code. Normally, the code is 2 bits. In general, the code corresponding to the minimum slew is set (2'b11).

The controls are configured via the "pad control group registers". There is one pad control register per pad control group. During deep sleep, all of these pad control registers automatically return to their power-on-reset state. Software should reprogram these registers as necessary following deep sleep.

Table 25 lists the register address for each pad control group. Additionally, the table describes the bit positions of the controls within each register.

For example, writing a 1 to bit 3 of register 0x700000884 will enable the Schmitt trigger mode for the pads in group "cdev1cfg" pins, CLK1_OUT and CLK1_REQ. Similarly, clearing bits 14 through 23 of register 0x70000900 will minimize the drive strength (both up and down) of pads in the gmacfg pad control group.

Table 25: Pad Control Groups Register Addresses

Pad Control Group	Register Address	HSM	SCHMT	LPMD	DRVDN	DRVUP	SLWR	SLWF
gmacfg	0x70000900	2	3	5:4	18:14	24:20	29:28	31:30
sdio1cfg	0x700008ec	2	3		18:12	26:20	29:28	31:30
sdio3cfg	0x700008b0	2	3		18:12	26:20	29:28	31:30
aocfg0	0x700009ac	2	3	5:4	16:12	24:20	29:28	31:30
aocfg1	0x70000868	2	3	5:4	16:12	24:20	29:28	31:30
aocfg2	0x7000086c	2	3	5:4	16:12	24:20	29:28	31:30
cdev1cfg	0x70000884	2	3	5:4	16:12	24:20	29:28	31:30
cdev2cfg	0x70000888	2	3	5:4	16:12	24:20	29:28	31:30
ceccfg	0x70000938	2	3	5:4	16:12	24:20	29:28	31:30
dap1cfg	0x70000890	2	3	5:4	16:12	24:20	29:28	31:30
dap2cfg	0x70000894	2	3	5:4	16:12	24:20	29:28	31:30
dap3cfg	0x70000898	2	3	5:4	16:12	24:20	29:28	31:30
dap4cfg	0x7000089c	2	3	5:4	16:12	24:20	29:28	31:30

hvcfg0	0x700009a4	2	3	5:4	16:12	24:20	29:28	31:30

9.4.3 Per I/O Power Rail

These per-power-rail controls are included in the PMC registers which maintain their state during deep sleep. Software does NOT need to reprogram these register following deep sleep. The following table summarizes the functionality of these signals along with how they are controlled in the PMC.

Pin Name	Pin Description	Control/Grouping Mechanism in PMC
E_33V	Active high 3.3V mode select. When low, selects VDDP 1.8V mode.	Generated based on respective PWR_DET signal and the logic is maintained in the PMC, i.e., AO domain By default, it is maintained at Logic 1 to ensure safe power up of I/Os that are pulled to 3.3V
E_NO_IOPWR	Active high. When high, prevents leakage when I/O power is gone while core power is still on.	Maintained per power rails for 16 power rails. Ideally, should have been set during Cold Reset so that I/O rail voltage ramping does not affect the pad. However, it is reset in the chips. Whenever an I/O power rail is shut off on any specific use case, this bit has to be set to Logic1 before the I/O rails are brought down to avoid excessive leakage to the pad.

Nine pads are used for Power Detect status of various I/O rails. They are used to sense the I/O rail voltage level (3.3V or not). They are reflected through the PWR_DET set of registers in the PMC which will in turn control the E_33V pin of the pad.

9.5 Pinmuxing

Tegra 4 processors include many types of I/O controllers (such as I^2C, SDMMC, NAND, and GMI). For some of these controller types, Tegra 4 processors include multiple “controller instances”. For example, Tegra 4 processors include five active I^2C controller instances.

Each controller instance on a Tegra 4 processor communicates with external devices via a set of “external signals”. For each controller instance, each signal can be brought out on (at least) one MPIO. For example, each I^2C controller has two external signals: CLK and DAT. The CLK signal of the I2C1 controller is available on the MPIO whose ball name is GEN1_I2C_SCL.

Many of the pins on Tegra 4 devices are connected to multi-purpose I/O (MPIO) pads. To connect an MPIO to a particular I/O controller, configure it as a Special-Function I/O (SFIO) rather than a General-Purpose I/O (GPIO). Each MPIO has up to four SFIO functions. Each MPIO can as also be programmed to function as a GPIO. For example, the pin named UART3_CTS_can act in one of these five ways:

- As a GPIO
- As the signal CTS for UART3
- As the signal CMD for SDMMC
- As the signal CLK for DTV
- As the signal CS3 for SPI4B controller

Though each MPIO supports multiple functions, a given MPIO can only act as a single function at a given point in time. The Pinmux controller on a Tegra 4 device includes the logic and registers to select a particular function for each MPIO.

Some controller instances have a particular signal available on more than one MPIO. Before using any controller, make sure that the pinmux registers are programmed to bring each signal out on at most ONE MPIO. For example, UART3’s TXD signal is available on the MPIOs whose ball names are ULPI_CLK, GMI_A16, etc. In a system which brings out UART3’s TXD signal on the GMI_A16 ball, the pinmux registers for ULPI_CLK should be programmed to select some other signal.

Some controller instances make their entire set of signals available on two or more sets of MPIOs. That is, such controllers have more than one “interface”. Before using any controller, make sure that the pinmux registers are programmed to bring out the controller’s signals on at most ONE interface.

Note: The Pinmux controller includes one register per MPIO. It can be controlled on a per-pin basis.

Figure 22 shows the pinmux logic associated with a single MPIO. The ENB in the diagram (equivalent to the EN pin at the pad) is active Low. Thus, the pad is active when ENB is Low and is in the High-Z state when ENB is High.

In the figure below, GPIO_OE and SFIO_OE[3:0] are considered active Low; that is, when they are Low, the pad's output is enabled.

Figure 22: Structure of Pinmux Controller (per MPIO)

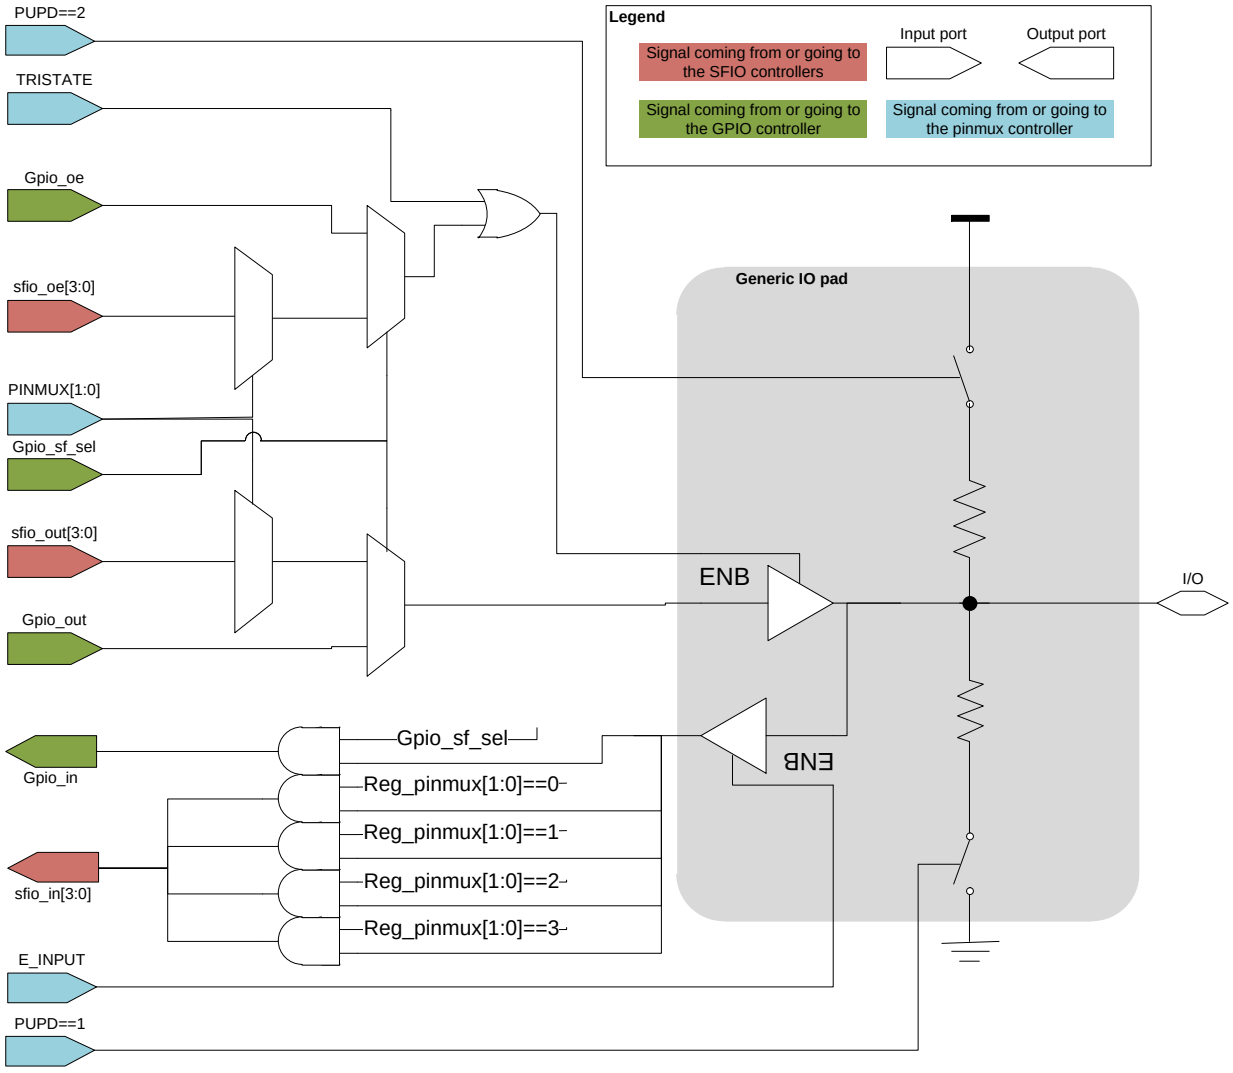

Table 26 describes the layout of each Pinmux controller register.

Table 26: Pinmux Register Format

Field Name	Bit Position	Default Value	Description
RCV_SEL	9	0/1 (depends on the type of interface)	Applicable for "OD" pads
IO_RESET	8	-	This is a dummy pin for MPIO pads and not used. The effect of applying IO_RESET is achieved by keeping A and EN pins of the pads to Logic 0.

Field Name	Bit Position	Default Value	Description
LOCK	7	0	0: Writes to this register are accepted 1: Writes to this register are ignored (until the next wake from Deep Sleep) This is a sticky bit. Once software sets this bit to 1, the only way to clear it is to reset the chip or enter and exit Deep Sleep.
E_OD	6	DD pads:1	0: the pad's output driver operates in push-pull mode. 1: the pad's output driver operates in open-drain mode. WARNING: the DD pads are only 3.3V tolerant when this bit is set. When this bit is cleared, the voltage tolerance is limited to the I/O power supply voltage. Before pulling/driving external I/Os to a value greater than the I/O power supply, this bit must be set to avoid excessive leakage. Default value recommended for DD pads is 1 to ensure that during power up no excessive leakage occurs irrespective of I/O voltage. Weak pull-ups are disabled if E_OD is set to 1 for DD pads.
		Other pads: 0	This bit only matters for DD pads. It is not implemented for other MPIO pad types.
E_INPUT	5	0/1 (depends on the type of functionality)	0: the pad's input receiver is disabled. 1: the pad's input receiver is enabled. Refer to the Tegra 4 Pinmux spreadsheet.
TRISTATE	4	0/1 (depends on the type of functionality)	0: the pad's output driver is enabled. 1: the pad's output driver is disabled (i.e., the output driver is in a high-impedance state). Refer to the Tegra 4 Pinmux spreadsheet.
PUPD	3:2	0/1 (depends on the type of functionality)	0: the pad's weak pull-up and pull-down are both disabled 1: the pad's weak pull-down is enabled and the weak pull-up is disabled. 2: the pad's weak pull-up is enabled and the weak pull-down is disabled. 3: this is an illegal combination. Refer to the Tegra 4 Pinmux spreadsheet.
PINMUX	1:0	00	0: set the pinmux logic for SFIO0. 1: set the pinmux logic for SFIO1. 2: set the pinmux logic for SFIO2. 3: set the pinmux logic for SFIO3. Note that the choice between SFIO and GPIO is controlled via the GPIO registers. Refer to the Tegra 4 Pinmux spreadsheet.

Refer to the Tegra 4 Pinmux spreadsheet for a list of the SFIO functions supported by each MPIO on Tegra 4 devices. Each SFIO is listed in the table with the following format: <ControllerType><ControllerInstance><InterfaceLetter>-<Signal>

- **ControllerType** indicates the type of I/O controller associated with this SFIO function
- **ControllerInstance** indicates the I/O controller, if the Tegra 4 processor has more than one I/O controller of the specified type
- **InterfaceLetter** differentiates between the pin sets, if the controller instance can connect to more than one set of pins
- **Signal** identifies the particular role this SFIO plays for the I/O controller.

For some of the MPIOs, the hardware includes SFIO functions that are omitted from the spreadsheet. Many of these are deprecated. Contact NVIDIA for more information.

9.6 Cold Boot Reset

The following list is a simplified description of the device power on/boot process for Tegra 4 devices concentrating on those aspects which relate to the MPIO pins.

1. System-level hardware executes the power-up sequence. This sequence ends when system-level hardware releases SYS_RESET_N.
2. Each MPIO pin has a deterministic power-on-reset state. The particular reset state for each pin is chosen to minimize the need of on-board components like pull-up resistors in a Tegra 4 based system. For example, the on-chip weak pull-ups are enabled during power-on-reset for pins which are usually used to drive active-low chip selects.
3. Because during power-up the core logic is up before I/O rails, the E_NO_IOPWR control pins of the pads must default to Logic 1.
4. Pins that act as a strap source for cold boot must have their inputs enabled (through E_INPUT control). If they have MPIO Pinmuxing enabled, the strap source should be the primary function.
5. The rising edge of SYS_RESET_N does not trigger any of the MPIOs to change their output state.

> **Note:** Refer to the Multi-Purpose I/O Pads section in *NVIDIA Tegra 4 Series 4-PLUS-1 Quad-Core Processors Data Sheet* (DS-06217-001) for a list of the power-on-reset states for each of the MPIOs. See the column labeled “Power on Reset & Wake/Strap”.

Following the power-up sequence, most of the MPIOs on the chip will stay in their power-on-reset state until system-dependent software (e.g., the Boot Loader or the OS) reprograms them. However, depending on the secondary boot device used in a given system, the Boot ROM may change the state of some of the MPIOs. The following sections list the MPIOs that the Boot ROM uses for each type of secondary boot device.

9.7 Secondary Boot

The following list is a simplified description of the device boot process for Tegra 4 devices concentrating on those aspects which relate to the MPIO pins.

1. System-level hardware executes the power-up sequence. This sequence ends when system-level hardware releases SYS_RESET_N.
2. The Boot ROM on the Tegra 4 device begins executing and programs the on-chip I/O controllers to access the secondary boot device.
3. The Boot ROM on the Tegra 4 device fetches the BCT and Boot Loader from the secondary boot device.
4. If the BCT and Boot Loader are fetched successfully, Boot ROM on the Tegra 4 device yields to the Boot Loader.
5. Otherwise, Boot ROM on the Tegra 4 device enters USB recovery mode.

Each MPIO pin has a deterministic power-on-reset state. The particular reset state for each pin is chosen to minimize the need of on-board components like pull-up resistors in a Tegra 4 based system. For example, the on-chip weak pull-ups are enabled during power-on-reset for pins which are usually used to drive active-low chip selects.

Pins that act as a strap source must have their inputs enabled by default. If they have MPIO functionality, then the default configuration group should choose strap functionality.

> **Note:** Refer to the Multi-Purpose I/O Pads section in *NVIDIA Tegra 4 Series 4-PLUS-1 Quad-Core Processors Data Sheet* (DS-06217-001) for a list of the power-on-reset states for each of the MPIOs. See the column labeled “Power on Reset & Wake/Strap”.

System designs must adhere to the described power-up sequence.

Following the power-up sequence, most MPIOs on the Tegra 4 device will stay in their power-on-reset state until system-dependent software (the Boot Loader or the OS) reprograms them. However, depending on the secondary boot device used in

a given system, the Boot ROM may change the state of some of the MPIOs and associated pinmux so that the Boot ROM can interface with the secondary device to fetch the Boot Loader.

The following subsections list the MPIOs that the Boot ROM uses for each type of secondary boot device. Depending on the type of secondary boot device used, the associated I/O rails have to be brought up by the Boot ROM/PMIC to facilitate the data exchange.

9.7.1 SPI Boot

In systems using a SPI flash as the secondary boot device, the Boot ROM for Tegra 4 devices reconfigures the pinmux for the following pins. SPI4 is used as SFIO-03.

Ball Name	SFIO Usage	I/O Power Rail
GMI_AD5	SPI|4|C|SCK:B	vddio_gmi
GMI_AD6	SPI|4|C|DOUT:B	vddio_gmi
GMI_AD7	SPI|4|C|DIN:B	vddio_gmi
GMI_CS6_N	SPI|4|C|CS1:B	vddio_gmi

9.7.2 eMMC Boot

There are four SDMMC interfaces; the one used as a secondary boot interface is SDMMC4. SDMMC4 has all the necessary functionality for SDMMC assigned as primary function, and thus there is no need to change the Pinmux configuration. However, the Boot ROM has to remove the TRISTATE control bit on these pins (through the Pinmux control register) to ensure the pins do not have the overriding TRISTATE that is making the pins inputs.

9.7.3 NAND Boot

The NAND Interface is multiplexed with the GMI Interface as a non-Primary interface. So the Boot ROM has to configure the Pinmux appropriately to choose these:

Ball Name	SFIO Usage	I/O Power Rail
GMI_WAIT	NAND_BSY0:i	vddio_gmi
GMI_ADV_N	NAND_ALE:o	vddio_gmi
GMI_CLK	NAND_CLE:o	vddio_gmi
GMI_CS4_N	NAND_CE4:o	vddio_gmi
GMI_CS2_N	NAND_CE2:o	vddio_gmi
GMI_CS3_N	NAND_CE3:o	vddio_gmi
GMI_AD0	NAND_D0:b	vddio_gmi
GMI_AD1	NAND_D1:b	vddio_gmi
GMI_AD2	NAND_D2:b	vddio_gmi
GMI_AD3	NAND_D3:b	vddio_gmi
GMI_AD4	NAND_D4:b	vddio_gmi
GMI_AD5	NAND_D5:b	vddio_gmi
GMI_AD6	NAND_D6:b	vddio_gmi
GMI_AD7	NAND_D7:b	vddio_gmi
GMI_AD8	NAND_D8:b	vddio_gmi
GMI_AD9	NAND_D9:b	vddio_gmi
GMI_AD10	NAND_D10:b	vddio_gmi
GMI_AD11	NAND_D11:b	vddio_gmi
GMI_AD12	NAND_D12:b	vddio_gmi
GMI_AD13	NAND_D13:b	vddio_gmi
GMI_AD14	NAND_D14:b	vddio_gmi

Ball Name	SFIO Usage	I/O Power Rail
GMI_AD15	NAND_D15:b	vddio_gmi
NAND_GMI_CLK_LB	nand_gmi_clk_lb:b	vddio_gmi
GMI_WR_N	NAND_WE:o	vddio_gmi
GMI_OE_N	NAND_RE:o	vddio_gmi
GMI_DQS_P	NAND_DQS:b	vddio_gmi
GMI_CS6_N	NAND_CE6:o	vddio_gmi
GMI_CS7_N	NAND_CE7:o	vddio_gmi
GMI_RST_N	NAND_CE5:o	vddio_gmi
GMI_WP_N	NAND_CE5:o	vddio_gmi

9.8 Deep Sleep Behaviors

Deep Sleep is an ultra-low-power standby state in which a Tegra 4 device maintains much of its I/O state while most of the chip is powered off. The following lists offer a simplified description of the deep sleep entry and exit concentrating on those aspects which relate to the MPIO pads.

9.8.1 Deep Sleep Entry

The steps to enter deep sleep are as follows:

1. Software programs the PMC to enter deep sleep.
2. I/O controllers are brought into the IDLE state.
3. The PMC latches much of the Tegra 4 device's I/O state. It is driven by functional logic by sampling the Pinmux controller's output. Latching of the I/O state is triggered by writing into the APBDEV_PMC_DPD_SAMPLE_0 register maintained in the PMC register space.
4. Along with latching the I/O values, various pad controls like E_OD, E_33V, and RCV_SEL have to be latched and driven depending on the pad type.
5. The PMC runs a state machine to drive the control pins in each pad, which puts them in the DPD state. There are two control pins (E_DPD and SEL_DPD) which have to be driven with proper timing as per the Pad datasheet. The PMC logic provides a configurable timer to select this. The timer is provided in the APBDEV_PMC_SEL_DPD_TIM_0 register, and entering into DPD is triggered through APBDEV_PMC_IO_DPD_REQ_0 in the PMC register space.
6. The PMC deasserts CORE_PWR_REQ.
7. The PMIC powers down VDD_CORE.
8. The PMC continues driving the I/O state that it has latched.

> **Note:** For more information about deep sleep entry, refer to the *NVIDIA Tegra 4 Series 4-PLUS-1 Quad-Core Processors Data Sheet* (DS-06217-001).

9.8.2 Deep Sleep Exit

1. The PMC detects a wake event (for example, a rising edge on an appropriately configured MPIO)
2. The PMC asserts CORE_PWR_REQ.
3. The PMIC powers up VDD_CORE.
4. The PMC resets the logic within VDD_CORE.
5. The PMC takes the I/Os out of E_DPD but continues to drive them in SEL_DPD mode.
6. The Boot ROM executes and wakes up software.
7. Software re-initializes the I/O controllers

8. Software changes the Pinmux configurations to the appropriate controller (based on what was configured during LP0) and clears the TRISTATE bit in the Pinmux register. Clearing of the TRISTATE bit is a trigger used for removing SEL_DPD.

> **Note:** For more information about deep sleep exits, refer to the *NVIDIA Tegra 4 Series 4-PLUS-1 Quad-Core Processors Data Sheet* (DS-06217-001).

9.8.3 Pad Capabilities During Deep Sleep

The MPIO pads do not all have identical behavior during deep sleep. They differ with respect to:

- Output buffer behavior during deep sleep:
  - Does it maintain a programmable (0, 1, or tristate) constant value OR
  - Is it capable of changing state while the chip is still in deep sleep (for example, a pin related to the keyboard controller)?
- Input buffer behavior during deep sleep:
  - Is it forcibly disabled OR
  - Can it be enabled for use as a “GPIO wake event” OR
  - Can it be enabled for some other purpose (for example, a “clock request” pin)?
- Weak pull-up/pull-down behavior during deep sleep
  - Are they forcibly disabled OR
  - Can they be configured?
- Behavior coming out of deep sleep
  - All the pads should maintain the state until software configures the I/O controller
- Pads that do not enter DPD mode during LP0
  - Some pads whose outputs are dynamic have a special type and they don’t enter DPD mode during LP0. The PMC has a configurable option to exclude specific pads from entering DPD during LP0 (see the PMC register APBDEV_PMC_DPD_PADS_ORIDE_0)
  - Pads that are associated with PMIC logic do not enter DPD mode during LP0
  - Some pads like JTAG do not enter DPD mode.

Refer to the “Multi-Purpose I/O Pads” section in the document entitled *NVIDIA Tegra 4 Series 4-PLUS-1 Quad-Core Processors Data Sheet* (DS-06217-001) for a summary of the capabilities of each MPIO during deep sleep. See the columns labeled “Output Buffer”, “Input Buffer”, “Weak Pull”, and “After Wake”. The following subsections describe in more detail how to interpret those columns.

9.8.3.1 Output Buffers During Deep Sleep

The output buffers of most MPIO pads are “configurable” during deep sleep. Immediately prior to entering deep sleep, the PMC latches the state of the output buffers for such pads. If the pad was driving high (or low) prior to entering deep sleep, the PMC ensures that it continues to drive high (or low) throughout deep sleep. If the pad was tristated during deep sleep, the PMC ensures that it remains tristated throughout deep sleep.

The weak pull-ups and pull-downs of most of the MPIO pads are “disabled” or “not available” during deep sleep to reduce the Tegra 4 device’s static current consumption. For the remainder of the MPIO pads, the weak pull-up and pull-down are “configurable” during deep sleep. If the pull-up (or pull-down) was enabled prior to entering deep sleep, the PMC ensures that it remains enabled throughout deep sleep. Similarly, if the pull-up (or pull-down) was disabled prior to entering deep sleep, the PMC ensures that it remains enabled throughout deep sleep.

Some MPIO pads have an output buffer which behaves in a “special” way during deep sleep. The output state of these pads may change while the Tegra 4 device remains in deep sleep. For example, the keyboard controller may continue scanning the keypad matrix during deep sleep.

9.8.3.2 Input Buffers During Deep Sleep

The input buffers of most MPIO pads are “disabled” during deep sleep. The input buffers are placed in an ultra-low power state. The Tegra 4 device will not respond to transitions on these pads while it is in deep sleep.

Some MPIO pads have an input buffer which has a “special” behavior during deep sleep. Most of these pads can act as “Deep Sleep Wake Sources”. Others offer some other functional behavior. For example CLK_REQ1 can function as a clock request pin even during deep sleep.

For a complete description of the behavior of these pads during deep sleep, refer to the *NVIDIA Tegra 4 Series 4-PLUS-1 Quad-Core Processors Data Sheet* (DS-06217-001). Pads whose input can be sampled during Deep Sleep are mentioned as ENABLED in the input buffer column. To ensure the PMC wake logic can sense these wake events, the signals must be directly taken from the ZI pin of the pad because pinmux controls are not available during LP0. Pads that are acting as wake source should satisfy the following condition: The pad’s power rail should be active.

9.8.3.3 Pinmuxing Constraints for Special Signals in LP0 Exit

Beyond wake events, there may be specific signals that are used during LP0 exit, that is, signals such as POWERGOOD/OVERCURRENT indication from the PMIC. Because these signals have to be sampled during LP0 recovery, they should be assigned to the primary function of the pinmux so that they can be sampled during LP0 exit (default Pinmux configurations are set at the Primary function).

9.8.3.4 Behavior During Deep Sleep Exit

MPIO pads “hold” their deep sleep state until system-dependent software deasserts the TRISTATE bit in the associated Pinmux controller registers. This gives software the opportunity to re-initialize the pinmux and I/O controllers without any glitches in the state of the MPIO pads.

9.9 GPIO Controller

The GPIO controller for Tegra 4 devices provides the tools for configuring each MPIO for use as a software-controlled GPIO.

The GPIO controller is divided into 8 banks. Each bank handles the GPIO functionality for up to 32 MPIOs. Within a bank, the GPIOs are arranged as four ports of 8 bits each. The ports are labeled consecutively from A through Z and then AA through FF. Ports A through D are in bank 0. Ports E through H are in bank 1. In total, there are 162 GPIOs, and the banking and numbering conventions will have some break in between but will maintain backward compatibility in register configurations for the GPIOs as that of previous generation chips.

> **Note:** Refer to the Multi-Purpose I/O Pads section in *NVIDIA Tegra 4 Series 4-PLUS-1 Quad-Core Processors Data Sheet* (DS-06217-001) for a map of each of the Tegra 4 device MPIO pads to a particular GPIO port and bit. See the column labeled “GPIO.”

Each GPIO can be individually configurable as Output/Input/Interrupt sources with level/edge controls.

GPIO configuration has a lock bit controlling every bit separately. When the LOCK bit is set, the associated control aspects of the bits (for example, whether it is an Output/Input or used as GPIO or SFIO or values driven) cannot be modified (locked). The LOCK bit gets cleared only by system reset; it is sticky. This bit can be used for security-related functionality where an authorized entity owning the GPIO can set the configuration and lock it. The lock bit also covers the GPIO output value, so this may not be varied dynamically once lock is enabled.

The GPIO controller also has masked-write registers. Values written to these registers specify both a mask of bits to be updated in the underlying state (the mask bits are not sticky) as well as new values for that state. Individual bits of the state

can be updated without the need for a read-modify-write sequence. Thus different portions of software can modify the GPIO controller state without coordination.

9.10 Programming Considerations

9.10.1 Controller Instances with Multiple Pin-outs

Several of the I/O controller instances on a Tegra 4 device have more than one pin-out. That is, the controller can communicate with the outside world via more than one set of pins. Special care is warranted when programming the Pinmux controller for these SFIOs. For a given signal on a given controller's interface, only a single pin-out should be selected in the pinmux registers.

For example, TXD is an output signal from UART A. It is available on six pins: ULPI_DATA0, SDMMC1_DATA2, SDMMC3_DATA1, GPIO_PU0, GPIO_PS1, and UART2_RTS_N. Depending on the value programmed into the corresponding pinmux registers, each of those six pins might toggle when UART A transmits data.

Similarly, RXD is an input signal to UART A. It is available on six pins: ULPI_DATA1, SDMMC1_DATA1, SDMMC3_CMD, GPIO_PU1, GPIO_PS2, and UART2_CTS_N. Depending on the value programmed into the corresponding pinmux registers, UART A might see the logical-OR of the signal on those six pins. This scenario will almost certainly lead to data corruption. If the UART A RXD signal is brought out on ULPI_DATA1, the pinmux registers for the other five pins should be programmed to some other function.

9.10.2 Resume From Deep Sleep

As the Tegra 4 device enters Deep Sleep, most of its register state is lost. In particular the pinmux, GPIO, and pad control registers lose their state during LP0. Software is responsible for reprogramming those registers upon resume from deep sleep.

9.10.3 Unused Pins

For each unused MPIO, assert its tristate and disable its input buffer. For pins whose internal pull-up is enabled during power-on-reset, assert the internal pull-up. Otherwise, assert the internal pull-down.

If all of the pins in a pad-control group are unused, set the drive strengths and slew rates to minimum.

If all of the pins on a power-rail are unused, assert E_NOIOPOWER for that rail in the PMC registers.

9.10.4 Security Considerations for the Pinmux Register

Though attacks via Pinmux are mostly Denial Of Service (DoS) attacks, there are specific cases which are a concern, for example:

- Pins interfacing with Platform PMICs (by reprogramming those pinmuxes, one can cause severe user disruption)
- Any I/O device that is transferring secret data (typically like Serial PROMs having keys). By reprogramming the pinmux, it is possible to redirect the data to wrong interface

In such cases, it is better to make use of the LOCK bit in the Pinmux control register so that values cannot be tampered with. The Boot Loader can perform this task so that customer software does not have to configure those pins. As part of LP0 exit, the lock bit will have to be re-enabled, because the lock is not retained across LP0. Similarly, the GPIO controller has a lock bit for each GPIO to preserve the configuration, value driven, and also the pin is configured as GPIO or SFIO. The configuration can be protected using the lock bit in the GPIO register. This way secure software such as a Boot Loader can ensure that certain pins have the required configuration, irrespective of the actions of less secure software.

9.10.5 Drive Strengths

For all pads that do not have corresponding calibration pads, the drive strength has to be programmed. The common default value assumed for the pad drive impedance is 50 ohms and hence pads have to be programmed with a code that can give 50 ohm impedance. Because the code depends on VDDP, i.e., I/O rail, and also PVT (Process, Voltage and Temperature) corners default a code corresponding to TT-NV-NT (Typical process, Normal Voltage, and Normal Temperature) corner as a function of VDDP voltage is chosen.

In Tegra 4 devices, the primary boot device (SDMMC4) has an auto-calibration option. Thus those pads get an impedance code that matches the PVT conditions, etc. and hence enable the boot process. For all other MPIO pads (which are not involved during boot), the BCT can have a value of the code based on the I/O rail and pad data sheet. The same is programmed by the Boot Loader or any platform-specific software, and it overrides the default Power on Reset values. If the values have to be changed based on SI results, then the same can be loaded in the primary device.

9.11 GPIO Registers

Refer to “Reading Register Tables” in the Introduction section for the register table protocol as well as recommendations for accessing registers.

Each port of each GPIO controller has several registers for the control and monitoring of the port’s 8 GPIO pins. The registers provide per-pin control of the following features:

- GPIO_CNF_* / GPIO_MSK_CNF — Select SPIO or GPIO
- GPIO_OE_* / GPIO_MSK_OE_* — Output Enable
- GPIO_OUT_* / GPIO_MSK_OUT_* — GPIO Output Value
- GPIO_IN_* — GPIO Input Value (Read Only)
- GPIO_INT_STA_* / GPIO_MSK_INT_STA_* — GPIO Interrupt Status
- GPIO_INT_ENB_* / GPIO_MSK_INT_ENB_* — Interrupt Enable
- GPIO_INT_LVL_* / GPIO_MSK_INT_LVL_* — Interrupt Selection (Edge/Level)
- GPIO_INT_CLR_* — Interrupt Flag Set-to-Clear

Many of the control registers are accessible from two offsets. Accesses to the lower offsets affect all 8 pins for the GPIO port. Accesses to the upper offsets provide a per-pin mask capability allowing adjustments to a subset of the pins. Using the upper offsets can eliminate the need for Read-Modify-Write operations. For example, a write to GPIO_MSK_CNF can substitute for a Read-Modify-Write of GPIO_CNF.

Table 27: Tegra 4 GPIO Register Summary

Register Name	Offset (Lower: Read-Modify-Write)				Offset (Upper: Per-Pin Mask Write)			
GPIO Controller 1 – Port	**A**	**B**	**C**	**D**	**A**	**B**	**C**	**D**
GPIO_CNF_0	000	004	008	00C	080	084	088	08C

9.11.1 GPIO_CNF_0

Designate whether each pin operates as a GPIO or as an SFIO. By default all pins come up in SFIO mode. These can be programmed to GPIO mode at any stage. This is an array of 4 identical register entries; the register fields below apply to each entry.

GPIO Port Configuration Registers

Offset: 0h..fh | Read/Write: R/W | Reset: 0b0000000000000000

Bit	Reset	Description
15	DISABLE	LOCK_7: Lock access to pin 7 CNF, OE and OUT 0 = DISABLE 1 = ENABLE
14	DISABLE	LOCK_6: Lock access to pin 6 CNF, OE and OUT 0 = DISABLE 1 = ENABLE
13	DISABLE	LOCK_5: Lock access to pin 5 CNF, OE and OUT 0 = DISABLE 1 = ENABLE
12	DISABLE	LOCK_4: Lock access to pin 4 CNF, OE and OUT 0 = DISABLE 1 = ENABLE

Bit	Reset	Description
11	DISABLE	LOCK_3: Lock access to pin 3 CNF, OE and OUT 0 = DISABLE 1 = ENABLE
10	DISABLE	LOCK_2: Lock access to pin 2 CNF, OE and OUT 0 = DISABLE 1 = ENABLE
9	DISABLE	LOCK_1: Lock access to pin 1 CNF, OE and OUT 0 = DISABLE 1 = ENABLE
8	DISABLE	LOCK_0: Lock access to pin 0 CNF, OE and OUT 0 = DISABLE 1 = ENABLE
7	0x0	BIT_7: Configures each pin to be in either GPIO or SFIO mode 0 = SPIO 1 = GPIO
6	0x0	BIT_6: Configures each pin to be in either GPIO or SFIO mode 0 = SPIO 1 = GPIO
5	0x0	BIT_5: Configures each pin to be in either GPIO or SFIO mode 0 = SPIO 1 = GPIO
4	0x0	BIT_4: Configures each pin to be in either GPIO or SFIO mode 0 = SPIO 1 = GPIO
3	0x0	BIT_3: Configures each pin to be in either GPIO or SFIO mode 0 = SPIO 1 = GPIO
2	0x0	BIT_2: Configures each pin to be in either GPIO or SFIO mode 0 = SPIO 1 = GPIO
1	0x0	BIT_1: Configures each pin to be in either GPIO or SFIO mode 0 = SPIO 1 = GPIO
0	0x0	BIT_0: Configures each pin to be in either GPIO or SFIO mode 0 = SPIO 1 = GPIO

9.11.2 GPIO_OE_0

GPIO mode (GPIO_CNF.x=1) must be true for this condition to be valid.

The set of registers below are used to either drive the signal out or as an Input. This needs to be programmed depending upon whether the pin needs to be in either Input or Output.

This is an array of 4 identical register entries; the register fields below apply to each entry.

GPIO Port Enable Registers

Offset: 10h..1fh | Read/Write: R/W | Reset: 0b00000000

Bit	Reset	Description
7	0x0	BIT_7: GPIO mode (GPIO_CNF.x=1) must be true for this condition to be valid. 0 = TRI_STATE 1 = DRIVEN

Bit	Reset	Description
6	0x0	BIT_6: GPIO mode (GPIO_CNF.x=1) must be true for this condition to be valid 0 = TRI_STATE 1 = DRIVEN
5	0x0	BIT_5: GPIO mode (GPIO_CNF.x=1) must be true for this condition to be valid 0 = TRI_STATE 1 = DRIVEN
4	0x0	BIT_4: GPIO mode (GPIO_CNF.x=1) must be true for this condition to be valid 0 = TRI_STATE 1 = DRIVEN
3	0x0	BIT_3: GPIO mode (GPIO_CNF.x=1) must be true for this condition to be valid 0 = TRI_STATE 1 = DRIVEN
2	0x0	BIT_2: GPIO mode (GPIO_CNF.x=1) must be true for this condition to be valid 0 = TRI_STATE 1 = DRIVEN
1	0x0	BIT_1: GPIO mode (GPIO_CNF.x=1) must be true for this condition to be valid 0 = TRI_STATE 1 = DRIVEN
0	0x0	BIT_0: GPIO mode (GPIO_CNF.x=1) must be true for this condition to be valid 0 = TRI_STATE 1 = DRIVEN

9.11.3 GPIO_OUT_0

GPIO_CNF.x=1 (in GPIO mode) AND GPIO_OE.x=1 (GPIO output enabled) must be true for this to be valid. This register will take affect only in GPIO mode. This register is used to drive the value out on a given pin.

This is an array of 4 identical register entries; the register fields below apply to each entry.

GPIO Port Output Value Registers (Read/Write)

Offset: 20h..2fh | Read/Write: R/W | Reset: 0b00000000

Bit	Reset	Description
7	0x0	BIT_7: GPIO_CNF.x=1 (in GPIO mode) AND GPIO_OE.x=1 (GPIO output enabled) must be true for this to be a valid state 0 = LOW 1 = HIGH
6	0x0	BIT_6: GPIO_CNF.x=1 (in GPIO mode) AND GPIO_OE.x=1 (GPIO output enabled) must be true for this to be a valid state 0 = LOW 1 = HIGH
5	0x0	BIT_5: GPIO_CNF.x=1 (in GPIO mode) AND GPIO_OE.x=1 (GPIO output enabled) must be true for this to be a valid state 0 = LOW 1 = HIGH
4	0x0	BIT_4: GPIO_CNF.x=1 (in GPIO mode) AND GPIO_OE.x=1 (GPIO output enabled) must be true for this to be a valid state 0 = LOW 1 = HIGH
3	0x0	BIT_3: GPIO_CNF.x=1 (in GPIO mode) AND GPIO_OE.x=1 (GPIO output enabled) must be true for this to be a valid state 0 = LOW 1 = HIGH

Bit	Reset	Description
2	0x0	BIT_2: GPIO_CNF.x=1 (in GPIO mode) AND GPIO_OE.x=1 (GPIO output enabled) must be true for this to be a valid state 0 = LOW 1 = HIGH
1	0x0	BIT_1: GPIO_CNF.x=1 (in GPIO mode) AND GPIO_OE.x=1 (GPIO output enabled) must be true for this to be a valid state 0 = LOW 1 = HIGH
0	0x0	BIT_0: GPIO_CNF.x=1 (in GPIO mode) AND GPIO_OE.x=1 (GPIO output enabled) must be true for this to be a valid state 0 = LOW 1 = HIGH

9.11.4 GPIO_IN_0

GPIO mode (GPIO_CNF.x=1) must be true for this condition to be valid. This is a read-only register used to read the value from the pin. This is an array of 4 identical register entries; the register fields below apply to each entry.

GPIO Port Input Value Registers (Read Only)

Offset: 30h..3fh | Read/Write: R/W | Reset: 0b00000000

Bit	Reset	Description
7	0x0	BIT_7: GPIO mode (GPIO_CNF.x=1) must be true for this condition to be valid. 0 = LOW 1 = HIGH
6	0x0	BIT_6: GPIO mode (GPIO_CNF.x=1) must be true for this condition to be valid 0 = LOW 1 = HIGH
5	0x0	BIT_5: GPIO mode (GPIO_CNF.x=1) must be true for this condition to be valid 0 = LOW 1 = HIGH
4	0x0	BIT_4: GPIO mode (GPIO_CNF.x=1) must be true for this condition to be valid 0 = LOW 1 = HIGH
3	0x0	BIT_3: GPIO mode (GPIO_CNF.x=1) must be true for this condition to be valid 0 = LOW 1 = HIGH
2	0x0	BIT_2: GPIO mode (GPIO_CNF.x=1) must be true for this condition to be valid 0 = LOW 1 = HIGH
1	0x0	BIT_1: GPIO mode (GPIO_CNF.x=1) must be true for this condition to be valid 0 = LOW 1 = HIGH
0	0x0	BIT_0: GPIO mode (GPIO_CNF.x=1) must be true for this condition to be valid 0 = LOW 1 = HIGH

All GPIO inputs can be independently programmed to generate an interrupt request.

In addition, the individual trigger level for interrupt on each input pin can be programmed as either active-on-high or active-on-low. For example, to program an active-on-high interrupt on bit 3 of GPIO-PORT_C, write '1' into bit 3 of GPIO_INT.LVL.C register (this sets the interrupt to be active-on-high), and then write '1' into bit 3 of GPIO_INT.ENB.C (this enables interrupt on the named bit).

The interrupt flag status can be read in the appropriate bit of the GPIO_INT.STA.C register. Once the programmed interrupt occurs, status should be cleared by writing into the appropriate bit of the GPIO_INT.CLR.C register. Note that the interrupt

thus generated is routed to the processor only if the corresponding bit for GPIO interrupts in the Secondary interrupt controller is enabled.

9.11.5 GPIO_INT_STA_0

GPIO mode (GPIO_CNF.x=1) and GPIO_INT.ENB.x=1 must be true for this condition to be valid. Every GPIO pin generates an Interrupt when switching from Low-High to High-Low. Interrupt status for each port is saved in an Interrupt status register.

This is an array of 4 identical register entries; the register fields below apply to each entry.

GPIO Port Interrupt Status Registers

Offset: 40h..4fh | Read/Write: R/W | Reset: 0b00000000

Bit	Reset	Description
7	0x0	BIT_7: GPIO mode (GPIO_CNF.x=1) and GPIO_INT.ENB.x=1 must be true for this condition to be valid. 0 = IN_ACTIVE = ACTIVE
6	0x0	BIT_6: GPIO mode (GPIO_CNF.x=1) and GPIO_INT.ENB.x=1 must be true for this condition to be valid. 0 = IN_ACTIVE 1 = ACTIVE
5	0x0	BIT_5: GPIO mode (GPIO_CNF.x=1) and GPIO_INT.ENB.x=1 must be true for this condition to be valid. 0 = IN_ACTIVE 1 = ACTIVE
4	0x0	BIT_4: GPIO mode (GPIO_CNF.x=1) and GPIO_INT.ENB.x=1 must be true for this condition to be valid. 0 = IN_ACTIVE 1 = ACTIVE
3	0x0	BIT_3: GPIO mode (GPIO_CNF.x=1) and GPIO_INT.ENB.x=1 must be true for this condition to be valid. 0 = IN_ACTIVE 1 = ACTIVE
2	0x0	BIT_2: GPIO mode (GPIO_CNF.x=1) and GPIO_INT.ENB.x=1 must be true for this condition to be valid. 0 = IN_ACTIVE 1 = ACTIVE
1	0x0	BIT_1: GPIO mode (GPIO_CNF.x=1) and GPIO_INT.ENB.x=1 must be true for this condition to be valid. 0 = IN_ACTIVE 1 = ACTIVE
0	0x0	BIT_0: GPIO mode (GPIO_CNF.x=1) and GPIO_INT.ENB.x=1 must be true for this condition to be valid. 0 = IN_ACTIVE 1 = ACTIVE

9.11.6 GPIO_INT_ENB_0

Every bit of the GPIO pin has an enable which, when enabled, routes the Interrupt to the Interrupt controller. This is an array of 4 identical register entries; the register fields below apply to each entry.

GPIO Port Interrupt Enable Registers

Offset: 50h..5fh | Read/Write: R/W | Reset: 0b00000000

Bit	Reset	Description
7	0x0	BIT_7: GPIO mode (GPIO_CNF.x=1) must be true for this condition to be valid. 0 = DISABLE 1 = ENABLE
6	0x0	BIT_6: GPIO mode (GPIO_CNF.x=1) must be true for this condition to be valid. 0 = DISABLE 1 = ENABLE
5	0x0	BIT_5: GPIO mode (GPIO_CNF.x=1) must be true for this condition to be valid. 0 = DISABLE 1 = ENABLE
4	0x0	BIT_4: GPIO mode (GPIO_CNF.x=1) must be true for this condition to be valid. 0 = DISABLE 1 = ENABLE
3	0x0	BIT_3: GPIO mode (GPIO_CNF.x=1) must be true for this condition to be valid. 0 = DISABLE 1 = ENABLE
2	0x0	BIT_2: GPIO mode (GPIO_CNF.x=1) must be true for this condition to be valid. 0 = DISABLE 1 = ENABLE
1	0x0	BIT_1: GPIO mode (GPIO_CNF.x=1) must be true for this condition to be valid. 0 = DISABLE 1 = ENABLE
0	0x0	BIT_0: GPIO mode (GPIO_CNF.x=1) must be true for this condition to be valid. 0 = DISABLE 1 = ENABLE

9.11.7 GPIO_INT_LVL_0

The GPIO can detect an interrupt for any edge- or level-sensitive signal.

This is an array of 4 identical register entries; the register fields below apply to each entry

GPIO Port Interrupt Activation Level Registers

Offset: 60h..6fh | Read/Write: R/W | Reset: 0b000000000000000000000000

Bit	Reset	Description
23	0x0	DELTA_7: 1 means Trigger Interrupt on ANY change of input if EDGE is TRUE
22	0x0	DELTA_6: 1 means Trigger Interrupt on ANY change of input if EDGE is TRUE
21	0x0	DELTA_5: 1 means Trigger Interrupt on ANY change of input if EDGE is TRUE
20	0x0	DELTA_4: 1 means Trigger Interrupt on ANY change of input if EDGE is TRUE
19	0x0	DELTA_3: 1 means Trigger Interrupt on ANY change of input if EDGE is TRUE
18	0x0	DELTA_2: 1 means Trigger Interrupt on ANY change of input if EDGE is TRUE
17	0x0	DELTA_1: 1 means Trigger Interrupt on ANY change of input if EDGE is TRUE
16	0x0	DELTA_0: 1 means Trigger Interrupt on ANY change of input if EDGE is TRUE
15	0x0	EDGE_7: 1 means Configure as Edge-Triggered Interrupt
14	0x0	EDGE_6: 1 means Configure as Edge-Triggered Interrupt

Bit	Reset	Description
13	0x0	EDGE_5: 1 means Configure as Edge-Triggered Interrupt
12	0x0	EDGE_4: 1 means Configure as Edge-Triggered Interrupt
11	0x0	EDGE_3: 1 means Configure as Edge-Triggered Interrupt
10	0x0	EDGE_2: 1 means Configure as Edge-Triggered Interrupt
9	0x0	EDGE_1: 1 means Configure as Edge-Triggered Interrupt
8	0x0	EDGE_0: 1 means Configure as Edge-Triggered Interrupt
7	0x0	BIT_7: Interrupt Activation Level or Edge (HIGH for High level or Rising Edge) 0 = LOW 1 = HIGH
6	0x0	BIT_6: Interrupt Activation Level or Edge (HIGH for High level or Rising Edge) 0 = LOW 1 = HIGH
5	0x0	BIT_5: Interrupt Activation Level or Edge (HIGH for High level or Rising Edge) 0 = LOW 1 = HIGH
4	0x0	BIT_4: Interrupt Activation Level or Edge (HIGH for High level or Rising Edge) 0 = LOW 1 = HIGH
3	0x0	BIT_3: Interrupt Activation Level or Edge (HIGH for High level or Rising Edge) 0 = LOW 1 = HIGH
2	0x0	BIT_2: Interrupt Activation Level or Edge (HIGH for High level or Rising Edge) 0 = LOW 1 = HIGH
1	0x0	BIT_1: Interrupt Activation Level or Edge (HIGH for High level or Rising Edge) 0 = LOW 1 = HIGH
0	0x0	BIT_0: Interrupt Activation Level or Edge (HIGH for High level or Rising Edge) 0 = LOW 1 = HIGH

9.11.8 GPIO_INT_CLR_0

This write-only register clears the Interrupts that are set. This is valid only in GPIO mode when GPIO_INT.ENB is set.

This is an array of 4 identical register entries; the register fields below apply to each entry.

GPIO Port Interrupt Flag Set-to-Clear Registers

Offset: 70h..7fh | Read/Write: R/W | Reset: 0b00000000

Bit	Reset	Description
7	0x0	BIT_7: GPIO mode (GPIO_CNF.x=1) and GPIO_INT.ENB.x=1 must be true for this condition to be valid. 0 = SET 1 = CLEAR
6	0x0	BIT_6: GPIO mode (GPIO_CNF.x=1) and GPIO_INT.ENB.x=1 must be true for this condition to be valid. 0 = SET 1 = CLEAR

Bit	Reset	Description
5	0x0	BIT_5: GPIO mode (GPIO_CNF.x=1) and GPIO_INT.ENB.x=1 must be true for this condition to be valid. 0 = SET 1 = CLEAR
4	0x0	BIT_4: GPIO mode (GPIO_CNF.x=1) and GPIO_INT.ENB.x=1 must be true for this condition to be valid. 0 = SET 1 = CLEAR
3	0x0	BIT_3: GPIO mode (GPIO_CNF.x=1) and GPIO_INT.ENB.x=1 must be true for this condition to be valid. 0 = SET 1 = CLEAR
2	0x0	BIT_2: GPIO mode (GPIO_CNF.x=1) and GPIO_INT.ENB.x=1 must be true for this condition to be valid. 0 = SET 1 = CLEAR
1	0x0	BIT_1: GPIO mode (GPIO_CNF.x=1) and GPIO_INT.ENB.x=1 must be true for this condition to be valid. 0 = SET 1 = CLEAR
0	0x0	BIT_0: GPIO mode (GPIO_CNF.x=1) and GPIO_INT.ENB.x=1 must be true for this condition to be valid. 0 = SET 1 = CLEAR

9.11.9 GPIO_MSK_CNF_0

Each register is provided with an individual 16-bit version for enabling Masked Writes to avoid a Read-Modify-Write operation by the firmware. The exception is for the interrupt clear register, whose functionality is combined in the interrupt status register. Individual pins only can be programmed by suitably enabling the write masks in the upper byte of these 16-bit registers.

This is an array of 4 identical register entries; the register fields below apply to each entry.

MASKED PRIMARY GPIO/SFIO Config Registers (Masked Writes)

Offset: 80h..8fh | Read/Write: R/W | Reset: 0b0000000000000000

Bit	R/W	Reset	Description

9.11.15 GPIO_LOCK_0

Lock bits are used to control the access to CNF and OE registers. When set, no one can write to the CNF and OE bits. These can be programmed ONLY during Boot and get reset by Chip Reset only.

This is an array of 4 identical register entries; the register fields below apply to each entry.

GPIO Port A - D Lock Bits (Read/Write)

Offset: f0h..ffh | Read/Write: R/W | Reset: 0b00000000

Bit	Reset	Description
7	DISABLE	BIT_7: Lock access to each pin 0 = DISABLE 1 = ENABLE
6	DISABLE	BIT_6: Lock access to each pin 0 = DISABLE 1 = ENABLE
5	DISABLE	BIT_5: Lock access to each pin 0 = DISABLE 1 = ENABLE
4	DISABLE	BIT_4: Lock access to each pin 0 = DISABLE 1 = ENABLE
3	DISABLE	BIT_3: Lock access to each pin 0 = DISABLE 1 = ENABLE
2	DISABLE	BIT_2: Lock access to each pin 0 = DISABLE 1 = ENABLE
1	DISABLE	BIT_1: Lock access to each pin 0 = DISABLE 1 = ENABLE
0	DISABLE	BIT_0: Lock access to each pin 0 = DISABLE 1 = ENABLE

9.12 Pinmux Registers

Refer to “Reading Register Tables” in the Introduction section for the register table protocol as well as recommendations for accessing registers.

This section defines the Pinmux selects, Pullup, Pulldn, and E_input programmability for each pin/ball in Tegra 4 devices. Every register has 7 bits defined for Functional Pin Select. The rest are specific to a few pads like OD and IO_RESET.

1:0 PM --> Functional Pin Select.

3:2 PUPD --> Pullup / PullDn control.

4 Tristate --> Tristate Enable / Disable.

5 E_INPUT --> Input Receiver Enable/Disable.

7 LOCK --> Locks access to all configurable bits for pins, including itself.

--> 1 = Enable (preferably done during boot)

--> 0 = Disable (can only be done by full system reset)

8 IO_RESET --> Forces output drivers disabled (PU/PD control only). Required to guarantee pin state on *LPDDR2* pads during POR.

--> IO_RESET_N will override the enable signal of main driver. After power-up, core controls should be enabled first to drive the pad with the same value as programmed by E_PULL. Then IO_RESET_N / E_PULL can be deasserted.

--> If IO_RESET_N is deasserted before core controls come up, there could be unknown outputs or glitches.

Optional bits:

6 OD --> Open Drain Enable / Disable. Specifically for I2C pads.

9 RCV_SEL --> Select between High and Normal VIL/VIH receivers. RCVR_SEL=1: High VIL/VIH RCVR_SEL=0: Normal VIL/VIH

9.12.1 PINMUX_AUX_ULPI_DATA0_0

Offset: 0x3000 | Read/Write: R/W | Reset: 0x00000038 (0bxxxxxxxxxxxxxxxxxxxxxxxxx0x111000)

Bit	Reset	Description
7	DISABLE	LOCK: 0 = DISABLE 1 = ENABLE
5	ENABLE	E_INPUT: 0 = DISABLE 1 = ENABLE
4	TRISTATE	TRISTATE: 0 = NORMAL 1 = TRISTATE
3:2	PULL_UP	PUPD: 0 = NORMAL 1 = PULL_DOWN 2 = PULL_UP 3 = RSVD
1:0	SPI3	PM: 0 = SPI3 1 = HSI 2 = UARTA 3 = ULPI

9.12.2 PINMUX_AUX_ULPI_DATA1_0

Offset: 0x3004 | Read/Write: R/W | Reset: 0x00000038 (0bxxxxxxxxxxxxxxxxxxxxxxxxx0x111000)

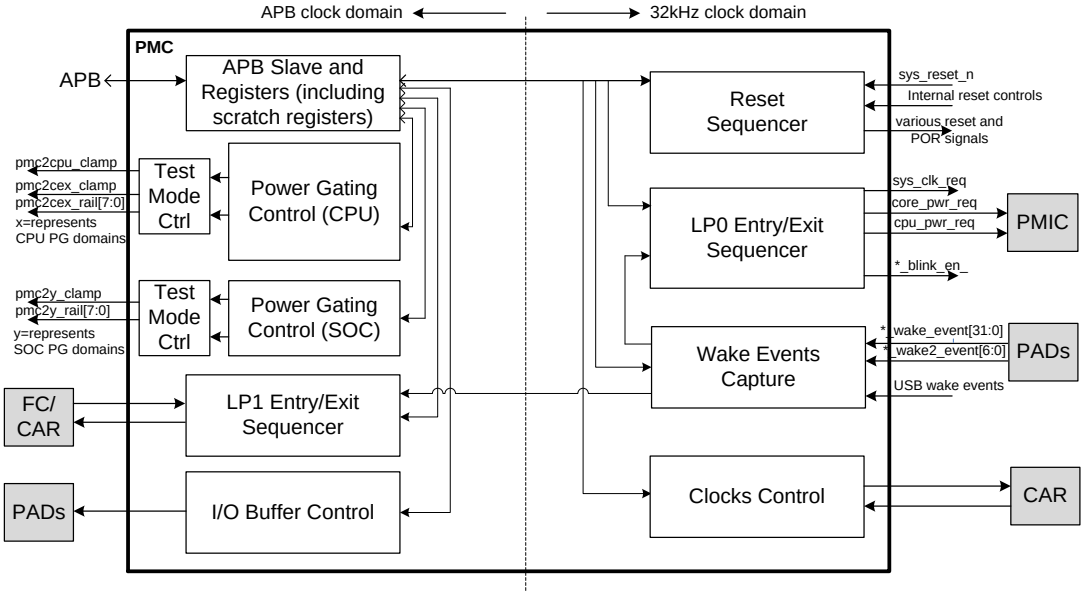
10.0 POWER MANAGEMENT CONTROLLER

The Power Management Controller (PMC) block interacts with an external Power Manager Integrated Circuit (PMIC). The PMC controls the entry and exit of the system from different sleep modes. It provides power-gating controllers for SOC and CPU power partitions and also provides scratch storage to save some of the context during sleep modes (when the CPU and/or SOC power rails are off).

Sleep (LP1) and deep sleep (LP0) require specific logic to maintain some states and control the power domains, including signaling to the external PMIC to provide power to the main logic in the Tegra® 4 devices. All this logic is centralized in the PMC block.

Figure 23: PMC Block Diagram



Glossary

- Cold boot: The SoC partition power transitions from OFF to ON with no previous state available. Software must construct all states from scratch. Boot ROM is executed. DRAM is brought on-line.
- Warm boot: Exit from LP0 state.
- LP0: Low Power 0 state. The system state is saved in the PMC and DRAM, DRAM is put in self-refresh, the PMC is configured to monitor LP0 exit wake events, and the VDD_SOC and VDD CPU rails are powered off. Also called the Deep Sleep state.
- LP1: Low Power 1 state. Devices are power-gated, SoC clock domains are set to the minimum frequency (32 kHz) the flow controller is configured to monitor LP1 exit wake events, DRAM is put in self-refresh, and the VDD_CPU rail is powered off. Also known as Suspend state.
- TSC: ARM Generic Timer System Counter (also known as Time Stamp Counter)
- VDD_AO: Always ON power rail (also known as VDD_RTC power rail)
- VDD_SOC: SOC power rail (also known as VDD_CORE power rail)
- VDD_CPU: CPU power rail

10.1 External Interface

Table 28: PMC External Interface Signals

Signal Name	Type	Signal Description
SYS_RESET_N	In	Hardware active-low reset signal. When this signal is asserted, the entire chip is reset including the PMC.
CORE_PWR_REQ	Out	Used to signal to the external PMIC device when to toggle the VDD_SOC and VDD_CPU voltage rails.
CPU_PWR_REQ	Out	
Wake-up Inputs	In	Up to 38 pins designated as wake-up are used for triggering wake-up from Deep Sleep mode. Note, there 4 additional (internal) wake events from Deep Sleep mode for USB (UTMIP and UHSIC).
SYS_CLK_REQ	Out	For systems where the system clock reference can be disabled during sleep
CLK_32K_OUT	Out	32 kHz clock out (active even during Deep Sleep). Can be used for systems that want a blinking LED during Deep Sleep

10.1.1 Flow Controller Interface

The Tegra 4 flow controller manages CPU power and rail gating transitions. When requested from the flow controller, the PMC CPU power domain sequencers power down CPU complex hardware. See the Flow Controller section for more information on CPU power gating

10.1.2 VDD_CPU Power-Good Signal

Some external PMICs support signaling when the VDD_CPU rail is fully powered on (CPU_PWR_GOOD). When enabled, CPU_PWR_GOOD signals when the PMC should start its internal CPUPWRGOOD_TIMER..

If PMC_CNTRL[CPUPWRGOOD_EN] is enabled:

- The PMC toggles CPU_PWR_REQ to signal the external PMIC to turn on VDD_CPU
- The PMC waits for a rising edge on CPU_PWR_GOOD
- Start the CPUPWRGOOD_TIMER and wait for it to expire
- The PMC sets PMC_PWRGATE_STATUS[CRAIL]
- The PMC ACKs the flow controller to complete the CPU power transition

If PMC_CNTRL[CPUPWRGOOD_EN] is disabled:

- The PMC toggles CPU_PWR_REQ to signal the external PMIC to turn on VDD_CPU
- The PMC starts the CPUPWRGOOD_TIMER and waits for it to expire
- The PMC sets PMC_PWRGATE_STATUS[CRAIL]
- The PMC ACKs the flow controller to complete the CPU power transition

10.1.2.1 Power-Good Software Configuration

- At cold boot:
  - Program CPU_PWR_GOOD pinmux appropriately (see PMC_CNTRL[CPUPWRGOOD_SEL]).
  - Program PMC_CPUPWRGOOD_TIMER.

The timeout register values need to be programmed differently based on whether the PowerGood feature is enabled or disabled. PMC_CPUPWRGOOD_TIMER will be shorter when the Power-Good feature is enabled because timer margin is not needed to account for VDD_CPU power up variances.

- Enable power-good signal usage by writing to PMC_CNTRL[CPUPWRGOOD_EN].

- The Power-Good feature cannot be enabled across LP0 transitions. Prior to LP0 entry:
  - Context save the PMC_CNTRL[CPUPWRGOOD_EN] bit and corresponding CPUPWRGOOD_TIMER value in DRAM.
  - Next update CPUPWRGOOD_TIMER with a value that is appropriate for the PowerGood feature.
  - Clear PMC_CNTRL[CPUPWRGOOD_EN].
- At LP0 exit:
  - Restore the state of PMC_CNTRL[CPUPWRGOOD_EN] followed by the CPUPWRGOOD_TIMER value.

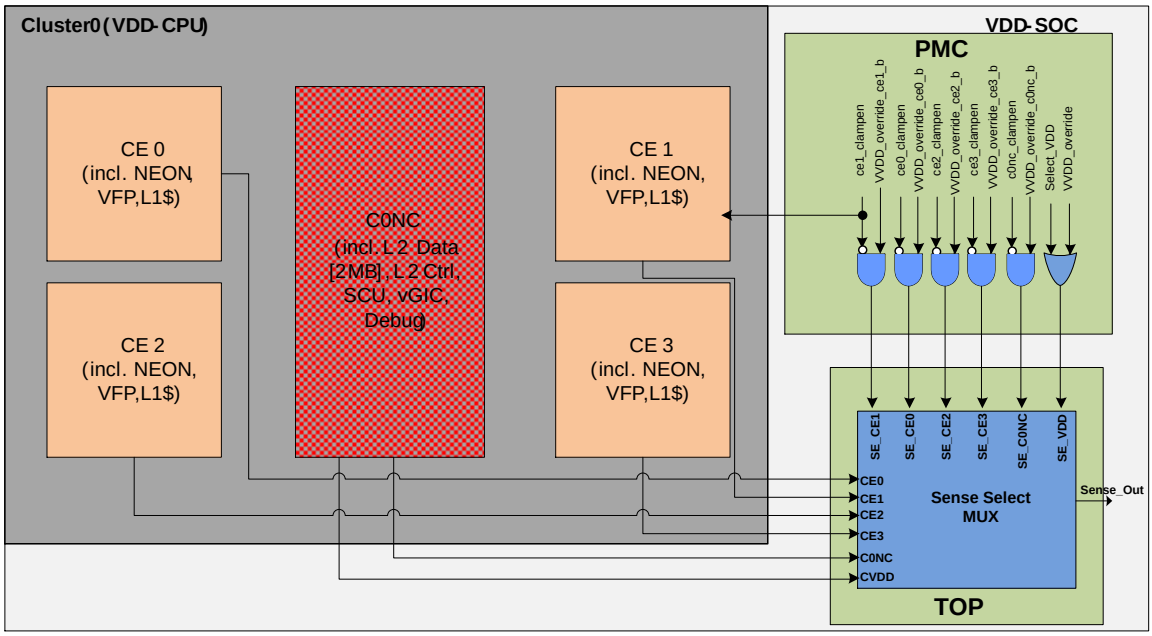
10.2 CPU Voltage Sensing Control

The Voltage Regulator (VR) delivers power to the board, then to the package and to the transistors in the silicon. The VR regulates its voltage output based on the sense feedback. To reduce inaccuracy in the VR output voltage level, the sense voltage needs to be as close to the transistors as possible.

For a power-gated partition, if the sense point is at the real VDD power grid, then the drop across the power-gate adds to the inaccuracy of the sense voltage. To reduce this inaccuracy, virtual VDD can be sensed. However, if the PG partition is power-gated, then its virtual VDD is off and cannot be used for sense feedback. Because partitions are power-gated/ungated dynamically, there needs to be control logic to provide dynamic control for the voltage-sense mux such that the virtual VDD is selected only when the corresponding PG partition is power-ungated.

As shown in the following diagram, a 6-input mux is used to select one (or more) of sensed voltages. The 6-input voltages are VVDD of each of the 5 PG partitions (in cluster0) and the real CPU VDD. The mux is expected to select the VVDD of all PG partitions that are power-ungated (powered on). If none of the 5 PG partitions are power-ungated, then real VDD is selected as the sense voltage.

Figure 24: CPU Voltage Sensing Mux Control Signals



The PMC provides a 6-bit mux select bus. The mux corresponding to 5 partitions is selected if those partitions are powered on. During normal operation, selection of the correct voltage sense signal is handled entirely by the PMC. For debug purposes, a per partition override register (see the CPU_VSENSE_OVERRIDE register) is provided which can be configured to disable input from any of the 5 PG partitions, and select real VDD. The sensing mux select control needs to be as follows:

- Never select the VVDD of a partition which is power-gated
- Select VVDD of all partitions that are power-ungated
- When all partitions are power-gated, select real VDD
  - During transition, both power-ungated (VVDD) and real VDD can be selected.

10.3 Generic Timer's System Counter (TSC)

The ARM Generic Timer Specification requires a system counter (also known as a Time Stamp Counter) to be implemented in SoCs. The Cortex™-A15 timers use this system counter as their reference clock input.

For the Generic Timer Specification, refer to ARM Architectural Reference Manual (ARMv7-A), section "The Generic Timer".

The ARM system counter requirements can be grouped into two groups: basic counter functionality and architectural control and status registers functionality.

10.3.1 Basic Counter Functionality

The basic counter functionality requirements are:

- It should run at a constant clock frequency regardless of the power and clocking state of the processor cores using it.
- A lower bound on the clock frequency of the counter is in the range 1-10MHz.
- When the system is running with an inherently low clock frequency, it is acceptable that the precision of the counter is reduced.
- It must maintain the required counter accuracy, so that it does not gain or lose more than one second in a 24-hour period.
- The size of the counter is recommended to be 64 bits to avoid any roll-over issues. For a counter clock frequency less than 50 MHz, a 56-bit counter is acceptable.

10.3.1.1 Basic Functionality Implementation

Tegra 4 devices include a 56-bit free-running TSC counting at the main oscillator clock frequency, and is reset by pmc-rst (also known as main-rst). During LP0, the oscillator clock can be disabled. The PMC provides support for running the counter off a 32.768 kHz clock.

To save power, in the TSC implementation, only an offset counter runs in 32.768 kHz mode. All external (to PMC) visible views of the TSC (i.e., the TSC bus from the PMC, and TSC register readable value) remain frozen during this mode.

Refer to the TSC Clock Switch Programming Requirement section below for more information.

10.3.1.2 TSC Clock Switch Programming Requirement

Normally, the TSC runs at the oscillator clock, which may be disabled during LP0.

Oscillator to 32.768 kHz Switch

If the oscillator needs to be disabled, then software has to ensure that the TSC clock is switched to 32.768 kHz before the oscillator is disabled. The clock switch (to 32.768 kHz) is triggered when software sets the PMC_DPD_ENABLE[TSC_MULT_EN] bit. Hardware waits for the first rising edge (on 32.768 kHz) before switching the clock. Software needs to use the following steps to ensure the TSC clock is switched (to 32.768 kHz):

- Set the PMC_DPD_ENABLE[TSC_MULT_EN] bit
- Poll for PMC_TSC_MULT[MULT_STS] to be ‘1’ OR wait for 31 µs (=1 cycle of 32.768 kHz)
- Initiate OSC disable

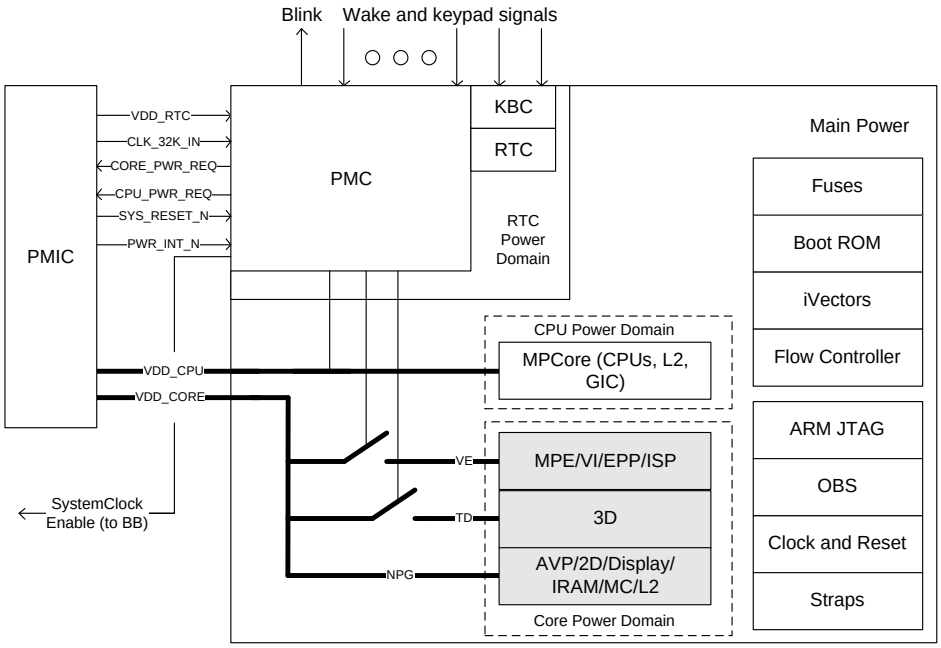
32.768 kHz to Oscillator Switch

Similar to the oscillator-to-32.768 kHz switch, hardware waits for the first rising edge on 32.768 kHz, before switching to the oscillator clock. It must be ensured that OSC is enabled before the TSC clock is switched to the oscillator. The PMC ensures that the oscillator is enabled at the LP0 exit. The LP0 restore software has to switch the TSC clock to the oscillator by clearing the PMC_DPD_ENABLE[TSC_MULT_EN] bit. After switching to the oscillator clock, software does not have to wait for PMC_TSC_MULT[MULT_STS] to be ‘0’ because 32.768 kHz is always running.

10.4 Functionality

The PMC is a part of the RTC power domain. The PMC manages the interface with the external PMIC, including the hardware reset pin, the 32.768 kHz clock, and the power request signal. A schematic view of the power domains inside the Tegra 4 devices is shown below.

Figure 25: Power Domains in Tegra 4 Devices



An important aspect of the PMC is the wake-up and reset logic. The following subsections show the expected behavior of the PMC under three scenarios:

- Frozen boot, that is, the VDD_RTC transitioning from OFF to ON, with or without VDD_CORE and VDD_CPU also transitioning from OFF to ON
- Deep Sleep wake-up, where the PMC is responsible to track wake-up events and to request a transition of VDD_CORE and optionally VDD_CPU from OFF to ON
- Suspend mode wake-up, where the PMC is responsible for establishing the power back to the CPU partition

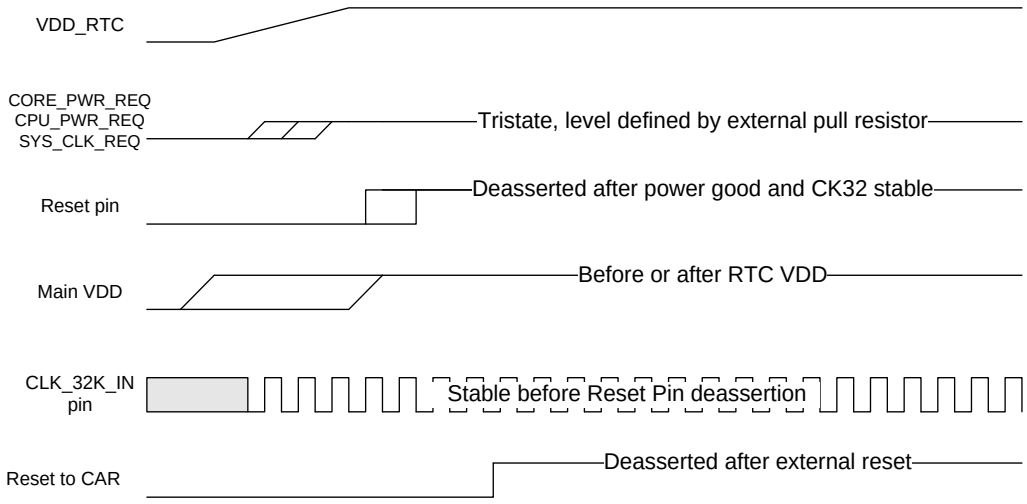
When reset is deasserted to the Tegra 4 devices, the PMC logic performs minimal processing. It forwards a reset signal and the 32.768 kHz clock to the Clock and Reset (CAR) block.

10.4.1 Frozen Boot Sequence

The Frozen Boot wake-up sequence happens when power has been deasserted to the RTC domain:

1. The PMIC detects a turn-on condition and enables power to VDD_RTC.
2. Simultaneously to VDD_RTC enable or shortly afterwards, the PMIC enables power to VDD_CORE and optionally to VDD_CPU.
3. More than 1 ms later, the PMIC enables power to 1.8V I/O rails that need to be enabled for boot.
4. More than 1 ms later, the PMIC enables power to 2.8V/3.3V I/O rails that need to be enabled for boot.
5. The PMIC drives a 32.768 kHz clock to Tegra 4 devices.
6. More than 1 ms later, the PMIC deasserts reset to Tegra 4 devices. The 32.768 kHz clock and all power rails must be stable and at their nominal value before reset is deasserted.
7. The PMC block resets and deasserts reset to the CAR block, which resets the rest of the Tegra 4 chip.
8. Tegra 4 devices begin boot from internal ROM.

Figure 26: Frozen Boot Sequence



10.4.2 Deep Sleep Wake-up Sequence

During Deep Sleep, VDD_CORE and VDD_CPU power rails are powered off. PMC logic resident in the always-on RTC power domain remains powered, detecting wake signals to initiate bringing the Tegra 4 device out of the Deep Sleep state. I/O rails associated with wake-up signals need to remain powered during Deep Sleep.

A full Deep Sleep / Wake-Up sequence proceeds according to the following steps:

Setting up Deep Sleep

1. Software configures the PMC CPU and core power request signal polarities and enables.
2. Software disables unneeded logic blocks and peripherals and disables their clocks.
3. Software programs the PMC with the wake-up condition.
4. Software programs scratch registers with information needed to restore state after wake-up.
5. Software interacts with the PMC to establish the idle conditions on the I/O.
6. Software programs the external SDRAM to enter self-refresh mode.
7. Software programs the PMC DPD to sample the state of all I/O lines. The sampled line states will remain driven during Deep Sleep.

8. Deep Sleep is typically entered when the last processor goes idle and managed by the Tegra 4 flow controller. Software needs to program the PMC to enter Deep Sleep prior to the last processor executing the WFI/WFE instruction used to signal the flow controller to initiate the transition
9. The PMC asserts the clamping signals for all power-gated islands.
10. The PMC deasserts CPU and core power requests.
11. The PMIC removes VDD_CORE and VDD_CPU power rails, and Deep Sleep is entered.

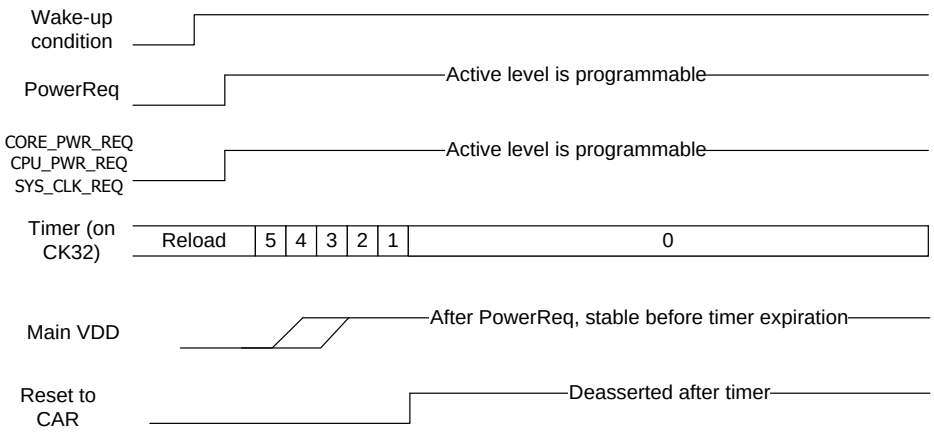
Note: To power-off VDD_CPU:
- Assert resets to CPU via CLK_RST_CONTROLLER_RST_CPU_CMPLX_SET
- Disable clock to CPU via CLK_RST_CONTROLLER_CLK_OUT_ENB_L_0_CLK_ENB_CPU
- Remove VDD_CPU

Deep Sleep Wakeup

1. The PMC detects a wake-up condition and latches the condition into a register.
2. The PMC asserts the core power request signal, asserts reset to the CAR, and starts a timer (power good delay).
3. The PMIC restores VDD_CORE and optionally VDD_CPU.
4. The power good timer expires, and the PMC releases the reset to main.

Note: To power-on VDD_CPU:
- Restore VDD_CPU
- Enable clock to CPU via CLK_RST_CONTROLLER_CLK_OUT_ENB_L_0_CLK_ENB_CPU
- If using PLLX as CPU clock source is desired, configure/enable PLLX and switch to PLLX (this step can be done after step 4).
- Deassert resets to CPU via CLK_RST_CONTROLLER_RST_CPU_CMPLX_CLR

Figure 27: Deep Sleep Wake-Up Sequence



10.4.3 Suspend Mode Wake-up Sequence

In the Suspend Mode wake-up sequence, the PMC needs to wake up the CPU by removing the power-gating:

Suspend Setup:

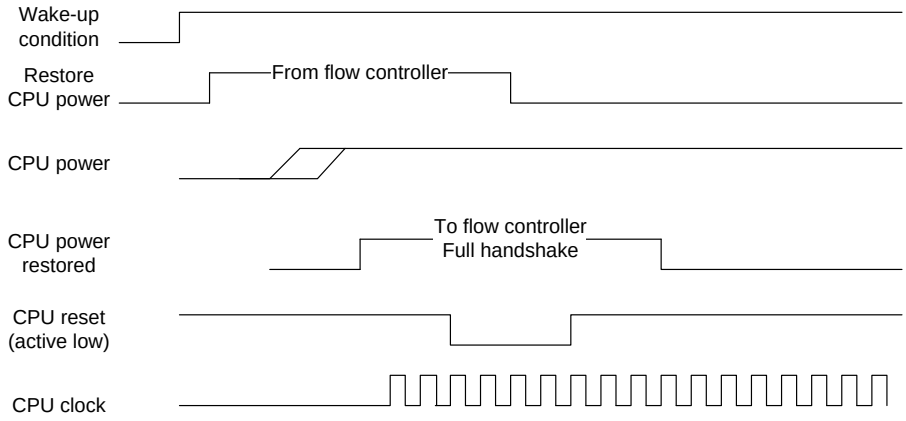
1. Software configures the Tegra flow controller with the Suspend Mode wake-up conditions.
2. The flow controller interacts with the CPU to ensure that no transactions are in flight.

3. The flow controller indicates to the CAR to reset the CPU.
4. The PMC clamps the CPU signals and removes power from the CPU.

Suspend Wakeup

1. The flow controller detects a Suspend mode wake-up condition.
2. The flow controller sends a trigger event to the PMC.
3. The PMC restores power to the CPU.
4. The PMC sends an acknowledge to the flow controller.
5. The flow controller restores the clock to the CPU.
6. The CAR asserts reset to the CPU.
7. The PMC removes clamping to the CPU.
8. The CAR deasserts reset to the CPU.

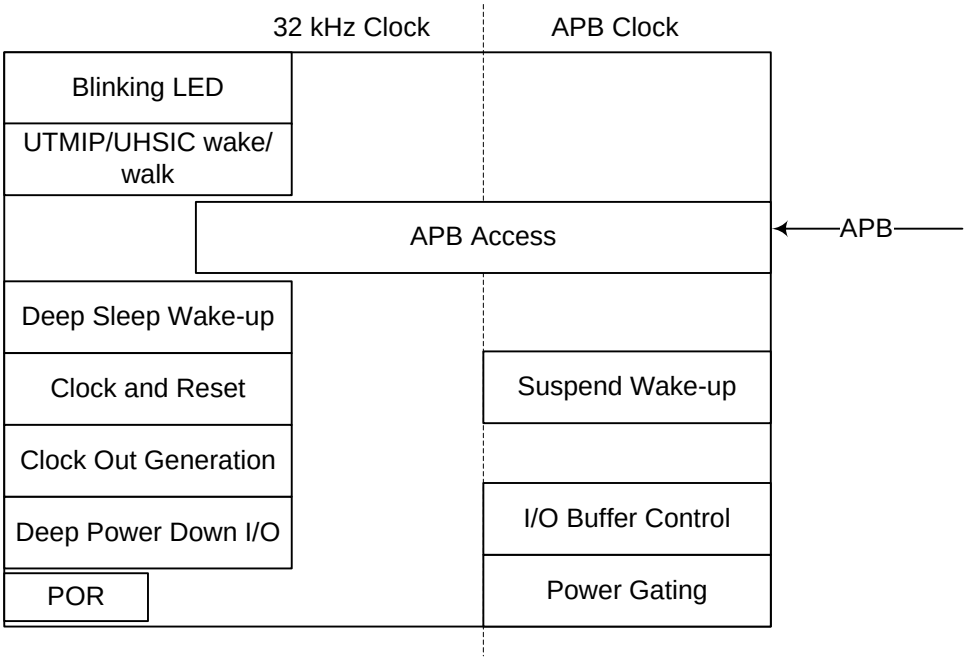
Figure 28: Suspend Mode Wake-Up Sequence



10.5 Reference Block Decomposition

The next figure shows a reference decomposition of the PMC.

Figure 29: Reference Block Decomposition Diagram



The blocks inside the PMC are:

- Wake-up logic for Deep Sleep and Suspend modes
- Power-gating logic
- External clock and reset
- Blinking LED
- I/O buffer control
- APB interface
- UTMIP/UHSIC wake/walk logic
- Deep power down I/O logic (independent on LP0)
- Clock out generation

10.5.1 Deep Sleep Entry Logic

There are two ways to enter Deep Sleep mode:

- Writing into the DPD register
- Interaction with the power gating logic when the DPD trigger enable (side effect) bit is set.

The second method is the recommended usage as described before. The exact sequence was described in more detail earlier in this section.

Note that entering Deep Sleep mode should happen after an ordered shutdown of Tegra 4 devices. As part of the shutdown procedure, external interfaces must be placed in their idle condition. The PMC provides logic that ensures these interfaces maintain their idle state during Deep Sleep itself. Software is responsible for sampling the idle state by writing to the DPD sample bit before entering Deep Sleep mode.

Software ensures that I/O paths that must remain active during Deep Sleep mode are identified as such, by correct configuration of ownership bits in a PMC register. These ownership bits are present for the signals used by the KBC (where the size of the scan matrix is defined by the customer, the exact required size is reflected in the ownership bits) and for the clock request signal (that may not be required depending on the customer clock logic).

Software must also ensure that wake-up conditions are programmed properly. Wake-up level and wake-up mask should reflect expected wake-up events. Power Good Timer and Power Down Timer must be set according to the PMIC Specification.

The Deep Sleep mode entry/wake-up logic operates largely on the 32.768 kHz clock, so software must respect a minimal delay between a Deep Sleep mode exit and before issuing the next Deep Sleep mode entry command. This delay is of the order of 2 periods of the 32.768 kHz clock. This should never be a problem given that the code to restore the processor state requires much more time.

There are two ways to enter Deep Sleep mode:

- Option 1 (side effect): First CPU power is gated, and as a result (“side effect”), the PMC performs an orderly LP0 entry. The PMC hardware also sets PMC_DPD_ENABLE (automatically). Normally, this is the only option for LP0 entry.
- Option 2 (direct write): Writing directly into the PMC_DPD_ENABLE register. This is not a safe option and is only for debug or diagnostic workaround purposes.

10.5.2 Deep Sleep Wake-Up Logic

The wake-up logic performs the following tasks:

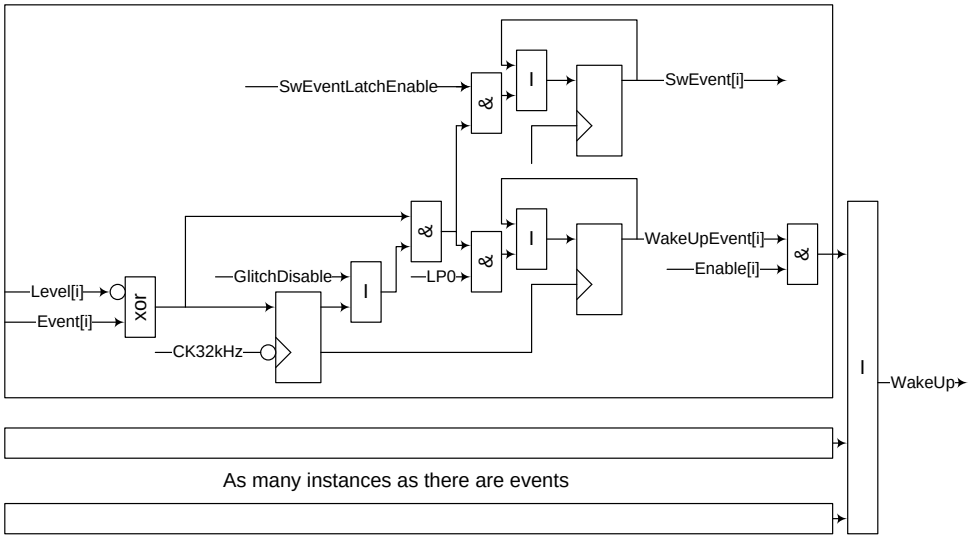
- Tracks the state of a programmable set of wake-up conditions
- Detects a wake-up condition
- Starts the sequence of action required by the Deep Sleep mode wake-up

A wake-up event is either a change of level on one in a set of specified pins or an assertion of RTC or KBC interrupts.

The logic that tracks for change of levels in external pins contains a glitch filter that may be optionally disabled. Internal interrupts do not require deglitching logic, but are passed through the same logic, as this is also the synchronization logic. A conceptual schematic is shown in the next figure. The different stages are:

- Normalizing the active level to high by inverting the wake-up signals identified as active low
- Latching either the direct signal or a deglitched version of it (global enable)
- Masking the latched signals to generate the wake-up signal

Figure 30: Deep Sleep Wake-up Logical Circuit



Note that the WakeUp signal shown is not directly the CORE_PWR_REQ signal, and there are two further processing steps defining the CORE_PWR_REQ signal:

- The polarity of the CORE_PWR_REQ signal is programmable
- CORE_PWR_REQ signal is disabled at reset. It should be enabled only after polarity is set accordingly to PMIC specification

Furthermore, there is a System Clock enable signal that is equal to CORE_PWR_REQ, but with its own independent control bits for polarity and output enable.

The set of latched wake-up events are readable by software once the processors are active. The logic accumulates all events that take place while in Deep Sleep mode. Normally only one enabled event is present in the set, but simultaneous events could take place. Each bit of the latched wake-up event register is cleared by writing a 1b to it.

A second set of latches is also present, with the same structure as the wake-up event register but under software control. The most important difference between the two sets is that events that occur outside of the Deep Sleep mode will be captured in the second set, including:

- Events that could occur during the Deep Sleep mode transition itself, i.e. before the hardware enters the Deep Sleep state, but after software has instructed hardware to enter Deep Sleep.
- Events that occur after the hardware wake-up, but before software has enabled the peripheral functions in the NPG that process the signals tied to the wake-up events, i.e., the GPIO event logic.

10.5.2.1 Deep Sleep Wake-up Event Input Path

The wake-up signals can be configured to be level (active high or low based on PMC_WAKE*_LVL registers) or pulse (based on WAKE2_LVL[ALLOW_PULSE_WAKE]). However, there has to be a minimum delay between two consecutive wake events handling (which is programmed in PMC_WAKE_DELAY). A level wake-up signal must be valid when the PMC can act upon it. For pulse wake-up signals, the PMC registers them even if they trigger during PMC_WAKE_DELAY window. However, the PMC will act upon a (registered) pulse event only after the PMC_WAKE_DELAY window has expired.

The PMC detects wake signals by using 32 kHz logic. Therefore, in either case (level or pulse), a signal has to last long enough for the PMC to recognize the change in signal. In addition, the PMC provides an option to filter out glitches.

The wake-up logic as defined, recognizes wake-up signals matching the programmed wake-up active level that exceed certain time limits and rejects events less than another limit as defined in the following table.

Table 29: Deep Sleep Wake-up Logic

Glitch disable bit	Never wake-up if event is less than	Always wake-up if more than
0 (Glitch reject)	0.5 period of 32.768 kHz clock = 15.25 µs	1.5 period of 32.768 kHz clock = 45.755 µs
1 (No glitch reject)	0 period of 32.768 kHz clock = 0 µs	1 period of 32.768 kHz clock = 30.50 µs

Between these two values, the probability of detection increases linearly from 0 to 1 when events are asynchronous to the 32.768 kHz clock. The latency delay is also a probabilistic function, varying linearly between the two limits presented in the above table.

10.5.3 Suspend Wake-up Logic

The only Suspend mode wake-up specific logic in the PMC is related to the power gating logic as described previously.

10.5.4 CPU Rail Partitions

CPU power-gating control is separated from SoC power-gating control because the CPU rail partitions need different inter-zone delay values (configured in PMC_PWRGATE_TIMER_* registers). There are 8 zones per CPU partition.

The following table provides a list of CPU rail partitions.

Table 30: CPU Rail Partitions

Partition	Partition Description	Notes
CE0	Cluster0 CPU0	Normally, power-gated on/off via flow-controller interaction. Can be power-gated on/off by direct register write. Uses PMC_PWRGATE_TIMER_CE* inter-zone delays.
CE1	Cluster0 CPU1	
CE2	Cluster0 CPU2	
CE3	Cluster0 CPU3	
C0NC	Cluster0 Non-CPU	
CRAIL	CPU Rail	Normally, power-gated on/off via flow-controller interaction. Can be power-gated on/off by direct register write. On/Off delays are programmed in PMC_CPUPWRGOOD_TIMER and PMC_CPUPWROFF_TIMER registers

10.5.5 SoC Rail Partitions

In SoC partitions, only CPULP and C1NC can be power-gated on/off via the flow controller. All other partitions can only be power-gated (on/off) by PMC register writes. Tegra 4 PG partitions have 8 zones per partition.

Partition	Partition Description	Notes
CELP	Cluster1 CPU	Normally, power-gated on/off via flow-controller interaction. Can be power-gated by direct register writes. Uses PMC_PWRGATE_TIMER_* inter-zone delays.
C1NC	Cluster1 Non-CPU	
TD	3D Engine	Power-gated only by direct register writes. Uses PMC_PWRGATE_TIMER_* inter-zone delays. In separate register is used for inter-partition delays GPU partitions are sequenced (one after another of this partition on/off request. There are a total of 6 partitions in the GPU.

Partition	Partition Description	Notes
n/a	3D Engine2	Power-gated only by direct register writes. Uses PMC_PWRGATE_TIMER_* inter-zone delays.
VE	CSI,ISP,VI	
VDE	Video Decode	
MPE	Video Encode	
HEG	VIC, Host1x, …	
n/a	SATA	
DIS	DisplayA	
DISB	DisplayB	
XUSBA	USB3 (XUSBA)	
XUSBB	USB3 (XUSBB)	
XUSBB	USB3 (XUSBC)	

10.5.6 PG Partitions

This subsection provides the default power, clamp, and reset status of the PG partitions.

10.5.6.1 Cold Boot (Power-on Reset)

By default, all of the CCPLEX related partitions (except the C0NC) are power-gated and non-CCPLEX partitions are power-ungated. The clamps are accordingly enabled (for the power-gated domain) or disabled (for the power-ungated domain). The C0NC is power-ungated by default (to keep the CAR reset defaults consistent with the PMC power status at LP0 exit).

Refer to the PMC_PWRGATE_STATUS and PMC_CLAMP_STATUS register descriptions for the default power and clamp status, respectively, of PG partitions.

10.5.6.2 LP0 Exit

At LP0 exit, the PMC retains power status of all the PG partitions. The PMC does not restore the CPU rail – if necessary, software needs to power-up the CPU rail during LP0 exit (via a PMC register write).

The CAR unit is powered off during LP0, so the CAR provided reset defaults at LP0 exit are the same as its cold boot defaults. At LP0 exit, the C0NC is expected to be power-ungated. Therefore, its cold boot default is power-ungated, so its reset (which is provided by the CAR block) can be kept the same for cold boot and LP0 exit.

10.5.7 Power-Gating Logic

The power-gating logic is a simple programmable sequencer. When the power-gating logic is triggered, it sequences the set of power-gating signals with a programmable period (measured in cycles) between the toggling of consecutive power-gating signals.

There are three power-gated domains. For all of them, the trigger can be a register write (see register definitions). The CPU power-gated domain has an extra trigger coming from the flow controller. The PMC and flow controller provide a full handshake, with the PMC providing an acknowledge back to the flow controller when the CPU power has completed its transition (this would normally only be for OFF to ON transition at Suspend mode wake-up).

The power-gating logic operates on the APB clock. The timing sequence may be dependent on the exact frequency, with a hardware limit that the minimum transition period is at least 64 ns.

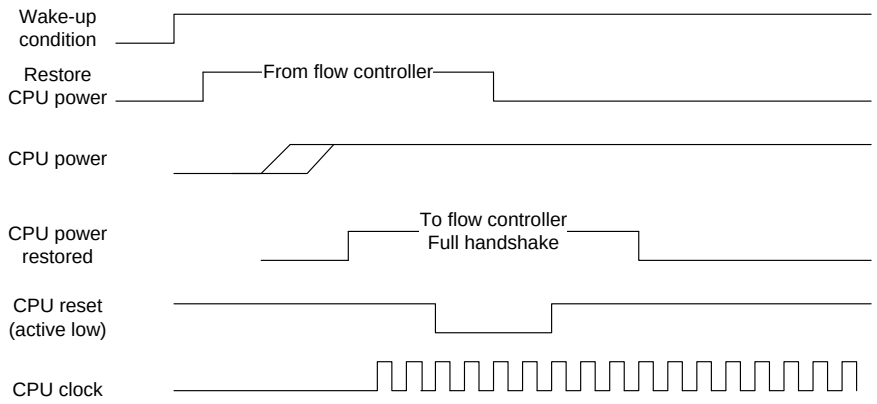
The power-gating logic may be triggered either by direct register writes using the PMC toggle register or by interaction with the flow controller. The second control path is used when entering Deep Sleep or Suspend mode to allow for an orderly shutdown of the processor. The sequence can be summarized in the following manner:

1. The CPU decides to enter either Deep Sleep or Suspend mode.
2. In both cases, power to the CPU must be gated off.
3. The CPU does any required clean-up. This is especially important for Deep Sleep (all interfaces in idle, save context, etc.).
4. The CPU informs the flow controller it wants to remove its power with two variants:
   - For Suspend mode, the CPU also defines the set of flow controller events that will wake up the CPU (the flow controller is not power gated together with the CPU).
   - For Deep Sleep, a write to a DPD sample register preserves the I/O state to be driven when the chip enters Deep Sleep mode.
     For Deep Sleep, the CPU must define in the PMC the set of wake-up events for the whole Tegra 4 device and set the DPD trigger enable bit.
5. The CPU enters an endless loop, executing the WFI/WFE instruction.
6. The flow controller asserts reset to the CPU.
7. The flow controller informs the PMC that CPU power-gating OFF is requested.
8. The PMC power gates the CPU OFF, then informs the flow controller.
9. If the DPD trigger enable was set, the PMC also performs a Deep Sleep entry, which will result after a while in the core power disappearing.

The Deep Sleep wake-up was described before and is essentially a full reset of the core logic. The Suspend mode wake-up logic includes an interlock with the flow controller that works like this:

1. The flow controller detects the Suspend mode wake-up condition.
2. The flow controller informs the PMC that power-gating ON is requested.
3. The PMC power gates the CPU ON, then informs the flow controller.
4. The flow controller deasserts the reset to the CPU.
5. The CPU checks different status registers to establish this was in fact a Suspend mode wake-up.

Figure 31: Power-Gating Logic



10.5.7.1 Software and Hardware PG Request Interlocking

The PMC power-gating controller can only power gate (or ungate) one partition at a time. However, the PMC can get independent PG requests from software by a direct register write and hardware through the flow controller.

In Tegra 3 devices, the PMC drops the PG request when it is busy sequencing a hardware-initiated request. In Tegra 4 devices, the behavior of the PMC_PWRGATE_TOGGLE[START] register bit is changed as follows:

- Software sets this bit to '1' to request a power-gate toggle.
- Hardware clears this bit to '1' when hardware starts to execute a power-gate toggle request.

For backward-compatibility, the PMC_PWRGATE_TOGGLE[START] register bit can be written to '0' by software. Normally, software should never write this bit to '0'. If software writes it to '1' and then writes it to '0' before hardware starts to execute the request, the software request gets dropped:

10.5.7.2 GPU Power Gating

Internally, the Tegra 4 3D engine has 6 partitions which are seen as one power partition by software (TD). Due to power restrictions, the 6 partitions should be brought up/down sequentially. This operation is normally transparent for software.

For debug purposes, the PMC provides support for sequencing all 6 partitions at the same time. The TD_PWRGATE_INTER_PART_TIMER register programs the period between each consecutive partition's power-gate up/down sequence. Partitions are powered up in order: TDA, TDB, TDC, TDD, TDE, and TDF. Power-gating down is executed in reverse order. Programming a 0 value in the TD_PWRGATE_INTER_PART_TIMER register will trigger simultaneous power-gating of all 6 partitions.

10.5.8 I/O Buffer Control

Deep Power Down I/O buffer management ensures that the I/Os are maintained in an idle state while in Deep Sleep mode. The procedure has been described before and requires software sequencing:

1. Software makes sure that the affected I/O ports are in their idle state, i.e., the state that will persist during Deep Sleep.
2. When software sets the DPD sample register , the idle state of the I/O control signals is captured, i.e., the driving direction and the data driven if the direction indicates output.
3. Software writes the DPD enable bit and muxes inside the I/O buffers now drive the stored idle state, while the corresponding control signals coming from the core are ignored.
4. Software triggers the Deep Sleep mode, killing itself.
5. Hardware detects the Deep Sleep wake-up condition.
6. Software wakes up and restores the state.
7. Software clears the DPD sample bit.
8. I/O control can be sequenced back to the controlling block once software has initialized the core block to drive outputs to the same idle state they maintained before entering DPD.

The PMC contains a software programmable register, with one bit per I/O rail. Each bit disables internal logic inside the I/O buffer that would otherwise consume power when the I/O power is OFF. Each bit should be set by software before shutting off the corresponding I/O power. Conversely, each bit should be reset after transitioning the I/O voltage to ON (and before enabling the set of interfaces using the corresponding I/O rail).

The PMC contains two registers related to 3.3V I/O support. Specific power detector cells per I/O voltage domain indicate if their supply voltage is low or high. The detector cells consume significant power, so they should not be left on all the time. The PMC contains a register enabling the detector cells.

10.5.9 Power Down I/O Logic

Tegra 4 PMC provides support for placing interfaces into a deep power down mode outside the Deep Sleep state. DPD domain groups include:

CSIA, CSIB, DSI, POP_CLK, POP_ADDR_CMD, DDR_ADDR_CMD, DISC_ADDR_CMD, DDR_DATA, SYS, NAND, UART, BB, VI, AUDIO, LCD, SD, IPI_BIAS, PEX_BIAS, PEX_CLK1, PEX_CLK2, COMP, POP_VTTGEN, DISC_VTTGEN, DAC, USB0, USB1, USB2, USB_BIAS, HSIC, HDMI, SDMMC1, SDMMC3, SDMMC4, CAM, PEX_CNTRL

- **DISC_VTTGEN** includes mem_addr_vttgen_1_pad, mem_addr_vttgen_2_pad, mem_vttgen_26_pad, mem_vttgen_27_pad, mem_vttgen_28_pad, mem_vttgen_29_pad
- **COMP** includes xm2_comp_pd_pad, xm2_comp_pu_pad
- **POP_CLK** includes xm2_mclk_addr_pad
- **POP_ADDR_CMD** includes dvi_d10_pad, dvi_d11_pad, dvi_vsync_pad, dvi_hsync_pad dvi_d0_pad, dvi_d1_pad, dvi_d2_pad, dvi_d3_pad, dvi_d4_pad, dvi_d5_pad, dvi_d6_pad, dvi_d7_pad, dvi_d8_pad, dvi_d9_pad
  DDR_ADDR_CMD includes xm2_mcas_n_pad, xm2_mras_n_pad, xm2_mwe_n_pad, xm2_mba[2:0]_pad, xm2_ma[14:10]_pad,xm2_odt0_pad, xm2_odt1_pad, xm2_reset_pad
- **DISC_ADDR_CMD** includes xm2_mclk_pad, xm2_mcke0_pad, xm2_mcke1_pad, xm2_mcsc_n_pad, xm2_mcsd_n_pad, xm2_ma[9:0]
- **DDR_DATA** includes xm2_data0_pad, xm2_data1_pad, xm2_data2_pad, xm2_data3_pad, xm2_mckfb0_pad, xm2_mckfb1_pad, xm2_mckfb2_pad, xm2_mckfb3_pad

Entering DPD mode for a single DPD domain has simplified steps of LP0 entry. To set a domain in DPD mode:

- Program the interface to drive the idle state out
- Set the sample register (PMC_DPD_SAMPLE)
- Set the fields corresponding to the DPD domains to 1 in the PMC_IO_DPD_REQ register or the PMC_IO_DPD2_REQ register and CODE to DPD_ON
  - Fields set to 0 indicate no status change
  - IO_DPD_STATUS and IO_DPD2_STATUS are read-only registers that display the status of each rail. The PMC_DPD_SAMPLE register must be reset before the next sample operation.
- Set PMC_SEL_DPD_TIM to the value corresponding to minimum 80 ns (this allows for proper timing sequence between sel_dpd, e_dpd)
- Set the interface to drive the idle state
- Set the fields corresponding to the DPD domains to 1 in the PMC_IO_DPD_REQ register or the PMC_IO_DPD2_REQ register and CODE to DPD_OFF
- Set the tristate field in the miscellaneous register to disable for all pads in the set of affected domains (this will deassert sel_dpd in the mini pad macros). Some bricks do not have mini_pad_macros. For those, this step will be skipped.
  - Fields set to 0 indicate no status change

The following DPD domains do not have mini pad macros or do not drive the state out during deep power down mode:

MIPI_BIAS, PEX_BIAS, PEX_CLK1, PEX_CLK2, COMP, POP_VTTGEN, DISC_VTTGEN, DAC, USB0, USB1, USB2, USB_BIAS, HSIC, HDMI, DDR_ADDR_CMD, DISC_ADDR_CMD, DDR_DATA, POP_CLK.

For the above domains the sequence of entering and leaving DPD mode is simpler:

To set the domain in DPD mode:

- Set the fields corresponding to the DPD domains to 1 in the MC_IO_DPD_REQ register or the MC_IO_DPD2_REQ register and CODE to DPD_ON
  - Fields set to 0 indicate no status change

To reset DPD mode for the DPD domain:

- Set PMC_SEL_DPD_TIM to the value corresponding to minimum 80 ns (this allows for proper timing sequence between sel_dpd, e_dpd)
- Set the fields corresponding to the DPD domains to 1 in the PMC_IO_DPD_REQ register or the PMC_IO_DPD2_REQ register and CODE to DPD_OFF

- Fields set to 0 indicate no status change

Note: In the current architecture only one sample signal exists to perform sampling while entering dpd_mode. This means that all interfaces are sampled at the same time. A sequence of multiple DPD sets requires keeping all interfaces already in DPD mode, and driven as idle. *We can either add a sample bit per interface, or try to modify mini pad macros to prevent sample for pads which are already in DPD mode*.

For regular LP0 mode, all pads enter/exit DPD at the same time.

Note about VI (called PVI): all pads in this group with exception of sdmmc2_vi_sclk_lb, dvi_mclk, dvi_pclk are covered by 2 groups –POP_ADDR_CMD and POP_CLK. So to fully turn off VI, all three groups need to be turned off.

The new registers associated with this feature:

- PMC_IO_DPD_REQ
- PMC_IO_DPD_STATUS
- PMC_IO_DPD2_REQ
- PMC_IO_DPD2_STATUS
- PMC_SEL_DPD_TIM

10.5.10 Clock Control Logic

Tegra 4 devices support enabling an external oscillator to run in Deep Sleep (LP0) mode. It is combined with the ability to output clock (CLK_OUT) which can be extended outside LP0. See the PMC_OSC_EDPD_OVER and PMC_CLK_OUT_CNTRL registers for register descriptions.

There are two functions embedded in this feature:

- Programmable option of keeping the oscillator ON during DPD mode
- For low-cost systems, the ability to output the clock on dap_mclk1, dap_mclk2, clk3_out pins.

Programmable option of keeping oscillator ON during DPD mode

The OSC_CTRL_SELECT bit in the PMC_OSC_EDPD_OVER register configures whether or not the PMC starts controlling the external oscillator. Setting the EN bit to 0 (disabling the oscillator) should only be used during deep power down mode with automatic enabling on leaving LP0 (this is to avoid system lockup). Based on PMC_OSC_EDPD_OVER setup, the external oscillator can be controlled as follows:

- Completely controlled by the CAR, entering deep power down mode on LP0 (shutting down oscillator)
- Controlled by the PMC, entering deep power down mode on LP0
- Controlled by the PMC, not entering deep power down mode, but the oscillator output is disabled (used to accelerate warm boot time)
- Controlled by the PMC, not entering deep power down mode, the oscillator output enabled – used for clock out feature.

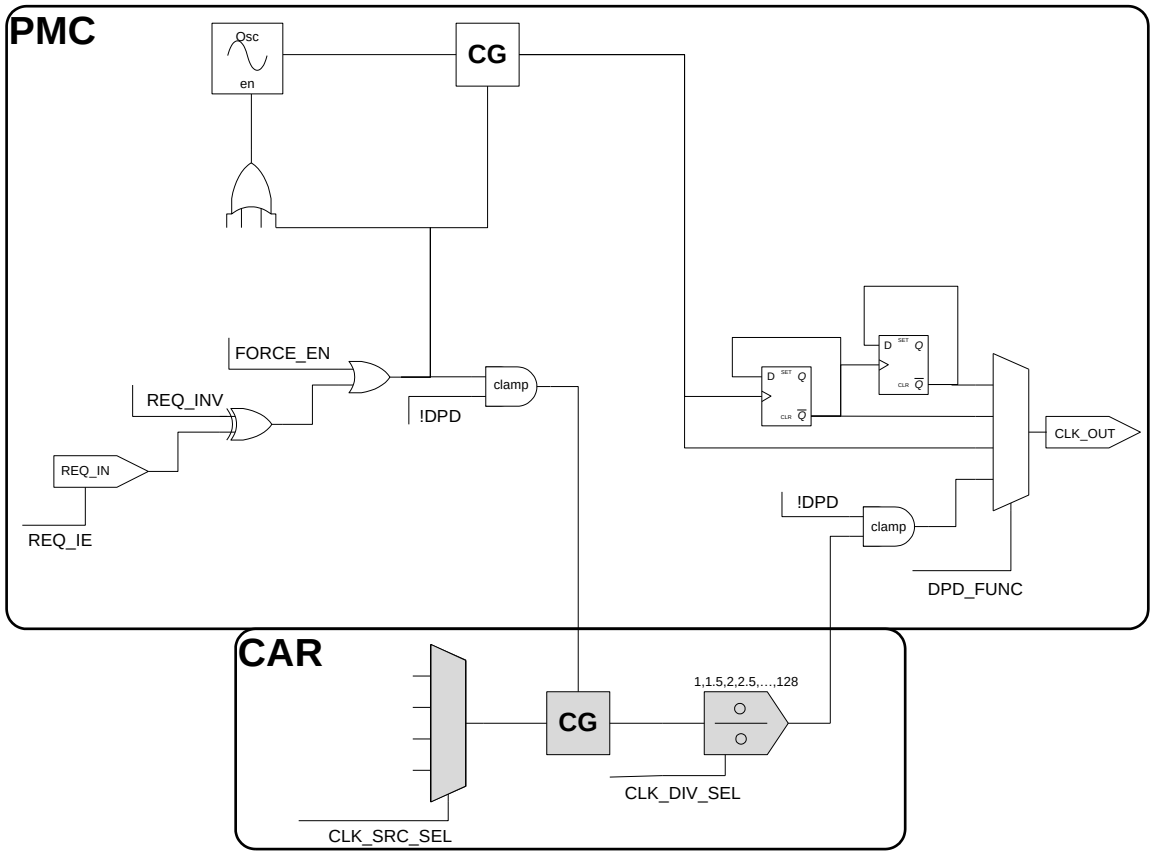
For low-cost systems, ability to output clock on dap_mclk1, dap_mclk2, clk3_out pins

The Clock out function is illustrated below. Three independent request lines (dap_mclk1_req, dap_mclk2_req, clk3_req) are used to assert clock requests on the corresponding clock outputs: dap_mclk1, dap_mclk2, clk3_out. When such a request is decoded, the PMC switches controls on new clock pad_macros to bypass regular pinmux route and output clock instead. There are a variety of options available for decoding the clock request and for the source of the clock output itself.

The request can be decoded as active high, low, or the clock output could be forced out independently of the state of request line. The clock output line, when idle, could be driving out 0, 1, or be tristated. Once the request is accepted, the clock source

could be a CAR output or an oscillator output divided by 1, 2, or 4. The request can be issued outside or in LP0, and the only difference in behavior should be that during LP0 CAR output as clock source is not available.

Figure 32: CLK_OUT Paths



10.5.11 Resets

The PMC receives the primary chip reset (from the SYS_RESET_N_ pad) and generates various resets for itself, the KBC, the RTC, the CAR, etc. From the PMC provided reset, the CAR unit generates resets for most of the units in the chip.

In addition to chip reset, the PMC receives other events (thermal, WDT, SW, LP0 wake), which also result in variants of the system reset.

10.5.12 Clamping

When a partition is power gated OFF, all signals leaving that partition are clamped to their idle value.

Applying clamping presents no problems, because all blocks into the partition are powered OFF and assumed to be in reset prior to the power gate transition.

Removing the clamping is more complex because Tegra 4 devices use a synchronous reset strategy, so the correct sequence is the following:

- Restore power, reset and clamping are both active at that time
- Restore clocks, so that reset conditions propagate
- Remove clamping
- Remove reset

For maximum flexibility, removing the clamping can be controlled by software. Writing to a trigger register removes the clamping for the identified set of partitions. This does not work for Suspend mode exit, where the CPU must be restarted by hardware only.

In Suspend mode exit, there is an interlock between the Clock And Reset (CAR) block and the PMC, so that the correct sequence is performed. The CAR indicates to the PMC when the CPU clamping may be removed. This signal is asserted after the clock to CPU is restarted. The reset to CPU will only be removed after a known delay following the request to remove the clamping. The PMC removes the CPU clamping as soon as it receives the request to do so. This is similar to the interlock between the PMC and flow controller, except that this is not a full handshake.

10.5.13 Scratch Registers

The PMC provides a number of scratch, secure scratch, and bondout registers. The scratch registers are used to save some of the system context information during LP0.

There are 120 PMC scratch registers and 24 secure registers. To save area, secure scratch registers 4-23 and scratch registers 1-119 are implemented in RAM. Due to the requirement of being backward compatible with prior Tegra device's address space, scratch registers do not have continuous address space.

Secure scratch registers are general-purpose read/write registers that can be locked by secure/trusted code. The read/write lock bit is reset by cold and LP0 resets.

10.5.14 Blinking

Tegra 4 devices support a blinking LED whenever the cell phone is not powered OFF, including in Deep Sleep mode. The blinking LED is controlled from the RTC partition.

The PMC contains a counter with two programmable values indicating the On and Off periods (in multiple of 16 cycles of the 32.768 kHz clock). The counter is 16 bits long, for a maximum On or Off period of 2^{16} * 16 / 32.768 10^{3} or about 16 seconds.

10.5.15 Pinmuxing

Some of the signals controlled by the PMC may not be required in certain customer designs, especially:

- The system clock may not support an enable function, so the system clock enable (SYS_CLK_REQ) is not used.
- The system may not require a LED active in Deep Sleep or another device (BB) may drive the LED, so the power LED is not used.

It is important to allow the corresponding balls to be reused for other purposes via pinmuxing. This is not directly a responsibility of the PMC but the correct pinmuxing must be present. The PMC provides a set of ownership registers that control if the RTC logic (PMC or KBC) has control of pins with multiple uses (KBC, PMC, or typically GPIO), some of which are not controlled by the RTC logic. The ownership bit controls a final stage of muxing on top of the more general pinmuxing stage.

As an important special case, the system clock enable is one of the Deep Sleep wake-up event pins. Obviously usage as a wake-up event pin is incompatible with usage as a system clock enable pin.

10.5.16 APB Access

The APB access logic is complicated by the need to not unduly block the bus for extended periods of time even when accessing registers that are logically in the 32 kHz domain. The following principles are used to avoid any delay when accessing registers logically in the 32 kHz domain:

- Write operations always take place in the APB clock domain; i.e., the corresponding registers are placed in the APB clock domain and passed as wires to the 32 kHz domain where they are used without further synchronization. This only works because values passed in this manner are considered essentially static. There is an insignificant

probability that the 32 kHz logic sees an intermediate value of a multiple bit field, but an enumeration of the affected fields shows that this cannot result in any significant problem at the system level.

- Read operations are to shadow registers in the APB clock domain. The shadow registers continuously reflect the values of the equivalent registers found in the 32 kHz clock domain. Only registers reflecting status present in the 32 kHz domain are affected.

10.6 Sensor Reset

The PMC monitors the temperature sensor signal. When the signal becomes active, the PMC resets the whole chip and might also power gate CPU1-3. Both reset and power gating are configurable and can be enabled or disabled. Reset of the whole chip automatically causes CPU1-3 power gating and request for turning down cpu_power.

Power gating is a simplified version of the regular power-gating function. In the first cycle, clamping is enabled. In the next cycle, CPU1-3 are power gated. The above approach simplifies the logic and allows for performing the function before apb_clk is shut down by reset.

The reset status register bit is set to indicate that the thermal sensor event has happened. If the PMC is entering LP0 mode when the temperature sensor triggers, the reset as a direct result of the active sensor will not happen (to avoid destruction of the PMC state). However, the process of entering LP0 causes a reset a few cycles later. CPU1-3 will be shut down in each situation.

10.7 Register Definitions for the PMC

To speed up operation, the PMC register file operates in the local peripheral interface bus domain (APB) rather than in the 32 kHz clock domain used for PMC processing.

Registers in the PMC control entering/exiting Deep Sleep/Suspend mode, power detect, and I/O power functions. They also control CORE_PWR_REQ, SYS_CLK_REQ, and LED_BLINK pins.

The following registers should be programmed/read for different power events in order for PMC to function properly.

IMPORTANT:	**NO_IO_POWER REGISTER (APBDEV_PMC_NO_IOPOWER_0)** This register is used to disable pads that have I/O power turned off. When an I/O power rail is turned off, ramping up, or no longer used and ready to turn off, the corresponding bit in this register should be set to 1. The bit only needs to be turned on when the I/O power rail is stable and you are ready to enable some interface on the I/O power rail. Leaving no_io_power set to 0 **for greater than 500 ms** when the rail is off may reduce the lifetime of the pad. Setting it to 1 when the power rail is on will disable pad from voltage stress.

BEFORE/ON ENTERING DEEP SLEEP MODE

- PMC Control Register (bits PWRREQ_POLARITY, PWRREQ_OE, SYSCLK_POLARITY,SYSCLK_OE, LATCHWAKE_EN)
- WAKE_MASK
- WAKE_LVL
- DPD_PADS_ORIDE (for required overrides)
- PWRGOOD_TIMER
- DPD_SAMPLE
- DPD_ENABLE

AFTER WAKE-UP FROM DEEP SLEEP

- WAKE_STATUS
- SW_WAKE_STATUS
- DPD_ENABLE
- PMC Control Register (bit LATCHWAKE_EN)

BEFORE/ON POWERING DOWN PARTITIONS

- PWRGATE_STATUS
- PWRGATE_TIMER_OFF (for power down)
- PWRGATE_TIMER_ON (for power up). This has been deprecated.
- PWRGATE_TOGGLE
- REMOVE_CLAMPING_CMD (for power up)

FOR POWER DETECT SEQUENCE

- PWR_DET
- PWR_DET_LATCH

FOR BLINK

- BLINK_TIMER
- PMC Control Register (bit BLINK_EN)
- DPD_PADS_ORIDE (for blink field)

All other operations require single register access.

10.8 Register Differences for Tegra 4 Devices

The following list indicates register differences in Tegra 4 devices compared with prior Tegra devices:

- PMC_SWRST function has been removed
- MAIN_RST bit in the PMC control register resets whole chip
- SEC_DISABLE registers now have granularity added per register
- WAKEUP events assignment changed
- PWRGATE_TOGGLE has more partition IDs
- REMOVE_CLAMPING_CMD has more fields due to more power partitions change

- POWER_GATE_STATUS has more fields due to more power partitions change
- NO_IOPWR has more fields due to new power rails
- PWR_DET has more fields due to new power rails
- Increased number of Bondout registers
- Increased number of Scratch registers
- PG_MASK new fields added for new power-gated domains
- PLLP_WB0_OVERRIDE new fields for M and U PLLs

10.9 PMC Registers

Refer to “Reading Register Tables” in the Introduction section for the register table protocol as well as recommendations for accessing registers.

10.9.1 APBDEV_PMC_CNTRL_0

This register controls the clock to the KBC and RTC, and the reset to the CAR, KBC, and RTC. It also manages polarity and output enable of the sys_clk_req and core_pwr_req pins. At reset, both are disabled since the PMIC properties are unknown.

Auxiliary functions include enabling of blinking functions, side-effect option, and software wake-up latching.

The LP0 entry is to be triggered by the PMC side-effect option. Software needs to configure the PMC for the side-effect option before triggering the power off of last CPU. If the side-effect option is set, then the PMC would initiate LP0 in the following cases:

- A power-off request for the CPU rail will lead to CPU rail power-off followed by LP0 entry.
- A power-gating request for cluster1 non-CPU (i.e., C1NC) will lead to power-gating of the C1NC followed by LP0 entry

PMC Control Register

Offset: 0x0 │ Read/Write: R/W │ Reset: 0x00000000 (0bxxxxxxxxxx00000000000000000000)

Bit	Reset	Description
21:20	0x0	CPUPWRGOOD_SEL: CPUPWRGOOD pin select. There are 4 potential source pins (soc_therm_oc{1,2,3,4}) used as PWRGOOD. This field needs to be programmed (at boot) based on which pin is used as PWRGOOD. 0 = SOC_THERM_OC1 (default) 1 = SOC_THERM_OC2 2 = SOC_THERM_OC3 3 = SOC_THERM_OC4
19	0x0	CPUPWRGOOD_EN:CPU_PWR_GOOD (From PMIC to PMC) signal is enabled. 0 = DISABLE 1 = ENABLE
18	0x0	FUSE_OVERRIDE: Fuse override 0 = DISABLE 1 = ENABLE
17	0x0	INTR_POLARITY: Inverts INTR polarity 0 = DISABLE 1 = ENABLE
16	0x0	CPUPWRREQ_OE: Power request output enable. Resets to tri-state 0 = DISABLE 1 = ENABLE

Bit	Reset	Description
15	0x0	CPUPWRREQ_POLARITY: Inverts power request polarity 0 = NORMAL 1 = INVERT
14	0x0	SIDE_EFFECT_LP0: When set, causes the side effect of entering LP0 after powering down the CPU 0 = DISABLE 1 = ENABLE
13	0x0	AOINIT: AO initialized purely software diagnostic and interpretation 0 = NOTDONE 1 = DONE
12	0x0	PWRGATE_DIS: Disable power gating - global override, will override function of PWRGATE_TOGGLE register. All partitions will stay enabled. 0 = DISABLE 1 = ENABLE
11	0x0	SYSCLK_OE: Enables output of system enable clock - works only if the SYS_CLK field in DPD_PADS_ORIDE is set to 1. 0 = DISABLE 1 = ENABLE
10	0x0	SYSCLK_POLARITY: Inverts SYS_CLK_REQ enable polarity 0 = NORMAL 1 = INVERT
9	0x0	PWRREQ_OE: CORE_PWR_REQ output enable. Resets to tristate 0 = DISABLE 1 = ENABLE
8	0x0	PWRREQ_POLARITY: Inverts CORE_PWR_REQ polarity 0 = NORMAL 1 = INVERT
7	0x0	BLINK_EN: Enables blinking counter and blink output works only if the BLINK field in DPD_PADS_ORIDE is set to 1. 0 = DISABLE 1 = ENABLE
6	0x0	GLITCHDET_DIS: Disable detecting glitches on wake-up event. In default operation, glitches are ignored on wakeup lines. if this bit is set to 1, glitch (event shorter than half 32 kHz clock, will be causing wake up from LP0. 0 = DISABLE 1 = ENABLE
5	0x0	LATCHWAKE_EN: Enables latching wakeup events - stops latching on transition from 1 to 0 (sequence - set to 1,set to 0) 0 = DISABLE 1 = ENABLE
4	0x0	MAIN_RST: Resets everything but scratch 0 and reset status. 0 = DISABLE 1 = ENABLE

Bit	Reset	Description
3	0x0	KBC_RST: Software reset to KBC. 0 = DISABLE 1 = ENABLE
2	0x0	RTC_RST: Software reset to RTC. 0 = DISABLE 1 = ENABLE
1	0x0	RTC_CLK_DIS: Disable 32 KHz clock to RTC. 0 = DISABLE 1 = ENABLE
0	0x0	KBC_CLK_DIS: Disable 32 kHz clock to KBC. 0 = DISABLE 1 = ENABLE

10.9.2 APBDEV_PMC_SEC_DISABLE_0

On separate reset (same as CAR), this register disables access (read/write to secure scratch registers). Once writes are disabled, secure registers cannot be written until power on reset or reset when exiting Deep Sleep mode.

Once reads are disabled, reads from scratch registers will return 0 until power on reset or reset when exiting Deep Sleep mode.

Single register can be disabled for reads/writes; bits 0 and 1 have an overwrite function.

Secure Register Disable

Offset: 0x4 │ Read/Write: R/W │ Reset: 0x00000000 (0bxxxxxxxxxx00000000000000000000)

Bit	Reset	Description
21	0x0	TSC_NS_WRITE: Non-secure (i.e., non-TZ) write-disable for the PMC_TSC_MULT register and the PMC_DPD_ENABLE[TSC_MULT_EN] register-bit. 0: Non-secure or secure can write. 1: Only secure can write. This bit is write-once only. Once it is set to '1', it remains '1' until reset by LP0 or system reset. 0 = OFF 1 = ON
20	0x0	AMAP_WRITE: Disable writes to the PMC_GLB_AMAP_CFG register 0 = OFF 1 = ON
19	0x0	READ7: Disable reads from secure register 7 0 = OFF 1 = ON
18	0x0	WRITE7: Disable writes to secure register 7 0 = OFF 1 = ON
17	0x0	READ6: Disable reads from secure register 6 0 = OFF 1 = ON
16	0x0	WRITE6: Disable writes to secure register 6 0 = OFF 1 = ON

Bit	Reset	Description
15	0x0	READ5: Disable reads from secure register 5 0 = OFF 1 = ON
14	0x0	WRITE5: Disable writes to secure register 5 0 = OFF 1 = ON
13	0x0	READ4: Disable reads from secure register 4 0 = OFF 1 = ON
12	0x0	WRITE4: Disable writes to secure register 4 0 = OFF 1 = ON
11	0x0	READ3: Disable reads from secure register 3 0 = OFF 1 = ON
10	0x0	WRITE3: Disable writes to secure register 3 0 = OFF 1 = ON
9	0x0	READ2: Disable reads from secure register 2 0 = OFF 1 = ON
8	0x0	WRITE2: Disable writes to secure register 2 0 = OFF 1 = ON
7	0x0	READ1: Disable reads from secure register 1 0 = OFF 1 = ON
6	0x0	WRITE1: Disable writes to secure register 1 0 = OFF 1 = ON
5	0x0	READ0: Disable reads from secure register 0 0 = OFF 1 = ON
4	0x0	WRITE0: Disable writes to secure register 0 0 = OFF 1 = ON
3:2	0x0	NOT_USED: legacy - redundant - not used
1	0x0	READ: Disable reads from all secure registers 0 = OFF 1 = ON
0	0x0	WRITE: Disable writes to all secure registers 0 = OFF 1 = ON

10.9.3 APBDEV_PMC_PMC_SWRST_0

Reset only by the POR cell; sets itself back to inactive after 2 clock cycles. Only used for emergency debugging purposes; not to be used in any functional mode.

Note: Defunct. Kept only for binary code compatibility only. Will not do anything

Register Write which Resets PMC Only

Offset: 0x8 | Read/Write: R/W | Reset: 0x00000000 (0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx0)

Bit	Reset	Description
0	0x0	RST: Software reset to the PMC only 0 = DISABLE 1 = ENABLE

10.9.4 APBDEV_PMC_WAKE_MASK_0

The APBDEV_PMC_WAKE registers handle wake events whose number is less than or equal to 32. For wave events whose number is greater than 32, refer to the APBDEV_PMC_WAKE2 registers below.

Current pin assignments wake_mask, wake_status, sw_wake_status, and wake levels:

- WAKE_STATUS[0] = ulpi_data4 (wake event 0)
- WAKE_STATUS[1] = gp3_pv[1] (wake event 1)
- WAKE_STATUS[3] = sdmmc3_dat1 (wake event 3)
- WAKE_STATUS[4] = hdmi_int (wake event 4)
- WAKE_STATUS[6] = gp3_pu[5] (wake event 6)
- WAKE_STATUS[7] = gp3_pu[6] (wake event 7)
- WAKE_STATUS[8] = gmi_wp_n (wake event 8)
- WAKE_STATUS[9] = gp3_ps[2] (wake event 9)
- WAKE_STATUS[10] = gmi_ad21 (wake event 10)
- WAKE_STATUS[11] = spi1_cs2_n (wake event 11)
- WAKE_STATUS[12] = spi1_cs1_n (wake event 12)
- WAKE_STATUS[13] = sdmmc1_dat1 (wake event 13)
- WAKE_STATUS[15] = gmi_cs1_n (wake event 15)
- WAKE_STATUS[18] = pwr_int (wake event 18)
- WAKE_STATUS[19] = usb0_vbus (wake event 19)
- WAKE_STATUS[21] = usb0_id (wake event 21)
- WAKE_STATUS[23] = gmi_iordy (wake event 23)
- WAKE_STATUS[24] = gp3_pv[0] (wake event 24)
- WAKE_STATUS[27] = gp3_ps[0] (wake event 27)
- WAKE_STATUS[30] = dap1_dout (wake event 30)

This register masks which event can cause a wake-up from Deep Sleep mode. It has to be set up before entering Deep Sleep mode. It works in conjunction with the WAKE_LVL register.

Only enabled events at the proper wake_lvl will cause exit from Deep Sleep mode.

PMC Wake-up Event Mask

Offset: 0xc │ Read/Write: R/W │ Reset: 0x00000000 (0b00000000000000000000000000000000)

Bit	Reset	Description
31	0x0	RESET_N: External reset wake enable 0 = DISABLE 1 = ENABLE
30:23	0x0	EVENT_RES: 0 = DISABLE 1 = ENABLE
22:19	0x0	USB_EVENT: 0 = ACTIVE_LOW 1 = ACTIVE_HIGH
18	0x0	PWR_INT_N: PWR_INT_N wake enable 0 = DISABLE 1 = ENABLE
17	0x0	KBC: KBC wake enable 0 = DISABLE 1 = ENABLE
16	0x0	RTC: RTC wake enable 0 = DISABLE 1 = ENABLE
15:0	0x0	EVENT: pin 0-15 wake enable 0 = DISABLE 1 = ENABLE

10.9.5 APBDEV_PMC_WAKE_LVL_0

This register sets the active level for the wake event. It will cause an exit from Deep Sleep mode if the input signal level matches the level set in this register and WAKE_MASK is set for the event to 1.

PMC Wake Level

Offset: 0x10 │ Read/Write: R/W │ Reset: 0x7f9fffff (0b01111111100111111111111111111111)

Bit	Reset	Description
31	0x0	RESET_N: External reset wake level (low active) 0 = ACTIVE_LOW 1 = ACTIVE_HIGH
30:23	0xff	EVENT_RES: 0 = ACTIVE_LOW 1 = ACTIVE_HIGH
22:19	0x3	USB_EVENT: 0 = ACTIVE_LOW 1 = ACTIVE_HIGH
18	0x1	PWR_INT_N: Power interrupt - permanently tied to bit 18 0 = ACTIVE_LOW 1 = ACTIVE_HIGH

Bit	Reset	Description
17	0x1	KBC: KBC wake level 0 = ACTIVE_LOW 1 = ACTIVE_HIGH
16	0x1	RTC: RTC wake level 0 = ACTIVE_LOW 1 = ACTIVE_HIGH
15:0	0xffff	EVENT: Pin 0-15 wake level 0 = ACTIVE_LOW 1 = ACTIVE_HIGH

10.9.6 APBDEV_PMC_WAKE_STATUS_0

This register stores the status of the wake events. The event will be set if the level matches and is not masked.

A write will reset the set wake event.

PMC Wake Status

Offset: 0x14 │ Read/Write: R/W │ Reset: 0x00000000 (0b00000000000000000000000000000000)

Bit	Reset	Description
31	0x0	RESET_N: external reset 0 = NOT_SET 1 = SET
30:23	0x0	EVENT_RES: 0 = NOT_SET 1 = SET
22:19	0x0	USB_EVENT: USB wake events 0 = NOT_SET 1 = SET
18	0x0	PWR_INT_N: power interrupt 0 = NOT_SET 1 = SET
17	0x0	KBC: KBC wake 0 = NOT_SET 1 = SET
16	0x0	RTC: RTC wake 0 = NOT_SET 1 = SET
15:0	0x0	EVENT: pin 0-15 wake 0 = NOT_SET 1 = SET

10.9.7 APBDEV_PMC_SW_WAKE_STATUS_0

This register stores status of the wake events. Latching of the events in software wake status is enabled by the PMC_CNTRL register bit LATCHWAKE_EN.

Latching will stop at a 1-to-0 transition on this bit. An event will be set if the level matches. Masking does not affect this register. A write will reset the set wake events.

PMC Software Wake Status

Offset: 0x18 │ Read/Write: R/W │ Reset: 0x00000000 (0b00000000000000000000000000000000)

Bit	Reset	Description
31	0x0	RESET_N: External reset 0 = NOT_SET 1 = SET
30:23	0x0	EVENT_RES: 0 = NOT_SET 1 = SET
22:19	0x0	USB_EVENT: USB wake events 0 = NOT_SET 1 = SET
18	0x0	PWR_INT: Power interrupt 0 = NOT_SET 1 = SET
17	0x0	KBC: KBC wake 0 = DISABLE 1 = ENABLE
16	0x0	RTC: RTC wake 0 = DISABLE 1 = ENABLE
15:0	0x0	EVENT: Pin 0-15 wake 0 = DISABLE 1 = ENABLE

10.9.8 APBDEV_PMC_DPD_PADS_ORIDE_0

This register enables overriding values from pinmux with values driven by the KBC (keyboard) or PMC (sys_clk_req, blink).

If a bit is set to 1, the associated I/O will drive the direct value from the KBC or PMC, not the pinmux value. During Deep Sleep mode, the pads with the bit set to 1 will not be in Deep Power Down mode. It will not drive data from mini pad macros stored during sample cycle, but direct data from the KBC or PMC.

Note: This register has to be set before entering Deep Sleep mode. The meaning of fields is no longer significant.

DPD Pads Override

Offset: 0x1c │ Read/Write: R/W │ Reset: 0x00200000 (0bxxxxxx00001000000000000000000000)

Bit	Reset	Description
25	0x0	KBC_ROW10: Override DPD idle state of the gp3_pq[7] pad 0 = DISABLE 1 = ENABLE

Bit	Reset	Description
24	0x0	KBC_ROW9: Override DPD idle state of the gp3_pq[6] pad 0 = DISABLE 1 = ENABLE
23	0x0	KBC_ROW8: Override DPD idle state of the gp3_pq[5] pad 0 = DISABLE 1 = ENABLE
22	0x0	KBC_ROW7: Override DPD idle state of the gp3_pq[4] pad 0 = DISABLE 1 = ENABLE
21	0x1	SYS_CLK_REQ: Override DPD idle state with column with SYS_CLK_REQ output 0 = DISABLE 1 = ENABLE
20	0x0	BLINK: Override DPD idle state with blink output 0 = DISABLE 1 = ENABLE
19	0x0	KBC_ROW6: 0 = DISABLE 1 = ENABLE
18	0x0	KBC_ROW5: 0 = DISABLE 1 = ENABLE
17	0x0	KBC_ROW4: 0 = DISABLE 1 = ENABLE
16	0x0	KBC_ROW3: 0 = DISABLE 1 = ENABLE
15	0x0	KBC_ROW2: 0 = DISABLE 1 = ENABLE
14	0x0	KBC_ROW1: Override DPD idle state of the gp3_pq[3] pad 0 = DISABLE 1 = ENABLE
13	0x0	KBC_ROW0: Override DPD idle state of the gp3_pq[2] pad 0 = DISABLE 1 = ENABLE
12	0x0	KBC_COL12: Override DPD idle state of the gp3_pq[1] pad 0 = DISABLE 1 = ENABLE
11	0x0	KBC_COL11: Override DPD idle state of the gp3_pq[0] pad 0 = DISABLE 1 = ENABLE
10	0x0	KBC_COL10: Override DPD idle state of the gp3_ps[2] pad 0 = DISABLE 1 = ENABLE

Bit	Reset	Description
9	0x0	KBC_COL9: Override DPD idle state of the gp3_ps[1] pad 0 = DISABLE 1 = ENABLE
8	0x0	KBC_COL8: Override DPD idle state of the gp3_ps[0] pad 0 = DISABLE 1 = ENABLE
7	0x0	KBC_COL7: Override DPD idle state of the gp3_pr[7] pad 0 = DISABLE 1 = ENABLE
6	0x0	KBC_COL6: Override DPD idle state of the gp3_pr[6] pad 0 = DISABLE 1 = ENABLE
5	0x0	KBC_COL5: Override DPD idle state of the gp3_pr[5] pad 0 = DISABLE 1 = ENABLE
4	0x0	KBC_COL4: Override DPD idle state of the gp3_pr[4] pad 0 = DISABLE 1 = ENABLE
3	0x0	KBC_COL3: Override DPD idle state of the gp3_pr[3] pad 0 = DISABLE 1 = ENABLE
2	0x0	KBC_COL2: Override DPD idle state of the gp3_pr[2] pad 0 = DISABLE 1 = ENABLE
1	0x0	KBC_COL1: Override DPD idle state of the gp3_pr[1] pad 0 = DISABLE 1 = ENABLE
0	0x0	KBC_COL0: Override DPD idle state of the gp3_pr[0] pad 0 = DISABLE 1 = ENABLE

10.9.9 APBDEV_PMC_DPD_SAMPLE_0

Setting this register will trigger sampling pads data and direction in which the pad will be driven during Deep Sleep mode.

Before writing to this register, all interfaces going to pads must be set to the ideal "idle" mode, which is expected to be driven by pads when the Tegra 4 chip enters Deep Sleep.

DPS Power Down Sample has to precede Deep Power Down Enable write. The DPD sample should not be deasserted until the transition from Deep Sleep to WB0.

The DPD sample feature works only for GPIO (MPIO) pads, not for brick pads.

Deep Power Down Sample

Offset: 0x20 | Read/Write: R/W | Reset: 0x00000000 (0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx0)

Bit	Reset	Description
0	0x0	ON: Sets the sampling of pads value 0 = DISABLE 1 = ENABLE

10.9.10 APBDEV_PMC_DPD_ENABLE_0

Setting this register will trigger entering Deep Sleep state. It must be preceded by a DPD_SAMPLE write.

Will cause request for shutting down the system clock and the core req power. Puts the PLLs and I/Os in Deep Power Down mode. Will cut off (clamp) all signals going from core power to AO and pads.

If none of the wake-up events is set, only power-on reset can re-enable access to the chip.

After servicing of the wake-up event is completed, the register should be set back to 0 to complete a Deep Sleep cycle.

Deep Power Down Enable

Offset: 0x24 | Read/Write: R/W | Reset: 0x00000000 (0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx00)

Bit	Reset	Description
1	0x0	TSC_MULT_EN: TSC multiplier enable. 0: DISABLE (i.e., counter runs at oscillator clock and increments by 1 every clock cycle). 1: ENABLE (i.e., counter runs at 32 kHz and increments by TSC_MULT_VALUE every clock cycle). 0 = DISABLE 1 = ENABLE
0	0x0	ON: Sets sampling of pads value 0 = DISABLE 1 = ENABLE

10.9.11 APBDEV_PMC_PWRGATE_TIMER_OFF_0

Specifies the number of APB cycles after which the rail line goes off (turns the power to part of power-gated partition). Each rail controls part of the powered partition. This register should be set before the write to Power Gate Toggle. Shared between all power partitions.

Power Gate Timer Off Register

Offset: 0x28 | Read/Write: R/W | Reset: 0xeca97531 (0b11101100101010010111010100110001)

Bit	Reset	Description
31:28	0xe	RAIL7: Timer value for rail 7
27:24	0xc	RAIL6: Timer value for rail 6
23:20	0xa	RAIL5: Timer value for rail 5
19:16	0x9	RAIL4: Timer value for rail 4

0	X	CRAIL: clamp status of CPU Rail 0 = DISABLE 1 = ENABLE

10.9.13 APBDEV_PMC_PWRGATE_TOGGLE_0

Write to this register will turn power on/off to the specified power-gated partition. Only one partition is turned on/off at a time.

PWRGATE_STATUS should be read to determine the state of the partition before writing to this register.

Turning the partition off will cause automatic clamping of all signals generated by the power-gated partition being turned off. Before the partition is turned off, all clocks to the partition should be stopped, and the reset to the partition should be asserted.

Turning the partition on will not remove clamping. Clamping is removed only after a REMOVE_CLAMPING_CMD write.

The user must allow a minimum 20 APB clock cycles between consecutive partition Power-Gate Toggle requests.

The role of the START bit has changed from prior Tegra devices. The START bit is cleared by hardware when the PMC accepts the request to power-gate or unpower-gate the partition. So in order to power-gate/unpower-gate a partition, software needs to do the following:

- Check to see if the partition is already in the correct state, by looking at the PWRGATE_STATUS register.
- If the partition is not in the correct state, software reads the PWRGATE_TOGGLE register to see if the START bit is 0.
- If the START bit is not 0, software polls until the start bit is set to 0.
- Then program the PWRGATE_TOGGLE register with the START bit set to 1 and choose the required partition to be power-gated.
- Ideally, software can poll to check the START bit going back to 0, which indicates that the PMC has accepted the request, and then poll the STATUS register to make sure the required partition is power-gated/unpower-gated.

Power Gate Toggle

Offset: 0x30 │ Read/Write: R/W │ Reset: 0x00000000 (0bxxxxxxxxxxxxxxxxxxxxxxxx0xxx00000)

Bit	Reset	Description
8	0x0	START: Start power down/up 0 = DISABLE 1 = ENABLE

Bit	Reset	Description

10.9.14 APBDEV_PMC_REMOVE_CLAMPING_CMD_0

This is a bitmap with one bit per power partition controller by the PMC.

When written to 1b, the PMC removes the clamp signals to the corresponding partition. If the partition is not powered on, the register write will be ignored.

The bit is automatically reset to 0b when the clamping has been removed. Software is responsible for writing to this register at the correct time, that is, when the clocks are started but the blocks in that partition are still held in reset.

Remove Clamping

Offset: 0x34 │ Read/Write: R/W │ Reset: 0x00000000 (0bxxxxxxxxx00000x000x0000x000x0000)

1	X	TD: Status of TD partition 0 = OFF 1 = ON
0	X	CRAIL: Status of CPU Rail 0 = OFF 1 = ON

10.9.16 APBDEV_PMC_PWRGOOD_TIMER_0

This register programs the length of the wake-up reset, asserted after wake-up from Deep Sleep. This register should be set before entering Deep Sleep mode.

Programmed values depend on the properties of the PMIC.

Timer value x 30.51 µs = reset pulse length

Power Good Timer

Offset: 0x3c │ Read/Write: R/W │ Reset: 0x0000007f (0bxxxxxxxxxxxxxxxx0000000001111111)

Bit	Reset	Description
15:8	0x0	DATA: Crystal (Xtal) timer * 32
7:0	0x7f	PMU_TIM: PMIC timer * 32

10.9.17 APBDEV_PMC_BLINK_TIMER_0

Will output value to pad only if the PMC Control register has BLINK_EN set and DPD_PADS_ORIDE has blink bit set.

Setting bit 15 to 1 will output 32 kHz clock (the registers above still have to be set)

- On time DATA_ON << 2 x 30.51 µs
- Off time DATA_OFF << 2 x 30.51 µs.

Blinker Timer for External Blinker

Offset: 0x40 │ Read/Write: R/W │ Reset: 0xffffffff (0b11111111111111111111111111111111)

Bit	Reset	Description
31:16	0xffff	DATA_OFF: Time off
15	0x1	FORCE_BLINK: if 0 32 kHz clock
14:0	0x7fff	DATA_ON: Time on

10.9.18 APBDEV_PMC_NO_IOPOWER_0

This register controls the power rails for each I/O level. It can only be set when a specific power rail is off. Setting it otherwise will damage the pad.

No I/O Power Register

Offset: 0x44 │ Read/Write: R/W │ Reset: 0x00000000 (0bxxxxxxxxxxxxxxxx00000x00x0x000000)

Bit	Reset	Description
16	0x0	MEM_COMP:MEM0 ADDR1 (comp cell I/Os) 0 = DISABLE 1 = ENABLE

Bit	Reset	Description
0	0x0	SYS: rail AO I/Os 0 = DISABLE 1 = ENABLE

10.9.19 APBDEV_PMC_PWR_DET_0

Active high, sets power detection for nine power rails only. - MIPI does not have power detect.

The proper sequence for turning on power detects:

- Write 1 to PWR_DET register for fields requiring power detect
- Allow for 3 µs delay (in APB clock cycles)
- Write 1 to PWR_DET_LATCH

For turning PWR_DET off:

- Write 0 to PWR_DET_LATCH
- No delay is necessary
- Write 0 to PWR_DET

Power Detect

Offset: 0x48 │ Read/Write: R/W │ Reset: 0x0000b42f (0bxxxxxxxxxxxxxxxx1x11x1xxxx1x1111)

Bit	Reset	Description

10.9.59 APBDEV_PMC_DDR_PWR_0

This register is used to program the "E_18V" pin of the DDR pads.

Offset: 0xe8 │ Read/Write: R/W │ Reset: 0x00000003 (0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx11)

Bit	Reset	Description
1	0x1	EMMC: GMI pins 0 = E_12V 1 = E_18V
0	0x1	VAL: DVI pins 0 = E_12V 1 = E_18V

10.9.60 APBDEV_PMC_USB_DEBOUNCE_DEL_0

Determines number of 32 kHz clock cycles to debounce USB signal events.

Note: The programmed debounce values must be greater than 1.

Reset values are for Cold Hardware Reset only.

Offset: 0xec │ Read/Write: R/W │ Reset: 0x00000000 (0bxxxxxxxx00000000000000000000000)

Bit	Reset	Description
23:20	0x0	UHSIC_LINE_DEB_CNT: Number of 32 kHz debounce cycles for UHSIC port 0
19:16	0x0	UTMIP_LINE_DEB_CNT: Number of 32 kHz debounce cycles for UTMIP port 0
15:0	0x0	VAL: Debounce period for ID and VBUS events on all USB ports

10.9.61 APBDEV_PMC_USB_AO_0

Power downs for various USB features controlled by the PMC.

Each UTMIP has the following power downs for features that can lead to wake-up events.

- USBOP_VAL_PD: Power down for D+ value detector (I/O pad)
- USBON_VAL_PD: Power down for D- value detector (I/O pad)
- ID_PD: Power down for ID detector (bias pad)
- VBUS_WAKEUP_PD: Power down for VBUS detector (bias pad)

Each UHSIC port has the following power downs for features that can lead to wake-up events:

- STROBE_VAL_PD: Power down for STROBE VALUE detector
- DATA_VAL_PD: Power down for DATA VALUE detector

Note: These HSIC pins have not been added to the pad yet.

Line Debounce Periods for UTMIP and HSIC PORTS

Offset: 0xf0 | Read/Write: R/W | Reset: 0x000fffff (0bxxxxxxxxxxxx11111111111111111111)

Bit	Reset	Description
19:18	0x3	UHSIC_RESERVED_P1: 2 bits reserved for UHSIC P1
17	0x1	DATA_VAL_PD_P1: Power Down D- DATA_VAL receiver for UHSIC P1
16	0x1	STROBE_VAL_PD_P1: Power Down D+ STROBE_VAL receiver for UHSIC P1
15:14	0x3	UHSIC_RESERVED_P0: 2 bits reserved for UHSIC P1
13	0x1	DATA_VAL_PD_P0: Power Down D- DATA_VAL receiver for UHSIC P0

2	0x1	VBUS_WAKEUP_PD_P0: Power Down Vbus Wake Up for UTMIP P0
1	0x1	USBON_VAL_PD_P0: Power Down D- USBOP_VAL receiver for UTMIP P0
0	0x1	USBOP_VAL_PD_P0: Power Down D+ USBOP_VAL receiver for UTMIP P0

10.9.62 APBDEV_PMC_CRYPTO_OP_0

A complete solution requires a "semi-sticky" bit in the always-on domain. The Boot ROM would clear this semi-sticky bit for cold boots, but use its value to propagate the crypto-disable flag across LP0. (The Boot ROM always requires crypto functionality, so a pure hardware solution probably isn't reasonable.)

The Boot ROM would be able to clear (to zero) and read the sticky bit, but outside the Boot ROM users would only be able to set (to one) and read the sticky bit. On cold boot, the Boot ROM would always clear the stick bit. On WB0, the Boot ROM would read the sticky bit and copy it's setting to the crypto disable flag.

Crypto Engine Disable Sticky Bit

Offset: 0xf4 | Read/Write: R/W | Reset: 0x00000001 (0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx1)

Bit	Reset	Description
0	0x1	VAL: Disabled by default 0 = ENABLE 1 = DISABLE

10.9.63 APBDEV_PMC_PLLP_WB0_OVERRIDE_0

Master control for all WB0 PLL overrides.

Offset: 0xf8 │ Read/Write: R/W │ Reset: 0x00000000 (0bxxxxxxxxxxxxxxxxxxxx0000000000000)

Bit	Reset	Description
12	0x0	PLLM_ENABLE: 1 = enable PLLM, 0 = disable PLLM
11	0x0	PLLM_OVERRIDE_ENABLE: 1 = override CAR PLLM setting, 0 = no override. PLLM WB to programmable frequency.
10	0x0	PLLU_ENABLE: 1 = enable PLLU, 0 = disable PLLU.
9	0x0	PLLU_OVERRIDE_ENABLE: 1 = override CAR PLLU setting, 0 = no override. PLLU WB to fixed frequency
8	0x0	OSC_OVERRIDE_ENABLE: 1 = override CAR OSC setting, 0 = no override. Controls OSC_FREQ and PLL_REF_DIV
7:6	0x0	PLL_REF_DIV: PLL reference clock divide for all PLLs. 00 = /1, 01 = /2, 10 = /4, 11 = reserve.
5:2	0x0	OSC_FREQ: Oscillator frequency for shared PLL reference 0000 = 13MHz, 0100 = 19.2MHz, 1000 = 12MHz, 1100 = 26MHz. 0001 = 16.8MHz, 0101 = 38.4MHz*, 1001 = 48.0MHz
1	0x0	PLLP_ENABLE: 1 = enable PLLP, 0 = disable PLLP
0	0x0	PLLP_OVERRIDE_ENABLE: 1 = override CAR PLLP setting, 0 = no override. PLLP WB to fixed frequency.

10.9.87 APBDEV_PMC_BONDOUT_MIRROR_ACCESS_0

On separate reset (same as the CAR) disables access (read/write to secure scratch registers)

Offset: 0x158 | Read/Write: R/W | Reset: 0x00000000 (0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx00)

Bit	Reset	Description
1	0x0	BREAD: disable read from bondout secure registers 0 = OFF 1 = ON
0	0x0	BWRITE: disable write to bondout secure registers 0 = OFF 1 = ON

10.9.88 APBDEV_PMC_GATE_0

This register is used for software controlled synchronization between APB domain and the 32 kHz domain. Software is expected to set the GAKE_WAKE/GATE_DBNS field high to cut the 32 kHz gated clock before updating WAKE_LVL, AUTO_WAKE_LVL, WAKE_MASK and USB_DEBOUNCE_DEL registers. After these registers have been written the GATE_WAKE/GATE_DBNS bit should be written back to '0' to enable the 32 kHz gated clock.

This gates the 32 kHz clock to just the flops that store the above fields.

Offset: 0x15c | Read/Write: R/W | Reset: 0x00000000 (0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx0)

Bit	Reset	Description
0	0x0	GATE_WAKE: 0 = OFF 1 = ON
0	0x0	GATE_DBNS: 0 = OFF 1 = ON

10.9.89 APBDEV_PMC_WAKE2_MASK_0

Auto-wake is not present for wake2 events in Tegra 4 devices.

The APBDEV_PMC_WAKE2 registers handle wake events whose number exceeds 32. For wave events whose number is less than or equal to 32, refer to the APBDEV_PMC_WAKE registers above.

Wake2 alignments for masks, level, and status:

- WAKE2_*[0] = ulpi_data3 (wake event 32)
- WAKE2_*[1] = gmi_cs0_n (wake event 33)
- WAKE2_*[2] = gmi_cs4_n (wake event 34)
- WAKE2_*[3] = gmi_cs7_n (wake event 35)
- WAKE2_*[12]= i2c1_sda (wake event 44)
- WAKE2_*[13]= gpio_pbb6 (wake event 45)
- WAKE2_*[14]= pwr_i2c_sda (wake event 46)
- WAKE2_*[15]= gp3_pt[6] (wake event 47)
- WAKE2_*[16]= cam_i2c_sda (wake event 48)
- WAKE2_*[17]= gp3_pr[7] (wake event 49)
- WAKE2_*[18]= gp3_pr[4] (wake event 50)
- WAKE2_*[19]= gp3_pq[0] (wake event 51)
- WAKE2_*[20]= cec (wake event 52)
- WAKE2_*[21]= cam_i2c_scl (wake event 53)
- WAKE2_*[22]= gp3_pq[5] (wake event 54)
- WAKE2_*[23]= uc3_cts (wake event 55)
- WAKE2_*[24]= gp3_pv[2] (wake event 56)
- WAKE2_*[25]= spdif_in (wake event 57)
- WAKE2_*[26] = wake2pmc_xusb_system_wakeup (wake event 58)

Offset: 0x160 │ Read/Write: R/W │ Reset: 0x00000000 (0bxxxxx00000000000000000000000000)

Bit	Reset	Description
26:12	0x0	EVENT_REST_1: 0 = DISABLE 1 = ENABLE
11:7	0x0	EVENT_REST: 0 = DISABLE 1 = ENABLE
6:5	0x0	USB_EVENT: 0 = ACTIVE_LOW 1 = ACTIVE_HIGH
4:0	0x0	EVENT: 0 = DISABLE 1 = ENABLE

10.9.90 APBDEV_PMC_WAKE2_LVL_0

This register sets the active level for a wake event. It causes an exit from the Deep Sleep state if the input signal level matches the level set in this register and if WAKE2_MASK is set for the event to 1. A level is not needed for 4 line wakeup events; the level is always 1.

PMC Wake Level

Offset: 0x164 │ Read/Write: R/W │ Reset: 0x01ffffe7 (0b00000001111111111111111111100111)

Bit	Reset	Description
31	0x0	ALLOW_PULSE_WAKE: Allows pulse wakes in case the USB wants to wake on pulse; otherwise it is a level wake (the signal must last longer than 1 ms)
30:27	0x0	FUTURE_CNTL: Reserved
26:12	0x1fff	EVENT_REST_1: 0 = ACTIVE_LOW 1 = ACTIVE_HIGH
11:7	0x1f	EVENT_REST: 0 = ACTIVE_LOW 1 = ACTIVE_HIGH
6:5	0x3	USB_EVENT: 0 = ACTIVE_LOW 1 = ACTIVE_HIGH
4:0	0x7	EVENT: Pin 0-2 wake level 0 = ACTIVE_LOW 1 = ACTIVE_HIGH

10.9.91 APBDEV_PMC_WAKE2_STATUS_0

This register stores status of the wake events. An event is set if the level matches and is not masked.

Writes will reset the set wake event.

PMC Wake Status

Offset: 0x168 │ Read/Write: R/W │ Reset: 0x00000000 (0bxxxxx00000000000000000000000000)

Bit	Reset	Description
26:12	0x0	EVENT_REST_1: 0 = NOT_SET 1 = SET
11:7	0x0	EVENT_REST: Internally set USB events 0 = NOT_SET 1 = SET
6:5	0x0	USB_EVENT: USB wake events 0 = NOT_SET 1 = SET
4:0	0x0	EVENT: Pin 0-2 wake enable 0 = NOT_SET 1 = SET

10.9.92 APBDEV_PMC_SW_WAKE2_STATUS_0

This register stores the status of the wake events. Latching of the events in software wake status is enabled by the PMC_CNTRL register bit LATCHWAKE_EN. Latching will stop at a 1-to-0 transition on this bit.

An event is set if the level matches. Masking does not affect this register. Writes will reset the set wake events.

PMC Software Wake Status

Offset: 0x16c │ Read/Write: R/W │ Reset: 0x00000000 (0bxxxxx00000000000000000000000000)

Defunct

Offset: 0x1a0 | Read/Write: R/W | Reset: 0x00000000 (0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx0)

Bit	Reset	Description
0	0x0	EN: when set to 1, sets the EDPD to PCX (PLL toggle) 0 = OFF 1 = ON

10.9.106 APBDEV_PMC_OSC_EDPD_OVER_0

This register can be programmed to keep the oscillator ON during LP0 mode. It cuts the latency time on LP0 wake if the oscillator pad does not have to be restarted.

When the oscillator pad is on, during LP0 mode, DSPARE, duty, strength, and bypass are controlled by the fields below.

The oscillator can be in one in four modes during LP0 - in DPD, not in DPD but not enabled, running, or running only when an external request is active.

Offset: 0x1a4 | Read/Write: R/W | Reset: 0x0000007e (0bxxxxxxxxxx00000000000000001111110)

Bit	Reset	Description
22	0x0	OSC_CTRL_SELECT: select whether the CAR's OSC_CTRL or the PMC's OSC_CTRL_OVER affects the oscillator cell . 0 = CAR 1 = PMC
21:20	0x0	XO_LP0_MODE: control the behavior of the oscillator during LP0 (assuming OSC_CTRL_SELECT is set to PMC during LP0). Put the oscillator in DPD mode during LP0, bypass DPD, but do not enable the oscillator during LP0, force the oscillator to run during LP0, or run the oscillator when requested by an external clock request pin 0 = DPD. 1 = OFF 2 = ON 3 = EXT_REQ
19:12	0x0	OSCFI_SPARE: Crystal oscillator spare register control.
11:7	0x0	XODS: Crystal oscillator duty cycle control.
6:1	0x3f	XOFS: Crystal oscillator drive strength control.
0	0x0	XOBP: Crystal oscillator bypass enable (1 = enable bypass).

10.9.107 APBDEV_PMC_CLK_OUT_CNTRL_0

This register controls 3 clock outputs of the Tegra 4 chip. Each of the clock outputs can be in 1 of 4 modes: not running, running when request is active high, running when request is active low, or always running. The clock output when not running can be tristated, high, or low.

The clock source might be from the CAR unit (not available when in LP0 mode), osc, osc_div2, osc_div4.

10.9.109 APBDEV_PMC_SENSOR_CTRL_0

For sensor shutdown and control.

The sensor control register defines chip behavior when a sensor request is triggered. It can power-gate down all CPUs if enabled. It can trigger a reset (will cause a CPU power request to go down and power-gates down all CPUs)

IMPORTANT-- to preserve RAM content, any reads/writes to scratch registers will be blocked after a sensor triggered reset.

Software must reset BLOCK_SCRATCH_WRITE to enable writes to scratch registers.

Offset: 0x1b0 │ Read/Write: R/W │ Reset: 0x00000000 (0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx000)

Bit	Reset	Description
2	0x0	BLOCK_SCRATCH_WRITE: Reset by user, set by the PMC when entering sensor reset 0 = OFF 1 = ON
1	0x0	ENABLE_RST: Enables reset on sensor going up. 0 = OFF 1 = ON

Bit	Reset	Description
2:0	0x0	RST_SOURCE: Source of reset 0 = POR

Bit	Reset	Description
		1 = WATCHDOG 2 = SENSOR 3 = SW_MAIN 4 = LP0

10.9.111 APBDEV_PMC_IO_DPD_REQ_0

Puts I/O rails in or out of DPD mode, even though the chip is not in LP0. Multiple bits are allowed to be set at the same time. No new operation will be triggered until previous one completes. Consecutive operations issued by completion time of first one will be dropped. The register is still updated.

Setting IO_DPD_REQ should be preceded by writing to the DPD_SAMPLE registers (to enable a snapshot of data to be driven) and the SEL_DPD_TIM register. SEL_DPD_TIM is set to a safe value, but it can be lowered if SYS clock is slower (a minimum of 200 ns is required).

DPD Request

Offset: 0x1b8 │ Read/Write: R/W │ Reset: 0x00000000 (0b0000000000000x0000000x0xxxxx0000)

0	0x0	SET_DSIA: 0 = OFF 1 = ON

10.9.123 APBDEV_PMC_UTMIP_UHSIC_TRIGGERS_0

PMC trigger events for the UTMIP ports as well as the UHSIC port. Sleep walk clearing returns the walk pointer to 00, the first entry in a USB line walk. This is the only way to return a pointer to 0.

Pad configuration captures a set of FLLS parameters prior to resting the port so their value can be retained in deep sleep.

The trigger should only happen on the fields that are set to TRIG (1) when writing. The returned read value should always be all NULL fields.

The FORCE_WALK bits trigger a SLEEP.

Any value read back should be 0.

Triggers for USB Ports

Offset: 0x1ec │ Read/Write: R/W │ Reset: 0x0000XXXX (0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx)

10.9.126 APBDEV_PMC_UTMIP_TERM_PAD_CFG_0

Set of termination configuration values for USB I/O pads under DPD mode. These configuration values are programmed, not captured, at a time prior to entering DPD. Capturing them would be complex because it would require costly synchronizers as well as some logic. The range for RCTRL and TCTRL is 0 to 16.

These values need to be converted to a thermal encoding (only one 0 to 1 transition allowed in the word from MSB to LSB). For example:

0 - 0000_0000_0000_0000

1 - 0000_0000_0000_0001

2 - 0000_0000_0000_0011

...

15 - 0111_1111_1111_1111

16 - 1111_1111_1111_1111

I/O Termination Configuration for all UTMIP Ports

Offset: 0x1f8 │ Read/Write: R/W │ Reset: 0x00000108 (0bxxxxxxxxxxxxxxxxxxxxxxxx0100001000)

Bit	Reset	Description
9:5	0x8	TCTRL_VAL: HS termination calibration value, range 0 to 16
4:0	0x8	RCTRL_VAL: 1.5kOhm pull up calibration value, range 0 to 16

10.9.127 APBDEV_PMC_UTMIP_UHSIC_SLEEP_CFG_0

Register that configures the value of the line that could cause a wake-up event.

- ANY -- signifies any line change DM EDGE or DP EDGE for UTMIP.
- NONE -- signifies no wakeup possible.

One can use the two most significant bits (3:2) of the WAKE_VAL to 4x1 select whether:

- 00: Check both bits for value on two LSB (1:0).
- 01: Check bit DM (or strobe for HSIC) against bit 0

- 10: Check bit DP (or DATA for HSIC) against bit 1
- 11: Check for edge on DP against bit 1, edge on DM against bit 0

10.9.128 APBDEV_PMC_UTMIP_UHSIC_SLEEPWALK_CFG_0

This register determines when sleep walking should take effect: upon a specific GPIO event, on any wake event, or on a line value change.

It is also possible to force a sleep walk; see register UTMIP_UHSIC_TRIGGERS to force the event.

Sleep Walk Sequence Enables

Offset: 0x200 │ Read/Write: R/W │ Reset: 0x00000000 (0b00000000000000000000000000000000)

10.9.129 APBDEV_PMC_UTMIP_SLEEPWALK_P0_0

These registers hold the sequence of control values to the UTMIP pads on the four consecutive cycles of a walk. The pad pins that are controlled are:

- MASTER_USBOP_RPD
- MASTER_USBON_RPD
- MASTER_USBOP_RPU
- MASTER_USBON_RPU
- MASTER_AP
- MASTER_AN
- MASTER_HIGHZ

For the walk to take effect at the pad, the MASTER_ENABLE pin must be set high in the config register. Otherwise the pad will ignore the values.

If no walk is enabled or forced, then the walk pointer remains stuck on phase A. The walk pointer should use a 2 bit Gray code so that Phase A is 00, Phase B is 01, Phase C is 11 and Phase D is 10. Once Phase D is reached, only a reset of the phase pointer can bring it back to Phase A.

Four phases should be sufficient to handle most wake-up events.

10.9.132 APBDEV_PMC_UHSIC_SLEEPWALK_P0_0

These registers hold the sequence of control values to the UTMIP pads on the four consecutive cycles of a walk. The pad pins that are controlled are:

- STROBE_RPD
- DATA_RPD
- STROBE_RPU
- DATA_RPU

At this time there are no STROBE, DATA ports that should be driven by the host. So these outputs from the module should be left unconnected until a time that departure may be implemented.

Signaling Sequence for UHSIC Port 0 Wakeup

Offset: 0x278 │ Read/Write: R/W │ Reset: 0x0000000f (0bxxxxxxxxxxxxxxxxxxxxxxxxxxxx1111)

Bit	Reset	Description
3:0	0xf	DATA: timing between consecutive partitions

10.9.159 APBDEV_PMC_UTMIP_UHSIC2_TRIGGERS_0

PMC trigger events for the UTMIP ports as well as the UHSIC port. Sleep walk clearing returns the walk pointer to 00, the first entry in a USB line walk. This is the only way to return a pointer to 0.

Pad configuration capture a set of FLLS parameters prior to resting the port so their value can be retained in deep sleep.

The trigger should only happen on the fields that are set to TRIG (1) when writing. Returned read value should always be all NULL fields. The FORCE_WALK bits trigger a SLEEP

This does not need to be a real register, so it should not consume much area. Any value read back should be 0.

Triggers for USB Ports

Offset: 0x27c │ Read/Write: R/W │ Reset: 0x00000000 (0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx)

Bit	Reset	Description
3	X	UHSIC_CLR_WAKE_ALARM_P1: Clear wake event for UHSIC port 0 0 = NULL 1 = TRIG
2	X	UHSIC_FORCE_WALK_P1: Force pointer walk for UHSIC port 0 0 = NULL 1 = TRIG
1	X	UHSIC_RESERVED_P1: Reserved for UHSIC port 0 0 = NULL 1 = TRIG
0	X	UHSIC_CLR_WALK_PTR_P1: Clear sleep walk pointer for UHSIC port 1 0 = NULL 1 = TRIG

10.9.160 APBDEV_PMC_UTMIP_UHSIC2_SAVED_STATE_0

Save some critical information about USB port prior to entering DPD in a suspend state.

SPEED

- HS: Suspend DPD was entered from a high speed mode, restore high speed at DPD exit
- FS: Suspend DPD was entered from a full speed mode, restore full speed at DPD exit
- LS: Suspend DPD was entered from a low speed mode, restore low speed at DPD exit
- RST: Reset Port, Hardware reset or DPD was not entered suspended bus, Reset and Re-enumerate port

SCRATCH -- Save other critical information about the port, software choice. Reset value should read 0x0F0F0F0F, reset should occur on Cold Hardware Reset only

Saved DPD State for all UTMIP and UHSIC Ports

Offset: 0x280 │ Read/Write: R/W │ Reset: 0x00000007 (0bxxxxxxxxxxxxxxxxxxxxxxxx00000111)

Bit	Reset	Description
7	0x0	UHSIC_WAKE_EX_P1: Wake up on anything except a particular line value 0 = OFF 1 = ON
6	0x0	UHSIC_IGNORE_MASTER_CFG_P1
5:1	0x3	UHSIC_SCRATCH_P1
0	0x1	UHSIC_MODE_P1: UHSIC Speed prior to DPD 0 = HS 1 = RST

10.9.161 APBDEV_PMC_UTMIP_UHSIC2_SLEEP_CFG_0

This register configures the value of the line that could cause a wake-up event.

- ANY: signifies any line change DM EDGE or DP EDGE for UTMIP.
- NONE: signifies no wake-up possible.

One can use the two most significant bits (3:2) of the WAKE_VAL to 4x1 select whether:

- 00: Check both bits for value on two LSB (1:0).
- 01: Check bit DM (or strobe for HSIC) against bit 0
- 10: Check bit DP (or DATA for HSIC) against bit 1
- 11: Check for edge on DP against bit 1, edge on DM against bit 0

Sleep Walk Sequence Enables

Offset: 0x284 │ Read/Write: R/W │ Reset: 0x000000c0 (0bxxxxxxxxxxxxxxxxxxxxxxxx11000000)

Bit	Reset	Description
7:4	0xc	UHSIC_WAKE_VAL_P1: Line Value Wake Up Condition on UHSIC P1 0 = SD00 1 = SD01 2 = SD10 3 = SD11 4 = S0 5 = S1 8 = D0 10 = D1 12 = NONE 13 = SEDGE 14 = DEDGE 15 = ANY

10.9.173 APBDEV_PMC_TSC_MULT_0

Offset: 0x2b4 | Read/Write: R/W | Reset: 0x000016e0 (0bxxxxxxxxxxxxxxxx0001011011100000)

Bit	R/W	Reset	Description
16	RO	X	FREQ_STS: Clock frequency being used for counter. 0 = Fast (i.e., oscillator frequency). 1 = Slow (i.e., 32kHz). When the PMC_DPD_ENABLE[TSC_MULT_EN] bit is set to '1', the PMC waits for first rising edge on the slow clock before switching the counter to the slow clock. This status is also set at the first rising edge of the slow clock (to indicate the change of clock for counter).

Bit	R/W	Reset	Description
15:0	RW	0x16e0	MULT_VAL: TSC multiply value (default based on 12 MHz oscillator).Value is (osc-freq * 16 / 32.768 kHz) when the oscillator is disabled and the TSC runs at the 32 kHz clock. For example, for a 12 MHz oscillator, VALUE = 5856.

10.9.174 APBDEV_PMC_CPU_VSENSE_OVERRIDE_0

Offset: 0x2b8 │ Read/Write: R/W │ Reset: 0x0000001f (0bxxxxxxxxxxxxxxxxxxxxxxxxxxxx011111)

5	0x0	VDD: VDD sensing override.
4	0x1	C0NC: C0NC VVDD partition sensing override.
3	0x1	CE3:CE3 VVDD partition sensing override.
2	0x1	CE2:CE2 VVDD partition sensing override.
1	0x1	CE1:CE1 VVDD partition sensing override.
0	0x1	CE0:CE0 VVDD partition sensing override.

10.9.175 APBDEV_PMC_GLB_AMAP_CFG_0

This register configures some of the address apertures (in CCPLEX-AXD) to be MMIO or DRAM. Each bit is used to configurable one of the address aperture. For each bit 0=>MMIO and 1=>DRAM.

By default, all configurable apertures are MMIO address space. But they can be configured (at boot time) to be DRAM by programming this register. This register can be write-disabled (by the PMC_SEC_DISABLE register). The bits of this register are used as follows.

GLB_AMAP_CFG

Offset: 0x2bc │ Read/Write: R/W │ Reset: 0x00000000 (0bxxxxxxxxxxxxxxx00000000000000000)

Bit	Reset	Description

10.10 PMC Counter 0 Registers

Refer to “Reading Register Tables” in the Introduction section for the register table protocol as well as recommendations for accessing registers.

10.10.1 SYSCTR0_CNTCR_0

The control registers are read/written by secure accesses only except the CNTFID0 and COUNTERID11-0 registers, which can be written only once by secure or non-secure access.

The CNTFID0 and COUNTERID11-0 registers are read-only; however, to initialize them at boot (by ARM7 or main CPU), they are defined as write once.

A non-secure write to the control registers is ignored. A non-secure read to the control registers returns all 1s.

Counter Control Register

Offset: 0x0 | Read/Write: R/W | Reset: 0x00000000 (0bxxxxxxxxxxxxxxxxxxxxxxxx0xxxxxx00)

Bit	Reset	Description
8	0x0	FCREQ: Requested frequency modes table entry. This bit is not used.
1	0x0	HDBG: Halt-on-debug. Controls whether a Halt-on-debug signal halts the system counter or not. 0: System counter ignores Halt-on-debug.1: Asserted Halt-on-debug signal halts the system counter update. 0 = DISABLE 1 = ENABLE
0	0x0	EN: Enables the counter. 0: System counter disabled. 1: System counter enabled. When this bit is written to '1', then the TSC is loaded with the CNTCVx register’s value, and starts incrementing from that value. When this bit is written to '0', the TSC halts counting and stays at that value. 0 = DISABLE 1 = ENABLE

10.10.2 SYSCTR0_CNTSR_0

Counter Status Register

Offset: 0x4 | Read/Write: RO | Reset: 0x00000X0X (0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx)

Bit	Reset	Description
8	X	FCREQ: Frequency change acknowledge. This bit is a copy of the value of the CNTCR[FCREQ] bit.
1	X	HDBG: Indicates whether or not the counter is halted because the Halt-on-Debug signal is asserted: 0: Counter is not halted.1: Counter is halted. 0 = DISABLE 1 = ENABLE
0	X	RESERVED: Reserved, no impact.

10.10.3 SYSCTR0_CNTCV0_0

Counter Count Value [31:0] Register

Offset: 0x8 | Read/Write: R/W | Reset: 0x00000000 (0b00000000000000000000000000000000)

Bit	Reset	Description
31:0	0x0	CV: Counter value [31:0]. A read of this register provides the TSC[31:0] value at the time of the read. When CNTCR[EN]=0, a write to this register is used to initialize the TSC[31:0] value. When CNTCR[EN]=1, a write to this register has an unpredictable behavior.

10.10.4 SYSCTR0_CNTCV1_0

Counter Count Value[63:32] Register

Offset: 0xc | Read/Write: R/W | Reset: 0x00000000 (0b00000000000000000000000000000000)

Bit	Reset	Description
31:0	0x0	CV: Counter value [63:32]. A read of this register provides the TSC[63:32] value at the time of the read. When CNTCR[EN]=0, a write to this register is used to initialize the TSC[63:32] value. When CNTCR[EN]=1, a write to this register has an unpredictable behavior.

10.10.5 SYSCTR0_CNTFID0_0

Frequency Table Entry Register

Offset: 0x20 | Read/Write: R/W | Reset: 0x00b71b00 (0b00000000101101110001101100000000)

Bit	Reset	Description
31:0	0xb71b00	FV: Counter frequency value in Hz. The default is set to 12 MHz. This register can be written only once.

10.10.6 SYSCTR0_CNTFID1_0

Frequency Table End Marker

Offset: 0x24 | Read/Write: RO | Reset: 0xXXXXXXXX (0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx)

Bit	Reset	Description
31:0	X	FV: Counter frequency value end marker (all-0s, read-only).

10.10.7 SYSCTR0_COUNTERID4_0

The COUNTERID11-0 registers are read-only; however, to initialize them at boot (by ARM7 or main CPU), they are defined as write once.

Offset: 0xfd0 | Read/Write: R/W | Reset: 0x00000000 (0bxxxxxxxxxxxxxxxxxxxx000000000000)

Bit	Reset	Description

11:0	0x0	VALUE: Component ID value

10.11 PMC Counter 1 Registers

Refer to “Reading Register Tables” in the Introduction section for the register table protocol as well as recommendations for accessing registers.

The status registers are some control registers readable via the CNTReadBase base address by secure or non-secure accesses.

These are the same physical registers that are described in the Control Register section.

10.11.1 SYSCTR1_CNTCV0_0

[THIS PAGE INTENTIONALLY LEFT BLANK]

11.0 REAL-TIME CLOCK

The Real-Time Clock (RTC) module maintains seconds and milliseconds counters, and five alarm registers. The RTC is in the ‘always-on’ power domain, allowing for the counters to run and alarms to trigger when the system is in low-power state. If configured, interrupts triggered by the RTC can cause the system to wake up from a low-power state.

Features

- 10-bit milliseconds counter that runs off of a 32.768 KHz clock source.
- 32-bit seconds counter that increments for every 1000 milliseconds.
- Alarm feature that triggers an interrupt when the specified value matches the milliseconds counter.
- Alarm feature that triggers an interrupt when the specified value matches the seconds counter.
- Count-down alarm feature that triggers an alarm after counting down the specified number of seconds.
- Count-down alarm feature that triggers an alarm after counting down the specified number of milliseconds.
- Security bit that disables further processor writes to the seconds counter and ensures that the RTC clock keeps running.
- Hardware adjusts drift in clock which can occur due to ppm variations in oscillator output.

11.1 Functional Description

The RTC operates in two clock domains: the APB clock domain and the 32 KHz clock domain. The RTC continues updating the milliseconds and seconds counters and continues triggering interrupts even when the MAIN partition is powered down. Since the APB clock is disabled when MAIN is powered down, registers are implemented in the 32 KHz clock domain.

All the registers except the BUSY register are implemented in the 32 KHz clock domain. Writes are transferred to the 32 KHz domain with BUSY.STATUS set to BUSY until the transfer is completed. Reads are shadowed in the APB clock domain and return immediately.

The RTC implements a Seconds Counter register, three Alarm registers, two countdown alarms, and various interrupt related registers.

Writes to the seconds counter can be disabled by writing to the CONTROL.DIS_WR_SEC_CNT bit. Alarm registers and countdown alarm registers set interrupt bits when corresponding events occur. Interrupt status, mask, set and source registers reflect the status and also allow setting and clearing of various bits. All registers (except the BUSY register) are implemented in the 32K clock domain.

Resets

The RTC receives an asynchronous reset which is synchronized to the APB clock and RTC clock domains.

11.2 RTC Registers

Refer to “Reading Register Tables” in the Introduction section for the register table protocol as well as recommendations for accessing registers.

11.2.1 APBDEV_RTC_CONTROL_0

The RTC implements a Seconds Counter register, three Alarm registers, two countdown alarms, and various interrupt related registers. Writes to the seconds counter can be disabled by writing to the CONTROL.DIS_WR_SEC_CNT bit.

Alarm registers and countdown alarm registers set interrupt bits when corresponding events occur. Interrupt status, mask, set and source registers reflect the status as well as allow setting and clearing of various bits.

All the registers except the BUSY registers are implemented in the 32K clock domain. Writes are transferred to the 32K domain with BUSY STATUS set to BUSY until the transfer completes. Reads are shadowed in the APB domain and will return immediately.

Control Register

Offset: 0x0 | Read/Write: R/W | Reset: 0x00000000 (0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx0)

Bit	Reset	Description
0	0x0	WR_SEC_CNT: When set, writes to the SECONDS counter are disabled. Can only be cleared by resetting the RTC module 0 = DISABLE 1 = ENABLE

11.2.2 APBDEV_RTC_BUSY_0

Busy Register

Offset: 0x4 | Read/Write: RO | Reset: 0x0000000X (0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx)

Bit	Reset	Description
0	X	STATUS: This bit is set when a write is initiated on the APB side. It is cleared once the write completes in RTC 32KHz clock domain, which could be several thousands of APB clocks. This must be IDLE before a write is initiated. Note that this bit is only for writes. 0 = IDLE 1 = BUSY

11.2.3 APBDEV_RTC_SECONDS_0

Seconds Counter Register

SECONDS register is copied over to APB side every eight 32 KHz clocks (~250 µs). Because of this, performing a read immediately after a write might return old value. This covers 49710.26 Days (or) 136.192 Years of 365 days each.

Offset: 0x8 | Read/Write: R/W | Reset: 0x00000000 (0b00000000000000000000000000000000)

Bit	Reset	Description
31:0	0x0	SECONDS: The seconds counter is incremented for every 1000 milliseconds

11.2.4 APBDEV_RTC_SHADOW_SECONDS_0

Shadowed Seconds Counter Register

Shadow SECONDS register is updated over to the APB side whenever there is a read to milliseconds counter.

Since the software cannot read both registers at any given point of time, the Seconds register content is captured in this register. If software needs to read both seconds and milliseconds, read the MILLI_SECONDS register followed by a read of this register.

Offset: 0xc | Read/Write: RO | Reset: 0xXXXXXXXX (0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx)

Bit	Reset	Description
31:0	X	SHADOW_SECONDS: A snapshot of the SECONDS counter is taken, whenever there is a read to MILLI_SECONDS Register.

11.2.5 APBDEV_RTC_MILLI_SECONDS_0

Milliseconds Counter Register

The Milliseconds register is copied over to APB side every eight 32 KHz clocks (~250 μs). Because of this, performing a read immediately after a write might return an old value.

Offset: 0x10 | Read/Write: RO | Reset: 0x00000XXX (0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx)

Bit	Reset	Description
9:0	X	MILLI_SECONDS: Milliseconds counter is incremented using the Bresenham algorithm

11.2.6 APBDEV_RTC_SECONDS_ALARM0_0

Seconds Alarm0 Registers

When the value in this register matches the seconds counter, corresponding interrupt status bit is set. If enabled, the interrupt line is asserted. A value of zero disables the alarm.

Offset: 0x14 | Read/Write: R/W | Reset: 0x00000000 (0b00000000000000000000000000000000)

Bit	Reset	Description
31:0	0x0	SECS_MATCH_VALUE: Match value to trigger the alarm

11.2.7 APBDEV_RTC_SECONDS_ALARM1_0

Seconds Alarm1 Registers

When the value in this register matches the seconds counter, corresponding interrupt status bit is set. If enabled, the interrupt line is asserted. A value of zero disables the alarm.

Offset: 0x18 | Read/Write: R/W | Reset: 0x00000000 (0b00000000000000000000000000000000)

Bit	Reset	Description
31:0	0x0	SECS_MATCH_VALUE: Match value to trigger the alarm

11.2.8 APBDEV_RTC_MILLI_SECONDS_ALARM_0

Milliseconds Alarm Register

When the value in this register matches the milliseconds counter, corresponding interrupt status bit is set. If enabled, the interrupt line is asserted. A value of zero disables the alarm.

Offset: 0x1c | Read/Write: R/W | Reset: 0x00000000 (0bxxxxxxxxxxxxxxxxxxxxxxx0000000000)

Bit	Reset	Description
9:0	0x0	MSEC_MATCH_VALUE: milliseconds match value.

11.2.9 APBDEV_RTC_SECONDS_COUNTDOWN_ALARM_0

Countdown Alarm Registers

If ENABLE is set to ENABLED, an internal counter is loaded with VALUE and counted down. The interrupt bit corresponding to the countdown_alarm_0 is set after the specified number of seconds have elapsed.

The interrupt bit corresponding to the countdown alarm (MSC_CDN_ALARM, SEC_CDN_ALARM) is set after the specified interval has expired. If REPEAT is ENABLED, the countdown operation is performed repeatedly.

Offset: 0x20 | Read/Write: R/W | Reset: 0x00000000 (0b00000000000000000000000000000000)

Bit	Reset	Description
31	0x0	ENABLE: enable bit for the countdown operation. If repeat is not set, this bit is cleared once the internal counters counts down to specified value. 0 = DISABLED 1 = ENABLED
30	0x0	REPEAT: repeat bit for the countdown operation 0 = DISABLED 1 = ENABLED
29:0	0x0	VALUE: number of seconds to countdown

11.2.10 APBDEV_RTC_MILLI_SECONDS_COUNTDOWN_ALARM_0

Offset: 0x24 | Read/Write: R/W | Reset: 0x00000000 (0b00000000000000000000000000000000)

Bit	Reset	Description
31	0x0	ENABLE: enable bit for the countdown operation. If repeat is not set, this bit is cleared once the internal counters counts down to specified value. 0 = DISABLED 1 = ENABLED
30	0x0	REPEAT: repeat bit for the countdown operation 0 = DISABLED 1 = ENABLED
29:0	0x0	VALUE: number of milliseconds to countdown

11.2.11 APBDEV_RTC_INTR_MASK_0

Interrupt Mask Register

This register stores the masks for the interrupts. If a bit is set 1 and the corresponding interrupt condition is satisfied, interrupt line to system interrupt controller is asserted.

Offset: 0x28 | Read/Write: R/W | Reset: 0x00000000 (0bxxxxxxxxxxxxxxxxxxxxxxxxxxxx00000)

Bit	Reset	Description
4	0x0	MSEC_CDN_ALARM
3	0x0	SEC_CDN_ALARM
2	0x0	MSEC_ALARM
1	0x0	SEC_ALARM1
0	0x0	SEC_ALARM0

11.2.12 APBDEV_RTC_INTR_STATUS_0

Interrupt Status Register

Bits in this register are high after the interrupt condition is satisfied. A write to this register clears the bits corresponding to the data bits that are high in the write data.

Offset: 0x2c | Read/Write: R/W | Reset: 0x00000000 (0bxxxxxxxxxxxxxxxxxxxxxxxxxxxx00000)

Bit	Reset	Description
4	0x0	MSEC_CDN_ALARM
3	0x0	SEC_CDN_ALARM
2	0x0	MSEC_ALARM
1	0x0	SEC_ALARM1
0	0x0	SEC_ALARM0

11.2.13 APBDEV_RTC_INTR_SOURCE_0

Interrupt Source Register

This read-only register returns the AND of the Interrupt Source and Interrupt Mask registers.

Offset: 0x30 | Read/Write: RO | Reset: 0x000000XX (0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx)

Bit	Reset	Description
4	X	MSEC_CDN_ALARM
3	X	SEC_CDN_ALARM
2	X	MSEC_ALARM
1	X	SEC_ALARM1
0	X	SEC_ALARM0

11.2.14 APBDEV_RTC_INTR_SET_0

Interrupt Set Register

This write-only register can be used to set the interrupt status bit. A write to this register causes the bits in status register to be set if the corresponding bit in write data is 1'b1. Reads always return 'h0.

Offset: 0x34 | Read/Write: R/W | Reset: 0x00000000 (0bxxxxxxxxxxxxxxxxxxxxxxxxxxxx00000)

Bit	Reset	Description
4	0x0	MSEC_CDN_ALARM
3	0x0	SEC_CDN_ALARM
2	0x0	MSEC_ALARM
1	0x0	SEC_ALARM1
0	0x0	SEC_ALARM0

11.2.15 APBDEV_RTC_CORRECTION_FACTOR_0

Correction Factor (Digital Trimming) Register

Support is for +/- 500ppm, but +/- 50 ppm is maximum

Offset: 0x38 | Read/Write: R/W | Reset: 0x00000000 (0bxxxxxxxxxxxxxxxxxxxxxxx0000000000)

Bit	Reset	Description
9	0x0	DIRECTION: 0 = DECREMENT 1 = INCREMENT
8:0	0x0	PPM

12.0 BOOT PROCESS

This section provides a functional description of the boot process.

Glossary and Acronyms

Table 31: Boot ROM Glossary

Acronym	Description
AES	Advanced Encryption Standard
BCT	Boot Configuration Table
BKV	Best Known Value. Configuration determined by system characterization.
BL	Boot Loader, the software that initiates loading the OS
BR	Boot ROM, the on-chip software that is executed first after reset.
COP	COProcessor (also known as AVP or ARM7)
FA	Failure Analysis
IRAM	Internal RAM used by the boot process until DRAM is configured.
IROM	Internal ROM which contains the Boot ROM code and data.
LP0	Low-Power 0 sleep state.
LX	LP0 Exit code
MB	Micro Boot, an optional second stage of the boot process
PKC	Public-Key Cryptography
RCM	Recovery Mode, used when the system is unable to boot normally
SE	Security Engine
WoA	Windows-on-ARM.

12.1 Boot Components

Table 32: Boot Components

Component	Execution	Stored Location	Run Location	Target	Ownership
Boot ROM	AVP	IROM	IROM	64KB	NVIDIA
BCT	n/a	Media	IRAM	4KB	OEM
MicroBoot	AVP	Media	IRAM	~175KB	NVIDIA + ODM
Boot Loader	AVP + CPU	Media	DRAM	Same	ODM
LP0 Exit Code	AVP	DRAM	DRAM	Same	NVIDIA
OS	CPU	Media	DRAM	Same	ODM
TSEC RNG	Falcon (µC)	Media	µC RAM	~4KB	NVIDIA
TSEC FW*	Falcon (µC)	Media	µC RAM		NVIDIA
MSENC FW*	Falcon (µC)	Media	µC RAM		NVIDIA

* Not required for boot

12.1.1 Boot ROM

The very first code to execute upon reset is the Boot ROM. It is contained in an on-chip 64KB IROM, executes completely on the AVP, and is the very first firmware to execute upon chip reset. It is hardcoded into the chip and is not reprogrammable. The Boot ROM represents the root-of-trust for boot. Its goal is to be as simple and robust as possible. The Boot ROM must be able to locate, configure, and read from the boot media based on fuses and hardware straps.

Before handoff to the MicroBoot or Boot Loader, the Boot ROM must restrict access to any sensitive information including the AES keys. Note that after lock down the keys are unreadable by software but remains present within key slots of the SE, and can be used for authentication and decryption by subsequent stages of boot.

12.1.2 Boot Configuration Table (BCT)

The Boot Configuration Table is read initially by the Boot ROM from the boot media, is approximately 4KB in size, and contains platform-specific configuration information to be used by the boot process. One important piece of information in the BCT is the DRAM geometry and timing information.

The BCT stores information needed to locate and verify a boot loader.

NvBootLoaderInfo Structure

There is one NvBootLoaderInfo structure for each copy of a BL stored on the device.

Table 33: NvBootLoaderInfoRec Structure in the BCT

Parameter Name	Type	Description
Attribute	NvU32	Specifies an attribute available for use by other code. Not interpreted by the Boot ROM.
EntryPoint	NvU32	Specifies the entry point address in the loaded BL image.
Length	NvU32	Specifies the length of the BL in bytes. BLs must be padded to an integral number of 16 bytes with the padding pattern. Note The end of the BL cannot fall within the last 16 bytes of a page. Add another 16 bytes to work around this restriction if needed.
LoadAddress	NvU32	Specifies the starting address of the memory region into which the BL will be loaded.
Signature	NvBootObjectSignature	Specifies the AES-CMAC MAC or RSASSA-PSS signature of the BL.
StartBlock	NvU32	Specifies the first physical block on the secondary boot device that contains the start of the BL. The first block can never be a known bad block.
StartPage	NvU32	Specifies the page within the first block that contains the start of the BL.
Version	NvU32	Specifies a version number for the BL. The assignment of numbers is arbitrary; the numbers are only used to identify redundant copies (which have the same version number) and to distinguish between different versions of the BL (which have different numbers).

The following table lists the enumerated types in the BCT that identify the devices from which the system booted.

Note that these no longer match the fuse API device values (for backward compatibility with legacy devices).

Table 34: Enumerated Types in the BCT

Type	Description
NvBootDevType_None	Specifies a default (unset) value. Set to 0.
NvBootDevType_Reserved	Reserved
NvBootDevType_Spi	Specifies the SPI NOR
NvBootDevType_Sdmmc	Specifies the SDMMC
NvBootDevType_Reserved	Reserved
NvBootDevType_Reserved	Reserved

Type	Description
NvBootDevType_Max	
NvBootDevType_Force32	Set to 0x7FFFFFFF

The NvBootConfigTableRec structure contains the information needed to load BLs from the secondary boot device.

- Supplying NumParamSets = 0 indicates not to load any of them.
- Supplying NumDramSets = 0 indicates not to load any of them.
- The RandomAesBlock member exists to increase the difficulty of key attacks based on knowledge of this structure.

Table 35: NvBootConfigTableRec Structure

Parameter Name	Type	Description
BadBlockTable	NvBootBadBlockTable	Specifies the bad block table, which is defined in nvboot_badblocks.h
Key	NvBootRsaKeyModulus	Specifies the RSA public key's modulus
Signature	NvBootObjectSignature	Specifies the AES-CMAC MAC or RSASSA-PSS signature for the rest of the BCT structure
CustomerData[NVBOOT_BCT_CUSTOMER_DATA_SIZE]	NvU8	Specifies a region of data available to customers of the BR. This data region is primarily used by a manufacturing utility or BL to store useful information that needs to be shared among manufacturing utility, BL, and OS image. The BR only provides framework and does not use this data
Signed Section of the BCT		
RandomAesBlock	NvBootHash	Specifies a chunk of random data
UniqueChipId	NvBootECID	Specifies the Unique ID / ECID of the chip that this BCT is specifically generated for. This field is required if SecureJtagControl == NV_TRUE. It is optional otherwise. This is to prevent a signed BCT with SecureJtagControl == NV_TRUE being leaked into the field that would enable JTAG debug for all devices signed with the same private RSA key
BootDataVersion	NvU32	Specifies the version of the BR data structures used to build this BCT. BootDataVersion must match the version number in the BR.
BlockSizeLog2	NvU32	Specifies the size of a physical block on the secondary boot device in log2(bytes)
PageSizeLog2	NvU32	Specifies the size of a page on the secondary boot device in log2(bytes)
PartitionSize	NvU32	Specifies the size of the boot partition in bytes. Used for internal error checking. BLs must fit within this region.

Parameter Name	Type	Description
NumParamSets	NvU32	Specifies the number of valid device parameter sets provided within this BCT. If the device straps are left floating, the same parameters should be replicated to all NVBOOT_BCT_MAX_PARAM_SETS sets.
DevType[NVBOOT_BCT_MAX_PARAM_SETS]	NvBootDevType	Specifies the type of device for parameter set DevParams[i].
DevParams[NVBOOT_BCT_MAX_PARAM_SETS]	NvBootDevParams	Specifies the device parameters with which to reinitialize the secondary boot device controller. The device straps index into this table. The definition of NvBootDevParams is contained within nvboot_devparams.h and the specific device nvboot_*_param.h files.
NumSdramSets	NvU32	Specifies the number of valid SDRAM parameter sets provided within this BCT. If the SDRAM straps are left floating, the same parameters should be replicated to all NVBOOT_BCT_MAX_SDRAM_SETS sets.
SdramParams[NVBOOT_BCT_MAX_SDRAM_SETS]	NvBootSdramParams	Specifies the SDRAM parameters with which to initialize the SDRAM controller. The SDRAM straps index into this table. The definition of NvBootDevParams is contained within nvboot_sdram_param.h.
BootLoadersUsed	NvU32	Specifies the number of BLs described in the BootLoader table
BootLoader[NVBOOT_MAX_BOOTLOADERS]	NvBootLoaderInfo	Specifies the information needed to locate and validate each BL. The BR uses entries 0 through BootLoadersUsed - 1
EnableFailBack	NvBool	Specifies whether FailBack should be used when looking for a good BL.
SecureJtagControl	NvBool	Specify whether or not to enable JTAG access when the JTAG disable fuse has not been burned. SecureJtagControl = NV_FALSE (0) = Disable JTAG access. SecureJtagControl = NV_TRUE (1) = Enable JTAG access.
Reserved[NVBOOT_BCT_RESERVED_SIZE]	NvU8	Specifies a reserved area at the end of the BCT that must be filled with the padding pattern.

12.1.3 Partition Table (PT)

12.1.3.1 Partition Allocation

Generally, a partition is specified in terms of a set of desired logical properties. The underlying physical properties might differ from the logical properties, for example, to hide the presence of bad blocks on the storage media.

The allocation policy governs how the logical partition properties are mapped to the physical partition properties when the partition is first created on the storage device.

The supported allocation properties are:

- Relative--The current partition is placed immediately after the previously defined partition on the storage device. If no previous partition has been defined on the storage device, the partition is placed at physical block zero.
- Absolute--The current partition is placed at the specified physical address on the storage device. The address must be aligned to block (erase) boundaries on the storage device.

For both policies, the client specifies the logical size of the partition in bytes. If the storage device contains any bad blocks when the partition is created, additional blocks will be allocated to the partition such that there will be enough good blocks to store the number of data bytes specified by the client. These good blocks are referred to as logical blocks.

To deal with the possibility that some good blocks might subsequently go bad in the operation, the client can also specify that additional good blocks be allocated to the partition. Depending on the device driver, it might be possible to use these additional good blocks to replace blocks that go bad. Thus, the additional blocks are referred to as *replacement blocks*.

The client specifies the number of replacement blocks as a percentage of the logical blocks. The calculation of replacement blocks is always rounded up to ensure that the client never gets fewer replacement blocks (percentage-wise) than requested.

The calculations for logical blocks and replacement blocks are as follows:

- LB = ceiling(LogicalPartitionSize/BlockSize)
- RB = ceiling(LB * PartitionPercentReserved / 100)

Where RB is the number of reserved blocks, and LB is the number of logical blocks. The block driver for the storage device knows the device's BlockSize attribute and hence can carry out the calculations.

Finally, there is a partition attribute that is passed to the device driver when the partition is created. Interpretation of this attribute is determined by the device driver. This provides a mechanism for associating driver-specific properties with the partition on a per-partition basis.

12.1.3.2 File System Attribute and Strings

There is one file system attribute used by the Partition Manager:

NvPartitionAttr_WriteProtect - 0x1

All strings are in UTF-8 format and have maximum lengths, as defined below.

- If NV_EMBEDDED_BUILD, NVPARTMGR_PARTITION_NAME_LENGTH = 21, otherwise NVPARTMGR_PARTITION_NAME_LENGTH = 4
- NVPARTMGR_MOUNTPATH_NAME_LENGTH = (NVPARTMGR_PARTITION_NAME_LENGTH)

12.1.3.3 Structures

NvFsMountInfoRec Structure

This structure specifies Fstab-like information for a partition. It identifies the location of the partition, the file system type for the partition, and the location (in the file system address space) where the partition is to be mounted.

* The typical process for mounting a partition is as follows:

> **Note:** Information about the size and location of the partition itself must be queried from the partition manager. For an example, see NvPartMgrGetPartInfo().

- Open the device driver for the storage device containing the partition based on the DeviceId, DeviceInstance, and DeviceAttr attributes.
- Open the file system driver for the partition based on the FileSystemType and FileSystemAttr attributes.

- Register the MountPath attribute in the global file system address space such that operations within the MountPath branch of the address space are directed to this instance of the file system driver.

The DeviceAttr and FileSystemAttr attributes are associated with the partition and are used during the mounting process above. They are used to tailor the behavior of the device driver and file system driver on a per-partition basis.

Table 36: NvFsMountInfoRec Structure

Parameter Name	Type	Description
DeviceId	NvU32	Holds the type of device on which partition is located.
DeviceInstance	NvU32	Holds the device instance on which partition is located.
DeviceAttr	NvU32	Not supported.
MountPath[NVPARTMGR_MOUNTPATH_NAME_LENGTH	UTF-8	Holds the path where partition will be mounted in the file system. WARNING: The current implementation requires PartitionName and MountPath to be identical.
FileSystemType	NvU32	Holds the type of file system to mount on this partition.
FileSystemAttr	NvU32	Holds the attribute passed to the file system driver when it is mounted on the partition. The file system driver determines the meaning of this value

NvPartInfoRec Structure

This structure provides MBR-like information for a partition.

Table 37: NvPartInfoRec Structure

Parameter Name	Type	Description
PartitionAttr	NvU32	Not supported.
Padding1	NvU32	Dummy bytes added to avoid implicit padding done on the device side for the PartitionAttr attribute based on the maximum data type of the structure (in this case, NvU64)
StartLogicalSectorAddress	NvU64	Holds the logical start address for the partition, in sectors (of the device where the partition is located).
NumLogicalSectors	NvU64	Holds the logical size of the partition in sectors (of the device where the partition is located).
StartPhysicalSectorAddress	NvU64	Holds the partition start physical sector on the storage media.
EndPhysicalSectorAddress	NvU64	Holds the partition end physical sector on the storage media (inclusive).
PartitionType	NvPartMgrPartitionType	Deprecated.

Parameter Name	Type	Description
Padding2	NvU32	If NV_EMBEDDED_BUILD, Dummy bytes added to avoid implicit padding done on the device side for the PartitionType attribute based on the maximum data type of the structure (in this case, NvU64).
IsWriteProtected	NvU32	If not NV_EMBEDDED_BUILD, Specifies if the partition is write-protected on boot.

NvPartitionStatRec Structure

This structure specifies public partition information.

Table 38: NvPartitionStatRec Structure

Parameter Name	Type	Description
PartitionSize	NvU64	Holds the partition size in bytes.

NvPartAllocInfoRec Structure

This structure defines the allocation policy.

Table 39: NvPartAllocInfoRec Structure

Parameter Name	Type	Description
AllocPolicy	NvPartMgrAllocPolicyType	The allocation policy governing the layout of the partition on the storage device.
StartAddress	NvU64	Physical start address of partition on the storage device, in bytes (must be block aligned). WARNING: This parameter is ignored except when AllocPolicy is NvPartMgrAllocPolicyType_Absolute.
Size	NvU64	The partition is guaranteed to hold the specified amount of data when it is created. The storage capacity of the partition may degrade over time if any of its data blocks fail afterward.
PercentReserved	NvU32	Number of reserved blocks to allocate in the partition, specified as a percentage of the number of logical blocks in the partition. PartitionPercentReserved must be an integer in the range [0, 100]. Calculations are rounded up to guarantee that the actual percentage of reserved blocks allocated meets or exceeds the caller's requirements
AllocAttribute	NvU32	Driver-dependent partition attribute. This value is passed to the relevant device driver when the partition is created. Its meaning is determined by the device driver.
IsWriteProtected	NvU32	If NV_EMBEDDED_BUILD, a flag indicating whether the partition is write-protected. On boot, this attribute is checked, and, if it is TRUE, the primary boot loader write protects the sectors corresponding to this partition.

12.1.3.4 Enumerated Types

The following table listed the enumerated types in the PT.

Table 40: Enumerated Types in the PT

Type	Description
Alignment Policy	
NvPartMgrAllocPolicyType_Absolute	Partition starts at a specified physical address; address must be block-aligned
NvPartMgrAllocPolicyType_Relative	Partition starts at the physical block address immediately following the end of the previous partition
NvPartMgrAllocPolicyType_Force32	Set to 0x7FFFFFFF.
Partition Attributes	
NvPartMgrPartitionAttribute_Preserve	Data should be backed up and then restored.
NvPartMgrPartitionAttribute_Force32	Set to 0x7FFFFFFF.

12.1.4 MicroBoot

MicroBoot may be optionally used by some customers for requirement such as single-boot-image to support multiple DRAM devices, DRAM training, special dead-battery-charging support, improved boot latency, etc. MicroBoot is read and invoked by Boot ROM from the boot media, executes completely on the AVP, and is invoked by the Boot ROM. MicroBoot is responsible for configuring and training DRAM and must itself run from IRAM until then. MicroBoot has combined ownership. It contains NVIDIA-provided boot functionality as well as substantial ODM-specific configuration code.

The Tegra 4 processor Boot adds more functionality and yet targets improved total cold boot latency. MicroBoot can be responsible for improving latency, by moving functionality from the Boot ROM where it was optimized for size and simplicity, to MicroBoot where it can be optimized for performance and parallelism.

12.1.5 Falcon Firmware

The MSENC and TSEC hardware units contain an NVIDIA proprietary Falcon microcontroller, and therefore require their own firmware (FW) to be loaded in order to function. The MSENC and TSEC driver FW, which are not required for boot, are loaded by their OS drivers. However, TSEC RNG FW is required to generate secure key during boot, which is shared with video decode engine. This FW needs to be loaded by secure boot (either by Boot ROM as part of Boot Loader “blob”, or by Boot Loader). The TSEC FWs (both RNG and Driver FWs) are authenticated by TSEC.

Each Falcon is expected to contain enough internal RAM to support the entirety of its firmware load. If for any reason the required firmware grows beyond the size of this internal RAM, it will be necessary for the firmware image to remain in DRAM so that Falcon may swap in the required portion for a given workload.

12.1.6 Boot Loader

The Boot Loader is read and invoked by Boot ROM or MicroBoot from the boot media, and executes initially on the AVP and primarily on the CPU. It is significantly larger in size than the MicroBoot, and the boot media should ideally be configured to its highest speed before the Boot Loader is read. The Boot Loader is generally the responsibility of the OEM, although NVIDIA may provide a reference implementation and/or substantial support. The Boot Loader is responsible for remaining system configuration, may display a splash screen or include a system update mechanism, and will eventually hand off to OS boot. There are several different Boot-Loader implementations.

- ***Boot Loader***: NVIDIA developed boot-loader used by Android/Linux
- ***UEFI***: Public domain APIs based NVIDIA implemented Boot Loader, used by WoA.
- ***QuickBoot***: Relatively smaller and faster (than Boot Loader), used by Automotive.

- ***U-Boot***: open source Boot Loader used by many SoCs / OEMs (e.g., used by Google Chrome).

Boot Loader Implementation

NVIDIA recommends that you do NOT program the FUSE_ARM_DEBUG_DIS fuse. Because DBGEN, NIDEN, SPNIDEN, and SPIDEN are all fixed at zero, they disable all access to CoreSight debug and performance counters.

The proper recommended usage is:

1. Leave FUSE_ARM_DEBUG_DIS unprogrammed (disabled, value = 0)
2. Use the SecureJtagControl bit in the BCT to communicate the security level to the Boot ROM/Boot Loader. The Boot Loader then takes the appropriate action to program the DBGEN.
3. The Boot Loader can be used to enable/disable the NIDEN, SPIDEN, and SPNIDEN bits.

> **Note:** When the SecureJtagControl bit in the BCT is either not provided or 0, then NIDEN remains at 1 while DBGEN, SPIDEN, and SPNIDEN remain at 0.

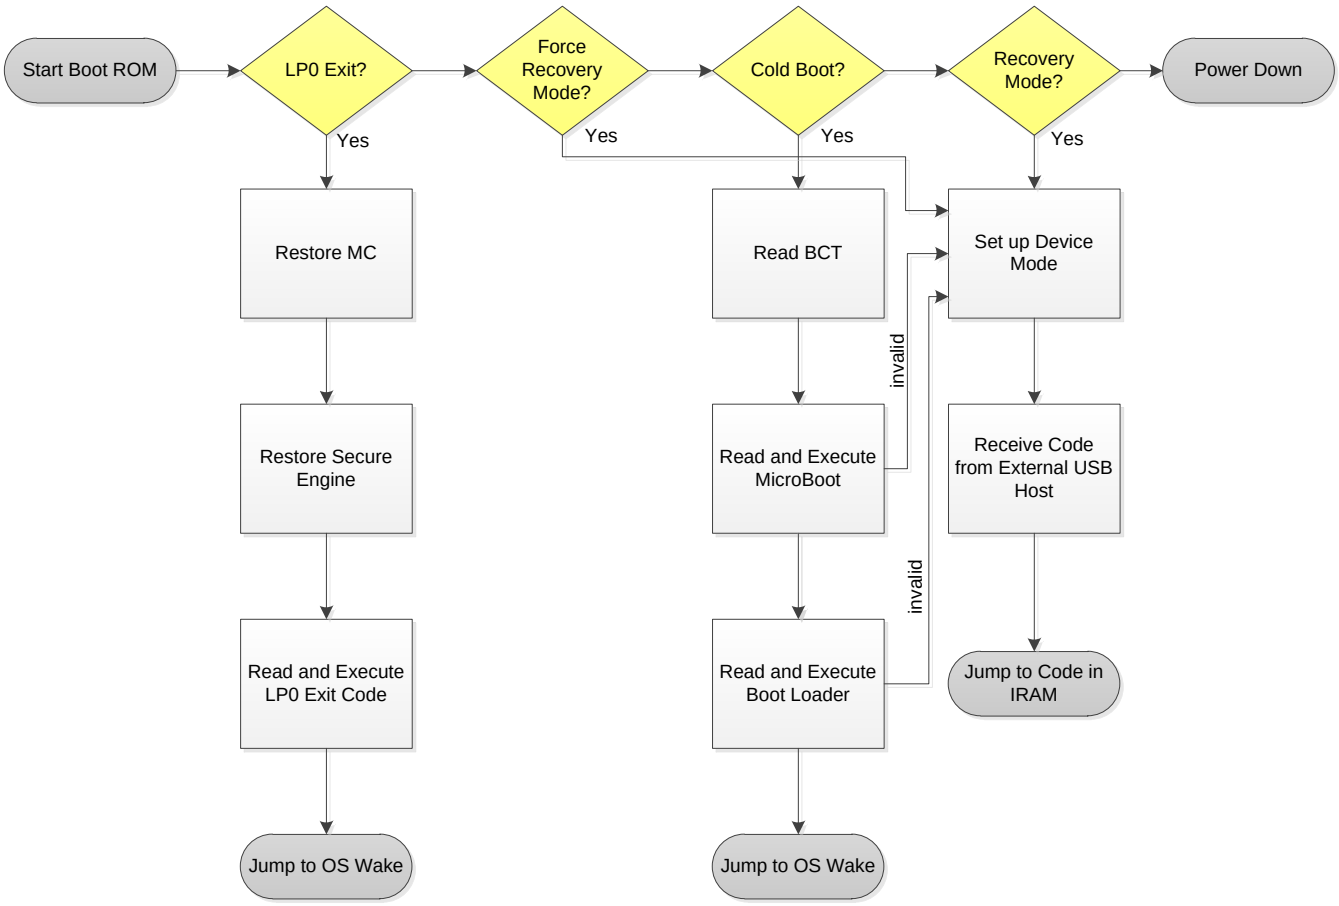
12.1.7 LP0 Exit (LPX) Code

During LP0 exit, Boot ROM configures MC/EMC (by restoring their context from PMC scratch registers) and authenticates LP0 restore code. After that, the Boot ROM hands the control to LPX which was loaded into DRAM (by the Boot Loader) during initial cold boot. The LPX executes on the AVP, communicates with the outside world solely via the PMC scratch registers, and is responsible for start up of the main CPU and hand off to the OS wake vector.

Since LPX executes on AVP, it cannot access TZ-only registers. Also, it cannot access platform-specific data from DRAM (LPX is location independent code) -- LPX can use PMC-scratch or fuses for platform-specific data.

12.2 Boot Sequences

Figure 33: Boot Sequences Overview



12.2.1 Cold Boot

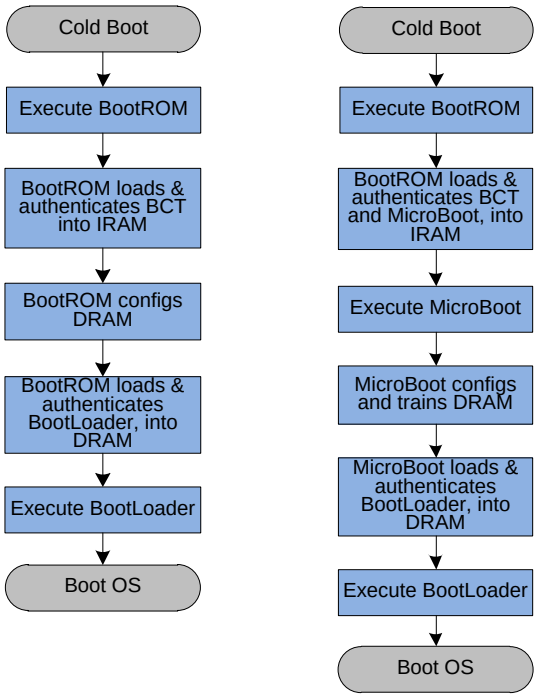
Cold Boot refers to the full boot sequence occurring upon full system reset. Cold boot is normally an uncommon occurrence on tablets and phones, and is not optimized for latency. However, some embedded applications and alternate operating systems will require a faster boot, and may require MicroBoot and other techniques for fast boot.

- [HW] AVP comes out of reset at the Tegra oscillator frequency (12-48MHz), begins executing Boot ROM from IROM.
- [BR AVP IROM] Raise AVP frequency to 216 MHz.
- [BR AVP IRAM] USB Dead Battery Charging - If the battery is dead, and device is connected to a USB Host, stop boot process and charge battery.
- [BR AVP IROM] Configure boot media based on fuses and straps.
- [BR AVP IROM] If PKC authentication, then Read and Validate Public Key from boot media into IRAM. (**Note**: Boot authentication can be PKC (public key) or SBK (symmetric key) based on Fuse. All of the boot components will be authenticated by the same option.)
- [BR AVP IROM] If invalid, go to Recovery Mode.
- [BR AVP IROM] Read and authenticate BCT from boot media into IRAM. (**Note**: After every DMA (from boot media to IRAM), the Boot ROM needs to wait 1 µs before using DMA-ed data)
- [BR AVP IROM] If invalid, go to Recovery Mode.

- [BR AVP IROM] Perform BCT-based system configuration. Optimize boot media performance.
- [BR AVP IROM] Read and authenticate MicroBoot from boot media into IRAM. *****
- [BR AVP IROM] If invalid, go to Recovery Mode.
- [BR AVP IROM] Lock down security. Restrict read access to SE key slots. (**Note**: Even if the Boot ROM goes to Recovery Mode, lock down still happens as the last step of the Boot ROM. This is not a security risk because commands RCM can use are not considered secure risk.)
- [BR AVP IROM] Jump to MicroBoot in IRAM.
- [MB AVP IRAM] Configure DRAM at each supported FV point.
- [MB AVP IRAM] Switch to highest DRAM frequency.******
- [MB AVP IRAM] Configure DRAM
- [BR/MB AVP IRAM] Read and Authenticate Boot Loader and TSEC-RNG from boot media into DRAM.
- [BR/MB AVP IRAM] If invalid, go to Recovery Mode.
- [BR/MB AVP IRAM] Jump to Boot Loader initial AVP code in DRAM.
- [BL AVP IRAM] Trigger TSEC to generate random numbers for keys
- [BL AVP DRAM] Initialize and bring bootstrap CPU core out of reset. Switch to executing the Boot Loader on main CPU.
- [BL CPU DRAM] OEM-specific platform initialization.
- [BL CPU DRAM] Display Splash Screen
- [BL CPU DRAM] Load and authenticate LP0 Exit Code.
- [BL CPU DRAM] Read and optionally authenticate OS boot sector.
- [BL CPU DRAM] Lock any Boot Loader-privileged security / sticky bits.
- [BL CPU DRAM] Hand off to OS.
- [OS CPU DRAM] Boot OS.
- [OS CPU DRAM] MSENC FW, and TSEC FW.

Note:	The MicroBoot layer is optional in Tegra 4 processors. If MicroBoot is not used, then steps listed under MicroBoot can be done by the Boot Loader.

Figure 34: Cold Boot Flow (without and with MicroBoot)



12.2.2 LP0 Exit

In most design applications except some embedded applications, Tegra 4 processors will spend the most time in LP0. LP0 Exit will therefore be the most common form of reset. Exit latency is critical to overall system responsiveness. There LP0 Exit process must not depend on things such as access to the boot media, or soft RSA for LP0 restore code authentication. Any required information must be stored in the PMC scratch registers or in DRAM itself, and hardware RSA should be used for LP0 restore code authentication.

- [HW] AVP comes out of reset at osc (normally 12 MHz), begins executing the Boot ROM from IROM.
- [BR AVP IROM] Raise AVP frequency to 216 MHz.
- [BR AVP IROM] Detect LP0 Exit.
- [BR AVP IROM] Restore “safe” memory configuration from PMC registers.
- [BR AVP IROM] Restore optimized memory configuration from DRAM.*****
- [BR AVP IROM] Initiate SE restore.
- [HW] Decrypt and install SE state from secure PMC registers.
- [BR AVP IROM] Authenticate LP0 Exit Code.
- [LX AVP DRAM] Initialize bootstrap CPU core. Start executing LP0 Exit Code on main CPU.
- [LX CPU DRAM] OEM-specific platform restore.
- [LX CPU DRAM] Hand off to OS wake vector.

Note: * This step may be required if DRAM training is employed

12.2.3 Recovery Mode

When the boot media is blank or corrupted, Recovery Mode (RCM) can be used to inject code into IRAM to begin a re-installation process. In Recovery Mode, the USB controller is initialized into device mode. Recovery code provided by an external USB host running NVIDIA software will be loaded into and run from IRAM. Recovery Mode is the mechanism by which boot components are initially signed and installed to the boot media during manufacturing.

- [BR AVP IROM] RCM initiated during cold boot by
  - Detect hardware strap, or
  - Detect invalid boot assets, or
  - Detect designated PMC scratch bit set.
- [BR AVP IROM] Initialize USB into device mode. (Note: only USB2 (also known as Synopsys USB IP) can be used for recovery)
- [BR AVP IROM] Receive code from external USB host into IRAM.
- [BR AVP IROM] Check integrity and optionally authenticate recovery code.
- [BR AVP IROM] If invalid, power down.
- [BR AVP IROM] Execute recovery code from IRAM.

12.3 Functional Requirement

12.3.1 Boot Security

The Boot ROM is the root-of-trust for the boot process. The Boot ROM is effectively hard-wired onto the chip, and is always the first piece of code to run upon reset. Each boot component has the ability to carry forward the chain-of-trust by authenticating and optionally decrypting the next boot component.

Sensitive information in the system including the readability of AES keys are cleared or locked via sticky bits before exiting the Boot ROM. Note that the AES keys, even when readability is disabled, can remain present within designated key slots of the SE so that they may be used to authenticate/decrypt later boot components.

In order to grant certain privileges to the Boot Loader, some access items may be locked down later by the Boot Loader before handoff to the OS. One example is that locking writability of the media in a protected boot design may be done by the Boot Loader so that it can provide system upgrade/recovery services if needed.

In addition to the hardware AES (symmetric key cryptography) engine located within the SE. The SE adds hardware RSA (public/private key cryptography – also known as PKC) implementation. The hardware RSA adds hundreds of microseconds of latency per signature calculation.

Tegra 4 processors can use either AES or RSA boot authentication based on a fuse setting.

12.3.1.1 AES Secure Boot

In case AES is used:

- Security depends upon keeping the key(s) hidden from OS/application software,
- Security is improved by employing as many different keys as possible; ideally a unique key per individual system, and
- Existing signing tools and manufacturing flow support this model.

Tegra 4 devices use 128-bit SBK (Secure Boot Key) fuses to store per system unique AES keys. The SBK fuses need to be programmed in a secure facility, which makes SBK boot authentication problematic for some customers. An alternative is to use RSA authentication.

The boot code can be optionally encrypted. The encryption/decryption is also done using same SBK keys.

12.3.1.2 RSA (also known as PKC) Secure Boot

In case RSA is used:

- The public key may remain present in memory; hiding it is not necessary,
- Security depends upon the OEM keeping their private key a secret, and
- Signing tools and manufacturing flow will need to change significantly.

The 2048-bit of public key is stored in the flash device. The 256-bit SHA hash of public key is stored in on-die fuses (PKC fuses) to validate public key from the flash device. The private key remains with OEM. Therefore, we cannot sign any generated code/information (which would require a private key) on-the-fly using PKC. As a result, any update to BCT, MicroBoot, or Boot Loader must be signed ahead of time by OEM (or OEM server for OTF/OTA updates). Anything which cannot be signed ahead of time will have to be either unsigned (if not a security risk, e.g., NAND bad-block-table), or handled differently (e.g., NAND start-sector-address which was generated as part of Boot Loader-information).

With RSA secure boot, LP0 restore code will be signed (as a separate component) using PKC. And at the LP0 exit, LP0 restore code will be authenticated using PKC.

With RSA secure boot, encryption/decryption (if required) would still be done using SBK keys.

12.3.2 USB

12.3.2.1 USB Dead Battery Charging

When the battery is dead or too weak to support a system boot, then it may be necessary to use power from a USB host or charger to boot the system and/or recharge the battery.

Tegra systems with a dead battery (and not connected to an AC power adapter) are may be able to boot when connected to a USB host, if they can operate within its power restrictions. Prior implementations assumed that the USB VBUS can provide up to 500 mA. This is not always in compliance with the USB specification. To comply with the specification, we can only assume that USB VBUS can provide up to 100mA, and only after negotiating with the host can the Tegra 4 system draw more than 100mA current from the USB VBUS.

Tegra 4 devices provide support for USB dead battery charging specification compliance. The compliance support is enabled by a fuse (which is default to disabled).

If compliance is enabled, then using 100mA is not enough to power LCD backlight, mass storage, DRAM, etc. Therefore USB charging support is implemented in the early Boot ROM, which provides support for negotiating with the charger (but does not provide support to negotiate with the host for being enumerated as high current *device*). The Boot ROM starts with the assumption that the USB VBUS can always provide 100mA current. It negotiates with the charger for higher current. If the host can provide >500mA current then boot continues; otherwise boot stalls and remains stalled for as long as dead/weak battery condition persists.

If the OEM wishes to have a different dead battery charging solution, they can have the Boot ROM based USB dead battery charging solution disabled (by not setting fuse) and implement their own solution in the MicroBoot. This is a possible option if the OEM platform is capable of powering the boot media (which is required for loading MicroBoot) while remaining under a 100mA power budget.

12.3.3 Watchdog Timer Usage

The Watchdog Timer (WDT) is intended to cover the situations where the system hangs in the boot phase for unexpected reasons. It may be due to flash device problem, power noise, or signal noise margin, or soft error, or some other error condition. The Watchdog Timer forces a reboot in these circumstances.

To be able to detect such hangs and reboot the system, an internal watchdog timer can be used. Tegra 4 devices provide five WDTs (one each for CPU0/1/2/3 and one for AVP) which can be configured to detect such hangs. Any one of these WDTs can be configured to generate a WDT interrupt (at first expiry of the timer) and/or reset the system (at fourth expiry of the timer).

If the WDT-enable fuse is set, then (at both cold and warm boot), the Boot ROM enables WDT0 as-early-as possible in the Boot ROM boot phase. If the WDT expires, then the PMC resets the *chip* similar to a thermal shutdown reset. As a result of this reset, the system reboots. During the reboot, the Boot ROM reads the cause of reset. If it was a WDT caused reboot and the PMIC command has been stored in PMC scratch, then the Boot ROM performs a *system* reset via the PMIC.

At cold boot, when the Boot ROM transfers control to the Boot Loader (or MicroBoot), then it leaves WDT4 enabled. The Boot Loader is expected to keep WDT4 enabled all through the Boot Loader (at AVP) phase, halt WDT4 when AVP is halted, and start WDT0 when the Boot Loader on CPU0 takes control. The Boot Loader will disable WDT0 just before transferring control to OS. Similarly, at warm boot (LP0 exit), when the Boot ROM transfers control to LP0 restore, then it leaves WDT4-enabled. LP0 restore is expected to keep WDT4 (for AVP)/WDT0 (for CPU0) enabled all through restore phase, and disable it just before transferring control to OS.

12.3.4 Thermal Shutdown Requirement

If the chip temperature is so high that it can cause permanent physical damage or chip cannot reliably function, then it is necessary to "shut down" the chip. For this purpose, soc_therm unit provides a mechanism which (if enabled) detects thermal shutdown condition (THERMTRIP) and asserts a signal to PMC to request thermal shutdown.

At the assertion of THERMTRIP condition, PMC hardware (if enabled) resets the *chip*, but stores the cause of reset (in APBDEV_PMC_RST_STATUS register) and retains contents of scratch registers. As a result of this reset, system reboots (in a similar manner to a cold boot). During this reboot, the Boot ROM reads the cause of reset, and if it was THERMTRIP caused reboot then the Boot ROM performs *system* reset or system shutdown via PMIC or GPIO. To avoid PMIC specific code in the Boot ROM, Boot Loader (at cold boot) stores the PMIC command (for system reset or shutdown) in PMC scratch, and the Boot ROM simply sends that command to PMIC.

THERMTRIP Detection Enable

To enable THERMTRIP, soc_therm has to be configured with sensor calibration values (from fuses) and THERMTRIP threshold (usually from boot media). Software will configure soc_therm to enable THERMTRIP detection, enables PMC thermal reset option, and stores THERMTRIP threshold in the PMC scratch register.

At LP0 exit, software will reconfigure soc_therm calibration values from fuses (or DRAM), and THERMTRIP threshold from PMC scratch (or DRAM depending upon whether LP0 restore of Kernel restore restores soc_therm).

12.3.5 CPU Cold Boot

At cold boot, the Boot Loader (on AVP) determines which CPU cluster (fast or shadow) to boot from. At boot time, the OS needs to discover the maximum number of CPUs, and allocate resource accordingly. So for this reason Tegra boots with the fast cluster (cluster0) to be able to discover maximum number of CPUs. An optimization can be to start boot from shadow cluster (cluster1), for example in the case of not enough battery power, or very high temperature.

At power-on-reset, all of the CPUs (fast and shadow) are power gated. In addition, shadow L2 is power gated, and CPU rail is off. Refer to PMC_PWRGATE_STATUS register description for the default of CPUs power status.

The Boot Loader powers up the CPU rail by configuring the PMIC (via I2C). At this stage CPU rail's status in APBDEV_PMC_PWRGATE_STATUS[CRAIL] would still be power-off (since the CPU rail is powered up without PMC hardware involvement). The Boot Loader needs to ensure that APBDEV_PMC_PWRGATE_STATUS[CRAIL] gets updated to power-on. It can be done as follows.

1. Power up the CPU rail by configuring PMIC via I2C
2. Configure PMC's CPU power good timer

Note if this configuration is done before next step (step #3), then the Boot Loader does not have to wait for CPU rail power good (instead it can just wait for PMC_PWRGATE_STATUS[CRAIL] status to be power on – step #4, which would be more efficient).

3. Request PMC to power up CPU rail (by writing PMC_PWRGATE_TOGGLE)

   At this stage cpu_pwr_req pad is disabled, so this power up request just updates the PMC status
4. Wait for PMC_PWRGATE_STATUS[CRAIL] status to be powered on
5. Enable cpu_pwr_req (by writing PMC_CNTRL)

After CPU rail power up, the Boot Loader power ungates CPU0 which can be done as follows.

1. Power ungate CPU0 (by PMC_PWRGATE_TOGGLE register write)
2. Removes CPU rail clamp (by PMC_REMOVE_CLAMP_CMD register write)
3. Enables CPU clock (by CAR register write)
4. Deassert C0NC reset followed by CPU0 reset (by CAR register write)

   Immediately after reset deassertion, CPU0 will start fetching from reset vector

Note, if the hardware default of CPU reset vector needs to be updated, then the Boot Loader (on AVP) will have to configure CPU reset vector (in EVP_CPU_RESET_VECTOR register) before transferring control to the Boot Loader (on CPU0).

After transferring control to CPU0, the Boot Loader (on AVP) puts AVP into halt. The Boot Loader (on CPU0) boots the CPU0, and then transfers control to OS. The CPUs other than CPU0 are powered up by OS.

12.3.6 IRAM Requirements

The Tegra 4 processor boot process currently requires 256KB of IRAM space.

There are two main requirements for IRAM space, both of which are during cold boot and largely depend upon MicroBoot size. One is during the Boot ROM phase, where the MicroBoot binary image must be resident, and the other is during MicroBoot execution phase, where both the code and data footprint of MicroBoot must be considered.

These are the current footprint sizes:

	Tegra 4 Estimate (KB)
Boot ROM phase footprint	216
MicroBoot phase footprint	170

12.3.7 Boot Devices

Tegra 4 series processor supports boot devices listed in the following table. Boot device frequency/mode requirements are also listed in the following table.

Table 41: Boot Devices Frequency/Mode Targets

Device	BR Frequency	MB/BL Frequency	Notes
eMMC	18MHz SDR (PPLP/DivN)	52MHz DDR 200MHz SDR	Tegra 4 devices use @52MHz DDR (=104Mt/s) 200 MHz SDR.
SPI	OSC/2	Device limited (<50MHz)	The Boot ROM does not support the SPI FAST_READ command, which is normally required for SPI > 20 MHz. Thus SPI > 48 MHz of OSC frequency is not supported unless the SPI device works without FAST_READ.

12.4 Performance Requirements

The following are boot performance targets followed by reference measurements from previous chips. These targets assume the AVP coming out of reset at 216 MHz.

12.4.1 Cold Boot Latency

TBD

12.4.2 LP0 Exit Latency

Tegra 4 LP0 Exit latency target:

- 5 ms from wake event to OS wake vector.

12.5 TSense Reset Handler

The TSense reset is handled at the beginning of the Boot ROM secure ROM entry. The PLLP and PMC clocks are available for this reset.

The SCRATCH54 and SCRATCH55 registers deal with PMIC board-specific support (these are defined in the Power Management Controller section). The PMIC driver configures them. The I2C controller is used to communicate to the PMIC.

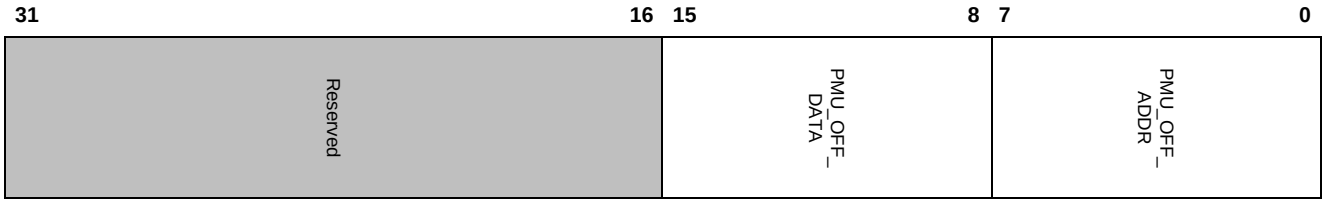
12.5.1 Scratch Registers

The SCRATCH54 and SCRATCH55 registers are used in the TSense reset handler in I2C mode.

Note: The Reserved bits must be set to 0.

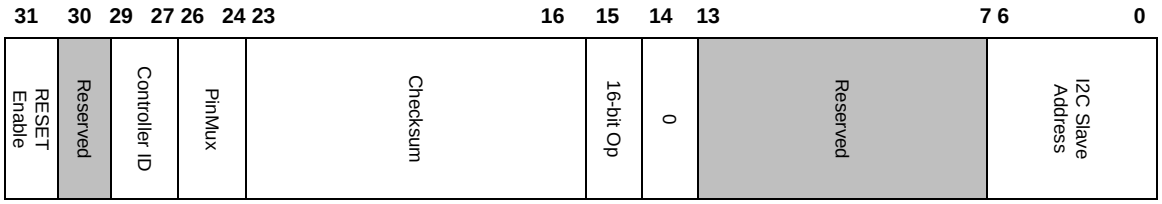
SCRATCH54 (PMIC Scratch Register A)

In I2C mode, the SCRATCH54 register bits are configured as shown below.



12.5.1.1 SCRATCH55 (PMIC Scratch Register B)

In I2C mode, the SCRATCH55 register bits are configured as shown below.



12.5.2 Pinmux Support

All Standard I2C pinmux signals are supported as shown for the three configurations below. Mixed pinmux configurations are not supported; for example, GEN1_I2C_SCL -> I2C1_CLK, SPDIF_IN -> I2C1_DAT is not supported. The I2C peripheral clock is targeted at 100 kHz (Standard mode). The Controller ID and PinMux columns in the following table are from the SCRATCH55 register.

I2C Controller	Controller ID	I2C Signals	Config 1	Config 2	Config 3
			PinMux = 0	PinMux = 1	PinMux = 2
I2C_1	0	I2C1_CLK	GEN1_I2C_SCL	SPDIF_OUT	SPI2_CS1_N
		I2C1_DAT	GEN1_I2C_SDA	SPDIF_IN	SPI2_CS2_N
I2C_2	1	I2C2_CLK	GEN2_I2C_SCL	-	-
		I2C2_DAT	GEN2_I2C_SDA	-	-
I2C_3	2	I2C3_CLK	SDMMC4_CMD	CAM_I2C_SCL	-
		I2C3_DAT	SDMMC4_DAT4	CAM_I2C_SDA	-
I2C_4	3	I2C4_CLK	DDC_SCL	-	-
		I2C4_DAT	DDC_SDA	-	-
I2C_PMU	4	I2CPMU_CLK	PWR_I2C_SCL	-	-
		I2CPMU_DAT	PWR_I2C_SDA	-	-

12.5.3 Checksum Calculation

Every byte in the SCRATCH54 and SCRATCH55 registers must add to 0. The two scratch registers contain 8 bytes total.

To calculate the checksum:

- Write 0 to the 8-bit checksum byte
- Add bytes 0 through 7 where: sum = ~sum+1 (2’s complement of sum)
- Write sum to the 8-bit checksum byte.

12.6 Boot ROM Fuses and Straps

Table 42: Boot ROM Related Fuses

Number of Bits	Location	Function	Values / Notes
1	FUSE_SECURITY_MODE	OdmMode and JTAG disable	Boolean
1	FUSE_PRODUCTION_MODE	ProductionMode	Boolean
1	FUSE_FA	Failure Analysis Fuse Mode Set	Not-zero = FA
6	FUSE_OPT_FAB_CODE[5:0]	Fab code	
32	FUSE_OPT_LOT_CODE[31:0]	Lot code	
4	FUSE_OPT_VENDOR_CODE[3:0]	Vendor code	
6	FUSE_OPT_WAFER_ID[5:0]	Wafer ID	
9	FUSE_OPT_X_COORDINATE[8:0]	X coordinate	
9	FUSE_OPT_Y_COORDINATE[8:0]	Y coordinate	
128	FUSE_PRIVATE_KEY0 FUSE_PRIVATE_KEY1 FUSE_PRIVATE_KEY2 FUSE_PRIVATE_KEY3	Secure Boot Key (SBK)	128-bit AES key
32	FUSE_PRIVATE_KEY4	Device Key (DK)	32-bit key
14	FUSE_BOOT_DEVICE_INFO[13:0]	Boot Device Config	See below
3	FUSE_RESERVED_SW[2:0]	Boot Device Select	0x0 = eMMC 0x1 = Reserved 0x2 = SPI 0x3 = Reserved 0x4 = Reserved 0x5 = Reserved 0x6 = Reserved 0x7 = Reserved
1	FUSE_RESERVED_SW[3]	Skip Device Selection straps	Boolean
8	FUSE_SKU_INFO[7:0]	SKU	Only [3:0] used in the Boot ROM
	FUSE_RESERVED_SW[7:6]	SW Reserved	
	FUSE_RESERVED_SW[5]	ENABLE_WATCHDOG	ENABLE_WATCHDOG = 1 enables watchdog. This fuse should be set to 1 for ODM mode only
3	FUSE_RESERVED_SW[4]	SW Reserved	ENABLE_CHARGER_DETECT
256	FUSE_PUBLIC_KEY0 FUSE_PUBLIC_KEY1 FUSE_PUBLIC_KEY2 FUSE_PUBLIC_KEY3 FUSE_PUBLIC_KEY4 FUSE_PUBLIC_KEY5 FUSE_PUBLIC_KEY6 FUSE_PUBLIC_KEY7	Public key hash	SHA-256 (256 bits) hash of public key modulus
1	FUSE_PKC_DISABLE	PKC disable control	Not-zero = PKC disable

Table 43: Fuse Boot Device Information

Device	Fuse Bits	Description	Values
eMMC	13	Reserved	Ignored; set to 0x0
	12:10	MultiPage support	0x0 = default Single page read (512 Byte)
			0x1 = Multi 2 page read (1024 Byte)
			0x2 = Multi 4 page read (2048 Byte)
			0x3 = Multi 8 page read (4096 Byte)
			0x4 = Multi 16 page read (8192 Byte)
			0x5 = Multi 32 page read 16384 Byte)
	9:6	Clock Divider PLLP clock @ 216MHz	0x0 = default clock divider 11 (clock @ 19.63 MHz)
			0x1 = clock divider 10 (clock @ 21.6 MHz)
			0x2 = clock divider 9 (clock @ 24 MHz)
			0x3 = clock divider 8 (clock @ 27 MHz)
			0x4 = clock divider 7 (clock @ 30.8 MHz)
			0x5 = clock divider 6 (clock @ 36 MHz)
			0x6 = clock divider 5 (clock @ 43.5 MHz)
			0x7 = clock divider 4 (clock @ 27 MHz)
			0x8 = clock divider 3 (clock @ 36 MHz)
			0x9 = clock divider 2 (clock @ 27 MHz)
	5	VDDIO_SDMMC4 Pads voltage	0x0 = 1.8V (power on default)
			0x1 = 1.2V
	4	Disable Boot Mode	0x0 = Boot mode On
			0x1 = Boot mode Off
	3:2	Voltage Range	0x0 = Query Voltage
			0x1 = High Voltage
			0x2 = Dual Voltage
			0x3 = Low Voltage
	1	DDR Mode Selection	0x0 = Normal
			0x1 = DDR
	0	Data bus width	0x0 = 4 bits
			0x1 = 8 bits
NAND	13:12	Toggle DDR	0x0 = Discovery (valid for <= 42nm NAND)
			0x1 = Disabled
			0x2 = Enabled
			0x3 = Reserved
	11:10	ErrorFree NAND Controller Version	0x0 = Disable Error Free
			0x1 = EF NAND 1.0
			0x2 = EF NAND 2.0
			0x3 = EF NAND 3.0
	9	BCH sector size	0x0 = 512 bytes
			0x1 = 1024 bytes
	7:8	Main ECC offset	0x0 = 4 byte

Device	Fuse Bits	Description	Values
			0x1 = 8 bytes
			0x2 = 12 bytes
			0x3 = 16 bytes
	6	Page/Block size offset	Page/Block size from read id is multiplied by 2^Offset to correct the interpretation of the data (< = 42nm NAND support).
			0x0 = 0
			0x1 = 1
	5	ONFI disable	0x0 = ONFI support on
			0x1 = ONFI support off
	4:3	Data bus width	0x0 = Discovery (valid for > 42nm NAND)
			0x1 = x8
			0x2 = x16
			0x3 = reserved
	2:0	ECC strength	0x0 = Discovery
			0x1 = BCH4
			0x2 = BCH8
			0x3 = BCH16
			0x4 = BCH24
			0x5 = ECC Off
SPI Flash	13:1	Reserved	Ignored; set to 0x0
	0	Page size (Block size is fixed to 32K due to block erase command's limitation)	0x0 = 2K
			0x1= 16K (Boot ROM data buffer size). This will be used for performance optimization.

Table 44: Boot ROM Straps

Number of Bits	Location	Function	Values	Notes
2	RAM_CODE[1:0]	Selects SDRAM configuration set within the BCT	STRAPPING_OPT_A[5:4]	-
2	RAM_CODE[3:2]	Selects secondary boot device configuration set within the BCT	STRAPPING_OPT_A[7:6]	-
1	FORCE_USB_RECOVERY	Forces USB Recovery Mode	STRAPPING_OPT_A[25]	-
4	BOOT_SELECT[3:0]	Device Selection	STRAPPING_OPT_A[29:26]	-
			0x0 = eMMC x4 BootModeOn	Maps to SDMMC with config = 0x0000
			0x1 = eMMC x8 BootModeOn	Maps to SDMMC with config = 0x0001
			0x2 = Reserved	Reserved
			0x3 = NAND	Maps to Legacy NAND with config = 0x1000
			0x4 = NAND with block and page offset = 1 (< 42nm NAND)	Maps to NAND with config = 0x00C8
			0x5 = Reserved	Reserved
			0x6 = Reserved	Reserved

Number of Bits	Location	Function	Values	Notes
			0x7 = EF NAND with block and page offset = 1(< 42nm NAND)	Maps to EF NAND with config = 0x08C8
			0x8 = SPI Flash	Maps to config with page size = 2K
			0x9 = Reserved	Reserved
			0xA = eMMC x4 BootModeOFF	Maps to SDMMC with config = 0x0010

			0xC = eMMC x8 BootModeOFF Clk Divider 4	Maps to SDMMC with config = 0x0111
			0xD = SATA	Maps to SATA with config = 0x0000
			0xE = eMMC x8 BootModeOFF Clk Divider 6	Maps to SDMMC with config = 0x0191
			0xF = Use fuse data	Maps to actual fuse values

13.0 HOST SUBSYSTEM

The Host1x unit provides the programming interface to various graphic and video engines, and display. In addition to Host1x's interfaces with these units, it also has an IP interface to the ARM7 crossbar (xbar), TSEC, and a memory interface. Commands are either gathered from a push-buffer in memory or provided directly by the CPU, and then supplied to the clients behind Host1x via Host1x channels. The channels also provide a means of synchronization between software and any individual block or amongst the blocks themselves via hardware Sync Point signals (syncpts).

13.1 Glossary

- **Channel** – A piece of hardware that provides a programming interface to one or more classes. A channel contains a sequence of commands embodied in a command FIFO. This sequence of commands can also be thought of as a thread of execution and of a single context. There exists only one sequence of commands or context per channel. That is to say, there is no hardware-managed context switching within a single channel.
- **Command FIFO** – Holds channel commands supplied by the CDMA or PIO accesses. It is stalled by synchronization methods, backpressure from its destination client, or ownership of the destination client by a different channel
- **Protected Channel** – Dedicated channel used by software for flow control.
- **Channel Commands** – Entries in the command FIFO. Commands take a common form interpretable by Host and are used for 3 main functions: controlling class ownership and class virtualization of the channel; command expansion via gather commands; and issuing class methods.
- **Client, device, resource** – A piece of hardware that resides behind Host, connected via the HRD and HRW buses. Client is the preferred terminology for this document. Generally mapped one-to-one with a class, although this is not a strict requirement.
- **Method** – An operation on a class. The most common example is a single register write.
- **Class method –** A method that belongs to an unspecified class.
- **Host method** – A method that belongs to the Host class.
- **Class** – An abstraction of a client, device, or resource. It is a collection of methods. A class can only be owned by multiple channels, but only one channel may actively be using any class, which is known as a channel's working class. The transfer of working class from one channel to another is known as a context switch, which is managed by Host.
- **Class ID** – A unique tag corresponding to each class.
- **SetClass** – A channel command that takes a class ID as an argument. SetClass is the sole means to indicate the current virtualization of the channel. It also the sole means that a channel can acquire ownership of a class. Subsequent channel commands are directed towards this class.
- **Gather** – A channel command to gather contiguous chunks of memory and inserts it into the command stream.
- **Nonincrement** – A channel command that specifies an offset and a count. The offset specifies a method in the current class and the count indicates the number of subsequent words to be written at that offset.
- **Increment** – A channel command that specifies an offset and a count. Increment works like nonincrement, except the offset is incremented by one on each on each write.
- **Mask** – A channel command that specifies an offset and a mask. A mask command works much like increment and non-increment, except the offsets are calculated by looking at the bits set in the mask. The bit position indicates the relative offset from the specified offset in the command. Mask expects the number of words to follow to be equal to the number of bits set in the mask.
- **Channel switch** – A transfer of ownership of a client from one channel to another; a type of context switch. Sometimes a source of confusion, this is not a transfer of ownership of a channel, but of a client. This is the preferred narrowed nomenclature to context switch in order to avoid confusion.

- **Class switch** – A change in the current in the active class of a client; a type of context switch. In the event that a class switch also involves a channel switch, channel switch is the preferred declaration.
- **Context switch** – A Host event where it facilitates a client's state transition. A context switch is either a channel switch or a class switch.
- **CDMA** – The command DMA. It is responsible for reading commands from memory and supplying them to all channels. It starts from the address in the channel's DMASTART register and continues until it reaches the address in the channel's DMAPUT register.
- **DMAGET** register – Holds the current address of the CDMA. One exists per channel.
- **DMAPUT** register – Holds the end address of a command stream in memory. One exists per channel.
- **DMASTART** register – Holds the start address of a command stream in memory. One exists per channel.
- **Direct register access –** Access to a client initiated by the CPU. If a channel and the CPU initiate a data transaction to the same client at the same time, the CPU gets priority. Direct register accesses are orthogonal to channels in regards to client ownership.
- **Host Master –** General term to indicate an entity that can control Host. The current list is the MPCore™, COP, and TSEC.
- **Push-buffer** – A set of commands residing contiguously in memory. It is a communication method between the processor and Host. Commands are placed at the end of the buffer and a pointer is updated in Host.
- **Indirect register access** – Access to a client initiated by the CPU, but requires two Host register accesses. This is deprecated in the SOC version of the host; it comes from the companion-chip mode where fixed-latency interfaces to the CPU may exist. Like direct register accesses, indirect takes priority over channel transactions. Indirect register accesses must be tied a channel because they require a read return FIFO.
- **WAIT** – A host method that takes a single vector argument. It is used in conjunction with syncpt. A WAIT stalls the command FIFO until the supplied vector intersects the RAISE register at all.
- **Tick Count** – Running count of the Host clock after it has been enabled.
- **Sync Point (Syncpt)** – A counter used for synchronization. Every time a specified event occurs, the counter is incremented. A channel can wait until the syncpt attains a specified value, or an interrupt can be generated when a specified value is reached.
- **Teardown** – Can be either a module or channel teardown. Essentially, it means all links and references within the Host between the specified module or the specified channel are removed and reset.

13.2 Features

13.2.1 Class Based Programming

Desktop GPUs support a programming interface that is based on writing to offsets within a "class" that implements a function, rather than to specific register offsets and formats.

By using "class" interface register offsets/formats need not to remain fixed so there is nothing chip specific in the API. This will allow both hardware flexibility and software driver compatibility.

13.2.2 Command Buffer DMA

To maximize the Host1x bandwidth, it is important to burst as many write cycles as possible, which requires processor to first combine writes. The write buffering typically requires sequential offsets to be written and also may not follow strict programming order. The CPU will first store this buffered data directly to memory and then program Host1x engine to DMA it.

13.2.3 Multiple Channels

A channel is a thread of execution within Host1x. Similar to a multithreaded CPU, a channel helps defining a context that can be used to allow multiple users of the Host1x and plays a role in context switching.

A channel switch does not always require a client module context switch. There will be a state change within the Host1x, but if channels have non-overlapping usage (e.g., possibly a 3D channel and MSENC encode channel), there may be no need to context switch any Host1x client module.

13.3 Hardware Features

13.3.1 Channels

The Tegra® 4 series processor has nine Host1x channels. Each channel has a set of registers and a command FIFO. Each channel can be associated with one or more Host1x clients. The channel is the primary means of delivering commands to clients, which is described in the Host1x Programming Model section.

13.3.1.1 Channel Registers

Channel registers are broken into two functional groups: one grouping is associated with the command FIFO and command delivery to clients; the other grouping is associated with register and memory access.

CDMA Registers

- **HOST1X_CHANNEL_DMASTART_0:** This register triggers a DMA fetch from memory for this channel, if PUT register does not equal the GET register.
- **HOST1X_CHANNEL_DMAPUT_0:** This register triggers a DMA fetch from memory for this channel, if the PUT register does not equal the GET register. This address is relative to the DMASTART base address. It does not support byte writes. All 4-byte data need to be programmed.
- **HOST1X_CHANNEL_DMAGET_0:** This register tracks the MC offset, which DMA engine has read. It gets incremented as entries are loaded from the channels command buffer into the FIFO. This address is relative to the DMASTART base address.
- **HOST1X_CHANNEL_DMAEND_0:** This is the boundary of illegal addresses (either end of push-buffer or end of physical memory). This is designed to prevent DMA from prefetching illegal addresses. If DMA reaches this address before seeing a RESTART, it will stop. This would be a software error condition.
- **HOST1X_CHANNEL_DMACTRL_0:** The various fields of DMA control register are described as below:
  - **DMAGETRST**: Reset GET pointer to '0'. Useful for cleaning up crashed channels. DMAGET value is not updated instantly. It takes 4 cycles between programming of reset and valid DMAGET.
  - **DMAGETINIT**: Reset GET pointer to the value of DMAPUT when DMAGETRST is asserted.
  - **DMASTOP**: Stop DMA from fetching on this channel.

> **Note:** A Command DMA channel needs to be enabled for PIO-gather to work.

Access Registers

- **HOST1X_CHANNEL_INDOFF_0 & HOST1X_CHANNEL_INDOFF2_0:** The INDOFF and INDOFF2 registers (along with INDCNT and INDDATA) are used to indirectly read/write modules outside the host. If AUTOINC is set, INDOFFSET value is increments by 4 on every access of INDDATA. REGFNUMEMPTY is polled to determine when valid data can be read from INDDATA. The INDOFF register has limited capability on chips with large memory maps. If the top bit of the memory address is >= 27, all of memory cannot be addressed with INDOFF. In these cases, use

INDOFF2 to set the offset while still using INDOFF to set other parameters. Always have INDOFFUPD set to NO_UPDATE in these cases.

- For register accesses, using INDOFF (with INDOFFUPD set to UPDATE) is always more efficient, since it only requires one write.
- **HOST1X_CHANNEL_INDCNT_0:** Indirect register access count used to trigger indirect reads. Holds the number of registers/memory locations that will be read out. Channels should not request more than there is space available in their output FIFO. Only the protected channel should make liberal use of this feature for speeding up context switching. For indirect frame buffer reads, each channel cannot issue more than NV_HOST1X_MAX_IND_FB_READS at once. The read data must return and be written into the per-channel output FIFO before any additional reads can be issued.
- **HOST1X_CHANNEL_INDDATA_0:** This register, when written, writes to the data to the INDOFFSET in INDOFF. For reads, a REGFNUMEMPTY number of 32-bit values can be read before needing to poll FIFOSTAT again. The per-channel output FIFO (OUTFENTRIES) is readable via this offset. A read of INDDATA will pop an entry off of the per-channel output FIFO.
- **HOST1X_CHANNEL_CMDSWAP_0:** Command swap control. Affects swapping on writes to the PIO region and the frame-buffer buffered memory write region.
- **HOST1X_CHANNEL_FIFOSTAT_0:** CFNUMEMPTY is the number of free slots available in the per-channel command FIFO (needed for PIO or polling for completion of a wait).

13.3.1.2 Channel Command FIFO

The command FIFO is loaded either the CDMA or via PIO access. PIO is mainly used for debug purposes, but it allows a Host1x master to fill the command FIFO with channel commands by writing into “command FIFO” region of the channel's address space. PIO Command FIFO accesses should not be issued while a “Gather” process is busy.

A command FIFO has a set of registers that point to a location in memory where a sequence of channel commands resides. This sequence of commands is generally referred to as a “Push-buffer”.

A Host1x master can write either to DMAPUT or DMASTART register to trigger command fetching by the CDMA. DMASTART indicates where to start fetching, and DMAPUT indicates where to stop. DMAGET is a read-only reference to the present location of the command FIFO; it is incremented when the command is popped from the command FIFO. DMAPUT and DMAGET are relative addresses to DMASTART.

DMAEND provides an upper boundary to prevent the CDMA from fetching illegal addresses; fetching will cease when DMAGET equals DMAEND.

The command FIFO can be halted by writing the DMASTOP field in the Dmactrl register. Dmactrl also provides a mechanism to reset the DMAGET pointer (*Dmagetrst* field) to either 0 or to the value of DMAPUT (Dmainitget field).

13.3.1.3 Channel Commands

Channel commands can be split into two categories:-

- **Class commands:** A class command is a mechanism to communicate a class write to a client. The channel must have an active class when processing class commands. The active class is set by a SETCL (SetClass) command.
- **DMA commands:** DMA commands control what is being fetched. They are processed at the top of the command FIFO while class commands are processed at the bottom of the command FIFO. This is because DMA commands change the command stream and must be processed before entering the FIFO.

Offsets in class commands are relative to the active class' base as they are limited to only the methods in the active class.

Channel Commands

- **SETCL (SetClass)** – A channel command that takes a class ID as an argument. SetClass is the sole means to indicate the current virtualization of the channel. It also means that a channel can acquire ownership of a class. Subsequent channel commands are directed towards this class.
- **NONINCR (NonIncrement) –** Takes an offset and count as arguments. There will be <count> datum following this class command that will be written to the specified offset. Nonincrement indicates that the offset will not be incremented per datum write.
- **INCR (Increment) –** Takes an offset and count as arguments. There will be <count> datum following this command that will be written starting at the specified offset. The offset is incremented after each write.
- **MASK (Mask) –** Takes an offset and count as arguments. The number of datum to write after the command is equal to the number of set bits in the count. Each datum is written to the specified offset plus the next active bit location. For example, a count equal to 0x5, would have 2 datum that are written to (offset+0) and (offset+2).
- **IMM (Immediate) –** Takes an offset and 16-bit datum as arguments. The 16-bit datum is written to the offset.

DMA Commands

- **RESTART (Restart or Jump) –** This command specifies an offset relative to DMASTAT. The next command fetched will be from (DMASTART + offset).
- **GATHER** – Command comprises 2 words and has arguments: offset, insert, type, count, and address. When GATHER is processed, <count> data is fetched from the address and inserted into the command stream. If the <insert> argument is enabled, it will insert either an INCR or NONINCR opcode preceding the fetched data, which is specified by <type>.

DMA commands do not need an active class, but often are processed when an active class exists. In the case of GATHER, if <insert> is enabled, there must be an active class.

13.3.1.4 Channel Control

Channel status and control resides in the synchronous register space of the Host1x address map. These registers are aliased in each channel's space. The details of these registers are as below:-

- **CH<0..8>_STATUS :** Status includes client ownership and whether the channel is blocked or not.
- **CH_TEARDOWN:** Using this register each channel can be reset, which is referred to as a teardown. This means all channel state is cleared and all client and class ownership is relinquished.
- **MOD_TEARDOWN:** Similar to channel teardown, there exists a mechanism to reset modules. Setting this register can clears all state associated with a given client/module.
- **<client>_STATUS** : This register indicates the client's currently active class.

13.3.2 Host1x Class

Host1x has its own class that can be executed from the command FIFO. It is comprised of methods to access client registers as well as methods to control channel flow.

13.3.2.1 INDOFF

The following Host1x methods operate identically to the channel registers used for indirect access. Refer to the Host Channel Registers and Indirect Register Access sections.

- INDOFF
- INDOFF2
- INDCTRL

- INDDATA

INDCNT is absent from the list above. In Host1x master-initiated indirect register reads, INDCNT is written to trigger the read. Conversely, reads from the command FIFO are trigged by a write to INDDATA. Reads issued from the command FIFO are returned to the channel's register return FIFO (return_FIFO).

13.3.2.2 DELAY_USEC

Delay_Usec stalls the command FIFO for the number of microseconds specified. This command has no impact on indirect register accesses if **not** initiated from the command FIFO. The microsecond period is calculated based on setting in the Usec_Clk register. The Usec_Clk register is programmed on the basis of Host1x clock for example if host clock is 250 MHz, then this register should be programmed to a value of 250.

13.3.2.3 TICKCOUNT

Tickcount_Hi, Tickcount_Lo, and Tickctrl can also be controlled from the command FIFO. Their operation is identical whether controlled from the command FIFO or a Host1x master.

13.3.2.4 INCR_SYNCPT

All Host1x modules, including the Host1x itself, implement the Incr_Syncpt class.

Incr_Syncpt <Cond> <Indx>

For the Host1x, this method immediately increments Syncpt[Indx] irrespective of the cond.

13.3.2.5 WAIT_SYNCPT

Wait on syncpt – the command dispatch will stall until the syncpt counter pointed by the index field reaches the threshold value specified in the Thresh field:-

Wait_Syncpt <Indx> <Thresh>

The channel will wait until the following is true:

Syncpt[Indx][15:0] >= Thresh[15:0]

where the “>=” takes into account wrapping (see the “Sync Points (SYNCPTs)” section for more information on wrapping). More specifically, the channel will wait until:

((Syncpt[indx] – thresh) & (1 << 15)) != 0

13.3.2.6 WAIT_SYNCPT_BASE

This method uses Syncpt Base registers to calculate threshold value for channel wait operation. The syncpt index, base index and also optional offset will be a part of Wait_Syncpt_Base command:-

Wait_Syncpt_Base <Indx> <Base_Indx> <Offset>

The channel will wait until the following is true:

Syncpt[Indx][15:0] >= (Syncpt_Base[Base_Indx] + Offset)[15:0]

Where the “>=” takes into account wrapping. See the “Sync Points (SYNCPTs)” section for more information on wrapping.

13.3.2.7 WAIT_SYNCPT_INCR

Wait until syncpt increments:

Wait_Syncpt_Incr <Indx>

The channel will stall until Syncpt[Indx] is incremented. Note that this wait method is subject to race conditions and should be used only for bug work-around.

13.3.2.8 LOAD_SYNCPT_BASE

Load a new value into the Syncpt_Base register:

load_syncpt_base <base_indx> <value>

Syncpt_Base[Base_Indx] will be loaded with <Value>.

13.3.2.9 INCR_SYNCPT_BASE

Add an offset to the value in the Syncpt_Base register:

Incr_Syncpt_Base <Base_Indx> <Offset>

The following operation will be done:

Syncpt_Base[Base_Indx] += Offset

Following are the new methods added for 32-bit sync point comparison:-

13.3.2.10 LOAD_SYNCPT_PAYLOAD_32 <Payload(32)>

This method loads a 32-bit value into the corresponding channel's Channel_Syncpt_Payload register:-

Channel_Syncpt_Payload[31:0]= <Payload(32)>

13.3.2.11 WAIT_SYNCPT_32 <Indx(8)>

This method stalls the current channel until following condition is true:-

(SYNCPT [<indx>][31:0] - PAYLOAD[31:0]) & 0x80000000) == 0

Here the Payload value is taken from Channel_Syncpt_Payload of the current channel.

This is essentially a wrapping stall until ((SYNCPT [<indx>][31:0] >= PAYLOAD[31:0])

13.3.2.12 WAIT_SYNCPT_BASE_32 <Indx(8)> <Base_Indx(8)> :

This method stalls the current channel until following condition is true:-

((Syncpt [<Indx>][31:0] - (Payload[31:0] + Syncpt_Base[<Base_Indx>][31:0]) & 0x80000000) == 0

Here the Payload value is taken from Channel_Syncpt_Payload register of the current channel.

This is essentially a wrapping:-

stall until ((Syncpt [<Indx>][31:0] >= (Payload[31:0] + Syncpt_Base[<Base_Indx>][31:0]))

13.3.2.13 LOAD_SYNCPT_BASE_32 <Base_Indx(8)>

This method copies the value from the current channel's Channel_Syncpt_Payload register into the Syncpt_Base register specified through the Base_Indx field:-

Syncpt_Base[<Base_Indx>][31:0] = Channel_Syncpt_Payload[31:0]

13.3.2.14 INCR_SYNCPT_BASE_32 <Base_Indx(8)>

This method adds the value of the current channel's Channel_Syncpt_Payload register into the Syncpt_Base register specified through Base_Indx:-

Syncpt_Base[<Base_Indx>][31:0] += Channel_Syncpt_Payload[31:0]

13.3.2.15 STALLCOUNT

Stallcount_Hi, Stallcount_Lo, and Stallctrl are methods to control “stall counters” through the command FIFO. Details of stall counters are given later in this document.

13.3.2.16 XFERCOUNT

Channel_Xfer_Hi, Channel_Xfer_Lo, and Xferctrl are methods to control “xfer counters” through the command FIFO.

13.3.3 Context Switching

Context management of Host1x 1x-based modules will be completely under software control (there will be no automatic context switching done by hardware). This mean a module will never produce a context switch interrupt, it will always operate in auto-acknowledge mode

A module with multiple hardware contexts (currently 2D), will have separate context IDs for each context. Software will have to do a SetClass to give the context ID associated with the hardware context that it wants to use. The 2D hardware will not automatically allocate contexts; software needs to program exactly the context it wants to use. For modules with a single hardware context (e.g., 3D), software must explicitly manage the save and restore of the context state.

13.3.4 Behavior of SetClass

The SetClass does not mean implicit acquisition of a module’s ownership. It is possible to send commands simultaneously from more than one channel to the same module. If exclusive ownership of a module is required for software correctness, then **acquire_mlock** and **release_mlock** opcodes should be used, which acquire and release the **MLOCKn** semaphore bits. An **acquire_mlock** that fails will cause that channel's commands to stall until it wins subsequent MLOCK arbitration (arbitrations happen with each **release_mlock**).

Here is the summary of SetClass behavior:-

- SetClass simply instructs the channel hardware which module and context to use for the following commands.
- If multiple channels write simultaneously to the same class ID, and no MLOCKs are used, then the actual commands are interleaved in round-robin fashion (one command per channel).
- If multiple channels write simultaneously to different class IDs in the same hardware module (and no MLOCKs are used), then the actual commands are interleaved, but in blocks of N-cycle bursts (each burst of commands must be preceded with a CTXSW to the module giving the new context ID).

  N in this case is programmable number configured through **Ctxsw_Timeout_Cfg** register.

13.3.5 Sync Points (SYNCPTs)

A Sync point is a mechanism to synchronize between software and Host1x clients and also in between Host1x clients. This is implemented as 32-bit counters which are incremented by 1 whenever some predestinated condition (or event) occurs. When a counter reaches its maximum value, it wraps back to zero on the next increment.

Tegra 4 series processors have 32 sync points. Sync points are not permanently associated with a channel; sync point allocation is done by software RM during initialization time.

There are two basic ways for sync point increments: -

- When a CPU writes an index to the Host1x's "syncpt_cpu_incr" register.
- When a Host1x client has received an "incr_syncpt" method and the condition specified by this method has become true.

Synchronization using sync points can be done in the following ways:

- A CPU can be interrupted when a sync point reaches a pre-specified value.
- A Host1x channel can have "wait" commands so that channel will wait for a pre-specified sync point value.

Sync points are normally not reset, but can wrap -- the comparison takes into account the possibility of wrapping.

Note:	Sync point wrapping works only if (Syncpt value - Syncpt Threshold) <= $2^{(syncpt\_width-1)}$ For 16-bit syncpt comparisons, the difference should be less than or equal to 32768. Software must take care of wrapping issues. For 32-bit comparisons, the difference should be less than or equal to 2,147,483,648, Because of the large value, software will not see any wrapping issues.

All Host1x clients (e.g., VI) implement the following increment syncpt method:

Incr_Syncpt <Condition> <Index>

The Host1x client would receive the "Incr_Syncpt" method and store the index for each condition. Whenever the "condition" event occurs, the client would return the index back to Host1x.

13.3.5.1 Client Model for Syncpt Behavior

Software Programming Model

The basic programming model that software will follow is:-

Each module will be programmed to do a unit of work (an operation) by Host1x using CDMA and push buffers.

Examples of an operation include:-

- BLT (VIC)
- Draw a set of triangles (GPU)
- Encode a single frame (MSENC).

If nothing else is programmed, then module will go idle until Host1x sends commands to start another operation (no continuous mode).To do its operation, a module reads data from memory and writes the results to memory. Modules interact with each other using memory buffers: one module is the producer of data, and another is the consumer of that data.

There are exceptions to this model which we will discuss in detail later, but should be mentioned here. The exceptions include VI and DISPLAY which work in continuous mode (they continue to process data without the need of additional Host1x programming).

Basic Synchronization

There are two basic needs for synchronization: management of memory buffers and timing of control register writes.

Memory buffers used to pass data from one module to the next use a producer/consumer model with circular buffers. To prevent buffer underflow and overflow, synchronization needs to be done in both directions:

- The consumer cannot read until producer is done writing (and the writes are committed to memory).
- The producer cannot reuse an output buffer (i.e., write to buffer) until the consumer is done reading the buffer.

Thus, the synchronization events required for memory buffers are:

- The module has completed all reads from the buffer.
- The module has completed all writes to the buffer (and they are committed by the memory controller).

To understand the requirements for timing the writes to control registers, a typical sequence is provided below:

1. reg wr for operation A
2. reg wr for operation A
3. reg wr (trigger) for operation A
4. reg wr for operation B
5. reg wr for operation B
6. reg wr (trigger) for operation B

If no WAIT method is placed between the trigger for A and the first register write for B, then in the worst case, corruption of operation A may occur because the new value of the control register is used before operation A is done. For modules that protect against this corruption, there is still the undesirable behavior of the module delaying the register write and subsequently causing back pressure on the Host1x write bus. If we wish to allow direct register reads to be used by ISRs they will happen asynchronously to the channel command writes, so one must ensure that the Host1x bus does not stall for significant periods of time.

For synchronizing writes to control register, a safe time to start writing register for the next operation is defined to be when:

- No corruption will occur for previous operations.
- No stall of the HWRBUS bus will result.

13.3.5.2 Standard Set of Incr_Syncpt Conditions

The following values of the “incr_syncpt cond” field are predefined:

- **0 (**Immediate): Return indx to Host1x immediately (used by software push-buffer allocation and helpful for debug).
- **1 (**Op_Done): Return indx to Host1x when all previously triggered operations have completed and their writes to memory are committed.
- **2** (Rd_Done): Return indx to Host1x when all previously triggered operations have completed their reads from memory.
- **3 (**Reg_Wr_Safe): Return indx to Host1x when it is safe to program registers for the next operation. Safe means no corruption to previous operations and no stalling of Host1x write bus will occur.

There are special cases which would require use of additional condition values. Some modules have multiple read buffers condition = 2 (all reads done) would mean all reads to all buffers done, but it might be useful to software to know when reads are done to a specific input buffer. For some modules, e.g., VI, there are different safe times to update different sets of registers, so condition = 3 will need several variations (one for each "safe time"). If a module can have two operations happening at one time (as in VI), then special considerations will need to be made for these cases: either two separate Incr_Syncpt methods, or one Incr_Syncpt method with many special conditions.

For some modules, one condition can replace another if the two conditions always happen within a short period of time of each other. Then the condition that always happens last can be used for both.

13.3.5.3 Continuous Mode — Display and VI / EPP

For each display, software wants a free-running syncpt increment on every display “Vsync”. The most appropriate implementation of this is to have an additional register which has “Enable” and “Indx” fields to control the increment of syncpt on every “Vsync” event. If enable is set, then on every “Vsync”, display would return this “Indx” back to Host1x.

A similar situation exists for VI, where besides a set of conditions for the “Incr_Syncpt” method, it would also need a register with “Enable” and “Indx” which would control the incrementing of a syncpt on every camera “Vsync”.

Host1x clients will implement the logic associated with these registers. When this continuous mode is enabled, client should set a pending bit for when the condition occurs. When the pending bit is set, client will arbitrate for the hrd_<client>2host1x bus and if selected it will send “Indx” tagged with “Syncpt type” on hrd_ bus. After successfully sending the indx on hrd bus, client will clear the pending bit.

One of the issues for continuous operation of VI and EPP is that not all modes of operation allow the consumer of their output buffers to signal backpressure when the consumer has fallen behind in reading. To alleviate this problem, VI and EPP have added registers which, when written to, signal that the reading of one buffer has completed.

13.3.5.4 Allowing Multiple Pending INCR_SYNCPTS

Clients can have multiple pending syncpts which are queued into the client’s syncpt FIFOs, which are dedicated ones for each syncpt conditions.

The behavior of these syncpt FIFOs is controlled by an “Incr_Syncpt_Cntrl” register in client’s register space:-

INCR_SYNCPT_CNTRL< No_Stall>< Soft_Reset>

- No_Stall:

  If this bit is 1 and an Incr_Syncpt method is received but the syncpt FIFO for that condition is full, then this method will be dropped and the Incr_Syncpt_Error[Cond] bit will be set.

  If this bit is 0, then instead of dropping next method in case of a syncpt FIFO full condition, the client will just stall the host interface.
- Soft_Reset:

  if Soft_Reset is set, then all internal state of the client syncpt block will be reset. To do a soft reset, first set Soft_Reset of all Host1x clients affected, then clear all Soft_Resets.

INCR_SYNCPT_ERROR<Cond_Status>

This register stores error status in case of above mentioned syncpt FIFO full condition.

13.3.5.5 32-bit Sync Point Comparison

In previous chips, sync point counters were implemented as 32-bit registers but comparison takes into account 16-bit value only. In Tegra 4 devices, sync point comparison is extended to 32 bits. To support this feature, Host1x has the following changes:-

Host1x Register Changes

Following are the registers that are extended to 32 bits.

- Syncpoint base register [Host1x 1x_Sync_Syncpt_Base]
- Syncpt Threshold register [Host1x 1x_Sync_Syncpt_Int_Thresh]

Following is a new 32-bit register to store payload value required in syncpt methods:

- Channel_Syncpt_Payload[31:0]

Host1x Method Changes

To support 32-bit syncpt comparisons, new Host1x methods have been introduced and are described later in this document.

13.4 Unit Description

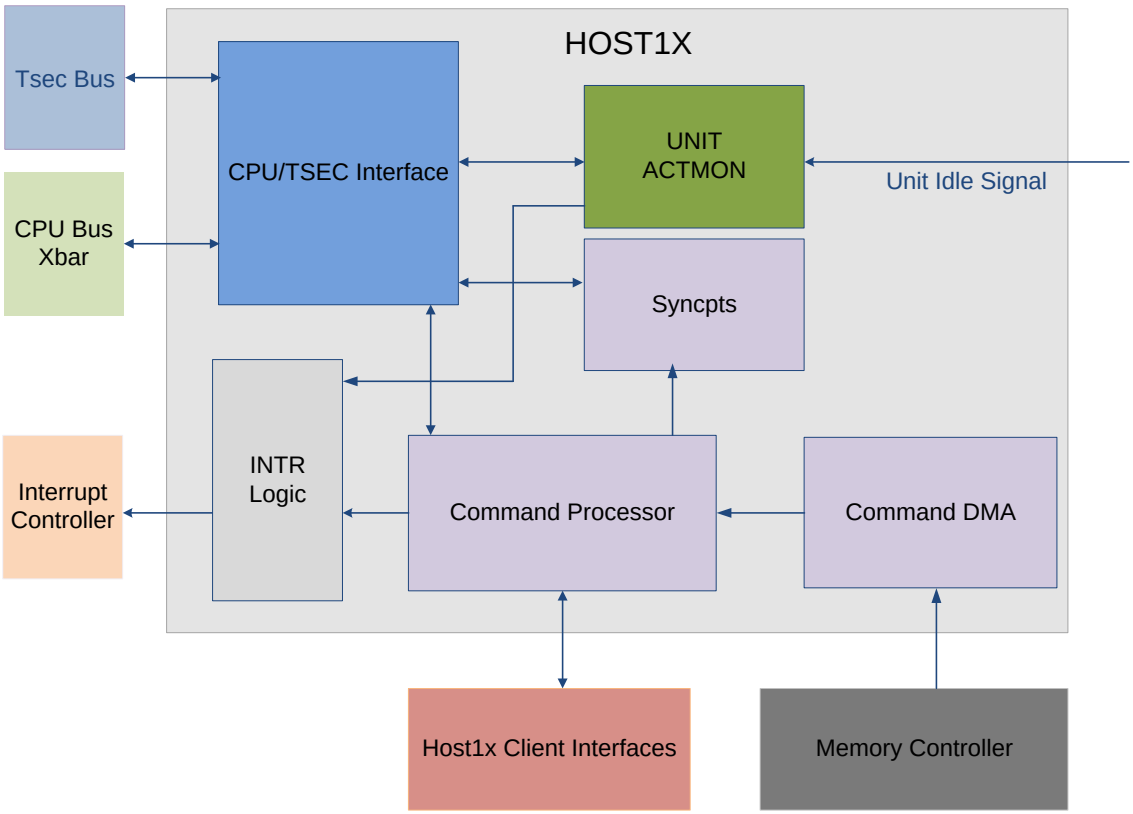
Host1x has master client interface with the CPU xbar bus and also TSEC unit to receive CPU/TSEC read/write commands. The incoming commands are either processed inside Host1x if they are Host1x specific or routed to clients.

Host1x has a point-to-point interface with its clients using HWR/HRD buses, which are used for sending requests and accepting responses from clients.

There is a memory controller interface to fetch Push-Buffer commands from memory through the “Command DMA” unit. The incoming Push-Buffer commands are processed inside “Command Processor” and afterwards either consumed inside host1x or it will generate tractions to client interface. There is an internal “syncpt” unit which is used to synchronize between Host1x clients and also between software.

There is a “Unit ActMon” block to monitor activities inside the GR3D unit which is used by software for power management.

Figure 35: Host1x Top-Level Block Diagram

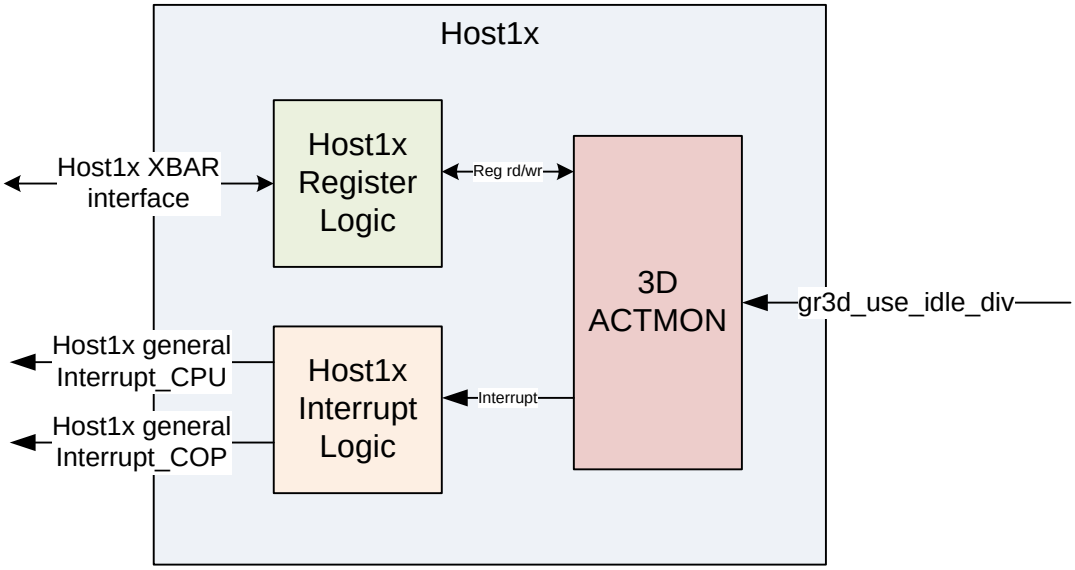


13.4.1 Activity Monitor for the 3D Unit

The Host1x unit implements 32-bit activity monitor counters to monitor the idleness of the 3D unit. The reason for choosing the Host1x unit is due to fact that register read latency is less in case of Host1x when compared to 3D unit.

The 3D engine sends idle/active information to Host1x through same “idle” signal which goes from 3D unit to CAR (which is a level signal). These activity monitor counters are a standard plug-in from activity monitor block. The activity monitor block provides averaging, watermark detection, histogramming, and interrupts functionality similar to the central ActMons. Host1x driver is changed to manage these monitors.

Figure 36: 3D ACTMON Interface



The 3D ACTMON register is a part of Host1x register space and can be accessed through native Host1x direct/indirect read and write. The interrupts from the 3D ACTMON unit are ORed with other Host1x general interrupt sources and passed on to the Host1x 1x_general_interrupt_cpu/cop output pin. The Host1x interrupt status register (HINTSTATUS) is modified to include an additional bit to indicate if the interrupt source is 3D ACTMON.

Table 45. Actmon Interrupt Status Register

Register([Bit]) Name	Description
HINTSTATUS[9]	Set by 3D ActMon (software needs to read HOST1X_gr3D_actmon Interrupt Status Register to determine the exact source of interrupt) When this bit is set, the HINTSTATUS_EXT_INT bit will also be set in the HINSTATUS register. This bit is sticky and PENDING until cleared (cleared by writing 1)

There is a corresponding mask bit inside Host1x interrupt registers.

13.4.2 Timeout Mechanism

Host1x has a mechanism to generate interrupt for unserviced CPU read/write requests which is controlled through a timeout register (HOST1X 1x_IP_TIMEOUT). Host1x will generate a timeout Interrupt and violating address is stored in following registers:-

- IP_READ_TIMEOUT_ADDR
- IP_WRITE_TIMEOUT_ADDR

In earlier chips, this timeout register is 16 bits, which is not sufficient because 3D unit read latency can be greater than 320 µs. So the width of the timeout register has been increased to 32 bits to provide a timeout value of ~19 seconds.

The Tsec master client interface also uses this mechanism to generate timout interrupt to CPU in case of illegal read/write access. HINTSTATUS_EXT register has been modified to indicate if the timeout is from native CPU access or TSEC access.

Also in case of TSEC read timeout the returned response packet will have an additional bit (tsec2host1x 1x_iprdata_timeout) to indicate a timeout error.

HINTSTATUS[Timeout_source=bit10] =0 Timeout from TSEC access.

1 Timeout from XBAR access.

The current scheme saves only the last timeout address in case of multiple timeout happens before clearing the timeout interrupt by software.

13.4.3 Performance Statistics Counters

Host1x has performance counters for profiling, which can be enabled independent of push-buffer commands. Host1x needs the following statistics per channel:

- Total clocks
- Clocks stalled waiting for syncpt
- Clocks transferring data

13.4.3.1 Tick Counter

Each channel has its own 64-bit tick counter that is incremented on each Host1x clock, given that it is enabled. TICKCTRL enables and disables the tick counter.

The TICKCOUNT_LO and TICKCOUNT_HI 32-bit registers can be written to initialize the tick counter. Reads of these registers return the tick count. TICKCOUNT_LO stores the lower 32 bits, and TICKCOUNT_HI stores the upper 32 bits. TICKCOUNT_HI is calculated as follows:

```
if (TICKCOUNT_LO == 0xFFFF_FFFF && TICKCTRL == enable) TICKCOUNT_HI++;
```

13.4.3.2 Channel Stall Counter

This is a 64-bit CHANNEL_STALL counter per channel, which when enabled will get increment on each clock cycles if that particular channel is waiting for syncpt.

Following are the registers to control this counter:

- STALLCTRL : - This is a 1-bit register to enable/disable CHANNEL_STALL counter.
- STALLCOUNT_LO :- This is a 32-bit register to initialize lower 32 bit of CHANNEL_STALL counter.
- STALLCOUNT_HI :- This is a 32-bit register to initialize upper 32 bit of CHANNEL_STALL counter.

Following are the new Host1x class methods to program this counter:

- STALLCOUNT_HI:- This method will initialize the high 32 bits of
  - tick count value in CHANNEL_STALL counter.
- STALLCOUNT_LO :- This method will initialize the low 32 bits of
  - tick count value in CHANNEL_STALL counter.
- STALLCTRL:- This method will enable/disable CHANNEL_STALL counter.

13.4.3.3 Channel Xfer Counter

This 64-bit CHANNEL_XFER counter per channel measures the data transfer interval per channel. This will be incremented at each clock cycles if channel is not idle (busy in fetching channel commands).

Following registers will be used to initialize this counter:

- XFERCTRL: This 1-bit register enables/disables the CHANNEL_XFER counter.
- CHANNEL_XFER_LO[31:0]: This 32-bit register initializes the lower 32 bits of the CHANNEL_XFER counter.
- CHANNEL_XFER_HI[31:0]: This 32-bit register initializes the lower 32 bits of the CHANNEL_XFER counter.

Following are the new Host1x class methods to program this counter:-

- CHANNEL_XFER_HI: This method will initialize the high 32 bits of the tick count value in the CHANNEL_XFER counter.
- CHANNEL_XFER_LO: This method will initialize the low 32 bits of the tick count value in the CHANNEL_XFER counter.
- XFERCTRL: This method will enable/disable the CHANNEL_XFER counter.

Note: Counter operations are identical irrespective of whether they are controlled through registers or other methods.

13.4.4 Interrupts

Host1x has following types of interrupts present:

13.4.4.1 Host1x Client Interrupt

Host1x is the collection point for all of its clients interrupts. Also it has control over those using status and mask registers with fields for each client. These client interrupts are forwarded to the central interrupt controller unit, individually through per client interrupt lines.

13.4.4.2 Host1x Interrupts

Host1x -specific interrupts are specified through the HOST1X_SYNC_HINTSTATUS_0 register while additional interrupts have been specified through the HOST1X_SYNC_HINTSTATUS_EXT_0 register (see Registers below).

13.4.4.3 Host1x Syncpt Interrupts

Host1x can generate a syncpt interrupt upon reaching a threshold value by syncpt registers. It can also generate an interrupt to either CPU0, which is the main CPU complex, or CPU1, which is the AVP.

An interrupt is routed to cpuN when:

(SYNCPT[indx] >= SYNCPT_INT_THRESH[indx]) && (SYNCPT_THRESH_INT_MASK[indx] == cpuN)

The comparison takes wrapping into account. See the “Sync Points (SYNCPTs)” section for more information on wrapping.

The status is sticky and is PENDING until cleared. Write 1's to clear.

13.4.5 Indirect Register Access

Host1x provides a means of indirect register access to all its clients. An indirect register access involves multiple steps and requires a channel for the read return data. All registers required for indirect accesses resides in a channel.

Writes involve two Host1x register writes in the owning channel's space; the first write indicates the address (INDOFF, or INDOFF2 and INDCTRL), and the second indicates the data (INDDATA).

Reads involve two direct Host1x writes, the first indicates the address (again INDOFF, or INDOFF2 and INDCTRL), and the second to indicate the number of reads (INDCNT). It also requires an indeterminable number of direct Host1x reads to the read return FIFO status register followed by a read to the read return FIFO.

- INDOFF
- INDOFF2
- INDCTRL
- INDDATA
- INDCNT

Pitfalls — Indirect accesses require a software mutex to ensure that no other software threads access the indirect registers while issuing the access (since the series of accesses is non-atomic). Indirect reads can only issue counts less than the read return FIFO size to prevent a deadlock – too many read requests can block popping of the read return FIFO. This restriction may be even tighter. All modules accesses must also be tied to a channel.

13.4.6 Direct Register Access

All clients under Host1x have 256KB of address space, which originates from the space specified by indirect offset register (INDOFF). Host1x's client address map is dictated by its client's module IDs; these IDs are used in INDOFF to specify the target module of the register access. A client's address in the Host1x space is calculated as:

address = direct_access_base_address(0x54000000) + (module_id << 18)

+ 4 * register_offset

There can only exist one pending read per interface. Reads are returned from the client when the client is ready. There are no latency restrictions.

Indirect versus Direct — pitfall of direct addressing is variable latency of Host1x's clients. While this has no impact on writes, the CPU is blocked until the read returns rendering the CPU idle during that time.

13.4.7 Host Clients

The following table lists the clients that are accessed via Host1x with their module (client) ID, which is used to determine addresses for direct addressing.

Table 46: Host1x Clients

Client	ID
Host1x	0x0
VI	0x2
CSI	0xf
EPP	0x3
ISP	0x4
2D	0x5
3D	0x6
Display A	0x8
Display B	0x9
HDMI	0xa
DSI	0xc
DSIB	0x10
MSENC	0x13
TSEC	0x14

13.4.8 Class IDs

The following table lists the class IDs.

Class	ID
NV_HOST1X_CLASS_ID	0x01
NV_VIDEO_ENCODE_MSENC_CLASS_ID	0x21
NV_VIDEO_STREAMING_VI_CLASS_ID	0x30

Class	ID
NV_VIDEO_STREAMING_EPP_CLASS_ID	0x31
NV_VIDEO_STREAMING_ISP_CLASS_ID	0x32
NV_GRAPHICS_2D_DOWNLOAD_CLASS_ID	0x50
NV_GRAPHICS_2D_CLASS_ID	0x51
NV_GRAPHICS_2D_SB_CLASS_ID	0x52
NV_GRAPHICS_2D_DOWNLOAD_CTX1_CLASS_ID	0x54
NV_GRAPHICS_2D_CTX1_CLASS_ID	0x55
NV_GRAPHICS_2D_SB_CTX1_CLASS_ID	0x56
NV_GRAPHICS_2D_DOWNLOAD_CTX2_CLASS_ID	0x58
NV_GRAPHICS_2D_SB_CTX2_CLASS_ID	0x5A
NV_GRAPHICS_3D_CLASS_ID	0x60
NV_DISPLAY_CLASS_ID	0x70
NV_DISPLAYB_CLASS_ID	0x71
NV_HDMI_CLASS_ID	0x77
NV_DISPLAY_DSI_CLASS_ID	0x79
NV_DISPLAY_DSIB_CLASS_ID	0x7A
NV_TSEC_CLASS_ID	0xE0

13.4.9 Host Address Space

Each channel is allocated 16KB of space, and they are aligned contiguously at the top of the Host's address space. A channel's space consists of channel registers, the command FIFO, and an aliased frame buffer region, which are unique per channel. The rest of the space consists of synchronous registers, which are aliased in each channel – there exists only one copy.

13.4.9.1 Channel Map

The following table gives offsets from the channel base address for different sets of registers available to each channel.

Table 47: Host1x Channel Map

0x0000	Channel Registers
0x0600	Reserved (former RDMA Registers)
0x0800	Command FIFO
0x1000	Frame Buffer
0x2000	Reserved (former Asynchronous Registers)
0x3000*	Synchronous Registers
0x3FFF	Bottom

* 0x3000 is the synchronous registers base (HOST1X_CHANNEL_SYNC_REG_BASE)

13.4.9.2 Host1x Map

The following table shows the Host1x addresses for CPU/COP. Channels starts at the lowest addresses and are aligned contiguously. Following the channels there is a protected channel, whose map looks like that of a channel's (although some of the registers are not functional, more on the protected channel later). Direct access to Host clients starts at 5400_0000, but this is configurable through a BAR register.

Table 48: Host1x Map

5000_0000-5000_3FFF	Channel 0 (16KB)
5000_4000-5000_7FFF	Channel 1 (16KB)
5000_8000-5000_BFFF	Channel 2 (16KB)
5000_E000-5001_2FFF	Channel 3 (16KB)
5001_3000-5001_6FFF	Channel 4 (16KB)
5001_7000-5001_AFFF	Channel 5 (16KB)
5001_B000-5001_BFFF	Channel 6 (16KB)
5001_C000-5001_FFFF	Channel 7 (16KB)
5002_0000-5002_3FFF	Channel 8 (16KB)
5002_4000-5002_7FFF	Protected Channel base

13.5 Performance

13.5.1 Key Use Cases

Command throughput must be sufficient when all channels are active, the CDMA is active, and spooling is active.

13.5.2 Latency Targets

Direct read latency must be under 1 ms. Clients that cannot guarantee that a read will return in under 1 ms must not be read directly but indirectly.

13.5.3 Bandwidth Targets

As Host1x unit is used only for sending control commands to clients and usually at frame interval.

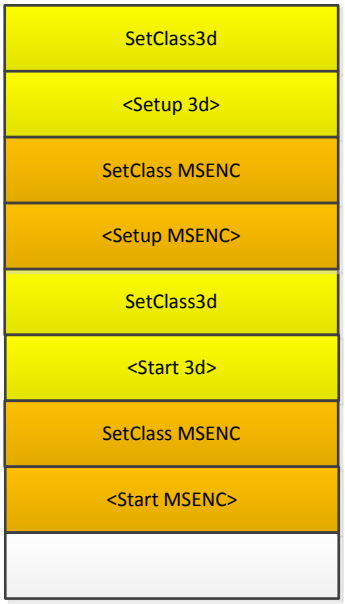
As these control commands are short (~200 -300 words maximum), it is expected that the bandwidth requirement on each client should be less than 1MB/s (3MB/s in case of 3D engine), whereas the maximum available bandwidth per client on the HWR bus will be (206*4B)/12 =68MB/s at 206 MHz Host1x clock. The minimum bandwidth on the HWR bus per client is 22 MB/s at 66 MHz clock which should easily meet the client requirement.

13.6 Host1x Programming Model

The Host programming models resides on top of the concept of channels. A channel provides the means for software to supply an ordered sequence of commands to one or more classes. There are no restrictions on how many classes a channel may own or how often it can switch between classes, but it can only operate on one class at a time (known as the working class) and one command at a time. A stalled channel does not allow any commands to proceed from any class – there is a strict ordering of commands. A channel starts processing commands simply when commands are present, either supplied by the CPU or gathered from memory. A channel can be stopped explicitly by a CPU write to channel state.

A single channel owning multiple classes and clients:

Figure 37: Single Channel Example



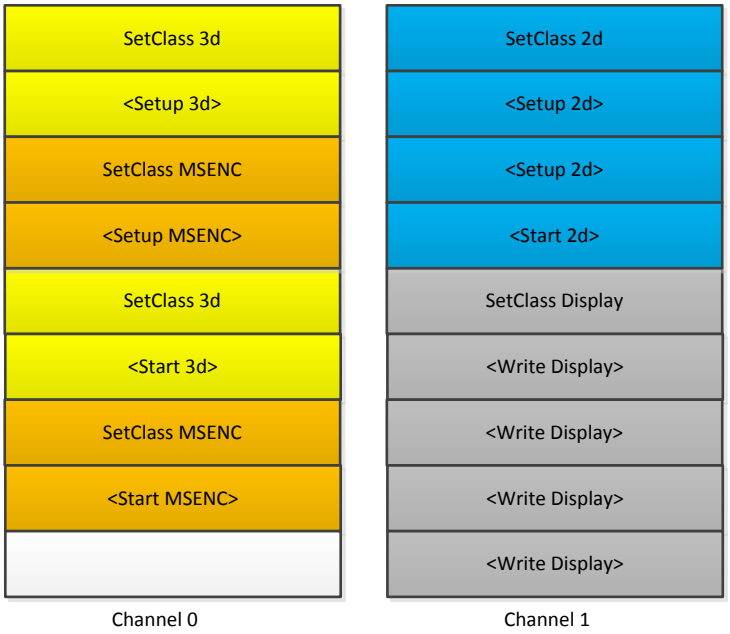
13.6.1 Concurrency

Channels operate in parallel and are unhindered by one another except in two specific cases:-

- Synchronization points
- Class contention

The following figure depicts such concurrency:

Figure 38: Channel Concurrency Example



In the example above, no channel is blocked by another at any time so both can work concurrently. Care must be taken when assigning clients to channels. Channel concurrency as well as channel throughput is crucial for performance. For example, a client that is event-driven with a low latency requirement should exist in its own channel. Conversely, two clients that must be steadily supplied with commands could possibly coexist in the same channel given that their synchronization points are not conflicting (if they have any real synchronization points at all). Clients that operate sequentially on the same piece of data can easily reside in the same channel.

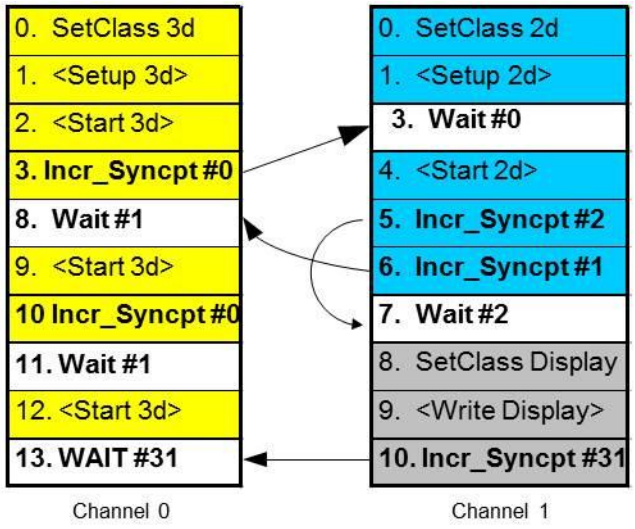
Clients with low-latency requirements like described in the first example above should possibly be moved to a PIO programming model and away from a channel-based model.

13.6.2 Synchronization

There are 32 unique synchronization points (syncpts) available per channel. Similar to semaphores, syncpt methods are issued to clients, mentioning syncpt counter index and returning condition. Any channel can be made to wait on a syncpt value of a particular syncpt index through Host1x “wait” method. Once the syncpt method is received by clients, based on syncpt condition, they will return a syncpt index back to Host1x. On receiving a syncpt index from the client, Host1x will increment that particular syncpt counter.

The following simple example below details how syncpts and waits allow for synchronization. The arrows simply indicate channel dependencies, which channel is waiting for syncpt increment from other channel.

Figure 39: Channel Synchronization Example



13.6.3 Progress Status

Channel progress is monitored through two means – GET and syncpts. GET is a channel state that indicates the address of the last command that has executed in the channel. GET is the same as DMAGET.

Syncpts are counter registers that are incremented when specified events occur (e.g., after the completion of each operation done by a module). The 32-bit syncpt values typically are monotonically increasing and can be used for in channel waits and out-of-channel interrupts.

The GET and syncpt registers can also be read directly (out-of-band) by the CPU.

13.6.4 Syncpt Base Register Use Case

The syncpt base registers are modified through LOAD_SYNCPT_BASE_32 or INCR_SYNCPT_BASE_32 methods and are used with the WAIT_SYNCPT_BASE_32 method.

This mechanism is useful when software wants to wait for a particular syncpt increment, but software does not know the absolute value of the sync point register until later.

Definition: the "future value" of a sync point is the value that the syncpt register will contain right after a particular increment has occurred.

Consider this example:-

In this example, time increases downward (later (lower) lines are ahead in time).

Software "knows" the syncpointA future-value equals N at this point; software "knows" the baseA future-value equals N at this point

1. command1
2. increment syncpointA to N+1
3. command2
4. increment syncpointA to N+2
5. command3
6. wait until command1 is done (syncpoint == N+1)

7. command4
8. wait until command2 is done (syncpoint == N+2)
9. command5

If software actually DOES know the value of N then regular WAIT_SYNCPT works fine here. The problem is that the user space software driver (which is creating this list of commands) does not know what the value N is until after these commands (1-9) are all flushed to the kernel space driver.

The kernel space driver receives packets of commands from many different user space processes. When it receives a packet of commands it queues those commands (i.e., writes the Host1x PUT pointer). It also keeps track of all increments that have occurred in all commands that have been queued so far. The "future-value" of each sync point is simply the total number of increments that have occurred since the beginning of time (actually "beginning of time" is really the point in time where the kernel space driver was initialized and reset all the syncpt registers to 0).

So when the kernel space driver queues these commands (1-9), it knows the value N (i.e., the sum of all increments since the beginning of time). It can pass this back to the user space driver. But the user space driver does not know how many increments will be queued before commands 1-9 are queued because any other process can queue commands (including increments) at any time (e.g., after the user space driver has written commands 2 and 4 to the buffer, but before those commands have been queued by the kernel driver).

To solve this, we add a command at the end of each packet that increments the base register the same number of times as the sync point was incremented:

10. baseA += 2

This means that, at the start of any packet of commands, the future value of syncpointA and the future value of baseA are always the same. So command 6 can be:

WAIT_SYNCPT_BASE syncpt=A base=A offset=1

and command 8 can be:

WAIT_SYNCPT_BASE syncpt=A base=A offset=2

Note: Software never writes a new value to the syncpointA or baseA register except when the kernel driver is initialized (e.g., when the system boots). After that we only increment the syncpoint register and only add to the base register. All of this depends on all software that creates command buffers cooperating. Software has this policy (e.g., the user space driver always tells the kernel driver how many increments are contained in each packet of commands)

13.6.5 Indirect/Direct Register Addressing Scheme

The indirect addressing scheme works as follows:

- An address is decoded and either routed to a channel register or to a synchronous register
- A write to INDCNT or INDDATA triggers a register access to the register specified in INDOFF
- A transaction is created and pushed into the REGF FIFO. The owning channel is specified by which INDCNT or INDDATA is written. The client and offset are specified in INDOFF.
- The transaction is routed to the target client over the HWR bus.
- If the access is a write, the transaction is complete. In the case of a read, the processor polls the channel's read return FIFO status (FIFOSTAT), waiting for a nonempty FIFO.
- The client returns the read to the channel's return FIFO.
- The processor reads INDDATA register of that particular channel to pops data from the return FIFO.

Direct addressing uses the same flow with some adjustments:

- An address is decoded and either routed to a channel register, a synchronous register, or a client
- This step is nonexistent; direct accesses do not require a trigger.
- In the case of a client decode, a transaction is created and pushed into a FIFO called REGF. The owning channel is specified as CPU_READ_RETURN_TAG. The client and offset are indicated by the address: the client is created by shifting the address down by 18; the offset is simply the lower 18 bits.
- The transaction is routed to the target client over the HWR bus. If the access is a write, the transaction is complete.
- In case of a read, client returns the read data and channel ID in the returned packet indicates its destination, be it interface or a channel's return FIFO. If the channel is 0-8, it is an indirect read and returned to the indicated channel. If the channel matches CPU_READ_RETURN_TAG(0xf), the data is returned to the IP interface.

Currently, there is support for only one pending read per interface.

13.7 Host Channel Opcodes

This section providesthe format of opcodes that can be sent through the command FIFO.

HCFCMD

Generic command FIFO packet (contains fields common to all opcodes) and is used for initial decode. All command FIFO packets are multiples of 32 bits.

HCFSETCL

The SetClass opcode is to specify which class is being to be referenced (may cause rerouting of subsequent methods/data). In addition to switching classes, the opcode allows some methods to be programmed on the switch similar to a HCFMASK opcode.

HCFINCR

The Incrementing opcode indicates the offset should be incremented, for each data that is part of the packet. The count argument indicates how many 32-bit values are following. If channel protect is enabled, it means the host should prevent a channel switch from occurring at the end of this command packet.

HCFNONINCR

The Non-Incrementing opcode indicates the same offset should be sent for each data that is part of the packet. The count argument indicates how many 32-bit values are following. If channel protect is enabled, it means the host should prevent a channel switch from occurring at the end of this command packet.

HCFMASK

The Mask opcode, from the starting offset, generates offsets based on where the bits are set in the mask. The host expects the amount of data following to equal the number of bits set. If channel protect is enabled, it means the host should prevent a channel switch from occurring at the end of this command packet.

HCFIMM

The Immediate opcode indicates the offset and data are contained in the same 32-bit datum. Only the lowest 16 bits of data are sent to the module (IMMDATA). The upper 16 bits are zeroed out.

HCFRESTART

The Restart opcode is specific to DMA operation and causes the host to set DMAGET to (ADDRESS << 4), so the next command fetch will be from (DMASTART + DMAGET).

In legacy chips, bits 27:0 were not decoded and assumed to be 0's (allowing only simply wrapping of GET back to the top of the command buffer). ADDRESS can be 0 for compatible RESTARTs or non-zero acting as a JUMP.

Note that the jump address granularity is 16 bytes, since the bottom 4 bits cannot be specified.

HCFGATHER

The Gather opcode allows contiguous portions of memory to be fetched and placed in line with the command stream, replacing the 2 words of the gather command. It optionally can put an incrementing or non-incrementing opcode in the stream ahead of the gathered data. This allows for the gathered data to be a pure data stream and not be required to have host opcodes inside.

HCFCHDONE

This opcode indicates to the command processor that the current channel is done processing for now and is willing to give up any of its owned modules to other channels that need them.

13.8 Host Channel Registers

Refer to “Reading Register Tables” in the Introduction section for the register table protocol as well as recommendations for accessing registers.

13.8.1 HOST1X_CHANNEL_FIFOSTAT_0

CFNUMEMPTY is the number of free slots available in the per-channel command. A FIFO is needed for PIO or polling for completion of a wait.

Offset: 0x0 │ Read/Write: RO │ Reset: 0x00000000 (0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx)

Bit	Reset	Description
31	X	INDRDY: Indicates that INDCOUNT==0, so it should be OK to issue another read
28:24	X	OUTFENTRIES: Number of entries available for reading in this channel's output FIFO
20:16	X	REGFNUMEMPTY: Register write/read FIFO free count
13	X	CFGATHER3D: Indicates whether GATHER3D is active. If a GATHER3D command issued via PIO, software must wait for the GATHER3D to be IDLE before issuing another command. 0 = IDLE 1 = BUSY
12	X	CFGATHER: Indicates whether GATHER is active. If a GATHER command issued via PIO, software must wait for the GATHER to be IDLE before issuing another command. 0 = IDLE 1 = BUSY
11	X	CFEMPTY: Indicates whether the command FIFO is empty or not 0 = NOTEMPTY 1 = EMPTY
10:0	X	CFNUMEMPTY: Command FIFO free count

13.8.2 HOST1X_CHANNEL_INDOFF_0

The INDOFF and INDOFF2 registers (along with INDCNT and INDDATA) are used to indirectly read/write modules outside the host. If AUTOINC is set, INDOFFSET increments by 4 on every access of INDDATA. REGFNUMEMPTY is polled to determine when valid data can be read from INDDATA.

The INDOFF register has limited capability on chips with large memory maps. If the top bit of the memory address is >= 27, all of memory cannot be addressed with INDOFF. In these cases, use INDOFF2 to set the offset while still using INDOFF to set the other parameters. Always have INDOFFUPD set to NO_UPDATE in these cases. For register accesses, using INDOFF (with INDOFFUPD set to UPDATE) is always more efficient, since it only requires one write.

Indirect frame buffer writes are STRONGLY DISCOURAGED. There are better ways to write to memory (direct and through the channel memory map) and there is limited flow control in the host. It is very easy to get into trouble with indirect frame buffer writes.

Offset: 0x4 │ Read/Write: R/W │ Reset: 0x00000000 (0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx)

Bit	Reset	Description
31	X	AUTOINC: Auto increment of read/write address 0 = DISABLE 1 = ENABLE
30	X	ACCTYPE: Access type: indirect register or indirect frame buffer 0 = REG 1 = FB
29	X	BUF32B: Buffer up 32 bits of register data before sending it. Otherwise, register writes will be sent as soon as they are received. Does not support byte writes in 16-bit host. Does not affect frame buffer writes. 0 = NOBUF 1 = BUF
28:27	X	INDSWAP: Indirect frame buffer access swap control. 00 = No byte swap 01 = 16-bit byte swap ([31:0] -> {[23:16],[31:24],[7:0],[15:8]}) 10 = 32-bit byte swap ([31:0] -> {[7:0],[15:8],[23:16],[31:24]}) 11 = 32-bit word swap ([31:0] -> {[15:8],[7:0],[31:24],[23:16]}) 0 = NONE 1 = BYTE16 2 = BYTE32 3 = WORD32
25:18	X	INDMODID: ACCTYPE=REG: Register module ID 0 = HOST1X 1 = MPE 2 = VI 3 = EPP 4 = ISP 5 = GR2D 6 = GR3D 8 = DISPLAY 9 = DISPLAYB 12 = DSI 10 = HDMI 16 = DSIB 19 = MSENC 20 = TSEC
25:2	X	INDOFFSET: ACCTYPE=FB: frame buffer address
17:2	X	INDROFFSET: ACCTYPE=REG: register offset ([15:0])
0	X	INDOFFUPD: Optionally disable the update of INDOFFSET when writing this register 0 = UPDATE 1 = NO_UPDATE

13.8.3 HOST1X_CHANNEL_INDCNT_0

Indirect Register Access Count

Used to trigger indirect reads. Holds the number of registers/memory locations that will be read out. Channels should not request more than there is space available in their output FIFO. Only the protected channel should make liberal use of this feature for speeding up context switching.

For indirect frame buffer reads, each channel cannot issue more than NV_HOST1X_MAX_IND_FB_READS at once. The read data must return and be written into the per-channel output FIFO before any additional reads can be issued.

Offset: 0x8 │ Read/Write: R/W │ Reset: 0x00000000 (0bxxxxxxxxxxxxxxxx0000000000000000)

Bit	Reset	Description
15:0	0x0	INDCOUNT

13.8.4 HOST1X_CHANNEL_INDDATA_0

This register, when written, writes to the data to the INDOFFSET in INDOFF. For reads, a REGFNUMEMPTY number of 32-bit values can be read before needing to poll FIFOSTAT again. The per-channel output FIFO (OUTFENTRIES) is readable via this offset. A read of INDDATA will pop an entry off of the per-channel output FIFO.

Offset: 0xc │ Read/Write: R/W │ Reset: 0x00000000 (0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx)

Bit	Reset	Description
31:0	X	INDDATA: read or write data

13.8.5 HOST1X_CHANNEL_RAISE_0

The general-purpose channels have DMA and RAISE/REFCOUNT functionality.

Any raise values returned from a client module are converted to vectors and update the per-channel raise register. The RAISE vector is also writable by the CPU. Any bits set in the RAISE field when written will be set in the RAISE register, allowing any pending WAITs to continue.

Offset: 0x10 │ Read/Write: R/W │ Reset: 0x00000000 (0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx)

Bit	Reset	Description
31:2	X	RAISE: This channel's RAISE vector

13.8.6 HOST1X_CHANNEL_DMASTART_0

This register triggers a DMA fetch from the frame buffer for this channel, if the Put register does not equal the DMA Get register.

Offset: 0x14 │ Read/Write: R/W │ Reset: 0x00000000 (0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx)

Bit	Reset	Description
31:2	X	DMASTART: cmdbuf frame buffer offset

13.8.7 HOST1X_CHANNEL_DMAPUT_0

This register triggers a DMA fetch from the frame buffer for this channel, if the PUT register does not equal the GET register. This address is relative to the DMASTART base address. Does not support byte writes. All 4-byte data need to be programmed.

Offset: 0x18 | Read/Write: R/W | Reset: 0x00000000 (0b00000000000000000000000000000xx)

Bit	Reset	Description
31:2	0x0	DMAPUT: cmdbuf frame buffer offset

13.8.8 HOST1X_CHANNEL_DMAGET_0

This register tracks the frame-buffer offset the DMA engine has read up to (incremented as entries are loaded from the channels command buffer into the FIFO). This address is relative to the DMASTART base address.

Offset: 0x1c | Read/Write: RO | Reset: 0x00000000 (0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx)

Bit	Reset	Description
31:2	X	DMAGET: cmdbuf frame buffer offset

13.8.9 HOST1X_CHANNEL_DMAEND_0

The boundary of illegal addresses (either end of push-buffer or end of physical memory). This is designed to prevent DMA from prefetching illegal addresses. If DMA reaches this address before seeing a RESTART, it will stop. This would be a software error condition.

Offset: 0x20 | Read/Write: R/W | Reset: 0x00000000 (0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx)

Bit	Reset	Description
31:2	X	DMAEND: cmdbuf frame buffer offset

13.8.10 HOST1X_CHANNEL_DMACTRL_0

DMA Control Register

DMAGETRST: Reset GET pointer to '0'. Useful for cleaning up crashed channels. DMAGET is not updated instantly. Takes 4 cycles between programming of reset and a valid DMAGET.

DMAGETINIT: Reset the GET pointer to the value of DMAPUT when DMAGETRST is asserted.

DMASTOP: Stop DMA from fetching on this channel.

Note: A Command DMA channel needs to be enabled for PIO-gather to work.

Offset: 0x24 | Read/Write: R/W | Reset: 0x00000001 (0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxx001)

Bit	Reset	Description
2	0x0	DMAINITGET: Reset GET pointer to the value of DMAPUT when DMAGETRST is asserted. 0 = DISABLE 1 = ENABLE
1	0x0	DMAGETRST: Reset GET pointer to '0'. Useful for cleaning up crashed channels. 0 = DISABLE 1 = ENABLE

Bit	Reset	Description
0	0x1	DMASTOP: Stop DMA from fetching on this channel. NOTE: a Command DMA channel needs to be enabled for PIO gather to work. 0 = RUN 1 = STOP

13.8.11 HOST1X_CHANNEL_INDOFF2_0

The INDOFF and INDOFF2 registers (along with INDCNT and INDDATA) are used to indirectly read/write modules outside the host. If AUTOINC is set, INDOFFSET increments by 4 on every access of INDDATA. REGFNUMEMPTY is polled to determine when valid data can be read from INDDATA.

The INDOFF register has limited capability on chips with large memory maps. If the top bit of the memory address is >= 27, all of memory cannot be addressed with INDOFF. In these cases, use INDOFF2 to set the offset while still using INDOFF to set the other parameters. Always have INDOFFUPD set to NO_UPDATE in these cases. For register accesses, using INDOFF (with INDOFFUPD set to UPDATE) is always more efficient, since it only requires one write.

Indirect frame-buffer writes are STRONGLY DISCOURAGED. There are better ways to write to memory (direct and through the channel memory map) and there is limited flow control in the host. It is very easy to get into trouble with indirect frame-buffer writes.

Offset: 0x8c │ Read/Write: R/W │ Reset: 0x00000000 (0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx)

13.9 Host SYNC Registers

Refer to “Reading Register Tables” in the Introduction section for the register table protocol as well as recommendations for accessing registers.

13.9.1 HOST1X_SYNC_INTSTATUS_0

INTSTATUS - interrupt status contains the interrupt status for all of the client modules. These status bits are only status. Writing '1' to them will not clear them. Software must clear the interrupt in the appropriate module, which should be reflected here.

Offset: 0x0 | Read/Write: RO | Reset: 0x00000000 (0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx)

Bit	Reset	Description
31	X	SYNCPT_CPU1_INT: set if SYNCPT_CPU1_INTSTATUS has a pending interrupt 0 = NOT_PENDING 1 = PENDING
30	X	SYNCPT_CPU0_INT: set if SYNCPT_CPU0_INTSTATUS has a pending interrupt 0 = NOT_PENDING 1 = PENDING
20	X	TSEC_INT: 0 = NOT_PENDING 1 = PENDING
19	X	MSENC_INT: 0 = NOT_PENDING 1 = PENDING
16	X	DSIB_INT: 0 = NOT_PENDING 1 = PENDING

13.9.11 HOST1X_SYNC_SYNCPT_THRESH_INT_MASK_0_0

Syncpt Threshold Interrupt Mask

If set to ENABLE_CPU0, interrupts are routed to the CPU complex.

If set to ENABLE_CPU1, interrupts are routed to the AVP.

0	0x0	CH0_CMDPROC_STOP: 0 = RUN 1 = STOP

13.9.28 HOST1X_SYNC_CH_TEARDOWN_0

Channel teardown register. Tells the hardware that a channel has gone away. Will reset that channel's command FIFO and release any locks it has in the arbiter. Will NOT reset that channel's output FIFO, which can be emptied by reading out all remaining entries.

Offset: 0xb0 | Read/Write: R/W | Reset: 0x00000000 (0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx)

Bit	Reset	Description
8	X	CH8_TEARDOWN: 0 = NO_ACTION 1 = TEARDOWN

Bit	Reset	Description

0	X	CH0_TEARDOWN: 0 = NO_ACTION 1 = TEARDOWN

13.9.29 HOST1X_SYNC_MOD_TEARDOWN_0

Module teardown register. If a module is reset, the host needs to reset its state with respect to which channels own that module. Whenever a module is reset, the corresponding teardown bit in this register should be written. Module teardown will only work if the command FIFO and command processor are in a good state (the FIFO is empty of traffic for that channel and the command processor is at an opcode boundary). If an entire channel needs to be reset, the CH_TEARDOWN register should be used instead.

Offset: 0xb4 │ Read/Write: R/W │ Reset: 0x00000000 (0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx)

13.9.51 HOST1X_SYNC_USEC_CLK_0

Number of host clocks needed to make a microsecond. Used for the DELAY host method. For example, if the host clock is 250 MHz, this register should be programmed to 250. If the host clock is 150 MHz, this register should be programmed to 150.

Offset: 0x1a4 | Read/Write: R/W | Reset: 0x0000015e (0bxxxxxxxxxxxxxxxxxxxx000101011110)

Bit	Reset	Description
11:0	0x15e	USEC_CLKS

13.9.52 HOST1X_SYNC_CTXSW_TIMEOUT_CFG_0

With channel ownership of modules removed, only generate CTXSW if a channel writes to a new class on a client. To keep from continually switching contexts if channels are addressing same client, keep a counter of commands issued to the client, and do not switch until the client has either received WAIT_CTXSW_CNT clocks before switching or the channel stops targeting it. So if 4 channels are currently in use with 2 channels targeting different classes on the same client, if the value were set to 6, it would guarantee 2 commands were sent from any channel to the client's current class.

Offset: 0x1a8 │ Read/Write: R/W │ Reset: 0x0000000f (0bxxxxxxxxxxxxxxxxxxxxxxxxxx00001111)

Bit	Reset	Description
7:0	0xf	WAIT_CTXSW_CNT: Number of cycles to wait

13.9.53 HOST1X_SYNC_INDREG_DMA_CTRL_0

Enable use of DMA engine to move data from indirect register interface to memory. ATTN_LVL controls flow between host and DMA. DMA will not start a transfer until the set number of slots are full:

- 00 = 1 slot
- 01 = 4 slots
- 10 = 8 slots

Offset: 0x1ac │ Read/Write: R/W │ Reset: 0x00000000 (0bxxxxxxxxxxxxxxxxxxxxxxxxx000x0000)

13.9.55 HOST1X_SYNC_CDMA_ASM_TIMEOUT_0

Timeout value determines how long the assembly logic will wait before it flushes data from the data FIFO to avoid head-of-line blocking.

Note: Do not use a value of zero -- causes immediate flushing so no forward progress is made.

Offset: 0x1b4 | Read/Write: R/W | Reset: 0x00000404 (0bxxxxxxxxxxxxxxxxxxxx00100xxx00100)

Bit	Reset	Description
12:8	0x4	CDMA_ASM_GFIFO_TIMEOUT
4:0	0x4	CDMA_ASM_DFIFO_TIMEOUT

13.9.56 HOST1X_SYNC_CDMA_MISC_0

CDMA_DELAY_PUT

Delay put_addr updates. This can potentially increase MC performance slightly by gathering multiple consecutive put_addr updates into 1 update, which reduces the amount of requests to the MC. In addition, it can be used to cover a race condition where a write to memory has not completed before CDMA starts fetching the data. But in this case, the counter has to be set to a high value, which *will* affect performance.

CDMA_SIMPLE_PREFETCH

Reduce per-channel requests to 1 every 3 cycles. This can reduce performance in 2 ways:

- The memory request FIFO will fill up slightly slower, but the impact will be minimal.
- It will cause the channel arbiter to switch to other channels when they have a request available, which will reduce locality. On the plus side, it has much less nasty corner cases.

CDMA_PUT_SYNC_DISABLE

CDMA_EN_STATS

Enable statistics counters.

- - Count the number of 128-bit words fetched by CDMA
- - Count the number of 128-bit words thrown away by CDMA

This allows us to get an idea how efficient the CDMA really is when there are multiple push-buffers active at the same time.

13.9.63 HOST1X_SYNC_HWLOCK0_0

HWLOCK REGISTERS

Hardware lock registers. These registers are general-purpose and allow software to do an atomic operation to gain ownership of a resource. These registers read back '1' if the reader has obtained ownership and '0' if not. This is done by initializing the register to '1'. The act of reading it resets it to '0'. Software must then write '1' back to it when it no longer needs the resource.

13.9.72 HOST1X_SYNC_MLOCK_0_0

MLOCK Registers

MLOCK is 1 whenever someone holds the lock, and is 0 otherwise. MLOCK is normally set and cleared using the host methods ACQUIRE_MLOCK and RELEASE_MLOCK.

If a CPU wants to acquire a lock, then it reads this register. If the value returned is 0, it has successfully acquired the MLOCK. A return value of 1 indicates that the acquire failed. At any time, the CPU can write 0 to MLOCK, releasing the MLOCK (note that hardware does not check if the CPU owned the lock). If the CPU writes a 1 to MLOCK, this is undefined and is ignored by the hardware (a NOP). Use MLOCK_OWNER to read the status of a lock (since reading MLOCK itself has a side effect).

13.9.88 HOST1X_SYNC_MLOCK_OWNER_0_0

MLOCK_OWNER is a read-only status for MLOCK. When MLOCK_*_OWNS are all zeros, it indicates that the MLOCK is free (zero). When MLOCK has been acquired (set), then one of MLOCK_*_OWNS will be non-zero.

Either bit 0 or 1 will be set -- indicating whether a channel or a CPU has acquired the MLOCK. If a channel owns the MLOCK, then the channel number is given by the MLOCK_OWNER_CHID field.

Syncpt interrupt thresholds

When a syncpt threshold interrupt is enabled, an interrupt is signaled when (SYNCPT_THRESH_INT_MASK[indx] == cpu) && (SYNCPT[indx] >= SYNCPT_INT_THRESH[indx]), where the comparison takes into account wrapping, and the interrupt is routed to the specified CPU.

13.9.169 HOST1X_SYNC_SYNCPT_BASE_0_0

Syncpt base registers are used by wait_syncpt_base method. The wait will be released when SYNCPT[indx] >= (BASE[base_indx] + offset), where indx, base_indx, and offset are supplied by the wait method.

There are 12 Syncpt Base registers, where n = 0 through 11.

Offset: 0x600 + (n * 0x4) │ Read/Write: R/W │ Reset: 0xXXXXXXXX (0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx)

Bit	Reset	Description
31:0	X	BASE_n

13.9.170 HOST1X_SYNC_SYNCPT_CPU_INCR_0

When a CPU writes the vector to this register, if vector[i] is set, then syncpt[i] is incremented. Read returns undefined value.

Offset: 0x700 │ Read/Write: R/W │ Reset: 0x00000000 (0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx)

Bit	Reset	Description
31:0	X	SYNCPT_CPU_INCR_VECTOR

13.10 Host Class Methods

Refer to “Reading Register Tables” in the Introduction section for the register table protocol as well as recommendations for accessing registers.

Class offsets are always relative to the class (based at 0).

13.10.1 NV_CLASS_HOST_INCR_SYNCPT_0

All Classes have the INCR_SYNCPT method. For host, this method, immediately increments SYNCPT[indx], irrespective of the condition. Note that INCR_SYNCPT_CNTRL and INCR_SYNCPT_ERROR are included for consistency with host clients, but writes to INCR_SYNCPT_CNTRL have no effect on the operation of Host1x, and because there are no condition FIFOs to overflow, INCR_SYNCPT_ERROR will never be set.

Offset: 0x0 │ Byte Offset: 0x0 │ Read/Write: R/W │ Reset: 0x00000000 (0bxxxxxxxxxxxxxxxx0000000000000000)

7:0	0x0	INDX: syncpt index value

13.10.2 NV_CLASS_HOST_INCR_SYNCPT_CNTRL_0

Offset: 0x1 │ Byte Offset: 0x4 │ Read/Write: R/W │ Reset: 0x00000000 (0bxxxxxxxxxxxxxxxxxxxxxxxx0xxxxxxx0)

Bit	Reset	Description
8	0x0	INCR_SYNCPT_NO_STALL: If NO_STALL is 1, then when FIFOs are full, INCR_SYNCPT methods will be dropped and the INCR_SYNCPT_ERROR[COND] bit will be set. If NO_STALL is 0, then when FIFOs are full, the client host interface will be stalled.
0	0x0	INCR_SYNCPT_SOFT_RESET: If SOFT_RESET is set, then all internal states of the client syncpt block will be reset. To do a soft reset, first set SOFT_RESET of all Host1x clients affected, then clear all SOFT_RESETs.

13.10.3 NV_CLASS_HOST_INCR_SYNCPT_ERROR_0

Offset: 0x2 │ Byte Offset: 0x8 │ Read/Write: R/W │ Reset: 0x00000000 (0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx)

Bit	Reset	Description
31:0	X	COND_STATUS: COND_STATUS[COND] is set if the FIFO for COND overflows. This bit is sticky and will remain set until cleared. Cleared by writing 1.

13.10.4 NV_CLASS_HOST_WAIT_SYNCPT_0

Wait on syncpt method.

Command dispatch will stall until:

SYNCPT[indx][NV_HOST1X_SYNCPT_THRESH_WIDTH-1:0] >= threshold[NV_HOST1X_SYNCPT_THRESH_WIDTH-1:0]

The comparison takes into account the possibility of wrapping. Note that more bits are allocated for index and threshold than may be used in an implementation. Use NV_HOST1X_SYNCPT_NB_PTS for the number of syncpts, and NV_HOST1X_SYNCPT_THRESH_WIDTH for the number of bits used by the comparison.

Offset: 0x8 │ Byte Offset: 0x20 │ Read/Write: R/W │ Reset: 0x00000000 (0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx)

Bit	Reset	Description
31:24	X	INDX
23:0	X	THRESH

13.10.5 NV_CLASS_HOST_WAIT_SYNCPT_BASE_0

Wait on syncpt method using base register.

Command dispatch will stall until:

SYNCPT[indx][NV_HOST1X_SYNCPT_THRESH_WIDTH-1:0] >= (SYNCPT_BASE[base_indx]+offset)

The comparison takes into account the possibility of wrapping. Note that more bits are allocated for INDX and BASE_INDX than may be used in an implementation. Use NV_HOST1X_SYNCPT_NB_PTS for the number of syncpts, Use NV_HOST1X_SYNCPT_NB_BASES for the number of syncpt_bases, and NV_HOST1X_SYNCPT_THRESH_WIDTH for the

number of bits used by the comparison If NV_HOST1X_SYNCPT_THRESH_WIDTH is greater than 16, the offset is sign-extended before it is added to SYNCPT_BASE.

Offset: 0x9 | Byte Offset: 0x24 | Read/Write: R/W | Reset: 0x00000000 (0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx)

Bit	Reset	Description

Bit	Reset	Description
0	X	TICKCNT_ENABLE: Enable or Disable tick counter 0 = DISABLE 1 = ENABLE

13.10.16 NV_CLASS_HOST_INDCTRL_0

Indirect Addressing

These registers (along with INDDATA) are used to indirectly read/write either register or memory. Host registers are not accessible using this interface. If AUTOINC is set, INDOFFSET increments by 4 on every access of INDDATA.

Either INDCTRL/INDOFF2 or INDOFF can be used, but INDOFF may not be able to address all memory in chips with large memory maps. The redundant bits in INDCTRL and INDOFF are shared, so writing either offset sets those bits.

Note: The following restrictions apply to the use of indirect memory writes:

- At initialization time, do a dummy indirect write (with all byte enables set to zero)
- Dedicate an MLOCK for indirect memory writes, then before a channel issues a set of indirect memory writes it must acquire this MLOCK; after the writes have been issued, the MLOCK is released -- this will restrict the use of indirect memory writes to a single channel at a time.

Offset: 0x2b │ Byte Offset: 0xac │ Read/Write: R/W │ Reset: 0x00000000 (0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx)

13.11 Host Proto Channel Registers

Refer to “Reading Register Tables” in the Introduction section for the register table protocol as well as recommendations for accessing registers.

13.11.1 HOST1X_PROTCHANNEL_FIFOSTAT_0

CFNUMEMPTY is the number of free slots available in the per-channel command FIFO (needed for PIO or polling for completion of a wait).

Offset: 0x0 | Read/Write: RO | Reset: 0x00000000 (0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx)

Bit	Reset	Description
31	X	INDRDY: Indicates that INDCOUNT==0, so it should be OK to issue another read
28:24	X	OUTFENTRIES: Number of entries available for reading in this channel's output FIFO
20:16	X	REGFNUMEMPTY: Register write/read FIFO free count
13	X	CFGATHER3D: Indicates whether GATHER3D is active. If a GATHER3D command issued via PIO, software must wait for the GATHER3D to be IDLE before issuing another command. 0 = IDLE 1 = BUSY
12	X	CFGATHER: Indicates whether or not GATHER is active. If a GATHER command issued via PIO, software must wait for the GATHER to be IDLE before issuing another command. 0 = IDLE 1 = BUSY
11	X	CFEMPTY: Indicates whether the command FIFO is empty or not 0 = NOTEMPTY 1 = EMPTY
10:0	X	CFNUMEMPTY: Command FIFO free count

13.11.2 HOST1X_PROTCHANNEL_INDOFF_0

The INDOFF and INDOFF2 registers (along with INDCNT and INDDATA) are used to indirectly read/write modules outside the host. If AUTOINC is set, INDOFFSET increments by 4 on every access of INDDATA. REGFNUMEMPTY is polled to determine when valid data can be read from INDDATA.

The INDOFF register has limited capability on chips with large memory maps. If the top bit of the memory address is >= 27, all of memory cannot be addressed with INDOFF. In these cases, use INDOFF2 to set the offset while still using INDOFF to set the other parameters. Always have INDOFFUPD set to NO_UPDATE in these cases. For register accesses, using INDOFF (with INDOFFUPD set to UPDATE) is always more efficient, since it only requires one write.

Indirect frame buffer writes are STRONGLY DISCOURAGED. There are better ways to write to memory (direct and through the channel memory map) and there is limited flow control in the host. It is very easy to get into trouble with indirect frame buffer writes.

Offset: 0x4 │ Read/Write: R/W │ Reset: 0x00000000 (0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx)

Bit	Reset	Description
31	X	AUTOINC: Auto increment of read/write address 0 = DISABLE 1 = ENABLE
30	X	ACCTYPE: access type: indirect register or indirect frame buffer 0 = REG 1 = FB
29	X	BUF32B: Buffer up 32 bits of register data before sending it. Otherwise, register writes will be sent as soon as they are received. Does not support byte writes in 16-bit host. Does not affect frame buffer writes. 0 = NOBUF 1 = BUF
28:27	X	INDSWAP: Indirect frame buffer access swap control. 00 = No byte swap 01 = 16-bit byte swap ([31:0] -> {[23:16],[31:24],[7:0],[15:8]}) 10 = 32-bit byte swap ([31:0] -> {[7:0],[15:8],[23:16],[31:24]}) 11 = 32-bit word swap ([31:0] -> {[15:8],[7:0],[31:24],[23:16]}) 0 = NONE 1 = BYTE16 2 = BYTE32 3 = WORD32

13.11.3 HOST1X_PROTCHANNEL_INDCNT_0

Indirect register access count

Used to trigger indirect reads. Holds the number of registers/memory locations that will be read out. Channels should not request more than there is space available in their output FIFO. Only the protected channel should make liberal use of this feature for speeding up context switching.

For indirect frame buffer reads, each channel cannot issue more than NV_HOST1X_MAX_IND_FB_READS at once. The read data must return and be written into the per-channel output FIFO before any additional reads can be issued.

Offset: 0x8 │ Read/Write: R/W │ Reset: 0x00000000 (0bxxxxxxxxxxxxxxxx0000000000000000)

Bit	Reset	Description
15:0	0X0	INDCOUNT

13.11.4 HOST1X_PROTCHANNEL_INDDATA_0

This register, when written, writes the data to the INDOFFSET in INDOFF. For reads, a REGFNUMEMPTY number of 32-bit values can be read before needing to poll FIFOSTAT again.

The per-channel output FIFO (OUTFENTRIES) is readable via this offset. A read of INDDATA will pop an entry off of the per-channel output FIFO.

Offset: 0xc │ Read/Write: R/W │ Reset: 0x00000000 (0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx)

Bit	Reset	Description
31:0	0X0	INDDATA: Read or write data

13.11.5 HOST1X_PROTCHANNEL_INDOFF2_0

Note: This spec file contains additions to the "common" registers that cannot be put in the common section, otherwise all of the other registers will shift.

The INDOFF and INDOFF2 registers (along with INDCNT and INDDATA) are used to indirectly read/write modules outside the host. If AUTOINC is set, INDOFFSET increments by 4 on every access of INDDATA. REGFNUMEMPTY is polled to determine when valid data can be read from INDDATA.

The INDOFF register has limited capability on chips with large memory maps. If the top bit of the memory address is >= 27, all of memory cannot be addressed with INDOFF. In these cases, use INDOFF2 to set the offset while still using INDOFF to set the other parameters. Always have INDOFFUPD set to NO_UPDATE in these cases. For register accesses, using INDOFF (with INDOFFUPD set to UPDATE) is always more efficient, since it only requires one write.

Indirect frame buffer writes are STRONGLY DISCOURAGED. There are better ways to write to memory (direct and through the channel memory map) and there is limited flow control in the host. It is very easy to get into trouble with indirect frame buffer writes.

14.0 GR2D

14.1 Introduction

GR2D is a 2D graphics acceleration block, capable of performing a range of copying, blending, scaling, rotation, and other 2D graphics operations. It is also sometimes used in conjunction with the Encode Pre-Processor (EPP), to which it has a direct path.

This section is not intended to be a programming guide to GR2D, as it is expected that NVIDIA supplied drivers will always be used with it. However, the register interface is documented to aid with understanding those drivers.

14.2 Registers

Refer to “Reading Register Tables” in the Introduction section for the register table protocol as well as recommendations for accessing registers.

14.2.1 G2SB_G2SBFORMAT_0

Offset: 0x1c │ Byte Offset: 0x70 │ Read/Write: R/W │ Reset: 0x00000000 (0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx)

Bit	Reset	Description
12:8	X	DIFMT: Destination Image Data Format. This parameter defines the data format of destination output. There are two groups of data formats, RGB and YCbCr (YUV) format. CbCr (UV) components may be represented in either offset binary or 2's complement. 00000: U8Y8V8Y8, YUV 4:2:2, 8-bit for each component, U/V in offset binary format 00001: Y8U8Y8V8, YUV 4:2:2, 8-bit for each component, U/V in offset binary format 00010: Y8V8Y8U8, YUV 4:2:2, 8-bit for each component, U/V in offset binary format 00011: V8Y8U8Y8, YUV 4:2:2, 8-bit for each component, U/V in offset binary format 00100: U8Y8V8Y8, YUV 4:2:2, 8-bit for each component, U/V is 2's complement 00101: Y8U8Y8V8, YUV 4:2:2, 8-bit for each component, U/V is 2's complement 00110: Y8V8Y8U8, YUV 4:2:2, 8-bit for each component, U/V is 2's complement 00111: V8Y8U8Y8, YUV 4:2:2, 8-bit for each component, U/V is 2's complement 01000: bpp16 5-6-5 {R[4:0], G[5:0], B[4:0]} 01001: RESERVED 01010: RESERVED 01011: RESERVED 01100: bpp16 5-6-5 Byte-swapped {G[2:0], B[4:0], R[4:0], G[5:3]} 01101: RESERVED 01110: R8G8B8A8 01111: B8G8R8A8 1xxxx: RESERVED 0 = U8Y8V8Y8_OB 1 = Y8U8Y8V8_OB 2 = Y8V8Y8U8_OB 3 = V8Y8U8Y8_OB 4 = U8Y8V8Y8_TC 5 = Y8U8Y8V8_TC 6 = Y8V8Y8U8_TC 7 = V8Y8U8Y8_TC 8 = B5G6R5 9 = RESERVED9 10 = RESERVED10 11 = RESERVED11 12 = B5G6R5BS 13 = RESERVED13 14 = R8G8B8A8 15 = B8G8R8A8 16 = RESERVED16

14.2.2 G2SB_G2CONTROLSB_0

Offset: 0x1d │ Byte Offset: 0x74 │ Read/Write: R/W │ Reset: 0x00000000 (0b00x00000000000000x0xx0xx00000xxx)

Bit	Reset	Description
31	0x0	DISDW: Output destination writes go either to image memory or the EPP. 0: Output data is sent to memory 1: YUV or RGB data is passed directly to the EPP module, and no destination writes take place. 0 = GOTO_IMAGE_BUFFER 1 = GOTO_EPP
30	0x0	ENDITH: Enable Dithering (ENDITH) For 16-bit RGB output modes, the LSB of the color components can be modified by adding a variable residual value that will reduce the banding artifacts that can appear on the display. 0: Normal operation 1: Enable dithering 0 = DISABLE 1 = ENABLE
28	0x0	KPOL: Key Signal Polarity (KPOL) Color/Chroma key signal is generated by comparing source input pixel color to a range of a color specified by lower and upper limit values. The key signal is interpreted in two ways, depending on which one of video and graphics images is foreground (and the other is background). This is effective only if Key signal generator is enabled. (see G2CMKEYL, G2CMKEYU) 0: Key signal is set to 1 when source pixel is within the lower and upper limit color range. 1: Key signal is set to 1 when source pixel is outside the lower and upper limit color range. 0 = WITHIN_BOUNDS 1 = OUTSIDE_BOUNDS
27	0x0	KEYEN: Key Signal Generator Enable (KEYEN) Key signal generator generates either chroma key signal (from YCbCr signal) or color

Bit	Reset	Description
		key signal (from RGB signal) 0: Key signal generator is disabled. 1: Key signal generator is enabled. 0 = DISABLE 1 = ENABLE
26	0x0	DBSEL: StretchBLT Destination Buffer Selection (DBSEL) StretchBLT processing involves frame-rate conversion from a series of source images to another series of destination images (field-rate of the source video to frame-rate of the PC display). In order to avoid image tearing, it is preferred to use two buffer sections in the destination video area. This bit selects one of the two buffering blocks to which this StretchBLT command delivers the destination image. The two buffering memory blocks are called A and B. 0: Destination image goes to ‘A’ buffer. 1: Destination image goes to ‘B’ buffer. 0 = DST_A 1 = DST_B
25	0x0	SBSEL: StretchBLT Source Buffer Selection (SBSEL) StretchBLT processing involves frame-rate conversion from a series of source images to another series of destination images (field-rate of the source video to frame-rate of the PC display). In order to avoid image tearing, it is preferred to use two buffer sections in the source video area. This bit selects one of the two buffering blocks from which this StretchBLT command receives the source image. The two buffering memory blocks are called source-A and source-B. 0: Source image comes from ‘source-A’ buffer. 1: Source image comes from ‘source-B’ buffer. 0 = SRC_A 1 = SRC_B
24	0x0	SITYPE: StretchBLT Source Type (SITYPE) This bit identifies two types of source images. If source image is 2-to-1 interlaced and StretchBLT processes either one of the two interlaced field-images, physical (positional) displacement between the two interlaced fields must be taken into account. One field-image that is placed higher in position than the other field-image is called top-field and the other is called bottom-field. StretchBLT processing has to lower the top-field (or raise the bottom-field) to match the corresponding two target images in the overlay window (that is progressively scanned) right at the same position. If source image is full frame-image obtained from two interlaced field-images, its type is ‘top-field’. If source images are progressively scanned, the type identification is not significant and they may be designated as one of the two types: 0: Source image is ‘top-field’. 1: Source image is ‘bottom-field’. 0 = TOP_FIELD 1 = BOTTOM_FIELD
23	0x0	RANGEREDFRM: In the VC-1 specification, when the value of RANGEREDFRM variable (1-bit) for a picture is equal to 1, the picture shall be scaled up according to the following equation: Y = clip(((Y-128)*2) + 128);Cb = clip(((Cb-128)*2) + 128);Cr = clip(((Cr-128)*2) + 128);The clip operator limits the output to [0, 255].The input is also limited to [0, 255].In the VC-1 nomenclature, the output (Y, Cb, Cr) tuple corresponds to the 'decoded' picture. The input (Y, Cb, Cr) tuple corresponds to the 'reconstructed' picture. The above equations create the decoded picture while keeping the reconstructed picture intact. Only YUV _OB formats are supported with range reducation enabled, not the YUV _TC or RGB formats. The YUV data coming from the video frame buffers (reconstructed picture) in DRAM was scaled up using the above equations and given to the display. The value of 1-bit wide RANGEREDFRM variable was configured in the DVO per frame and the frame was scaled whenever RANGEREDFRM == 1. 0 = DISABLE 1 = ENABLE

Bit	Reset	Description
22:20	0x0	HFTYPE: StretchBLT Horizontal Filter Mode (HFTYPE[2:0]) The six-tap horizontal interpolation filter can be operated in various operation modes. For the image expansion, it should be programmed as a pure 6-tap interpolator. For the image contraction, it can work as partly lowpass filter and partly interpolater with varying degree depending on the contraction ratio. For StretchBLT, this parameter is used as an index (selection) to an internal lookup table that stores the group of filter coefficients for the different modes of horizontal filtering. 000: Pure interpolation filter. 001, 010, 011, 100, 101, 110: mix of interpolation and low pass filters 111: DISABLE. 0 = INTERP 1 = LPF1 2 = LPF2 3 = LPF3 4 = LPF4 5 = LPF5 6 = LPF6 7 = DISABLE
19	0x0	DISCSC: enabled color space converter by default 0 = ENABLE 1 = DISABLE
18	0x0	VFEN: StretchBLT Vertical Filter Enable (VFEN) Vertical filter shall be disabled if source images come from host CPU via CPU Read-FIFO. (SISEL) Vertical filter may be disabled to save some memory bandwidth but this will likely result in degradation of image quality. This option may also be used in the case where source image is progressive scanning and there is no vertical scaling. 0: Vertical filter is disabled. 1: Vertical filter is enabled. 0 = DISABLE 1 = ENABLE
17:16	0x0	VFTYPE: StretchBLT Vertical Filter Mode (VFTYPE[1:0]) This bit is effective when the Vertical Filter is enabled. (bit 18) The two-tap vertical interpolation filter can be operated in various modes. For the image expansion, it should be programmed as a pure 2-tap interpolator. For the image contraction, it can work as partly averager and partly interpolator with varying degree depending on the contraction ratio. For StretchBLT, this parameter is used as an index (selection) to an internal lookup table that stores the group of filter-coefficients for the different modes of vertical filtering. 00: Pure interpolation filter. 01: 25% averager, 75% interpolator. 10: 50% averager, 50% interpolator. 11: 100% averager. 0 = INTERP 1 = AVG25_INTERP75 2 = AVG50_INTERP50 3 = AVG
9:8	X	UVST: 00= 1/2 of Luma Buffer Stride; in this case Luma Buffer Stride should be a multiple of 2 bytes. 01= Equal to Luma Buffer Stride 10= 1/4 of Luma Buffer Stride; in this case Luma Buffer Stride should be a multiple of 4 bytes. 11= use uvstride. **Note**: Use care when using a tiled surface, since 1/2 or 1/4 of luma stride may yield an invalid pitch (stride). 0 = UVS2X 1 = UVS1X 2 = UVS4X 3 = UVS_G2UVSTRIDE

Bit	Reset	Description
7	0x0	ENAHF: enable horizontal alpha filtering if disabled, use the alpha value of third tap for output pixel U,V line stride in 4:2:0 Format. 0 = DISABLE 1 = ENABLE
6	0x0	ENAVF: enable alpha vertical filter 0 = DISABLE 1 = ENABLE
5	0x0	IMODE: Source (input) Data Mode (IMODE). This parameter defines the data mode of source input. 0: Multiplexed Mode (data format is specified by SIFMT[2:0]). One block of source data in the Image Buffer memory contains multiplexed component signals. 1: Planar mode, 4:2:0 YUV (SIFMT[2] specifies data format of U/V components). Three blocks of source data in the Image Buffer memory contain separate Y, U, and V component signals. For a circular buffer input to gr2d, the input format cannot be planar. It must be multiplex, i.e., no YUV420 planar circular buffer input to gr2d. 0 = MULTIPLEX 1 = PLANAR
4	0x0	YUV422PLANAR: Source data is yuv422 planar valid when imode==PLANAR
3	0x0	YUV422ROTATION: YUV422 planar rotated.

14.2.4 G2SB_G2CONTROLMAIN_0

G2 Blit Formats:

(1) G2 Blit size is based on height in lines, width in pixels, stride in bytes, and pixel size (color depth). Unless alpha blending is enabled, G2 does not care about pixel components.

Source color depths supported by G2 Blit:

- color depth same as destination: G2CONTROLMAIN.SRCCD = 1
- monochrome: G2CONTROLMAIN.SRCCD = 0

(source monochrome color determined by G2SRCBGC, G2SRCFGC)

Pattern color depths supported by G2 Blit:

- color depth same as destination: G2PATOS.PATCD = 1
- monochrome: G2PATOS.PATCD = 0

(pattern monochrome color determined by G2PATBGC, G2PATFGC)

Destination color depths supported by G2 Blit:

- 1 byte per pixel: G2CONTROLMAIN.DSTCD = BPP8
- 2 bytes per pixel: G2CONTROLMAIN.DSTCD = BPP16
- 4 bytes per pixel: G2CONTROLMAIN.DSTCD = BPP32

(2) Alpha blending operates on 3 or 4 component pixels of a specified color depth. One of the components may be alpha (A), depending on the alpha blend format, which is only allowed in certain component positions defined below. The only format rule of the remaining components is that they must be in the same source and destination position because the alpha blend engine does not support component swapping. For example, valid 32BPP formats are: RGBA_8888->RGBA_8888, BGRA_8888->BGRA_8888, GRBA_8888->GRBA_8888, etc.

Source formats supported by G2 alpha blend:

- color depth BPP8: no supported formats
- color depth BPP16:
  - ALPTYPE_PLS1BPP: xxxA_5551 (for example, BGRA_5551 = A[15] R[14:10] G[9:5] B[4:0])
  - ALPTYPE_PLS4BPP: xxxA_4444 (for example, BGRA_4444 = A[15:12] R[11:8] G[7:4] B[3:0])
  - (other): xxx_565 (for example, BGR_565 = R[15:11] G[10:5] B[4:0])
- color depth BPP32:
  - (all) : xxxA_8888 (for example, BRGA_8888 = A[31:24] R[23:16] G[15:8] B[7:0])

Destination formats supported by G2 alpha blend:

- color depth BPP8: no supported formats
- color depth BPP16: xxx_565 (for example, BGR_565 = R[15:11] G[10:5] B[4:0])
- color depth BPP32: xxxA_8888 (for example, BRGA_8888 = A[31:24] R[23:16] G[15:8] B[7:0])

VCAA Resolve Engine

(1) Format support

srcColor format	srcCoverage format	legal dest format(s)
A1B5G5R5	VCAA	A1B5G5R5
R8G8B8A8	VCAA	R8G8B8A8, B5G6R5
B5G6R5	VCAA	B5G6R5

To program resolve type:

ALPTYPE == FIX: B5G6R5 -> B5G6R5

ALPTYPE == PLS1BPPAL: A1B5G5R5 -> A1B5G5R5

ALPTYPE == PLS8BPP: R8G8B8A8 -> R8G8B8A8

ALPTYPE == PLS8BX: R8G8B8A8 -> B5G6R5

(2) Color surface programming

- color surface base address: SRCBA
- sub-surface start x: SRCX (pixel index)
- sub-surface start y: SRCY (line index)
- color surface stride: SRCS (bytes)

The engine supports sub-surface resolve. One can imagine a full color buffer of 1024x768, but

```
    [pseudo_code]
      color_surface_start_address_fetch = pcurctx->regs.rG2SRCBA.uSRCBA() +
       (pcurctx->regs.rG2SRCPS.uSRCX() * VCAAState.color_surface_depth) +
       (pcurctx->regs.rG2SRCPS.uSRCY() * VCAAState.color_surface_stride);
```

(3) VCAA surface programming

- vcaa surface base address: PATBA
- vcaa surface stride: PATST (bytes)

```
[pseudo_code]
     vcaa_surface_start_address_fetch = pcurctx->regs.rG2PATBA.uPATBA();
```

Software *MUST* directly program this register to the proper sub-surface location in the VCAA surface which corresponds to the SRCX and SRCY programming. The calculation is PATBA = vcaa_base_address + SRCX * (1) + SRCY * PATST;

(4) Resolve surface programming

- resolve window width: DSTWIDTH (pixels)
- resolve window height: DSTHEIGHT (lines)
- resolve output stride: DSTS (bytes)

These values program the width and height of the resolved surface. In the base case,

- DSTWIDTH = color surface width
- DSTHEIGHT = color sufrace height
- DSTS = resolve surface format bpp * DSTWIDTH

The VCAA engine technically supports DSTX and DSTY (like SRCX and SRCY).

```
 [pseudo_code]
    resolve_surface_start_address_put = pcurctx->regs.rG2DSTBA.uDSTBA() +
      (pcurctx->regs.rG2DSTPS.uDSTX() * resolve_surface_color_depth) +
      (pcurctx->regs.rG2DSTPS.uDSTY() * resolve_surface_color_stride);
```

(5) Resolving a pixel

The coverage surface is a 8 bits per pixel surface (C4X4). The surface is initialized to all 1s by 3d.

For a given pixel, we need to look up 4 bits of coverage data. If the data is 0xf, the pixel does not need to be resolved. Otherwise, we need to reblend the pixel with certain weightings of its neighbors (i.e., we're on the edge of some geometry)

If any coverage bit is 0, we need to resolve the color. To do so, we calculate the following equation:

```
   color_new = (
```

```
                20*color_old +
                27*(
                    ((cover_down  == 0) ? color_down  : color_old) +
                    ((cover_right == 0) ? color_right : color_old) +
                    ((cover_left  == 0) ? color_left  : color_old) +
                    ((cover_up    == 0) ? color_up    : color_old)
                    )
            ) / 128;
```

If coverage bit == 0, then we use the neighbor color value in the resolve

If coverage bit == 1, then we use the center color value in the resolve

The resolve is done on a per channel (r/g/b/a) basis:

- format convert input channel to 8-bit
- perform resolve equation above
- format convert to output format

For the resolution of the alpha channel:

- In B5G6R5: no alpha information. do nothing.
- In A1B5G5R5: no resolve. keep the source color alpha bit.
- In R8G8B8A8: normal 8-bit channel resolve

(6) Resolving a pixel on the edge

When on an edge, the vcaa engine treats the coverage bit as a 1. Use the center color value. This holds true even on the edge of the sub-surface resolve window when located in the middle of the larger surface

(7) Maximum dimensions

The maximum resolve sub-surface is 4096 pixels wide.

(8) Surface restrictions

The VCAA engine has the following restrictions with respect to input surfaces

- input base address is 128-bit memory word aligned

- input stride is a multiple of 128 bits (16 bytes)

The VCAA engine has the following restrictions with respect to output surfaces

- output base address is 128-bit memory word aligned

- output stride is a multiple of 128 bits (16 bytes)

(9) Coverage surface layout

The surface is C4X4.

Surface layout (C4X4)

```
       (lsb2msb)  C0_C1_C2_C3_X_X_X_X     (X is a don't care.  Qrast inits to 1)
       (msb2lsb)  X_X_X_X_C3_C2_C1_C0

    +          o          o
         C0
            C1    Cov(0,1)
     C2
```

```
          C3
     o          o          o

       Cov(1,0)    Cov(1,1)

     o          o          o

     +/o = pixel centers
```

In the example above,

```
        Cov(0,0) = X_X_X_X_C3_C2_C1_C0
        C3       = V_C3(Cov(0,0));
        ..         ..
        C0       = V_C0(Cov(0,0));
     #define V_C3(bits) (bits & 0x8)
     #define V_C2(bits) (bits & 0x4)
     #define V_C1(bits) (bits & 0x2)
     #define V_C0(bits) (bits & 0x1)
```

Resolving a pixel

In an ideal world, the coverage would be simply laid out such that when resolving Pixel(x,y), we would need only to fetch Cov(x,y) to get all 4 bits of information.

In actuality, the coverage surface was rearranged to help qrast in performance. To resolve Pixel(x,y) gr2d has to fetch 4 C4X4 bytes [Cov(x,y), Cov(x-1,y), Cov(x,y-1), Cov(x-1,y-1)]. From each C4X4 byte, it extracts one bit which is used in the resolve equations shown in (5).

Need the logical VCAA bits (DRLU) for blend which is spread across four C4X4 coverage bytes

```
          U
    L
        o
            R
      D
```

where

```
     o = Pixel(x,y)
     D = V_C1(Cov(x-1,y))
     R = V_C0(Cov(x,y))
     L = V_C3(Cov(x-1,y-1))
     U = V_C2(Cov(x,y-1))
```

Offset: 0x1f | Byte Offset: 0x7c | Read/Write: R/W | Reset: 0x00000000 (0bx000000x00xx00xx0000000000000000)

14.2.45 G2SB_G2SRCBA_SB_SURFBASE_0

SB_SURFBASE Registers

These registers need only be programmed when using SB. They point to the base of the various source and destination surfaces. Technically, they are only needed when tiling is enabled, but there is no harm in always programming them.

Their counterpart registers (_SB_SURFBASE with SB_SURFBASE stripped off) indicate the location of the first pixel to be sourced or written within the surface.

This register exists to mimic the X, Y (SRCX, SRCY) functionality found in the BitBlt engine.

For example, to get at pixel X, Y:

SRCBA = SRCBA_SB_SURFBASE + Y*stride + X*Bpp

Offset: 0x48 │ Byte Offset: 0x120 │ Read/Write: R/W │ Reset: 0x00000000 (0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx)

Bit	Reset	Description
31:0	X	COND_STATUS: COND_STATUS[COND] is set if the FIFO for COND overflows. This bit is sticky and will remain set until cleared. Cleared by writing 1.

14.3.4 G2SB_CTX1_G2CLASSCHANNEL_REGONLY_0

This register can be accessed by both register read/write and command FIFO in order not to break exsting code , keep suffix REGONLY.

2D syncpt behavior

- Each 2D context has its own syncpt client.
- OP_DONE increments when 2D's memory write client is idle, meaning all preceding operations are complete.
- RD_DONE behaves like OP_DONE
- REG_WR_SAFE behaves like IMMEDIATE meaning a syncpt increment returns immediately and does not indicate that a register write will NOT block. The implications are that 2D's host FIFO can fill and block access to 2D, which will indeterminately block a direct CPU access.

Bit	Reset	Description
31:0	X	VDSTEP: Vertical Scaling DDA. Reset value: xxxx-xxxxh. Vertical DDA Step (Increment) Value (VDSTEP[18:0]) (upper 13 bits should be set to '0'). This parameter specifies the increment value of the DDA used for vertical scaling and it is in the form of a 6-bit integer and 12-bit fraction. This value is determined by the equation: (Actual_source_height-1-VDTINI) / (Actual_destination_height-1) Truncate the remaining bits to keep the 12-bit fraction. Since we have to meet (Actual_source_height-1)*1.0 >= (Actual_destination_height - 1)*VDSTEP + VDTINI. The 6-bit integer allows maximum contraction ratio of 1/64, and 12-bit fraction ensures the maximum limit of accumulated error less than half line spacing for up to approximately 2000 target lines. For example, image expansion from 240 lines to 400 lines VDSTEP[17:0] = 19'b00_0000_1001_1001_1010 and image contraction from 240 lines to 150 lines VDSTEP[17:0] = 19'b00_0001_1001_1001_1010.

14.3.13 G2SB_CTX1_G2VDDAINI_0

Offset: 0x4012 │ Byte Offset: 0x10048 │ Read/Write: R/W │ Reset: 0x00000000 (0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx)

Bit	Reset	Description
15:8	X	VDBINI: Vertical DDA Initial Value for Bottom-Field (VDBINI[7:0]) (see description above)
7:0	X	VDTINI: Vertical Scaling DDA Initial Values. Vertical DDA Initial Value for Top-Field (VDTINI[7:0]) This parameter specifies the fraction part of initial value of the DDA used for vertical scaling. Given a pair of consecutive source image lines representing positions 0.0 and 1.0, a destination line-image will be created at any position in [0.0, 1.0), that is specified by the fraction part of the

Bit	Reset	Description
		vertical DDA. The 8-bit initial fraction value specifies the position of the first output (destination) line-image located between the first and the second input (source) line-images, respectively at position 0.0 and 1.0. This parameter provides a way to compensate relative displacement of top and bottom fields of a source image. Suppose, 2-to-1 interlaced original video field images #1 and #2 are in the image buffer, to be displayed in an overlay window. Assume that the #1 field image is the top-field. Using VDTINI = 8'hC0 for the top-field image and VDBINI = 8'h40 for the bottom-field image, for example, the two images from #1 and #2 fields get mapped to identically positioned destination images in the overlay window.

14.3.14 G2SB_CTX1_G2HDDA_0

Offset: 0x4013 | Byte Offset: 0x1004c | Read/Write: R/W | Reset: 0x00000000 (0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx)

Bit	Reset	Description
31:0	X	HDSTEP: Horizontal Scaling DDA. Reset value: xxxx-xxxxh. Horizontal DDA Step (Increment) Value (HDSTEP[18:0]) (upper 13 bits should be set to '0') This parameter specifies the increment value of the DDA used for horizontal scaling and it is in the form of 6-bit integer and 12-bit fraction. This value is determined by the equation: (Actual_source_width-1-HDINI) / (Actual_destination_width-1) Truncate the remaining bits to keep the 12-bit fraction. The 6-bit integer allows maximum contraction ratio of 1/64, and 12-bit fraction ensures the maximum limit of accumulated error less than half pixel-spacing for up to approximately 2000 destination pixels. For example, image expansion from 720 pixels to 800 pixels HDSTEP[17:0] = 19'b000_0000_1110_0110_0111 and image contraction from 720 pixels to 250 pixels HDSTEP[17:0] = 19'b000_0010_1110_0001_0101.

14.3.15 G2SB_CTX1_G2HDDAINILS_0

Offset: 0x4014 | Byte Offset: 0x10050 | Read/Write: R/W | Reset: 0x00000000 (0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx)

Bit	Reset	Description
7:0	X	HDINI: Horizontal Scaling DDA Initial Value. Horizontal DDA Initial Value (HDINI[7:0]) This parameter specifies the fraction part of initial value of the DDA used for horizontal scaling. Given a group of six consecutive source pixels that the two pixels at the center representing positions 0.0 and 1.0, a destination pixel will be created at any position in [0.0, 1.0), that is specified by the fraction part of the horizontal DDA. The 8-bit initial fraction value specifies the position of the first output (destination) pixel located between the first and the second input (source) pixels, respectively at position 0.0 and 1.0.For horizontal scaling, this value may normally be set to 0.

14.3.16 G2SB_CTX1_G2CSCFIRST_0

The next 3 registers contain 8 parameters used by the YCbCr (YUV) to RGB color space conversion logic. This logic can also be used for RGB gain/gamma correction in RGB to RGB modes, and for luma gain in YUV to YUV modes.

Two parameters (G2U, G2V) have been added for RGB to YUV conversion in address 0x38. The equations have the form:

if (yuv2rgb)

(r,g,b) = matrix*(y+sbreg_yos,u,v)

matrix: sbreg_cyx, sbreg_cur, sbreg_cvr,
sbreg_cyx, sbreg_cug, sbreg_cvg,
sbreg_cyx, sbreg_cub, sbreg_cvb,

else if (rgb2rgb)

(r,g,b) = matrix*(r,g+sbreg_yos,b)

matrix:	sbreg_cvr,	0,	sbreg_cur,
	sbreg_cvg,	sbreg_cyx,	sbreg_cug,
	sbreg_cvb,	0,	sbreg_cub,

else if (yuv2yuv)

(y,u,v) = matrix*(y,u,v)

matrix:	sbreg_cub,	0,	sbreg_cvb,
	sbreg_cug,	sbreg_cyx,	sbreg_cvg,
	sbreg_cur,	0,	sbreg_cvr,

else if (rgb2yuv)

(y,u,v) = matrix*(r,g,b) + (sbreg_yos,0,0)

matrix:	sbreg_cvb,	sbreg_cyx,	sbreg_cub,
	sbreg_cvg,	sbreg_g2u,	sbreg_cug,
	sbreg_cvr,	sbreg_g2v,	sbreg_cur,

Offset: 0x4015 │ Byte Offset: 0x10054 │ Read/Write: R/W │ Reset: 0x00000000 (0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx)

Bit	Reset	Description
31:24	X	YOS: Y-Offset (YOFFSET[7:0]) for YUV generation. This parameter consists of 8-bit 2's complement in the range [-128,127]. For YUV->RGB, the recommended value is -16 (decimal) or 0xF0. For YUV->YUV & RGB->RGB, this parameter should be set to 0. For RGB->YUV, the recommended value is +16 (decimal) or 0x10.
21:12	X	CVR: multiplier for V/R for V or R generation. This parameter consists of a sign bit and 9-bit magnitude (s2.7). For YUV->RGB, the recommended value is 1.5960 (decimal) or 0x0CCIf source data is in RGB format, this parameter may be used as gain adjustment for R component. For RGB->YUV, the recommended value is +0.439 (decimal) or 0x038.
9:0	X	CUB: multiplier for U/B for Y or B generation. Consists of a sign bit and 9-bit magnitude (s2.7). For YUV->RGB, the recommended value is 2.0172 (decimal) or 0x102. If source data is in RGB format, this parameter may be used as gain adjustment for B component. This register changes precision when doing RGB to YUV conversion (SIFMT=1xxx, DIFMT=0xxx). CUB becomes s1.8 and the recommended value is +0.098 or 0x019.

14.3.17 G2SB_CTX1_G2CSCSECOND_0

Bit	Reset	Description
31:24	X	CYX: Multiplier for Y/G (G gain). This positive-only parameter consists of 8-bit magnitude (1.7). For YUV->YUV, the recommended value is 1.1644 (decimal) or 0x95. For YUV->YUV or RGB->RGB, this may be used as gain adjustment for Y or G component. For RGB->YUV, the recommended value is +0.504 (decimal) or 0x041.
21:12	X	CUR: Multiplier for U/B for V or R generation. This parameter consists of a sign bit and 9-bit magnitude (s2.7). For YUV->RGB, normally this parameter is programmed to 0.0. This parameter takes non-zero value if hue is rotated. For YUV->YUV & RGB->RGB, this parameter should be set to 0. For RGB->YUV, the recommended value is -0.071 (decimal) or 0x209.
8:0	X	CUG: Multiplier for U/B for U or G generation. Consists of a sign bit and 8-bit magnitude (s1.7). For YUV->RGB, the recommended value is -0.3918 (decimal) or 0x132. For RGB->RGB, this parameter should be set to 0. For YUV->YUV, this parameter should be set to 1 (0x080). For RGB->YUV, the recommended value is +0.439 (decimal) or 0x038.

14.3.18 G2SB_CTX1_G2CSCTHIRD_0

Offset: 0x4017 │ Byte Offset: 0x1005c │ Read/Write: R/W │ Reset: 0x00000000 (0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx)

Bit	Reset	Description
25:16	X	CVB: Multiplier for V/R for Y or B generation. This parameter consists of a sign bit and 9-bit magnitude (s2.7). For YUV->RGB, normally this parameter is programmed to 0.0. This coefficient takes non-zero value if hue is rotated. For YUV->YUV & RGB->RGB, this parameter should be set to 0. For RGB->YUV, the recommended value is +0.257 (decimal) or 0x021.
8:0	X	CVG: Multiplier for V/R for U or G generation. This parameter consists of a sign bit and 8-bit magnitude (s1.7). For YUV->RGB the recommended value is -0.8130 (decimal) or 0x168. For YUV->YUV & RGB->RGB, this parameter should be set to 0. For RGB->YUV, the recommended value is -0.148 (decimal) or 0x113.

14.3.19 G2SB_CTX1_G2CMKEYL_0

When key generation is enabled, the value of this register is the lower color/chroma limit and G2CMKEYU is the upper color/chroma limit for component pixel data. Three component signal values (YCrCb/YUV or RGB) of every output pixel are compared to a set of three ranges that are specified by three pairs of lower and upper color/chroma key values.

If the Key Polarity is 0, the Key is set to 1 only when all three component values of an input pixel are respectively within the set of ranges (inclusive of the limit values), else the Key is set to 0.

If the Key Polarity is 1, the Key is set to 1 when any of the three component values of an input pixel are outside the set of ranges; otherwise, the Key is set to 0.

StretchBLT, Color/Chroma Key Lower Limit Register

Offset: 0x4018 │ Byte Offset: 0x10060 │ Read/Write: R/W │ Reset: 0x00000000 (0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx)

Bit	Reset	Description
23:16	X	CKRL:R or Cr Color Chroma Key Lower Limit (CKRL[7:0]) Cr signal must be treated in offset binary format so that the binary interpretation retains monotonicity from the minimum signal level to the maximum signal level.
15:8	X	CKGL:G or Cb Color Chroma Key Lower Limit (CKGL[7:0]) Cb signal must be treated in offset binary format so that the binary interpretation retains monotonicity from the minimum signal level to the maximum signal level.
7:0	X	CKBL: B or Y Color/Chroma Key Lower Limit (CKBL[7:0])

14.3.24 G2SB_CTX1_G2CONTROLSB_0

Offset: 0x401d │ Byte Offset: 0x10074 │ Read/Write: R/W | Reset: 0x00000000 (0b00x00000000000000x0xx0xx00000xxx)

Bit	Reset	Description
31	0x0	DISDW: Output destination writes go either to image memory or the EPP. 0: Output data is sent to memory 1: YUV or RGB data is passed directly to the EPP module, and no destination writes take place. 0 = GOTO_IMAGE_BUFFER 1 = GOTO_EPP
30	0x0	ENDITH: Enable Dithering (ENDITH). For 16 bit RGB output modes, the LSB of the color components can be modified by adding a variable residual value that will reduce the banding artifacts that can appear on the display. 0: Normal operation 1: Enable Dithering 0 = DISABLE 1 = ENABLE

Bit	Reset	Description
28	0x0	KPOL: Key Signal Polarity (KPOL) Color/Chroma key signal is generated by comparing source input pixel color to a range of a color specified by lower and upper limit values. The key signal is interpreted in two ways, depending on which one of video and graphics images is foreground (and the other is background). This is effective only if Key signal generator is enabled. (see G2CMKEYL, G2CMKEYU) 0: Key signal is set to 1 when source pixel is within the lower and upper limit color range. 1: Key signal is set to 1 when source pixel is outside the lower and upper limit color range. 0 = WITHIN_BOUNDS 1 = OUTSIDE_BOUNDS
27	0x0	KEYEN: Key Signal Generator Enable (KEYEN) Key signal generator generates either chroma key signal (from YCbCr signal) or color key signal (from RGB signal) 0: Key signal generator is disabled. 1: Key signal generator is enabled. 0 = DISABLE 1 = ENABLE
26	0x0	DBSEL: StretchBLT Destination Buffer Selection (DBSEL) StretchBLT processing involves frame-rate conversion from a series of source images to another series of destination images (field-rate of the source video to frame-rate of the PC display). In order to avoid image tearing, it is preferred to use two buffer sections in the destination video area. This bit selects one of the two buffering blocks to which this StretchBLT command delivers the destination image. The two buffering memory blocks are called A and B. 0: Destination image goes to ‘A’ buffer. 1: Destination image goes to ‘B’ buffer. 0 = DST_A 1 = DST_B
25	0x0	SBSEL: StretchBLT Source Buffer Selection (SBSEL) StretchBLT processing involves frame-rate conversion from a series of source images to another series of destination images (field-rate of the source video to frame-rate of the PC display). In order to avoid image tearing, it is preferred to use two buffer sections in the source video area. This bit selects one of the two buffering blocks from which this StretchBLT command receives the source image. The two buffering memory blocks are called source-A and source-B. 0: Source image comes from ‘source-A’ buffer. 1: Source image comes from ‘source-B’ buffer. 0 = SRC_A 1 = SRC_B
24	0x0	SITYPE: StretchBLT Source Type (SITYPE). This bit identifies two types of source images. If source image is 2-to-1 interlaced and StretchBLT processes either one of the two interlaced field-images, physical (positional) displacement between the two interlaced fields must be taken into account. One field-image that is placed higher in position than the other field-image is called top-field and the other is called bottom-field. StretchBLT processing has to lower the top-field (or raise the bottom-field) to match the corresponding two target images in the overlay window (that is progressively scanned) right at the same position. If source image is full frame-image obtained from two interlaced field-images, its type is ‘top-field’. If source images are progressively scanned, the type identification is not significant and they may be designated either one of the two types 0: Source image is ‘top-field’. 1: Source image is ‘bottom-field’. 0 = TOP_FIELD 1 = BOTTOM_FIELD

Bit	Reset	Description
23	0x0	RANGEREDFRM:In the VC-1 specification, when the value of RANGEREDFRM variable (1-bit) for a picture is equal to 1, the picture shall be scaled up according to the following equation:Y = clip(((Y-128)*2) + 128);Cb = clip(((Cb-128)*2) + 128);Cr = clip(((Cr-128)*2) + 128);The clip operator limits the output to [0, 255].The input is also limited to [0, 255].In the VC-1 nomenclature, the output (Y, Cb, Cr) tuple corresponds to the 'decoded' picture. The input (Y, Cb, Cr) tuple corresponds to the 'reconstructed' picture. The above equations create the decoded picture while keeping the reconstructed picture intact.Only YUV _OB formats are supported with range reducation enabled, not the YUV _TC or RGB formats The YUV data coming from the video frame buffers (reconstructed picture) in the SDRAM was scaled up using the above equations and given to the display. the value of 1-bit wide RANGEREDFRM variable was configured in the DVO per frame and the frame was scaled whenever RANGEREDFRM == 1. 0 = DISABLE 1 = ENABLE
22:20	0x0	HFTYPE: StretchBLT Horizontal Filter Mode (HFTYPE[2:0]) The six-tap horizontal interpolation filter can be operated in various operation modes. For the image expansion, it should be programmed as a pure 6-tap interpolator. For the image contraction, it can work as partly low-pass filter and partly interpolater with varying degree depending on the contraction ratio. For StretchBLT, this parameter is used as an index (selection) to an internal lookup table that stores the group of filter-coefficients for the different modes of horizontal filtering. 000: Pure interpolation filter 001, 010, 011, 100, 101, 110: mix of interpolation and low pass filters 111: DISABLE. 0 = INTERP 1 = LPF1 2 = LPF2 3 = LPF3 4 = LPF4 5 = LPF5 6 = LPF6 7 = DISABLE
19	0x0	DISCSC: enabled color space converter by default 0 = ENABLE 1 = DISABLE
18	0x0	VFEN: StretchBLT Vertical Filter Enable (VFEN). Vertical filter shall be disabled if source images come from host CPU via CPU Read-FIFO. (SISEL) Vertical filter may be disabled to save some memory bandwidth but this will likely result in degradation of image quality. This option may also be used in the case where source image is progressive scanning and there is no vertical scaling. 0: Vertical filter is disabled. 1: Vertical filter is enabled. 0 = DISABLE 1 = ENABLE
17:16	0x0	VFTYPE: StretchBLT Vertical Filter Mode (VFTYPE[1:0]). This bit is effective when the Vertical Filter is enabled. (bit 18) The two-tap vertical interpolation filter can be operated in various modes. For the image expansion, it should be programmed as a pure 2-tap interpolator. For the image contraction, it can work as partly averager and partly interpolator with varying degree depending on the contraction ratio. For StretchBLT, this parameter is used as an index (selection) to an internal lookup table that stores the group of filter-coefficients for the different modes of vertical filtering. 00: Pure interpolation filter. 01: 25% averager, 75% interpolator. 10: 50% averager, 50% interpolator. 11: 100% averager. 0 = INTERP 1 = AVG25_INTERP75 2 = AVG50_INTERP50 3 = AVG

Bit	Reset	Description
9:8	X	UVST: 00: 1/2 of Luma Buffer Stride; in this case Luma Buffer Stride should be a multiple of 2 bytes. 01: Equal to Luma Buffer Stride 10: 1/4 of Luma Buffer Stride; in this case Luma Buffer Stride should be a multiple of 4 bytes. 11: Use uvstride. Note: Use care when using a tiled surface, since 1/2 or 1/4 of luma stride may yield an invalid pitch (stride). 0 = UVS2X 1 = UVS1X 2 = UVS4X 3 = UVS_G2UVSTRIDE
7	0x0	ENAHF: Enable horizontal alpha filtering if disabled, use the alpha value of third tap for output pixelU,V line stride in 4:2:0 format, 0 = DISABLE 1 = ENABLE
6	0x0	ENAVF: Enable alpha vertical filter 0 = DISABLE 1 = ENABLE
5	0x0	IMODE: Source (input) Data Mode (IMODE). This parameter defines the data mode of source input. 0: Multiplexed Mode (data format is specified by SIFMT[2:0]). One block of source data in the Image Buffer memory contains multiplexed component signals. 1: Planar mode, 4:2:0 YUV (SIFMT[2] specifies data format of U/V components). Three blocks of source data in the Image Buffer memory contain separate Y, U, and V component signals. For a circular buffer input to gr2d, the input format cannot be planar. It must be multiplex, i.e., no YUV420 planar circular buffer input to gr2d. 0 = MULTIPLEX 1 = PLANAR
4	0x0	YUV422PLANAR: Source data is yuv422 planar valid when imode==PLANAR
3	0x0	YUV422ROTATION: YUV422 planar rotated.

14.3.26 G2SB_CTX1_G2CONTROLMAIN_0

G2 Blit Formats:

(1) G2 Blit size is based on height in lines, width in pixels, stride in bytes, and pixel size (color depth). Unless alpha blending is enabled, G2 does not care about pixel components.

Source color depths supported by G2 Blit:

- Color depth same as destination: G2CONTROLMAIN.SRCCD = 1
- Monochrome: G2CONTROLMAIN.SRCCD = 0

(source monochrome color determined by G2SRCBGC, G2SRCFGC)

Pattern color depths supported by G2 Blit:

- Color depth same as destination: G2PATOS.PATCD = 1
- Monochrome: G2PATOS.PATCD = 0

(pattern monochrome color determined by G2PATBGC, G2PATFGC)

Destination color depths supported by G2 Blit:

- 1 byte per pixel: G2CONTROLMAIN.DSTCD = BPP8
- 2 bytes per pixel: G2CONTROLMAIN.DSTCD = BPP16
- 4 bytes per pixel: G2CONTROLMAIN.DSTCD = BPP32

(2) Alpha blending operates on 3 or 4 component pixels of a specified color depth. One of the components may be alpha (A), depending on the alpha blend format, which is only allowed in certain component positions defined below. The only format rule of the remaining components is that they must be in the same source and destination position because the alpha blend engine does not support component swapping. For example, valid 32BPP formats are: RGBA_8888->RGBA_8888, BGRA_8888->BGRA_8888, GRBA_8888->GRBA_8888, etc.

Source formats supported by G2 alpha blend:

- Color depth BPP8: no supported formats
- Color depth BPP16:
  - ALPTYPE_PLS1BPP: xxxA_5551 (for example, BGRA_5551 = A[15] R[14:10] G[9:5] B[4:0])
  - ALPTYPE_PLS4BPP: xxxA_4444 (for example, BGRA_4444 = A[15:12] R[11:8] G[7:4] B[3:0])
  - (other) : xxx_565 (for example, BGR_565 = R[15:11] G[10:5] B[4:0])
- Color depth BPP32:
  - (all) : xxxA_8888 (for example, BRGA_8888 = A[31:24] R[23:16] G[15:8] B[7:0])

Destination formats supported by G2 alpha blend:

- Color depth BPP8: no supported formats
- Color depth BPP16: xxx_565 (for example, BGR_565 = R[15:11] G[10:5] B[4:0])
- Color depth BPP32: xxxA_8888 (for example, BRGA_8888 = A[31:24] R[23:16] G[15:8] B[7:0])

src cd	src format	dst cd	dst format	examples
BPP8	no support	BPP8	no support	
BPP16	xyzA_5551, xyzA_4444, xyz_565	BPP16	xyz_565	BGRA_5551->BGR_565, RGB_565->RGB565
BPP32	xyzA_8888	BPP32	xyzA_8888	RGBA_8888->RGBA_8888, BGRA_8888->BGRA_8888
BPP32	xyzA_8888	BPP16	xyz_565	RGBA_8888->RGB_565, BGRA_8888->BGR_565

VCAA Resolve Engine

(1) Format support

srcColor format	srcCoverage format	legal dest format(s)
A1B5G5R5	VCAA	A1B5G5R5
R8G8B8A8	VCAA	R8G8B8A8, B5G6R5
B5G6R5	VCAA	B5G6R5

To program resolve type:

- ALPTYPE == FIX: B5G6R5 -> B5G6R5
- ALPTYPE == PLS1BPPAL: A1B5G5R5 -> A1B5G5R5
- ALPTYPE == PLS8BPP: R8G8B8A8 -> R8G8B8A8
- ALPTYPE == PLS8BX: R8G8B8A8 -> B5G6R5

(2) Color surface programming

- color surface base address: SRCBA
- sub-surface start x: SRCX (pixel index)
- sub-surface start y: SRCY (line index)
- color surface stride: SRCS (bytes)

The engine supports subsurface resolve. One can imagine a full color buffer of 1024x768, but

```
[pseudo_code]
      color_surface_start_address_fetch = pcurctx->regs.rG2SRCBA.uSRCBA() +
       (pcurctx->regs.rG2SRCPS.uSRCX() * VCAAState.color_surface_depth) +
       (pcurctx->regs.rG2SRCPS.uSRCY() * VCAAState.color_surface_stride);
```

(3) VCAA surface programming

- VCAA surface base address: PATBA
- VCAA surface stride: PATST (bytes)

```
[pseudo_code]
      vcaa_surface_start_address_fetch = pcurctx->regs.rG2PATBA.uPATBA();
```

Software *MUST* directly program this register to the proper sub-surface location in the vcaa surface which corresponds to the SRCX and SRCY programming. The calculation is PATBA = vcaa_base_address + SRCX * (1) + SRCY * PATST;

(4) Resolve surface programming

- resolve window width: DSTWIDTH (pixels)
- resolve window height: DSTHEIGHT (lines)

- resolve output stride: DSTS (bytes)

These values program the width and height of the resolved surface. In the base case,

- DSTWIDTH = color surface width
- DSTHEIGHT = color sufrace height
- DSTS = resolve surface format bpp * DSTWIDTH

The VCAA engine technically supports DSTX and DSTY (like SRCX and SRCY).

```
[pseudo_code]
   resolve_surface_start_address_put = pcurctx->regs.rG2DSTBA.uDSTBA() +
     (pcurctx->regs.rG2DSTPS.uDSTX() * resolve_surface_color_depth) +
     (pcurctx->regs.rG2DSTPS.uDSTY() * resolve_surface_color_stride);
```

(5) Resolving a pixel

The coverage surface is an 8 bits per pixel surface (C4X4). The surface is initialized to all 1s by 3d.

For a given pixel, we need to look up 4 bits of coverage data. If the data is 0xf, the pixel does not need to be resolved. Otherwise, we need to reblend the pixel with certain weightings of its neighbors (i.e. we're on the edge of some geometry).

If any coverage bit is 0, we need to resolve the color. To do so, calculate the following equation:

```
color_new = (
              20*color_old +
              27*(
                  ((cover_down  == 0) ? color_down  : color_old) +
                  ((cover_right == 0) ? color_right : color_old) +
                  ((cover_left  == 0) ? color_left  : color_old) +
                  ((cover_up    == 0) ? color_up    : color_old)
                 )
            ) / 128;
```

If coverage bit == 0, then we use the neighbor color value in the resolve

If coverage bit == 1, then we use the center color value in the resolve

The resolve is done on a per channel (r/g/b/a) basis:

- format convert input channel to 8-bit
- perform resolve equation above
- format convert to output format

For the resolution of the alpha channel:

- In B5G6R5: No alpha information. Do nothing.
- In A1B5G5R5: No resolve. Keep the source color alpha bit.
- In R8G8B8A8: Normal 8-bit channel resolve

(6) Resolving a pixel on the edge

When on an edge, the vcaa engine treats the coverage bit as a 1. Use the center color value. This holds true even on the edge of the sub-surface resolve window when located in the middle of the larger surface

(7) Maximum dimensions

The maximum resolve sub-surface is 4096 pixels wide.

(8) Surface restrictions

The VCAA engine has the following restrictions with respect to input surfaces

- input base address is 128-bit memory word aligned

- input stride is a multiple of 128 bits (16 bytes)

The VCAA engine has the following restrictions with respect to output surfaces

- output base address is 128-bit memory word aligned

- output stride is a multiple of 128 bits (16 bytes)

(9) Coverage surface layout

The surface is C4X4.

Surface layout (C4X4)

```
(lsb2msb)  C0_C1_C2_C3_X_X_X_X     (X is a don't care.  Qrast inits to 1)
(msb2lsb)  X_X_X_X_C3_C2_C1_C0
    +          o          o
         C0
            C1   Cov(0,1)
       C2
         C3
    o          o          o

      Cov(1,0)   Cov(1,1)

    o          o          o

    +/o = pixel centers
```

In the example above,

```
        Cov(0,0) = X_X_X_X_C3_C2_C1_C0
        C3       = V_C3(Cov(0,0));
        ..         ..
        C0       = V_C0(Cov(0,0));
    #define V_C3(bits) (bits & 0x8)
    #define V_C2(bits) (bits & 0x4)
    #define V_C1(bits) (bits & 0x2)
    #define V_C0(bits) (bits & 0x1)
```

Resolving a pixel

In an ideal world, the coverage would be simply laid out such that when resolving Pixel(x,y), we would need only to fetch Cov(x,y) to get all 4 bits of information.

In actuality, the coverage surface was rearranged to help qrast in performance. To resolve Pixel(x,y) gr2d has to fetch 4 C4X4 bytes [Cov(x,y), Cov(x-1,y), Cov(x,y-1), Cov(x-1,y-1)]. From each C4X4 byte, it extracts one bit which is used in the resolve equations shown in (5).

Need the logical VCAA bits (DRLU) for blend which is spread across four C4X4 coverage bytes

```
          U
    L
        o
            R
      D
```

where

o = Pixel(x,y)

D = V_C1(Cov(x-1,y))

R = V_C0(Cov(x,y))

L = V_C3(Cov(x-1,y-1))

U = V_C2(Cov(x,y-1))

Offset: 0x401f | Byte Offset: 0x1007c | Read/Write: R/W | Reset: 0x00000000 (0bx000000x00xx00xx0000000000000000)

14.3.67 G2SB_CTX1_G2SRCBA_SB_SURFBASE_0

SB_SURFBASE Registers

These registers need only be programmed when using SB. They point to the base of the various source and destination surfaces. Technically they are only needed when tiling is enabled, but there is no harm in always programming them.

Their counterpart registers (_SB_SURFBASE with SB_SURFBASE stripped off) indicate the location of the first pixel to be sourced or written within the surface.

This register exists to mimic the X, Y (SRCX, SRCY) functionality found in the BitBlt engine.

For example, to get at pixel X, Y:

SRCBA = SRCBA_SB_SURFBASE + Y*stride + X*Bpp

Offset: 0x4048 │ Byte Offset: 0x10120 │ Read/Write: R/W │ Reset: 0x00000000 (0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx)

8	0x0	INCR_SYNCPT_NO_STALL: If NO_STALL is 1, then when FIFOs are full, INCR_SYNCPT methods will be dropped and the INCR_SYNCPT_ERROR[COND] bit will be set. If NO_STALL is 0, then when FIFOs are full, the client host interface will be stalled.
0	0x0	INCR_SYNCPT_SOFT_RESET: If SOFT_RESET is set, then all internal state of the client syncpt block will be reset. To do soft reset, first set SOFT_RESET of all host1x clients affected, then clear all SOFT_RESETs.

14.4.3 G2SB_CTX2_INCR_SYNCPT_ERROR_0

Offset: 0x8002 │ Byte Offset: 0x20008 │ Read/Write: R/W │ Reset: 0x00000000 (0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx)

Bit	Reset	Description
31:0	X	COND_STATUS: COND_STATUS[COND] is set if the FIFO for COND overflows. This bit is sticky and will remain set until cleared. Cleared by writing 1.

14.4.4 G2SB_CTX2_G2CLASSCHANNEL_REGONLY_0

This register can be accessed by both register read/write and command FIFO in order not to break exsting code, keep suffix REGONLY.

2D syncpt behavior:

- Each 2D context has its own syncpt client.
- OP_DONE increments when 2D's memory write client is idle, meaning all preceding operations are complete.
- RD_DONE behaves like OP_DONE
- REG_WR_SAFE behaves like IMMEDIATE meaning a syncpt increment returns immediately and does not indicate that a register write will NOT block. The implications are that 2D's host FIFO can fill and block access to 2D, which will indeterminately block a direct CPU access.

Bit	Reset	Description
31:0	X	VDSTEP: Vertical Scaling DDA. Reset value: xxxx-xxxxh. Vertical DDA Step (Increment) Value (VDSTEP[18:0]) (upper 13 bits should be set to '0') This parameter specifies the increment value of the DDA used for vertical scaling and it is in the form of 6-bit integer and 12-bit fraction. This value is determined by the equation: (Actual_source_height-1-VDTINI) / (Actual_destination_height-1). Truncate the rest of the bits to keep the 12-bit fraction. Since we have to meet (Actual_source_height-1)*1.0 >= (Actual_destination_height - 1)*VDSTEP + VDTINI. The 6-bit integer allows a maximum contraction ratio of 1/64, and 12-bit fraction ensures the maximum limit of accumulated error less than half line spacing for up to approximately 2000 target lines. For example, image expansion from 240 lines to 400 lines VDSTEP[17:0] = 19'b00_0000_1001_1001_1010 and image contraction from 240 lines to 150 lines VDSTEP[17:0] = 19'b00_0001_1001_1001_1010.

14.4.13 G2SB_CTX2_G2VDDAINI_0

Offset: 0x8012 | Byte Offset: 0x20048 | Read/Write: R/W | Reset: 0x00000000 (0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx)

Bit	Reset	Description
15:8	X	VDBINI: Vertical DDA Initial Value for Bottom-Field (VDBINI[7:0]) (see description above)
7:0	X	VDTINI: Vertical Scaling DDA Initial Values. Vertical DDA Initial Value for Top-Field (VDTINI[7:0]) This parameter specifies the fraction part of initial value of the DDA used for vertical scaling.

Bit	Reset	Description
		Given a pair of consecutive source image lines representing positions 0.0 and 1.0, a destination line-image will be created at any position in [0.0, 1.0], that is specified by the fraction part of the vertical DDA. The 8-bit initial fraction value specifies the position of the first output (destination) line-image located between the first and the second input (source) line-images, respectively, at positions 0.0 and 1.0. This parameter provides a way to compensate relative displacement of top and bottom fields of a source image. Suppose, 2-to-1 interlaced original video field images #1 and #2 are in the image buffer, to be displayed in an overlay window. Assume that the #1 field image is the top-field. Using VDTINI = 8'hC0 for the top-field image and VDBINI = 8'h40 for the bottom-field image, for example, the two images from #1 and #2 fields get mapped to identically positioned destination images in the overlay window.

14.4.14 G2SB_CTX2_G2HDDA_0

Offset: 0x8013 │ Byte Offset: 0x2004c │ Read/Write: R/W │ Reset: 0x00000000 (0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx)

Bit	Reset	Description
31:0	X	HDSTEP: Horizontal Scaling DDA. Reset value: xxxx-xxxxh. Horizontal DDA Step (Increment) Value (HDSTEP[18:0]) (upper 13 bits should be set to '0') This parameter specifies the increment value of the DDA used for horizontal scaling and it is in the form of 6-bit integer and 12-bit fraction. This value is determined by the equation: (Actual_source_width-1-HDINI) / (Actual_destination_width-1) Truncate the remaining bits to keep the 12-bit fraction. The 6-bit integer allows maximum contraction ratio of 1/64, and 12-bit fraction ensures the maximum limit of accumulated error less than half pixel-spacing for up to approximately 2000 destination pixels. For example, image expansion from 720 pixels to 800 pixels HDSTEP[17:0] = 19'b000_0000_1110_0110_0111 and image contraction from 720 pixels to 250 pixels HDSTEP[17:0] = 19'b000_0010_1110_0001_0101.

14.4.15 G2SB_CTX2_G2HDDAINILS_0

Offset: 0x8014 │ Byte Offset: 0x20050 │ Read/Write: R/W │ Reset: 0x00000000 (0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx)

Bit	Reset	Description
7:0	X	HDINI: Horizontal Scaling DDA Initial Value. Horizontal DDA Initial Value (HDINI[7:0]) This parameter specifies the fraction part of initial value of the DDA used for horizontal scaling. Given a group of six consecutive source pixels that the two pixels at the center representing positions 0.0 and 1.0, a destination pixel will be created at any position in [0.0, 1.0), that is specified by the fraction part of the horizontal DDA. The 8-bit initial fraction value specifies the position of the first output (destination) pixel located between the first and the second input (source) pixels, respectively at position 0.0 and 1.0.For horizontal scaling this value may normally be set to 0.

14.4.16 G2SB_CTX2_G2CSCFIRST_0

The next 3 registers contain 8 parameters used by the YCbCr (YUV) to RGB color space conversion logic. This logic can also be used for RGB gain/gamma correction in RGB to RGB modes, and for luma gain in YUV to YUV modes.

Two new parameters (G2U, G2V) have been added for RGB to YUV conversion. These are in address 0x38. The equations have the form:

if (yuv2rgb)

(r,g,b) = matrix*(y+sbreg_yos,u,v)

matrix: sbreg_cyx, sbreg_cur, sbreg_cvr,
sbreg_cyx, sbreg_cug, sbreg_cvg,
sbreg_cyx, sbreg_cub, sbreg_cvb,

else if (rgb2rgb)

(r,g,b) = matrix*(r,g+sbreg_yos,b)

matrix:	sbreg_cvr,	0,	sbreg_cur,
	sbreg_cvg,	sbreg_cyx,	sbreg_cug,
	sbreg_cvb,	0,	sbreg_cub,

else if (yuv2yuv)

(y,u,v) = matrix*(y,u,v)

matrix:	sbreg_cub,	0,	sbreg_cvb,
	sbreg_cug,	sbreg_cyx,	sbreg_cvg,
	sbreg_cur,	0,	sbreg_cvr,

else if (rgb2yuv)

(y,u,v) = matrix*(r,g,b) + (sbreg_yos,0,0)

matrix:	sbreg_cvb,	sbreg_cyx,	sbreg_cub,
	sbreg_cvg,	sbreg_g2u,	sbreg_cug,
	sbreg_cvr,	sbreg_g2v,	sbreg_cur,

Offset: 0x8015 │ Byte Offset: 0x20054 │ Read/Write: R/W │ Reset: 0x00000000 (0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx)

Bit	Reset	Description
31:24	X	YOS: Y-Offset (YOFFSET[7:0]) for YUV generation. This parameter consists of 8-bit 2's complement in the range [-128,127]. For YUV->RGB, the recommended value is -16 (decimal) or 0xF0. For YUV->YUV & RGB->RGB, this parameter should be set to 0. For RGB->YUV, the recommended value is +16 (decimal) or 0x10
21:12	X	CVR: Multiplier for V/R for V or R generation. This parameter consists of a sign bit and 9-bit magnitude (s2.7) For YUV->RGB, the recommended value is 1.5960 (decimal) or 0x0CC If source data is in RGB format, this parameter may be used as gain adjustment for the R component. For RGB->YUV, the recommended value is +0.439 (decimal) or 0x038
9:0	X	CUB: Multiplier for U/B for Y or B generation. Consists of a sign bit and 9-bit magnitude (s2.7). For YUV->RGB, the recommended value is 2.0172 (decimal) or 0x102. If source data is in RGB format, this parameter may be used as gain adjustment for the B component. This register changes precision when doing an RGB to YUV conversion (SIFMT=1xxx, DIFMT=0xxx). CUB becomes s1.8 and the recommended value is +0.098 or 0x019

14.4.17 G2SB_CTX2_G2CSCSECOND_0

Bit	Reset	Description
31:24	X	CYX: Multiplier for Y/G (G gain). This positive-only parameter consists of an 8-bit magnitude (1.7). For YUV->YUV, the recommended value is 1.1644 (decimal) or 0x95. For YUV->YUV or RGB->RGB, this may be used as a gain adjustment for the Y or G component. For RGB->YUV, the recommended value is +0.504 (decimal) or 0x041.
21:12	X	CUR: Multiplier for U/B for V or R generation. This parameter consists of a sign bit and 9-bit

Bit	Reset	Description
		magnitude (s2.7). For YUV->RGB, normally this parameter is programmed to 0.0. This parameter takes a non-zero value if the hue is rotated. For YUV->YUV and RGB->RGB, this parameter should be set to 0. For RGB->YUV, the recommended value is -0.071 (decimal) or 0x209
8:0	X	CUG: Multiplier for U/B for U or G generation. Consists of a sign bit and 8-bit magnitude (s1.7). For YUV->RGB, the recommended value is -0.3918 (decimal) or 0x132. For RGB->RGB, this parameter should be set to 0. For YUV->YUV, this parameter should be set to 1 (0x080). For RGB->YUV the recommended value is +0.439 (decimal) or 0x038

14.4.18 G2SB_CTX2_G2CSCTHIRD_0

Offset: 0x8017 │ Byte Offset: 0x2005c │ Read/Write: R/W │ Reset: 0x00000000 (0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx)

Bit	Reset	Description
25:16	X	CVB: Multiplier for V/R for Y or B generation. This parameter consists of a sign bit and 9-bit magnitude (s2.7). For YUV->RGB, normally this parameter is programmed to 0.0. This coefficient takes a non-zero value if the hue is rotated. For YUV->YUV and RGB->RGB, this parameter should be set to 0. For RGB->YUV, the recommended value is +0.257 (decimal) or 0x021.
8:0	X	CVG: Multiplier for V/R for U or G generation. This parameter consists of a sign bit and 8-bit magnitude (s1.7). For YUV->RGB, the recommended value is -0.8130 (decimal) or 0x168. For YUV->YUV and RGB->RGB, this parameter should be set to 0. For RGB->YUV, the recommended value is -0.148 (decimal) or 0x113.

14.4.19 G2SB_CTX2_G2CMKEYL_0

When key generation is enabled, the value of this register is the lower color/chroma limit and G2CMKEYU is the upper color/chroma limit for component pixel data. Three component signal values (YCrCb/YUV or RGB) of every output pixel are compared to a set of three ranges that are specified by three pairs of lower and upper color/chroma key values. If the Key Polarity is 0, the Key is set to 1 only when all three component values of an input pixel are respectively within the set of ranges (inclusive of the limit values), else the Key is set to 0. If the Key Polarity is 1, the Key is set to 1 when any of the three component values of an input pixel are outside the set of ranges, else the Key is set to 0.

StretchBLT, Color/Chroma Key Lower Limit Register

14.4.24 G2SB_CTX2_G2CONTROLSB_0

Offset: 0x801d │ Byte Offset: 0x20074 │ Read/Write: R/W │ Reset: 0x00000000 (0b00x00000000000000x0xx0xx00000xxx)

Bit	Reset	Description
31	0x0	DISDW: Output destination writes go either to image memory or the EPP. 0: Output data is sent to memory 1: YUV or RGB data is passed directly to the EPP module, and no destination writes take place. 0 = GOTO_IMAGE_BUFFER 1 = GOTO_EPP
30	0x0	ENDITH: Enable Dithering (ENDITH). For 16-bit RGB output modes, the LSB of the color components can be modified by adding a variable residual value that will reduce the banding artifacts that can appear on the display. 0: Normal operation 1: Enable Dithering 0 = DISABLE 1 = ENABLE
28	0x0	KPOL: Key Signal Polarity (KPOL). Color/Chroma key signal is generated by comparing source input pixel color to a range of a color specified by lower and upper limit values. The key signal is interpreted in two ways, depending on which one of video and graphics images is foreground (and the other is background). This is effective only if Key signal generator is enabled. (see G2CMKEYL, G2CMKEYU) 0: Key signal is set to 1 when source pixel is within the lower and upper limit color range. 1: Key signal is set to 1 when source pixel is outside the lower and upper limit color range. 0 = WITHIN_BOUNDS 1 = OUTSIDE_BOUNDS
27	0x0	KEYEN: Key Signal Generator Enable (KEYEN). Key signal generator generates either chroma key signal (from YCbCr signal) or color key signal (from RGB signal) 0: Key signal generator is disabled. 1: Key signal generator is enabled. 0 = DISABLE 1 = ENABLE
26	0x0	DBSEL: StretchBLT Destination Buffer Selection (DBSEL). StretchBLT processing involves frame-rate conversion from a series of source images to another series of destination images (field-rate of the source video to frame-rate of the PC display). In order to avoid image tearing, it is preferred to use two buffer sections in the destination video area. This bit selects one of the two buffering blocks to which this StretchBLT command delivers the destination image. The two buffering memory blocks are called A and B. 0: Destination image goes to ‘A’ buffer. 1: Destination image goes to ‘B’ buffer. 0 = DST_A 1 = DST_B
25	0x0	SBSEL: StretchBLT Source Buffer Selection (SBSEL). StretchBLT processing involves frame-rate conversion from a series of source images to another series of destination images (field-rate of the source video to frame-rate of the PC display). In order to avoid image tearing, it is preferred to use two buffer sections in the source video area. This bit selects one of the two buffering blocks from which this StretchBLT command receives the source image. The two buffering memory blocks are called source-A and source-B. 0: Source image comes from ‘source-A’ buffer. 1: Source image comes from ‘source-B’ buffer. 0 = SRC_A 1 = SRC_B
24	0x0	SITYPE: StretchBLT Source Type (SITYPE). This bit identifies two types of source images. If source image is 2-to-1 interlaced and StretchBLT processes either one of the two interlaced

Bit	Reset	Description
		field-images, physical (positional) displacement between the two interlaced fields must be taken into account. One field image that is placed higher in position than the other field image is called top field and the other is called bottom field. StretchBLT processing has to lower the top field (or raise the bottom field) to match the corresponding two target images in the overlay window (that is progressively scanned) right at the same position. If source image is a full frame image obtained from two interlaced field-images, its type is 'top-field'. If source images are progressively scanned, the type identification is not significant and they may be designated either one of the two types 0: Source image is 'top field'. 1: Source image is 'bottom field'. 0 = TOP_FIELD 1 = BOTTOM_FIELD
23	0x0	RANGEREDFRM:In the VC-1 specification, when the value of RANGEREDFRM variable (1-bit) for a picture is equal to 1, the picture shall be scaled up according to the following equation:Y = clip(((Y-128)*2) + 128);Cb = clip(((Cb-128)*2) + 128);Cr = clip(((Cr-128)*2) + 128). The clip operator limits the output to [0, 255].The input is also limited to [0, 255]. In the VC-1 nomenclature, the output (Y, Cb, Cr) tuple corresponds to the 'decoded' picture. The input (Y, Cb, Cr) tuple corresponds to the 'reconstructed' picture. The above equations create the decoded picture while keeping the reconstructed picture intact.Only YUV _OB formats are supported with range reducation enabled, not the YUV _TC or RGB formats The YUV data coming from the video frame buffers (reconstructed picture) in the SDRAM was scaled up using the above equations and given to the display. The value of 1-bit wide RANGEREDFRM variable was configured in the DVO per frame and the frame was scaled whenever RANGEREDFRM == 1. 0 = DISABLE 1 = ENABLE
22:20	0x0	HFTYPE: StretchBLT Horizontal Filter Mode (HFTYPE[2:0]). The six-tap horizontal interpolation filter can be operated in various operation modes. For the image expansion, it should be programmed as a pure 6-tap interpolator. For the image contraction, it can work as partly lowpass filter and partly interpolater with varying degree depending on the contraction ratio. For StretchBLT, this parameter is used as an index (selection) to an internal lookup table that stores the group of filter-coefficients for the different modes of horizontal filtering. 000: Pure interpolation filter. 001, 010, 011, 100, 101, 110: mix of interpolation and low pass filters 111: DISABLE. 0 = INTERP 1 = LPF1 2 = LPF2 3 = LPF3 4 = LPF4 5 = LPF5 6 = LPF6 7 = DISABLE
19	0x0	DISCSC: Enabled color space converter by default 0 = ENABLE 1 = DISABLE
18	0x0	VFEN: StretchBLT Vertical Filter Enable (VFEN). Vertical filter shall be disabled if source images come from host CPU via CPU Read-FIFO. (SISEL) Vertical filter may be disabled to save some memory bandwidth but this will likely result in degradation of image quality. This option may also be used in the case where source image is progressive scanning and there is no vertical scaling. 0: Vertical filter is disabled. 1: Vertical filter is enabled. 0 = DISABLE 1 = ENABLE

Bit	Reset	Description
17:16	0x0	VFTYPE: StretchBLT Vertical Filter Mode (VFTYPE[1:0]). This bit is effective when the Vertical Filter is enabled. (bit 18) The two-tap vertical interpolation filter can be operated in various modes. For the image expansion, it should be programmed as a pure 2-tap interpolator. For the image contraction, it can work as partly averager and partly interpolator with varying degree depending on the contraction ratio. For StretchBLT, this parameter is used as an index (selection) to an internal lookup table that stores the group of filter-coefficients for the different modes of vertical filtering. 00: Pure interpolation filter. 01: 25% averager, 75% interpolator. 10: 50% averager, 50% interpolator. 11: 100% averager. 0 = INTERP 1 = AVG25_INTERP75 2 = AVG50_INTERP50 3 = AVG
9:8	X	UVST: 00= 1/2 of Luma Buffer Stride; in this case Luma Buffer Stride should be a multiple of 2 bytes. 01= Equal to Luma Buffer Stride 10= 1/4 of Luma Buffer Stride; in this case Luma Buffer Stride should be a multiple of 4 bytes. 11= use uvstride. Note: Use care when using a tiled surface, since 1/2 or 1/4 of luma stride may yield an invalid pitch (stride). 0 = UVS2X 1 = UVS1X 2 = UVS4X 3 = UVS_G2UVSTRIDE
7	0x0	ENAHF: Enable horizontal alpha filtering if disabled, use the alpha value of the third tap for output pixelU,V line stride in 4:2:0 Format. 0 = DISABLE 1 = ENABLE
6	0x0	ENAVF:Enable alpha vertical filter 0 = DISABLE 1 = ENABLE
5	0x0	IMODE: Source (input) Data Mode (IMODE). This parameter defines the data mode of source input. 0: Multiplexed Mode (data format is specified by SIFMT[2:0]). One block of source data in the Image Buffer memory contains multiplexed component signals. 1: Planar mode, 4:2:0 YUV (SIFMT[2] specifies data format of U/V components). Three blocks of source data in the Image Buffer memory contain separate Y, U, and V component signals. For a circular buffer input to gr2d, the input format cannot be planar. It must be multiplex, i.e., no YUV420 planar circular buffer input to gr2d. 0 = MULTIPLEX 1 = PLANAR
4	0x0	YUV422PLANAR: Source data is yuv422 planar valid when imode==PLANAR
3	0x0	YUV422ROTATION: YUV422 planar rotated.

14.4.26 G2SB_CTX2_G2CONTROLMAIN_0

G2 Blit Formats:

(1) G2 Blit size is based on height in lines, width in pixels, stride in bytes, and pixel size (color depth). Unless alpha blending is enabled, G2 does not care about pixel components.

Source color depths supported by G2 Blit:

- color depth same as destination: G2CONTROLMAIN.SRCCD = 1
- monochrome: G2CONTROLMAIN.SRCCD = 0

(source monochrome color determined by G2SRCBGC, G2SRCFGC)

Pattern color depths supported by G2 Blit:

- color depth same as destination: G2PATOS.PATCD = 1
- monochrome: G2PATOS.PATCD = 0

(pattern monochrome color determined by G2PATBGC, G2PATFGC)

Destination color depths supported by G2 Blit:

- 1 byte per pixel: G2CONTROLMAIN.DSTCD = BPP8
- 2 bytes per pixel: G2CONTROLMAIN.DSTCD = BPP16
- 4 bytes per pixel: G2CONTROLMAIN.DSTCD = BPP32

(2) Alpha blending operates on 3 or 4 component pixels of a specified color depth. One of the components may be alpha (A), depending on the alpha blend format, which is only allowed in certain component positions defined below. The only format rule of the remaining components is that they must be in the same source and destination position because the alpha blend engine does not support component swapping. For example, valid 32BPP formats are: RGBA_8888->RGBA_8888, BGRA_8888->BGRA_8888, GRBA_8888->GRBA_8888, etc.

Source formats supported by G2 alpha blend:

- color depth BPP8: no supported formats
- color depth BPP16:
  - ALPTYPE_PLS1BPP: xxxA_5551 (for example, BGRA_5551 = A[15] R[14:10] G[9:5] B[4:0])

- ALPTYPE_PLS4BPP: xxxA_4444 (for example, BGRA_4444 = A[15:12] R[11:8] G[7:4] B[3:0])
- (other) : xxx_565 (for example, BGR_565 = R[15:11] G[10:5] B[4:0])

- color depth BPP32:
  - (all) : xxxA_8888 (for example, BRGA_8888 = A[31:24] R[23:16] G[15:8] B[7:0])

Destination formats supported by G2 alpha blend:

- color depth BPP8: no supported formats
- color depth BPP16: xxx_565 (for example, BGR_565 = R[15:11] G[10:5] B[4:0])
- color depth BPP32: xxxA_8888 (for example, BRGA_8888 = A[31:24] R[23:16] G[15:8] B[7:0])

src cd	src format	dst cd	dst format	examples

VCAA Resolve Engine

(1) Format support

srcColor format	srcCoverage format	legal dest format(s)
A1B5G5R5	VCAA	A1B5G5R5
R8G8B8A8	VCAA	R8G8B8A8, B5G6R5
B5G6R5	VCAA	B5G6R5

To program resolve type:

- ALPTYPE == FIX: B5G6R5 -> B5G6R5
- ALPTYPE == PLS1BPPAL: A1B5G5R5 -> A1B5G5R5
- ALPTYPE == PLS8BPP: R8G8B8A8 -> R8G8B8A8
- ALPTYPE == PLS8BX: R8G8B8A8 -> B5G6R5

(2) Color surface programming

- color surface base address: SRCBA
- subsurface start x: SRCX (pixel index)
- subsurface start y: SRCY (line index)
- color surface stride: SRCS (bytes)

The engine supports subsurface resolve. One can imagine a full color buffer of 1024x768, but

```
[pseudo_code]
      color_surface_start_address_fetch = pcurctx->regs.rG2SRCBA.uSRCBA() +
       (pcurctx->regs.rG2SRCPS.uSRCX() * VCAAState.color_surface_depth) +
       (pcurctx->regs.rG2SRCPS.uSRCY() * VCAAState.color_surface_stride);
```

(3) VCAA surface programming

- VCAA surface base address: PATBA
- VCAA surface stride: PATST (bytes)

```
[pseudo_code]
      vcaa_surface_start_address_fetch = pcurctx->regs.rG2PATBA.uPATBA();
```

Software *MUST* directly program this register to the proper subsurface location in the vcaa surface which corresponds to the SRCX and SRCY programming. The calculation is PATBA = vcaa_base_address + SRCX * (1) + SRCY * PATST;

(4) Resolve surface programming

- resolve window width: DSTWIDTH (pixels)
- resolve window height: DSTHEIGHT (lines)
- resolve output stride: DSTS (bytes)

These values program the width and height of the resolved surface. In the base case,

- DSTWIDTH = color surface width
- DSTHEIGHT = color sufrace height
- DSTS = resolve surface format bpp * DSTWIDTH

The VCAA engine technically supports DSTX and DSTY (like SRCX and SRCY).

```
[pseudo_code]
   resolve_surface_start_address_put = pcurctx->regs.rG2DSTBA.uDSTBA() +
     (pcurctx->regs.rG2DSTPS.uDSTX() * resolve_surface_color_depth) +
     (pcurctx->regs.rG2DSTPS.uDSTY() * resolve_surface_color_stride);
```

(5) Resolving a pixel

The coverage surface is an 8 bits per pixel surface (C4X4). The surface is initialized to all 1s by 3d.

For a given pixel, we need to look up 4 bits of coverage data. If the data is 0xf, the pixel does not need to be resolved. Otherwise, we need to reblend the pixel with certain weightings of its neighbors (i.e., we are on the edge of some geometry).

If any coverage bit is 0, we need to resolve the color. To do so, calculate the following equation:

```
color_new = (
              20*color_old +
              27*(
                  ((cover_down  == 0) ? color_down  : color_old) +
                  ((cover_right == 0) ? color_right : color_old) +
                  ((cover_left  == 0) ? color_left  : color_old) +
                  ((cover_up    == 0) ? color_up    : color_old)
                  )
            ) / 128;
```

If coverage bit == 0, then we use the neighbor color value in the resolve

If coverage bit == 1, then we use the center color value in the resolve

The resolve is done on a per channel (r/g/b/a) basis:

- format convert input channel to 8-bit
- perform resolve equation above
- format convert to output format

For the resolution of the alpha channel:

- In B5G6R5: no alpha information. do nothing.
- In A1B5G5R5: no resolve. keep the source color alpha bit.
- In R8G8B8A8: normal 8-bit channel resolve

(6) Resolving a pixel on the edge

When on an edge, the VCAA engine treats the coverage bit as a 1. Use the center color value. This holds true even on the edge of the sub-surface resolve window when located in the middle of the larger surface

(7) Maximum dimensions

The maximum resolve subsurface is 4096 pixels wide.

(8) Surface restrictions

The VCAA engine has the following restrictions with respect to input surfaces

- input base address is 128-bit memory word aligned
- input stride is a multiple of 128 bits (16 bytes)

The VCAA engine has the following restrictions with respect to output surfaces

- output base address is 128-bit memory word aligned
- output stride is a multiple of 128 bits (16 bytes)

(9) Coverage surface layout

The surface is C4X4.

Surface layout (C4X4)

```
(lsb2msb)  C0_C1_C2_C3_X_X_X_X     (X is a don't care.  Qrast inits to 1)
(msb2lsb)  X_X_X_X_C3_C2_C1_C0

    +          o          o
         C0
            C1   Cov(0,1)
       C2
         C3
    o          o          o

      Cov(1,0)   Cov(1,1)

    o          o          o
    +/o = pixel centers
```

In the example above,

```
       Cov(0,0) = X_X_X_X_C3_C2_C1_C0
       C3       = V_C3(Cov(0,0));
       ..         ..
       C0       = V_C0(Cov(0,0));
    #define V_C3(bits) (bits & 0x8)
    #define V_C2(bits) (bits & 0x4)
    #define V_C1(bits) (bits & 0x2)
```

```
#define V_C0(bits) (bits & 0x1)
```

Resolving a pixel

In an ideal world, the coverage would be simply laid out such that when resolving Pixel(x,y), we would need only to fetch Cov(x,y) to get all 4 bits of information.

In actuality, the coverage surface was rearranged to help qrast in performance. To resolve Pixel(x,y) gr2d has to fetch 4 C4X4 bytes [Cov(x,y), Cov(x-1,y), Cov(x,y-1), Cov(x-1,y-1)]. From each C4X4 byte, it extracts one bit which is used in the resolve equations shown in (5).

Need the logical VCAA bits (DRLU) for blend which is spread across four C4X4 coverage bytes:

```
        U

  L

     o

        R

    D
```

Where:

o = Pixel(x,y)

D = V_C1(Cov(x-1,y))

R = V_C0(Cov(x,y))

L = V_C3(Cov(x-1,y-1))

U = V_C2(Cov(x,y-1))

31:0	X	SRCBA: Source base address (byte address)

14.4.45 G2SB_CTX2_G2SRCBA_B_0

SB only

Offset: 0x8032 │ Byte Offset: 0x200c8 │ Read/Write: R/W │ Reset: 0x00000000 (0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx)

Bit	Reset	Description
31:0	X	SRCBA_B: This parameter specifies the start address of source image stored in the image buffer memory. In 4:2:0 format mode, this image block accommodates for Y-image. This address specifies byte position; however, bits [2:0] are restricted with respect to the data formats to fit multiple pixels in one memory word (8 bytes). For example, {0, 4} for any YCrCb formats, {0, 2, 4, 6} for RGB 16-bit format. Since one Y pixel takes 8 bits, all 8 byte positions are valid in 4:2:0 mode. (Unlike multiplexed pixels format, there are no restrictions on this value.)

14.4.46 G2SB_CTX2_G2SRCST_0

Offset: 0x8033 | Byte Offset: 0x200cc | Read/Write: R/W | Reset: 0x00000000 (0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx)

Bit	Reset	Description
15:0	X	SRCS: Source Stride coordinate (bytes) with respect to SRCBA. In order to fit multiple pixels in one memory word (8 bytes), bits [2:0] are restricted with respect to the data formats. For example, {0, 4} for any YCrCb formats, {0, 2, 4, 6} for RGB 16-bit format.

31:0	X	PAT_BASE: Pattern base address in tile mode, PATBA is the linear address where pixel start

14.4.67 G2SB_CTX2_G2SRCBA_SB_SURFBASE_0

SB_SURFBASE Registers

These registers need only be programmed when using SB. They point to the base of the various source and destination surfaces. Technically they are only needed when tiling is enabled, but there is no harm in always programming them.

Their counterpart registers (_SB_SURFBASE with SB_SURFBASE stripped off) indicate the location of the first pixel to be sourced or written within the surface.

This register exists to mimic the X, Y (SRCX, SRCY) functionality found in the BitBlt engine.

For example, to get at pixel X, Y:

SRCBA = SRCBA_SB_SURFBASE + Y*stride + X*Bpp

Offset: 0x8048 | Byte Offset: 0x20120 | Read/Write: R/W | Reset: 0x00000000 (0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx)

Bit	Reset	Description
8	0x0	INCR_SYNCPT_NO_STALL: If NO_STALL is 1, then when FIFOs are full, INCR_SYNCPT methods will be dropped and the INCR_SYNCPT_ERROR[COND] bit will be set. If NO_STALL is 0, then when FIFOs are full, the client host interface will be stalled.
0	0x0	INCR_SYNCPT_SOFT_RESET: If SOFT_RESET is set, then all internal state of the client syncpt block will be reset. To do soft reset, first set SOFT_RESET of all host1x clients affected, then clear all SOFT_RESETs.

14.5.3 G2SB_CTX3_INCR_SYNCPT_ERROR_0

Offset: 0x1002 | Byte Offset: 0x4008 | Read/Write: R/W | Reset: 0x00000000 (0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx)

Bit	Reset	Description
31:0	X	COND_STATUS: COND_STATUS[COND] is set if the FIFO for COND overflows. This bit is sticky and will remain set until cleared. Cleared by writing 1.

14.5.4 G2SB_CTX3_G2CLASSCHANNEL_REGONLY_0

This register can be accessed by both register read/write and command FIFO in order not to break exsting code , keep suffix REGONLY.

2D syncpt behavior

- Each 2D context has its own syncpt client.
- OP_DONE increments when 2D's memory write client is idle, meaning all preceding operations are complete.

- RD_DONE behaves like OP_DONE
- REG_WR_SAFE behaves like IMMEDIATE meaning a syncpt increment returns immediately and does not indicate that a register write will NOT block. The implications are that 2D's host FIFO can fill and block access to 2D, which will indeterminately block a direct CPU access.

Offset: 0x1011 | Byte Offset: 0x4044 | Read/Write: R/W | Reset: 0x00000000 (0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx)

Bit	Reset	Description
31:0	X	VDSTEP: Vertical Scaling DDA. Reset value: xxxx-xxxxh. Vertical DDA Step (Increment) Value (VDSTEP[18:0]) (upper 13 bits should be set to '0') This parameter specifies the increment value of the DDA used for vertical scaling and it is in the form of 6-bit integer and 12-bit fraction. This value is determined by the equation: (Actual_source_height-1-VDTINI) / (Actual_destination_height-1). Truncate the remaining bits to keep the 12-bit fraction. Since we have to meet (Actual_source_height-1)*1.0 >= (Actual_destination_height - 1)*VDSTEP + VDTIN. The 6-bit integer allows maximum contraction ratio of 1/64, and 12-bit fraction ensures the maximum limit of accumulated error less than half line-spacing for up to approximately 2000 target lines. For example, image expansion from 240 lines to 400 lines VDSTEP[17:0] = 19'b00_0000_1001_1001_1010 and image contraction from 240 lines to 150 lines VDSTEP[17:0] = 19'b00_0001_1001_1001_1010.

14.5.13 G2SB_CTX3_G2VDDAINI_0

Offset: 0x1012 | Byte Offset: 0x4048 | Read/Write: R/W | Reset: 0x00000000 (0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx)

Bit	Reset	Description
15:8	X	VDBINI: Vertical DDA Initial Value for Bottom-Field (VDBINI[7:0]) (see description above)
7:0	X	VDTINI: Vertical Scaling DDA Initial Values. Vertical DDA Initial Value for Top-Field (VDTINI[7:0]) This parameter specifies the fraction part of initial value of the DDA used for vertical scaling. Given a pair of consecutive source image lines representing positions 0.0 and 1.0, a destination line-image will be created at any position in [0.0, 1.0), that is specified by the fraction part of the vertical DDA. The 8-bit initial fraction value specifies the position of the first output (destination) line-image located between the first and the second input (source) line-images, respectively at position 0.0 and 1.0. This parameter provides a way to compensate relative displacement of top and bottom fields of a source image. Suppose, 2-to-1 interlaced original video field images #1 and #2 are in the image buffer, to be displayed in an overlay window. Assume that the #1 field image is the top-field. Using VDTINI = 8'hC0 for the top-field image and VDBINI = 8'h40 for the bottom-field image, for example, the two images from #1 and #2 fields get mapped to identically positioned destination images in the overlay window.

14.5.14 G2SB_CTX3_G2HDDA_0

Offset: 0x1013 | Byte Offset: 0x404c | Read/Write: R/W | Reset: 0x00000000 (0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx)

Bit	Reset	Description
31:0	X	HDSTEP: Horizontal Scaling DDA. Reset value: xxxx-xxxxh. Horizontal DDA Step (Increment) Value (HDSTEP[18:0]) (upper 13 bits should be set to '0') This parameter specifies the increment value of the DDA used for horizontal scaling and it is in the form of 6-bit integer and 12-bit fraction. This value is determined by the equation: (Actual_source_width-1-HDINI) / (Actual_destination_width-1). Truncate the remaining bits to keep the 12-bit fraction. The 6-bit integer allows maximum contraction ratio of 1/64, and 12-bit fraction ensures the maximum limit of accumulated error less than half pixel-spacing for up to approximately 2000 destination pixels. For example, image expansion from 720 pixels to 800 pixels HDSTEP[17:0] = 19'b000_0000_1110_0110_0111 and image contraction from 720 pixels to 250 pixels HDSTEP[17:0] = 19'b000_0010_1110_0001_0101.

14.5.15 G2SB_CTX3_G2HDDAINILS_0

Offset: 0x1014 | Byte Offset: 0x4050 | Read/Write: R/W | Reset: 0x00000000 (0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx)

Bit	Reset	Description
7:0	X	HDINI: Horizontal Scaling DDA Initial Value. Horizontal DDA Initial Value (HDINI[7:0]) This parameter specifies the fraction part of initial value of the DDA used for horizontal scaling. Given a group of six consecutive source pixels that the two pixels at the center representing positions 0.0 and 1.0, a destination pixel will be created at any position in [0.0, 1.0), that is specified by the fraction part of the horizontal DDA. The 8-bit initial fraction value specifies the position of the first output (destination) pixel located between the first and the second input (source) pixels, respectively at position 0.0 and 1.0.For horizontal scaling this value may normally be set to 0.

14.5.16 G2SB_CTX3_G2CSCFIRST_0

The next 3 registers contain 8 parameters used by the YCbCr (YUV) to RGB color space conversion logic. This logic can also be used for RGB gain/gamma correction in RGB to RGB modes, and for luma gain in YUV to YUV modes.

Two new parameters (G2U, G2V) have been added for RGB to YUV conversion. These are in address 0x38. The equations have the form:

if (yuv2rgb)

(r,g,b) = matrix*(y+sbreg_yos,u,v)

matrix: sbreg_cyx, sbreg_cur, sbreg_cvr,
sbreg_cyx, sbreg_cug, sbreg_cvg,
sbreg_cyx, sbreg_cub, sbreg_cvb,

else if (rgb2rgb)

(r,g,b) = matrix*(r,g+sbreg_yos,b)

matrix: sbreg_cvr, 0, sbreg_cur,
sbreg_cvg, sbreg_cyx, sbreg_cug,
sbreg_cvb, 0, sbreg_cub,

else if (yuv2yuv)

(y,u,v) = matrix*(y,u,v)

matrix: sbreg_cub, 0, sbreg_cvb,
sbreg_cug, sbreg_cyx, sbreg_cvg,
sbreg_cur, 0, sbreg_cvr,

else if (rgb2yuv)

(y,u,v) = matrix*(r,g,b) + (sbreg_yos,0,0)

matrix: sbreg_cvb, sbreg_cyx, sbreg_cub,
sbreg_cvg, sbreg_g2u, sbreg_cug,
sbreg_cvr, sbreg_g2v, sbreg_cur,

Offset: 0x1015 | Byte Offset: 0x4054 | Read/Write: R/W | Reset: 0x00000000 (0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx)

Bit	Reset	Description
31:24	X	YOS: Y-Offset (YOFFSET[7:0]) for YUV generation This parameter consists of 8-bit 2's complement in the range [-128,127]. For YUV->RGB, the recommended value is -16 (decimal) or 0xF0. For YUV->YUV & RGB->RGB, this parameter should be set to 0. For RGB->YUV, the recommended value is +16 (decimal) or 0x10

Bit	Reset	Description
21:12	X	CVR: Multiplier for V/R for V or R generation. This parameter consists of a sign bit and 9-bit magnitude (s2.7). For YUV->RGB, the recommended value is 1.5960 (decimal) or 0x0CCIf source data is in RGB format, this parameter may be used as gain adjustment for R component. For RGB->YUV, the recommended value is +0.439 (decimal) or 0x038
9:0	X	CUB: Multiplier for U/B for Y or B generation. Consists of a sign bit and 9-bit magnitude (s2.7). For YUV->RGB, the recommended value is 2.0172 (decimal) or 0x102. If source data is in RGB format, this parameter may be used as gain adjustment for B component. This register changes precision when doing RGB to YUV conversion (SIFMT=1xxx, DIFMT=0xxx). CUB becomes s1.8 and the recommended value is +0.098 or 0x019

25:16	X	CVB: Multiplier for V/R for Y or B generation. This parameter consists of a sign bit and 9-bit magnitude (s2.7). For YUV->RGB, normally this parameter is programmed to 0.0. This coefficient takes non-zero value if hue is rotated. For YUV->YUV & RGB->RGB, this parameter should be set to 0. For RGB->YUV, the recommended value is +0.257 (decimal) or 0x021
8:0	X	CVG: Multiplier for V/R for U or G generation. This parameter consists of a sign bit and 8-bit magnitude (s1.7). For YUV->RGB, the recommended value is -0.8130 (decimal) or 0x168. For YUV->YUV & RGB->RGB, this parameter should be set to 0. For RGB->YUV, the recommended value is -0.148 (decimal) or 0x113

14.5.19 G2SB_CTX3_G2CMKEYL_0

When key generation is enabled, the value of this register is the lower color/chroma limit and G2CMKEYU is the upper color/chroma limit for component pixel data. Three component signal values (YCrCb/YUV or RGB) of every output pixel are compared to a set of three ranges that are specified by three pairs of lower and upper color/chroma key values. If the Key Polarity is 0, the Key is set to 1 only when all three component values of an input pixel are respectively within the set of ranges (inclusive of the limit values), else the Key is set to 0. If the Key Polarity is 1, the Key is set to 1 when any of the three component values of an input pixel are outside the set of ranges, else the Key is set to 0.

Bit	Reset	Description
31	0x0	DISDW: Output destination writes go either to image memory or the EPP. 0: Output data is sent to memory 1: YUV or RGB data is passed directly to the EPP module, and no destination writes take place. 0 = GOTO_IMAGE_BUFFER 1 = GOTO_EPP
30	0x0	ENDITH: Enable Dithering (ENDITH). For 16 bit RGB output modes, the LSB of the color components can be modified by adding a variable residual value that will reduce the banding artifacts that can appear on the display. 0 Normal operation 1 Enable Dithering 0 = DISABLE 1 = ENABLE
28	0x0	KPOL: Key Signal Polarity (KPOL). Color/Chroma key signal is generated by comparing source input pixel color to a range of a color specified by lower and upper limit values. The key signal is interpreted in two ways, depending on which one of video and graphics images is foreground (and the other is background). This is effective only if Key signal generator is enabled. (see G2CMKEYL, G2CMKEYU) 0: Key signal is set to 1 when source pixel is within the lower and upper limit color range. 1: Key signal is set to 1 when source pixel is outside the lower and upper limit color range. 0 = WITHIN_BOUNDS 1 = OUTSIDE_BOUNDS
27	0x0	KEYEN: Key Signal Generator Enable (KEYEN) Key signal generator generates either chroma key signal (from YCbCr signal) or color key signal (from RGB signal) 0: Key signal generator is disabled. 1: Key signal generator is enabled. 0 = DISABLE 1 = ENABLE
26	0x0	DBSEL: StretchBLT Destination Buffer Selection (DBSEL) StretchBLT processing involves frame-rate conversion from a series of source images to another series of destination images (field-rate of the source video to frame-rate of the PC display). In order to avoid image tearing, it is preferred to use two buffer sections in the destination video area. This bit selects one of the two buffering blocks to which this StretchBLT command delivers the destination image. The two buffering memory blocks are called A and B. 0: Destination image goes to ‘A’ buffer. 1: Destination image goes to ‘B’ buffer. 0 = DST_A 1 = DST_B

Bit	Reset	Description
25	0x0	SBSEL: StretchBLT Source Buffer Selection (SBSEL) StretchBLT processing involves frame-rate conversion from a series of source images to another series of destination images (field-rate of the source video to frame-rate of the PC display). In order to avoid image tearing, it is preferred to use two buffer sections in the source video area. This bit selects one of the two buffering blocks from which this StretchBLT command receives the source image. The two buffering memory blocks are called source-A and source-B. 0: Source image comes from 'source-A' buffer. 1: Source image comes from 'source-B' buffer. 0 = SRC_A 1 = SRC_B
24	0x0	SITYPE: StretchBLT Source Type (SITYPE). This bit identifies two types of source images. If source image is 2-to-1 interlaced and StretchBLT processes either one of the two interlaced field-images, physical (positional) displacement between the two interlaced fields must be taken into account. One field-image that is placed higher in position than the other field-image is called top-field and the other is called bottom-field. StretchBLT processing has to lower the top-field (or raise the bottom-field) to match the corresponding two target images in the overlay window (that is progressively scanned) right at the same position. If source image is full frame-image obtained from two interlaced field-images, its type is 'top-field'. If source images are progressively scanned, the type identification is not significant and they may be designated either one of the two types 0: Source image is 'top-field'. 1: Source image is 'bottom-field'. 0 = TOP_FIELD 1 = BOTTOM_FIELD
23	0x0	RANGEREDFRM:In the VC-1 specification, when the value of RANGEREDFRM variable (1-bit) for a picture is equal to 1, the picture shall be scaled up according to the following equation:Y = clip(((Y-128)*2) + 128);Cb = clip(((Cb-128)*2) + 128);Cr = clip(((Cr-128)*2) + 128);The clip operator limits the output to [0, 255].The input is also limited to [0, 255]. In the VC-1 nomenclature, the output (Y, Cb, Cr) tuple corresponds to the 'decoded' picture. The input (Y, Cb, Cr) tuple corresponds to the 'reconstructed' picture. The above equations create the decoded picture while keeping the reconstructed picture intact.Only YUV _OB formats are supported with range reducation enabled, not the YUV _TC or RGB formats. The YUV data coming from the video frame buffers (reconstructed picture) in the SDRAM was scaled up using the above equations and given to the display. the value of 1-bit wide RANGEREDFRM variable was configured in the DVO per frame and the frame was scaled whenever RANGEREDFRM == 1. 0 = DISABLE 1 = ENABLE
22:20	0x0	HFTYPE: StretchBLT Horizontal Filter Mode (HFTYPE[2:0]) The six-tap horizontal interpolation filter can be operated in various operation modes. For the image expansion, it should be programmed as a pure 6-tap interpolator. For the image contraction, it can work as partly lowpass filter and partly interpolater with varying degree depending the contraction ratio. For StretchBLT, this parameter is used as an index (selection) to an internal lookup table that stores the group of filter-coefficients for the different modes of horizontal filtering. 000: Pure interpolation filter. 001, 010, 011, 100, 101, 110: mix of interpolation and low pass filters 111: DISABLE. 0 = INTERP 1 = LPF1 2 = LPF2 3 = LPF3 4 = LPF4 5 = LPF5 6 = LPF6 7 = DISABLE

Bit	Reset	Description
19	0x0	DISCSC: enabled color space converter by default 0 = ENABLE 1 = DISABLE
18	0x0	VFEN: StretchBLT Vertical Filter Enable (VFEN) Vertical filter shall be disabled if source images come from host CPU via CPU Read-FIFO. (SISEL) Vertical filter may be disabled to save some memory bandwidth but this will likely result in degradation of image quality. This option may also be used in the case where source image is progressive scanning and there is no vertical scaling. 0: Vertical filter is disabled. 1: Vertical filter is enabled. 0 = DISABLE 1 = ENABLE
17:16	0x0	VFTYPE: StretchBLT Vertical Filter Mode (VFTYPE[1:0]). This bit is effective when the Vertical Filter is enabled. (bit 18) The two-tap vertical interpolation filter can be operated in various modes. For the image expansion, it should be programmed as a pure 2-tap interpolator. For the image contraction, it can work as partly averager and partly interpolator with varying degree depending on the contraction ratio. For StretchBLT, this parameter is used as an index (selection) to an internal lookup table that stores the group of filter-coefficients for the different modes of vertical filtering. 00: Pure interpolation filter 01: 25% averager, 75% interpolator 10: 50% averager, 50% interpolator 11: 100% averager. 0 = INTERP 1 = AVG25_INTERP75 2 = AVG50_INTERP50 3 = AVG

14.5.26 G2SB_CTX3_G2CONTROLMAIN_0

G2 Blit Formats:

(1) G2 Blit size is based on height in lines, width in pixels, stride in bytes, and pixel size (color depth). Unless alpha blending is enabled, G2 does not care about pixel components.

Source color depths supported by G2 Blit:

- color depth same as destination: G2CONTROLMAIN.SRCCD = 1
- monochrome: G2CONTROLMAIN.SRCCD = 0

(source monochrome color determined by G2SRCBGC, G2SRCFGC)

Pattern color depths supported by G2 Blit:

- color depth same as destination: G2PATOS.PATCD = 1
- monochrome: G2PATOS.PATCD = 0

(pattern monochrome color determined by G2PATBGC, G2PATFGC)

Destination color depths supported by G2 Blit:

- 1 byte per pixel: G2CONTROLMAIN.DSTCD = BPP8
- 2 bytes per pixel: G2CONTROLMAIN.DSTCD = BPP16
- 4 bytes per pixel: G2CONTROLMAIN.DSTCD = BPP32

(2) Alpha blending operates on 3 or 4 component pixels of a specified color depth. One of the components may be alpha (A), depending on the alpha blend format, which is only allowed in certain component positions defined below. The only format rule of the remaining components is that they must be in the same source and destination position because the alpha blend engine

does not support component swapping. For example, valid 32BPP formats are: RGBA_8888->RGBA_8888, BGRA_8888->BGRA_8888, GRBA_8888->GRBA_8888, etc.

Source formats supported by G2 alpha blend:

- color depth BPP8: no supported formats
- color depth BPP16:
  - ALPTYPE_PLS1BPP: xxxA_5551 (for example, BGRA_5551 = A[15] R[14:10] G[9:5] B[4:0])
  - ALPTYPE_PLS4BPP: xxxA_4444 (for example, BGRA_4444 = A[15:12] R[11:8] G[7:4] B[3:0])
  - (other) : xxx_565 (for example, BGR_565 = R[15:11] G[10:5] B[4:0])
- color depth BPP32:
  - (all) : xxxA_8888 (for example, BRGA_8888 = A[31:24] R[23:16] G[15:8] B[7:0])

Destination formats supported by G2 alpha blend:

- color depth BPP8: no supported formats
- color depth BPP16: xxx_565 (for example, BGR_565 = R[15:11] G[10:5] B[4:0])
- color depth BPP32: xxxA_8888 (for example, BRGA_8888 = A[31:24] R[23:16] G[15:8] B[7:0])
- Destination formats supported by G2 alpha blend:

src cd	src format	dst cd	dst format	examples
BPP8	no support	BPP8	no support	
BPP16	xyzA_5551, xyzA_4444, xyz_565	BPP16	xyz_565	BGRA_5551->BGR_565, RGB_565->RGB565
BPP32	xyzA_8888	BPP32	xyzA_8888	RGBA_8888->RGBA_8888, BGRA_8888->BGRA_8888
BPP32	xyzA_8888	BPP16	xyz_565	RGBA_8888->RGB_565, BGRA_8888->BGR_565

VCAA Resolve Engine

(1) Format support

srcColor format	srcCoverage format	legal dest format(s)
A1B5G5R5	VCAA	A1B5G5R5
R8G8B8A8	VCAA	R8G8B8A8, B5G6R5
B5G6R5	VCAA	B5G6R5

To program resolve type:

- ALPTYPE == FIX: B5G6R5 -> B5G6R5
- ALPTYPE == PLS1BPPAL: A1B5G5R5 -> A1B5G5R5
- ALPTYPE == PLS8BPP: R8G8B8A8 -> R8G8B8A8
- ALPTYPE == PLS8BX: R8G8B8A8 -> B5G6R5

(2) Color surface programming

- color surface base address: SRCBA
- subsurface start x: SRCX (pixel index)
- subsurface start y: SRCY (line index)
- color surface stride: SRCS (bytes)

The engine supports subsurface resolve. One can imagine a full color buffer of 1024x768, but

```
[pseudo_code]
```

```
      color_surface_start_address_fetch = pcurctx->regs.rG2SRCBA.uSRCBA() +
       (pcurctx->regs.rG2SRCPS.uSRCX() * VCAAState.color_surface_depth) +
       (pcurctx->regs.rG2SRCPS.uSRCY() * VCAAState.color_surface_stride);
```

(3) VCAA surface programming

- VCAA surface base address: PATBA
- VCAA surface stride: PATST (bytes)

```
[pseudo_code]
      vcaa_surface_start_address_fetch = pcurctx->regs.rG2PATBA.uPATBA();
```

Software *MUST* directly program this register to the proper subsurface location in the VCAA surface which corresponds to the SRCX and SRCY programming. The calculation is PATBA = vcaa_base_address + SRCX * (1) + SRCY * PATST;

(4) Resolve surface programming

- resolve window width: DSTWIDTH (pixels)
- resolve window height: DSTHEIGHT (lines)
- resolve output stride: DSTS (bytes)

These values program the width and height of the resolved surface. In the base case,

- DSTWIDTH = color surface width
- DSTHEIGHT = color surface height
- DSTS = resolve surface format bpp * DSTWIDTH

The VCAA engine technically supports DSTX and DSTY (like SRCX and SRCY).

```
  [pseudo_code]
     resolve_surface_start_address_put = pcurctx->regs.rG2DSTBA.uDSTBA() +
       (pcurctx->regs.rG2DSTPS.uDSTX() * resolve_surface_color_depth) +
       (pcurctx->regs.rG2DSTPS.uDSTY() * resolve_surface_color_stride);
```

(5) Resolving a pixel

The coverage surface is 8 bits per pixel surface (C4X4). The surface is initialized to all 1s by 3d.

For a given pixel, we need to look up 4 bits of coverage data. If the data is 0xf, the pixel does not need to be resolved. Otherwise, the pixel needs to be reblended with certain weightings of its neighbors (i.e., we are on the edge of some geometry).

If any coverage bit is 0, the color needs to be resolved. To do so, the following equation is calculated:

```
   color_new = (
                 20*color_old +
                 27*(
                     ((cover_down  == 0) ? color_down  : color_old) +
                     ((cover_right == 0) ? color_right : color_old) +
                     ((cover_left  == 0) ? color_left  : color_old) +
                     ((cover_up    == 0) ? color_up    : color_old)
                    )
               ) / 128;
```

If coverage bit == 0, then use the neighbor color value in the resolve.

If coverage bit == 1, then use the center color value in the resolve.

The resolve is done on a per channel (r/g/b/a) basis:

format convert input channel to 8-bit

perform resolve equation above

format convert to output format

For the resolution of the alpha channel:

- In B5G6R5: no alpha information. do nothing.
- In A1B5G5R5: no resolve. keep the source color alpha bit.
- In R8G8B8A8: normal 8-bit channel resolve

(6) Resolving a pixel on the edge

When on an edge, the VCAA engine treats the coverage bit as a 1. Use the center color value. This holds true even on the edge of the subsurface resolve window when located in the middle of the larger surface

(7) Maximum dimensions

The maximum resolve sub-surface is 4096 pixels wide.

(8) Surface restrictions

The VCAA engine has the following restrictions with respect to input surfaces

- input base address is 128-bit memory word aligned

- input stride is a multiple of 128 bits (16 bytes)

The VCAA engine has the following restrictions with respect to output surfaces:

- output base address is 128-bit memory word aligned

- output stride is a multiple of 128 bits (16 bytes)

(9) Coverage surface layout

The surface is C4X4.

Surface layout (C4X4)

```
(lsb2msb)  C0_C1_C2_C3_X_X_X_X     (X is a don't care.  Qrast inits to 1)
(msb2lsb)  X_X_X_X_C3_C2_C1_C0

    +          o          o
         C0
            C1   Cov(0,1)
       C2
         C3
    o          o          o

      Cov(1,0)   Cov(1,1)

    o          o          o

    +/o = pixel centers
```

In the example above,

```
Cov(0,0) = X_X_X_X_C3_C2_C1_C0
C3       = V_C3(Cov(0,0));
..         ..
C0       = V_C0(Cov(0,0));
#define V_C3(bits) (bits & 0x8)
#define V_C2(bits) (bits & 0x4)
#define V_C1(bits) (bits & 0x2)
#define V_C0(bits) (bits & 0x1)
```

Resolving a pixel

In an ideal world, the coverage would be simply laid out such that when resolving Pixel(x,y), we would need only to fetch Cov(x,y) to get all 4 bits of information.

In actuality, the coverage surface was rearranged to help qrast in performance. To resolve Pixel(x,y) gr2d has to fetch 4 C4X4 bytes [Cov(x,y), Cov(x-1,y), Cov(x,y-1), Cov(x-1,y-1)]. From each C4X4 byte, it extracts one bit which is used in the resolve equations shown in (5).

Need the logical VCAA bits (DRLU) for blend which is spread across four C4X4 coverage bytes

```
      U
  L
    o
       R
   D
```

Where

o = Pixel(x,y)
D = V_C1(Cov(x-1,y))
R = V_C0(Cov(x,y))
L = V_C3(Cov(x-1,y-1))
U = V_C2(Cov(x,y-1))

Bit	Reset	Description
31:0	X	SRCBA: Source base address (byte address)

14.5.45 G2SB_CTX3_G2SRCBA_B_0

SB only

Offset: 0x1032 │ Byte Offset: 0x40c8 │ Read/Write: R/W │ Reset: 0x00000000 (0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx)

Bit	Reset	Description
31:0	X	SRCBA_B: This parameter specifies the start address of source image stored in the image buffer memory. In 4:2:0 format mode, this image block accommodates for Y-image. This address specifies byte position; however, bits [2:0] are restricted with respect to the data formats to fit multiple pixels in one memory word (8 bytes). For example, {0, 4} for any YCrCb formats, {0, 2, 4, 6} for RGB 16-bit format. Since one Y pixel takes 8 bits, all 8 byte positions are valid in 4:2:0 mode. (Unlike multiplexed pixels format, there are no restrictions on this value.)

14.5.46 G2SB_CTX3_G2SRCST_0

Offset: 0x1033 | Byte Offset: 0x40cc | Read/Write: R/W | Reset: 0x00000000 (0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx)

Bit	Reset	Description
15:0	X	SRCS: Source Stride coordinate (bytes) with respect to SRCBA. In order to fit multiple pixels in one memory word (8 bytes), bits [2:0] are restricted with respect to the data formats. For example, {0, 4} for any YCrCb formats, {0, 2, 4, 6} for RGB 16-bit format.

Offset: 0x1047 | Byte Offset: 0x411c | Read/Write: R/W | Reset: 0x00000000 (0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx)

Bit	Reset	Description
31:0	X	PAT_BASE: pattern base address in tile mode, PATBA is the linear address where pixel start

14.5.67 G2SB_CTX3_G2SRCBA_SB_SURFBASE_0

SB_SURFBASE Registers

These registers need only be programmed when using SB. They point to the base of the various source and destination surfaces. Technically, they are only needed when tiling is enabled, but there is no harm in always programming them.

Their counterpart registers (_SB_SURFBASE with SB_SURFBASE stripped off) indicate the location of the first pixel to be sourced or written within the surface.

This register exists to mimic the X, Y (SRCX, SRCY) functionality found in the BitBlt engine.

For example, to get at pixel X, Y:

SRCBA = SRCBA_SB_SURFBASE + Y*stride + X*Bpp

Offset: 0x1048 | Byte Offset: 0x4120 | Read/Write: R/W | Reset: 0x00000000 (0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx)

Bit	Reset	Description
31:0	X	SRC_ADDR: surface address corresponding to G2SRCBA: -base of interleaved sources (RGB, YUV) -base of Y plane. Only used by the StretchBlit Engine

14.5.68 G2SB_CTX3_G2DSTBA_SB_SURFBASE_0

Offset: 0x1049 | Byte Offset: 0x4124 | Read/Write: R/W | Reset: 0x00000000 (0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx)

Bit	Reset	Description
31:0	X	DST_ADDR: surface address corresponding to G2DSTBA. Only used by the StretchBlit Engine

		3 = REG_WR_SAFE 4 = COND_4 5 = COND_5 6 = COND_6 7 = COND_7 8 = COND_8 9 = COND_9 10 = COND_10 11 = COND_11 12 = COND_12 13 = COND_13 14 = COND_14 15 = COND_15
7:0	0x0	INDX: syncpt index value

14.6.2 G2SB_CTX4_INCR_SYNCPT_CNTRL_0

Offset: 0x5001 | Byte Offset: 0x14004 | Read/Write: R/W | Reset: 0x00000000 (0bxxxxxxxxxxxxxxxxxxxxxxxx0xxxxxxx0)

Bit	Reset	Description
8	0x0	INCR_SYNCPT_NO_STALL: If NO_STALL is 1, then when FIFOs are full, INCR_SYNCPT methods will be dropped and the INCR_SYNCPT_ERROR[COND] bit will be set. If NO_STALL is 0, then when FIFOs are full, the client host interface will be stalled.
0	0x0	INCR_SYNCPT_SOFT_RESET: If SOFT_RESET is set, then all internal state of the client syncpt block will be reset. To do soft reset, first set SOFT_RESET of all host1x clients affected, then clear all SOFT_RESETs.

14.6.3 G2SB_CTX4_INCR_SYNCPT_ERROR_0

Offset: 0x5002 | Byte Offset: 0x14008 | Read/Write: R/W | Reset: 0x00000000 (0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx)

Bit	Reset	Description
31:0	X	COND_STATUS: COND_STATUS[COND] is set if the FIFO for COND overflows. This bit is sticky and will remain set until cleared. Cleared by writing 1.

14.6.4 G2SB_CTX4_G2CLASSCHANNEL_REGONLY_0

This register can be accessed by both register read/write and command FIFO in order not to break exsting code , keep suffix REGONLY.

2D syncpt behavior

- Each 2D context has its own syncpt client.
- OP_DONE increments when 2D's memory write client is idle, meaning all preceding operations are complete.
- RD_DONE behaves like OP_DONE
- REG_WR_SAFE behaves like IMMEDIATE meaning a syncpt increment returns immediately and does not indicate that a register write will NOT block.
- The implications are that 2D's host FIFO can fill and block access to 2D, which will indeterminately block a direct CPU access.

Bit	Reset	Description
31:0	X	VDSTEP: Vertical Scaling DDA. Reset value: xxxx-xxxxh. Vertical DDA Step (Increment) Value (VDSTEP[18:0]) (upper 13 bits should be set to '0') This parameter specifies the increment value of the DDA used for vertical scaling and it is in the form of 6-bit integer and 12-bit fraction. This value is determined by the equation: (Actual_source_height-1-VDTINI) / (Actual_destination_height-1). Truncate the remaining bits to keep the 12-bit fraction. Since we have to meet (Actual_source_height-1)*1.0 >= (Actual_destination_height - 1)*VDSTEP + VDTINI. The 6-bit integer allows maximum contraction ratio of 1/64, and 12-bit fraction ensures the maximum limit of accumulated error less than half line-spacing for up to

Bit	Reset	Description
		approximately 2000 target lines. For example, image expansion from 240 lines to 400 lines VDSTEP[17:0] = 19'b00_0000_1001_1001_1010 and image contraction from 240 lines to 150 lines VDSTEP[17:0] = 19'b00_0001_1001_1001_1010.

14.6.13 G2SB_CTX4_G2VDDAINI_0

Offset: 0x5012 | Byte Offset: 0x14048 | Read/Write: R/W | Reset: 0x00000000 (0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx)

Bit	Reset	Description
15:8	X	VDBINI: Vertical DDA Initial Value for Bottom-Field (VDBINI[7:0]) (see description above)
7:0	X	VDTINI: Vertical Scaling DDA Initial Values. Vertical DDA Initial Value for Top-Field (VDTINI[7:0]) This parameter specifies the fraction part of initial value of the DDA used for vertical scaling. Given a pair of consecutive source image lines representing positions 0.0 and 1.0, a destination line-image will be created at any position in [0.0, 1.0), that is specified by the fraction part of the vertical DDA. The 8-bit initial fraction value specifies the position of the first output (destination) line-image located between the first and the second input (source) line images, respectively at position 0.0 and 1.0. This parameter provides a way to compensate relative displacement of top and bottom fields of a source image. Suppose, 2-to-1 interlaced original video field images #1 and #2 are in the image buffer, to be displayed in an overlay window. Assume that the #1 field image is the top-field. Using VDTINI = 8'hC0 for the top-field image and VDBINI = 8'h40 for the bottom-field image, for example, the two images from #1 and #2 fields get mapped to identically positioned destination images in the overlay window.

Bit	Reset	Description
7:0	X	HDINI: Horizontal Scaling DDA Initial Value. Horizontal DDA Initial Value (HDINI[7:0]) This parameter specifies the fraction part of initial value of the DDA used for horizontal scaling. Given a group of six consecutive source pixels that the two pixels at the center representing positions 0.0 and 1.0, a destination pixel will be created at any position in [0.0, 1.0), that is specified by the fraction part of the horizontal DDA. The 8-bit initial fraction value specifies the position of the first output (destination) pixel located between the first and the second input (source) pixels, respectively at position 0.0 and 1.0.For horizontal scaling this value may normally be set to 0.

14.6.16 G2SB_CTX4_G2CSCFIRST_0

The next 3 registers contain 8 parameters used by the YCbCr (YUV) to RGB color space conversion logic. This logic can also be used for RGB gain/gamma correction in RGB to RGB modes, and for luma gain in YUV to YUV modes.

Two new parameters (G2U, G2V) have been added for RGB to YUV conversion. These are in address 0x38. The equations have the form:

if (yuv2rgb)

(r,g,b) = matrix*(y+sbreg_yos,u,v)

matrix: sbreg_cyx, sbreg_cur, sbreg_cvr,
sbreg_cyx, sbreg_cug, sbreg_cvg,
sbreg_cyx, sbreg_cub, sbreg_cvb,

else if (rgb2rgb)

(r,g,b) = matrix*(r,g+sbreg_yos,b)

matrix: sbreg_cvr, 0, sbreg_cur,
sbreg_cvg, sbreg_cyx, sbreg_cug,
sbreg_cvb, 0, sbreg_cub,

else if (yuv2yuv)

(y,u,v) = matrix*(y,u,v)

matrix: sbreg_cub, 0, sbreg_cvb,
sbreg_cug, sbreg_cyx, sbreg_cvg,
sbreg_cur, 0, sbreg_cvr,

else if (rgb2yuv)

(y,u,v) = matrix*(r,g,b) + (sbreg_yos,0,0)

matrix: sbreg_cvb, sbreg_cyx, sbreg_cub,
sbreg_cvg, sbreg_g2u, sbreg_cug,
sbreg_cvr, sbreg_g2v, sbreg_cur,

Bit	Reset	Description
31:24	X	YOS:Y-Offset (YOFFSET[7:0]) for YUV generation This parameter consists of 8-bit 2's complement in the range [-128,127]. For YUV->RGB, the recommended value is -16 (decimal) or 0xF0. For YUV->YUV & RGB->RGB, this parameter should be set to 0. For RGB->YUV the recommended value is +16 (decimal) or 0x10
21:12	X	CVR: multiplier for V/R for V or R generation. This parameter consists of a sign bit and 9-bit magnitude (s2.7). For YUV->RGB, the recommended value is 1.5960 (decimal) or 0x0CCIf source data is in RGB format, this parameter may be used as gain adjustment for R component. For RGB->YUV, the recommended value is +0.439 (decimal) or 0x038.
9:0	X	CUB: multiplier for U/B for Y or B generation. Consists of a sign bit and 9-bit magnitude (s2.7). For YUV->RGB, the recommended value is 2.0172 (decimal) or 0x102. If source data is in RGB format, this parameter may be used as gain adjustment for B component. This register changes precision when doing RGB to YUV conversion (SIFMT=1xxx, DIFMT=0xxx). CUB becomes s1.8 and the recommended value is +0.098 or 0x019.

25:16	X	CVB: multiplier for V/R for Y or B generation. This parameter consists of a sign bit and 9-bit magnitude (s2.7). For YUV->RGB, normally this parameter is programmed to 0.0. This coefficient takes non-zero value if hue is rotated. For YUV->YUV & RGB->RGB, this parameter should be set to 0. For RGB->YUV the recommended value is +0.257 (decimal) or 0x021
8:0	X	CVG: multiplier for V/R for U or G generation. This parameter consists of a sign bit and 8-bit magnitude (s1.7). For YUV->RGB the recommended value is -0.8130 (decimal) or 0x168. For YUV->YUV & RGB->RGB, this parameter should be set to 0. For RGB->YUV, the recommended value is -0.148 (decimal) or 0x113

14.6.19 G2SB_CTX4_G2CMKEYL_0

When key generation is enabled, the value of this register is the lower color/chroma limit and G2CMKEYU is the upper color/chroma limit for component pixel data. Three component signal values (YCrCb/YUV or RGB) of every output pixel are compared to a set of three ranges that are specified by three pairs of lower and upper color/chroma key values.

If the Key Polarity is 0, the Key is set to 1 only when all three component values of an input pixel are respectively within the set of ranges (inclusive of the limit values), else the Key is set to 0.

If the Key Polarity is 1, the Key is set to 1 when any of the three component values of an input pixel are outside the set of ranges, else the Key is set to 0.

Bit	Reset	Description
31	0x0	DISDW: Output destination writes go either to image memory or the EPP. 0: Output data is sent to memory 1: YUV or RGB data is passed directly to the EPP module, and no destination writes take place. 0 = GOTO_IMAGE_BUFFER 1 = GOTO_EPP
30	0x0	ENDITH: Enable Dithering (ENDITH). For 16 bit RGB output modes, the LSB of the color components can be modified by adding a variable residual value that will reduce the banding artifacts that can appear on the display. 0: Normal operation 1: Enable Dithering 0 = DISABLE 1 = ENABLE
28	0x0	KPOL: Key Signal Polarity (KPOL). Color/Chroma key signal is generated by comparing source input pixel color to a range of a color specified by lower and upper limit values. The key signal is interpreted in two ways, depending on which one of video and graphics images is foreground (and the other is background). This is effective only if Key signal generator is enabled. (see G2CMKEYL, G2CMKEYU) 0: Key signal is set to 1 when source pixel is within the lower and upper limit color range. 1: Key signal is set to 1 when source pixel is outside the lower and upper limit color range. 0 = WITHIN_BOUNDS 1 = OUTSIDE_BOUNDS
27	0x0	KEYEN: Key Signal Generator Enable (KEYEN) Key signal generator generates either chroma key signal (from YCbCr signal) or color key signal (from RGB signal) 0: Key signal generator is disabled. 1: Key signal generator is enabled. 0 = DISABLE 1 = ENABLE
26	0x0	DBSEL: StretchBLT Destination Buffer Selection (DBSEL) StretchBLT processing involves frame-rate conversion from a series of source images to another series of destination images (field-rate of the source video to frame-rate of the PC display). In order to avoid image tearing, it is preferred to use two buffer sections in the destination video area. This bit selects one of the two buffering blocks to which this StretchBLT command delivers the destination image. The two buffering memory blocks are called A and B. 0: Destination image goes to ‘A’ buffer. 1: Destination image goes to ‘B’ buffer. 0 = DST_A 1 = DST_B

Bit	Reset	Description
25	0x0	SBSEL: StretchBLT Source Buffer Selection (SBSEL) StretchBLT processing involves frame-rate conversion from a series of source images to another series of destination images (field-rate of the source video to frame-rate of the PC display). In order to avoid image tearing, it is preferred to use two buffer sections in the source video area. This bit selects one of the two buffering blocks from which this StretchBLT command receives the source image. The two buffering memory blocks are called source-A and source-B. 0: Source image comes from ‘source-A’ buffer. 1: Source image comes from ‘source-B’ buffer. 0 = SRC_A 1 = SRC_B
24	0x0	SITYPE: StretchBLT Source Type (SITYPE). This bit identifies two types of source images. If source image is 2-to-1 interlaced and StretchBLT processes either one of the two interlaced field-images, physical (positional) displacement between the two interlaced fields must be taken into account. One field-image that is placed higher in position than the other field-image is called top-field and the other is called bottom-field. StretchBLT processing has to lower the top-field (or raise the bottom-field) to match the corresponding two target images in the overlay window (that is progressively scanned) right at the same position. If source image is full frame-image obtained from two interlaced field-images, its type is ‘top-field’. If source images are progressively scanned, the type identification is not significant and they may be designated either one of the two types 0: Source image is ‘top-field’. 1: Source image is ‘bottom-field’. 0 = TOP_FIELD 1 = BOTTOM_FIELD
23	0x0	RANGEREDFRM:In the VC-1 specification, when the value of RANGEREDFRM variable (1-bit) for a picture is equal to 1, the picture shall be scaled up according to the following equation:Y = clip(((Y-128)*2) + 128);Cb = clip(((Cb-128)*2) + 128);Cr = clip(((Cr-128)*2) + 128);The clip operator limits the output to [0, 255].The input is also limited to [0, 255]. In the VC-1 nomenclature, the output (Y, Cb, Cr) tuple corresponds to the 'decoded' picture. The input (Y, Cb, Cr) tuple corresponds to the 'reconstructed' picture. The above equations create the decoded picture while keeping the reconstructed picture intact.Only YUV _OB formats are supported with range reducation enabled, not the YUV _TC or RGB formats The YUV data coming from the video frame buffers (reconstructed picture) in the SDRAM was scaled up using the above equations and given to the display. the value of 1-bit wide RANGEREDFRM variable was configured in the DVO per frame and the frame was scaled whenever RANGEREDFRM == 1. 0 = DISABLE 1 = ENABLE
22:20	0x0	HFTYPE: StretchBLT Horizontal Filter Mode (HFTYPE[2:0]) The six-tap horizontal interpolation filter can be operated in various operation modes. For the image expansion, it should be programmed as a pure 6-tap interpolator. For the image contraction, it can work as partly lowpass filter and partly interpolater with varying degree depending the contraction ratio. For StretchBLT, this parameter is used as an index (selection) to an internal lookup table that stores the group of filter-coefficients for the different modes of horizontal filtering. 000: Pure interpolation filter. 001, 010, 011, 100, 101, 110: mix of interpolation and low pass filters 111: DISABLE. 0 = INTERP 1 = LPF1 2 = LPF2 3 = LPF3 4 = LPF4 5 = LPF5 6 = LPF6 7 = DISABLE

Bit	Reset	Description
19	0x0	DISCSC: enabled color space converter by default 0 = ENABLE 1 = DISABLE
18	0x0	VFEN: StretchBLT Vertical Filter Enable (VFEN) Vertical filter shall be disabled if source images come from host CPU via CPU Read-FIFO. (SISEL) Vertical filter may be disabled to save some memory bandwidth but this will likely result in degradation of image quality. This option may also be used in the case where source image is progressive scanning and there is no vertical scaling. 0 Vertical filter is disabled.1 Vertical filter is enabled. 0 = DISABLE 1 = ENABLE
17:16	0x0	VFTYPE: StretchBLT Vertical Filter Mode (VFTYPE[1:0]). This bit is effective when the Vertical Filter is enabled. (bit 18) The two-tap vertical interpolation filter can be operated in various modes. For the image expansion, it should be programmed as a pure 2-tap interpolator. For the image contraction, it can work as partly averager and partly interpolator with varying degree depending on the contraction ratio. For StretchBLT, this parameter is used as an index (selection) to an internal lookup table that stores the group of filter-coefficients for the different modes of vertical filtering. 00: Pure interpolation filter. 01: 25% averager, 75% interpolator. 10: 50% averager, 50% interpolator. 11: 100% averager. 0 = INTERP 1 = AVG25_INTERP75 2 = AVG50_INTERP50 3 = AVG
9:8	X	UVST: 00= 1/2 of Luma Buffer Stride; in this case Luma Buffer Stride should be a multiple of 2 bytes. 01= Equal to Luma Buffer Stride 10= 1/4 of Luma Buffer Stride; in this case Luma Buffer Stride should be a multiple of 4 bytes. 11= use uvstride. Note: Use care when using a tiled surface, since 1/2 or 1/4 of luma stride may yield an invalid pitch (stride). 0 = UVS2X 1 = UVS1X 2 = UVS4X 3 = UVS_G2UVSTRIDE

14.6.26 G2SB_CTX4_G2CONTROLMAIN_0

G2 Blit Formats:

(1) G2 Blit size is based on height in lines, width in pixels, stride in bytes, and pixel size (color depth). Unless alpha blending is enabled, G2 does not care about pixel components.

Source color depths supported by G2 Blit:

- color depth same as destination: G2CONTROLMAIN.SRCCD = 1
- monochrome: G2CONTROLMAIN.SRCCD = 0

(source monochrome color determined by G2SRCBGC, G2SRCFGC)

Pattern color depths supported by G2 Blit:

- color depth same as destination: G2PATOS.PATCD = 1
- monochrome: G2PATOS.PATCD = 0

(pattern monochrome color determined by G2PATBGC, G2PATFGC)

Destination color depths supported by G2 Blit:

- 1 byte per pixel: G2CONTROLMAIN.DSTCD = BPP8
- 2 bytes per pixel: G2CONTROLMAIN.DSTCD = BPP16
- 4 bytes per pixel: G2CONTROLMAIN.DSTCD = BPP32

(2) Alpha blending operates on 3 or 4 component pixels of a specified color depth. One of the components may be alpha (A), depending on the alpha blend format, which is only allowed in certain component positions defined below. The only format rule of the remaining components is that they must be in the same source and destination position because the alpha blend engine does not support component swapping. For example, valid 32BPP formats are: RGBA_8888->RGBA_8888, BGRA_8888->BGRA_8888, GRBA_8888->GRBA_8888, etc.

Source formats supported by G2 alpha blend:

- color depth BPP8: no supported formats
- color depth BPP16:
  - ALPTYPE_PLS1BPP: xxxA_5551 (for example, BGRA_5551 = A[15] R[14:10] G[9:5] B[4:0])
  - ALPTYPE_PLS4BPP: xxxA_4444 (for example, BGRA_4444 = A[15:12] R[11:8] G[7:4] B[3:0])
  - (other) : xxx_565 (for example, BGR_565 = R[15:11] G[10:5] B[4:0])
- color depth BPP32:
  - (all) : xxxA_8888 (for example, BRGA_8888 = A[31:24] R[23:16] G[15:8] B[7:0])

Destination formats supported by G2 alpha blend:

- color depth BPP8: no supported formats
- color depth BPP16: xxx_565 (for example, BGR_565 = R[15:11] G[10:5] B[4:0])
- color depth BPP32: xxxA_8888 (for example, BRGA_8888 = A[31:24] R[23:16] G[15:8] B[7:0])

src cd	src format	dst cd	dst format	examples
BPP8	no support	BPP8	no support	
BPP16	xyzA_5551, xyzA_4444, xyz_565	BPP16	xyz_565	BGRA_5551->BGR_565, RGB_565->RGB565
BPP32	xyzA_8888	BPP32	xyzA_8888	RGBA_8888->RGBA_8888, BGRA_8888->BGRA_8888

VCAA Resolve Engine

(1) Format support

srcColor format	srcCoverage format	legal dest format(s)
A1B5G5R5	VCAA	A1B5G5R5
R8G8B8A8	VCAA	R8G8B8A8, B5G6R5
B5G6R5	VCAA	B5G6R5

To program resolve type:

- ALPTYPE == FIX: B5G6R5 -> B5G6R5
- ALPTYPE == PLS1BPPAL: A1B5G5R5 -> A1B5G5R5
- ALPTYPE == PLS8BPP: R8G8B8A8 -> R8G8B8A8
- ALPTYPE == PLS8BX: R8G8B8A8 -> B5G6R5

(2) Color surface programming

- color surface base address: SRCBA
- subsurface start x: SRCX (pixel index)
- subsurface start y: SRCY (line index)
- color surface stride: SRCS (bytes)

The engine supports subsurface resolve. One can imagine a full color buffer of 1024x768, but

```
[pseudo_code]
      color_surface_start_address_fetch = pcurctx->regs.rG2SRCBA.uSRCBA() +
       (pcurctx->regs.rG2SRCPS.uSRCX() * VCAAState.color_surface_depth) +
       (pcurctx->regs.rG2SRCPS.uSRCY() * VCAAState.color_surface_stride);
```

(3) VCAA surface programming

- VCAA surface base address: PATBA
- VCAA surface stride: PATST (bytes)

```
[pseudo_code]
      vcaa_surface_start_address_fetch = pcurctx->regs.rG2PATBA.uPATBA();
```

Software *MUST* directly program this register to the proper subsurface location in the VCAA surface which corresponds to the SRCX and SRCY programming. The calculation is PATBA = vcaa_base_address + SRCX * (1) + SRCY * PATST;

(4) Resolve surface programming

- resolve window width: DSTWIDTH (pixels)
- resolve window height: DSTHEIGHT (lines)
- resolve output stride: DSTS (bytes)

These values program the width and height of the resolved surface. In the base case,

- DSTWIDTH = color surface width
- DSTHEIGHT = color sufrace height
- DSTS = resolve surface format bpp * DSTWIDTH

The vcaa engine technically supports DSTX and DSTY (like SRCX and SRCY).

```
  [pseudo_code]
     resolve_surface_start_address_put = pcurctx->regs.rG2DSTBA.uDSTBA() +
       (pcurctx->regs.rG2DSTPS.uDSTX() * resolve_surface_color_depth) +
       (pcurctx->regs.rG2DSTPS.uDSTY() * resolve_surface_color_stride);
```

(5) Resolving a pixel

The coverage surface is a 8 bits per pixel surface (C4X4). The surface is initialized to all 1s by 3d.

For a given pixel, we need to look up 4 bits of coverage data. If the data is 0xf, the pixel does not need to be resolved. Otherwise, we need to reblend the pixel with certain weightings of its neighbors (i.e. we're on the edge of some geometry).

If any coverage bit is 0, we need to resolve the color. To do so, we calculate the following equation:

```
   color_new = (
                 20*color_old +
                 27*(
                     ((cover_down  == 0) ? color_down  : color_old) +
                     ((cover_right == 0) ? color_right : color_old) +
                     ((cover_left  == 0) ? color_left  : color_old) +
                     ((cover_up    == 0) ? color_up    : color_old)
                     )
               ) / 128;
```

If coverage bit == 0, then we use the neighbor color value in the resolve

If coverage bit == 1, then we use the center color value in the resolve

The resolve is done on a per channel (r/g/b/a) basis:

format convert input channel to 8-bit

perform resolve equation above

format convert to output format

For the resolution of the alpha channel:

- In B5G6R5: no alpha information. do nothing.
- In A1B5G5R5: no resolve. keep the source color alpha bit.
- In R8G8B8A8: normal 8-bit channel resolve

(6) Resolving a pixel on the edge

When on an edge, the VCAA engine treats the coverage bit as a 1. Use the center color value. This holds true even on the edge of the subsurface resolve window when located in the middle of the larger surface

(7) Maximum dimensions

The maximum resolve subsurface is 4096 pixels wide.

(8) Surface restrictions

The VCAA engine has the following restrictions with respect to input surfaces

- input base address is 128-bit memory word aligned

- input stride is a multiple of 128 bits (16 bytes)

The VCAA engine has the following restrictions with respect to output surfaces

- output base address is 128-bit memory word aligned

- output stride is a multiple of 128 bits (16 bytes)

(9) Coverage surface layout

The surface is C4X4.

Surface layout (C4X4)

```
(lsb2msb)  C0_C1_C2_C3_X_X_X_X     (X is a don't care.  Qrast inits to 1)
(msb2lsb)  X_X_X_X_C3_C2_C1_C0

     +          o          o
          C0
             C1   Cov(0,1)
        C2
          C3
     o          o          o

       Cov(1,0)   Cov(1,1)

     o          o          o

     +/o = pixel centers
```

In the example above,

```
        Cov(0,0) = X_X_X_X_C3_C2_C1_C0
        C3       = V_C3(Cov(0,0));
        ..         ..
```

```
        C0        = V_C0(Cov(0,0));
    #define V_C3(bits)  (bits & 0x8)
    #define V_C2(bits)  (bits & 0x4)
    #define V_C1(bits)  (bits & 0x2)
    #define V_C0(bits)  (bits & 0x1)
```

Resolving a pixel

In an ideal world, the coverage would be simply laid out such that when resolving Pixel(x,y), we would need only to fetch Cov(x,y) to get all 4 bits of information.

In actuality, the coverage surface was rearranged to help qrast in performance. To resolve Pixel(x,y) gr2d has to fetch 4 C4X4 bytes [Cov(x,y), Cov(x-1,y), Cov(x,y-1), Cov(x-1,y-1)]. From each C4X4 byte, it extracts one bit which is used in the resolve equations shown in (5).

Need the logical vcaa bits (DRLU) for blend which is spread across four C4X4 coverage bytes

```
          U

    L

        o

            R

      D
```

where

o = Pixel(x,y)
D = V_C1(Cov(x-1,y))
R = V_C0(Cov(x,y))
L = V_C3(Cov(x-1,y-1))
U = V_C2(Cov(x,y-1))

Offset: 0x501f | Byte Offset: 0x1407c | Read/Write: R/W | Reset: 0x00000000 (0bx000000x00xx00xx0000000000000000)

SB only

Offset: 0x5032 | Byte Offset: 0x140c8 | Read/Write: R/W | Reset: 0x00000000 (0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx)

Bit	Reset	Description
31:0	X	SRCBA_B: This parameter specifies the start address of source image stored in the image buffer memory. In 4:2:0 format mode, this image block accommodates for Y-image. This address specifies byte position, however, bits [2:0] are restricted with respect to the data formats to fit multiple pixels in one memory word (8 bytes). For example, {0, 4} for any YCrCb formats, {0, 2, 4, 6} for RGB 16-bit format. Since one Y pixel takes 8-bit, all 8 byte positions are valid in 4:2:0 mode. (Unlike multiplexed pixels format, there are no restrictions on this value.)

14.6.67 G2SB_CTX4_G2SRCBA_SB_SURFBASE_0

SB_SURFBASE Registers

These registers need only be programmed when using SB. They point to the base of the various source and destination surfaces. Technically they are only needed when tiling is enabled, but there is no harm in always programming them.

Their counterpart registers (_SB_SURFBASE with SB_SURFBASE stripped off) indicate the location of the first pixel to be sourced or written within the surface.

This register exists to mimic the X, Y (SRCX, SRCY) functionality found in the BitBlt engine.

For example, to get at pixel X, Y:

SRCBA = SRCBA_SB_SURFBASE + Y*stride + X*Bpp

Offset: 0x5048 | Byte Offset: 0x14120 | Read/Write: R/W | Reset: 0x00000000 (0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx)

Offset: 0x2001 │ Byte Offset: 0x8004 │ Read/Write: R/W │ Reset: 0x00000000 (0bxxxxxxxxxxxxxxxxxxxxxxxx0xxxxxxx0)

Bit	Reset	Description
8	0x0	INCR_SYNCPT_NO_STALL: If NO_STALL is 1, then when FIFOs are full, INCR_SYNCPT methods will be dropped and the INCR_SYNCPT_ERROR[COND] bit will be set. If NO_STALL is 0, then when FIFOs are full, the client host interface will be stalled.
0	0x0	INCR_SYNCPT_SOFT_RESET: If SOFT_RESET is set, then all internal state of the client syncpt block will be reset. To do soft reset, first set SOFT_RESET of all host1x clients affected, then clear all SOFT_RESETs.

14.7.3 G2SB_CTX5_INCR_SYNCPT_ERROR_0

Offset: 0x2002 │ Byte Offset: 0x8008 │ Read/Write: R/W │ Reset: 0x00000000 (0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx)

Bit	Reset	Description
31:0	X	COND_STATUS: COND_STATUS[COND] is set if the FIFO for COND overflows. This bit is sticky and will remain set until cleared. Cleared by writing 1.

14.7.4 G2SB_CTX5_G2CLASSCHANNEL_REGONLY_0

This register can be accessed by both register read/write and command FIFO in order not to break existing code , keep suffix REGONLY.

2D syncpt behavior

- Each 2D context has its own syncpt client.
- OP_DONE increments when 2D's memory write client is idle, meaning all preceding operations are complete.
- RD_DONE behaves like OP_DONE
- REG_WR_SAFE behaves like IMMEDIATE meaning a syncpt increment returns immediately and does not indicate that a register write will NOT block. The implications are that 2D's host FIFO can fill and block access to 2D, which will indeterminately block a direct CPU access.

Bit	Reset	Description
31:0	X	VDSTEP: Vertical Scaling DDA. Reset value: xxxx-xxxxh. Vertical DDA Step (Increment) Value (VDSTEP[18:0]) (upper 13 bits should be set to '0') This parameter specifies the increment value of the DDA used for vertical scaling and it is in the form of 6-bit integer and 12-bit fraction. This value is determined by the equation: (Actual_source_height-1-VDTINI) / (Actual_destination_height-1). Truncate the remaining bits to keep the 12-bit fraction. Since we have to meet (Actual_source_height-1)*1.0 >= (Actual_destination_height - 1)*VDSTEP + VDTINI. The 6-bit integer allows maximum contraction ratio of 1/64, and 12-bit fraction ensures the maximum limit of accumulated error less than half line-spacing for up to approximately 2000

Bit	Reset	Description
		target lines. For example, image expansion from 240 lines to 400 lines VDSTEP[17:0] = 19'b00_0000_1001_1001_1010 and image contraction from 240 lines to 150 lines VDSTEP[17:0] = 19'b00_0001_1001_1001_1010.

14.7.13 G2SB_CTX5_G2VDDAINI_0

Offset: 0x2012 | Byte Offset: 0x8048 | Read/Write: R/W | Reset: 0x00000000 (0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx)

Bit	Reset	Description
15:8	X	VDBINI: Vertical DDA Initial Value for Bottom Field (VDBINI[7:0]) (see description above)
7:0	X	VDTINI: Vertical Scaling DDA Initial Values. Vertical DDA Initial Value for Top-Field (VDTINI[7:0]) This parameter specifies the fraction part of initial value of the DDA used for vertical scaling. Given a pair of consecutive source image lines representing positions 0.0 and 1.0, a destination line-image will be created at any position in [0.0, 1.0), that is specified by the fraction part of the vertical DDA. The 8-bit initial fraction value specifies the position of the first output (destination) line-image located between the first and the second input (source) line-images, respectively at position 0.0 and 1.0. This parameter provides a way to compensate relative displacement of top and bottom fields of a source image. Suppose, 2-to-1 interlaced original video field images #1 and #2 are in the image buffer, to be displayed in an overlay window. Assume that the #1 field image is the top-field. Using VDTINI = 8'hC0 for the top-field image and VDBINI = 8'h40 for the bottom-field image, for example, the two images from #1 and #2 fields get mapped to identically positioned destination images in the overlay window.

14.7.14 G2SB_CTX5_G2HDDA_0

Offset: 0x2013 | Byte Offset: 0x804c | Read/Write: R/W | Reset: 0x00000000 (0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx)

Bit	Reset	Description
31:0	X	HDSTEP: Horizontal Scaling DDA. Reset value: xxxx-xxxxh. Horizontal DDA Step (Increment) Value (HDSTEP[18:0]) (upper 13 bits should be set to '0') This parameter specifies the increment value of the DDA used for horizontal scaling and it is in the form of 6-bit integer and 12-bit fraction. This value is determined by the equation: (Actual_source_width-1-HDINI) / (Actual_destination_width-1). Truncate the remaining bits to keep the 12-bit fraction. The 6-bit integer allows maximum contraction ratio of 1/64, and 12-bit fraction ensures the maximum limit of accumulated error less than half pixel-spacing for up to approximately 2000 destination pixels. For example, image expansion from 720 pixels to 800 pixels HDSTEP[17:0] = 19'b000_0000_1110_0110_0111 and image contraction from 720 pixels to 250 pixels HDSTEP[17:0] = 19'b000_0010_1110_0001_0101.

Bit	Reset	Description
7:0	X	HDINI: Horizontal Scaling DDA Initial Value. Horizontal DDA Initial Value (HDINI[7:0]) This parameter specifies the fraction part of initial value of the DDA used for horizontal scaling. Given a group of six consecutive source pixels that the two pixels at the center representing positions 0.0 and 1.0, a destination pixel will be created at any position in [0.0, 1.0), that is specified by the fraction part of the horizontal DDA. The 8-bit initial fraction value specifies the position of the first output (destination) pixel located between the first and the second input (source) pixels, respectively at position 0.0 and 1.0.For

Bit	Reset	Description
		horizontal scaling this value may normally be set to 0.

14.7.16 G2SB_CTX5_G2CSCFIRST_0

The next 3 registers contain 8 parameters used by the YCbCr (YUV) to RGB color space conversion logic. This logic can also be used for RGB gain/gamma correction in RGB to RGB modes, and for luma gain in YUV to YUV modes.

Two new parameters (G2U, G2V) have been added for RGB to YUV conversion. These are in address 0x38. The equations have the form:

if (yuv2rgb)

(r,g,b) = matrix*(y+sbreg_yos,u,v)

matrix: sbreg_cyx, sbreg_cur, sbreg_cvr,
sbreg_cyx, sbreg_cug, sbreg_cvg,
sbreg_cyx, sbreg_cub, sbreg_cvb,

else if (rgb2rgb)

(r,g,b) = matrix*(r,g+sbreg_yos,b)

matrix: sbreg_cvr, 0, sbreg_cur,
sbreg_cvg, sbreg_cyx, sbreg_cug,
sbreg_cvb, 0, sbreg_cub,

else if (yuv2yuv)

(y,u,v) = matrix*(y,u,v)

matrix: sbreg_cub, 0, sbreg_cvb,
sbreg_cug, sbreg_cyx, sbreg_cvg,
sbreg_cur, 0, sbreg_cvr,

else if (rgb2yuv)

(y,u,v) = matrix*(r,g,b) + (sbreg_yos,0,0)

matrix: sbreg_cvb, sbreg_cyx, sbreg_cub,
sbreg_cvg, sbreg_g2u, sbreg_cug,
sbreg_cvr, sbreg_g2v, sbreg_cur,

Offset: 0x2015 │ Byte Offset: 0x8054 │ Read/Write: R/W │ Reset: 0x00000000 (0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx)

Bit	Reset	Description
31:24	X	YOS:Y-Offset (YOFFSET[7:0]) for YUV generation. This parameter consists of 8-bit 2's complement in the range [-128,127]. For YUV->RGB, the recommended value is -16 (decimal) or 0xF0. For YUV->YUV & RGB->RGB, this parameter should be set to 0. For RGB->YUV the recommended value is +16 (decimal) or 0x10
21:12	X	CVR: multiplier for V/R for V or R generation. This parameter consists of a sign bit and 9-bit magnitude (s2.7). For YUV->RGB, the recommended value is 1.5960 (decimal) or 0x0CCIf source data is in RGB format, this parameter may be used as gain adjustment for R component. For RGB->YUV, the recommended value is +0.439 (decimal) or 0x038.
9:0	X	CUB: multiplier for U/B for Y or B generation. Consists of a sign bit and 9-bit magnitude (s2.7). For YUV->RGB, the recommended value is 2.0172 (decimal) or 0x102. If source data is in RGB format, this parameter may be used as gain adjustment for B component. This register changes precision when doing RGB to YUV conversion (SIFMT=1xxx, DIFMT=0xxx). CUB becomes s1.8 and the recommended value is +0.098 or 0x019.

14.7.17 G2SB_CTX5_G2CSCSECOND_0

Bit	Reset	Description
31:24	X	CYX: multiplier for Y/G (G gain). This positive-only parameter consists of 8-bit magnitude (1.7). For YUV->YUV, the recommended value is 1.1644 (decimal) or 0x95. For YUV->YUV or RGB->RGB, this may be used as gain adjustment for Y or G component. For RGB->YUV, the recommended value is +0.504 (decimal) or 0x041
21:12	X	CUR: multiplier for U/B for V or R generation. This parameter consists of a sign bit and 9-bit magnitude (s2.7). For YUV->RGB, normally this parameter is programmed to 0.0. This parameter takes non-zero value if hue is rotated. For YUV->YUV & RGB->RGB, this parameter should be set to 0. For RGB->YUV, the recommended value is -0.071 (decimal) or 0x209
8:0	X	CUG: multiplier for U/B for U or G generation. Consists of a sign bit and 8-bit magnitude (s1.7). For YUV->RGB, the recommended value is -0.3918 (decimal) or 0x132 For RGB->RGB, this parameter should be set to 0. For YUV->YUV, this parameter should be set to 1 (0x080). For RGB->YUV, the recommended value is +0.439 (decimal) or 0x038

14.7.18 G2SB_CTX5_G2CSCTHIRD_0

Offset: 0x2017 | Byte Offset: 0x805c | Read/Write: R/W | Reset: 0x00000000 (0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx)

Bit	Reset	Description
25:16	X	CVB: multiplier for V/R for Y or B generation. This parameter consists of a sign bit and 9-bit magnitude (s2.7). For YUV->RGB, normally this parameter is programmed to 0.0. This coefficient takes non-zero value if hue is rotated. For YUV->YUV & RGB->RGB, this parameter should be set to 0. For RGB->YUV, the recommended value is +0.257 (decimal) or 0x021
8:0	X	CVG: multiplier for V/R for U or G generation. This parameter consists of a sign bit and 8-bit magnitude (s1.7). For YUV->RGB, the recommended value is -0.8130 (decimal) or 0x168. For YUV->YUV & RGB->RGB, this parameter should be set to 0. For RGB->YUV, the recommended value is -0.148 (decimal) or 0x113

14.7.19 G2SB_CTX5_G2CMKEYL_0

When key generation is enabled, the value of this register is the lower color/chroma limit and G2CMKEYU is the upper color/chroma limit for component pixel data. Three component signal values (YCrCb/YUV or RGB) of every output pixel are compared to a set of three ranges that are specified by three pairs of lower and upper color/chroma key values.

If the Key Polarity is 0, the Key is set to 1 only when all three component values of an input pixel are respectively within the set of ranges (inclusive of the limit values); otherwise the Key is set to 0.

If the Key Polarity is 1, the Key is set to 1 when any of the three component values of an input pixel are outside the set of ranges; otherwise the Key is set to 0.

StretchBLT, Color/Chroma Key Lower Limit Register

Bit	Reset	Description
31	0x0	DISDW: Output destination writes go either to image memory or the EPP. 0: Output data is sent to memory 1: YUV or RGB data is passed directly to the EPP module, and no destination writes take place. 0 = GOTO_IMAGE_BUFFER 1 = GOTO_EPP
30	0x0	ENDITH: Enable Dithering (ENDITH). For 16 bit RGB output modes, the LSB of the color components can be modified by adding a variable residual value that will reduce the banding artifacts that can appear on the display. 0: Normal operation 1: Enable Dithering 0 = DISABLE 1 = ENABLE
28	0x0	KPOL: Key Signal Polarity (KPOL). Color/Chroma key signal is generated by comparing source input pixel color to a range of a color specified by lower and upper limit values. The key signal is interpreted in two ways, depending on which one of video and graphics images is foreground (and the other is background). This is effective only if Key signal generator is enabled. (see G2CMKEYL, G2CMKEYU) 0: Key signal is set to 1 when source pixel is within the lower and upper limit color range. 1: Key signal is set to 1 when source pixel is outside the lower and upper limit color range. 0 = WITHIN_BOUNDS 1 = OUTSIDE_BOUNDS
27	0x0	KEYEN: Key Signal Generator Enable (KEYEN). Key signal generator generates either chroma key signal (from YCbCr signal) or color key signal (from RGB signal) 0: Key signal generator is disabled. 1: Key signal generator is enabled. 0 = DISABLE 1 = ENABLE
26	0x0	DBSEL: StretchBLT Destination Buffer Selection (DBSEL) StretchBLT processing involves frame-rate conversion from a series of source images to another series of destination images (field-rate of the source video to frame-rate of the PC display). In order to avoid image tearing, it is preferred to use two buffer sections in the destination video area. This bit selects one of the two buffering blocks to which this StretchBLT command delivers the destination image. The two buffering memory blocks are called A and B. 0: Destination image goes to ‘A’ buffer. 1: Destination image goes to ‘B’ buffer. 0 = DST_A 1 = DST_B
25	0x0	SBSEL: StretchBLT Source Buffer Selection (SBSEL) StretchBLT processing involves frame-rate conversion from a series of source images to another series of destination images (field-rate of the source video to frame-rate of the PC display). In order to avoid image tearing, it is preferred to use two buffer sections in the source video area. This bit selects one of the two buffering blocks from which this StretchBLT command receives the source image. The two buffering memory blocks are called source-A and source-B. 0: Source image comes from ‘source-A’ buffer. 1: Source image comes from ‘source-B’ buffer. 0 = SRC_A 1 = SRC_B
24	0x0	SITYPE: StretchBLT Source Type (SITYPE). This bit identifies two types of source images. If source image is 2-to-1 interlaced and StretchBLT processes either one of the two interlaced

Bit	Reset	Description
		field-images, physical (positional) displacement between the two interlaced fields must be taken into account. One field-image that is placed higher in position than the other field-image is called top-field and the other is called bottom-field. StretchBLT processing has to lower the top-field (or raise the bottom-field) to match the corresponding two target images in the overlay window (that is progressively scanned) right at the same position. If source image is full frame-image obtained from two interlaced field-images, its type is 'top-field'. If source images are progressively scanned, the type identification is not significant and they may be designated either one of the two types 0: Source image is 'top-field'. 1: Source image is 'bottom-field'. 0 = TOP_FIELD 1 = BOTTOM_FIELD
23	0x0	RANGEREDFRM:In the VC-1 specification, when the value of RANGEREDFRM variable (1-bit) for a picture is equal to 1, the picture shall be scaled up according to the following equation:Y = clip(((Y-128)*2) + 128);Cb = clip(((Cb-128)*2) + 128);Cr = clip(((Cr-128)*2) + 128);The clip operator limits the output to [0, 255].The input is also limited to [0, 255]. In the VC-1 nomenclature, the output (Y, Cb, Cr) tuple corresponds to the 'decoded' picture. The input (Y, Cb, Cr) tuple corresponds to the 'reconstructed' picture. The above equations create the decoded picture while keeping the reconstructed picture intact.Only YUV _OB formats are supported with range reducation enabled, not the YUV _TC or RGB formats The YUV data coming from the video frame buffers (reconstructed picture) in the SDRAM was scaled up using the above equations and given to the display. the value of 1-bit wide RANGEREDFRM variable was configured in the DVO per frame and the frame was scaled whenever RANGEREDFRM == 1. 0 = DISABLE 1 = ENABLE
22:20	0x0	HFTYPE: StretchBLT Horizontal Filter Mode (HFTYPE[2:0]) The six-tap horizontal interpolation filter can be operated in various operation modes. For the image expansion, it should be programmed as a pure 6-tap interpolator. For the image contraction, it can work as partly lowpass filter and partly interpolater with varying degree depending the contraction ratio. For StretchBLT, this parameter is used as an index (selection) to an internal lookup table that stores the group of filter-coefficients for the different modes of horizontal filtering. 000: Pure interpolation filter 001, 010, 011, 100, 101, 110: mix of interpolation and low pass filters 111: DISABLE. 0 = INTERP 1 = LPF1 2 = LPF2 3 = LPF3 4 = LPF4 5 = LPF5 6 = LPF6 7 = DISABLE
19	0x0	DISCSC: enabled color space converter by default 0 = ENABLE 1 = DISABLE
18	0x0	VFEN: StretchBLT Vertical Filter Enable (VFEN) Vertical filter shall be disabled if source images come from host CPU via CPU Read-FIFO. (SISEL) Vertical filter may be disabled to save some memory bandwidth but this will likely result in degradation of image quality. This option may also be used in the case where source image is progressive scanning and there is no vertical scaling. 0 Vertical filter is disabled.1 Vertical filter is enabled. 0 = DISABLE 1 = ENABLE

Bit	Reset	Description
17:16	0x0	VFTYPE: StretchBLT Vertical Filter Mode (VFTYPE[1:0]). This bit is effective when the Vertical Filter is enabled. (bit 18) The two-tap vertical interpolation filter can be operated in various modes. For the image expansion, it should be programmed as a pure 2-tap interpolator. For the image contraction, it can work as partly averager and partly interpolator with varying degree depending on the contraction ratio. For StretchBLT, this parameter is used as an index (selection) to an internal lookup table that stores the group of filter-coefficients for the different modes of vertical filtering. 00: Pure interpolation filter. 01: 25% averager, 75% interpolator. 10: 50% averager, 50% interpolator. 11: 100% averager. 0 = INTERP 1 = AVG25_INTERP75 2 = AVG50_INTERP50 3 = AVG
9:8	X	UVST: 00= 1/2 of Luma Buffer Stride; in this case Luma Buffer Stride should be a multiple of 2 bytes. 01= Equal to Luma Buffer Stride 10= 1/4 of Luma Buffer Stride; in this case Luma Buffer Stride should be a multiple of 4 bytes. 11= use uvstride. Note: Use care when using a tiled surface, since 1/2 or 1/4 of luma stride may yield an invalid pitch (stride). 0 = UVS2X 1 = UVS1X 2 = UVS4X 3 = UVS_G2UVSTRIDE
7	0x0	ENAHF: enable horizontal alpha filtering if disabled, use the alpha value of third tap for output pixel U,V line stride in 4:2:0 Format. 0 = DISABLE 1 = ENABLE
6	0x0	ENAVF:enable alpha vertical filter 0 = DISABLE 1 = ENABLE
5	0x0	IMODE: Source (input) Data Mode (IMODE). This parameter defines the data mode of source input. 0: Multiplexed Mode (data format is specified by SIFMT[2:0]). One block of source data in the Image Buffer memory contains multiplexed component signals. 1: Planar mode, 4:2:0 YUV (SIFMT[2] specifies data format of U/V components). Three blocks of source data in the Image Buffer memory contain separate Y, U, and V component signals. For a circular buffer input to gr2d, the input format cannot be planar. It must be multiplex, i.e., no YUV420 planar circular buffer input to gr2d. 0 = MULTIPLEX 1 = PLANAR
4	0x0	YUV422PLANAR: Source data is yuv422 planar valid when imode==PLANAR
3	0x0	YUV422ROTATION: YUV422 planar rotated.

14.7.26 G2SB_CTX5_G2CONTROLMAIN_0

G2 Blit Formats:

(1) G2 Blit size is based on height in lines, width in pixels, stride in bytes, and pixel size (color depth). Unless alpha blending is enabled, G2 does not care about pixel components.

Source color depths supported by G2 Blit:

- color depth same as destination: G2CONTROLMAIN.SRCCD = 1
- monochrome: G2CONTROLMAIN.SRCCD = 0

(source monochrome color determined by G2SRCBGC, G2SRCFGC)

Pattern color depths supported by G2 Blit:

- color depth same as destination: G2PATOS.PATCD = 1
- monochrome: G2PATOS.PATCD = 0

(pattern monochrome color determined by G2PATBGC, G2PATFGC)

Destination color depths supported by G2 Blit:

- 1 byte per pixel: G2CONTROLMAIN.DSTCD = BPP8
- 2 bytes per pixel: G2CONTROLMAIN.DSTCD = BPP16
- 4 bytes per pixel: G2CONTROLMAIN.DSTCD = BPP32

(2) Alpha blending operates on 3 or 4 component pixels of a specified color depth. One of the components may be alpha (A), depending on the alpha blend format, which is only allowed in certain component positions defined below. The only format rule of the remaining components is that they must be in the same source and destination position because the alpha blend engine does not support component swapping. For example, valid 32BPP formats are: RGBA_8888->RGBA_8888, BGRA_8888->BGRA_8888, GRBA_8888->GRBA_8888, etc.

Source formats supported by G2 alpha blend:

- color depth BPP8: no supported formats
- color depth BPP16:
  - ALPTYPE_PLS1BPP: xxxA_5551 (for example, BGRA_5551 = A[15] R[14:10] G[9:5] B[4:0])
  - ALPTYPE_PLS4BPP: xxxA_4444 (for example, BGRA_4444 = A[15:12] R[11:8] G[7:4] B[3:0])
  - (other) : xxx_565 (for example, BGR_565 = R[15:11] G[10:5] B[4:0])
- color depth BPP32:
  - (all) : xxxA_8888 (for example, BRGA_8888 = A[31:24] R[23:16] G[15:8] B[7:0])

Destination formats supported by G2 alpha blend:

- color depth BPP8: no supported formats
- color depth BPP16: xxx_565 (for example, BGR_565 = R[15:11] G[10:5] B[4:0])
- color depth BPP32: xxxA_8888 (for example, BRGA_8888 = A[31:24] R[23:16] G[15:8] B[7:0])

VCAA Resolve Engine

(1) Format support

srcColor format	srcCoverage format	legal dest format(s)
A1B5G5R5	VCAA	A1B5G5R5
R8G8B8A8	VCAA	R8G8B8A8, B5G6R5
B5G6R5	VCAA	B5G6R5

To program resolve type:

- ALPTYPE == FIX: B5G6R5 -> B5G6R5
- ALPTYPE == PLS1BPPAL: A1B5G5R5 -> A1B5G5R5
- ALPTYPE == PLS8BPP: R8G8B8A8 -> R8G8B8A8
- ALPTYPE == PLS8BX: R8G8B8A8 -> B5G6R5

(2) Color surface programming

- color surface base address: SRCBA
- subsurface start x: SRCX (pixel index)
- subsurface start y: SRCY (line index)
- color surface stride: SRCS (bytes)

The engine supports subsurface resolve. One can imagine a full color buffer of 1024x768, but

```
[pseudo_code]
      color_surface_start_address_fetch = pcurctx->regs.rG2SRCBA.uSRCBA() +
       (pcurctx->regs.rG2SRCPS.uSRCX() * VCAAState.color_surface_depth) +
       (pcurctx->regs.rG2SRCPS.uSRCY() * VCAAState.color_surface_stride);
```

(3) VCAA surface programming

- VCAA surface base address: PATBA
- VCAA surface stride: PATST (bytes)

```
[pseudo_code]
      vcaa_surface_start_address_fetch = pcurctx->regs.rG2PATBA.uPATBA();
```

Software *MUST* directly program this register to the proper subsurface location in the VCAA surface which corresponds to the SRCX and SRCY programming. The calculation is PATBA = vcaa_base_address + SRCX * (1) + SRCY * PATST;

(4) Resolve surface programming

- resolve window width: DSTWIDTH (pixels)
- resolve window height: DSTHEIGHT (lines)
- resolve output stride: DSTS (bytes)

These values program the width and height of the resolved surface. In the base case:

- DSTWIDTH = color surface width
- DSTHEIGHT = color sufrace height
- DSTS = resolve surface format bpp * DSTWIDTH

The VCAA engine technically supports DSTX and DSTY (like SRCX and SRCY).

```
[pseudo_code]
   resolve_surface_start_address_put = pcurctx->regs.rG2DSTBA.uDSTBA() +
     (pcurctx->regs.rG2DSTPS.uDSTX() * resolve_surface_color_depth) +
     (pcurctx->regs.rG2DSTPS.uDSTY() * resolve_surface_color_stride);
```

(5) Resolving a pixel

The coverage surface is an 8 bits per pixel surface (C4X4). The surface is initialized to all 1s by 3d.

For a given pixel, we need to look up 4 bits of coverage data. If the data is 0xf, the pixel does not need to be resolved. Otherwise, the pixel needs to be reblended with certain weightings of its neighbors (i.e., we are on the edge of some geometry).

If any coverage bits are 0, the color needs to be resolved. To do so, the following equation is calculated:

```
color_new = (
              20*color_old +
              27*(
                  ((cover_down  == 0) ? color_down  : color_old) +
                  ((cover_right == 0) ? color_right : color_old) +
                  ((cover_left  == 0) ? color_left  : color_old) +
                  ((cover_up    == 0) ? color_up    : color_old)
                  )
            ) / 128;
```

If coverage bit == 0, then use the neighbor color value in the resolve.

If coverage bit == 1, then use the center color value in the resolve.

The resolve is done on a per channel (r/g/b/a) basis:

format convert input channel to 8 bits

perform resolve equation above

format convert to output format

For the resolution of the alpha channel:

- In B5G6R5: No alpha information. Do nothing.
- In A1B5G5R5: No resolve. Keep the source color alpha bit.
- In R8G8B8A8: Normal 8-bit channel resolve

(6) Resolving a pixel on the edge

When on an edge, the VCAA engine treats the coverage bit as a 1. Use the center color value. This holds true even on the edge of the subsurface resolve window when located in the middle of the larger surface.

(7) Maximum dimensions

The maximum resolve subsurface is 4096 pixels wide.

(8) Surface restrictions

The VCAA engine has the following restrictions with respect to input surfaces:

- input base address is 128-bit memory word aligned
- input stride is a multiple of 128 bits (16 bytes)

The VCAA engine has the following restrictions with respect to output surfaces

- output base address is 128-bit memory word aligned
- output stride is a multiple of 128 bits (16 bytes)

(9) Coverage surface layout

The surface is C4X4.

Surface layout (C4X4)

```
(lsb2msb)  C0_C1_C2_C3_X_X_X_X     (X is a don't care.  Qrast inits to 1)
(msb2lsb)  X_X_X_X_C3_C2_C1_C0

    +          o          o
         C0
            C1   Cov(0,1)
       C2
         C3
    o          o          o

      Cov(1,0)   Cov(1,1)

    o          o          o

    +/o = pixel centers
```

In the example above,

```
       Cov(0,0) = X_X_X_X_C3_C2_C1_C0
       C3       = V_C3(Cov(0,0));
       ..         ..
       C0       = V_C0(Cov(0,0));
    #define V_C3(bits) (bits & 0x8)
    #define V_C2(bits) (bits & 0x4)
    #define V_C1(bits) (bits & 0x2)
    #define V_C0(bits) (bits & 0x1)
```

Resolving a pixel

In an ideal world, the coverage would be simply laid out such that when resolving Pixel(x,y), we would need only to fetch Cov(x,y) to get all 4 bits of information.

In actuality, the coverage surface was rearranged to help qrast in performance. To resolve Pixel(x,y) gr2d has to fetch 4 C4X4 bytes [Cov(x,y), Cov(x-1,y), Cov(x,y-1), Cov(x-1,y-1)]. From each C4X4 byte, it extracts one bit which is used in the resolve equations shown in (5).

Need the logical vcaa bits (DRLU) for blend which is spread across four C4X4 coverage bytes

```
          U

    L

        o

            R

      D
```

where

o = Pixel(x,y)

D = V_C1(Cov(x-1,y))

R = V_C0(Cov(x,y))

L = V_C3(Cov(x-1,y-1))

U = V_C2(Cov(x,y-1))

20	X	SRCCD:

Bit	Reset	Description
		0: Source mono 1: Source has same color depth as destination SRCCD==0 xdir/ydir has to be 0
19:18	0x0	DSTT: Destination read transparency enable: 0x=destination read transparency disabled 10=color destination read transparency 11=inverse color destination read transparency. 20 rw INIC Initiate Command (1=initiate command immediately, 0=wait for launch write)
17:16	X	DSTCD: Destination color depth: 00=8-bpp, 01=16-bpp, 10=32-bpp. 11=reserved 0 = BPP8 1 = BPP16 2 = BPP32 3 = RESERVED3
15	0x0	SRCSEL: Source Data Select: 0 = SCREEN 1 = MEMORY
14	0x0	YFLIP: flip y direction to make image upside down or the other way. If YFLIP==1, ROP cannot include destination. 0 = DISABLE 1 = ENABLE
13	0x0	PATPACK: Pattern Data is in Pack Mode. PATLNGAP in G2PATPACK is the line gap for pattern packed mode If (PATPACK && ~PATSEl), pattern data is packed and from screen, PATMONOW/PATMONOH should be programmed properly to fetch pattern data from frame buffer. Note, PACK is not officially supported when the surface is tiled. 0 = DISABLE 1 = ENABLE
12	0x0	SRCPACK: Source Data is in Pack Mode. SRCLNGAP in G2SRCPACK is the line gap for source packed mode. If (SRCPACK && ~SRCSEL), source data is packed and from screen, SRCMONOW/SRCMONOH should be programmed properly to fetch data from frame buffer. Note, PACK is not officially supported when the surface is tiled. 0 = DISABLE 1 = ENABLE
11	0x0	XYTDW: xy transpose, Line stride DSTS has to be 16-byte aligned if enabled. If XYTDW==1, ROP cannot include destination.
10	0x0	YDIR: 0=incrementing, 1=decrementing. ydir should not be set when source surface has different color depth as destination surface. SRCCD==0 (mono src) OR PATCD==0 (mono pat), ydir has to be 0
9	0x0	XDIR: 0=incrementing, 1=decrementing. xdir should not be set when source surface has different color depth as destination surface.For example, ALPTYPE=PLS8BX (32bpp blending with 16bpp), xdir has to be 0 SRCCD==0 (mono src) OR PATCD==0 (mono pat), xdir has to be 0.
8	0x0	PATFL: When mono pattern is set, we use mono tile pattern fill. current pattern client can support a 16x16 bit tile which can be used to generate a larger surface (i.e. tile this surface in the x and y direction) The tile is stored in memory. Currently, PATXO and PATYO indicate where to start in the 16x16 tile when expanding the monochrome data. See patxo and patyo comments below for programming. When xdir==1 Patxo = pattern width - (patxo+destination width)&0xF -- For xoffsets y offsets PATYO remains the same when xdir/ydir change. How the tile replication pattern looks based on xdir/ydir (without programming patxo above): xdir=0 ydir=0 xdir=1 ydir=0 +---+--+ +--+---+ |^|^|^|| ||^|^|^|

SB only

Offset: 0x2032 | Byte Offset: 0x80c8 | Read/Write: R/W | Reset: 0x00000000 (0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx)

Bit	Reset	Description
31:0	X	SRCBA_B: This parameter specifies the start address of source image stored in the image buffer memory. In 4:2:0 format mode, this image block accommodates for Y-image.This address specifies byte position; however, bits [2:0] are restricted with respect to the data formats to fit multiple pixels in one memory word (8 bytes). For example, {0, 4} for any YCrCb formats, {0, 2, 4, 6} for RGB 16-bit format. Since one Y pixel takes 8 bits, all 8 byte positions are valid in 4:2:0 mode. (Unlike multiplexed pixels format, there are no restrictions on this value.)

14.7.46 G2SB_CTX5_G2SRCST_0

31:0	X	PAT_BASE: pattern base address in tile mode, PATBA is the linear address where pixel start

14.7.67 G2SB_CTX5_G2SRCBA_SB_SURFBASE_0

SB_SURFBASE Registers

These registers need only be programmed when using SB. They point to the base of the various source and destination surfaces. Technically they are only needed when tiling is enabled, but there is no harm in always programming them.

Their counterpart registers (_SB_SURFBASE with SB_SURFBASE stripped off) indicate the location of the first pixel to be sourced or written within the surface.

This register exists to mimic the X, Y (SRCX, SRCY) functionality found in the BitBlt engine.

For example, to get at pixel X, Y:

SRCBA = SRCBA_SB_SURFBASE + Y*stride + X*Bpp

Offset: 0x2048 │ Byte Offset: 0x8120 │ Read/Write: R/W │ Reset: 0x00000000 (0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx)

Bit	Reset	Description
31:0	X	SRC_ADDR: surface address corresponding to G2SRCBA: -base of interleaved sources (RGB, YUV) -base of Y plane. Only used by the StretchBlit Engine

Offset: 0x6001 | Byte Offset: 0x18004 | Read/Write: R/W | Reset: 0x00000000 (0bxxxxxxxxxxxxxxxxxxxxxxxx0xxxxxxx0)

Bit	Reset	Description
8	0x0	INCR_SYNCPT_NO_STALL: If NO_STALL is 1, then when FIFOs are full, INCR_SYNCPT methods will be dropped and the INCR_SYNCPT_ERROR[COND] bit will be set. If NO_STALL is 0, then when FIFOs are full, the client host interface will be stalled.
0	0x0	INCR_SYNCPT_SOFT_RESET: If SOFT_RESET is set, then all internal state of the client syncpt block will be reset. To do soft reset, first set SOFT_RESET of all Host1x clients affected, then clear all SOFT_RESETs.

14.8.3 G2SB_CTX6_INCR_SYNCPT_ERROR_0

Offset: 0x6002 | Byte Offset: 0x18008 | Read/Write: R/W | Reset: 0x00000000 (0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx)

Bit	Reset	Description
31:0	X	COND_STATUS: COND_STATUS[COND] is set if the FIFO for COND overflows. This bit is sticky and will remain set until cleared. Cleared by writing 1.

14.8.4 G2SB_CTX6_G2CLASSCHANNEL_REGONLY_0

This register can be accessed by both register read/write and command FIFO in order not to break exsting code, keep suffix REGONLY.

2D syncpt behavior

- Each 2D context has its own syncpt client.
- OP_DONE increments when 2D's memory write client is idle, meaning all preceding operations are complete.
- RD_DONE behaves like OP_DONE
- REG_WR_SAFE behaves like IMMEDIATE meaning a syncpt increment returns immediately and does not indicate that a register write will NOT block. The implications are that 2D's host FIFO can fill and block access to 2D, which will indeterminately block a direct CPU access.

Bit	Reset	Description
31:0	X	VDSTEP: Vertical Scaling DDA. Reset value: xxxx-xxxxh. Vertical DDA Step (Increment) Value (VDSTEP[18:0]) (upper 13 bits should be set to '0') This parameter specifies the increment value of the DDA used for vertical scaling and it is in the form of 6-bit integer and 12-bit fraction. This value is determined by the equation: (Actual_source_height-1-VDTINI) / (Actual_destination_height-1). Truncate the remaining bits to keep the 12-bit fraction. Since we have to meet (Actual_source_height-1)*1.0 >= (Actual_destination_height - 1)*VDSTEP + VDTINI. The 6-bit integer allows maximum contraction ratio of 1/64, and 12-bit fraction enensures the maximum limit of accumulated error less than half line-spacing for up to approximately 2000 target lines. For example, image expansion from 240 lines to 400 lines VDSTEP[17:0] = 19'b00_0000_1001_1001_1010 and image contraction from 240 lines to 150 lines VDSTEP[17:0] = 19'b00_0001_1001_1001_1010.

14.8.13 G2SB_CTX6_G2VDDAINI_0

Offset: 0x6012 | Byte Offset: 0x18048 | Read/Write: R/W | Reset: 0x00000000 (0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx)

Bit	Reset	Description
15:8	X	VDBINI:Vertical DDA Initial Value for Bottom-Field (VDBINI[7:0]) (see description above)
7:0	X	VDTINI: Vertical Scaling DDA Initial Values. Vertical DDA Initial Value for Top-Field (VDTINI[7:0]) This parameter specifies the fraction part of initial value of the DDA used for vertical scaling.

Bit	Reset	Description
		Given a pair of consecutive source image lines representing positions 0.0 and 1.0, a destination line-image will be created at any position in [0.0, 1.0), that is specified by the fraction part of the vertical DDA. The 8-bit initial fraction value specifies the position of the first output (destination) line-image located between the first and the second input (source) line-images, respectively, at position 0.0 and 1.0. This parameter provides a way to compensate relative displacement of top and bottom fields of a source image. Suppose, 2-to-1 interlaced original video field images #1 and #2 are in the image buffer, to be displayed in an overlay window. Assume that the #1 field image is the top-field. Using VDTINI = 8'hC0 for the top-field image and VDBINI = 8'h40 for the bottom-field image, for example, the two images from #1 and #2 fields get mapped to identically positioned destination images in the overlay window.

14.8.14 G2SB_CTX6_G2HDDA_0

Offset: 0x6013 │ Byte Offset: 0x1804c │ Read/Write: R/W │ Reset: 0x00000000 (0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx)

Bit	Reset	Description
31:0	X	HDSTEP: Horizontal Scaling DDA. Reset value: xxxx-xxxxh. Horizontal DDA Step (Increment) Value (HDSTEP[18:0]) (upper 13 bits should be set to '0') This parameter specifies the increment value of the DDA used for horizontal scaling and it is in the form of 6-bit integer and 12-bit fraction. This value is determined by the equation: (Actual_source_width-1-HDINI) / (Actual_destination_width-1). Truncate the remaining bits to keep the 12-bit fraction. The 6-bit integer allows maximum contraction ratio of 1/64, and 12-bit fraction ensures the maximum limit of accumulated error less than half pixel-spacing for up to approximately 2000 destination pixels. For example, image expansion from 720 pixels to 800 pixels HDSTEP[17:0] = 19'b000_0000_1110_0110_0111 and image contraction from 720 pixels to 250 pixels HDSTEP[17:0] = 19'b000_0010_1110_0001_0101.

14.8.15 G2SB_CTX6_G2HDDAINILS_0

Offset: 0x6014 │ Byte Offset: 0x18050 │ Read/Write: R/W │ Reset: 0x00000000 (0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx)

Bit	Reset	Description
7:0	X	HDINI: Horizontal Scaling DDA Initial Value. Horizontal DDA Initial Value (HDINI[7:0]) This parameter specifies the fraction part of initial value of the DDA used for horizontal scaling.Given a group of six consecutive source pixels that the two pixels at the center representing positions 0.0 and 1.0, a destination pixel will be created at any position in [0.0, 1.0), that is specified by the fraction part of the horizontal DDA. The 8-bit initial fraction value specifies the position of the first output (destination) pixel located between the first and the second input (source) pixels, respectively at position 0.0 and 1.0.For horizontal scaling this value may normally be set to 0.

14.8.16 G2SB_CTX6_G2CSCFIRST_0

The next 3 registers contain 8 parameters used by the YCbCr (YUV) to RGB color space conversion logic. This logic can also be used for RGB gain/gamma correction in RGB to RGB modes, and for luma gain in YUV to YUV modes.

Two new parameters (G2U, G2V) have been added for RGB to YUV conversion. These are in address 0x38. The equations have the form:

if (yuv2rgb)

(r,g,b) = matrix*(y+sbreg_yos,u,v)

matrix: sbreg_cyx, sbreg_cur, sbreg_cvr,
sbreg_cyx, sbreg_cug, sbreg_cvg,
sbreg_cyx, sbreg_cub, sbreg_cvb,

else if (rgb2rgb)

(r,g,b) = matrix*(r,g+sbreg_yos,b)

matrix: sbreg_cvr, 0, sbreg_cur,
sbreg_cvg, sbreg_cyx, sbreg_cug,
sbreg_cvb, 0, sbreg_cub,

else if (yuv2yuv)

(y,u,v) = matrix*(y,u,v)

matrix: sbreg_cub, 0, sbreg_cvb,
sbreg_cug, sbreg_cyx, sbreg_cvg,
sbreg_cur, 0, sbreg_cvr,

else if (rgb2yuv)

(y,u,v) = matrix*(r,g,b) + (sbreg_yos,0,0)

matrix: sbreg_cvb, sbreg_cyx, sbreg_cub,
sbreg_cvg, sbreg_g2u, sbreg_cug,
sbreg_cvr, sbreg_g2v, sbreg_cur,

Offset: 0x6015 | Byte Offset: 0x18054 | Read/Write: R/W | Reset: 0x00000000 (0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx)

Bit	Reset	Description
31:24	X	YOS: Y-Offset (YOFFSET[7:0]) for YUV generation. This parameter consists of 8-bit 2's complement in the range [-128,127]. For YUV->RGB, the recommended value is -16 (decimal) or 0xF0. For YUV->YUV & RGB->RGB, this parameter should be set to 0. For RGB->YUV, the recommended value is +16 (decimal) or 0x10
21:12	X	CVR: multiplier for V/R for V or R generation.This parameter consists of a sign bit and 9-bit magnitude (s2.7). For YUV->RGB, the recommended value is 1.5960 (decimal) or 0x0CCIf source data is in RGB format, this parameter may be used as gain adjustment for R component. For RGB->YUV, the recommended value is +0.439 (decimal) or 0x038
9:0	X	CUB: multiplier for U/B for Y or B generation. Consists of a sign bit and 9-bit magnitude (s2.7). For YUV->RGB, the recommended value is 2.0172 (decimal) or 0x102. If source data is in RGB format, this parameter may be used as gain adjustment for B component. This register changes precision when doing RGB to YUV conversion (SIFMT=1xxx, DIFMT=0xxx). CUB becomes s1.8 and the recommended value is +0.098 or 0x019

14.8.17 G2SB_CTX6_G2CSCSECOND_0

Bit	Reset	Description
25:16	X	CVB: Multiplier for V/R for Y or B generation. This parameter consists of a sign bit and 9-bit magnitude (s2.7). For YUV->RGB, normally this parameter is programmed to 0.0. This coefficient takes a non-zero value if the hue is rotated. For YUV->YUV & RGB->RGB, this parameter should be set to 0. For RGB->YUV, the recommended value is +0.257 (decimal) or 0x021
8:0	X	CVG: Multiplier for V/R for U or G generation.This parameter consists of a sign bit and 8-bit magnitude (s1.7). For YUV->RGB, the recommended value is -0.8130 (decimal) or 0x168. For YUV->YUV & RGB->RGB, this parameter should be set to 0. For RGB->YUV, the recommended value is -0.148 (decimal) or 0x113

14.8.19 G2SB_CTX6_G2CMKEYL_0

When key generation is enabled, the value of this register is the lower color/chroma limit and G2CMKEYU is the upper color/chroma limit for component pixel data. Three component signal values (YCrCb/YUV or RGB) of every output pixel are compared to a set of three ranges that are specified by three pairs of lower and upper color/chroma key values.

If the Key Polarity is 0, the Key is set to 1 only when all three component values of an input pixel are respectively within the set of ranges (inclusive of the limit values), else the Key is set to 0.

If the Key Polarity is 1, the Key is set to 1 when any of the three component values of an input pixel are outside the set of ranges, else the Key is set to 0.

StretchBLT, Color/Chroma Key Lower Limit Register

14.8.24 G2SB_CTX6_G2CONTROLSB_0

Offset: 0x601d │ Byte Offset: 0x18074 │ Read/Write: R/W │ Reset: 0x00000000 (0b00x00000000000000x0xx0xx00000xxx)

Bit	Reset	Description
31	0x0	DISDW: Output destination writes go either to image memory or the EPP. 0: Output data is sent to memory 1: YUV or RGB data is passed directly to the EPP module, and no destination writes take place. 0 = GOTO_IMAGE_BUFFER 1 = GOTO_EPP
30	0x0	ENDITH: Enable Dithering (ENDITH). For 16 bit RGB output modes, the LSB of the color components can be modified by adding a variable residual value that will reduce the banding artifacts that can appear on the display. 0: Normal operation 1: Enable Dithering 0 = DISABLE 1 = ENABLE

Bit	Reset	Description
28	0x0	KPOL: Key Signal Polarity (KPOL) Color/Chroma key signal is generated by comparing source input pixel color to a range of a color specified by lower and upper limit values. The key signal is interpreted in two ways, depending on which one of video and graphics images is foreground (and the other is background). This is effective only if Key signal generator is enabled. (see G2CMKEYL, G2CMKEYU) 0: Key signal is set to 1 when source pixel is within the lower and upper limit color range. 1: Key signal is set to 1 when source pixel is outside the lower and upper limit color range. 0 = WITHIN_BOUNDS 1 = OUTSIDE_BOUNDS
27	0x0	KEYEN: Key Signal Generator Enable (KEYEN). Key signal generator generates either chroma key signal (from YCbCr signal) or color key signal (from RGB signal) 0: Key signal generator is disabled. 1: Key signal generator is enabled. 0 = DISABLE 1 = ENABLE
26	0x0	DBSEL: StretchBLT Destination Buffer Selection (DBSEL). StretchBLT processing involves frame-rate conversion from a series of source images to another series of destination images (field-rate of the source video to frame-rate of the PC display). In order to avoid image tearing, it is preferred to use two buffer sections in the destination video area. This bit selects one of the two buffering blocks to which this StretchBLT command delivers the destination image. The two buffering memory blocks are called A and B. 0: Destination image goes to ‘A’ buffer. 1: Destination image goes to ‘B’ buffer. 0 = DST_A 1 = DST_B
25	0x0	SBSEL: StretchBLT Source Buffer Selection (SBSEL). StretchBLT processing involves frame-rate conversion from a series of source images to another series of destination images (field-rate of the source video to frame-rate of the PC display). In order to avoid image tearing, it is preferred to use two buffer sections in the source video area. This bit selects one of the two buffering blocks from which this StretchBLT command receives the source image. The two buffering memory blocks are called source-A and source-B. 0: Source image comes from ‘source-A’ buffer. 1: Source image comes from ‘source-B’ buffer. 0 = SRC_A 1 = SRC_B
24	0x0	SITYPE: StretchBLT Source Type (SITYPE). This bit identifies two types of source images. If source image is 2-to-1 interlaced and StretchBLT processes either one of the two interlaced field-images, physical (positional) displacement between the two interlaced fields must be taken into account. One field-image that is placed higher in position than the other field-image is called top-field and the other is called bottom-field. StretchBLT processing has to lower the top-field (or raise the bottom-field) to match the corresponding two target images in the overlay window (that is progressively scanned) right at the same position. If source image is full frame-image obtained from two interlaced field-images, its type is ‘top-field’. If source images are progressively scanned, the type identification is not significant and they may be designated either one of the two types 0: Source image is ‘top-field’. 1: Source image is ‘bottom-field’. 0 = TOP_FIELD 1 = BOTTOM_FIELD

Bit	Reset	Description
23	0x0	RANGEREDFRM:In the VC-1 specification, when the value of RANGEREDFRM variable (1-bit) for a picture is equal to 1, the picture shall be scaled up according to the following equation:Y = clip(((Y-128)*2) + 128);Cb = clip(((Cb-128)*2) + 128);Cr = clip(((Cr-128)*2) + 128);The clip operator limits the output to [0, 255].The input is also limited to [0, 255]. In the VC-1 nomenclature, the output (Y, Cb, Cr) tuple corresponds to the 'decoded' picture. The input (Y, Cb, Cr) tuple corresponds to the 'reconstructed' picture. The above equations create the decoded picture while keeping the reconstructed picture intact.Only YUV _OB formats are supported with range reducation enabled, not the YUV _TC or RGB formats. The YUV data coming from the video frame buffers (reconstructed picture) in the SDRAM was scaled up using the above equations and given to the display. The value of 1-bit wide RANGEREDFRM variable was configured in the DVO per frame and the frame was scaled whenever RANGEREDFRM == 1. 0 = DISABLE 1 = ENABLE
22:20	0x0	HFTYPE: StretchBLT Horizontal Filter Mode (HFTYPE[2:0]) The six-tap horizontal interpolation filter can be operated in various operation modes. For the image expansion, it should be programmed as a pure 6-tap interpolator. For the image contraction, it can work as partly lowpass filter and partly interpolater with varying degree depending on the contraction ratio. For StretchBLT, this parameter is used as an index (selection) to an internal lookup table that stores the group of filter-coefficients for the different modes of horizontal filtering. 000: Pure interpolation filter. 001, 010, 011, 100, 101, 110: mix of interpolation and low pass filters 111: DISABLE. 0 = INTERP 1 = LPF1 2 = LPF2 3 = LPF3 4 = LPF4 5 = LPF5 6 = LPF6 7 = DISABLE
19	0x0	DISCSC: enabled color space converter by default 0 = ENABLE 1 = DISABLE
18	0x0	VFEN: StretchBLT Vertical Filter Enable (VFEN) Vertical filter shall be disabled if source images come from host CPU via CPU Read-FIFO. (SISEL) Vertical filter may be disabled to save some memory bandwidth but this will likely result in degradation of image quality. This option may also be used in the case where source image is progressive scanning and there is no vertical scaling. 0: Vertical filter is disabled. 1: Vertical filter is enabled. 0 = DISABLE 1 = ENABLE

Bit	Reset	Description
17:16	0x0	VFTYPE: StretchBLT Vertical Filter Mode (VFTYPE[1:0]). This bit is effective when the Vertical Filter is enabled. (bit 18) The two-tap vertical interpolation filter can be operated in various modes. For the image expansion, it should be programmed as a pure 2-tap interpolator. For the image contraction, it can work as partly averager and partly interpolator with varying degree depending on the contraction ratio. For StretchBLT, this parameter is used as an index (selection) to an internal lookup table that stores the group of filter-coefficients for the different modes of vertical filtering. 00: Pure interpolation filter. 01: 25% averager, 75% interpolator. 10: 50% averager, 50% interpolator. 11: 100% averager. 0 = INTERP 1 = AVG25_INTERP75 2 = AVG50_INTERP50 3 = AVG
9:8	X	UVST: 00= 1/2 of Luma Buffer Stride; in this case Luma Buffer Stride should be a multiple of 2 bytes. 01= Equal to Luma Buffer Stride 10= 1/4 of Luma Buffer Stride; in this case Luma Buffer Stride should be a multiple of 4 bytes. 11= use uvstride. Note: Use care when using a tiled surface, since 1/2 or 1/4 of luma stride may yield an invalid pitch (stride). 0 = UVS2X 1 = UVS1X 2 = UVS4X 3 = UVS_G2UVSTRIDE
7	0x0	ENAHF: enable horizontal alpha filtering if disabled, use the alpha value of third tap for output pixel U,V line stride in 4:2:0 Format. 0 = DISABLE 1 = ENABLE
6	0x0	ENAVF:enable alpha vertical filter 0 = DISABLE 1 = ENABLE
5	0x0	IMODE: Source (input) Data Mode (IMODE). This parameter defines the data mode of source input. 0: Multiplexed Mode (data format is specified by SIFMT[2:0]). One block of source data in the Image Buffer memory contains multiplexed component signals. 1: Planar mode, 4:2:0 YUV (SIFMT[2] specifies data format of U/V components). Three blocks of source data in the Image Buffer memory contain separate Y, U, and V component signals. For a circular buffer input to gr2d, the input format cannot be planar. It must be a multiplex, i.e., no YUV420 planar circular buffer input to gr2d. 0 = MULTIPLEX 1 = PLANAR
4	0x0	YUV422PLANAR: Source data is yuv422 planar valid when imode==PLANAR
3	0x0	YUV422ROTATION: YUV422 planar rotated.

14.8.26 G2SB_CTX6_G2CONTROLMAIN_0

G2 Blit Formats:

(1) G2 Blit size is based on height in lines, width in pixels, stride in bytes, and pixel size (color depth). Unless alpha blending is enabled, G2 does not care about pixel components.

Source color depths supported by G2 Blit:

- color depth same as destination: G2CONTROLMAIN.SRCCD = 1
- monochrome: G2CONTROLMAIN.SRCCD = 0

(source monochrome color determined by G2SRCBGC, G2SRCFGC)

Pattern color depths supported by G2 Blit:

- color depth same as destination: G2PATOS.PATCD = 1
- monochrome: G2PATOS.PATCD = 0

(pattern monochrome color determined by G2PATBGC, G2PATFGC)

Destination color depths supported by G2 Blit:

- 1 byte per pixel: G2CONTROLMAIN.DSTCD = BPP8
- 2 bytes per pixel: G2CONTROLMAIN.DSTCD = BPP16
- 4 bytes per pixel: G2CONTROLMAIN.DSTCD = BPP32

(2) Alpha blending operates on 3 or 4 component pixels of a specified color depth. One of the components may be alpha (A), depending on the alpha blend format, which is only allowed in certain component positions defined below. The only format rule of the remaining components is that they must be in the same source and destination position because the alpha blend engine does not support component swapping. For example, valid 32BPP formats are: RGBA_8888->RGBA_8888, BGRA_8888->BGRA_8888, GRBA_8888->GRBA_8888, etc.

Source formats supported by G2 alpha blend:

- color depth BPP8: no supported formats
- color depth BPP16:
  - ALPTYPE_PLS1BPP: xxxA_5551 (for example, BGRA_5551 = A[15] R[14:10] G[9:5] B[4:0])
  - ALPTYPE_PLS4BPP: xxxA_4444 (for example, BGRA_4444 = A[15:12] R[11:8] G[7:4] B[3:0])
  - (other) : xxx_565 (for example, BGR_565 = R[15:11] G[10:5] B[4:0])
- color depth BPP32:
  - (all) : xxxA_8888 (for example, BRGA_8888 = A[31:24] R[23:16] G[15:8] B[7:0])

Destination formats supported by G2 alpha blend:

- color depth BPP8: no supported formats
- color depth BPP16: xxx_565 (for example, BGR_565 = R[15:11] G[10:5] B[4:0])
- color depth BPP32: xxxA_8888 (for example, BRGA_8888 = A[31:24] R[23:16] G[15:8] B[7:0])

VCAA Resolve Engine

(1) Format support

srcColor format	srcCoverage format	legal dest format(s)
A1B5G5R5	VCAA	A1B5G5R5
R8G8B8A8	VCAA	R8G8B8A8, B5G6R5
B5G6R5	VCAA	B5G6R5

To program resolve type:

- ALPTYPE == FIX: B5G6R5 -> B5G6R5
- ALPTYPE == PLS1BPPAL: A1B5G5R5 -> A1B5G5R5
- ALPTYPE == PLS8BPP: R8G8B8A8 -> R8G8B8A8
- ALPTYPE == PLS8BX: R8G8B8A8 -> B5G6R5

(2) Color surface programming

- color surface base address: SRCBA
- subsurface start x: SRCX (pixel index)
- subsurface start y: SRCY (line index)
- color surface stride: SRCS (bytes)

The engine supports subsurface resolve. One can imagine a full color buffer of 1024x768, but

```
[pseudo_code]
      color_surface_start_address_fetch = pcurctx->regs.rG2SRCBA.uSRCBA() +
       (pcurctx->regs.rG2SRCPS.uSRCX() * VCAAState.color surface depth) +
       (pcurctx->regs.rG2SRCPS.uSRCY() * VCAAState.color_surface_stride);
```

(3) VCAA surface programming

- VCAA surface base address: PATBA
- VCAA surface stride: PATST (bytes)

```
[pseudo_code]
      vcaa_surface_start_address_fetch = pcurctx->regs.rG2PATBA.uPATBA();
```

Software *MUST* directly program this register to the proper sub-surface location in the vcaa surface which corresponds to the SRCX and SRCY programming. The calculation is PATBA = vcaa_base_address + SRCX * (1) + SRCY * PATST;

(4) Resolve surface programming

- resolve window width: DSTWIDTH (pixels)

- resolve window height: DSTHEIGHT (lines)
- resolve output stride: DSTS (bytes)

These values program the width and height of the resolved surface. In the base case:

- DSTWIDTH = color surface width
- DSTHEIGHT = color surface height
- DSTS = resolve surface format bpp * DSTWIDTH

The VCAA engine technically supports DSTX and DSTY (like SRCX and SRCY).

```
[pseudo_code]
   resolve_surface_start_address_put = pcurctx->regs.rG2DSTBA.uDSTBA() +
     (pcurctx->regs.rG2DSTPS.uDSTX() * resolve_surface_color_depth) +
     (pcurctx->regs.rG2DSTPS.uDSTY() * resolve_surface_color_stride);
```

(5) Resolving a pixel

The coverage surface is an 8 bits per pixel surface (C4X4). The surface is initialized to all 1s by 3d.

For a given pixel, we need to look up 4 bits of coverage data. If the data is 0xf, the pixel does not need to be resolved. Otherwise, the pixel needs to be reblended with certain weightings of its neighbors (i.e., we are on the edge of some geometry).

If any coverage bits are 0, the color needs to be resolved. To do so, calculate the following equation:

```
color_new = (
              20*color_old +
              27*(
                  ((cover_down  == 0) ? color_down  : color_old) +
                  ((cover_right == 0) ? color_right : color_old) +
                  ((cover_left  == 0) ? color_left  : color_old) +
                  ((cover_up    == 0) ? color_up    : color_old)
                  )
            ) / 128;
```

If coverage bit == 0, then use the neighbor color value in the resolve

If coverage bit == 1, then use the center color value in the resolve

The resolve is done on a per channel (r/g/b/a) basis:

format convert input channel to 8-bit

perform resolve equation above

format convert to output format

For the resolution of the alpha channel:

- In B5G6R5: No alpha information. Do nothing.
- In A1B5G5R5: No resolve. Keep the source color alpha bit.
- In R8G8B8A8: Normal 8-bit channel resolve

(6) Resolving a pixel on the edge

When on an edge, the VCAA engine treats the coverage bit as a 1. Use the center color value. This holds true even on the edge of the sub-surface resolve window when located in the middle of the larger surface

(7) Maximum dimensions

The maximum resolve subsurface is 4096 pixels wide.

(8) Surface restrictions

The VCAA engine has the following restrictions with respect to input surfaces

- input base address is 128-bit memory word aligned
- input stride is a multiple of 128 bits (16 bytes)

The VCAA engine has the following restrictions with respect to output surfaces

- output base address is 128-bit memory word aligned
- output stride is a multiple of 128 bits (16 bytes)

(9) Coverage surface layout

The surface is C4X4.

Surface layout (C4X4)

```
(lsb2msb)  C0_C1_C2_C3_X_X_X_X     (X is a don't care.  Qrast inits to 1)
(msb2lsb)  X_X_X_X_C3_C2_C1_C0

     +          o          o

             C1   Cov(0,1)
        C2
          C3
     o          o          o

       Cov(1,0)   Cov(1,1)

     o          o          o
     +/o = pixel centers
```

In the example above,

```
        Cov(0,0) = X_X_X_X_C3_C2_C1_C0
        C3       = V_C3(Cov(0,0));
        ..         ..
        C0       = V_C0(Cov(0,0));
     #define V_C3(bits) (bits & 0x8)
     #define V_C2(bits) (bits & 0x4)
     #define V_C1(bits) (bits & 0x2)
     #define V_C0(bits) (bits & 0x1)
```

Resolving a pixel

In an ideal world, the coverage would be simply laid out such that when resolving Pixel(x,y), we would need only to fetch Cov(x,y) to get all 4 bits of information.

In actuality, the coverage surface was rearranged to help qrast in performance. To resolve Pixel(x,y) gr2d has to fetch 4 C4X4 bytes [Cov(x,y), Cov(x-1,y), Cov(x,y-1), Cov(x-1,y-1)]. From each C4X4 byte, it extracts one bit which is used in the resolve equations shown in (5).

Need the logical VCAA bits (DRLU) for blend which is spread across four C4X4 coverage bytes

```
          U

    L

        o

            R

      D
```

Where:

o = Pixel(x,y)

D = V_C1(Cov(x-1,y))

R = V_C0(Cov(x,y))

L = V_C3(Cov(x-1,y-1))

U = V_C2(Cov(x,y-1))

Offset: 0x601f | Byte Offset: 0x1807c | Read/Write: R/W | Reset: 0x00000000 (0bx000000x00xx00xx0000000000000000)

Bit	Reset	Description
31:0	X	PAT_BASE:pattern base address in tile mode, PATBA is the linear address where pixel start

14.8.67 G2SB_CTX6_G2SRCBA_SB_SURFBASE_0

SB_SURFBASE Registers

These registers need only be programmed when using SB. They point to the base of the various source and destination surfaces. Technically they are only needed when tiling is enabled, but there is no harm in always programming them.

Their counterpart registers (_SB_SURFBASE with SB_SURFBASE stripped off) indicate the location of the first pixel to be sourced or written within the surface.

This register exists to mimic the X, Y (SRCX, SRCY) functionality found in the BitBlt engine.

For example, to get at pixel X, Y:

SRCBA = SRCBA_SB_SURFBASE + Y*stride + X*Bpp

Bit	Reset	Description
8	0x0	INCR_SYNCPT_NO_STALL: If NO_STALL is 1, then when FIFOs are full, INCR_SYNCPT methods will be dropped and the INCR_SYNCPT_ERROR[COND] bit will be set. If NO_STALL is 0, then when FIFOs are full, the client host interface will be stalled.
0	0x0	INCR_SYNCPT_SOFT_RESET: If SOFT_RESET is set, then all internal states of the client syncpt block will be reset. To do a soft reset, first set SOFT_RESET of all host1x clients affected, then clear all SOFT_RESETs.

14.9.3 G2SB_CTX7_INCR_SYNCPT_ERROR_0

Offset: 0xa002 │ Byte Offset: 0x28008 │ Read/Write: R/W │ Reset: 0x00000000 (0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx)

Bit	Reset	Description
31:0	X	COND_STATUS: COND_STATUS[COND] is set if the FIFO for COND overflows. This bit is sticky and will remain set until cleared. Cleared by writing 1.

14.9.4 G2SB_CTX7_G2CLASSCHANNEL_REGONLY_0

This register can be accessed by both register read/write and command FIFO in order not to break exsting code, keep suffix REGONLY.

2D syncpt behavior

- Each 2D context has its own syncpt client.
- OP_DONE increments when 2D's memory write client is idle, meaning all preceding operations are complete.
- RD_DONE behaves like OP_DONE
- REG_WR_SAFE behaves like IMMEDIATE meaning a syncpt increment returns immediately and does not indicate that a register write will NOT block.
- The implications are that 2D's host FIFO can fill and block access to 2D, which will indeterminately block a direct CPU access.

Bit	Reset	Description
31:0	X	VDSTEP: Vertical Scaling DDA. Reset value: xxxx-xxxxh. Vertical DDA Step (Increment) Value (VDSTEP[18:0]) (upper 13 bits should be set to '0') This parameter specifies the increment value of the DDA used for vertical scaling and it is in the form of 6-bit integer and 12-bit fraction. This value is determined by the equation: (Actual_source_height-1-VDTINI) / (Actual_destination_height-1). Truncate the remaining bits to keep the 12-bit fraction. Since we have to meet (Actual_source_height-1)*1.0 >= (Actual_destination_height - 1)*VDSTEP + VDTINI. The 6-bit integer allows maximum contraction ratio of 1/64, and 12-bit fraction ensures the maximum limit of accumulated error less than half line-spacing for up to approximately 2000 target lines.

Bit	Reset	Description
		For example, image expansion from 240 lines to 400 lines VDSTEP[17:0] = 19'b00_0000_1001_1001_1010 and image contraction from 240 lines to 150 lines VDSTEP[17:0] = 19'b00_0001_1001_1001_1010.

14.9.13 G2SB_CTX7_G2VDDAINI_0

Offset: 0xa012 | Byte Offset: 0x28048 | Read/Write: R/W | Reset: 0x00000000 (0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx)

Bit	Reset	Description
15:8	X	VDBINI: Vertical DDA Initial Value for Bottom-Field (VDBINI[7:0]) (see description above)
7:0	X	VDTINI: Vertical Scaling DDA Initial Values. Vertical DDA Initial Value for Top-Field (VDTINI[7:0]) This parameter specifies the fraction part of initial value of the DDA used for vertical scaling. Given a pair of consecutive source image lines representing positions 0.0 and 1.0, a destination line-image will be created at any position in [0.0, 1.0), that is specified by the fraction part of the vertical DDA. The 8-bit initial fraction value specifies the position of the first output (destination) line-image located between the first and the second input (source) line-images, respectively at position 0.0 and 1.0.This parameter provides a way to compensate relative displacement of top and bottom fields of a source image. Suppose, 2-to-1 interlaced original video field images #1 and #2 are in the image buffer, to be displayed in an overlay window. Assume that the #1 field image is the top-field. Using VDTINI = 8'hC0 for the top-field image and VDBINI = 8'h40 for the bottom-field image, for example, the two images from #1 and #2 fields get mapped to identically positioned destination images in the overlay window.

14.9.14 G2SB_CTX7_G2HDDA_0

Offset: 0xa013 | Byte Offset: 0x2804c | Read/Write: R/W | Reset: 0x00000000 (0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx)

Bit	Reset	Description
31:0	X	HDSTEP: Horizontal Scaling DDA. Reset value: xxxx-xxxxh. Horizontal DDA Step (Increment) Value (HDSTEP[18:0]) (upper 13 bits should be set to '0') This parameter specifies the increment value of the DDA used for horizontal scaling and it is in the form of 6-bit integer and 12-bit fraction. This value is determined by the equation: (Actual_source_width-1-HDINI) / (Actual_destination_width-1). Truncate the remaining bits to keep the 12-bit fraction. The 6-bit integer allows maximum contraction ratio of 1/64, and 12-bit fraction ensures the maximum limit of accumulated error less than half pixel-spacing for up to approximately 2000 destination pixels. For example, image expansion from 720 pixels to 800 pixels HDSTEP[17:0] = 19'b000_0000_1110_0110_0111 and image contraction from 720 pixels to 250 pixels HDSTEP[17:0] = 19'b000_0010_1110_0001_0101.

14.9.15 G2SB_CTX7_G2HDDAINILS_0

Offset: 0xa014 | Byte Offset: 0x28050 | Read/Write: R/W | Reset: 0x00000000 (0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx)

Bit	Reset	Description
7:0	X	HDINI: Horizontal Scaling DDA Initial Value. Horizontal DDA Initial Value (HDINI[7:0]) This parameter specifies the fraction part of initial value of the DDA used for horizontal scaling.Given a group of six consecutive source pixels that the two pixels at the center representing positions 0.0 and 1.0, a destination pixel will be created at any position in [0.0, 1.0), that is specified by the fraction part of the horizontal DDA. The 8-bit initial fraction value specifies the position of the first output (destination) pixel located between the first and the second input (source) pixels, respectively at position 0.0 and 1.0.For horizontal scaling this value may normally be set to 0.

14.9.16 G2SB_CTX7_G2CSCFIRST_0

The next 3 registers contain 8 parameters used by the YCbCr (YUV) to RGB color space conversion logic. This logic can also be used for RGB gain/gamma correction in RGB to RGB modes, and for luma gain in YUV to YUV modes.

Two new parameters (G2U, G2V) have been added for RGB to YUV conversion. These are in address 0x38. The equations have the form:

if (yuv2rgb)

(r,g,b) = matrix*(y+sbreg_yos,u,v)

matrix:	sbreg_cyx,	sbreg_cur,	sbreg_cvr,
	sbreg_cyx,	sbreg_cug,	sbreg_cvg,
	sbreg_cyx,	sbreg_cub,	sbreg_cvb,

else if (rgb2rgb)

(r,g,b) = matrix*(r,g+sbreg_yos,b)

matrix:	sbreg_cvr,	0,	sbreg_cur,
	sbreg_cvg,	sbreg_cyx,	sbreg_cug,
	sbreg_cvb,	0,	sbreg_cub,

else if (yuv2yuv)

(y,u,v) = matrix*(y,u,v)

matrix:	sbreg_cub,	0,	sbreg_cvb,
	sbreg_cug,	sbreg_cyx,	sbreg_cvg,
	sbreg_cur,	0,	sbreg_cvr,

else if (rgb2yuv)

(y,u,v) = matrix*(r,g,b) + (sbreg_yos,0,0)

matrix:	sbreg_cvb,	sbreg_cyx,	sbreg_cub,
	sbreg_cvg,	sbreg_g2u,	sbreg_cug,
	sbreg_cvr,	sbreg_g2v,	sbreg_cur,

Offset: 0xa015 │ Byte Offset: 0x28054 │ Read/Write: R/W │ Reset: 0x00000000 (0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx)

Bit	Reset	Description
31:24	X	YOS:Y-Offset (YOFFSET[7:0]) for YUV generationThis parameter consists of 8-bit 2's complement in the range [-128,127]. For YUV->RGB, the recommended value is -16 (decimal) or 0xF0. For YUV->YUV & RGB->RGB, this parameter should be set to 0. For RGB->YUV, the recommended value is +16 (decimal) or 0x10
21:12	X	CVR: multiplier for V/R for V or R generation.This parameter consists of a sign bit and 9-bit magnitude (s2.7). For YUV->RGB, the recommended value is 1.5960 (decimal) or 0x0CCIf source data is in RGB format, this parameter may be used as gain adjustment for R component. For RGB->YUV, the recommended value is +0.439 (decimal) or 0x038
9:0	X	CUB: multiplier for U/B for Y or B generation. Consists of a sign bit and 9-bit magnitude (s2.7). For YUV->RGB, the recommended value is 2.0172 (decimal) or 0x102. If source data is in RGB format, this parameter may be used as gain adjustment for B component. This register changes precision when doing RGB to YUV conversion (SIFMT=1xxx, DIFMT=0xxx). CUB becomes s1.8 and the recommended value is +0.098 or 0x019

14.9.17 G2SB_CTX7_G2CSCSECOND_0

Offset: 0xa016 | Byte Offset: 0x28058 | Read/Write: R/W | Reset: 0x00000000 (0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx)

Bit	Reset	Description
31:24	X	CYX: Multiplier for Y/G (G gain). This positive-only parameter consists of 8-bit magnitude (1.7). For YUV->YUV, the recommended value is 1.1644 (decimal) or 0x95. For YUV->YUV or RGB->RGB, this may be used as gain adjustment for Y or G component. For RGB->YUV, the recommended value is +0.504 (decimal) or 0x041
21:12	X	CUR: Multiplier for U/B for V or R generation.This parameter consists of a sign bit and 9-bit magnitude (s2.7). For YUV->RGB, normally this parameter is programmed to 0.0. This parameter takes non-zero value if hue is rotated. For YUV->YUV & RGB->RGB, this parameter should be set to 0. For RGB->YUV, the recommended value is -0.071 (decimal) or 0x209
8:0	X	CUG: Multiplier for U/B for U or G generation. Consists of a sign bit and 8-bit magnitude (s1.7). For YUV->RGB, the recommended value is -0.3918 (decimal) or 0x132. For RGB->RGB, this parameter should be set to 0. For YUV->YUV, this parameter should be set to 1 (0x080). For RGB->YUV, the recommended value is +0.439 (decimal) or 0x038

14.9.18 G2SB_CTX7_G2CSCTHIRD_0

Bit	Reset	Description
25:16	X	CVB: multiplier for V/R for Y or B generation. This parameter consists of a sign bit and 9-bit magnitude (s2.7). For YUV->RGB, normally this parameter is programmed to 0.0. This coefficient takes non-zero value if hue is rotated. For YUV->YUV & RGB->RGB, this parameter should be set to 0. For RGB->YUV, the recommended value is +0.257 (decimal) or 0x021
8:0	X	CVG: multiplier for V/R for U or G generation.This parameter consists of a sign bit and 8-bit magnitude (s1.7). For YUV->RGB, the recommended value is -0.8130 (decimal) or 0x168. For YUV->YUV & RGB->RGB, this parameter should be set to 0. For RGB->YUV, the recommended value is -0.148 (decimal) or 0x113

14.9.19 G2SB_CTX7_G2CMKEYL_0

When key generation is enabled, the value of this register is the lower color/chroma limit and G2CMKEYU is the upper color/chroma limit for component pixel data. Three component signal values (YCrCb/YUV or RGB) of every output pixel are compared to a set of three ranges that are specified by three pairs of lower and upper color/chroma key values.

If the Key Polarity is 0, the Key is set to 1 only when all three component values of an input pixel are respectively within the set of ranges (inclusive of the limit values), else the Key is set to 0.

If the Key Polarity is 1, the Key is set to 1 when any of the three component values of an input pixel are outside the set of ranges, else the Key is set to 0.

StretchBLT, Color/Chroma Key Lower Limit Register

Offset: 0xa01d │ Byte Offset: 0x28074 │ Read/Write: R/W │ Reset: 0x00000000 (0b00x00000000000000x0xx0xx00000xxx)

Bit	Reset	Description
31	0x0	DISDW: Output destination writes go either to image memory or the EPP. 0: Output data is sent to memory 1: YUV or RGB data is passed directly to the EPP module, and no destination writes take place. 0 = GOTO_IMAGE_BUFFER 1 = GOTO_EPP
30	0x0	ENDITH: Enable Dithering (ENDITH). For 16-bit RGB output modes, the LSB of the color components can be modified by adding a variable residual value that will reduce the banding artifacts that can appear on the display. 0: Normal operation 1: Enable Dithering 0 = DISABLE 1 = ENABLE
28	0x0	KPOL: Key Signal Polarity (KPOL) Color/Chroma key signal is generated by comparing source input pixel color to a range of a color specified by lower and upper limit values. The key signal is interpreted in two ways, depending on which one of video and graphics images is foreground (and the other is background). This is effective only if Key signal generator is enabled. (see G2CMKEYL, G2CMKEYU) 0: Key signal is set to 1 when source pixel is within the lower and upper limit color range. 1: Key signal is set to 1 when source pixel is outside the lower and upper limit color range. 0 = WITHIN_BOUNDS 1 = OUTSIDE_BOUNDS
27	0x0	KEYEN: Key Signal Generator Enable (KEYEN). Key signal generator generates either chroma key signal (from YCbCr signal) or color key signal (from RGB signal) 0: Key signal generator is disabled. 1: Key signal generator is enabled. 0 = DISABLE 1 = ENABLE
26	0x0	DBSEL: StretchBLT Destination Buffer Selection (DBSEL). StretchBLT processing involves frame-rate conversion from a series of source images to another series of destination images (field-rate of the source video to frame-rate of the PC display). In order to avoid image tearing, it is preferred to use two buffer sections in the destination video area. This bit selects one of the two buffering blocks to which this StretchBLT command delivers the destination image. The two buffering memory blocks are called A and B. 0: Destination image goes to ‘A’ buffer. 1: Destination image goes to ‘B’ buffer. 0 = DST_A 1 = DST_B
25	0x0	SBSEL: StretchBLT Source Buffer Selection (SBSEL) StretchBLT processing involves frame-rate conversion from a series of source images to another series of destination images (field-rate of the source video to frame-rate of the PC display). In order to avoid image tearing, it is preferred to use two buffer sections in the source video area. This bit selects one of the two buffering blocks from which this StretchBLT command receives the source image. The two buffering memory blocks are called source-A and source-B. 0: Source image comes from ‘source-A’ buffer. 1: Source image comes from ‘source-B’ buffer. 0 = SRC_A 1 = SRC_B

Bit	Reset	Description
24	0x0	SITYPE: StretchBLT Source Type (SITYPE). This bit identifies two types of source images. If source image is 2-to-1 interlaced and StretchBLT processes either one of the two interlaced field-images, physical (positional) displacement between the two interlaced fields must be taken into account. One field-image that is placed higher in position than the other field-image is called top-field and the other is called bottom-field. StretchBLT processing has to lower the top-field (or raise the bottom-field) to match the corresponding two target images in the overlay window (that is progressively scanned) right at the same position. If source image is full frame-image obtained from two interlaced field-images, its type is 'top-field'. If source images are progressively scanned, the type identification is not significant and they may be designated either one of the two types 0: Source image is 'top-field'. 1: Source image is 'bottom-field'. 0 = TOP_FIELD 1 = BOTTOM_FIELD
23	0x0	RANGEREDFRM:In the VC-1 specification, when the value of RANGEREDFRM variable (1-bit) for a picture is equal to 1, the picture shall be scaled up according to the following equation:Y = clip(((Y-128)*2) + 128);Cb = clip(((Cb-128)*2) + 128);Cr = clip(((Cr-128)*2) + 128);The clip operator limits the output to [0, 255].The input is also limited to [0, 255]. In the VC-1 nomenclature, the output (Y, Cb, Cr) tuple corresponds to the 'decoded' picture. The input (Y, Cb, Cr) tuple corresponds to the 'reconstructed' picture. The above equations create the decoded picture while keeping the reconstructed picture intact.Only YUV _OB formats are supported with range reducation enabled, not the YUV _TC or RGB formats. The YUV data coming from the video frame buffers (reconstructed picture) in the SDRAM was scaled up using the above equations and given to the display. the value of 1-bit wide RANGEREDFRM variable was configured in the DVO per frame and the frame was scaled whenever RANGEREDFRM == 1. 0 = DISABLE 1 = ENABLE
22:20	0x0	HFTYPE: StretchBLT Horizontal Filter Mode (HFTYPE[2:0]) The six-tap horizontal interpolation filter can be operated in various operation modes. For the image expansion, it should be programmed as a pure 6-tap interpolator. For the image contraction, it can work as partly lowpass filter and partly interpolater with varying degree depending on the contraction ratio. For StretchBLT, this parameter is used as an index (selection) to an internal lookup table that stores the group of filter-coefficients for the different modes of horizontal filtering. 000: Pure interpolation filter. 001, 010, 011, 100, 101, 110: mix of interpolation and low pass filters 111: DISABLE. 0 = INTERP 1 = LPF1 2 = LPF2 3 = LPF3 4 = LPF4 5 = LPF5 6 = LPF6 7 = DISABLE
19	0x0	DISCSC: enabled color space converter by default 0 = ENABLE 1 = DISABLE
18	0x0	VFEN: StretchBLT Vertical Filter Enable (VFEN). Vertical filter shall be disabled if source images come from host CPU via CPU Read-FIFO. (SISEL) Vertical filter may be disabled to save some memory bandwidth but this will likely result in degradation of image quality. This option may also be used in the case where source image is progressive scanning and there is no vertical scaling. 0: Vertical filter is disabled. 1: Vertical filter is enabled. 0 = DISABLE 1 = ENABLE

Bit	Reset	Description
17:16	0x0	VFTYPE: StretchBLT Vertical Filter Mode (VFTYPE[1:0]). This bit is effective when the Vertical Filter is enabled. (bit 18) The two-tap vertical interpolation filter can be operated in various modes. For the image expansion, it should be programmed as a pure 2-tap interpolator. For the image contraction, it can work as partly averager and partly interpolator with varying degree depending on the contraction ratio. For StretchBLT, this parameter is used as an index (selection) to an internal lookup table that stores the group of filter-coefficients for the different modes of vertical filtering. 00: Pure interpolation filter. 01: 25% averager, 75% interpolator. 10: 50% averager, 50% interpolator. 11: 100% averager. 0 = INTERP 1 = AVG25_INTERP75 2 = AVG50_INTERP50 3 = AVG
9:8	X	UVST: 00= 1/2 of Luma Buffer Stride; in this case Luma Buffer Stride should be a multiple of 2 bytes. 01= Equal to Luma Buffer Stride 10= 1/4 of Luma Buffer Stride; in this case Luma Buffer Stride should be a multiple of 4 bytes. 11= use uvstride. Note: Use care when using a tiled surface, since 1/2 or 1/4 of luma stride may yield an invalid pitch (stride). 0 = UVS2X 1 = UVS1X 2 = UVS4X 3 = UVS_G2UVSTRIDE
7	0x0	ENAHF: enable horizontal alpha filtering if disabled, use the alpha value of third tap for output pixel U,V line stride in 4:2:0 Format. 0 = DISABLE 1 = ENABLE
6	0x0	ENAVF:enable alpha vertical filter 0 = DISABLE 1 = ENABLE
5	0x0	IMODE: Source (input) Data Mode (IMODE). This parameter defines the data mode of source input. 0: Multiplexed Mode (data format is specified by SIFMT[2:0]). One block of source data in the Image Buffer memory contains multiplexed component signals. 1: Planar mode, 4:2:0 YUV (SIFMT[2] specifies data format of U/V components). Three blocks of source data in the Image Buffer memory contain separate Y, U, and V component signals. For a circular buffer input to gr2d, the input format cannot be planar. It must be multiplex, i.e., no YUV420 planar circular buffer input to gr2d. 0 = MULTIPLEX 1 = PLANAR
4	0x0	YUV422PLANAR: Source data is yuv422 planar valid when imode==PLANAR
3	0x0	YUV422ROTATION: YUV422 planar rotated.

14.9.26 G2SB_CTX7_G2CONTROLMAIN_0

G2 Blit Formats:

(1) G2 Blit size is based on height in lines, width in pixels, stride in bytes, and pixel size (color depth). Unless alpha blending is enabled, G2 does not care about pixel components.

Source color depths supported by G2 Blit:

- color depth same as destination: G2CONTROLMAIN.SRCCD = 1
- monochrome: G2CONTROLMAIN.SRCCD = 0

(source monochrome color determined by G2SRCBGC, G2SRCFGC)

Pattern color depths supported by G2 Blit:

- color depth same as destination: G2PATOS.PATCD = 1
- monochrome: G2PATOS.PATCD = 0

(pattern monochrome color determined by G2PATBGC, G2PATFGC)

Destination color depths supported by G2 Blit:

- 1 byte per pixel: G2CONTROLMAIN.DSTCD = BPP8
- 2 bytes per pixel: G2CONTROLMAIN.DSTCD = BPP16
- 4 bytes per pixel: G2CONTROLMAIN.DSTCD = BPP32

(2) Alpha blending operates on 3 or 4 component pixels of a specified color depth. One of the components may be alpha (A), depending on the alpha blend format, which is only allowed in certain component positions defined below. The only format rule of the remaining components is that they must be in the same source and destination position because the alpha blend engine does not support component swapping. For example, valid 32BPP formats are: RGBA_8888->RGBA_8888, BGRA_8888->BGRA_8888, GRBA_8888->GRBA_8888, etc.

Source formats supported by G2 alpha blend:

- color depth BPP8: no supported formats
- color depth BPP16:

- ALPTYPE_PLS1BPP: xxxA_5551 (for example, BGRA_5551 = A[15] R[14:10] G[9:5] B[4:0])
- ALPTYPE_PLS4BPP: xxxA_4444 (for example, BGRA_4444 = A[15:12] R[11:8] G[7:4] B[3:0])
- (other) : xxx_565 (for example, BGR_565 = R[15:11] G[10:5] B[4:0])

- color depth BPP32:
  - (all) : xxxA_8888 (for example, BRGA_8888 = A[31:24] R[23:16] G[15:8] B[7:0])

Destination formats supported by G2 alpha blend:

- color depth BPP8: no supported formats
- color depth BPP16: xxx_565 (for example, BGR_565 = R[15:11] G[10:5] B[4:0])
- color depth BPP32: xxxA_8888 (for example, BRGA_8888 = A[31:24] R[23:16] G[15:8] B[7:0])

srcColor format	srcCoverage format	legal dest format(s)
A1B5G5R5	VCAA	A1B5G5R5
R8G8B8A8	VCAA	R8G8B8A8, B5G6R5
B5G6R5	VCAA	B5G6R5

To program resolve type:

- ALPTYPE == FIX: B5G6R5 -> B5G6R5
- ALPTYPE == PLS1BPPAL: A1B5G5R5 -> A1B5G5R5
- ALPTYPE == PLS8BPP: R8G8B8A8 -> R8G8B8A8
- ALPTYPE == PLS8BX: R8G8B8A8 -> B5G6R5

(2) Color surface programming

- color surface base address: SRCBA
- sub-surface start x: SRCX (pixel index)
- sub-surface start y: SRCY (line index)
- color surface stride: SRCS (bytes)

The engine supports sub-surface resolve. One can imagine a full color buffer of 1024x768, but

```
[pseudo_code]
      color_surface_start_address_fetch = pcurctx->regs.rG2SRCBA.uSRCBA() +
        (pcurctx->regs.rG2SRCPS.uSRCX() * VCAAState.color_surface_depth) +
        (pcurctx->regs.rG2SRCPS.uSRCY() * VCAAState.color_surface_stride);
```

(3) VCAA surface programming

- VCAA surface base address: PATBA
- VCAA surface stride: PATST (bytes)

```
[pseudo_code]
      vcaa_surface_start_address_fetch = pcurctx->regs.rG2PATBA.uPATBA();
```

Software *MUST* directly program this register to the proper sub-surface location in the vcaa surface which corresponds to the SRCX and SRCY programming. The calculation is PATBA = vcaa_base_address + SRCX * (1) + SRCY * PATST;

(4) Resolve surface programming

- resolve window width: DSTWIDTH (pixels)
- resolve window height: DSTHEIGHT (lines)
- resolve output stride: DSTS (bytes)

These values program the width and height of the resolved surface. In the base case,

- DSTWIDTH = color surface width
- DSTHEIGHT = color sufrace height
- DSTS = resolve surface format bpp * DSTWIDTH

The VCAA engine technically supports DSTX and DSTY (like SRCX and SRCY).

```
[pseudo_code]
   resolve_surface_start_address_put = pcurctx->regs.rG2DSTBA.uDSTBA() +
     (pcurctx->regs.rG2DSTPS.uDSTX() * resolve_surface_color_depth) +
     (pcurctx->regs.rG2DSTPS.uDSTY() * resolve_surface_color_stride);
```

(5) Resolving a pixel

The coverage surface is an 8 bits per pixel surface (C4X4). The surface is initialized to all 1s by 3d.

For a given pixel, we need to look up 4 bits of coverage data. If the data is 0xf, the pixel does not need to be resolved. Otherwise, the pixel needs to be reblended with certain weightings of its neighbors (i.e., we are on the edge of some geometry).

If any coverage bits are 0, the color needs to be resolved. To do so, calculate the following equation:

```
color_new = (
              20*color_old +
              27*(
                  ((cover_down  == 0) ? color_down  : color_old) +
                  ((cover_right == 0) ? color_right : color_old) +
                  ((cover_left  == 0) ? color_left  : color_old) +
                  ((cover_up    == 0) ? color_up    : color_old)
                  )
            ) / 128;
```

If coverage bit == 0, then use the neighbor color value in the resolve.

If coverage bit == 1, then use the center color value in the resolve.

The resolve is done on a per channel (r/g/b/a) basis:

format convert input channel to 8-bit

perform resolve equation above

format convert to output format

For the resolution of the alpha channel:

- In B5G6R5: No alpha information. Do nothing.
- In A1B5G5R5: No resolve. Keep the source color alpha bit.

- In R8G8B8A8: Normal 8-bit channel resolve

(6) Resolving a pixel on the edge

When on an edge, the VCAA engine treats the coverage bit as a 1. Use the center color value. This holds true even on the edge of the sub-surface resolve window when located in the middle of the larger surface

(7) Maximum dimensions

The maximum resolve subsurface is 4096 pixels wide.

(8) Surface restrictions

The VCAA engine has the following restrictions with respect to input surfaces

- input base address is 128-bit memory word aligned

- input stride is a multiple of 128 bits (16 bytes)

The VCAA engine has the following restrictions with respect to output surfaces

- output base address is 128-bit memory word aligned

- output stride is a multiple of 128 bits (16 bytes)

(9) Coverage surface layout

The surface is C4X4.

Surface layout (C4X4)

```
(lsb2msb)  C0_C1_C2_C3_X_X_X_X     (X is a don't care.  Qrast inits to 1)
(msb2lsb)  X_X_X_X_C3_C2_C1_C0

    +          o          o
         C0
            C1   Cov(0,1)
       C2
         C3
    o          o          o

      Cov(1,0)   Cov(1,1)

    o          o          o

    +/o = pixel centers
```

In the example above,

```
Cov(0,0) = X_X_X_X_C3_C2_C1_C0
C3       = V_C3(Cov(0,0));
..         ..
C0       = V_C0(Cov(0,0));
```

```
#define V_C3(bits) (bits & 0x8)
#define V_C2(bits) (bits & 0x4)
#define V_C1(bits) (bits & 0x2)
#define V_C0(bits) (bits & 0x1)
```

Resolving a Pixel

In an ideal world, the coverage would be simply laid out such that when resolving Pixel(x,y), we would need only to fetch Cov(x,y) to get all 4 bits of information.

In actuality, the coverage surface was rearranged to help qrast in performance. To resolve Pixel(x,y) gr2d has to fetch 4 C4X4 bytes [Cov(x,y), Cov(x-1,y), Cov(x,y-1), Cov(x-1,y-1)]. From each C4X4 byte, it extracts one bit which is used in the resolve equations shown in (5).

Need the logical VCAA bits (DRLU) for blend which is spread across four C4X4 coverage bytes

```
      U
  L
    o
      R
    D
```

where

o = Pixel(x,y)

D = V_C1(Cov(x-1,y))

R = V_C0(Cov(x,y))

L = V_C3(Cov(x-1,y-1))

U = V_C2(Cov(x,y-1))

31:0	X	PAT_BASE:pattern base address in tile mode, PATBA is the linear address where pixel start

14.9.67 G2SB_CTX7_G2SRCBA_SB_SURFBASE_0

SB_SURFBASE Registers

These registers need only be programmed when using SB. They point to the base of the various source and destination surfaces. Technically, they are only needed when tiling is enabled, but there is no harm in always programming them.

Their counterpart registers (_SB_SURFBASE with SB_SURFBASE stripped off) indicate the location of the first pixel to be sourced or written within the surface.

This register exists to mimic the X, Y (SRCX, SRCY) functionality found in the BitBlt engine.

For example, to get at pixel X, Y:

SRCBA = SRCBA_SB_SURFBASE + Y*stride + X*Bpp

Offset: 0xa048 | Byte Offset: 0x28120 | Read/Write: R/W | Reset: 0x00000000 (0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx)

Bit	Reset	Description

14.10 G2SB Switch Registers

14.10.1 G2SB_SWITCH_G2INTERRUPT_0

Interrupt Status Register

These registers can be only accessed by register read/write not command FIFO interface. When context switch fails, the CPU received an interrupt from G2.

Context switch steps:

1. Clears G2INTERRUPT/CTXSW_INT bit

2. Read out G2NXTCXTSWITCH/NEXT_CLASS NEXT_CHANNEL to determine failing on which class channel
3. Decide which context can be switched to
4. Back up the context contents that will be overwritten
5. Write channel into G2CLASSCHANNEL_REGONLY/CURR_CHANNEL
6. Command FIFO flow resumes.

14.10.10 G2SB_SWITCH_G2_MCCIF_FIFOCTRL_0

Memory Client Interface FIFO Control Register

Note: The FIFO timing aspects of this register are no longer supported, but retained for software compatibility.

The clock enable fields of this register control the second-level clock gating for the MC side of the MCCIF.

A '1' written to the override field will result in that clock reverting to the legacy mode of operation (where the msc*clk is on whenever the client clock is enabled.

Offset: 0xf009 │ Byte Offset: 0x3c024 │ Read/Write: R/W │ Reset: 0x00000000 (0bxxxxxxxxxxxxxxx00xxxxxxxxxxx0000)

15.0 GR3D

15.1 Introduction

GR3D is the Tegra® GPU, a 3D graphics acceleration block, capable of a broad range of graphics and computing functions.

This section is not intended to be a programming guide to GR3D, or even a complete register description, but is provided solely to document which registers contain memory addresses. This allows software to be implemented which checks if the memory addresses being programmed are within valid ranges.

15.2 Registers

Refer to “Reading Register Tables” in the Introduction section for the register table protocol as well as recommendations for accessing registers.

The 3D unit can be instructed to access memory directly. To prevent using the 3D unit unintentionally, software might want to control access to the registers in 3D that contain memory addresses.

15.2.1 AR3D_IDX_ATTRIBUTE_0

Attribute Address and Format

This array sets the base address for each attribute.

This is an array of 16 identical register entries; the register fields below apply to each entry. There are 16 entries, where n is an integer from 0 through 15.

Offset: 0x100 + (n*2) | Byte Offset: 0x400 + (n*8) | Read/Write: R/W | Reset: 0xXXXXXXXX (0bxxxxxxxxxxxx0xxxxxxxxxxxxxxxxxxxx)

Bit	Reset	Description
31:0	X	ATTR_BASE: Base address of attribute array

15.2.2 AR3D_IDX_INDEX_BASE_0

Index Array Base

This register sets the index base for DrawElements commands.

Offset: 0x121 | Byte Offset: 0x484 | Read/Write: R/W | Reset: 0xXXXXXXXX (0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx)

Bit	Reset	Description
31:0	X	INDEX_BASE: Base address of the index array for DrawElements.

15.2.3 AR3D_QR_ZTAG_ADDR_0

Offset: 0x415 | Byte Offset: 0x1054 | Read/Write: R/W | Reset: 0xXXXXXXX0 (0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx0)

Bit	Reset	Description
31:6	X	BASE_ADDRESS: Start of the Z tag surface. This field defines the base address in 64-byte units/alignment.

15.2.4 AR3D_QR_CTAG_ADDR_0

Offset: 0x417 | Byte Offset: 0x105c | Read/Write: R/W | Reset: 0xXXXXXXX0 (0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx)

Bit	Reset	Description
31:6	X	BASE_ADDRESS: Start of the C tag surface. This field defines the base address in 64-byte units/alignment.

15.2.5 AR3D_QR_CZ_ADDR_0

Offset: 0x419 | Byte Offset: 0x1064 | Read/Write: R/W | Reset: 0xXXXXXXX0 (0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx)

Bit	Reset	Description
31:6	X	BASE_ADDRESS: Start of the CZ tag surface. This field defines the base address in 64-byte units/alignment.

15.2.6 AR3D_QR_FRAGMENT_PIPE_REGISTER_ADDR_0

This is an array of 4 identical register entries; the register fields below apply to each entry.

Offset: 0x420..0x423 | Byte Offset: 0x1080..0x108c | Read/Write: R/W | Reset: 0x000X0XXX (0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx)

Bit	Reset	Description
17	X	READ
16	X	INCR
11:0	X	ADDR

15.2.7 AR3D_TEX_TEXADDR_0

TEXADDR contains the base address for the texture surfaces.

This is an array of 16 identical register entries; the register fields below apply to each entry.

Offset: 0x710..0x71f | Byte Offset: 0x1c40..0x1c7c | Read/Write: R/W | Reset: 0xXXXXXXXX (0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx)

Bit	Reset	Description
31:0	X	BASE_ADDRESS: This surface base address should be 16-byte aligned.

15.2.8 AR3D_DW_MEMORY_OUTPUT_ADDRESS_0

Offset: 0x904 | Byte Offset: 0x2410 | Read/Write: R/W | Reset: 0xXXXXXXXX (0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx)

Bit	Reset	Description
31:0	X	BASE_ADDRESS

15.2.9 AR3D_GLOBAL_SURFADDR_0

SURFADDR -- Base Address for Frame Buffer Surfaces

This is an array of 16 identical register entries; the register fields below apply to each entry.

Offset: 0xe00..0xe0f | Byte Offset: 0x3800..0x383c | Read/Write: R/W | Reset: 0xXXXXXXXX (0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx)

Bit	Reset	Description
31:0	X	BASE_ADDRESS

15.2.10 AR3D_GLOBAL_SPILLSURFADDR_0

Base Address of a Pixel Spill Surface

Offset: 0xe2a | Byte Offset: 0x38a8 | Read/Write: R/W | Reset: 0xXXXXXXXX (0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx)

Bit	Reset	Description
31:0	X	BASE_ADDRESS

15.2.11 AR3D_GLOBAL_SURFOVERADDR_0

Overlap Buffer

This is an array of 16 identical register entries; the register fields below apply to each entry.

Offset: 0xe30..0xe3f | Byte Offset: 0x38c0..0x38fc | Read/Write: R/W | Reset: 0xXXXXXXXX (0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx)

Bit	Reset	Description
31:0	X	BASE_ADDRESS

15.2.12 AR3D_GLOBAL_SAMP01SURFADDR_0

Surface Address for Multisample Sample 0 and 1 Buffers

This is an array of 16 identical register entries; the register fields below apply to each entry.

Offset: 0xe50..0xe5f | Byte Offset: 0x3940..0x397c | Read/Write: R/W | Reset: 0xXXXXXXXX (0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx)

Bit	Reset	Description
31:0	X	BASE_ADDRESS

15.2.13 AR3D_GLOBAL_SAMP23SURFADDR_0

Surface Address for Multisample Sample 2 and 3 Buffers

This is an array of 16 identical register entries; the register fields below apply to each entry.

Offset: 0xe60..0xe6f | Byte Offset: 0x3980..0x39bc | Read/Write: R/W | Reset: 0xXXXXXXXX (0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx)

Bit	Reset	Description
31:0	X	BASE_ADDRESS

16.0 ENCODER PRE-PROCESSOR (EPP)

The Encoder Pre-Processor (EPP) is an engine used for pixel manipulation, usually in conjunction with GR2D, the 2D graphics engine.

This section is not intended to be a programming guide to EPP, as it is expected that NVIDIA supplied drivers will always be used with it. However, the register interface is documented to aid with understanding those drivers.

16.1 Capabilities

The EPP receives input stream or surface data from GR2D, the 2D graphics engine (or VI, the video/camera input path, but this path is not currently used).

The EPP receives input data on a 24-bit data bus with the format compatible to CSI output format. The input data formats are in 6 possible formats as far as EPP is concerned:

- 24-bit YUV444 (Y in bits 23:16, U in bits 15:8, V in bits 7:0)
- 24-bit RGB888 (R in bits 23:16, G in bits 15:8, B in bits 7:0)
- 1-byte Raw in bits 7:0
- 2-byte Raw in bits 15:0
- MIPI CSI YUV420 8-bit legacy
- MIPI CSI YUV420 8-bit

EPP supports various output data formats to memory: planar YUV, non-planar YUV, RGB, and Raw formats.

Supported YUV Planar Output Formats

a. YUV420P: planar YUV420 (3-plane YUV420)

Y-plane: YYYY...

YYYY...

U-plane: UU...

V-plane: VV...

b. YUV422P: planar YUV422 (3-plane YUV422)

Y-plane: YYYY...

U-plane: UU...

V-plane: VV...

c. YUV422R: planar YUV422 rotated (3-plane YUV422 rotated)

Y-plane: YYYY...

YYYY...

U-plane: UUUU...

V-plane: VVVV...

d. YUV420SP: semi-planar YUV420 (2-plane YUV420)

Y-plane: YYYY...

YYYY...

UV-plane: UVUV...

e. YUV422SP: semi-planar YUV422 (2-plane YUV422)

Y-plane: YYYY...

UV-plane: UVUV...

f. YUV422SPR: semi-planar YUV422 rotated (2-plane YUV422 rotated)

Y-plane: YY...

YY...

UV-plane: UVUV...

Supported YUV and RGB 32-bit Non-Planar Output Formats

This table, and the ones that follow it, show the specific bit mappings. The characters YUV and RGB refer to the corresponding fields of each color space; and A refers to an alpha value. A single row of digits below those characters shows the bit mapping of the sub-field corresponding to the letter above. For the fields with two rows of digits, the first row shows the ordering of multiple sub-fields; e.g., format ‘b’ contains two Y fields, so 0 and 1 show the mappings of each of those.

                                              012345
```

For all output formats that require alpha (A), the alpha value is programmed by the host and the same programmed value is used for all output pixels.

If EPP output processing is stalled due to a stall from the memory controllers or due to an output trigger stall, the EPP will propagate the stall condition to its input FIFO. If the input FIFO becomes full, then the EPP will not accept any more input data.

This stall may cause input data stream to be dropped (thrown away) if the input stream cannot be stalled or if the input stream comes from the host via VI, then VI will stall host input stream processing.

16.2 Reset Sequence for EPP

1. Raise VI at the end of the EPP frame.

   If the first_output of VI is connected to the EPP, then RAISE_FRAME_1_VECTOR should be sent to register NV_VI_RAISE_VIP_FRAME_FIRST_OUTPUT_0 (offset 0x3e). If the second output of VI is connected to the EPP, then RAISE_FRAME_2_VECTOR should be sent to register NV_VI_RAISE_VIP_FRAME_SECOND_OUTPUT_0 (offset 0x40).
2. Disable the VI output to the EPP by setting bits 4:2 to 0 of register NV_VI_VI_CORE_CONTROL_0 (offset 0x3)
3. Raise the EPP at end of frame from host, NV_EPP_RAISE_FRAME_0 (offset 0x1a)
4. Read the NV_EPP_CTXW_0 (0ffset 0) register, and save the value as EPP_CTXSW_DATA

5. Write 0 to NV_MC_CLIENT_CTRL_0 (offset 0x18), bit 4 to block EPP requests inside the MC.
6. Reset the EPP by write 0 to bit 6 of NV_HOST1X_ASYNC_RSTREG_0 (offset 0x14). Do a read-modify-write.
7. Write 0 to NV_MC_CLIENT_HOTRESETN_0 (offset 0x19), bit 4 to clear EPP requests blocked inside the MC.
8. Poll on NV_MC_EPP_ORRC_0 (offset 0x1e), MC_EPP_ORRC_0_EPP_OUTREQCNT_RANGE field (0xFF), till it is zero.
9. Write 1 to NV_MC_CLIENT_HOTRESETN_0, bit 4 to disable the clear of EPP requests inside the MC.
10. Write 1 to NV_MC_CLIENT_CTRL_0, bit 4 to unblock the EPP request inside the MC.
11. Bring the EPP out of reset by writing 1 to bit 6 of NV_HOST1X_ASYNC_RSTREG_0 (offset 0x14). Do a read-modify-write.
12. Program NV_EPP_CTXSW_0 (0x0) with the previously saved EPP_CTXSW_DATA.
13. Program the EPP registers
14. Enable the encoder
15. Enable the VI EPP output by programming bits 4:2 to the desired format of NV_VI_VI_CORE_CONTROL_0 (offset 0x3)

16.3 EPP Registers

Refer to “Reading Register Tables” in the Introduction section for the register table protocol as well as recommendations for accessing registers.

16.3.1 EPP_INCR_SYNCPT_0

Offset: 0x0 | Byte Offset: 0x0 | Read/Write: R/W | Reset: 0x00000000 (0bxxxxxxxxxxxxxxxx0000000000000000)

Bit	Reset	Description
15:8	0x0	COND: Condition mapped from raise/wait 0 = IMMEDIATE 1 = OP_DONE 2 = RD_DONE 3 = REG_WR_SAFE 4 = COND_4 5 = COND_5 6 = COND_6 7 = COND_7 8 = COND_8 9 = COND_9 10 = COND_10 11 = COND_11 12 = COND_12 13 = COND_13 14 = COND_14 15 = COND_15
7:0	0x0	INDX: syncpt index value

16.3.2 EPP_INCR_SYNCPT_CNTRL_0

Offset: 0x1 | Byte Offset: 0x4 | Read/Write: R/W | Reset: 0x00000000 (0bxxxxxxxxxxxxxxxxxxxxxxxx0xxxxxxx0)

Bit	Reset	Description
8	0x0	INCR_SYNCPT_NO_STALL: If NO_STALL is 1, then when the FIFOs are full, INCR_SYNCPT methods will be dropped and the INCR_SYNCPT_ERROR[COND] bit will be set. If NO_STALL is 0, then when the FIFOs are full, the client host interface will be stalled.

Bit	Reset	Description
0	0x0	INCR_SYNCPT_SOFT_RESET: If SOFT_RESET is set, then all internal states of the client syncpt block will be reset. To do a soft reset, first set SOFT_RESET of all host1x clients affected, then clear all SOFT_RESETs.

16.3.3 EPP_INCR_SYNCPT_ERROR_0

Offset: 0x2 │ Byte Offset: 0x8 │ Read/Write: R/W │ Reset: 0x00000000 (0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx)

Bit	Reset	Description
31:0	X	COND_STATUS: COND_STATUS[COND] is set if the FIFO for COND overflows. This bit is sticky and will remain set until cleared. Cleared by writing 1.

16.3.4 EPP_EPP_SYNCPT_DEST_0

This is for COND_FIFO_DEPTH (ignored for COND 0). COND_TRIG_MODE applies to COND 1..x (ignored for 0,1).

Offset: 0x8 │ Byte Offset: 0x20 │ Read/Write: R/W │ Reset: 0x00000001 (0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx01)

Bit	Reset	Description
1	0x0	MPE
0	0x1	HOST

16.3.5 EPP_CTXSW_0

Context Switch Register. Should be common to all modules. Includes the current channel/class (which is writable by software) and the next channel/class (which the hardware sets when it receives a context switch).

Context switch works like this:

Any context switch request triggers an interrupt to the host and causes the new channel/class to be stored in NEXT_CHANNEL/NEXT_CLASS (see vmod/chexample). Software sees that there is a context switch interrupt and does the necessary operations to make the module ready to receive traffic from the new context. It clears the context switch interrupt and writes CURR_CHANNEL/CLASS to the same value as NEXT_CHANNEL/CLASS, which causes a context switch acknowledge packet to be sent to the host. This completes the context switch and allows the host to continue sending data to the module.

Context switches can also be pre-loaded. If CURR_CLASS/CHANNEL are written and updated to the next CLASS/CHANNEL before the context switch request occurs, an acknowledge will be generated by the module and no interrupt will be triggered. This is one way for software to avoid dealing with context switch interrupts.

Another way to avoid context switch interrupts is to set the AUTO_ACK bit. This bit tells the module to automatically acknowledge any incoming context switch requests without triggering an interrupt. CURR_* and NEXT_* will be updated by the module so they will always be current.

Offset: 0x9 │ Byte Offset: 0x24 │ Read/Write: R/W │ Reset: 0xf000f800 (0bxxxxxxxxxxxxxxxx11111x0000000000)

Bit	R/W	Reset	Description
31:28	RO	X	NEXT_CHANNEL: Next requested channel
25:16	RO	X	NEXT_CLASS: Next requested class
15:12	RW	0xf	CURR_CHANNEL: Current working channel, reset to 'invalid'
11	RW	0x1	AUTO_ACK: Automatically acknowledge any incoming context switch requests 0 = MANUAL 1 = AUTOACK

Bit	R/W	Reset	Description
9:0	RW	0x0	CURR_CLASS: Current working class

16.3.6 EPP_INTSTATUS_0

Interrupt Status. This register reflects the status of all pending interrupts, which is valid as long as the interrupt is not cleared even if the interrupt is masked. A pending interrupt can be cleared by writing a '1' to the corresponding interrupt status bit in this register.

Offset: 0xa │ Byte Offset: 0x28 │ Read/Write: R/W │ Reset: 0xff000000 (0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx)

Bit	R/W	Reset	Description
31:24	RO	X	LAST_BUFFER_INDEX: Last buffer index status. This indicates the index of the previous (last) buffer written to memory by the EPP.
8	RW	X	SHORT_FRAME_INT: Short Frame Interrupt Status. If enabled, an interrupt is generated when a shorter than expected frame is detected. Input stream end-of-frame flag and OUTPUT_FRAME_SIZE are used to determine this condition. 0 = NOTPENDING: interrupt not pending 1 = PENDING: interrupt pending
2	RW	X	BUFFER_END_INT: Output Buffer End Interrupt Status. If enabled, an interrupt is generated every time an end of buffer is reached. Typically, this is determined when OB0_V_SIZE count expires and after all buffer data is written to memory. Note that the buffer may not be completely filled for first and last buffer of each frame. This interrupt should be used together with LAST_BUFFER_INDEX status. 0 = NOTPENDING: interrupt not pending 1 = PENDING: interrupt pending
1	RW	X	FRAME_END_INT: Frame End Interrupt Status. If enabled, an interrupt is generated every time the FRAME_HEIGHT count expires after all frame data is written to memory. 0 = NOTPENDING: interrupt not pending 1 = PENDING: interrupt pending
0	RW	X	CTXSW_INT: Context Switch Interrupt Status (this is cleared on write). 0 = NOTPENDING: interrupt not pending 1 = PENDING: interrupt pending

16.3.7 EPP_EPP_CONTROL_0

EPP Control Register. This specifies processing control.

Offset: 0xb │ Byte Offset: 0x2c │ Read/Write: R/W │ Reset: 0x00000000 (0bxxxxxxx0xx00000000000000000000)

Bit	Reset	Description
24	0x0	SW_FLOW_CONTROL: enable software flow control default is disabled. 0 = DISABLE 1 = ENABLE
21:18	0x0	OUTPUT_FORMAT_EXT: Output data format extension. This specifies output data format together with OUTPUT_FORMAT. RGB formats are specified from lsb to msb. 0 = EXT0 : YUV420: planar YUV422: non-planar if OUTPUT_PLANAR=DISABLE, planar if OUTPUT_PLANAR=ENABLE. YUV422R: planar YUV444: AYUV444 non-planar if OUTPUT_PLANAR=DISABLE RGB888: B8G8R8A8 if OUTPUT_PLANAR=DISABLE, R8G8B8A8 if OUTPUT_PLANAR=ENABLE. RGBRAW: B5G6R5 if OUTPUT_PLANAR=DISABLE, R5G6B5 if OUTPUT_PLANAR=ENABLE. BAYERRAW: 2-byte bayer/raw 1 = EXT1 : YUV420: semi-planar YUV422: semi-planar if OUTPUT_PLANAR=ENABLE. YUV422R: semi-planar RGB888: A8B8G8R8 if OUTPUT_PLANAR=DISABLE, A8R8G8B8 if OUTPUT_PLANAR=ENABLE. RGBRAW: A1B5G5R5 if OUTPUT_PLANAR=DISABLE, A1R5G5B5 if OUTPUT_PLANAR=ENABLE. BAYERRAW: 1-byte bayer/raw 2 = EXT2 : YUV420: planar, CSI YUV420 legacy input RGBRAW: B5G5R5A1 if OUTPUT_PLANAR=DISABLE, R5G5B5A1 if OUTPUT_PLANAR=ENABLE. 3 = EXT3 : YUV420: semi-planar, CSI YUV420 legacy input RGBRAW: A4B4G4R4 if OUTPUT_PLANAR=DISABLE, A4R4G4B4 if OUTPUT_PLANAR=ENABLE.

Bit	Reset	Description
		4 = EXT4 : YUV420: planar, CSI YUV420 input. RGBRAW: B4G4R4A4 if OUTPUT_PLANAR=DISABLE, R4G4B4A4 if OUTPUT_PLANAR=ENABLE. 5 = EXT5 : YUV420: semi-planar, CSI YUV420 input.
17	0x0	ENABLE_DUP: Pixel duplication at start and end of lines. This enables duplication of the first pixel and last pixel of each line to 128-bit boundary, if there is unused space in the 128-bit memory word that contains the first and last pixel. This may be enabled if the output of the EPP is used as input of JPEG encoder. The JPEGE encoder can duplicate lines to ensure JPEGE has a full MCU to encode. If the EPP Is used as an input to the MPEG encoder, the output height of the EPP has to be set to multiples of 16 because the MPEG encoder does not duplicate lines. This is only applicable for planar YUV output formats (OUTPUT_PLANAR=ENABLE and output Format!=RAWRGB and output Format!=RGB888). 0 = DISABLE : First and last pixel duplication is disabled. 1 = ENABLE : First and last pixel duplication is enabled for each line.
16	0x0	DMA_ENABLE: DMA enable. Software should program this bit to a 1 every time DMA is enabled and buffer configuration changes This bit is now sent out as init for all the host counters and logic. This enables EPP trigger at end of each buffer to be sent to Read DMA. The Read DMA must be properly programmed to fetch EPP buffers in memory upon receiving these triggers. 0 = DISABLE: EPP trigger to Read DMA is disabled 1 = ENABLE: EPP trigger to Read DMA is enabled
15	0x0	CHROMA_SIGN: Chroma data sign. This indicates chroma data format. 0 = UNSIGNED: unsigned chroma data, Cb/Cr 1 = SIGNED: signed chroma data, U/V, in 2's complement
14:12	0x0	OUTPUT_FORMAT: Output data format. This specifies output data format together with OUTPUT_FORMAT_EXT. 0 = YUV420: YUV420 planar/semi-planar. ENABLE_422 must be set to ENABLE for this output format. ENABLE_420 must be set to ENABLE if the input format is not MIPI CSI YUV420 formats and must be set to DISABLE if the input format is MIPI CSI YUV420 formats. 1 = YUV422: YUV422 non-planar/planar/semi-planar. If YUV422 planar/semi-planar format is selected and XY swap is enabled, then the output will be written to memory in YUV422R planar/semi-planar format correspondingly. YUV422 non-planar format cannot be used with XY swap enabled. ENABLE_422 must be set to ENABLE and ENABLE_420 must be set to DISABLE for this output format. 2 = YUV422R: YUV422R planar/semi-planar. If YUV422R planar/semi-planar format is selected and XY swap is enabled, then the output will be written to memory in YUV422 planar/semi-planar format correspondingly. ENABLE_422 must be set to DISABLE and ENABLE_420 must be set to ENABLE for this output format. 3 = YUV444 : AYUV444 non-planar if OUTPUT_PLANAR=DISABLE. 4 = RGB888 : ARGB888 5 = RGBRAW : RGBRAW 6 = BAYERRAW : BAYERRAW
11	0x0	CHROMA_FILTER_422: Chroma YUV444 to YUV422 conversion. This controls chroma reduction when YUV444 to YUV422 conversion is enabled. This is effective only when ENABLE_422 is set to ENABLE. 0 = DROP: Even chroma pixels are dropped. This may be used if the incoming YUV444 stream has chroma pixel duplication of odd and even pixels. 1 = FILTER: Horizontal chroma filtering is applied for YUV444 to YUV422 conversion.
10	0x0	OUTPUT_PLANAR: Output planar format. This should be set to ENABLE if output format is YUV planar or semi-planar and should be DISABLE if output format is YUV non-planar. For RGB output data formats, this bit has alternate function of swapping R and B. 0 = DISABLE: For YUV output formats, output is YUV non-planar format. For RGB output formats, R is in upper bits and B is in lower bits. 1 = ENABLE: Output is YUV planar/semi-planar format. For RGB output formats, B is in upper bits and R is in lower bits.
9:8	0x0	OUTPUT_NP_FORMAT: Non-planar YUV422 output format. This selects output format when output format is set to YUV422 non-planar. 0 = UYVY: UY0VY1, where U is LSB and Y1 is MSB 1 = VYUY: VY0UY1, where V is LSB and Y1 is MSB 2 = YUYV: Y0UY1V, where Y0 is LSB and V is MSB 3 = YVYU: Y0VY1U, where Y0 is LSB and U is MSB

Bit	Reset	Description
7:6	0x0	CHROMA_FILTER_420: Chroma YUV422 to YUV420 conversion. This controls chroma reduction when YUV422 to YUV420 conversion is enabled. This is effective only when ENABLE_420 is set to ENABLE. 0 = DROP: Even chroma lines are dropped. 1 = AVERAGE: Averaging is done for each pair (odd and even) of chroma lines.
5	0x0	ENABLE_PP: Luma PreProcess filter enable. This controls luma pre-encoding filter for YUV output formats including YUV420 when input format is YUV420 CSI format. Enabling the luma pre-encoding filter will reduce noise in the input stream and may result in more compact encoding. 0 = DISABLE: Luma pre-encoding filter is disabled. 1 = ENABLE: Luma pre-encoding filter is enabled.
4	0x0	ENABLE_420: YUV422 to YUV420 enable. If set to ENABLE, chroma data is vertically reduced by half. YUV422 to YUV420 conversion must be enabled when OUTPUT_FORMAT is YUV420 and input format is not MIPI CSI YUV420. YUV422 to YUV420 conversion must also be enabled when OUTPUT_FORMAT is YUV422R. The vertical chroma reduction method is controlled by CHROMA_FILTER_420 field. 0 = DISABLE: YUV422 to YUV420 conversion is disabled. 1 = ENABLE: YUV422 to YUV420 conversion is enabled.
3	0x0	ENABLE_422: YUV444 to YUV422 enable. If set to ENABLE, chroma data is horizontally reduced by half. YUV444 to YUV422 conversion must be enabled when OUTPUT_FORMAT is YUV422 or YUV420. YUV444 to YUV422 conversion must be disabled when OUTPUT_FORMAT is YUV422R. The horizontal chroma reduction method is controlled by CHROMA_FILTER_422 field. 0 = DISABLE: YUV444 to YUV422 conversion is disabled. 1 = ENABLE: YUV444 to YUV422 conversion is enabled.
2	0x0	ENABLE_CC: Color Space Converter enable. This enables RGB to YUV color space converter and should be enabled only for RGB input format if the output format is YUV. If enabled, the output of the color space converter is YUV444 therefore conversion to YUV422 or YUV420 may be needed also. 0 = DISABLE: RGB input format is not converted to YUV. 1 = ENABLE: RGB input format is converted to YUV.
1:0	0x0	INPUT_SOURCE: Input source. 0 = VI: Input source from VI. 1 = SB: Input source from StretchBLT (2D). 2 = DISPLAY: Input source from DISPLAY. 3 = DISPLAYB : Input source from DISPLAY B

16.3.8 EPP_OUTPUT_FRAME_SIZE_0

Captured, Input Frame Size

This specifies the width and height of the input frame with respect to the size of the active area to be processed by the EPP. For some planar and semi-planar YUV output formats, there are 2:1 ratio of luma vs chroma pixels horizontally and/or vertically. In this case, output frame size specifies luma plane size and should be programmed to even values if the corresponding chroma plane dimension is half of the luma plane dimension.

Offset: 0xc │ Byte Offset: 0x30 │ Read/Write: R/W │ Reset: 0x00000000 (0b00000000000000000000000000000000)

Bit	Reset	Description
31:16	0x0	FRAME_HEIGHT: Frame height in lines (minimum 1 line).
15:0	0x0	FRAME_WIDTH: Frame width in pixels (minimum 16 pixels).

16.3.9 EPP_INPUT_FRAME_AOI_0

Input Frame Area of Interest

This specifies the position of the first pixel in the input frame to be processed by the EPP. Together with the output frame size, this parameter defines the active size of the input surface.

Offset: 0xd │ Byte Offset: 0x34 │ Read/Write: R/W │ Reset: 0x00000000 (0b00000000000000000000000000000000)

Bit	Reset	Description
31:16	0x0	FRAME_VERT_OFFSET: Vertical offset in term of line position (minimum 0).
15:0	0x0	FRAME_HORI_OFFSET: Horizontal offset in term of pixel position (minimum 0).

16.3.10 EPP_OUTPUT_SCAN_DIR_0

Output Scan Direction

This register can be used to program the output frame orientation as follows:

XY_SWAP	VERT_DIR	HORI_DIR	Output frame orientation
0	0	0	Normal (same as input frame orientation)
0	0	1	H flip (mirror on vertical axis)
0	1	0	V flip (mirror on horizontal axis)
0	1	1	180-degree rotation
1	0	0	Reserved, do not use.
1	0	1	Reserved, do not use.
1	1	0	Reserved, do not use.
1	1	1	Reserved, do not use.

Notes:

a. XY swap feature is deprecated and must not be used.

b. Output buffer start address should be programmed in consideration of the scan directions.

OB0_Start_Address = OBSA + hsd * (width * bpp - 1) + vsd * (height - 1) * line_stride, where line_stride >= ((width * bpp) + 15) & 0xFFFFFFF0).

In the above formulae, OBSA is the start address of output buffer 0, hsd and vsd are H/V scan direction, bpp is bytes per pixel, width and height are the sizes of input image in pixels, and line_stride is the line stride of output buffer in bytes.

c. For YUV422 non-planar, since chroma data is shared by multiple pixels, XY swap CANNOT be performed.

Offset: 0xe │ Byte Offset: 0x38 │ Read/Write: R/W │ Reset: 0x00000000 (0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxx000)

Bit	Reset	Description
2	0x0	XY_SWAP: Reserved, set to DISABLE (zero) 0 = DISABLE
1	0x0	VERT_DIR: Vertical scan direction. 0 = INCREASE: Increasing address. 1 = DECREASE: Decreasing address.
0	0x0	HORI_DIR: Horizontal scan direction. 0 = INCREASE: Increasing address. 1 = DECREASE: Decreasing address.

Output buffer start addresses define the start address of the first buffer (buffer index 0) and taking into account the output orientation. Note that since output buffer start addresses depend on output orientation, therefore it must be reprogrammed when output orientation is changed.

All addresses must be on pixel boundaries.

Output format is either Planar or Non-planar format. For non-planar output format, only luma buffer is used.

For semi-planar output formats, only 2 planes are used. Chroma data is interleaved in a single plane. So for semi-planar outputs, only OB0_START_ADDRESS_U is used to specify chroma buffer start address. Enough memory should be reserved to store U and V data for the chroma buffer.

16.3.11 EPP_OB0_BASE_ADDRESS_Y_0

Offset: 0x10 | Byte Offset: 0x40 | Read/Write: R/W | Reset: 0x00000000 (0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx)

Bit	Reset	Description
31:0	X	OB0_BASE_ADDRESS_Y: OB0 Y BASE address.

16.3.12 EPP_OB0_BASE_ADDRESS_U_0

Output buffer 0 U base address. This is used to specify the U buffer base address for planar output format. This is also used for the semi-planar chroma buffer base address. This is not used for the non-planar output format.

Offset: 0x12 | Byte Offset: 0x48 | Read/Write: R/W | Reset: 0x00000000 (0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx)

Bit	Reset	Description
31:0	X	OB0_BASE_ADDRESS_U: OB0 U start address.

16.3.13 EPP_OB0_START_ADDRESS_V_0

Output buffer 0 V start address. This is used to specify the V buffer start address for the planar output format. This is not used for semi-planar or non-planar output format.

Offset: 0x13 | Byte Offset: 0x4c | Read/Write: R/W | Reset: 0x00000000 (0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx)

Bit	Reset	Description
31:0	X	OB0_START_ADDRESS_V: OB0 V start address.

16.3.14 EPP_OB0_BASE_ADDRESS_V_0

Output buffer 0 V base address. This is used to specify the V buffer base address for the planar output format. This is not used for semi-planar or non-planar output format.

Offset: 0x14 | Byte Offset: 0x50 | Read/Write: R/W | Reset: 0x00000000 (0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx)

Bit	Reset	Description
31:0	X	OB0_BASE_ADDRESS_V: OB0 V start address.

16.3.15 EPP_OB0_XY_OFFSET_LUMA_0

XY Offset to first pixel in the image. The value is expressed in pixels. For non-rotated surfaces, this points to the TOP-LEFT of the image.

Offset: 0x15 | Byte Offset: 0x54 | Read/Write: R/W | Reset: 0x00000000 (0b00000000000000000000000000000000)

Bit	Reset	Description
31:16	0x0	START_Y_LUMA: Y offset in pixels for the first pixel in the image in the Y buffer.
15:0	0x0	START_X_LUMA: X offset in pixels for the first pixel written in the image in the Y buffer

16.3.16 EPP_OB0_XY_OFFSET_CHROMA_0

XY Offset to first pixel in the image. The value is expressed in pixels. For non-rotated surfaces, this points to the TOP-LEFT of the image.

Offset: 0x16 | Byte Offset: 0x58 | Read/Write: R/W | Reset: 0x00000000 (0b00000000000000000000000000000000)

Bit	Reset	Description
31:16	0x0	START_Y_CHROMA: Y offset in pixels for the first pixel in the image in the U and V buffer.
15:0	0x0	START_X_CHROMA: X offset in pixels for the first pixel written in the image in the U and V buffer. For YUV422R or YUV420P with Chroma Averaging on START_X_CHROMA must be aligned to a 16 byte boundary.

16.3.17 EPP_OB0_SIZE_0

Output buffer 0 size. This specifies the number of output buffers and the vertical size of each buffer. Note that horizontal size of each buffer is implied from OB_LINE_STRIDE.

Offset: 0x17 | Byte Offset: 0x5c | Read/Write: R/W | Reset: 0x00000000 (0bxxxxxxxxxxxxxxxxxxxxxxxxx00000000)

Bit	Reset	Description
28:16	X	OB0_V_SIZE: Output buffer vertical size. This specifies the number of lines. In the case of xyswap, the vertical size should be programmed as the vertical size before xyswap.
7:0	0x0	OB0_COUNT: Output buffer count. This specifies the number of buffers in output buffer set 0.

16.3.18 EPP_OB0_LINE_STRIDE_L_0

Output buffer line stride. Line stride should be programmed taking into account XY swap. If XY swap is enabled, line stride should be programmed as after xyswap.

Offset: 0x18 | Byte Offset: 0x60 | Read/Write: R/W | Reset: 0x00000000 (0b00000000000000000000000000000000)

Bit	Reset	Description
31:16	0x0	OB0_LINE_STRIDE_C: Output buffer chroma line stride. This parameter must be programmed as a 16-byte multiple so the 4 lsbs must be set to zeros.
15:0	0x0	OB0_LINE_STRIDE_L: Output buffer luma line stride. This parameter must be programmed as a 16-byte multiple so the 4 lsbs must be set to zeros.

Color Space Converter related registers are CSC_RGB2Y_COEFF, CSC_RGB2U_COEFF, CSC_RGB2V_COEFF and CSC_YOFFSET_COEFF.

The recommended coefficient values differ based on the type of conversion either RGB to ITU-R BT.601 Y/Cb/Cr or RGB to ITU-R BT.709 Y/Cb/Cr is used. For both the type of conversions, R,G,B values are expected to be in the range of [0,255] and after Color Space Conversion operation, Y value is in the range of [16,235] with Y-Offset of 16, Cb and Cr are in the range of [16,240] with offset of 128. The Offset of 128 for Cb and Cr are hard-coded in the design.

16.3.19 EPP_CSC_RGB2Y_COEFF_0

RGB to Y Coefficients

The coefficient for R component CSC_R2Y_COEFF is represented as Unsigned U0.8 (8 bits), the coefficient for G component CSC_G2Y_COEFF is represented as Unsigned U1.8 (9 bits), and the coefficient for B component CSC_B2Y_COEFF is represented as Unsigned U0.8 (8 bits).

For RGB to ITU-R BT.601 Y/Cb/Cr conversion, the recommended coefficient values are:

[CSC_R2Y_COEFF CSC_G2Y_COEFF CSC_B2Y_COEFF] = [0.256788 0.504129 0.097906]

The coefficients are represented with an 8-bit fraction (U1.8 or U0.8). Therefore for a dynamic range of 256 (8 bits), the programmed coefficient values are [66 129 25] = [42h 81h 19h]

For RGB to ITU-R BT.709 Y/Cb/Cr conversion, the recommended coefficient values are:

[CSC_R2Y_COEFF CSC_G2Y_COEFF CSC_B2Y_COEFF] = [0.182586 0.614231 0.062007]

The coefficients are represented with an 8-bit fraction (U1.8 or U0.8). Therefore for a dynamic range of 256 (8 bits), the programmed coefficient values are [47 157 16] = [2fh 9dh 10h]

Offset: 0x1b │ Byte Offset: 0x6c │ Read/Write: R/W │ Reset: 0x00000000 (0bxxxxxxx00000000000000000000000)

Bit	Reset	Description
24:17	0x0	CSC_B2Y_COEFF: Coefficient for B to Y component.
16:8	0x0	CSC_G2Y_COEFF: Coefficient for G to Y component.
7:0	0x0	CSC_R2Y_COEFF: Coefficient for R to Y component.

16.3.20 EPP_CSC_RGB2U_COEFF_0

RGB to U Coefficients

The coefficient for R component CSC_R2U_COEFF is represented as Sign Magnitude S0.8 (9-bits), the coefficient for G component CSC_G2U_COEFF is represented as Sign Magnitude S0.8 (9-bits), the coefficient for B component CSC_B2U_COEFF is represented as Sign Magnitude S0.8 (9-bits).

The most significant bit (9th bit) is either set to 0 or 1 based on the coefficient value being positive or negative, respectively.

For RGB to ITU-R BT.601 Y/Cb/Cr conversion, the recommended coefficient values are:

[CSC_R2U_COEFF CSC_G2U_COEFF CSC_B2U_COEFF] = [-0.148223 -0.290993 0.439216]

The coefficients are represented with an 8-bit fraction (S0.8). Therefore for a dynamic range of 256 (8 bits), the programmed coefficient values are [-38 -74 112] = [-26h -4ah 70h] = [126h 14ah 70h]

For RGB to ITU-R BT.709 Y/Cb/Cr conversion, the recommended coefficient values are:

[CSC_R2U_COEFF CSC_G2U_COEFF CSC_B2U_COEFF] = [-0.100644 -0.338572 0.439216]

The coefficients are represented with an 8-bit fraction (S0.8). Therefore for a dynamic range of 256 (8 bits), the programmed coefficient values are [-26 -87 112] = [-1ah -57h 70h] = [11ah 157h 70h]

Offset: 0x1c │ Byte Offset: 0x70 │ Read/Write: R/W │ Reset: 0x00000000 (0bxxxxx00000000000000000000000)

Bit	Reset	Description
26:18	0x0	CSC_B2U_COEFF: Coefficient for B to U component.
17:9	0x0	CSC_G2U_COEFF: Coefficient for G to U component.
8:0	0x0	CSC_R2U_COEFF: Coefficient for R to U component.

16.3.21 EPP_CSC_RGB2V_COEFF_0

RGB to V Coefficients

The coefficient for R component CSC_R2V_COEFF is represented as Sign Magnitude S0.8 (9 bits), the coefficient for G component CSC_G2V_COEFF is represented as Sign Magnitude S0.8 (9 bits), and the coefficient for B component CSC_B2V_COEFF is represented as Sign Magnitude S0.8 (9 bits).

The most significant bit (9th bit) is either set to 0 or 1 based on the coefficient value being positive or negative, respectively.

For RGB to ITU-R BT.601 Y/Cb/Cr conversion, the coefficient values recommended are:

[CSC_R2V_COEFF CSC_G2V_COEFF CSC_B2V_COEFF] = [0.439216 -0.367788 -0.040274]

The coefficients are represented with 8-bit fraction (S0.8) therefore for a dynamic range of 256 (8-bits), the programmed coefficient values are [112 -94 -18] = [70h -5eh -12h] = [70h 15eh 112h]

For RGB to ITU-R BT.709 Y/Cb/Cr conversion, the coefficient values recommended are:

[CSC_R2V_COEFF CSC_G2V_COEFF CSC_B2V_COEFF] = [0.439216 -0.398942 -0.071427]

The coefficients are represented with an 8-bit fraction (S0.8). Therefore for a dynamic range of 256 (8 bits), the programmed coefficient values are [112 -102 -10] = [70h -66h -0ah] = [70h 166h 10ah]

Offset: 0x1d │ Byte Offset: 0x74 │ Read/Write: R/W │ Reset: 0x00000000 (0bxxxxx00000000000000000000000000)

Bit	Reset	Description
26:18	0x0	CSC_B2V_COEFF: Coefficient for B to V component.
17:9	0x0	CSC_G2V_COEFF: Coefficient for G to V component.
8:0	0x0	CSC_R2V_COEFF: Coefficient for R to V component.

16.3.22 EPP_CSC_YOFFSET_COEFF_0

Y Offset for the Color Space Conversion

Offset: 0x1e │ Byte Offset: 0x78 │ Read/Write: R/W │ Reset: 0x00000000 (0bxxxxxxxxxxxxxxxxxxxxxxxxx00000000) │ Default: 0x00000010

Bit	Reset	SW Default	Description
7:0	0x0	0x10	CSC_YOFF_COEFF: Coefficient for Y Offset.

There are two filters in EPP -- luma pre-processing filter and chroma 444 to 420 filter. Each filter is designed to be 7 tab, LPF.

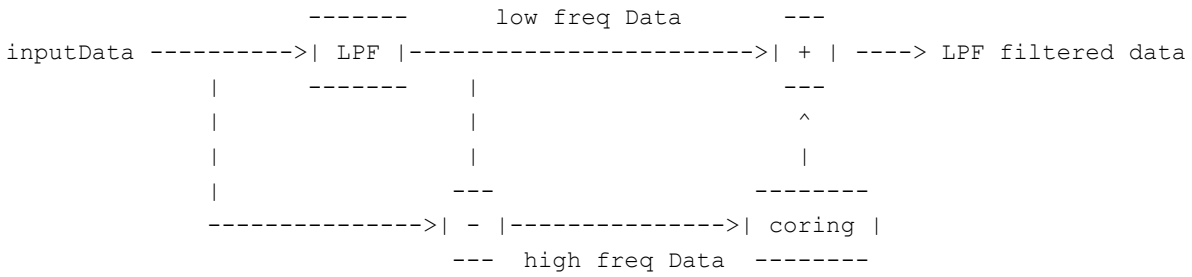
The recommended coefficients for luma pre-processing filter are: (0 1 4 6 4 1 0)/16. The filter coefficients are symmetric; therefore only four coefficients are programmed.

The recommended coefficient base is 16 and programmed to 4, in terms of powers of 2. The sum of all coefficients should not exceed the coefficient base value.

The recommended coefficients for chroma 444-to-422 filter are: (-1 0 9 16 9 0 -1)/64. The filter coefficients are symmetric, therefore only four coefficients are programmed.

The recommended coefficient base is 64 and programmed to 6, in terms of powers of 2. The sum of all coefficients should not exceed the coefficient base value.

The basic concept for this filter is:



16.3.23 EPP_FILTER_BOUND_0

Filter coring bound. This specifies minimum/maximum values for filter coring for both the luma pre-processing filter and the chroma 444-to-422 filter.

Offset: 0x1f │ Byte Offset: 0x7c │ Read/Write: R/W │ Reset: 0x00000000 (0b00000000000000000000000000000000) │ Default: 0xff00ff00

Bit	Reset	SW Default	Description
31:24	0x0	0xff	CHROMA_THRESHOLD_HIGH: Chroma high bound
23:16	0x0	_NONE_	CHROMA_THRESHOLD_LOW: Chroma low bound
15:8	0x0	0xff	LUMA_THRESHOLD_HIGH: Luma high bound
7:0	0x0	_NONE_	LUMA_THRESHOLD_LOW: Luma low bound

16.3.24 EPP_FILTER_BASE_0

Filter coefficient base

Offset: 0x20 │ Byte Offset: 0x80 │ Read/Write: R/W │ Reset: 0x00000000 (0bxxxxxxxx00000000xxxxxxxx00000000) │ Default: 0x00040004

Bit	Reset	SW Default	Description
23:16	0x0	0x4	CHROMA_BASE: Chroma 444-to-422 filter coefficient base. This is a positive value programmed in terms of power of 2.
7:0	0x0	0x4	PP_BASE: Luma pre-processing filter coefficient base. This is a positive value programmed in terms of power of 2.

16.3.25 EPP_PP_FILTER_COEF_0

Luma pre-processing filter coefficients. This 7-tap filter is symmetric therefore only four coefficients are programmed. The sum of all 7 coefficients should not exceed the filter base value.

Recommended luma pre-processing filter is a 5-tap filter (0,1,4,6,4,1,0)/16.

An alternate recommendation is a 7-tap filter (1,6,15,20,15,6,1)/64.

Offset: 0x21 │ Byte Offset: 0x84 │ Read/Write: R/W │ Reset: 0x00000000 (0bxxxxxxxxxxxxxx00000000000000000000) │ Default: 0x00031020

Bit	Reset	Default	Description
18:13	0x0	0x18	PP_COEF_3: Luma pre-processing filter coefficients 4. This is an unsigned value 0 to 63
12:8	0x0	0x10	PP_COEF_2: Luma pre-processing filter coefficients 3, 5. This is a unsigned value 0 to 31.
7:3	0x0	0x4	PP_COEF_1: Luma pre-processing filter coefficients 2, 6. This is a signed value -16 to +15.
2:0	0x0	0x0	PP_COEF_0: Luma pre-processing filter coefficients 1, 7. This is a signed value -4 to +3.

16.3.26 EPP_CHROMA_FILTER_COEF_0

Chroma 444-to-422 filter coefficients. This 7-tap filter is symmetric therefore only four coefficients are programmed. The sum of all 7 coefficients should not exceed the filter base value.

Recommended chroma 444-to-422 filter is a 5-tap filter (0,1,4,6,4,1,0)/16.

An alternate recommendation is a 7-tap filter (-1,0,9,16,9,0,-1)/64.

Offset: 0x22 | Byte Offset: 0x88 | Read/Write: R/W | Reset: 0x00000000 (0bxxxxxxxxxxxxxx00000000000000000000) | Default: 0x00031020

Bit	Reset	SW Default	Description
18:13	0x0	0x18	CHROMA_COEF_3: Chroma 444-to-422 filter coefficients 4. This is an unsigned value 0 to 63
12:8	0x0	0x10	CHROMA_COEF_2: Chroma 444-to-422 filter coefficients 3, 5. This is a unsigned value 0 to 31.
7:3	0x0	0x4	CHROMA_COEF_1: Chroma 444-to-422 filter coefficients 2, 6. This is a signed value -16 to +15.
2:0	0x0	0x0	CHROMA_COEF_0: Chroma 444-to-422 filter coefficients 1, 7. This is a signed value -4 to +3.

16.3.27 EPP_ALFA_VALUE_0

Output alpha value. This is an appended alpha value for RGB and/or YUV444 output data formats that requires alpha. If the data format requires less than 8 bits of alpha, then the necessary least significant bits are used.

Offset: 0x23 | Byte Offset: 0x8c | Read/Write: R/W | Reset: 0x00000000 (0bxxxxxxxxxxxxxxxxxxxxxxxx00000000)

Bit	Reset	Description
7:0	0x0	ALFA: Output alpha value.

16.3.28 EPP_U_LINE_BUFFER_ADDR_0

Chroma line buffer for U and V data. Chroma buffer needs to be allocated whenever ENABLE_420 is set to ENABLE, and CHROMA_FILTER_420 is set to AVERAGE.

Offset: 0x24 | Byte Offset: 0x90 | Read/Write: R/W | Reset: 0x00000000 (0b00000000000000000000000000000000)

Bit	Reset	Description
31:0	0x0	U_LINE_BUFFER_ADDR: Chroma line buffer for U & V data. This must be specified on a 16-byte boundary (the four LSBs must be set to zeros). The size of this line buffer must be sufficient to store one line of U & V.

16.3.29 EPP_V_LINE_BUFFER_ADDR_0

Note: This register is no longer used.

Offset: 0x25 | Byte Offset: 0x94 | Read/Write: R/W | Reset: 0x00000000 (0b00000000000000000000000000000000)

Bit	Reset	Description
31:0	0x0	V_LINE_BUFFER_ADDR: Reserved.

EPP may accept a raise from VI via the same input data bus from VI or two types of raises from host.

A raise from VI is returned when all preceding input data have been processed and written to memory.

Two types of raises maybe sent from the host:

- Raise Buffer
- Raise Frame

For raises from host, EPP tags last write for each buffer and each frame when sending it to memory client and then it waits for the tag to be returned. Typically, raise buffer will be acknowledged when the next end of buffer tag is returned by the memory write client.

Similarly, typically, raise frame will be acknowledged when the next end of frame tag is returned by the memory write client.

If raise buffer or raise frame is issued during vertical blank time (between end-of-frame marker of previous frame and start-of-frame of next frame) then an option bit is added to either acknowledge the raise immediately or return the raise when the next end of buffer or end of frame tag is returned by the memory write client correspondingly.

When one or more event that returns data to host are pending, priority will be assigned as follows:

1. Context Switch Acknowledgement
2. Raise from VI
3. Raise Buffer
4. Raise Frame
5. Refcount or register read

16.3.30 EPP_RAISE_BUFFER_0

Raise Buffer (end of buffer raise). The end of buffer event is generated when the last data of the output buffer is written to memory. This is independent of output trigger so the end of buffer raise acknowledge is returned even though there may be an output trigger stall pending.

Offset: 0x26 │ Byte Offset: 0x98 │ Read/Write: R/W │ Reset: 0x00000000 (0bxxxxxxxxxxxxx00000xxxxxxxxxx00000)

Bit	Reset	Description
19:16	0x0	CHANNEL_ID_BUFFER: 4-bit channel ID which will be returned when the end-of-buffer event occurs after raise buffer is issued.
15	0x0	RAISE_BUFFER_VBLANK: Raise buffer control during V Blank. This specifies when to return raise buffer if it is issued during vertical blank time. 0 = IMMEDIATE: Raise buffer is acknowledged immediately if it is issued during vertical blank time. 1 = DELAYED: Raise buffer is acknowledged at the end of the first buffer of the next frame if it is issued during vertical blank time.
4:0	0x0	RAISE_VECTOR_BUFFER: 5-bit raise vector

16.3.31 EPP_RAISE_FRAME_0

Raise Frame (end of frame raise). The end of frame event is generated when the last data of the output buffer is written to memory. This is independent of output trigger so the end of buffer raise acknowledge is returned even though there may be an output trigger stall pending.

Offset: 0x27 │ Byte Offset: 0x9c │ Read/Write: R/W │ Reset: 0x00000000 (0bxxxxxxxxxxxxx00000xxxxxxxxxx00000)

Bit	Reset	Description
19:16	0x0	CHANNEL_ID_FRAME: 4-bit channel ID which will be returned when the end-of-frame event occurs after raise frame is issued.
15	0x0	RAISE_FRAME_VBLANK: Raise frame control during V Blank. This specifies when to return raise frame if it is issued during vertical blank time. 0 = IMMEDIATE: Raise frame is acknowledged immediately if it is issued during vertical blank time. 1 = DELAYED: Raise frame is acknowledged at the end of the next frame if it is issued during vertical blank time.
4:0	0x0	RAISE_VECTOR_FRAME: 5-bit raise vector

17.0 KEYBOARD CONTROLLER

The Keyboard Controller (KBC) is used to interface a maximum of 19 pins with an external keypad. The number of pins used in the KBC depends on the external keypad row and column count.

A keyboard controller for a keypad matrix implemented completely in software can result in significant overhead. The KBC lowers the burden on software by supporting keypad scan, debounce and wake-up on any key press in hardware. It also reduces power consumption in keypad associated operations. The remaining pins can be used as GPIO. If no external keypad is connected all the pins can be used as GPIO. The KBC module is a slave on the APB bus and a part of the APBDEV module.

The typical software scanning flow is shown in Figure 40. Most of the tasks in the flowchart can be done in hardware, off-loading them from software. The three main operations done by the KBC are:

- Keypad scan
- Debounce
- Control state machine (SM)

In the presence of a KBC, the software flowchart for keyboard control is reduced to what is shown in Figure 41. The software only needs to configure the keyboard controller and serve the interrupts. This automatically reduces the power consumption related to keypad operations.

Features

The KBC supports:

- Keypad matrix size of up to 11X8.
- Wake-up on interrupt mode on unmasked pins
- Restricts active rows to be mapped starting from row0 in order
- Continuous polling mode
- Multi-key press support (dependency on keypad hardware)
- Joystick (16 ms key-press speed)

The keypad matrix provides ghost key protection in case of three or more simultaneous key presses. The system has a power ON/OFF key. The handling of this key is a little different from the rest of the keys. The KBC is not aware of this difference and treats it as any other key; different modules in the Tegra® 4 series processor (e.g., Always ON) monitor this key when the device is powered off.

Row 0 should always be enabled. Rows remain inactivate during the wakeup mode when all the columns of that row are masked. Rows that are enabled must be contiguous. For example, if we need to enable three rows, then they must be rows 0, 1, and 2. Enabling rows 0, 1, and 3, for example, is an invalid combination since the rows are not contiguous.

All the wakeup keys must be on the same column [n], other non-wakeup keys should not be part of the column [n] to avoid spurious wake-up interrupts.

Figure 40: Typical Software Scanning Flow

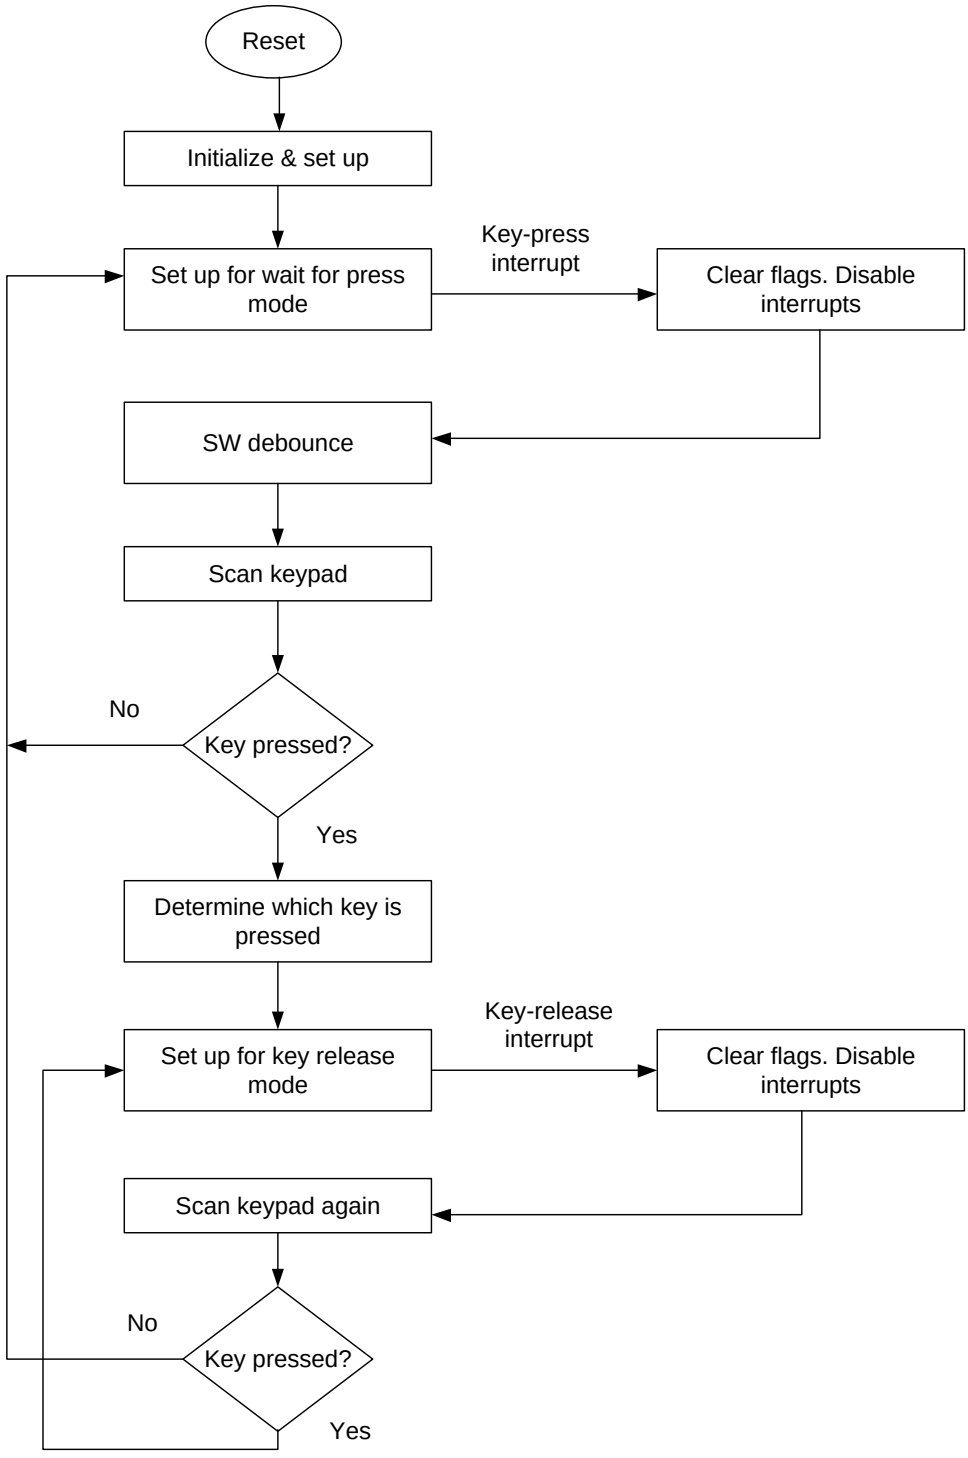


Figure 41: Software Flow with Hardware Keyboard Controller

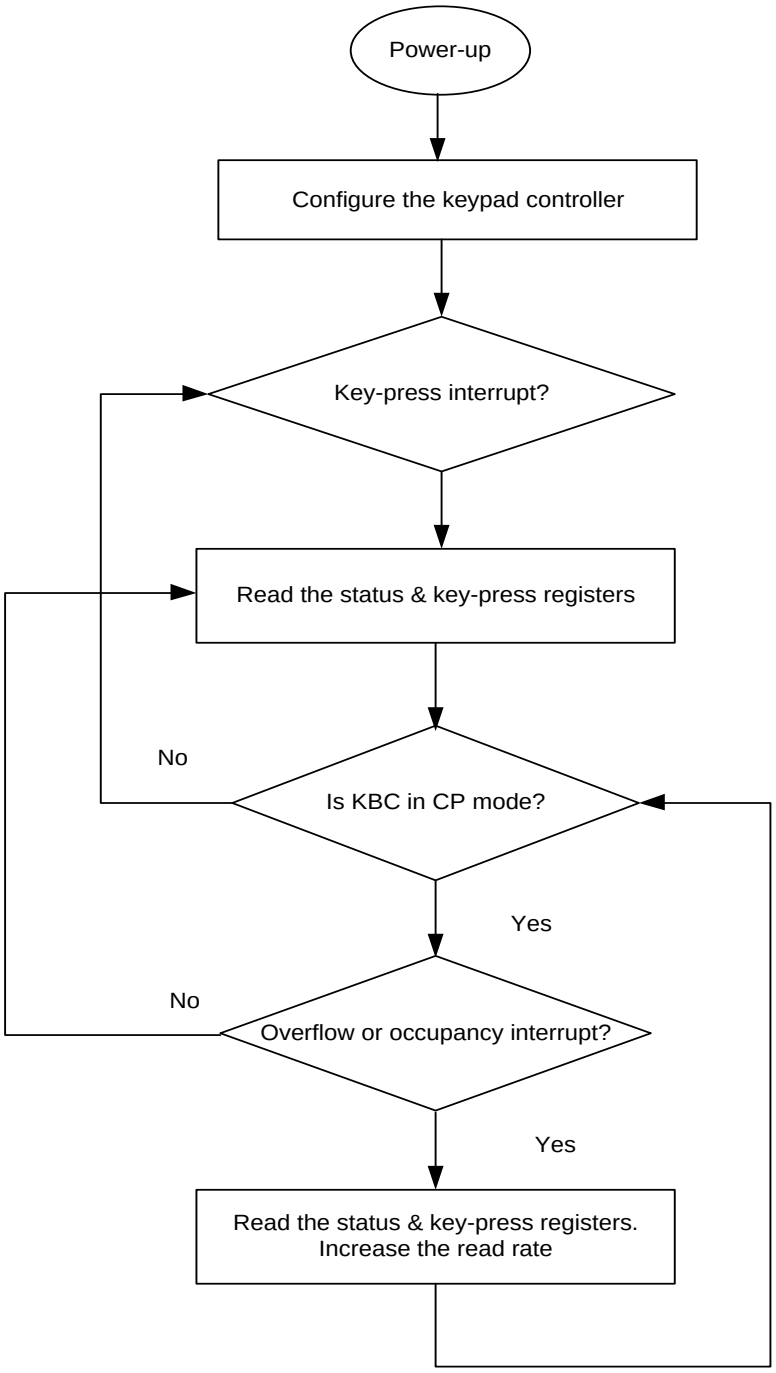

Figure 42: Power ON/OFF Key Example

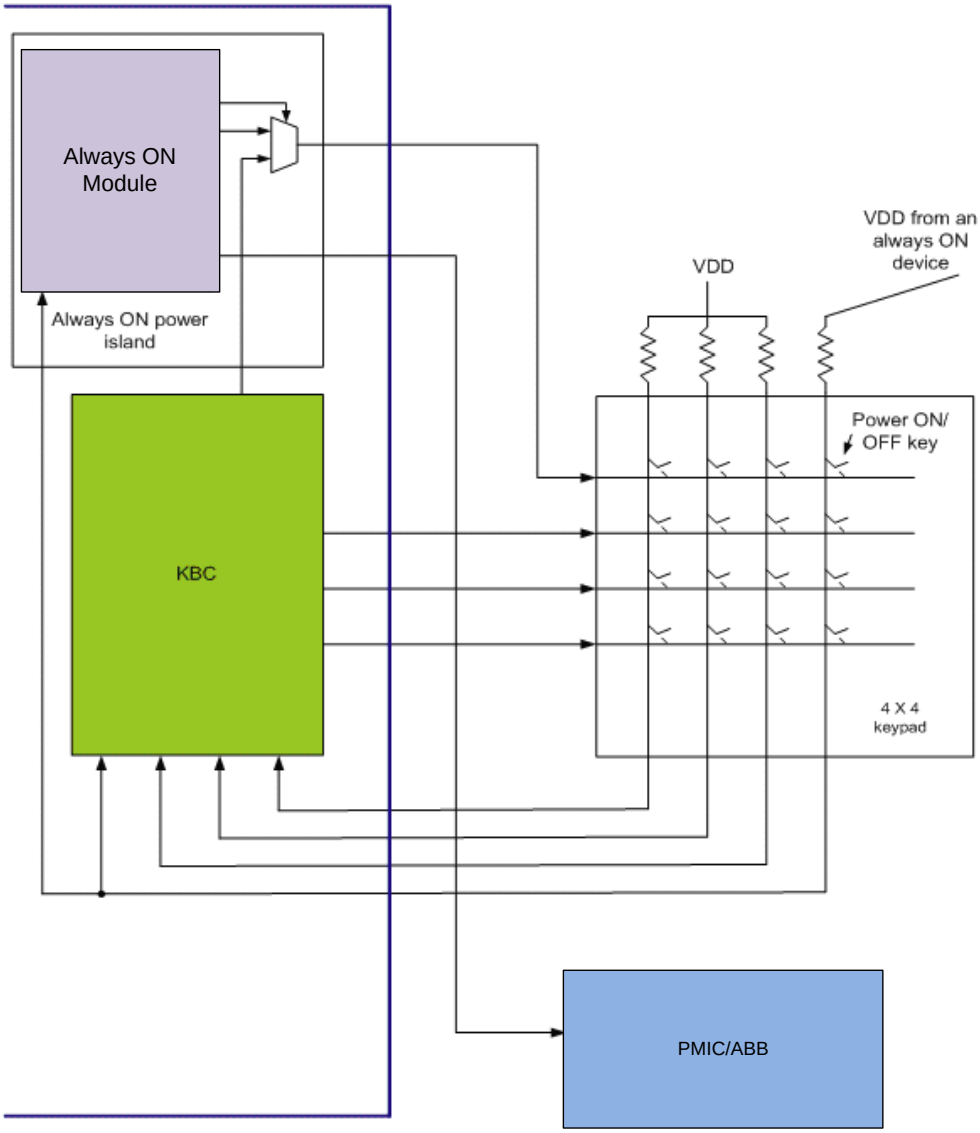
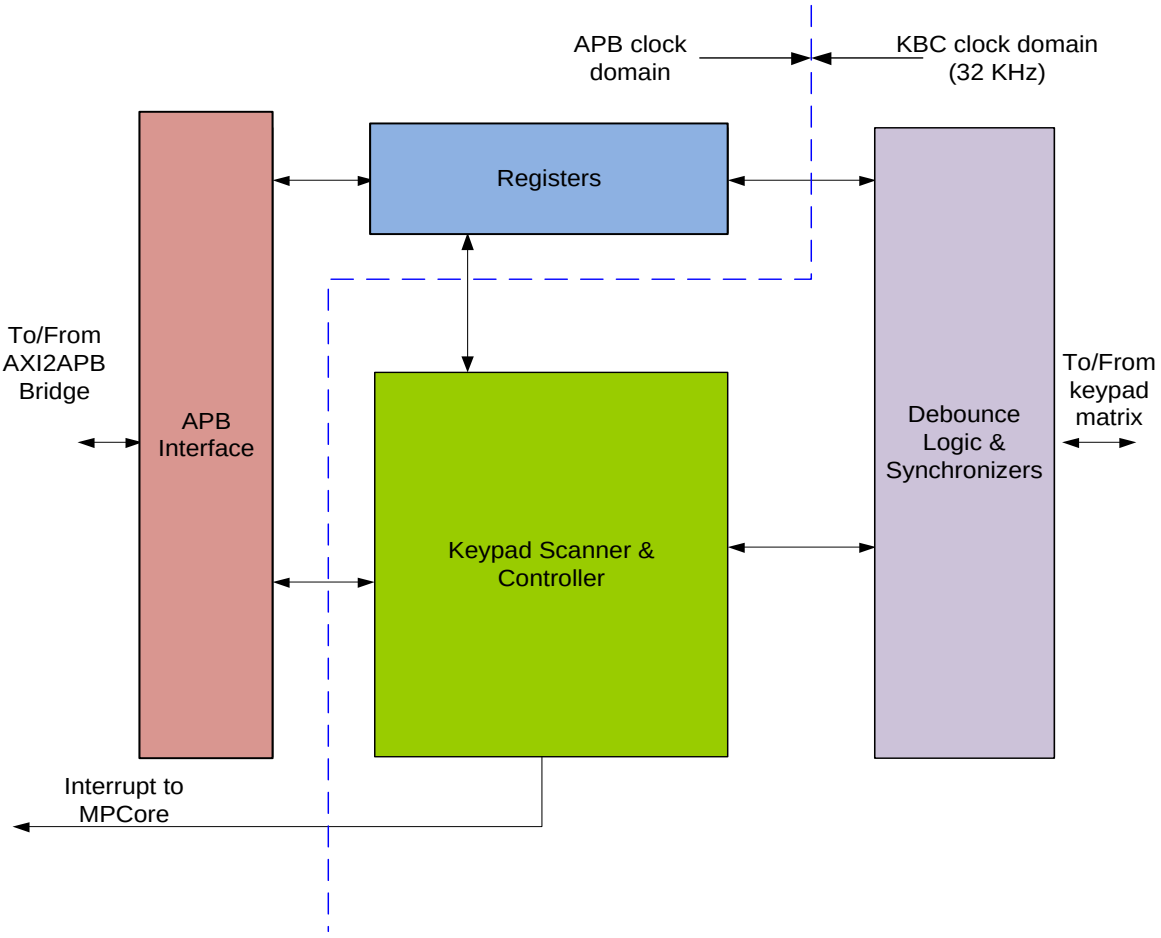


Clocking

- APB clock for APB interface and register sub-module
- KBC clock for keypad scanner and controller (32 KHz)

17.1 Functionality

Figure 43: KBC Functional Block Diagram



The keyboard controller is enabled when the enable bit is set, and some pins are configured for interfacing with keypad matrix. The pins which are not interfaced to the keypad matrix can be used as GPIO pins. To configure the KBC, the following registers should be programmed:

- APBDEV_KBC_ROW_CFG
- APBDEV_KBC_INT
- APBDEV_KBC_COL_CFG
- APBDEV_KBC_CONTROL

The KBC supports a keypad of maximum size 11 X 8 (row X column). All the pins interfacing with the keypad use debounce logic to detect a valid key press (filter out glitches).

Initially, the KBC is in wake-up state on key press (WuKP). In this mode, it waits for any key press. All rows are driven low to detect any key press in this state. Once a key is pressed, the KBC generates an optional key-press interrupt (KP_INT_STATUS in APBDEV_KBC_INT register), goes to continuous polling (CP) state and starts scanning after INIT_DLY_VAL (in APBDEV_KBC_INIT_DLY register) cycles.

In the CP state, the delay between two consecutive full scans is RPT_DLY_VAL (in APBDEV_KBC_RPT_DLY register) cycles. In the CP state, it scans all the rows one-by-one by driving one row low while other rows are configured as inputs so they are driven "Z". Then all the columns are sampled for each row scan.

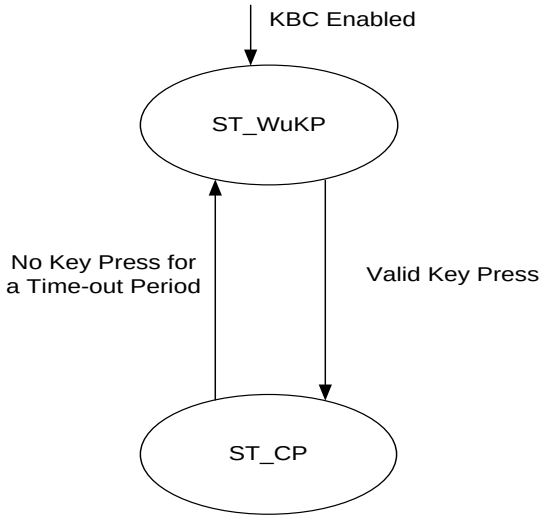
The driving of rows and sampling of columns is based on the debounce cycle. The KBC cycle is 32 KHz (time period = 31.25 microseconds). So if the debounce count is 4, one row scan takes 125 microseconds. One complete scan of all rows (16 maximum) takes 2 milliseconds. In one second there can be 500 complete scans (if RPT_DLY_VAL = 0).

The KBC supports up to eight simultaneous key presses per complete scan. These eight key numbers are stored in the APBDEV_KBC_KP_ENT0 and APBDEV_KBC_KP_ENT1 registers. The FIFO pointer increments on the second register entry register (APBDEV_KBC_KP_ENT1) read. Software should always read the two entry registers consecutively. It should first read APBDEV_KBC_KP_ENT0 and then read APBDEV_KBC_KP_ENT1.

To avoid more than one wrong key press, software should check the AV_FIFO_CNT value in APBDEV_KBC_INT register. The entry registers give new key-press information only when the AV_FIFO_CNT value is non-zero. A zero value indicates that there are no new key presses after the last read. To indicate whether an entry is valid or not, a valid bit is associated with every entry in the two entry registers.

Software should read the entry register fast enough in CP state to avoid overflow. To avoid an overflow in case of slow reads, the first level warning indicator can be programmed in FIFO_TH_CNT field of the APBDEV_KBC_CONTROL register. An optional interrupt (FIFO_CNT_INT_STATUS in APBDEV_KBC_INT register) can be generated when the FIFO occupancy count reaches this value. In case of overflow an optional interrupt (FIFO_OVF_INT_STATUS in APBDEV_KBC_INT register) is generated and software will have two options of treating the new entries. It can either drop them or overwrite them. This bit is FIFO_MODE in APBDEV_KBC_CONTROL register. The figure below shows KBC control of the SM.

Figure 44: KBC Control Logic



17.2 LP0 Entry/Exit Procedure

- The KBC shall be in Wake/Interrupt mode, i.e., the default state where all rows are driving zero and non-scan mode. To immediately abort the scan operation and enter wake mode, program a zero to the KBC register APBDEV_KBC_TO_CNT_0.
- Confirm the KBC enters wake mode, i.e., APBDEV_KBC_INT_0[KBC_ST_STATUS] shall be zero, restore the APBDEV_KBC_TO_CNT_0 with the appropriate value.
- Initiate LP0 Entry sequence.
- Exit the LP0 mode on KBC event.

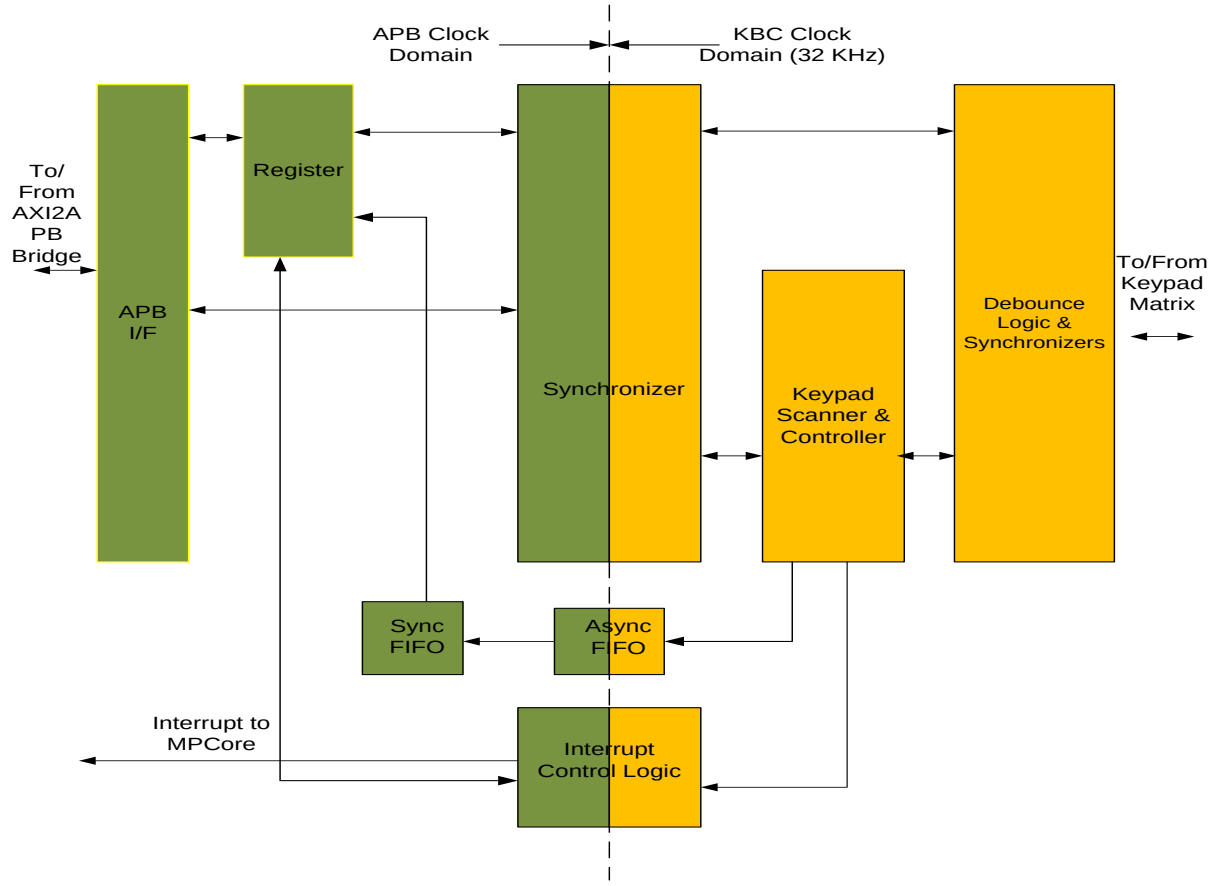
17.3 Micro-Architecture

17.3.1 Keypad Matrix

The next figure shows the top level diagram of the KBC with all the sub-modules. The Tegra 4 series KBC controller supports an 11x8 keypad matrix (11 rows and 8 columns). Up to eight simultaneous key presses can be stored per full scan (row scanning). Storage for key-press events is as follows: an asynchronous FIFO stores 1 key-press event, a synchronous FIFO stores 8 events, and a register stores 1 event.

A minimum of two rows must always be enabled.

Figure 45: KBC Block Diagram



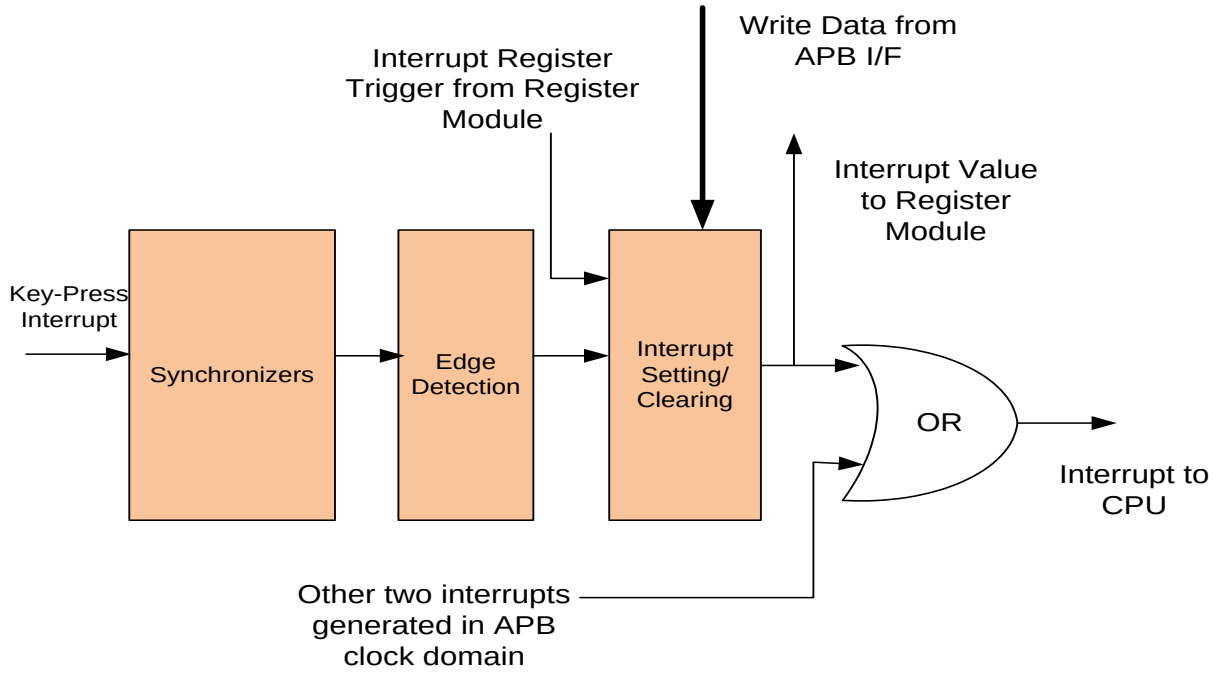
17.3.2 Synchronizer

Register sync from one synchronization from one clock domain to another is achieved through generation of a ‘valid’ signal. This valid signal is synchronized instead of all the data bits of the register. Unless an acknowledgment is received (for this ‘valid’) from the receiving side, the valid request is not deasserted and data (going to the receiving side) is not changed. The acknowledgment is deasserted only when valid request is deasserted. If there is no valid asserted for a register, the value to be transmitted is compared with the previous sent value and if they are unequal, the valid is asserted and the new data transmitted. Otherwise, valid remains deasserted and data is not changed. The module “async_cross_c” is used for this synchronization.

17.3.3 Interrupt Control Logic

The key-press interrupt is generated on the KBC clock, which is much slower than the APB and MPCore clocks. The interrupt should be cleared on the APB clock so that the delay between an interrupt clear in a register bit to actual deassertion of the interrupt is not visible to the MPCore. To deassert the interrupt in the APB clock domain, it is first synchronized. On a positive edge of interrupt from keypad scanner the interrupt to the MPCore is asserted and it is cleared when the corresponding register bit is written with a ‘1’. The other two interrupts (FIFO threshold count and overflow) are generated in the APB clock domain.

Figure 46: Interrupt Control Logic

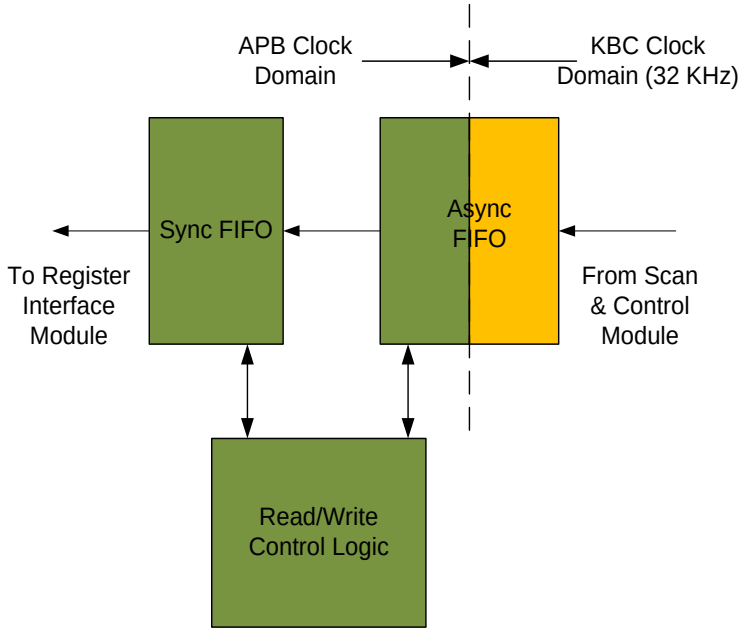


17.3.4 Keypad Scanner and Controller

This sub-module contains the main state machine. It controls the scanning, generates interrupts, identifies the keys which are pressed, and puts them into the appropriate registers. It also updates the KP_NEW_ENT* bits associated with all keys to indicate whether a key in the register is valid or not.

The software can program the KBC for two options in case of FIFO overflow. Either drop the new entries or overwrite the old entries with new entries. The design has two FIFOs: one single deep asynchronous FIFO and an eight deep synchronous FIFO. When the KBC is configured to overwrite on FIFO overflow, on getting an asynchronous FIFO non-empty signal when synchronous FIFO is full, a dummy read is done from synchronous FIFO. Then the asynchronous FIFO read value is written to

synchronous FIFO. This effectively overwrites the old entry. When the KBC is configured to drop new entries on FIFO overflow, this dummy read is not done which will effectively drop the entry.



17.3.5 Additional Interface Signals

kbc_interrrupt : An interrupt in the 32 KHz domain is sent to PMC and is used to wake up the system.

17.3.6 Pull-ups and Pull-downs in Pads

All the pads have pull-ups and pull-down bits which can be programmed by the software per your requirement(s). Contact your NVIDIA representative for details on the pull-up/pull-down registers.

Rows are always outputs to the Tegra 4 series processor and Columns are inputs. Row and Columns for the I/O can be programmed by software as needed. For Tegra 4 series processors the following I/O mapping is used:

ROW [15:0] --- gp3_pr [7:0], gp3_ps [2:0]

COLUMN [7:0] --- gp3_pq[7:0]

17.4 Programming Guidelines

The keyboard controller is enabled when the enable bit is set and some pins are configured for interfacing with the keypad matrix. The pins which are not interfaced to the keypad matrix can be used as GPIO pins.

To configure the KBC, the following registers should be programmed:

- APBDEV_KBC_ROW_CFG
- APBDEV_KBC_INT
- APBDEV_KBC_COL_CFG
- APBDEV_KBC_CONTROL.

The KBC supports a keypad of maximum size 11 X 8 (row X column). All the pins interfacing with the keypad use debounce logic to detect a valid key press (filter out glitches).

To avoid an overflow in case of slow reads, the first level warning indicator can be programmed in the FIFO_TH_CNT field of the APBDEV_KBC_CONTROL register.

In case of overflow, software will have two options of treating the new entries: either drop them or overwrite them. This bit is FIFO_MODE in the APBDEV_KBC_CONTROL register.

17.5 KBC Registers

Refer to “Reading Register Tables” in the Introduction section for the register table protocol as well as recommendations for accessing registers.

17.5.1 APBDEV_KBC_CONTROL_0

KBC control register. This register is the main control register. It should be configured last after all other settings are configured.

Offset: 0x0 | Read/Write: R/W | Reset: 0x00010000 (0bxxxxxxxxxxxxxx00100000000000000000)

Bit	Reset	Description
18	0x0	FIFO_MODE: Selects the behavior in case of FIFO overflow. 0 = Drop the new detected key presses. 1 = Overwrite the new detected key presses
17:14	0x4	FIFO_TH_CNT: FIFO threshold count. Keeps the threshold FIFO occupancy count. If the FIFO reaches/crosses that count an optional interrupt will be raised. Should not be programmed as 0. N = Threshold occupancy count is N
13:4	0x0	DBC_CNT: Debounce count. This value sets the debounce FSM associated with each KBC input pin evaluate the input transitions. 0 = No debounce. N = N KBC clocks
3	0x0	FIFO_CNT_INT_EN: FIFO threshold count interrupt enable. Setting this bit will enable interrupts when FIFO occupancy reaches/crosses the value specified in FIFO_TH_CNT. 0 = Disable FIFO overflow interrupt. 1 = Enable FIFO overflow interrupt
2	0x0	FIFO_OVF_INT_EN: FIFO overflow interrupt enable. Setting this bit will enable interrupt on FIFO overflow
1	0x0	KP_INT_EN: Key-press interrupt enable. Setting this bit will enable interrupt on any key press 0 = DISABLE 1 = ENABLE
0	0x0	EN: Keyboard controller enable. Setting this bit will override the pins settings done in GPIO 0 = DISABLE 1 = ENABLE

17.5.2 APBDEV_KBC_INT_0

KBC Interrupt Status and Clear Register

Offset: 0x4 | Read/Write: R/W | Reset: 0x00000000 (0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx000)

Bit	R/W	Reset	Description
7:4	RO	X	AV_FIFO_CNT: FIFO occupancy count. Shows the number of unread registers.
3	RO	X	KBC_ST_STATUS: KBC status. 0 = WuKP (Wake-up on key press) interrupt mode. 1 = CP (Continuous polling) mode
2	RW	0x0	FIFO_CNT_INT_STATUS: FIFO threshold count interrupt status. Writing '1' to this bit will clear the interrupt. 0 = FIFO threshold count interrupt deasserted. 1 = FIFO threshold count interrupt asserted (read). 1 = Clear FIFO overflow interrupt (write)

Bit	R/W	Reset	Description
1	RW	0x0	FIFO_OVF_INT_STATUS: FIFO overflow interrupt status. Writing '1' to this bit will clear the interrupt. 0 = FIFO overflow interrupt deasserted. 1 = FIFO overflow interrupt asserted (read). 1 = Clear FIFO overflow interrupt (write)
0	RW	0x0	KP_INT_STATUS: Key-press interrupt status. Writing '1' to this bit will clear the interrupt. 0 = Key-press interrupt deasserted. 1 = Key-press interrupt asserted (read). 1 = Clear key-press interrupt (write)

17.5.3 APBDEV_KBC_ROW_CFG0_0

First row configuration register. This register setting will take precedence in case the same GPIO pin is configured in the column register also. It does the mapping between the GPIO pins and rows of the keypad matrix. It configures for GPIO pin numbers 0 to 5.

Offset: 0x8 | Read/Write: R/W | Reset: 0x00000000 (0bxx00000000000000000000000000000000)

Bit	Reset	Description
29:26	0x0	GPIO_5_ROW_NUM: Mapping of GPIO pin #5 to row number. Valid only if GPIO_5_ROW_EN is set. Indicates row number. 0x0 = Row number 0. 0xF = Row number 15
25	0x0	GPIO_5_ROW_EN: Indicates whether GPIO pin #5 is mapped to any row of the keypad matrix. This bit overrides any setting done for pin #5 in column configuration 0 = NOT_MAPPED 1 = MAPPED
24:21	0x0	GPIO_4_ROW_NUM: Mapping of GPIO pin #4 to row number. Valid only if GPIO_4_ROW_EN is set. Indicates row number. 0x0 = Row number 0. 0xF = Row number 15
20	0x0	GPIO_4_ROW_EN: Indicates whether GPIO pin #4 is mapped to any row of the keypad matrix. This bit overrides any setting done for pin #4 in column configuration 0 = NOT_MAPPED 1 = MAPPED
19:16	0x0	GPIO_3_ROW_NUM: Mapping of GPIO pin #3 to row number. Valid only if GPIO_3_ROW_EN is set. Indicates row number. 0x0 = Row number 0. 0xF = Row number 15
15	0x0	GPIO_3_ROW_EN: Indicates whether GPIO pin #3 is mapped to any row of the keypad matrix. This bit overrides any setting done for pin #3 in column configuration 0 = NOT_MAPPED 1 = MAPPED
14:11	0x0	GPIO_2_ROW_NUM: Mapping of GPIO pin #2 to row number. Valid only if GPIO_2_ROW_EN is set. Indicates row number. 0x0 = Row number 0. 0xF = Row number 15
10	0x0	GPIO_2_ROW_EN: Indicates whether GPIO pin #2 is mapped to any row of the keypad matrix. This bit overrides any setting done for pin #2 in column configuration 0 = NOT_MAPPED 1 = MAPPED
9:6	0x0	GPIO_1_ROW_NUM: Mapping of GPIO pin #1 to row number. Valid only if GPIO_1_ROW_EN is set. Indicates row number. 0x0 = Row number 0. 0xF = Row number 15
5	0x0	GPIO_1_ROW_EN: Indicates whether GPIO pin #1 is mapped to any row of the keypad matrix. This bit overrides any setting done for pin #1 in column configuration 0 = NOT_MAPPED 1 = MAPPED
4:1	0x0	GPIO_0_ROW_NUM: Mapping of GPIO pin #0 to row number. Valid only if GPIO_0_ROW_EN is set. Indicates row number. 0x0 = Row number 0. 0xF = Row number 15

Bit	Reset	Description
0	0x0	GPIO_0_ROW_EN: Indicates whether GPIO pin #0 is mapped to any row of the keypad matrix. This bit overrides any setting done for pin #0 in column configuration 0 = NOT_MAPPED 1 = MAPPED

17.5.4 APBDEV_KBC_ROW_CFG1_0

Second row configuration register. This register setting will take precedence in case the same GPIO pin is configured in the column register also. It does the mapping between the GPIO pins and rows of the keypad matrix. It configures for GPIO pin numbers 6 to 11.

Offset: 0xc | Read/Write: R/W | Reset: 0x00000000 (0bxx00000000000000000000000000000000)

Bit	Reset	Description
29:26	0x0	GPIO_11_ROW_NUM: Mapping of GPIO pin #11 to row number. Valid only if GPIO_11_ROW_EN is set. Indicates row number. 0x0 = Row number 0. 0xF = Row number 15
25	0x0	GPIO_11_ROW_EN: Indicates whether GPIO pin #11 is mapped to any row of the keypad matrix. This bit overrides any setting done for pin #11 in column configuration 0 = NOT_MAPPED 1 = MAPPED
24:21	0x0	GPIO_10_ROW_NUM: Mapping of GPIO pin #10 to row number. Valid only if GPIO_10_ROW_EN is set. Indicates row number. 0x0 = Row number 0. 0xF = Row number 15
20	0x0	GPIO_10_ROW_EN: Indicates whether GPIO pin #10 is mapped to any row of the keypad matrix. This bit overrides any setting done for pin #10 in column configuration 0 = NOT_MAPPED 1 = MAPPED
19:16	0x0	GPIO_9_ROW_NUM: Mapping of GPIO pin #9 to row number. Valid only if GPIO_9_ROW_EN is set. Indicates row number. 0x0 = Row number 0. 0xF = Row number 15
15	0x0	GPIO_9_ROW_EN: Indicates whether GPIO pin #9 is mapped to any row of the keypad matrix. This bit overrides any setting done for pin #9 in column configuration 0 = NOT_MAPPED 1 = MAPPED
14:11	0x0	GPIO_8_ROW_NUM: Mapping of GPIO pin #8 to row number. Valid only if GPIO_8_ROW_EN is set. Indicates row number. 0x0 = Row number 0. 0xF = Row number 15
10	0x0	GPIO_8_ROW_EN: Indicates whether GPIO pin #8 is mapped to any row of the keypad matrix. This bit overrides any setting done for pin #8 in column configuration 0 = NOT_MAPPED 1 = MAPPED
9:6	0x0	GPIO_7_ROW_NUM: Mapping of GPIO pin #7 to row number. Valid only if GPIO_7_ROW_EN is set. Indicates row number. 0x0 = Row number 0. 0xF = Row number 15
5	0x0	GPIO_7_ROW_EN: Indicates whether GPIO pin #7 is mapped to any row of the keypad matrix. This bit overrides any setting done for pin #7 in column configuration 0 = NOT_MAPPED 1 = MAPPED
4:1	0x0	GPIO_6_ROW_NUM: Mapping of GPIO pin #6 to row number. Valid only if GPIO_6_ROW_EN is set. Indicates row number. 0x0 = Row number 0. 0xF = Row number 15
0	0x0	GPIO_6_ROW_EN: Indicates whether GPIO pin #6 is mapped to any row of the keypad matrix. This bit overrides any setting done for pin #6 in column configuration 0 = NOT_MAPPED 1 = MAPPED

17.5.5 APBDEV_KBC_ROW_CFG2_0

Third row configuration register. This register setting will take precedence in case the same GPIO pin is configured in column register also. It does the mapping between the GPIO pins and rows of the keypad matrix. It configures for GPIO pin numbers 12 to 17.

Offset: 0x10 | Read/Write: R/W | Reset: 0x00000000 (0bxx00000000000000000000000000000000)

Bit	Reset	Description
29:26	0x0	GPIO_17_ROW_NUM: Mapping of GPIO pin #17 to row number. Valid only if GPIO_17_ROW_EN is set. Indicates row number. 0x0 = Row number 0. 0xF = Row number 15
25	0x0	GPIO_17_ROW_EN: Indicates whether GPIO pin #17 is mapped to any row of the keypad matrix. This bit overrides any setting done for pin #17 in column configuration 0 = NOT_MAPPED 1 = MAPPED
24:21	0x0	GPIO_16_ROW_NUM: Mapping of GPIO pin #16 to row number. Valid only if GPIO_16_ROW_EN is set. Indicates row number. 0x0 = Row number 0. 0xF = Row number 15
20	0x0	GPIO_16_ROW_EN: Indicates whether GPIO pin #16 is mapped to any row of the keypad matrix. This bit overrides any setting done for pin #16 in column configuration 0 = NOT_MAPPED 1 = MAPPED
19:16	0x0	GPIO_15_ROW_NUM: Mapping of GPIO pin #15 to row number. Valid only if GPIO_15_ROW_EN is set. Indicates row number. 0x0 = Row number 0. 0xF = Row number 15
15	0x0	GPIO_15_ROW_EN: Indicates whether GPIO pin #15 is mapped to any row of the keypad matrix. This bit overrides any setting done for pin #15 in column configuration 0 = NOT_MAPPED 1 = MAPPED
14:11	0x0	GPIO_14_ROW_NUM: Mapping of GPIO pin #14 to row number. Valid only if GPIO_14_ROW_EN is set. Indicates row number. 0x0 = Row number 0. 0xF = Row number 15
10	0x0	GPIO_14_ROW_EN: Indicates whether GPIO pin #14 is mapped to any row of the keypad matrix. This bit overrides any setting done for pin #14 in column configuration 0 = NOT_MAPPED 1 = MAPPED
9:6	0x0	GPIO_13_ROW_NUM: Mapping of GPIO pin #13 to row number. Valid only if GPIO_13_ROW_EN is set. Indicates row number. 0x0 = Row number 0. 0xF = Row number 15
5	0x0	GPIO_13_ROW_EN: Indicates whether GPIO pin #13 is mapped to any row of the keypad matrix. This bit overrides any setting done for pin #13 in column configuration 0 = NOT_MAPPED 1 = MAPPED
4:1	0x0	GPIO_12_ROW_NUM: Mapping of GPIO pin #12 to row number. Valid only if GPIO_12_ROW_EN is set. Indicates row number. 0x0 = Row number 0. 0xF = Row number 15
0	0x0	GPIO_12_ROW_EN: Indicates whether GPIO pin #12 is mapped to any row of the keypad matrix. This bit overrides any setting done for pin #12 in column configuration 0 = NOT_MAPPED 1 = MAPPED

17.5.6 APBDEV_KBC_ROW_CFG3_0

Fourth row configuration register. This register setting will take precedence in case the same GPIO pin is configured in the column register also. It does the mapping between the GPIO pins and rows of the keypad matrix. It configures for GPIO pin numbers 18 to 23.

Offset: 0x14 | Read/Write: R/W | Reset: 0x00000000 (0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx00000)

Bit	Reset	Description
4:1	0x0	GPIO_18_ROW_NUM: Mapping of GPIO pin #18 to row number. Valid only if GPIO_18_ROW_EN is set. Indicates row number. 0x0 = Row number 0. 0xF = Row number 15
0	0x0	GPIO_18_ROW_EN: Indicates whether GPIO pin #18 is mapped to any row of the keypad matrix. This bit overrides any setting done for pin #18 in column configuration 0 = NOT_MAPPED 1 = MAPPED

17.5.7 APBDEV_KBC_COL_CFG0_0

First column configuration register. It does the mapping between the GPIO pins and columns of the keypad matrix. It configures for GPIO pin numbers 0 to 7.

Offset: 0x18 | Read/Write: R/W | Reset: 0x00000000 (0b00000000000000000000000000000000)

Bit	Reset	Description
31:29	0x0	GPIO_7_COL_NUM: Mapping of GPIO pin #7 to column number. Valid only if GPIO_7_COL_EN is set. Indicates row number. 0x0 = Column number 0. 0x7 = Column number 7
28	0x0	GPIO_7_COL_EN: Indicates whether GPIO pin #7 is mapped to any column of the keypad matrix. This bit should be set to '1' only when GPIO_7_ROW_EN in ROW_CFG1 is set to 0. 0 = NOT_MAPPED 1 = MAPPED
27:25	0x0	GPIO_6_COL_NUM: Mapping of GPIO pin #6 to column number. Valid only if GPIO_6_COL_EN is set. Indicates row number. 0x0 = Column number 0. 0x7 = Column number 7
24	0x0	GPIO_6_COL_EN: Indicates whether GPIO pin #6 is mapped to any column of the keypad matrix. This bit should be set to '1' only when GPIO_6_ROW_EN in ROW_CFG1 is set to 0. 0 = NOT_MAPPED 1 = MAPPED
23:21	0x0	GPIO_5_COL_NUM: Mapping of GPIO pin #5 to column number. Valid only if GPIO_5_COL_EN is set. Indicates row number. 0x0 = Column number 0. 0x7 = Column number 7
20	0x0	GPIO_5_COL_EN: Indicates whether GPIO pin #5 is mapped to any column of the keypad matrix. This bit should be set to '1' only when GPIO_5_ROW_EN in ROW_CFG0 is set to 0. 0 = NOT_MAPPED 1 = MAPPED
19:17	0x0	GPIO_4_COL_NUM: Mapping of GPIO pin #4 to column number. Valid only if GPIO_4_COL_EN is set. Indicates row number. 0x0 = Column number 0. 0x7 = Column number 7
16	0x0	GPIO_4_COL_EN: Indicates whether GPIO pin #4 is mapped to any column of the keypad matrix. This bit should be set to '1' only when GPIO_4_ROW_EN in ROW_CFG0 is set to 0. 0 = NOT_MAPPED 1 = MAPPED
15:13	0x0	GPIO_3_COL_NUM: Mapping of GPIO pin #3 to column number. Valid only if GPIO_3_COL_EN is set. Indicates row number. 0x0 = Column number 0. 0x7 = Column number 7
12	0x0	GPIO_3_COL_EN: Indicates whether GPIO pin #3 is mapped to any column of the keypad matrix. This bit should be set to '1' only when GPIO_3_ROW_EN in ROW_CFG0 is set to 0. 0 = NOT_MAPPED 1 = MAPPED
11:9	0x0	GPIO_2_COL_NUM: Mapping of GPIO pin #2 to column number. Valid only if GPIO_2_COL_EN is set. Indicates row number. 0x0 = Column number 0. 0x7 = Column number 7

Bit	Reset	Description
8	0x0	GPIO_2_COL_EN: Indicates whether GPIO pin #2 is mapped to any column of the keypad matrix. This bit should be set to '1' only when GPIO_2_ROW_EN in ROW_CFG0 is set to 0. 0 = NOT_MAPPED 1 = MAPPED
7:5	0x0	GPIO_1_COL_NUM: Mapping of GPIO pin #1 to column number. Valid only if GPIO_1_COL_EN is set. Indicates row number. 0x0 = Column number 0. 0x7 = Column number 7
4	0x0	GPIO_1_COL_EN: Indicates whether GPIO pin #1 is mapped to any column of the keypad matrix. This bit should be set to '1' only when GPIO_1_ROW_EN in ROW_CFG0 is set to 0. 0 = NOT_MAPPED 1 = MAPPED
3:1	0x0	GPIO_0_COL_NUM: Mapping of GPIO pin #0 to column number. Valid only if GPIO_0_COL_EN is set. Indicates row number. 0x0 = Column number 0. 0x7 = Column number 7
0	0x0	GPIO_0_COL_EN: Indicates whether GPIO pin #0 is mapped to any column of the keypad matrix. This bit should be set to '1' only when GPIO_0_ROW_EN in ROW_CFG0 is set to 0. 0 = NOT_MAPPED 1 = MAPPED

17.5.8 APBDEV_KBC_COL_CFG1_0

Second column configuration register. It does the mapping between the GPIO pins and columns of the keypad matrix. It configures for GPIO pin numbers 8 to 15.

Offset: 0x1c | Read/Write: R/W | Reset: 0x00000000 (0b00000000000000000000000000000000)

Bit	Reset	Description
31:29	0x0	GPIO_15_COL_NUM: Mapping of GPIO pin #15 to column number. Valid only if GPIO_15_COL_EN is set. Indicates row number. 0x0 = Column number 0. 0x7 = Column number 7
28	0x0	GPIO_15_COL_EN: Indicates whether GPIO pin #15 is mapped to any column of the keypad matrix. This bit should be set to '1' only when GPIO_15_ROW_EN in ROW_CFG2 is set to 0. 0 = NOT_MAPPED 1 = MAPPED
27:25	0x0	GPIO_14_COL_NUM: Mapping of GPIO pin #14 to column number. Valid only if GPIO_14_COL_EN is set. Indicates row number. 0x0 = Column number 0. 0x7 = Column number 7
24	0x0	GPIO_14_COL_EN: Indicates whether GPIO pin #14 is mapped to any column of the keypad matrix. This bit should be set to '1' only when GPIO_14_ROW_EN in ROW_CFG2 is set to 0. 0 = NOT_MAPPED 1 = MAPPED
23:21	0x0	GPIO_13_COL_NUM: Mapping of GPIO pin #13 to column number. Valid only if GPIO_13_COL_EN is set. Indicates row number. 0x0 = Column number 0. 0x7 = Column number 7
20	0x0	GPIO_13_COL_EN: Indicates whether GPIO pin #13 is mapped to any column of the keypad matrix. This bit should be set to '1' only when GPIO_13_ROW_EN in ROW_CFG2 is set to 0. 0 = NOT_MAPPED 1 = MAPPED
19:17	0x0	GPIO_12_COL_NUM: Mapping of GPIO pin #12 to column number. Valid only if GPIO_12_COL_EN is set. Indicates row number. 0x0 = Column number 0. 0x7 = Column number 7
16	0x0	GPIO_12_COL_EN: Indicates whether GPIO pin #12 is mapped to any column of the keypad matrix. This bit should be set to '1' only when GPIO_12_ROW_EN in ROW_CFG2 is set to 0. 0 = NOT_MAPPED 1 = MAPPED
15:13	0x0	GPIO_11_COL_NUM: Mapping of GPIO pin #11 to column number. Valid only if GPIO_11_COL_EN is set. Indicates row number. 0x0 = Column number 0. 0x7 = Column number 7

Bit	Reset	Description
12	0x0	GPIO_11_COL_EN: Indicates whether GPIO pin #11 is mapped to any column of the keypad matrix. This bit should be set to '1' only when GPIO_11_ROW_EN in ROW_CFG1 is set to 0. 0 = NOT_MAPPED 1 = MAPPED
11:9	0x0	GPIO_10_COL_NUM: Mapping of GPIO pin #10 to column number. Valid only if GPIO_10_COL_EN is set. Indicates row number. 0x0 = Column number 0. 0x7 = Column number 7
8	0x0	GPIO_10_COL_EN: Indicates whether GPIO pin #10 is mapped to any column of the keypad matrix. This bit should be set to '1' only when GPIO_10_ROW_EN in ROW_CFG1 is set to 0. 0 = NOT_MAPPED 1 = MAPPED
7:5	0x0	GPIO_9_COL_NUM: Mapping of GPIO pin #9 to column number. Valid only if GPIO_9_COL_EN is set. Indicates row number. 0x0 = Column number 0. 0x7 = Column number 7
4	0x0	GPIO_9_COL_EN: Indicates whether GPIO pin #9 is mapped to any column of the keypad matrix. This bit should be set to '1' only when GPIO_9_ROW_EN in ROW_CFG1 is set to 0. 0 = NOT_MAPPED 1 = MAPPED
3:1	0x0	GPIO_8_COL_NUM: Mapping of GPIO pin #8 to column number. Valid only if GPIO_8_COL_EN is set. Indicates row number. 0x0 = Column number 0. 0x7 = Column number 7
0	0x0	GPIO_8_COL_EN: Indicates whether GPIO pin #8 is mapped to any column of the keypad matrix. This bit should be set to '1' only when GPIO_8_ROW_EN in ROW_CFG1 is set to 0. 0 = NOT_MAPPED 1 = MAPPED

17.5.9 APBDEV_KBC_COL_CFG2_0

Third column configuration register. It does the mapping between the GPIO pins and columns of the keypad matrix. It configures for GPIO pin numbers 16 to 23.

Offset: 0x20 | Read/Write: R/W | Reset: 0x00000000 (0bxxxxxxxxxxxxxxxxxxxxxx000000000000)

Bit	Reset	Description
11:9	0x0	GPIO_18_COL_NUM: Mapping of GPIO pin #18 to column number. Valid only if GPIO_18_COL_EN is set. Indicates row number. 0x0 = Column number 0. 0x7 = Column number 7
8	0x0	GPIO_18_COL_EN: Indicates whether GPIO pin #18 is mapped to any column of the keypad matrix. This bit should be set to '1' only when GPIO_18_ROW_EN in ROW_CFG3 is set to 0. 0 = NOT_MAPPED 1 = MAPPED
7:5	0x0	GPIO_17_COL_NUM: Mapping of GPIO pin #17 to column number. Valid only if GPIO_17_COL_EN is set. Indicates row number. 0x0 = Column number 0. 0x7 = Column number 7
4	0x0	GPIO_17_COL_EN: Indicates whether GPIO pin #17 is mapped to any column of the keypad matrix. This bit should be set to '1' only when GPIO_17_ROW_EN in ROW_CFG2 is set to 0. 0 = NOT_MAPPED 1 = MAPPED
3:1	0x0	GPIO_16_COL_NUM: Mapping of GPIO pin #16 to column number. Valid only if GPIO_16_COL_EN is set. Indicates row number. 0x0 = Column number 0. 0x7 = Column number 7
0	0x0	GPIO_16_COL_EN: Indicates whether GPIO pin #16 is mapped to any column of the keypad matrix. This bit should be set to '1' only when GPIO_16_ROW_EN in ROW_CFG2 is set to 0. 0 = NOT_MAPPED 1 = MAPPED

17.5.10 APBDEV_KBC_TO_CNT_0

Continuous polling (CP) state time-out count register. This register holds the time-out count value.

In CP state, if the corresponding counter crosses this value KBC goes back to WuKP (Wake-up on Key-press state).

Offset: 0x24 | Read/Write: R/W | Reset: 0x00027100 (0bxxxxxxxxxxxxx00100111000100000000)

Bit	Reset	Description
19:0	0x27100	TO_CNT_VAL: Time-out count value. The default value is 5 seconds. The value should be calculated for a 32 KHz clock.

17.5.11 APBDEV_KBC_INIT_DLY_0

This register holds the initial delay for scan when KBC goes from WuKP mode to CP mode.

Offset: 0x28 | Read/Write: R/W | Reset: 0x00000400 (0bxxxxxxxxxxxxx00000000010000000000)

Bit	Reset	Description
19:0	0x400	INIT_DLY_VAL: Initial delay value. The default value is 32.25 milliseconds. The value should be calculated for a 32 KHz clock.

17.5.12 APBDEV_KBC_RPT_DLY_0

This register holds the repeat scan delay. This is the delay between two successive scans in CP mode.

Offset: 0x2c | Read/Write: R/W | Reset: 0x00000400 (0bxxxxxxxxxxxxx00000000010000000000)

Bit	Reset	Description
19:0	0x400	RPT_DLY_VAL: delay value. The default value is 32.25 milliseconds. The value should be calculated for a 32 KHz clock.

17.5.13 APBDEV_KBC_KP_ENT0_0

First key-press entries register. This register holds the key numbers of the keys which have been pressed. It holds the first four entries.

Note: Both entry registers should be read consecutively. A read of the first register changes the FIFO read pointer

Offset: 0x30 | Read/Write: RO | Reset: 0x00000000 (0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx)

Bit	Reset	Description
31	X	KP_NEW_ENT3: Indicates whether fourth entry is valid or not. 0x0 = Entry not valid. 0x1 = Valid entry
30:27	X	KP_ROW_NUM_ENT3: Row number for fourth key. 0x0 = Row number 0. 0xF = Row number 15
26:24	X	KP_COL_NUM_ENT3: Column number for fourth key. 0x0 = Column number 0. 0x7 = Column number 7
23	X	KP_NEW_ENT2: Indicates whether third entry is valid or not. 0x0 = Entry not valid. 0x1 = Valid entry
22:19	X	KP_ROW_NUM_ENT2: Row number for third key. 0x0 = Row number 0. 0xF = Row number 15
18:16	X	KP_COL_NUM_ENT2: Column number for third key. 0x0 = Column number 0. 0x7 = Column number 7
15	X	KP_NEW_ENT1: Indicates whether second entry is valid or not. 0x0 = Entry not valid. 0x1 = Valid entry

Bit	Reset	Description
14:11	X	KP_ROW_NUM_ENT1: Row number for second key. 0x0 = Row number 0. 0xF = Row number 15
10:8	X	KP_COL_NUM_ENT1: Column number for second key. 0x0 = Column number 0. 0x7 = Column number 7
7	X	KP_NEW_ENT0: Indicates whether first entry is valid or not. 0x0 = Entry not valid. 0x1 = Valid entry
6:3	X	KP_ROW_NUM_ENT0: Row number for first key. 0x0 = Row number 0. 0xF = Row number 15
2:0	X	KP_COL_NUM_ENT0: Column number for first key. 0x0 = Column number 0. 0x7 = Column number 7

17.5.14 APBDEV_KBC_KP_ENT1_0

Second key-press entries register. This register holds the key numbers of the keys which have been pressed. It holds the last four entries (out of eight entries)

Note: Both entry registers should be read consecutively. A read of the first register changes the FIFO read pointer

Offset: 0x34 | Read/Write: RO | Reset: 0x00000000 (0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx)

Bit	Reset	Description
31	X	KP_NEW_ENT7: Indicates whether eighth entry is valid or not. 0x0 = Entry not valid. 0x1 = Valid entry
30:27	X	KP_ROW_NUM_ENT7: Row number for eighth key. 0x0 = Row number 0. 0xF = Row number 15
26:24	X	KP_COL_NUM_ENT7: Column number for eighth key. 0x0 = Column number 0. 0x7 = Column number 7
23	X	KP_NEW_ENT6: Indicates whether seventh entry is valid or not. 0x0 = Entry not valid. 0x1 = Valid entry
22:19	X	KP_ROW_NUM_ENT6: Row number for seventh key. 0x0 = Row number 0. 0xF = Row number 15
18:16	X	KP_COL_NUM_ENT6: Column number for seventh key. 0x0 = Column number 0. 0x7 = Column number 7
15	X	KP_NEW_ENT5: Indicates whether sixth entry is valid or not. 0x0 = Entry not valid. 0x1 = Valid entry
14:11	X	KP_ROW_NUM_ENT5: Row number for sixth key. 0x0 = Row number 0. 0xF = Row number 15
10:8	X	KP_COL_NUM_ENT5: Column number for sixth key. 0x0 = Column number 0. 0x7 = Column number 7
7	X	KP_NEW_ENT4: Indicates whether fifth entry is valid or not. 0x0 = Entry not valid. 0x1 = Valid entry
6:3	X	KP_ROW_NUM_ENT4: Row number for fifth key. 0x0 = Row number 0. 0xF = Row number 15
2:0	X	KP_COL_NUM_ENT4: Column number for fifth key. 0x0 = Column number 0. 0x7 = Column number 7

17.5.15 APBDEV_KBC_ROW0_MASK_0

Offset: 0x38 | Read/Write: R/W | Reset: 0x00000000 (0bxxxxxxxxxxxxxxxxxxxxxxxx00000000)

18.0 CPU

The NVIDIA® Tegra® 4 series processor CPU complex contains quad ARM® Cortex™-A15 CPUs in a 4-PLUS-1 configuration with a fifth architecturally identical power-saving Cortex-A15 Companion Core.

18.1 Cortex-A15 CPU

Cortex-A15 is an advanced processor design with many features for high instruction throughput. It integrates the L2 cache controller into the CPU complex unlike Cortex-A9. All of the CPUs include the NEON Media Processing Engine. Further details of the Cortex-A15 itself are available from ARM.

These two documents are the key references on Cortex-A15, and both are available from ARM's website:

- Cortex-A15
  Revision: r2p1
  Technical Reference Manual

  Published by ARM Limited, document number ARM DDI 0438D.
- ARM Architecture Reference Manual
  ARM v7-A and ARM v7-R edition

  Published by ARM Limited, document number ARM DDI 0406C.

Note: These are the current versions at the time of writing. You should periodically look for updates and always refer to the latest available version of this material.

You should also review the latest version of the ARM errata for Cortex-A15. We expect ARM to publish this on their website, but at the time of writing it is not available publicly. Consult your NVIDIA AE for more details.

18.1.1 Cortex-A15 Implementation Details

Many aspects of the Cortex-A15 may be configured for a specific implementation. The Tegra 4 implementation has the following features:

Cortex-A15 Processor Configuration		
	Option	
Feature	**Main Quad-Core Complex**	**Companion Core**
Processor Revision	r2p3	r2p3
Number of processors	4	1
L2 Cache Size	2MB	512KB
L2 Arbitration register slice	1	0
L2 Tag RAM register slice	1	1
L2 Data RAM register slice	1	1
L2 Tag RAM latency	2	2
L2 Data RAM latency	3 cycle	2 cycle
L2 Logic idle gated clock	Included	Included
ECC/parity support	None	None

Cortex-A15 Processor Configuration		
	Option	
Feature	Main Quad-Core Complex	Companion Core
VFP and Neon	Included	Included
Generic Interrupt Controller	Included	Included
Shared Peripheral Interrupts	160	160

18.2 4-Plus-1 Configuration and Control

The NVIDIA 4-PLUS-1 processor architecture has a fifth Companion Core available for low power operation. In addition to the main quad core CPU complex, the Companion Core is an additional CPU complex replicating CPU 0 of the main complex, and implemented in a low-leakage technology. The Companion Core is also sometimes referred to by its engineering name, the "shadow" core; and also is commonly referred to as the LP Core or LP CPU Cluster referring to its Low Power operating capability.

The goal of this architecture is to provide efficient CPU operation across a very broad range of processor loads, with the quad-core complex optimized for high-speed operation with low dynamic power, and the Companion Core optimized for low-speed operation where transistor leakage becomes an important factor in power. These two CPU complexes operate exclusively to each other, meaning the hardware does not support simultaneous operation in any form. The main quad core complex has 2 Megabytes of L2 cache RAM, the companion core as a separate 512 Kilobyte L2 cache RAM.

The quad core complex implements separate power-gating for each of the four cores, and also a fifth power gate domain for the shared logic and L2.

Refer to the Flow Controller section of this document for details on how this is controlled.

19.0 FLOW CONTROLLER

The flow controller provides the sequencing of hardware-controlled CPU power states for the main CPU complex and the AVP coprocessor (also known as COP). It also provides hardware support for CPU cluster switching between the fast quad-core complex and the companion core.

The flow controller receives CPU power-state requests from CPUs, prioritizes them, and sends power on/off requests to PMC, which powers gates/un-gates corresponding CPUs. It monitors per CPU interrupts and events to determine CPU wake condition and initiates the CPU wake based on wake events/interrupts.

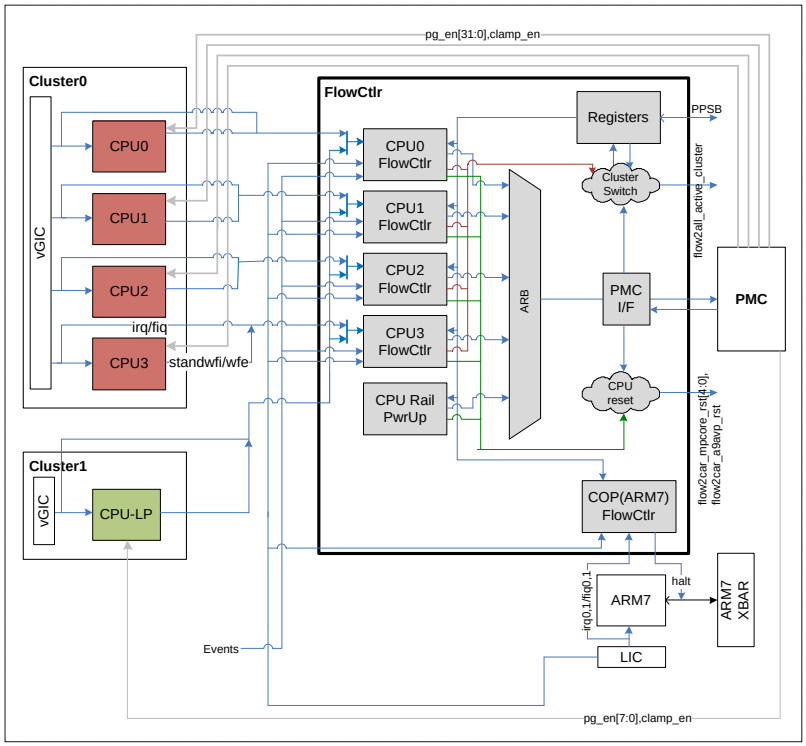
The flow controller provides configuration registers for software to configure wake events, etc. The flow controller provides a mechanism to halt conditionally or unconditionally:

- Conditional halt/resume is based on a variety of events, including timers, external trigger, and internal clocks.
- COP (AVP) is halted by extending a bus cycle.
- CPU can be halted by software interaction: software issues the WFE instruction to stop the processor, the flow controller asserts the EVENT input of the CPU to restart it.

19.1 Features and Functionality

The flow controller receives requests from processors (Cortex™-A15 processors and COP) to change their power state, or system power state. It also receives the interrupts from the interrupt controllers (vGIC and LIC) and other events which it uses to wake them up. It also provides support for cluster-switching.

Figure 47: Flow Controller Block Diagram



19.1.1 WFI/WFE Instructions and STANDBYWFI/WFE Signals Usage

The WFI (Wait For Interrupt) and WFE (Wait For Event) are the instructions of ARMv7-A architecture (supported by both Cortex-A15 and Cortex-A9 processors), which are used by the CPU to interlock with the flow controller for the purpose of triggering low-power-state transitions.

When executing WFx (WFI/WFE), the processor waits for all prior instructions to complete before entering the idle (low-power) state. The WFx instruction ensures that all explicit memory accesses that are prior to the WFx instruction in program order have completed. Also, WFx ensures that all speculative memory accesses have completed.

After executing WFI, the processor asserts STANDBYWFx signal. Assertion of STANDBYWFx guarantees that the processor is in idle, and there is no outstanding memory access. The processor continues to assert STANDBYWFI until one of the interrupt (IRQ or FIQ) is asserted or processor is reset. Similarly, the processor continues to assert STANDBYWFE until an “event” is received by processor.

The flow controller can be configured to trigger (per CPU) power-gating based on WFI instruction execution.

19.1.2 CPU (A15) Low-Power States

19.1.2.1 CPU Clock Gating

If a CPU is idle for a short period of time, then it can be halted which results in its CPU clock-gating. This is referred to as LP3 CPU power-state. The WFI instruction is executed for putting CPU into LP3 (i.e. for clock-gating). After executing WFI, CPU disables most of the clocks in the CPU except the clock for the small wake up logic clock.

Exit from halt state occurs when the CPU detects an interrupt on IRQ or FIQ pins. Note that this state is per CPU, and that this clock-gating is internal to the Cortex-A15 processor, so it does not require any support from flow-controller.

19.1.2.2 CPU Power Gating

The flow-controller uses a (separate) state machine to sequence power-gating for each CPU. The main CPUs flow-controller state machines are different from that for the CPU Rail PwrUp, and COP. So it has three different variants of state machines: one for main CPUs (which is instantiated 4 times, one for each CPU), one for CPU Rail PwrUp and one for COP. If the active cluster is cluster1, then based on CPU-ID, corresponding state-machine is used for CPU-LP.

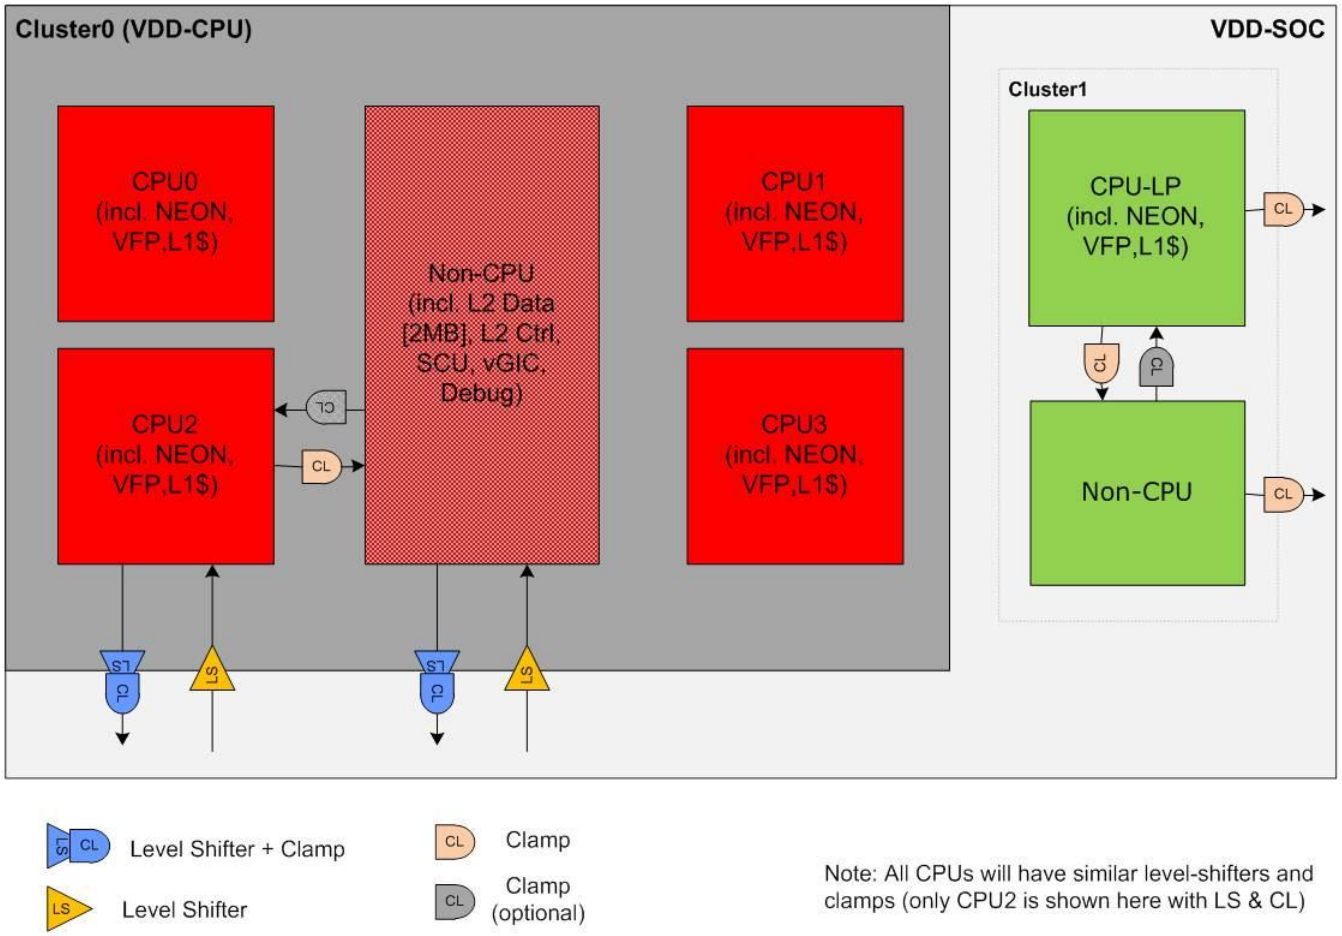
The flow controller can have one or more power-gating requests outstanding. However, it only issues one request at a time to PMC. A fixed priority arbiter is used to arbitrate among CPU power-gating on/off requests, and winning request is sent to PMC. This is primarily for two reasons: i) to avoid power noise issues, only one partition is power gated/ungated at a time, ii) PMC’s power-gating controller supports only one request at a time.

The flow controller to PMC interface includes core-ID which explicitly indicates which CPU or non-CPU partition should be power gated/ungated. PMC is not expected to use cluster-ID for identifying whether request is for cluster0 or cluster1 CPU.

CPU Power Gated Domains

As shown in the figure below, each CPU is an independent power-gated domain. The cluster0 non-CPU may be power gated as a separate domain. The cluster1 non-CPU is power-gated as a separate domain. The flow controller provides option for cluster0 L2 to be power gated.

Figure 48: CPUs PG Domains



19.1.2.3 Cluster0 CPU-Rail Gating

At boot, CPU rail is off by default, and is powered on by the AVP boot code using a **direct register write** to PMC (or by direct I2C commands to PMIC). Also, at LP0 exit, CPU rail (if need be) is powered-on (by SOFTWARE) by **direct register write** to PMC (or by direct I2C commands to PMIC).

The CPU rail is powered off (with the help of the flow controller) when last CPU is power-gated (see the section on “Cluster0 CPU Power Gating”). Similarly, when first CPU is woken up (by flow-controller based on wake-event) then CPU rail is first powered-on (if it was off) followed by CPU power-ungating (see the section on Cluster0 CPU Power Gating”).

19.1.2.4 Cluster0 CPU Power Gating

Each of the cluster0 CPUs can be independently power-gated with the help of the flow controller. If the CPU being power-gated is not the last one (or is not requesting the CPU rail to be powered off), then it is power gated/ungated as described in the section on “CPU Power Gating/Ungating Sequence”.

The last CPU being power-gated can request non-CPU to be power-gated or CPU rail to be powered off. Similar when the first CPU is being woken up, then the flow controller would power on (if it was off) CPU rail or power-ungate non-CPU (if it was power-gated).

Note:	The flow controller will only sequence CPU-rail or non-CPU (with last CPU power-gating request), but not both.

The flow controller can be set up to power gate/ungate each of the CPU independently. In addition, flow controller can be set up to power gate/ungate non-CPU (or power off/on CPU-rail) as result of CPU power gate/ungate request. The following section describes non-CPU power gate/ungate (or CPU power off/on) along with CPU. The individual CPU only power gate/ungate is described in the section on “CPU Power Gating/Ungating Sequence”.

Power-Gating (power-off) Last CPU and CPU Rail (or non-CPU)

Software initiates the last CPU power-gating request (with CPU-rail power-off or non-CPU power-gating). As a result, the flow-controller sequences CPU and CPU-rail (or non-CPU) power-gating as follows.

> **Note:** The following sequence is for last CPU power-gating with CPU rail power off option, but the same sequence will be used for CPU power-gating with non-CPU power-gating option.

- [SW-CPU] Initiate last CPU power gating with CPU rail power-off (section on CPU Power-Gating (Power OFF) Sequence has details of SOFTWARE steps)
- [HW-Flow] CPU power-gating step
  - Request PMC to power-gate the CPU
  - Wait for PMC ack
- [HW-Flow] CPU rail power-off step
  - If the CPU rail is off (see CPU_PWR_CSR[RAIL_STS]) or in the process of being powered on, then this step is done (skip the CPU rail power-off step).

> **Note:** For debug purposes, CPU_PWR_CSR[RAIL_STS] register bits can be updated to indicate CPU rail power off. This can help force the flow controller to skip rail power-off.
> The CPU rail may be in the process of being powered on because of another CPU wake up event. In that case, we don’t want this step to power-off CPU rail.

- Update CPU rail status register (CPU_PWR_CSR[RAIL_STS]) to be in the process powering off
- Request PMC to power off CPU rail (see section on “CPU Rail Gating/Ungating Sequence”)
- Waits for PMC acknowledge
- Update CPU rail power status (CPU_PWR_CSR[RAIL_STS]) to be powered off

The following table indicates possible power off options which can be triggered as a result of a CPU power-gating request.

Per CPU Pwr-Gate	Non-CPU Pwr-Gate	CPU Rail-Off	Comments
Yes	No	No	Individual CPU power-gating
Yes	Yes	No	
Yes	No	Yes	

Power-Ungating (power-on) first CPU and CPU Rail (and/or non-CPU)

Based on CPU wakeup-event (see HALT_CPUx_EVENT register), the flow controller power-ungates the CPU including the CPU rail or non-CPU power-off (if required).

- [HW-Flow] Receives CPU wakeup event
- [HW-Flow] CPU rail power-on step
  - If CPU rail is powered on, then this step is done. Else,
  - If CPU rail is in the process of being powered on, then wait for it to be powered on. After wait, this step is done. Else,
  - If CPU rail is in the process of being powered off, then wait for it to be powered off. After that continue to power it on.
  - Update CPU rail status register (CPU_PWR_CSR[RAIL_STS]) to be in the process of powering on.

- Request PMC to power on CPU rail
- Waits for PMC acknowledgment
- Update CPU rail status register (CPU_PWR_CSR[RAIL_STS]) to be powering on.

- [HW-Flow] Non-CPU power-ungating step
  - If non-CPU is power-ungated, then this step is done. Else,
  - If non-CPU is in the process of being powered on, then wait for it to be powered on. After wait, this step is done. Else,
  - If non-CPU is in the process of being powered off, then wait for it to be powered off. After that continue to power it on.
  - Update non-CPU pwr status register (CPU_PWR_CSR[C0NC_STS]) to be in the process of powering on.
  - Request PMC to power-ungate non-CPU
  - Wait for PMC acknowledgment
  - Update non-CPU pwr status register (CPU_PWR_CSR[RAIL_STS]) to be powered on.
  - Note, in terms of power-status, normally we would have either CPU rail or non-CPU to be off (but not both). However, SOFTWARE can program CPU-PWR_CSR register such that both the CPU rail and non-CPU will have to be powered on.
- [HW-Flow] CPU power-ungating step
  - Request PMC to power-ungate CPU
  - Waits for PMC acknowledgment

The following table indicates power-on options which can be triggered when the flow controller receives CPU wakeup event.

Per CPU Power Ungate	Non-CPU Power UnGate	CPU Rail Power On	Comments
Yes	No	No	Individual CPU power-ungating
Yes	Yes	No	
Yes	No	Yes	
Yes	Yes	Yes	

19.1.2.5 Cluster1 CPU Power Gating

The cluster1 CPU (also known as shadow CPU or CPU-LP) can be power gated/ungated with the help of the flow controller. Along with CPU-LP power-gating, its non-CPU can be power gated (by configuring flow controller before requesting CPU power-gating). From PMC perspective, CPU-LP and non-CPU are two separate power-gated domains. The flow controller sends CPU-LP and non-CPU power-gating requests to the PMC as follows:

The flow controller can be set up to power gate/ungate CPU-LP only. In addition, the flow controller can be set up to power gate/ungate non-CPU along with CPU-LP as result of CPU-LP power gate/ungate request. The next section describes non-CPU power gate/ungate along with CPU-LP. The CPU-LP only power gate/ungate is described in the section on “CPU Power Gating/Ungating Sequence”.

Power-gating (power-off) CPU and non-CPU

To initiate CPU-LP power-gating, SOFTWARE configures the flow-controller registers associated with CPU-ID (in MPID register). The SOFTWARE initiates CPU-LP (with non-CPU) power-gating request as described in section on CPU Power-Gating (Power OFF) Sequence. After that, flow-controller sequences CPU-LP and non-CPU power-gatings as follows:

- [SW-CPU] Initiate CPU-LP power gating with non-CPU power-gating rail (refer to the section on CPU Power-Gating (Power OFF) Sequence) for details of SOFTWARE steps

- [HW-Flow] CPU power-gating step
  - Request PMC to power-gate the CPU (Refer to section on “CPU Power-Gating (Power OFF) Sequence”)
  - Wait for PMC acknowledgment
- [HW-Flow] non-CPU power-gating step
  - If non-CPU is off (see CPU_PWR_CSR[C1NC_STS]), or in the process of being powered on or off then this step is done.

    Note: This condition should never be seen. But this makes the cluster1 sequence the same as that of cluster0, so it is all right to make this check in the state machine.
  - Update non-CPU pwr status register (CPU_PWR_CSR[C1NC_STS]) to be in the process powering off
  - Request PMC to power-gate non-CPU (refer to the section on “Non-CPU Power Gating/Ungating Sequence”)
  - Waits for PMC acknowledgment
  - Update non-CPU power status (CPU_PWR_CSR[C1NC_STS]) to be powered off

Power-Ungating (Power On) CPU and Non-CPU

Based on CPU-LP wake-up event ((see HALT_CPUx_EVENT register), the flow controller power-ungates CPU-LP (and non-CPU).

- [HW-Flow] Receives CPU-LP wake event
- [HW-Flow] Non-CPU power-ungating step
  - If non-CPU is power-ungated, then this step is done. Else,
  - If non-CPU is in the process of being powered on, then wait for it to be powered on. After that, this step is done. Else,
  - If non-CPU is in the process of being powered off, then wait for it to be powered off. After that continue to power it off.

    Note: The above two steps should never be encountered. But making these checks is all right and makes this sequence similar to corresponding cluster0 sequence.
  - Update non-CPU power status register (CPU_PWR_CSR[C0NC_STS]) to be in the process of powering on.
  - Request PMC to power-ungate non-CPU
  - Wait for PMC acknowledgment
  - Update non-CPU power status register (CPU_PWR_CSR[RAIL_STS]) to be powered on.
- [HW-Flow] CPU power-ungating step
  - Request PMC to power-ungate CPU
  - Waits for PMC ack

19.1.3 Cluster Switch

19.1.3.1 Cluster1 (Shadow) to Cluster0 Switch

The cluster switch is a variant of LP2 low-power state transition. From usage perspective, cluster1 to cluster0 switch is latency critical. For cluster1 to cluster0 switch, the cluser1 CPU is power-gated (with its non-CPU power-gating), cluster switched is performed, and a cluster0 CPU is powered on (either immediately or conditional on a wake event).

Following is the cluster1 to cluster0 migration sequence:

- [SW-CPU] Configure the flow controller for cluster switch
- [SW-CPU] Configure cluster0 CPU wake event
  - Software has to configure wake event for the CPU which is in the CPU-ID. After cluster switch, the flow controller can only wake-up the CPU which is pointed to by CPU-ID.
- [SW-CPU] Trigger **CPU rail on** sequence as described in “CPU Rail Gating/Ungating Sequence”.

  Note: This step allows the CPU rail (cluster0 power) to be powered up in parallel with the cluster1 power-gate sequence. However, cluster1 is still an active cluster (until the cluster state is switched by the flow controller).
- [SW-CPU] Initiate power-gating of cluster1 CPU (with non-CPU)
- [HW-Flow] Perform cluster1 non-CPU and CPU-LP power-gating as described in the section on “Cluster1 CPU Power Gating”
- [HW-Flow] After cluster1 power-gating, wait for pre-cluster-switch delay (programmed in a flow-controller register)
- [HW-Flow] Perform cluster switch
- [HW-Flow] Wait for post-cluster-switch-delay (programmed in a flow-controller register)
- [HW-Flow] Waits for the wake event (this could be immediate)
- [HW-Flow] Power-on first CPU of cluster0 as described in the section on Cluster0 CPU Power Gating

19.1.3.2 Cluster0 to Cluster1 (Shadow) Switch

The cluster switch is a variant of LP2 low-power state transition. For cluster0 to cluster1 switch, the last CPU of cluster0 is power-gated (with the option of powering off CPU rail), the cluster is switched, and cluster1 CPU is power ungated (either immediately or conditional on wake event).

Following is the cluster0 to cluster1 migration sequence:

- [SW-CPU] Configure the flow controller for cluster switch
- [SW-CPU] Configure cluster1 CPU wake event
- [SW-CPU] Configure the CPU-ID of CPU which is being migrated to CPU-LP
- [SW-CPU] Initiate power-gating of last CPU (with CPU rail off option) as described in section on “Cluster0 CPU Power Gating” for CPU power-gating and CPU rail gating.
- [HW-Flow] After CPU rail gating, wait for pre-cluster-switch delay (programmed in flow-controller register)
- [HW-Flow] Perform cluster switch
- [HW-Flow] Wait for post-cluster-switch-delay (programmed in flow-controller register)
- [HW-Flow] Waits for the wake event (if needed)
- At the wake event, flow controller powers up cluster1 as described in section on “Cluster1 CPU Power Gating”

19.1.4 CPU-ID Function

When the active cluster is cluster1, then the flow controller uses CPU-ID (programmed in MPID register) to associate CPU-LP to corresponding CPU state machine which is used to power gate/ungate CPU-LP. Also, during cluster1 to cluster0 switch, flow-controller uses CPU-ID to wake the corresponding cluster0 CPU (based on configured wake events).

Also, CPU-ID is used to drive cluster1 CPU-ID pins, which are captured in the CPU (CP15) register that software uses to read the CPU-ID of the current CPU. Note that the CP15 register captures the MPID value, which is the virtualized MPIDR, not the physical MPIDR. Thus, it must be read by the CPU in monitor mode or virtualization mode.

Once cluster0 is active and cluster migration has been completed, then the flow controller does not have any use of CPU-ID.

19.1.5 COP Low-Power States

19.1.5.1 Halt (Clock Gating)

There is no specific halt instruction in the COP. However, its memory bus cycle can be extended by any number of cycles.

When configured to put the COP into halt, the flow controller forces its memory bus interface into wait-state. After that if the COP issues any bus cycle (e.g., fetching next instruction), then that bus cycle does not return unless flow-controller releases its bus (i.e., wakes it up). The flow controller can be configured to wake up the COP by IRQ/FIQ or other wake up events. During a COP halt state, its clock is automatically gated by hardware.

19.1.5.2 Power-Gating

The COP is not power-gated.

19.1.5.3 CPU Power Gating/Ungating Sequence

The processor's (A15 or A9) power-gating can be triggered by either i) a direct register write to PMC or ii) interacting with the flow controller. This section describes the power-gating sequence via flow-controller interaction.

The flow controller interfaces with the Processors, PMC, and CAR to implement power-gating on/off hardware-sequence. The power-gating controller is in the PMC, while clock and reset controls are in CAR.

19.1.5.4 CPU Power-Gating (Power OFF) Sequence

- [SW-CPU] Prepare processor (flush CPU L1$, context save, set up Flow Controller) for power-gating
- [SW-CPU] Execute WFI to make sure there is no outstanding processor transaction
- [HW-CPU] Assert *STANDBYWFI* to the flow controller
- [HW-Flow] Assert flow2car_*_rst
  - This is not used in power gate sequence when powergate_enable is high
  - When powergate enable is "0", CAR uses this to assert CPU reset
- [HW-Flow] Request PMC (by asserting flow2pmc_req and associated bus) to power-off CPU
- [HW-PMC] Assert the clamp control signal. This goes to ccplex and also goes to CAR.
- [HW-CAR] Assert CPU reset and reset the CPU clock
  - [HW-CPU] Stop CPU clock
- [HW-CAR] Ack PMC to indicate CPU clock is stopped
- [HW-PMC] Power off CPU (assert CPU PG-enables)
- [HW-PMC] Clear PWRGATE_STS register bit. This is to indicate that CPU is power-gated.
- [HW-PMC] Ack to the flow controller to confirm power-off (by asserting pmc2flow_ack)

Note: After receiving ack from the PMC, the flow controller must not issue a new request to the PMC until pmc2flow_ack goes idle.

- [HW-Flow] Deassert flow2pmc_req (after seeing the Ack)
- [HW-PMC] Deassert Ack (after seeing request deassertion)
- [HW-Flow] Do not start another request until Ack goes down

19.1.5.5 CPU Power-Ungating (Power ON) Sequence

The generic CPU power-ungating (power OFF) sequence is described below. The specific details of main CPU (Cortex-A15) or COP1 (A9AVP) are described in their respective power-gating sections.

- [HW-Flow] After detecting wake up condition, request PMC to power-on CPU (by asserting flow2pmc_req and associated bus)
- [HW-PMC] Power-on the CPU (deassert CPU PG-enables)
- [HW-PMC] Set PWRGATE_STS register bit. This indicates that the CPU is power-ungated
- [HW-PMC] Ack flow controller (by asserting pmc2flow_ack) that CPU is powered on
- [HW-Flow] Deassert flow2car_*_rst to CAR
- [HW-CAR] Request CPU to ungate CPU clock (by deasserting car2ce*_cke)
- [HW-CPU] Ungate CPU clock
- [HW-CAR] Request PMC to remove CPU clamp (by asserting car2pmc_ack)
  - This is to make sure that clock gets ungated well ahead of reset deassertion
- [HW-PMC] Removes the clamping (by deasserting pmc2ce*_clamp)
  - This goes to the CPU and and also to the CAR
- [HW-PMC] Ack flow controller (by deasserting pmc2flow_ack)
- [HW-CAR] Deasserts reset
- [SW-CPU] CPU fetches code from reset vector.
- Note all of the Cortex-A15 CPUs share one reset-vector register (in EVP registers).

19.1.6 Non-CPU Power Gating/Ungating Sequence

From a software perspective, non-CPU power gating/ungating is done as part of CPU power gating/ungating request. The flow controller issues a separate request (to PMC) for power-gating CPU and non-CPU domain. The main reason is that PMC can only sequence one power domain at a time, so the flow controller serializes requests on behalf of PMC. From the flow controller hardware perspective, the sequence for non-CPU domain power gating is similar to CPU domain power gating/ungating which is described in above sections.

19.1.7 CPU Rail Gating/Ungating Sequence

This section only describes about CPU rail gating/ungating with the help of the flow controller.

From a software perspective, the CPU rail is powered on/off as part of CPU power-gating on/off request. The flow controller issues a separate request (to PMC) for CPU power gating/ungating and CPU rail gating/ungating. The main reason is that PMC can only sequence one power-domain at a time, so flow-controller serializes requests on behalf of PMC. From a flow-controller hardware perspective, the sequence for CPU rail gating is similar to individual CPU power gating, which is described in above sections. However, as part of CPU rail-ungating, flow controller also triggers RAM re-repair as described below.

19.1.7.1 CPU Rail Ungating Step

- [HW-Flow] Request the PMC to power-on the CPU rail
- [HW-Flow] Wait for PMC acknowledgment
- [HW-Flow] Request Reshift block (also known as re-repair block) to re-repair all of the segments of CPU repair chain
  - [HW-Reshift] Performs repair of all segments of CPU chain in parallel
- [HW-Flow] Wait for re-repair acknowledgments (from all segments)
- [HW-CAR] Deassert the CPU cluster0 reset

19.1.8 Cortex-A15 Debug Power Up/Down Requirements

The Cortex-A15 processor requires debug power up/down related support. The flow controller provides the following debug support.

19.1.8.1 DBGPWRUPREQ

The CoreSight can initiate power-up (for a CPU which is power-gated via the flow controller) by writing to the Cortex-A15 DBGPRCR register. As a result of this register write, A15 asserts DBGPWRUPREQ signal (a per CPU active-high level). Note, this signal can never be asserted when C0NC (or C1NC) is power-gated (since the logic generating this is inside those partitions).

The flow controller uses this signal as a wake-event (in addition to the wake-events programmed in CPUx_CSR register) to wake the corresponding CPU-only. The flow controller qualifies this signal by corresponding PWRUPREQ_QUAL bit (of FLOW_DBG_QUAL register). In summary, the flow controller uses the following condition to wake up a CPU.

*CEx wake-condition = (CEx wake-event as programmed in CPUx_CSR) || (<**ccplex2flow**>**_DBGPWRUPREQx && PWRUPREQ_QUALx**)*

19.1.8.2 DBGNOPWRDWN

The CoreSight can force CPU power-down to be power-down “emulation” only by writing to the Cortex-A15 DBGPRCR register. As a result of this register write, the Cortex-A15 asserts DBGNOPPWRDWN signal (a per CPU active-high level). Note, this signal is asserted to emulate CPU-only power-gating.

The flow controller qualifies <ccplex2flow>_DBGNOPPWRDWNx signal by corresponding NOPPWRDWN_QUALx bit (of FLOW_DBG_QUAL register) and uses that as an indication of CPU power-gating without the pg_enable option.

Note that CPU power-gating is still triggered by CPUx_CSR write only (based on WFI or WFE). But regardless of CPUx_CSR register configuration, if (<>_ DBGNOPPWRDWNx && NOPPWRDWN_QUALx == TRUE), then only CPUx is power-gated without the pg_enable option.

19.1.8.3 DBGPWRDWNREQ/DBGPWRDWNACK

Cortex-A15 debug logic needs to know about power-gating requests. It also needs to make sure that power-gating starts only after it has acknowledged (so it can flush trace buffers, etc.). For this purpose, the Cortex-A15 provides per CPU DBGPWRDWNREQ/ DBGPWRDWNACK interface.

Logically, STANDBYWFIx (Cortex-A15 output) can be fed to DBGPWRDWNREQx (Cortex-A15 input). But STANDBYWFI can be asserted for many reasons, so it has to be qualified when it is asserted for CPU power-gating. The flow controller provides qualifier (PWRDWNREQ_QUALx bits of FLOW_DBQ_QUAL register) which will be set by software at the power-gating entry, and cleared by software at CPU power-ungating.

Also, if qualifier (i.e., PWRDWNREQ_QUALx) is set, then the flow controller needs to wait for DBGPWRDWNACKx (in addition to waiting for existing STANDBYWFIx/WFEx condition) before starting the CPUx power-gating.

In summary, the following is needed in each ccplex cluster:

<ccplex>_ DBGPWRDWNREQx = <ccplex>_STANDBYWFIx & <flow2ccplex>_PWRDWNREQ_QUALx

The flow controller needs to wait for **<ccplex2flow>_DBGPWRDWNACKx & PWRDWNREQ_QUALx** (in addition to existing wait for STANDBYWFIx/STANDBYWFIx etc condition).

19.2 Flow Controller Registers

Refer to “Reading Register Tables” in the Introduction section for the register table protocol as well as recommendations for accessing registers.

In the Flow Controller register descriptions, CPU refers to CPU0, and COP refers to the AVP coprocessor. CPU-LP (CPU4) has its own set of control registers. This is required because there is a case (cluster1 to cluster0 switch) where both sets of registers can be configured in parallel. Also, since CPU-LP may morph into any of the four CPUs, it is better to keep its control register separate.

The EVENTS register is replicated per core, once for COP, four times for the cores of Cluster0.

The fields and enums have the following interpretation:

- MODE defines how the flow controller logic operates; the reset value is 0x0 for CPU0 and COP (does nothing) and 0x2 for CPU1, 2, 3 (WAITEVENT). This is related to the default behavior of the reset generator.
- Enumerated values for the field MODE are defined below.

Field Mode	Enumerated Value	Description
FLOW_MODE_NONE	0	No flow control
FLOW_MODE_RUN_AND_INT	1	Keep running but generate interrupt when event conditions met (not used)
FLOW_MODE_WAITEVENT	2	Stop running until event conditions met
FLOW_MODE_WAITEVENT_AND_INT	3	Same as FLOW_MODE_WAITEVENT but generate an interrupt when resumed (not used)
FLOW_MODE_STOP_UNTIL_IRQ	4	Stop until an interrupt controller interrupt occurs
FLOW_MODE_STOP_UNTIL_IRQ_AND_INT	5	Same as FLOW_MODE_STOP_UNTIL_INT but generate another interrupt when resumed (not used)
FLOW_MODE_STOP_UNTIL_EVENT_AND_IRQ	6	Stop until event conditions met AND an interrupt controller interrupt occurs

There is no enum for 7

- Bit 31: (also known as Halt) = This bit is set to configure the wake up (of corresponding CPU) by any of the interrupts (LIC_IRQ/FIQ, or GIC_RIQ/FIQ) corresponding to that CPU. If this bit is set, then none of the other fields of this register need to be set for CPU wake. This bit is set by software and cleared by hardware when any of these interrupt is received by hardware.
- Bit 30: (also known as Wait) = This bit is set to configure the wake up (of corresponding CPU) by any of the enabled "events". The events can be enabled by setting other fields of this register (incl. *_IRQ, *_FIQ). If this bit is set, then at least one of the events needs to be enabled to generate wake event. This bit is set by software and cleared by hardware when wait event is observed by hardware.
- Bit 29: (also known as Sync) = This bit causes the NEXT Flow Controller register read to stall the processor until the wake event occurs (Used for COP. Obsolete for CPUs).

The rest of the fields define which conditions will be taken into account to restart a halted processor.

There are two types of events:

- Counted events: Decrement the field called ZERO. Flow controller resumes when this counter reaches 0
- Activity events: The flow controller resumes when the activity occurs, no counting

All conditions are disabled at reset:

- JTAG: Resume on JTAG activity
- SCLK : Resume on Nth SYSCLK cycle ticks
- X32K : Resume on Nth X32K clock input ticks

- uSEC: Resume on Nth uSEC clock ticks (uSEC = microsecond)
- mSEC: Resume on Nth mSEC clock ticks (mSEC = millisecond)
- SEC : Resume on Nth second RTC clock ticks
- X_RDY: Resume on Nth XIO.RDY Ext. IO Ready events
- SMP3[1,0]: Resume on Nth SMP.3[1,0] Semaphore set events
- XRQ_[D,C,B,A] : Resume on Nth XRQ.[D,C,B,A] External Trigger events
- [O,I]B[E,F]: Resume on Nth [O,I]B[E,F] [Outbox, Inbox] [Empty, Full] Events
- [LIC, GIC]_[IRQ,FIQ]: Resume on [LIC, GIC] [IRQ,FIQ].
- ZERO: Initialized then decremented

Note: If more than one event is enabled, the event counter will decrement based on an OR condition of enabled events

19.2.3 FLOW_CTLR_CPU_CSR_0

The CPU_CSR registers are replicated for each CPU cores. They define additional characteristics of the flow controller linked to CPU cores, especially the interaction of the flow controller with power management functions. The LP1 state is normally entered and exited via side effects of the flow controller operation.

All fields of the CPU_CSR register have an initial value of 0. The different fields are:

- PWR_STATE : Current state of the PowerGate State Machine
- WAIT_EVENT: CPU is waiting, wake up is via an event
- HALT: CPU is halted
- P2F_ACK: pmc2flow_ack signal, this is the same signal for both CPU cores
- F2P_PWRUP: flow2pmc_pwrup, this is the same signal for both CPU cores
- F2P_REQ: flow2pmc_req valid, this is the same signal for both CPU cores
- F2C_MPCORE_RST: TRUE when requesting reset of MPCore™
- PWR_OFF_STS: TRUE when CPU PowerGated OFF by Flow Controller
- INTR_FLAG: TRUE when Interrupt is Active -- Write-1-to-Clear
- EVENT_FLAG: TRUE when Event is Active -- Write-1-to Clear
- ENABLE_EXT: If ENABLE is TRUE, then this specifies what to power off.
    - 00b: PowerGate CPU only.
    - 01b: PowerGate CPU and non-CPU (note, this option must be used only when last CPU is being power-gated)
    - 10b: PowerGate CPU and turn CPU rail off (note, this option is valid for cluster0 CPU, and must be used only when last CPU is being power-gated).
    - 11b: PG Emulation. Note, this option is for CPU-only PG emulation except for cluster-switch case (i.e. with SWITCH_CLUSTER=1) in which emulation applies to all PG steps of source cluster. In PG emulation, PG partition is reset but not power-gated.
- IMMEDIATE_WAKE: If set, CPU is powered up immediately (without waiting for an interrupt or event). Note: If this is set then HALT_CPUx_EVENTS[MODE] should be set to 0x2 for immediate wake.
- SWITCH_CLUSTER: If set, the active cluster will be switched when all indicated CPU reach STANDBY_WFI. This bit self clears once the cluster switch sequence is completed
- WAIT_WFI_BITMAP: All cores indicated in bitmap must be in STANDBY_WFI before switching Cluster
- WAIT_WFE_BITMAP: All cores indicated in bitmap must be in STANDBY_WFE before CPU PowerGating. This is deprecated and should not be used. It may work, but it is not being verified.
- EVENT_ENABLE: Generates an event when the flow controller exits the halted state
- ENABLE: PowerGate Enable - STANDBYWFx causes power-gating based on ENABLE_EXT values.

Note 1: Software sets this bit to '1' for requesting CPU power-gating. CPU is power-gated based on the value of ENABLE_EXT field.

Note 2: This bit is set by software and cleared by hardware (when power-gating sequence is completed).

19.2.15 FLOW_CTLR_CPU_PWR_CSR_0

Offset: 0x38 | Read/Write: R/W | Reset: 0x00000100 (0bxxxxxxxxxxxxxxxxxxxxxxxx100000000)

Bit	Reset	Description
8	0x1	CPU_RG_CFG: If this bit is set, then the flow controller would initiate last-CPU PG (along with CPU RG (rail-gating) or non-CPU PG) only when other 3 CPUs are already power-gated. This is primarily for debug purposes. Note that the flow controller uses PMC pwrgate-status of CPU partitions to identify whether CPUs are power-gated or not. 0 = DISABLE 1 = ENABLE
7:6	0x0	C1NC_STS: Hardware updates this register based on the current status of the C1NC partition. Before requesting a power-off (or on) request, flow controller updates this status to "in the process" status. Note that the flow controller requests C1NC power on/off based on this register value or PMC pwrgate-status of C1NC depending upon the USE_FLOW_STS register. For debug purposes, this can be written by software. 0 = PARTITION_OFF 1 = PG_IN_PROGRESS 2 = PU_IN_PROGRESS 3 = PARTITION_ON
5:4	0x0	C0NC_STS: hardware updates this register based on the current status of the C0NC partition. Before requesting a power-off (or on) request, flow controller updates this status to "in the process" status. Note, flow controller requests C0NC power on/off based on this register value or PMC pwrgate-status of C0NC depending upon USE_FLOW_STS register. For debug purposes, this can be written by software. 0 = PARTITION_OFF 1 = PG_IN_PROGRESS 2 = PU_IN_PROGRESS 3 = PARTITION_ON
3	0x0	USE_FLOW_STS:If this is set (=1), then the flow controller will use C0NC_STS/ C1NC_STS/RAIL_STS bits to determine whether to power-gate C0NC/C1NC/CRAIL domains. If this bit is clear (=0), then the flow controller will use the PMC pwrgate-status of C0NC/C1NC/CRAIL to determine whether to power-gate the C0NC (and C1NC) domains. In either case, the C0NC_STS/C1NC_STS/RAIL_STS fields are updated in the same way.
2:1	0x0	RAIL_STS: Hardware updates this register based on the current status of the CPU-rail. Before requesting a power-off (or on) request, flow controller updates this status to "in the process" status. Note, flow controller requests CPU-RAIL power on/off based on this register value or PMC pwrgate-status of CRAIL depending upon USE_FLOW_STS register. For debug purposes, this can be written by software. 0 = RAIL_OFF 1 = RG_IN_PROGRESS 2 = RU_IN_PROGRESS 3 = RAIL_ON
0	0x0	RAIL_ENABLE: CPU rail power-on request. Software sets this to request CPU rail pwr-on by flow-controller interaction. As a result of this request, CPU rail is powered up and RAM-re-repair is completed. If rail is already on, writing to this is ignored. Hardware clears this bit when CPU power rail in turned on (including RAM re-repair is done). Note: For cluster1 -> cluster0 switch, software would request CPU rail power-on, followed by cluster1 context save, followed by cluster-switch request.

19.2.16 FLOW_CTLR_MPID_0

Offset: 0x3c │ Read/Write: R/W │ Reset: 0x00000000 (0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx00)

Bit	Reset	Description
1:0	0x0	CPU_ID: CPU-ID of C1 CPU. Software programs this field before cluster0 -> cluster1 switch. This ID is provided to MPCore_LP which is what is read when OS reads MPIDR. Also, flow-controller uses this to identify wake interrupts to be used for CPULP wakeup.

19.2.17 FLOW_CTLR_RAM_REPAIR_0

Offset: 0x40 │ Read/Write: R/W │ Reset: 0x00000004 (0bxxxxxxxxxxxxxxxx00000000xxxx01x0)

Bit	R/W	Reset	Description
23:16	RO	X	DBG_STS: Repair done (acknowledge) from repair logic.
15:8	RW	0x0	DBG_REQ: Repair request for individual segments. This field is valid only when DBG_EN is set to '1'. Bit[0]: segment0 of repair chain, Bit[1]: segment1 of repair chain, ..., Bit[7]: segment7 of repair chain
3	RW	0x0	DBG_EN: Debug enable to be able to repair of individual segments of the cluster0 repair chain 0 = DISABLE 1 = ENABLE
2	RW	0x1	BYPASS_EN: RAM repair bypass enable. 0: Flow-controller requests RAM-repair at CPU RAIL power-up. 1: Flow-controller does not request RAM-repair at CPU RAIL power-up 0 = DISABLE 1 = ENABLE
1	RO	X	STS: Indicates Cluster repair chain status. hardware sets this to '1' when repair of all segments is done. hardware clears this to '0' when RAM repair is in progress (either due to hardware or software request)
0	RW	0x0	REQ: Cluster0 RAM repair request. Software sets this bit to '1' to initiate RAM repair request to all segments in parallel. Note, software will have to trigger RAM repair in all cases when software powers-on CPU-rail (via direct register write). If CPU-rail is powered on via the flow controller, then hardware (flow controller) takes care of RAM repair. hardware clears this bit when software triggered repair is done (i.e. STS=1) 0 = DISABLE 1 = ENABLE

19.2.18 FLOW_CTLR_FLOW_DBG_SEL_0

20.0 MEMORY CONTROLLER

Tegra® 4 devices feature a dual-channel memory controller with two separate 32-bit DRAM interfaces. These are interleaved to provide high performance with the load shared across both channels.

The Tegra 4 memory controller (MC) handles memory requests from internal clients and arbitrates among them to allocate memory bandwidth for DDR3, LPDDR2, and LPDDR3 SDRAMs. There are two external memory controller (EMC) modules, which interface with the external DDR/LPDDR devices.

Key features in the Tegra 4 memory controller include:

- Enhanced arbiter design for higher memory efficiency
- System Memory Management Unit (SMMU) for virtual to physical address mapping for any device
- Support for DDR3, low-voltage DDR3, LPDDR2, and LPDDR3 SDRAMs
- Dual-channel support (2 x 32-bit interfaces)
- QUSE functionality for qualification of the tristatable DQS clock in SDRAMs
- CA training for LPDDR3 devices with byte/bit swizzling

The memory interface speed varies with memory type, and the specific Tegra 4 SKU, so is not stated in this document.

20.1 Memory Controller Architecture

The memory controller architecturally consists of the following parts:

- Arbitration Domains, which can handle a single request or response per clock from a group of clients. Typically, a system has a single Arbitration Domain, but an implementation may divide the client space into multiple Arbitration Domains to increase the effective system bandwidth.
- Protocol Arbiter, which manage a related pool of memory devices. A system may have a single Protocol Arbiter or multiple Protocol Arbiters.
- Memory Crossbar, which routes request and responses between Arbitration Domains and Protocol Arbiters. In the simplest version of the system, the Memory Crossbar is just a pass through between a single Arbitration Domain and a single Protocol Arbiter.
- Global Resources, which include things like configuration registers which are shared across the Memory Subsystem.

20.2 Hardware Features

20.2.1 DRAM Protocol Arbiter Features

- 1 channel, 32 bits of data bus, 16 MB to 2 GB attached DRAM
  - 2 chip selects, up to 2 GB attached DRAM per chip select
  - 2 individually controllable clock-enables
  - 2 individually controllable ODTs (for DDR3)
- Each chip select may support different geometries
  - 3 bank bits
  - DDR3: up to 15 bits of row address if using 2 chip selects, up to 16 bits if using 1 chip select
  - Support for up to 11 column bits[1], i.e., up to 4KB page-size

[1] This includes C0, which is not pinned out on the DRAM, and C1, which will be zero for all burst-length four bursts.

- Per-byte data masks
- BL4 or BL8 for both DDR3 and LPDDR2. BL8 for LPDDR3. For DDR3, BC4_on_the_fly.
- Up to 8 Gb DDR3 devices. 8 Gb x 16 and 4 Gb x 8 devices are restricted on single-channel configurations
- Up to 8 Gb LPDDR2/LPDDR3 devices, supported as single or double rank, single-channel or dual-channel configurations
- Support for low-power modes:
  - Software controllable entry/exit from: self-refresh, power down, deep power down
  - Hardware dynamic entry/exit from: power-down, self-refresh
  - Support for intermittent or disabled DLL
  - Disable unused address/command taps based on whether in POP or Discrete mode, and whether Discrete is in in DDR3 or LPDDR2 mode.
  - Pads use DPD-mode during idle periods
- For Tegra 4 devices, trims can be set/adjusted per-byte AND per-chip-select. The PVT-compensated value can still be used and a PVT/frequency-compensated adjustment can be added to it (1/16, 1/8, 3/16 of a cycle) or a non-PVT-offset can be added. There is no hardware training mechanism. Either software or characterization needs to determine the best settings.
- Support for x32, x16, or x8 chips attached to the channel
  - DQ/DQS swizzling: MRR_BYTESEL need to match byte swizzling.

20.2.2 Memory Crossbar

The Memory Crossbar (MXB) is in charge of adapting Arbitration Domains to Protocol Arbiters. In a simple system, the MXB is a direct connection. In a more complex system, the MXB does the following:

- Conflict arbitration for ingress of requests to a single PA from multiple ADs.
- Conflict arbitration for egress of responses to a single AD from multiple PAs, with skid buffering to handle backpressure.
- Clock-domain crossing FIFOs for requests and responses destined for PAs that run on an asynchronous clock.
- Fragmentation of wide requests from a wider AD into a narrower PA.
- Reassembly of wide responses from a narrower PA to a wider AD.

20.2.3 Global Resources

The Memory Subsystem also contains some global resources not owned by a particular AD or PA:

- SMMU
- Configuration registers and statistics counters

20.2.4 Supported SDRAM Topologies

The following table lists the supported topologies for DDR3 devices. The EMC shares CS1 with A15. It supports either single rank configurations with up to 16 row address bits or two rank configurations with up to 15 row bits.

Table 49: Supported DDR3 Topologies

DRAM Configuration				**DRAM Device Information**					
Density (GB)	Number of Channels	Number of Ranks Per Channel	Number of Devices Per Rank	Density (Gb)	Package	Page Size (Kb)	Bank Width	Row Width	Col Width

DRAM Configuration				DRAM Device Information					
1	2	1	2	2	x16	2	3	14	10
2	2	1	2	4	x16	2	3	15	10
2	2	1	4	2	x8	1	3	15	10
4	2	1	4	4	x8	1	3	16	10
2	2	2	2	2	x16	2	3	14	10
4	2	2	2	4	x16	2	3	15	10
2	2	2	2	2	x16	2	3	14	10
4	2	2	2	4	x16	2	3	15	10

The following table lists the supported topologies for LPDDR2/LPDDR3 devices. The EMC supports the same topologies on LPDDR2 and LPDDR3 up to 8Gb device density.

Table 50: Supported LPDDR2/LPDDR3 Topologies

DRAM Configuration				DRAM Device Information					
Density (GB)	Number of Channels	Number of Ranks Per Channel	Number of Devices Per Rank	Density (Gb)	Variety	Package	Bank Width	Row Width	Col Width
1	2	1	1	4	S2/S4	x32	3	14	10
2	2	1	1	8	S2/S4	x32	3	15	10
2	2	2	1	4	S2/S4	x32	3	14	10
4	2	2	1	8	S2/S4	x32	3	15	10

2	1	2	1	8	S2/S4	X32	3	15	10
4	2	2	2	4	S2/S4	X16	3	14	11
2	1	2	1	4	S2/S4	x16	3	14	11
4	1	2	2	8	S2/S4	x16	3	15	11

20.3 Software Features

The majority of software interaction with the memory subsystem involves:

- Initial configuration
- Power management
- Device management
- SMMU translation management
- Surface allocation
- Statistics and debugging

20.3.1 Initial Configuration

The details of configuring the Memory Subsystem (MSS) can be broken down into the following:

- Client configuration
- Protocol Arbiter configuration
- Global Memory Subsystem configuration

> **Note:** This configuration must be performed as part of the chip-wide boot sequence

20.3.1.1 Client Configuration

The primary per-client configuration knob is the target latency. The target latency value is the expected latency hiding of the client. It is statically configured based on the clients request rate and request buffering capability. The value is used by the Memory Subsystem to track the maximum allowed request lifetime in the system.

As an example of client latency tolerance, consider a Display client which has a 32-atom FIFO. If that Display client is expected to handle a 74.25 megapixel per second HDMI interface and is outputting 32-bit RGBA data on that interface, the client's latency tolerance is 32 atoms × 16 bytes per atom ÷ 4 bytes per pixel ÷ 74.25 Mpixels per second = 1.72 µs.

The latency configuration knobs for the system are calculated off a programmable divide-down of the DRAM clock. This divide-down can be changed whenever the DRAM clock is changed, so that the latency knobs always represent the same relative amount of time to the system. For example, at 533 MHz, the divide-down would be programmed to divide by 16 to give a 30 ns tick. If the DRAM speed dropped to 400 MHz, the divide-down would be changed to 12 to maintain the 30 ns tick.

For the above example, the latency timeout would be 1.72 µs ÷ 30 ns = 57 ticks. However, the Memory System does not guarantee that the maximum latency will never be exceeded, so some amount of headroom should be added to this number. Even so, clients should be designed to gracefully handle excessively-delayed transactions; hard-isochronous clients like Display and VI should not require a reset if a pixel does not arrive in time.

In the above scenario, the latency tolerance is use-case dependent. If the Display was doing 16 bits per pixel instead of 32, it would have double the amount of latency. Software can choose to recalculate the latency tolerance, or it can just pick a worst-case value. In general, given an acceptable amount of client buffering, the latency tolerance need not be tuned on a per-use-case basis (but if software does choose to tune the latency, it need only be done within the context of a single driver, since the latency value neither depends on other clients nor on the Protocol Arbiter clock).

Modules like the CPU, which have no well-defined latency requirements (beyond "as fast as possible") can use the latency tolerance value as a tuning knob, trading off performance of the latency-sensitive client versus the overall performance of the memory system. Some tuning of these parameters may be necessary to maximize system performance.

Module designers should choose an appropriate conservative default value for their client's latency tolerance registers. Software should be able to use the default configuration and still meet system use-case targets.

20.3.1.2 Protocol Arbiter Configuration

Each Protocol Arbiter has its own requirements for initialization. Timing parameters specific to the Arbiter, the DRAM and the current operating clock speed have to be written into Protocol Arbiter configuration registers. The type and geometry of the attached DRAM also have to be programmed. Afterwards, the DRAM will require a set of initialization cycles to be issued.

Device Geometry

DRAM devices come in many sizes, widths, etc. The arbiter must be programmed to drive the correct combination of address bits, data bits, and protocol.

Device Timing and Arbiter Timing

A DRAM arbiter has configuration related to timing parameters specific to the attached device. The JEDEC timing specifications for the device have to be converted from nanoseconds to cycle counts. The controller must also be programmed with the cycles per tick number for their particular clock domain (see also the subsection on “Global Memory Subsystem Configuration” below).

Other Arbiter Parameters

Other parameters related to arbitration that need to be configured include:

- overall number of requests outstanding
- which clients are considered isochronous
- which clients participate in power-saving hysteresis operations

Device Initialization and Calibration Cycles

In particular, PAs will need to write registers in the DRAM devices via special cycles to initialize the DRAM. In general all special cycles to a device are done via a hardware/software handshake that looks like:

- Software writes information about the special cycle to an Arbiter-specific register
- The Controller does the special cycle out to the DRAM device(s) when timing requirements are met
- Software checks a status register to ensure the special cycle is complete; or for Mode Register Read operations, the Controller issues an interrupt to indicate that the special cycle has been consumed

Special cycles may be emitted during normal operation as well; the Arbiter will inject them into the data stream at appropriate places (typically along with refresh cycles).

During device initialization, software must ensure that no client can access the memory. This can be done with per-module flush-enable bits.

20.3.1.3 Global Memory Subsystem Configuration

Some parts of the Memory Subsystem must be configured before any transfers are allowed into the system. The address map must be configured to set which portions of the physical address map are allocated to which Protocol Arbiters, and what portions of it are protected by the physical address protection mechanisms. Hardware may enforce address-range-based protection to carve out memory that is only accessible via a Secure TrustZone transaction, or memory that is read-only (to protect OS code). This is in addition to the translations available via the SMMU.

The Arbitration Domains operate off of a unified arbitration clock. This clock is further divided-down to produce a clock-rate independent clock for counting latency intervals across the Memory System (also known as “ticks”). This divide-down should be programmed to a constant interval at initialization (and any other clock-rate change). A 30 ns interval is suggested since it is an even divide-down of many common DRAM clocks, but any convenient granularity may be chosen.

There are also a few global memory system tuning options that tend to shape the memory performance. They are mentioned here for reference:

- The *expiration* value, which is in latency-count units. This is the expected amount of time that the Memory Subsystem thinks it will need on average to "fast-path" a request through the system. A request becomes "hot" when the latency timer reaches the expiration value, and has expired once the latency timeout hits zero[2]. Increasing the expiration value reduces the number of requests that exceed the latency timeout, but at a cost of overall efficiency.
- The *priority inversion limit*, which limits how long a low-priority (non-expired) group of requests can keep a bank open before a high-priority (expired) group of requests will close the bank. The priority inversion limit is in atoms; if a lower-priority page has this many atoms or fewer to retire, it is allowed to keep the bank open and finish its request. If it has more, the bank is closed to allow the high-priority requests and the low-priority requests must re-open the bank later to finish the request group. The priority inversion limit parameter increases worst-case latency while increasing efficiency.
- SMMU configuration. The SMMU will require software to set up and maintain page tables in memory, enable translation for clients, and assign clients to address space identifiers.

20.3.2 Power Management

The primary forms of system power management involve transition to and from low-power DRAM states. The DRAM controller can be programmed to automatically enter a precharge power-down or self-refresh state after some amount of time without a request. The power-down state can be independently entered for each individual DRAM device – it is possible for one device to be in power-down while another is active. If software knows that the system will not be making further DRAM requests, it can cause an immediate transfer to the self-refresh state by writing an override register. If multiple chip selects are available for the DRAM controller, both the hardware and software may choose to enter low-power states on a per-chip-select basis.

Once a request is queued to the controller for that DRAM the hardware will automatically wake from the low-power state if it entered that state via hardware control. This can take a relatively long amount of time since the controller may be required to issue a number of refresh cycles first. For software-initiated self-refresh, software must issue a register write to start the transition from self-refresh back to a fully-powered state.

Deep power-down must be explicitly requested by software, since it causes DRAM data to be lost. Software must disable new incoming requests to the MSS, wait for all outstanding in-flight requests to retire, and then write a register to transition to the deep power-down state. To exit the state, software must reinitialize the DRAM and controller before re-enabling transfers. Deep power-down mode may be enabled for each chip-select in a Protocol Arbiter independently and each Protocol Arbiter independently.

Normal active bank power optimization is managed principally by the Protocol Arbiter. The arbiter will arrange to close banks as soon as possible and to hold requests for as long as the latency timer will allow, with the intent of grouping same-page accesses into a coherent burst. One important case of active power management is the "OSIdle" use case where only Display is active. The Display client can be prone to "dribbling" – that is, sending isolated requests at infrequent intervals.

When doing the OSIdle use case, the Protocol Arbiter will not have enough traffic to keep the client dribble from becoming DRAM dribble (isolated requests that open and close the DRAM pages more often than necessary). To manage DRAM dribble, the controller adds the concept of the "*hysteresis hold-off*", which is a per-controller state bit. When the hold-off is active, the controller is held off from issuing activate commands to open new DRAM pages. Incoming requests will back up in the Protocol Arbiter's row sorter and store buffer until the hold-off is released.

The hold-off is enabled whenever an individual device goes idle due to lack of work. It is released automatically whenever a latency timer expires, or the Protocol Arbiter stalls due to fullness. The net effect of the hold-off is to group *all* requests for the DRAM into activity bursts.

[2] In practice, the latency timeout doesn't actually count down; rather hardware time-stamps the incoming request and computes a deadline value which is based on the current time + latency timeout – expiration. The request has expired when the current time passes the deadline.

The hold-off causes a delay in requests transitioning from a memory-idle state. This can affect some traffic in a negative manner – principally requests that are low-latency like the CPU. To keep the hold-off from impacting these requests, software has a per-module configuration bit that disables the hold-off for certain known-latency-sensitive clients. Whenever a request with the holdoff-disable bit set enters the Protocol Arbiter, the hold-off is released.

A final aspect of power management is scaling the Memory System clocks. Generally there are two sets of clocks that can be controlled:

- The overall Memory System “arbitration clock”, which is the clock used by the Arbitration Domains. Changing this clock reduces the overall bandwidth of the system and reduces the power required by the client interfaces and cross-chip Memory System routing.
- Individual Protocol Arbiter clocks. These reduce the bandwidth available to a particular memory pool and reduce the power consumed by the external pins and the external DRAM. Some Protocol Arbiters may be synchronous to the arbitration clock and not be explicitly controllable via a separate clock enable.

Both clocks may be changed as part of frequency scaling. Changing the arbitration clock rate affects the Arbitration Domain’s idea of the latency timeout. As described in the above section, software should change the divide-down register to keep the scale of latency timeout “ticks” to a (relatively) constant time unit. Generally a tick time of 30 ns is used since it divides evenly into most of the common DRAM frequencies, but any value of tick granularity may be chosen.

Both the arbitration clock and memory clock have separate divide-downs.

Changing the Protocol Arbiter clock rate affects the relative memory timing parameters. The DRAM timing parameters are double-buffered to allow software to update the timing values for the next clock speed setting and then simultaneously switch to using the new values by writing a trigger.

The DRAM protocol itself may require further clock-change restrictions. For example, DDR3 requires a certain number of cycles in which to re-lock the on-DRAM DLL. To further facilitate the hardware/software handoff, and reduce latency for the clock-change operation, a hardware handshake exists between the clock controller module and the Protocol Arbiter.

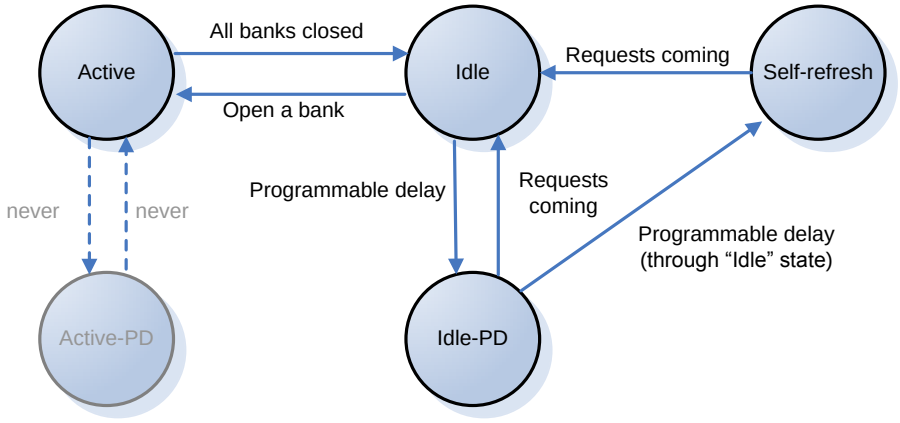
The MSS maintains two copies of each configuration register that may need to change due to a clock-change, the “active” and “assembly” copies; this is also known as a “shadowed” register. The active copy is what the MSS is currently configured to use, and cannot be written to. The assembly copy can be written to at any time, and it can be copied onto the active via a trigger mechanism. The clock-change handshake includes a hardware-initiated trigger for this shadow update.

To assist in full-system power analysis using silicon, the Protocol Arbiter should include enough statistics about the DRAM bus cycles to be able to calculate the DRAM power consumed.

20.3.2.1 Power State Transitions

The power state transitioning is illustrated in the following figure. When all banks are closed, DRAM transitions from active mode to idle mode, from which it can enter idle-powerdown mode. If DRAM accesses are coming, the DRAM will wake up and go back to idle. Otherwise if a long period of time has passed, the DRAM will quit idle-powerdown mode and enter self-refresh mode to save more power. Active-powerdown mode is supported by the EMC but will not happen because the MC does not tell the EMC it is idle until it closes all banks:

Figure 49: DRAM State Transitions and Conditions



20.3.3 Surface Allocation

For linear buffers, software needs to allocate a range of virtual addresses for the buffer and map them to physical pages; the address mapping of bytes within the buffer corresponds to the buffer’s virtual address. For 2D surfaces there are multiple options for layout of the bytes in the surface.

Pitched surfaces are the most straightforward. Assuming 8-bit pixels, for a given pixel coordinate (x, y), the pixel’s byte address is:

Address = Surface_base + y * Surface_pitch + x

For larger pixels, “x” is first multiplied by the number of bytes per pixel.

The Surface_pitch value is the line-to-line stride in bytes of the surface. This may be equal to the surface’s width times the bytes-per-pixel value or it may be additionally padded to a larger stride. Pitched surfaces are conceptually straightforward to use, but they can be inefficient if accesses walk in a vertical or diagonal direction through the surface, since each line may be in a different DRAM row. Software can help on pathologically-sized surfaces (where vertical traversal causes a bank collision) by padding out the Surface_pitch value, but in general they are best used when the surface will only be traversed horizontally or as an interface to naive software that assumes a pitched arrangement.

Tiled surfaces attempt to improve performance for vertical and diagonal traversal by making the DRAM page map more square in the surface. Previous chips used a form of tiling that ordered bytes within the surface into 16x16 tiles:

Address = Surface_base + (y / 16) * (Surface_pitch * 16) + (x / 16) * 256 + (y % 16) * 16 + (x % 16)

The previous memory controller design put the DRAM bank bits at the 1 KB boundary, so a DRAM page ends up being a 64x16 arrangement of bytes. Clients that traverse horizontally get four 16-byte atoms in-page before moving to a new bank, and with a four-bank DRAM get 16 atoms before needing to cycle a bank for a given row, which was enough to ensure efficient access to the page.

Similarly, clients that accessed vertically got 16 atoms in-page before moving outside the tile. Software would still need to pitch-pad the surface to ensure that moving vertically did not cause a bank collision – to do this it needed to make sure that Surface_pitch was not a multiple of 1 KB.

20.3.4 Statistics and Debugging

Statistics are used for performance monitoring and for generating usage information for guiding dynamic voltage and frequency scaling. Hardware will provide a set of statistics counters that are used for DVFS, both for global MSS bandwidth and for individual PA bandwidth. A separate set of counters with additional filtering support will be available for performance monitoring and debugging.

The hardware blocks illegal transfers to memory. Some transfers are based on physical DRAM limitations (addressing outside of the address map), permissions (addressing “secure” physical memory from a non-secure client) and from the SMMU (accessing an unmapped page). All of these are reported via a fault interface which records the transfer information of the last faulting address, including the following data:

- Virtual address of fault
- Module and client ID of fault
- Fault type

Faulting transfers continue through the system, but faulting reads return all-ones and faulting writes discard the write data. Writing a fault triggers a (maskable) interrupt.

20.4 Coherency and Ordering

- The MSS does not guarantee the coherency between different clients.
- The MSS does guarantee that within a single write client, if a write is sent with a write-response tag, all previous writes from that client will complete before returning the write completion tag.
- The MSS also guarantees that within a single client, writes to the same address will complete in-order.

The combination of the three above rules can produce problems if a module accessing memory assumes PCI-like ordering rules; since write ordering is not guaranteed as seen by other clients in the system, it is possible for this scenario to occur:

- Client A is polling a flag location in memory to see that a packet arrives.
- Client B sends write request for packet data to a buffer in memory.
- Client B sends write request to flip the flag to “available”.
- Client B writes to the flag complete.
- Client A sees this and starts reading the packet data.
- Client B’s packet data writes complete.

Obviously in this scenario, Client A reads incorrect data. The recommended way to solve this problem is to avoid polling loops in software as they are inefficient in both performance and power, and instead architect synchronization points in the hardware so that Client B can directly interrupt Client A when it determines all work is complete.

If such modifications cannot be made to the clients, then the writing client must be restricted to one request outstanding. Individual Protocol Arbiters may provide further ordering guarantees. If only one PA exists, then the ordering rules for the MSS may be relaxed to match that of the PA.

For Tegra 4 devices, the SMMU implementation guarantees that the lower 10 bits of the virtual address are untranslated. The Protocol Arbiter implementation guarantees that writes from a single client made to a single page will complete in-order. The Protocol Arbiter also guarantees that the lower 10 bits of the physical address are always column bits. Therefore, Tegra 4 devices can guarantee that writes within the same kilobyte-aligned kilobyte of address will complete in-order, regardless of whether the client is dealing in virtual or untranslated physical addresses.

20.5 Hardware / Software Partitioning

Software needs to be involved in the configuration, translation, and power management services as described above. The main CPUs will run their clients as untranslated by the SMMU, instead relying on the CPU's MMU to do translation. The system does not provide SMMU translation for the CPU clients. It is up to software to keep the CPU and SMMU page tables matched.

Surface allocation is straightforward; software allocates the surface out of the device's virtual space, and then backs the mappings with physical pages. Software should make sure to make the surface mappings not bank collide by pitch-padding surfaces to prevent vertical bank conflicts (generally, this means making sure the pitch for block-linear surfaces is not a multiple of 256 bytes). For surfaces that are accessed in tandem (YUV planar surfaces, Depth and Color for 3D, etc.) software should align the surfaces to start on different banks and use the BANKSWIZ surface kinds to remove page collisions.

20.6 LPDDR3 CA Training and Swizzling

LPDDR3 CA training is required from the latest JEDEC committee conference and is still being defined.

CA training is required at cold boot, and likely not needed on the fly or at warm boot. The CA training sequence is in the Boot ROM. Software can alternatively use micro-boot instead of Boot ROM code to initialize DRAM. The extra delay caused by that at cold boot is not an issue.

Reset, CA training entry, and CA training exit are the only three commands that are – or can be issued as – single data rate. Thus they can be issued at normal frequency without CA training. Resetting after each stepping of training may not be necessary, but it can prevent a training pattern that could be latched as training-exit command by mistake.

Byte swizzling and bit swizzling in bytes are required for CA training. Channel swizzling is requested for DSC 64-bit memory support. The differences between the different swizzling operations are:

- Byte swizzling: the bytes can swap. Bytes are swapped together with their corresponding DQS and DQM signals.
- Bit swizzling: The bits can swap inside any byte.
- Channel swizzling: A specific swizzling is requested for a second method of mapping pin signals. Each channel has three address stacks. You may swizzle within each stack but are not allowed to swizzle among different stacks. Data bytes may be swapped within each channel as well as bits within a byte. DQS/DQM must remain with their byte groups.

For more information on configuring the registers for CA training and swizzling, refer to the EMC_CA_TRAINING_START_0 register description.

20.7 Software Interfaces

The primary software interface for configuration is via the APB bus registers.

- Initial configuration
- Power management
- Device management
- SMMU translation management
- Surface allocation
- Statistics and debugging

The most important tool for configuration is **emc_reg_calc**, which is a tool to generate the DRAM timing and configuration sequences based on information from a vendor's datasheet. Contact your NVIDIA support engineer for further details.

20.7.1 Boot

Tegra 4 devices have a two-stage boot:

- The Boot ROM is responsible for getting the chip out of reset to where driver-level software can take over.
- The Boot Loader or the OS-recovery code is the portion of the driver responsible for completing the boot process to the general-purpose OS.

The Boot ROM is an actual ROM built into the chip, and the Boot Loader and OS recovery section is externally loaded code. The Boot Loader is only used for Cold boot; Warm boot utilizes operating-system recovery code.

Tegra 4 devices can “boot” in two ways: “Warm boot” or “Cold boot”. Cold boot is defined as booting from a fully powered-off or fully reset state. Warm boot is defined as recovery from the lowest-power state (LP0), where the external DRAM has been held in self-refresh mode while the Tegra 4 core was powered off. Warm boot use case occurs much more often; for example, it is the use case hit whenever a SmartPhone wakes from Standby to answer a call.

20.7.1.1 Cold Boot

Before Memory Subsystem boot can begin, the Boot ROM must read the Boot Configuration Tables (BCTs) from flash memory (slow storage) into on-chip RAM. These tables include the configuration data for up to 4 initial DRAM configurations supported. The Boot ROM then reads the strap signals assigned to the SDRAM and begins to bring up the memory subsystem.

The Cold boot Boot ROM sequence:

1. Configure PLL used by the MC/EMC based on BCT values
2. Wait for PLLs to lock
3. Program necessary always-on static pad configurations in the PMC
4. Configure memory clocks based on BCT values
5. Enable the MC/EMC clocks
6. Release memory subsystem resets
7. Program other necessary pad/pad-macro configuration
8. Program initial configuration for the MC/EMC based on BCT values
9. Perform the DRAM initialization sequence. This sequence is specific to the DRAM protocol used and varies depending on the requirements of a particular device. For example, a DDR3 sequence goes as follows:
    a. Apply power to the device
    b. Wait until voltage is stable
    c. Assert DRAM reset
    d. Wait 200 µs
    e. Deassert DRAM reset
    f. Apply stable clocks
    g. Wait 500 µs
    h. Assert and hold CKE high
    i. Precharge all banks
    j. Send 2 Auto-refresh commands
    k. Write to Mode register 0, 1, 2, 3
    l. Issue ZQ Calibration command
    m. Wait for ZQ calibration and DRAM DLL lock time to complete
10. Enable power saving features such as clock stop, active power down, dynamic-self-refresh

11. Start periodic sequences such as auto refresh, ZQ calibration, auto-calibration
12. Release the memory-initialization hardware lock[3]

After this, the external DRAM and Memory Subsystem are ready for use.

20.7.1.2 Warm Boot

The Warm Boot sequence is very similar to the Cold Boot sequence, and many of the same steps are performed. One difference is that instead of powering on the DRAM, we are waking it out of SelfRefresh. Another difference is the configuration data for Boot ROM portion of MC/EMC initialization is stored in the Power Management Controller (PMC) Scratch registers.

The PMC Scratch registers are in the Always-On partition, and are powered during LP0. The power and area limitations of this implementation restricts the number of PMC Scratch registers available; there are a smaller number of PMC Scratch Registers than the number of bits needed to fully configure the MC and EMC. The Scratch Registers are only used to store the minimum required configuration to get to working DRAM. The Boot ROM may not be able to Warm boot to full POR speed using only the Scratch Register data; if this limitation is confirmed, the BootLoader may be required to mimic DVFS software and reprogram the MC/EMC to full-speed operation using data stored in DRAM. It is up to the LP0 Entry software code to ensure the proper configuration gets written to the Scratch Registers.

The Warm boot code provided by the MSS includes algorithms for deriving the approximate MC arbiter performance parameters from the EMC timing parameters. The EMC has provided generation code for the packing/unpacking calls for the scratch registers to ease the software maintenance burden.

The Warm boot Boot ROM sequence:

1. Configure memory PLLs and memory clocks based on Scratch values
2. Wait for PLLs to lock
3. Configure memory clocks based on scratch values
4. Enable the MC/EMC clocks
5. Release memory subsystem resets. Program any necessary static pad configuration that was powered-off in LP0
6. Program initial configuration for the MC/EMC based on Scratch values
7. Release the DRAM from software-controlled Self Refresh. This sequence is specific to the DRAM protocol used and may further vary depending on the requirements of a particular device. For example, a DDR3 sequence goes as follows:
    a. Apply stable clocks
    b. Assert and hold CKE high
    c. Issue ZQ Calibration command
    d. Wait for ZQ calibration and DRAM DLL lock time to complete
    e. Write to Mode registers if different from LP0 entry values
    f. Issue refreshes to ensure tREFI is satisfied
8. Enable power saving features such as clock stop, active power down, dynamic-self-refresh
9. Start periodic sequences such as auto refresh, ZQ calibration, auto-calibration
10. Release the memory-initialization hardware lock

After the Boot ROM sequence is complete, the operating system restore code may access DRAM and restore a different or higher-speed operation. The operating system may also restore translation or client configuration settings before allowing any user code to execute.

[3] AHB_ARBITRATION_XBAR_CTRL.MEM_INIT_DONE

20.7.2 Security Apertures

To secure the MC registers, the ARM® Cortex™-A15 MPCore™ page table entries for the MC register space must be marked as secured. Then to access the registers securely, the Cortex-A15 must be switched into secure mode. For more details about these Cortex-A15 operations, please read the Cortex-A15 architecture manual from ARM.

To secure a region of EMEM, the Cortex-A15's page table entries for that region must be marked as secured. Then the MC registers must be configured for the secured region, using Cortex-A15 in the secured mode:

RegWrite(MC_SECURITY_CFG0, security_aperture_base_address);

RegWrite(MC_SECURITY_CFG1, security_aperture_size_in_megabytes);

After the registers are updated, the Cortex-A15 must be in secure mode to access the described region of memory.

To protect a region of EMEM, the MC register must be configured for the protected region, using Cortex-A15 in the secured mode:

RegWrite(MC_SECURITY_CFG2, carveout_base_address);

For more information on handling security violations, see the subsection "MC Interrupts" below.

20.7.3 Virtual Addressing: Using the SMMU

For a discussion of the virtual-address translation features provided by the SMMU, please read subsection on "Virtual Addressing" below.

In Tegra 4 devices, it is physically impossible to enable SMMU translation for the Cortex-A15 CPU.

There is no way to apply different ASIDs to requests that arrive at the MC through the same MCCIF client. An example would be all three USB controllers access EMEM through the AHBSLV clients on Tegra 4 devices; thus there is no way to assign those USB controllers to different ASIDs.

There is a need on the software side to distinguish between an invalid mapping (which has an invalid PA field) and a mapping that is valid, but has no access. The following pseudo-code describes the recommended conventions.

```
// page/section/address space permission types
//
// note that INVALID implies the PA field is unused.
// PA is valid for all others, including NO ACCESS.
enum Permission {
     INVALID           = NvU32(0),
     NO ACCESS         =                        NONSECURE,
     SECURE WRITE ONLY =            WRITABLE,
     WRITE ONLY        =            WRITABLE | NONSECURE,
     SECURE READ ONLY  = READABLE,
     READ ONLY         = READABLE |             NONSECURE,
     SECURE            = READABLE | WRITABLE,
     ANY               = READABLE | WRITABLE | NONSECURE
 };
```

For more information on handling SMMU faults, see the subsection on "MC Interrupts" below.

20.7.3.1 SMMU Initialization

1. For each Virtual Address Space (VAS) to be used, set up the page table in the DRAM. See the subsection on "Virtual Addressing" below for details on the page-table formats supported.
2. For each ASID, set up the pointer to the page-table base and the ASID-wide protection bits. Since the PTB pointers are stored in a RAM, this uses an indirect access mechanism involving two register writes:

a. Write MC_SMMU_PTB_ASID_0 with the ASID to be modified.
b. Write MC_SMMU_PTB_DATA_0 with the information for this VAS:
    - Page Table Base pointer
    - Whether non-secure accesses are allowed
    - Whether reads are allowed
    - Whether writes are allowed

3. Assign hardware engines (SWNAMES) to the ASIDs and turn on translation for those engines. This involves writes to various MC_SMMU_<SWNAME>_ASID_0 registers.
4. If needed for Hardware Diagnostics purposes, disable or enable translation within a SWNAME on a per-client basis. This involves writes to various bits in MC_SMMU_TRANSLATION_ENABLE_*_0 registers.
5. If desired, secure the ASIDs, which prevent untrusted code from modifying the ASID PTB pointers by enabling a requirement for TrustZone security on register writes that modify the PTBs. This operation involves a write to MC_SMMU_ASID_SECURITY_0. Note that this register itself is secured by TrustZone to prevent it from being modified by untrusted sources, and in some situations writes to it must also be TrustZone secured for them to take effect. In particular, you cannot change a module's ASID with a non-secure write if you are trying to change it to a secure ASID, or if it is already a secure ASID.
6. If desired, enable ASID promotion, which allows clients without security access to inherit the security status based on the page-table translation. This operation involves a write to MC_SMMU_ASID_SECURITY_0.
7. Write PTC_FLUSH_TYPE=ALL to MC_SMMU_PTC_FLUSH_0.
8. Write TLB_FLUSH_VA_MATCH=ALL to MC_SMMU_TLB_FLUSH_0.
9. Configure reserved bits found to be necessary during chip bring-up, if any. There are reserved bits in MC_SMMU_PTC_CONFIG_0 and MC_SMMU_TLB_CONFIG_0.
10. Enable the SMMU by writing SMMU_ENABLE=ENABLE to MC_SMMU_CONFIG_0. Note that this register is secured by TrustZone to prevent it from being modified by untrusted sources, and writes to it must also be TrustZone secured for them to take effect.

20.7.3.2 Page Table Modifications after Initialization

Modifications may be made to the page tables while the system is operating, however, care must be taken to avoid modifying an entry that is in active use. Modifying an entry in active use will result in undefined operation; the most likely failure is the use of an out-of-date cached translation. The general rules for safe modification are:

- If no client is using an ASID, then that ASID and its page table can be modified.
- If no client is using any PTE in a PDE, that PDE can be modified.
- If no client is using a PTE, that PTE can be modified.

It is up to software to ensure these rules are followed when virtual address translations need changed. Once software has updated the page-table or ASID mappings, the final step is to perform PTC and TLB flushes on the modified entries. Note that the granularity of flushing is at the PTE group, which is the number of PTEs that fit in a memory atom. Software can write:

- MC_SMMU_TLB_FLUSH_0 to flush a specific page group, 4MB section, entire ASID or the entire TLB.
- MC_SMMU_PTC_FLUSH_0 to flush a specific PTE or PDE from the PTC

20.7.3.3 Collecting Statistics on SMMU Performance

The TLB and PTC each have hit and miss statistics counters. To enable statistics collection, set MC_SMMU_*_CONFIG_0.*_STATS_ENABLE == ENABLE, where * stands for PTC or TLB. The counters will begin collecting information when enabled. To check the results, read the appropriate registers:

- MC_SMMU_STATS_TLB_HIT_COUNT_0

- MC_SMMU_STATS_TLB_MISS_COUNT_0
- MC_SMMU_STATS_PTC_HIT_COUNT_0
- MC_SMMU_STATS_PTC_MISS_COUNT_0

These counters do not saturate when full; instead they wrap from MAX_UINT to 0. There is no explicit reset for these counters; the only reset-like option is to force the counter bits to all 1's using the MC_SMMU_*_CONFIG_0.*_STATS_TEST trigger bits. This is essentially like resetting the counters to -1.

20.7.4 DVFS Sequences

DVFS (Dynamic Voltage and Frequency Scaling) is a software feature for controlling system power. A key hardware feature for supporting that is changing SDRAM frequency on the fly with minimal impact on system performance. That indicates the following requirements:

- EMC timing parameters and their corresponding MC arbitration timing parameters need to be adjusted to the optimal performance for the new frequency. These parameters can usually be derived from DRAM datasheet and do not need characterization.
- All trimmer values need to be adjusted for the new frequency. These values need to be characterized across PVT (process, voltage, temperature) and frequencies.
- The pad configurations that can be turned off to save power at low frequencies should also change with frequency change, such as pad terminations and DQS pulls.
- All registers involved in frequency change should be shadowed. That includes the reserved register fields that can possible be turned on only in a certain frequency range. Note that any Hardware Diagnostics feature that has power implications should be considered to be shadowed.
- No software interference should be expected from software after software pulls the trigger to change frequency and before the clock change completes: Software runs on CPU from SDRAM. Once the EMC blocks the requests to SDRAM, the CPU may be frozen until the EMC finishes frequency change and unblocks the requests. Note that the CPU can also possibly run out of the contents in cache during clock change, so we need to consider both scenarios.
- The delay caused by clock change should not cause functional failures or visible artifacts.

That result in a design as follows:

- The CAR module handshakes with the EMC on clock change. The EMC handshakes with the MC on shadow register latching. The whole process is done by hardware and transparent to software.
- A rough estimation of clock change delay is 1-4 µs for LPDDR2, 2-6 µs for DDR3.
- Supports two clock change mode: self-refresh clock change mode and power-down clock change mode. Both LPDDR2 and DDR3 support both modes. We recommend clock change power-down mode for LPDDR2 since it takes shorter time. We recommend self-refresh clock change mode for DDR3, since power-down clock change mode does not allow DLL to be turned off.
- For flexibility, EMC has a 16-deep FIFO to hold register programming and release them during or immediately after clock change. That enables us to send DRAM command or latch in unshadowed registers. Here are a few examples:
  - Self-refresh clock change mode requires programming EMC_SELF_REF to put DRAM in self-refresh during clock change.
  - DDR3 precharge-power-down mode requires programming EMC_PRE to close all banks before clock change.
  - Both DDR3 and LPDDR2 clock change requires writing mode registers after clock change.
  - To support DLL-ON/DLL-OFF mode switching on DDR3, program mode registers before or after clock change according to the DDR3 specification.

This is a summary of the frequency change process:

- Software turns off features like self-refresh or auto-calibration if necessary to minimize their interference with the DVFS sequence.
- Software programs MC/EMC shadow registers for the new frequency
- Software programs EMC clock change flow control registers, such as entering self-refresh before clock change and programming SDRAM mode registers after clock change.
- Software programs the MC/EMC clock source register to trigger the clock change.
- The CAR sends clock change request to the EMC (clock divider and/or clock source).
- The EMC stalls all DRAM commands including refreshes.
- The EMC handshakes with the MC to stalls incoming transactions and waits until EMC pipe is flushed
  Within handshaking, EMC may enters power down state if it is in power-down clock change mode.
- The EMC executes pre-clock change sequence such as entering self-refresh and programming mode register to turn off DLL.
- The EMC latches in shadowed registers and requests the MC to latch in shadow registers.
- The EMC acknowledges the CAR to change clock.
- The CAR changes the MC/EMC clock.
- The CAR deasserts the clock change request to the EMC indicating the clock change is done.
- The EMC executes post-clock-change sequence, such as exiting self-refresh and programming SDRAM mode registers.
- The EMC deasserts the clock change acknowledgement to the CAR.
- The EMC unstalls DRAM commands including refresh and resumes incoming MC transactions.
- Software waits 1µs before continuing.

Software programming sequence on the Tegra 4 clock change sequence:

- Before any clock change, usually at boot time:
  - Keep these register fields in reset values:
    CLKCHANGE_REQ_ENABLE = ENABLED
    CLKCHANGE_SR_ENABLE = DISABLED
  - CLKCHANGE_PD_ENABLE:
    ENABLED: power-down clock change mode (for LPDDR2)
    DISABLED: self-refresh clock change mode (for DDR3)
- At each clock change:
  - Clear clockchange_complete flag so we can poll it later for clock change completion:
    EMC_INTSTATUS.CLKCHANGE_COMPLETE_INT = SET
  - Disable DSR (dynamic-self-refresh) if it is currently enabled
    EMC_CFG. DYN_SELF_REF = DISABLE
  - If this clock change is going to switch from SCHMITT to VREF DQ mode, enable VREF DQ:
    EMC_XM2DQSPADCTRL2.EMC2TMC_CFG_XM2DQS_E_VREF_DQ = 1
  - If this clock change is going to switch from SCHMITT to VREF DQS mode, enable VREF DQS:
    EMC_XM2DQSPADCTRL3.EMC2PMACRO_CFG_XM2DQS_E_VREF_DQS = 1
  - If this clock change is going to turn on QUSE IVREF, enable it:
    EMC_XM2QUSEPADCTRL.EMC2TMC_CFG_XM2QUSE_E_IVREF = 1

- Latch shadow registers:
  EMC_TIMING_CONTROL = 1
  Poll for latching completion: EMC_EMC_STATUS_TIMING_UPDATE_STALLED == 0
- Wait 5µs to allow all actions above have finished
- If CFG_XM2COMP_VREF_CAL_EN mode needs to change with the clock change, turn off auto-calibration:
  EMC_AUTO_CAL_INTERVAL = 0
  Then poll for the possible on-going auto-cal to complete:
  EMC_AUTO_CAL_STATUS.AUTO_CAL_ACTIVE == 0
- Program the shadow registers for the new frequency, listed below:
  EMC_RC, EMC_RFC, EMC_RAS, EMC_RP, EMC_R2W, EMC_W2R, EMC_R2P, EMC_W2P, EMC_RD_RCD, EMC_WR_RCD, EMC_RRD, EMC_REXT, EMC_WEXT, EMC_WDV, EMC_QUSE, EMC_QRST, EMC_QSAFE, EMC_RDV, EMC_REFRESH, EMC_BURST_REFRESH_NUM, EMC_PRE_REFRESH_REQ_CNT, EMC_PDEX2WR, EMC_PDEX2RD, EMC_PCHG2PDEN, EMC_ACT2PDEN, EMC_AR2PDEN, EMC_RW2PDEN, EMC_TXSR, EMC_TXSRDLL, EMC_TCKE, EMC_TFAW, EMC_TRPAB, EMC_TCLKSTABLE, EMC_TCLKSTOP, EMC_TREFBW, EMC_QUSE_EXTRA, EMC_FBIO_CFG6, EMC_ODT_WRITE, EMC_ODT_READ, EMC_FBIO_CFG5, EMC_CFG_DIG_DLL, EMC_CFG_DIG_DLL_PERIOD, EMC_DLL_XFORM_DQS0, EMC_DLL_XFORM_DQS1, EMC_DLL_XFORM_DQS2, EMC_DLL_XFORM_DQS3, EMC_DLL_XFORM_DQS4, EMC_DLL_XFORM_DQS5, EMC_DLL_XFORM_DQS6, EMC_DLL_XFORM_DQS7, EMC_DLL_XFORM_QUSE0, EMC_DLL_XFORM_QUSE1, EMC_DLL_XFORM_QUSE2, EMC_DLL_XFORM_QUSE3, EMC_DLL_XFORM_QUSE4, EMC_DLL_XFORM_QUSE5, EMC_DLL_XFORM_QUSE6, EMC_DLL_XFORM_QUSE7, EMC_DLI_TRIM_TXDQS0, EMC_DLI_TRIM_TXDQS1, EMC_DLI_TRIM_TXDQS2, EMC_DLI_TRIM_TXDQS3, EMC_DLI_TRIM_TXDQS4, EMC_DLI_TRIM_TXDQS5, EMC_DLI_TRIM_TXDQS6, EMC_DLI_TRIM_TXDQS7, EMC_DLL_XFORM_DQ0, EMC_DLL_XFORM_DQ1, EMC_DLL_XFORM_DQ2, EMC_DLL_XFORM_DQ3, EMC_XM2CMDPADCTRL, EMC_XM2DQSPADCTRL2, EMC_XM2DQPADCTRL2, EMC_XM2COMPPADCTRL, EMC_XM2VTTGENPADCTRL, EMC_XM2VTTGENPADCTRL2, EMC_XM2QUSEPADCTRL, EMC_XM2DQSPADCTRL3, EMC_CTT_TERM_CTRL, EMC_ZCAL_INTERVAL, EMC_ZCAL_WAIT_CNT, EMC_MRS_WAIT_CNT, EMC_AUTO_CAL_CONFIG, EMC_CTT, EMC_CTT_DURATION, EMC_DYN_SELF_REF_CONTROL, EMC_FBIO_SPARE, EMC_CFG_RSV, MC_EMEM_ARB_CFG, MC_EMEM_ARB_OUTSTANDING_REQ, MC_EMEM_ARB_TIMING_RCD, MC_EMEM_ARB_TIMING_RP, MC_EMEM_ARB_TIMING_RC, MC_EMEM_ARB_TIMING_RAS, MC_EMEM_ARB_TIMING_FAW, MC_EMEM_ARB_TIMING_RRD, MC_EMEM_ARB_TIMING_RAP2PRE, MC_EMEM_ARB_TIMING_WAP2PRE, MC_EMEM_ARB_TIMING_R2R, MC_EMEM_ARB_TIMING_W2W, MC_EMEM_ARB_TIMING_R2W, MC_EMEM_ARB_TIMING_W2R, MC_EMEM_ARB_DA_TURNS, MC_EMEM_ARB_DA_COVERS, MC_EMEM_ARB_MISC0, MC_EMEM_ARB_RING1_THROTTLE
- If this clock change is going to enable DDR3 DLL (and previous frequency disables it), program the time needed for DLL latching into MRS_LONG_WAIT_CNT. You can minus the time that DLL locking overlaps with other commands (such as ZQ-long calibration time, if it is inserted in post clock change sequence below) to reduce this latency.
  EMC_MRS_WAIT_CNT_MRS_LONG_WAIT_CNT = 512 – overlapping-clocks-with-other-commands
- Program STALL_THEN_EXE_BEFORE_CLKCHANGE = 1
  All following EMC register programming will happen after flushing DRAM requests and stalling further DRAM commands, including auto-refreshes.
  IMPORTANT NOTE: EMC register read still stop functioning from this point until the clock change completes: issuing an EMC register read in this duration will hang the system.
- (optional) Program unshadowed EMC registers that need to change with clock change. For example, if periodic_qrst needs to be enabled during clock change, it can be done here. If that register is shadowed, use WRITE_MUX = ACITVE before writing the register, then restore WRITE_MUX after writing the register.

- Disable auto-refresh to reduce the latency of clock change:
  EMC_REFCTRL.DEVICE_REFRESH_DISABLE = depending on DRAM configuration
  EMC_REFCTRL.REF_VALID = DISABLE
- (self-refresh clock change mode only, DLL-ON to DLL-OFF mode switching only, DDR3 only)
  Program EMC_MRS to disable DLL.
- (self-refresh clock change mode only) Program SELF_REF to enter self-refresh:
  SELF_REF.DISABLED = ENABLED
  SELF_REF.DEV_SELECTN = depending on DRAM configuration
- Program STALL_THEN_EXE_AFTER_CLKCHANGE = 1
  All following EMC register programming will happen after clock change but before unblocking DRAM requests
- (optional) Program other unshadowed registers that need to be programmed during self-refresh, such as EMC_XM2CLKPADCTRL register. If periodic_qrst is enabled in clock change but not meant for the new frequency, the value can be restored here.
- (self-refresh clock change mode only) Program SELF_REF to exit self-refresh
  EMC_SELF_REF.DISABLED = DISABLED
  EMC_SELF_REF.DEV_SELECTN = depending on DRAM configuration
- Program DRAM mode registers by MRS/EMRS (DDR3) or MRW (LPDDR2) to change CL/WL/TWR etc.
  On DLL-OFF to DLL-ON switch on DDR3, DLL is turned on with this step. Note that if a mode register has the same value at both the old and new frequencies, it does not have to be programmed.
- Issue ZQ calibration if the clock change is switching from a ZQ calibration disabled frequency to a ZQ calibration enabled frequency.
- Program UNSTALL_RW_AFTER_CLKCHANGE = 1
  Note that all following EMC register programming will happen after clock change, possible with on-going SDRAM access
- Read and discard an arbitrary MC register (Note: cannot use an EMC register) to ensure the register writes are complete.
- Do clock change. Note that until this step, SDRAM access were still happening in the system
  Program CLK_SOURCE_EMC to change clock:
  EMC_2X_CLK_SRC: MC/EMC clock source
  USE_PLLM_UD: use low jitter clock
  MC_EMC_SAME_FREQ: drive EMC vs. MC clock ration at 1:1, otherwise 2:1
  EMC_2X_CLK_DIVISOR: EMC clock divider
- Poll for clock change completion:
  EMC_INTSTATUS.CLKCHANGE_COMPLETE_INT == 1
- Re-enable auto-refresh
  EMC_REFCTRL.DEVICE_REFRESH_DISABLE = depending on DRAM configuration
  EMC_REFCTRL.REF_VALID = ENABLE
- Re-enable auto-calibration if it was previously enabled and then temporarily disabled during clock change:
  EMC_AUTO_CAL_INTERVAL = new value
- Re-enable DSR (dynamic-self-refresh) if it was previously enabled
  EMC_CFG. DYN_SELF_REF = ENABLE
- If EMC_ZCAL_WAIT_CNT was changed before clock change for issuing ZQ-long calibration command, restore the value:
  EMC_ZCAL_WAIT_CNT = new value
- Wait 2 µs for the actions above to complete

- Update shadow registers
  EMC_TIMING_CONTROL = 1
  Poll for latching completion: EMC_EMC_STATUS_TIMING_UPDATE_STALLED == 0

20.7.5 ZQ Calibration Sequence

ZQ calibration is a feature of LPDDR2 and DDR3 to calibrate R on (the output driver) across PVT (process, voltage, temperature), and also ODT values on DDR3. The EMC supports periodically sending ZQ calibration commands to both DRAMs, requiring only initial configuration after booting. The EMC also supports one time calibration commands at booting.

For cold booting, the boot ROM does a ZQ-init on LPDDR2 and a ZQ-long on DDR3, and then enables periodic ZQ-short.

For warm booting, boot ROM does ZQ-long on both LPDDR2 and DDR3, and then enables periodic ZQ-short.

One time calibration:

- LPDDR2, Write MC_MRW:
  - MRW_DEV_SELECTN: 2 for device 0, 1 for device 1. Or use 0 for both (not used because software must control the delays between commands in boot ROM).
  - MRW_MA: 10
  - MRW_OP: 0xFF for ZQ-init. 0xAB for ZQ-long, 0x56 for ZQ-short
- DDR3: Write EMC_ZQ_CAL
  - ZQ_CAL_DEV_SELECTN: 2 for device 0, 1 for device 1. Or use 0 for both (not used because software must control the delays between commands in boot ROM)
  - ZQ_CAL_LENGTH:
    SHORT: issue ZQ-short command
    LONG: issue ZQ-long command
  - ZQ_CAL_CMD: 1

Periodic calibration:

- EMC_ZCAL_INTERVAL: Number of microseconds to wait between periodical ZQ commands. Program this register to 0 to disable periodic ZQ calibration
- EMC_ZCAL_WAIT_CNT: Number of clocks to wait after each ZQ command before other commands
- EMC_ZCAL_MRW_CMD:
  - ZQ_MRW_DEV_SELECTN
    2 for device 0 only, 1 for device 1 only, 0 for both devices
  - ZQ_MRW_MA
    LPDDR2: 10
    DDR3: 0 for ZQ-short, 1 for ZQ-long
  - ZQ_MRW_OP
    LPDDR2: 0x56 for ZQ-short; 0xAB for ZQ-long
    DDR3: 0

20.7.6 MRR Sequence

Mode Register Read (MRR) is desirable on LPDDR2 for reading the manufacturer ID to identify DRAM vendors, or reading back from the LPDDR2 temperature sensor.

Simple sequence:

- Before any MRR, such as at booting:
  - Set MRR_BYTESEL and MRR_BYTESEL_X16 corresponding to data byte sizzling, if applied on board. The reason is that LPDDR2 always returns MRR at low byte of a data strobe, which is the only case that EMC needs to know about swizzling.
- For each MRR
  - Check EMC_STATUS.MRR_DIVLD = 0. If not true, read EMC_MRR until it becomes true
  - Issue MRR:
    MRR_MA: the index of the mode register to read back
    MRR_DEV_SELECTN: 2 for device 0, 1 for device 1. 0 or 3 are illegal. If both devices are desired, repeat this sequence on each device.
  - Poll for EMC_STATUS.MRR_DIVLD = 1
  - Read EMC_MRR. Data is in the MRR.DATA field

20.7.7 Auto-Calibration Sequence

Auto-calibration is for periodically calibrating the output driver of Tegra 4 pads. The EMC supports periodic auto-calibration without software interference, usually initiated at booting.

To enable auto-calibration:

- Program AUTO_CAL_INTERVAL: the number of microseconds between two auto-calibrations
- Program EMC_AUTO_CAL_CONFIG:
  AUTO_CAL_START = 1
  AUTO_CAL_ENABLE = 1
  AUTO_CAL_OVERRIDE: 1 to enable override, 0 to use normal auto-calibration
  AUTO_CAL_PD_OFFSET: override value
  AUTO_CAL_PU_OFFSET: override value
  AUTO_CAL_E_CAL_UPDATE: number of EMC clocks E_CAL_UPDATE is asserted
  AUTO_CAL_STEP: number of microseconds between each calibration step

To disable auto-calibration:

- Program AUTO_CAL_INTERVAL to 0

To re-enable auto-calibration after disabling it

- Program AUTO_CAL_INTERVAL to the new value

20.7.8 LP0/LP1 Entry/Exit

LP0 and LP1 are both power saving modes with DRAM in self-refresh mode. The only difference is that the MC and the EMC are ON during LP1 but powered OFF during LP0.

LP0 and LP1 entry share the same sequence:

- Disable ZQ calibration: EMC_ZCAL_INTERVAL = 0
- Disable Auto calibration: EMC_AUTO_CAL_INTERVAL = 0
- Disable DSR (Dynamic self-refresh) EMC_CFG. DYN_SELF_REF = DISABLED

- Latch shadow registers:
  EMC_TIMING_CONTROL = 1
  Poll for latching completion: EMC_EMC_STATUS_TIMING_UPDATE_STALLED == 0
- Wait 5 µs for worst case DSR exit time
- Program EMC_REQ_CTRL to stall all transactions
  STALL_ALL_WRITES = 1
  STALL_ALL_READS = 1
- Wait until the EMC pipe is flushed
  poll EMC_EMC_STATUS.NO_OUTSTANDING_TRANSACTIONS == 1
- Enter self-refresh
  EMC_SELF_REF.SELF_REF_CMD = 1
  EMC_SELF_REF.SREF_DEV_SELECTN: 2 for device 0 only, 1 for device 1 only, 0 for both
- Wait until the device is in self-refresh
  poll EMC_EMC_STATUS.DRAM_IN_SELF_REFRESH ==
  1: dev0 is in self-refresh; 2: dev1 is in self-refresh; 3: both devices are in self-refresh
- Put VTTGEN in lowest power mode:
  EMC_XM2VTTGENPADCTRL.EMC2TMC_CFG_XM2VTTGEN_DRVUP = 0
  EMC_XM2VTTGENPADCTRL.EMC2TMC_CFG_XM2VTTGEN_DRVDN = 0
  EMC_XM2VTTGENPADCTRL2.EMC2TMC_CFG_XM2VTTGEN_E_NO_VTTGEN = 7
- Latch shadow registers:
  EMC_TIMING_CONTROL = 1
  Poll for latching completion: EMC_EMC_STATUS_TIMING_UPDATE_STALLED == 0
- Put pads in lowest power mode (must program in a single register write):
  APBDEV_PMC_IO_DPD_REQ.CODE = DPD_ON
  APBDEV_PMC_IO_DPD_REQ.POP_ADDR_CMD == ON
  APBDEV_PMC_IO_DPD_REQ.POP_CLK = ON
  APBDEV_PMC_IO_DPD_REQ.DDR_ADDR_CMD = ON
  APBDEV_PMC_IO_DPD_REQ.DISC_ADDR_CMD = ON
  APBDEV_PMC_IO_DPD_REQ.DDR_DATA = ON
  APBDEV_PMC_IO_DPD_REQ.COMP = 1
- Now it is safe to disable PLL, which will freeze EMC and DRAM clocks

LP0-exit is also called warm boot. Refer to the “Warm Boot” subsection.

LP1-exit:

- Enable PLL and waits until clocks stabilize
- Restore pad power state to normal. Note that writing back the original value to this register does not guarantee restoring to the original state. Instead, read and save the value of APBDEV_PMC_IO_DPD_STATUS before LP1 entry (which has value 0 on the register fields representing the enabled pads), and in this step write the inverted value of it (so that it has 1 on register fields representing the same enabled pads) to APBDEV_PMC_IO_DPD_REQ with the field “CODE” set to “DPD_OFF” (meaning “turn it on”).
- Restore the registers to original values before LP1 entry. The register values need to be read and saved before LP1 entry and restored here.
  EMC_XM2VTTGENPADCTRL
  EMC_XM2VTTGENPADCTRL2
  EMC_AUTO_CAL_INTERVAL (this will re-enable auto-calibration)
- Relock DLL.
  Read and write back EMC_CFG_DIG_DLL with field DLL_RESET set to 1.

- Latch shadow registers:
  EMC_TIMING_CONTROL = 1
  Poll for latching completion: EMC_EMC_STATUS_TIMING_UPDATE_STALLED == 0
- Do a single auto-calibration:
  Read and write back EMC_AUTO_CAL_CONFIG with field AUTO_CAL_START set to 1
- Wait for the auto-calibration to complete:
  EMC_AUTO_CAL_STATUS.AUTO_CAL_ACTIVE == 0
- Exit self-refresh
  EMC_SELF_REF.SELF_REF_CMD = 0
  EMC_SELF_REF.SREF_DEV_SELECTN = 2 for device 0 only, 1 for device 1 only, 0 for both
- poll for self-refresh completes
  poll for EMC_EMC_STATUS.DRAM_IN_SELF_REFRESH == 0
- Issue a ZQ calibration:
  LPDDR2:
  1. Write EMC_MRW with
     MRW_DEV_SELECTN = 2
     MRW_MA = 10
     MRW_OP = 0xAB
  2. Wait 1 µs
  3. If this is a two rank configuration, repeat step 1 with MRW_DEV_SELECTN = 1, then repeat step 2

  DDR3:
  1. Write EMC_ZQ_CAL with
     ZQ_CAL_DEV_SELECTN = 2
     ZQ_CAL_LENGTH = LONG
     ZQ_CAL_CMD = 1
  2. Wait 10 µs
  3. If this is a two rank configuration, repeat step 1 with ZQ_CAL_DEV_SELECTN = 1, then repeat step 2
- Program EMC_REQ_CTRL to unstall all transactions
  STALL_ALL_WRITES = 0
  STALL_ALL_READS = 0
- If ZQ calibration was enabled before LP1 entry, re-enable it.
  EMC_ZCAL_INTERVAL = saved value
- If DSR was enabled before LP1 entry, re-enable it:
  EMC_CFG. DYN_SELF_REF = ENABLED
  Latch in the shadow by EMC_TIMING_CONTROL.TIMING_UPDATE = 1
  The poll for latching completion: EMC_EMC_STATUS_TIMING_UPDATE_STALLED == 0

20.7.9 Performance Tuning

The Tegra 4 MSS is architected in such a way that, other than the per-client latency allowance setting, only minimal performance tuning is required.

> **Note:** The capitalization in the below sections refers to the actual register name of the associated setting.

20.7.9.1 Arbitration Knobs

The suggested configuration values produced by the emc_reg_calc program are the best-known values, software should use these values.

The Arbitration Domain provides a set of arbitration knobs that affect the entire MSS, particularly the fairness algorithm in the snap-arbitration. These knobs are:

- RING1_THROTTLE
- RING3_THROTTLE
- Per-partition SNAP_LEVELS

The Protocol Arbiter provides a set of arbitration knobs that affect the entire PA. These knobs are:

- MAX_OUTSTANDING count, and the related controls
- TURN and COVER costs for the Direction Arbiter
- PRIORITY_INVERSION thresholds
- BC2AA_HOLDOFF threshold
- EXPIRING_SOON threshold
- REFRESH_ACK threshold
- DEADLOCK_PREVENTION_SLACK threshold

It is *not* expected that software will need to change these values for best performance; the emc_reg_calc script has been used in the performance verification effort.

20.7.9.2 Per Client Knobs

Each client of the MSS has some configuration knobs that affect the behavior of the request in the PA. These knobs are:

- ISOchronous
- HYSTeresis
- Latency ALLOWANCE

Most clients set their ISO and HYST bits based on the behavior profile of the client; which is static for all systems. The default programming should be acceptable for these bits. The Latency Allowance may need to be programmed on a per-use case basis for some clients.

20.7.9.3 Activity indication for DVFS

The Tegra 4 MSS does not maintain statistics information for DVFS. However, it does send two signals to the centralized Statistics Monitor for that unit that maintains the threshold and interrupts that are used by DVFS. The number of atoms between toggles for these signals can be controlled by ATOMS_PER_DVFS_PULSE.

20.7.9.4 Statistics

Memory Subsystem statistics are for debugging/profiling only. There are two sets:

- MC statistics provide ability to view bandwidth/latency/per-client information.
- EMC statistics provide the ability to view DRAM commands, which you can then use to calculate approximate DRAM power consumption.

20.7.10 Errors (Interrupts)

Both the MC and the EMC implement a handful of interrupts to inform the software of completed events or error conditions encountered by the hardware. Both the MC and the EMC have implemented the same style of interrupt interface, so this section will use the MC as the example.

The interrupt interface for MC consists of two registers and a hardware output wire. The output signal is wired to the central interrupt handling module on Tegra 4 devices; from there it can be routed to any of the CPU complexes. The first register,

INTSTATUS, contains the interrupt vector for MC. Each bit in this register is set when the hardware detects an interrupt. Writing a 1 to the interrupt vector bit will clear the associated interrupt. The second register is INTMASK, each bit in this register corresponds to a vector bit in INTSTATUS. If the MASK bit for an interrupt is *clear (MASKED)*, the corresponding interrupt will *not* forward the interrupt to the central interrupt handling module. If any UNMASKED interrupt vector bits are set, the MC will assert the interrupt to the central interrupt handling module.

20.7.10.1 MC Interrupts

The MC contains two classes of interrupts: address decode errors and performance warnings.

There is currently only one performance warning type interrupt: ARBITRATION_EMEM. It fires when the MC detects that a request has been pending in the Row Sorter long enough for to hit the DEADLOCK_PREVENTION_SLACK_THRESHOLD. In addition to true performance problems, this interrupt may fire in situations like clock-change where the EMC backpressures pending traffic for long periods of time. This interrupt is intended to help developers identify and debug performance issues and configuration issues.

There are three types of address decode errors implemented for Tegra 4 devices, discussed below. All the decode errors share a single pair of information-capture registers that are intended to assist developers in debugging such errors (ERR_STATUS and ERR_ADR). The capture registers record the following information about the error:

- the Virtual or Physical address of the error (depending on the type of fault)
- which type of fault the captured error corresponds to
- a read/write indicator
- the requesting client's ID
- If the error was an INVALID_SMMU_PAGE, then information about the page's protection status is also captured:
  - whether the page was marked non secure in the page-table
  - whether the page was marked readable in the page-table
  - whether the page was marked writeable in the page-table
  - Note that SMMU page protection bits are formed by ANDing the page protection bits from the Page Table Base, PDE and PTEs from all three stages of the page-walk. The ANDed protection bits and the type of the provoking transaction are both available in the status register.

Subsequent errors (of any type) will not change the status and address registers until the corresponding interrupt is cleared.

To prevent requests with address decode errors from modifying memory or accessing memory they do not have permission to, the MC "squashes" the requests. A write request that is "squashed" has had its byte-enables forced to all-zeros, this prevents the write data from being applied to DRAM. A read request that is "squashed" will have its read-return data forced to all-ones, this protects the data in DRAM from being read by non-secure sources.

The three types of address decode errors are:

- DECERR_EMEM: Decode Errors: there is no DRAM attached at the Physical Address.
- SECURITY_VIOLATION: Legacy Security Apertures: the Physical Address is in one of the Legacy Security Apertures, and the client permissions are not sufficient to allow access. There are two Legacy Security Apertures which decode as different ERR_STATUS.ERR_TYPE.

  Note: If a single request causes both a TrustZone and Protected security violation, the ERR_TYPE will report the Protected Aperture violation.

- SMMU_FAULT: The SMMU translation engine encountered either a security permission error, a read/write type error, or an invalid translation error during translation.

SMMU-Translated Requests and Physical Aperture Errors

All Virtual Addresses are translated through the SMMU, then run through the Physical Aperture checks. There are a number of confusing scenarios when debugging these interactions including:

- SMMU fault followed by any physical aperture error of any sort: because the SMMU translation occurs first, the data captured by the ERR_ADR and ERR_STATUS registers will always be the SMMU fault information. Both interrupt bits are set.
- Decode error on a successfully translated (i.e., no SMMU fault indicated) client request: the PA checks will throw a decode error; the data captured includes the Physical Address, not the Virtual Address. The client request is squashed. The decode-error interrupt bit is set.
- Decode error on a Page-Table fetch (PDE or PTE): the page-table fetch will throw a decode error; the data captured includes the Physical Address of the PDE or PTE, and the client ID corresponds to the PTC. In addition, the data returned to the PTC is modified to turn off all access permissions, marking the page INVALID. This forces the client request to also throw a SMMU fault when it is translated. Both the decode-error and SMMU-fault interrupt bits are set. The PDE or PTE are then cached with those modified access permissions, so any subsequent requests to that virtual page are also SMMU fault.
- TrustZone security violation on a translated client request: the PA checks throw a security error, the data captured includes the Physical Address, not the Virtual Address. The security violation interrupt bit is set. The client request is squashed. This behavior allows the Secure Aperture to stand as a “last line of defense” against SMMU page-table modification attacks.
- Protected-region security violation on a translated client request: the PA checks throw a security error. The data captured includes the Physical Address, not the Virtual Address. The security violation interrupt bit is set. However, the client request is not squashed. Due to this behavior, it is not recommended that the Protected Aperture be used in conjunction with SMMU translation.

20.7.11 Software Client-Groupings

The Memory Subsystem inherently implements a hardware mapping of memory clients (“MCCIFs”) to super-clients, and super-clients to the hardware modules. Additionally, the MSS implements a system of mapping modules to “software groups” (also known as SWGROUP or SWNAME). This allows a single point of control for all clients for that hardware “engine”. Often the list of clients in a SWGROUP is the same as the list of clients in the module that implements the hardware engine.

The mapping of SWGROUP to modules for Tegra 4 devices is listed here:

SWGROUP	Modules	Translatable?	Further description
AFI	PCIE	Yes	PCI Express
AVPC	AVP Cache	Yes	Arm7 Audio-Video Processor (AVP)
DC	Display, 1st instance	Yes	Display reads
DCB	Display, 2nd instance	Yes	Display reads, instance b
EPP	EPP	Yes	Encoder Pre-Processor
G2	GR2D	Yes	2D engine
HC	Host1x	Yes	Host interface
HDA	HDA	Yes	High-definition Audio engine
ISP	ISP	Yes	Image Signal Processor
MPCORE	AXICIF	No	Cortex-A15
MPCORELP	AXICIF_LP	No	Cortex-A15
MPE	MPEA, MPEB, MPEC	Yes	MPEG4 Encoder
NV	TEX, IDX, FDC	Yes	3D engine, 1st instance
NV2	TEX, IDX, FDC	Yes	3D engine, 2nd instance
PPCS	AHBDMA, AHBSLV	Yes	Clients in the AHB cluster.

SWGROUP	Modules	Translatable?	Further description
PTC	MC (SMMU)	N/A	Misses from SMMU PTC.
SATA	SATA	Yes	Serial ATA.
VDE	VDE	Yes	Video Decode Engine
VI	VI	Yes	Video Input engine.

20.8 Functionality

20.8.1 Addressing

The physical address space supported by the MC is 4GB. Within this 4GB range, one physical aperture and two virtual apertures are defined. The physical aperture maps external memory. The security aperture allows software to define a region of external memory as secure so that only trusted clients[4] can access that region. The protected aperture allows software to define a region of external memory as carve-out so that only certain clients can access that region.

For any particular chip, the size and locations of these apertures are fixed based on project specific definitions. For Tegra 4 devices, these apertures are defined to be: 2GB maximum for external memory, up to 2GB secured region, up to 2GB protected region.

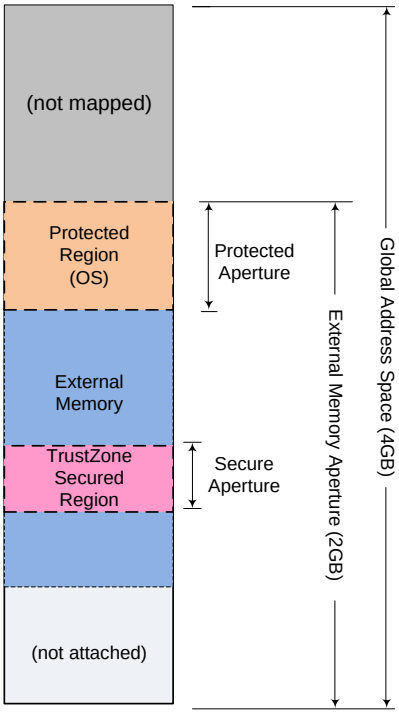
In addition to the physical address apertures and spaces, the MC supports a full virtual addressing scheme via the SMMU.

The MC receives a full 32-bit physical address and decodes it in the following way:

- The external memory is present in a fixed aperture of 2GB at a naturally aligned boundary defined by the system address map. The actual size of the external memory is defined by a programmable register; addresses outside the programmed range are treated as invalid. The offset in the external memory is given by the 31 LSBs of the address.
- A secured region of variable size can be defined in the external memory range.
- A protected region of variable size can be defined in the external memory range, but always starts from offset 0x0.

[4] See subsection on TrustZone Security Region below for a discussion of security.

Figure 50: Physical Address Map Example



Accesses that do not match one of the three address spaces are detected and an error logged. The MC returns a predefined pattern[5] for reads to invalid addresses and acknowledges invalid write addresses, but otherwise the EMC drops the write.

20.8.2 Granularity

The access granularity[6] inside the MC is 128 bits (16 bytes) for external memory accesses. Byte access remains possible but involves a minimum granularity access. Write accesses can use byte enables to write a set of bytes (including a null set), read accesses always return a full word with potentially unneeded data (also known as overfetch).

The granularity of external access is linked to the burst size programmed for DRAM access. Bursts into external memory always start at a 16-byte aligned boundary. For LPDDR2, this corresponds to a burst length of 4 data transfers (or 2 clock cycles at double data rate, known as BL4).

The DDR3 situation is complicated by the DRAM's minimum internal burst length of 8; because the MSS works in 16-byte atoms, a naïve implementation using BL4 or BL8 setting would result in 50% efficiency loss. However, the DDR3 specification also includes a burst-chop on-the-fly mode that allows the controller to indicate for each CAS command whether it wants to transfer 4 or 8 data beats. The BL4 or BC4 accesses still consume a full 8 data beats, but some amount of power is saved by not transferring the data off-chip. The MC and EMC implement support for coalescing of 2 atoms into a 32-byte-aligned pair.

[5] All data bits are forced to 1's.

[6] A datum of 128-bit-granularity may be referred to as a "memory atom".

20.8.3 Virtual Addressing

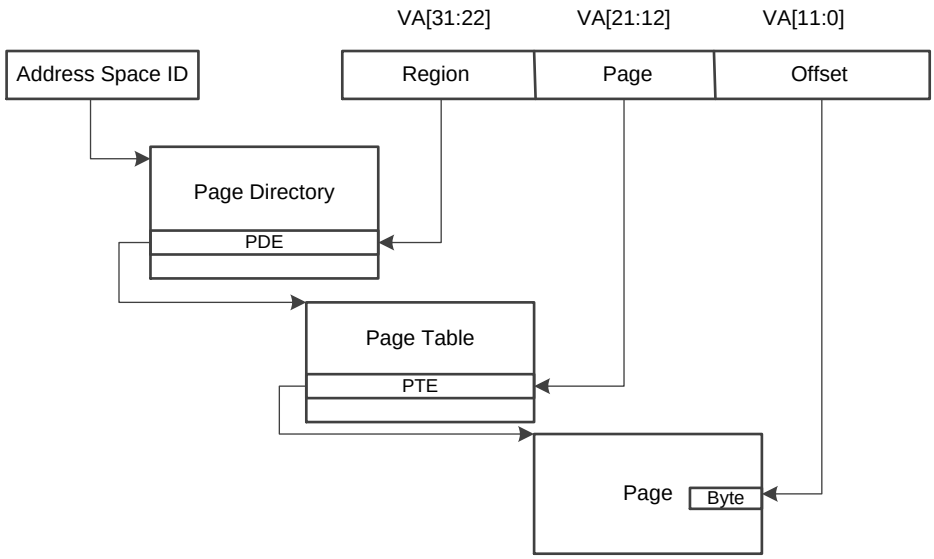
The SMMU is a centralized virtual-to-physical translation for MSS. It allows the following:

- Memory allocation for hardware pools (surfaces and buffers) could be made from non-contiguous page-sized chunks of memory
- Areas of the hardware memory map could be marked as protected, preventing access from hardware devices
- Hardware memory access can be controlled on a per-device or per-process basis

The virtual-to-physical translation uses a two-level page table that carves up the virtual address as follows:

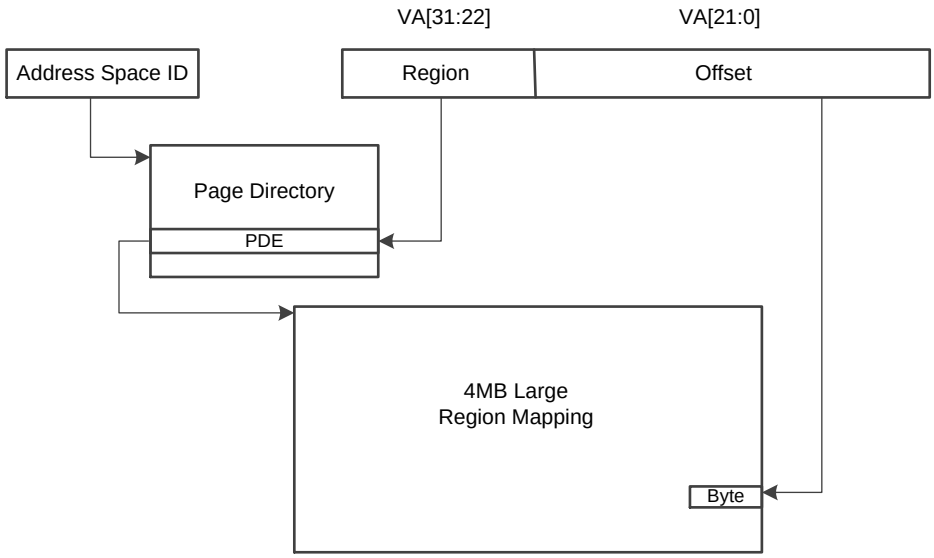
- Bits 31:22 choose a page directory entry (PDE). Each page directory has 1,024 PDEs, each mapping 4MB region.
- Bits 21:12 choose a page table entry (PTE) from a page table. Each page table has 1,024 PDEs, each mapping a 4kB page.
- Bits 11:0 choose a byte within a page

Figure 51: Page Table and Virtual Address



Each PTE or PDE consumes 32 bits of memory, so that each page directory or page table consumes one 4kB memory page. In addition, the page directory lookup does an early-out either to map an entire 4MB region of the virtual space as invalid, or to map the region to a contiguous range of physical pages.

Figure 52: Large Region Mapping



Both the page and directory tables are stored in DRAM. A translation look-aside buffer (TLB) is used to cache recently used translations. Translations that miss in the TLB incur potentially two additional round-trip DRAM delays, but the latency-scheduling features of the Protocol Arbiter is used to hide this latency behind the normal latency incurred by the DRAM reordering policy. The TLB is backed by a page-table cache (PTC) to reduce this memory traffic further.

In addition, the SMMU supports multiple address spaces, each tagged with an address space identifier (ASID). The ASID allows for multiple virtual mappings to exist at the same time. Typically, software uses these to assign different mappings to each process that directly uses the hardware drivers, allowing process isolation. The number of ASIDs in a Tegra 4 device is 4. Software is responsible for managing the assignments between processes and ASIDs, flushing ASIDs out of the TLB as needed when they are remapped between processes.

ASIDs are assigned based on the SWNAME of the incoming request. An on-chip mapping between SWNAME and the ASID is maintained by the SMMU. For register-based devices, the driver is responsible for updating the mapping between the SWNAME and the ASID when a device in context is swapped between processes.

Untranslated modules are also supported. The SWNAME-to-ASID mapping has a translation-enable bit to allow translation on a per-SWNAME basis. There is also a per-client translation-enable bit for Hardware Diagnostics purposes.

Typically, only the CPU uses the untranslated mode, since it has its own MMU and can map any physical page into a process at will. Untranslated accesses for all clients are fast-pathed through the MC/SMMU system so that the latency of such accesses are not impacted more than necessary. To further improve CPU latency, the Tegra 4 CPU low-latency read paths bypass the SMMU altogether; the hardware also restricts the CPU write paths to untranslated-mode to prevent any configuration mishaps. In addition, a global “translation enable” bit disables all translation when cleared (cleared is the default out of reset).

20.8.3.1 Page Table Layout

The in-memory layout of a PTE looks like

- 20 bits of physical address (PA[31:12]) for the base of the page
- Protection bits which include
  - A “readable” bit which allows clients to read this page
  - A “writeable” bit which allows clients to write this
  - A “nonsecure” bit which (when unset) restricts access of this page to “secure” TrustZone clients

The remaining bits in the 32-bit word are reserved.

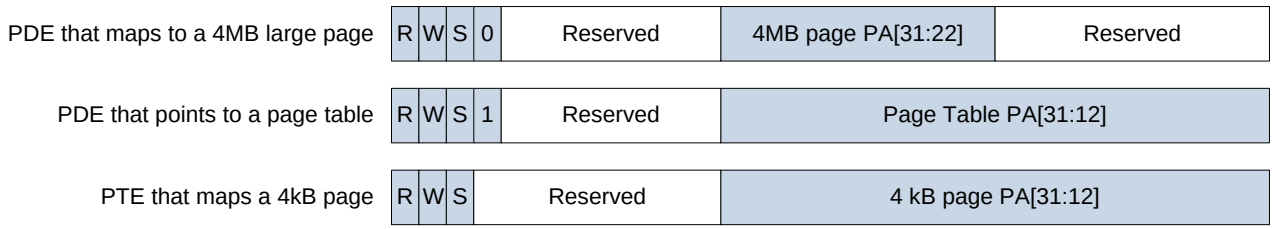
> **Note:** Wherever physical addresses are used in this document, it is assumed that the device can address 4GB of physical memory. The actual physical memory that can be attached to the device may be smaller or larger, and if so, any of the hardware structures that hold physical addresses shrink or grow accordingly. This means that, for example, in a 2GB system, the physical addresses in the PDE and PTEs have only a 19 bit field, and the TLB and PTC need only cache those 19 bits instead of the full 20.

The in-memory layout of a PDE looks like:

- A “next level” bit which says if this PDE maps a single 4MB region, or if it points to a page containing a table of PTEs for the second level of translation
- If the “next level” bit is set, there are 20 bits of physical address (PA[31:12]) that point to a page containing the base of the PTE table for this PTE. If the “next level” bit is clear, we use 10 bits (PA[31:22]) to point to the base of an aligned 4MB physical region mapped directly by the PDE.
- The remaining bits set the permissions for the access. For 4MB large pages, these are used directly for the region. For PDEs that point to a second-level page table, these permissions are ANDed with those of the PTE to give the final permission
  - A “readable” bit for the region
  - A “writeable” bit for the region
  - A “nonsecure” bit for the region

The remaining bits in both interpretations are reserved.

Figure 53: PDE and PTE Formats



The base address of the page directory for a particular ASID is stored on-chip in the ASID table. Changes to this table may require flushing the ASID in question from the TLB.

20.8.3.2 Faults

When an access violates the “readable”, “writable” or “nonsecure” bits for the region, it generates a fault. A fault can cause an interrupt to be generated if desired. In addition, information about the most recent fault is stored on chip, consisting of the following:

- VA[31:4] of the faulting access
- Access type (read/write, secure/non-secure)
- Client ID
- The page permissions at the time of fault (readable, writeable, nonsecure)

Only faults for translated requests use this mechanism. Untranslated requesters (including the SMMU itself) report other types of faults (address out of range, etc.) via the existing MC fault reporting mechanism.

20.8.3.3 Flushes and Page Table Updates

Changes to the page tables require the TLB to be flushed. A software interface for selectively flushing parts of the TLB is provided. The flush command can flush any TLB entries that match a particular subset of virtual addresses. Each address component may be included for matching:

- Match on the ASID, or not
- Match VA[31:24], or Match VA[31:14], or no VA match

Disabling all matches flushes the entire TLB. Note that the TLB is 4 entries wide, so when you match any particular VA you flush the entire line, which is why the VA matches are down to 24 and 14, rather than 22 and 12.

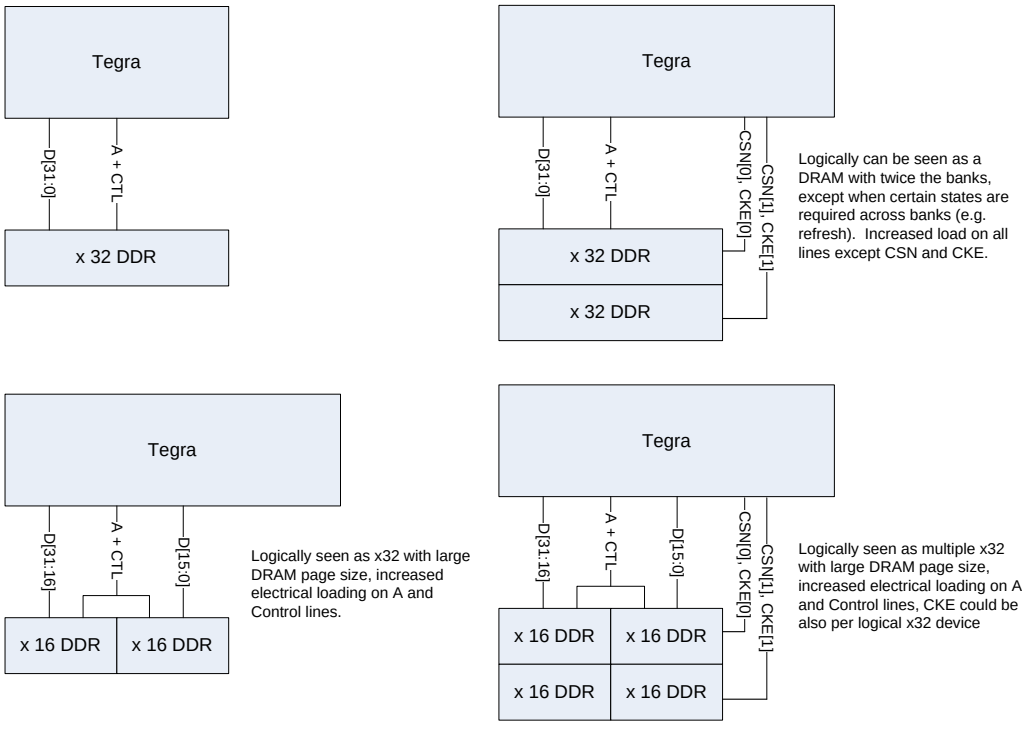
In addition to the TLB, page table updates require flushing stale entries out of the PTC. This needs to be done on a slot-by-slot basis by writing the PDE or PTE's physical address (PA[31:4]) to the PTC flush command. Each flush flushes four aligned PTEs or PDEs (one DRAM atom's worth) out of the cache.

A page table update requires three writes – one to write the PTE to memory, one to flush the stale PTE out of the PTC, and a third to flush the stale VA mapping out of the TLB. However, since a single PTC flush flushes four PTE or PDEs and a single TLB flush can flush the entire TLB, software can reduce the flush traffic by merging flushes from multiple updates.

20.8.4 DRAM Device, Bank and Page Mapping

This relates to the external memory devices, the EMC supports multiple devices with data widths of 8, 16, or 32 bits[7], all identical. Examples of configurations are shown in the next figure. The EMC controller uses specific bits in the address to identify the chip select associated with the address.

Figure 54: Multiple Chip Select Signals (x8 cases not shown)



The POR specifies support for 2 CS and 2 CKE. Having the same number of CS as CKE is important to limit the operating power consumption of the external DRAM.

[7] A x32 device may be a single x32 chip or two x16 chips in parallel.

The two ways of supporting multiple external devices have the following consequences for the inside logic.

- Width extension, when two x16 (or four x8) DRAM chips are used as one x32 device
  - Results in the apparent page size of the apparent x32 devices to be twice the size of the external x16 device page size but the number of banks is unchanged.
  - The EMC only needs one state machine corresponding to the apparent x32 device.
  - Data-bit loading is unchanged but address/control-bit loading is doubled.
- Depth extension, when multiple x32 devices are used at different address offsets,
  - Results in an apparent page size equal to the external device page size but the apparent number of banks is multiplied by the number of devices
  - The EMC needs to maintain multiple bank and device state machines
  - Loading on all interface bits except CKE and CS are doubled.

Each DRAM device also exposes a bank and page structure that affects performance. For better performance, a stream of accesses to the DRAM should be such that

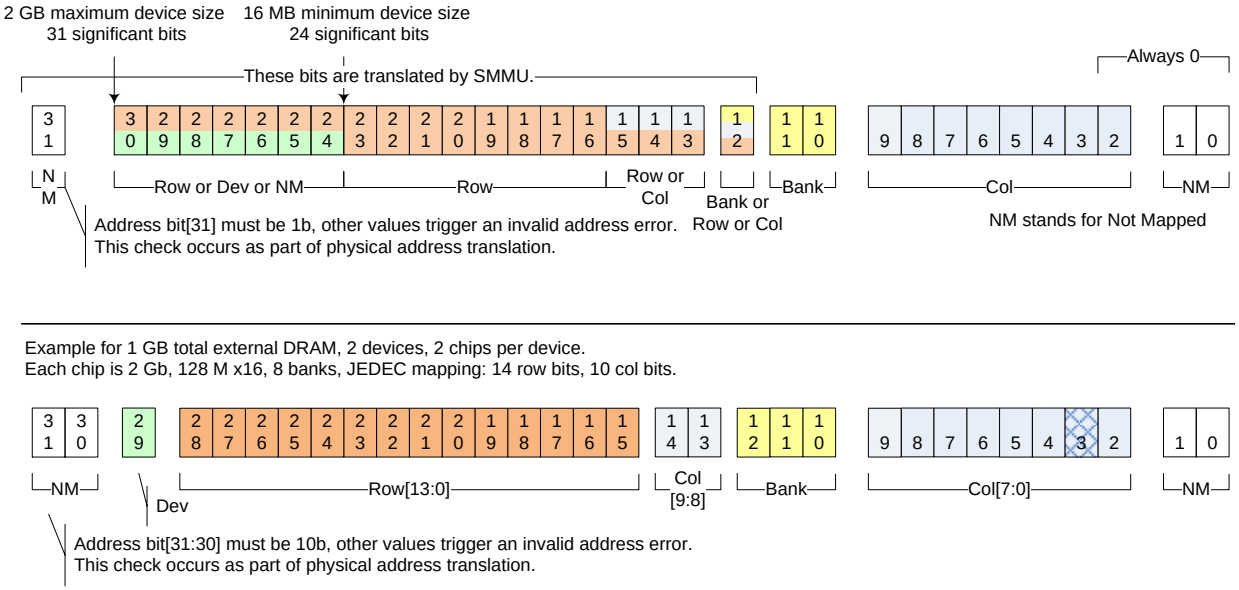
- Access to different banks are interleaved
- Consecutive accesses to the same bank are for the same page in that bank

The external memory arbiter attempts to generate a request stream with such characteristics, but it is dependent on the requests it receives from the different clients. It is more important to ensure bank interleaving for robust performance, this is achieved by ensuring that banks are also interleaved with a small pitch in the address space, with a pitch small compared to the size of expected data structures in memory. However, the pitch should not be too small either to ensure that address locality in a client results in same page accesses.

The proposed bank pitch corresponds to 64 DRAM data bursts, each of 16 bytes, for a final pitch of 1024 bytes. The bit mapping between the internal linear address and the device, row, column and bank bits is performed like this:

- The 2 LSBs of the linear address are ignored as the address granularity of the DRAM is 32 bits/4 bytes
- Bits[9:2] of the linear address are mapped as column bits[7:0]
- Bits [11:10] are bank bits.
- Bit [12] is a bank bit if the device has more than two bank bits.
- The next bits of the linear address are mapped as column bits, as many as remaining after previous mapping
- The next bits of the linear address are mapped as row bits, as many as needed for the selected device
- The next bit is a device bit if device bits are needed

Figure 55: Address Mapping Example



The number of bank, column, row, and device bits is limited by the number of address pins available:

- Bank width: 2 or 3
- Column width: 8 to 11
- Row width, depends on if DDR3 is being used with 1 device:
  - Yes: up to 16 bits
  - No: up to 15 bits
- Logical Devices (also known as chip selects): 1 or 2

When two logical devices are used, the total memory mapped by the second device must be less than or equal to the first device. The second device also may have a different row, bank, column mapping from the first device.

20.8.5 DRAM Power Modes

The following table maps between the system power modes and DRAM power modes.

Table 51: System Power Modes and DRAM Power Modes

	VDD_CORE	VDD_CPU	MC/EMC Power	PLL	MC/EMC Clock	DRAM State
LP0 (deep sleep)	off	off	off	off	off	self-refresh
LP1 (suspend)	on	off	on	off	off	self-refresh
LP2 (idle)	on	off	on	on	on	active

This subsection briefly describes the Tegra 4 system power modes. Refer to the PMC section for more details.

- LP0: The goal is ultra-long standby time in a cell phone. In this mode, major power rails are off and I/Os are held constant. DRAM is commanded by the AVP to enter self-refresh. The MC and EMC are powered off. Exiting LP0 is called warm boot, in comparison to cold boot which restarts the system. On warm boot, the MC and EMC are re-initialized from the PMC scratch registers and then DRAM is brought out of self-refresh. The LP0 entry code is executed from IRAM and the LP0 exit code is executed from boot ROM, both by the AVP.

- LP1: The goal is to suspend the CPU while allowing the hardware path to be externally accessible. All PLLs are turned off, and therefore MC/EMC/DRAM clocks are frozen. The DRAM is commanded by the AVP to enter self-refresh (it shares the same code with LP0 entry). Because the MC and EMC keep power during LP1, they do not need re-initialization. To exit LP1, simply enable the clock and exit self-refresh. Both LP1 entry and exit code are executed by the AVP from IRAM.
- LP2: The goal is to power off the CPU while still appearing functional to users. The DRAM can still be accessed by the display, audio, video, and other system modules, although no access comes from the CPU. The LP2 entry/exit sequences do not involve the MC/EMC/DRAM.

For pads and DRAM, LP0 and LP1 are in the same state, LP2 and normal running mode are in the same state.

20.8.6 Refresh and Self-Refresh

Two important EMC power features, DSR and DVFS, are related to refresh and self-refresh:

- For all DRAM types, a minimum number of refreshes are required in any rolling tREF window. A typical value is 4096 refreshes in a rolling 32ms window.
- If self-refreshes happen in a tREF rolling window, such time can be subtracted from the length of the tREF window, and the rest of the window requires the number of refreshes proportional to its length.
- DDR3 supports burst refreshes of up to 8 refreshes. LPDDR2/LPDDR3 does not set a maximum burst size, as long as the two requirements above are not violated.
- On self-refresh entry, the DRAM specification suggests that it is not necessary to issue a refresh in single refresh mode. In burst refresh mode, DDR3 does not require it, but LPDDR2 requires it.
  - LPDDR2
    - Burst refresh mode: recommended to issue a burst refresh (but may not be necessary)
    - Single refresh mode: not necessary to issue a refresh.
  - LPDDR3
    - LPDDR3 specification is not yet finalized, but Micron indicates that statements similar to LPDDR2 will be proposed.
  - DDR3
    - Both single and burst refresh: not necessary to issue refreshes (DDR3 supports burst refresh sizes of up to 8)
- For all DRAM types, refresh must be issued at self-refresh exit, because the last time of the internally scheduled self-refresh in DRAM is unknown.
- Beside the minimum refresh number requirement above, DRAM specifications also have the requirement on the maximum refresh number. On LPDDR2/LPDDR3, no more than 8 refreshes can be issued in any rolling tREFBW window. Without that parameter, DDR3 similarly requires no more than 16 refreshes issued in any 8 * tREFI rolling window. Since they are similar, the tREFBW function is reused for DDR3.

20.8.7 TrustZone Security Region

The MC can secure a region in the physical address aperture from insecure software sources. The region can be defined on 1MB boundaries in the external memory region, in multiples of 1 MB. If a non-secure request is made to the secured region, MC throws an interrupt and logs the details of the request (address, client ID). After the details are logged, write requests are dropped and read requests forced to return all 1's, thus protecting the secured region from corruption by the insecure source.

Only clients configured for security are able to make secure requests. In Tegra 4 devices, the CPU is configured to allow secure requests (via the PL310 and AXICIF), as well as the AHB slave clients and the VDE bitstream decode engine (BSEV). The AXICIF follows the AXI protocol of using aprot[1]==0 as the "secure" indication. The AHB bus adds a secure-bit as a

sideband to the request, and translates this bit to the MCCIF secure indication. The VDE BSEV connects directly to a secure MCCIF client.

The SMMU's memory client (PTCR, used for page-table misses) may also access secured memory if the SMMU is configured to allow secure accesses. See subsection on "Virtual Addressing" above for details.

In addition to securing the region in memory, register accesses that would modify the location of the secure region must also be secured. The two registers controlling security may only be modified by secure register requests.

20.8.8 OS-Protection Memory Region

The MC can secure a region in memory from access and modification by the GPU hardware engines. The intended use of this section is to prevent modification of the OS image from untrusted software via the hardware engines. The protected region is defined to start at EMEM_BOM and can be extended in multiples of 1MB. The clients allowed to access the protected region are the CPU, the COP, the AHB, VDE's BSEV, and the PTC and anything translated through the SMMU. All other clients attempting to access this region will cause MC to throw and interrupt and log the details of the request (address, client id). After the details are logged, write requests will be dropped and read requests will be forced to return all 1's, thus protecting the region from corruption by the insecure source.

In addition to protecting the region in memory, register accesses that would modify the boundary of the protected region are also secured by TrustZone.

20.9 Programming Model

There are three apertures that can be programmed, starting from EMC0_BASE, EMC1_BASE, and EMCB_BASE. The register reads/writes to EMC0/1_BASE go to a single EMC instance. The writes to EMCB_BASE go to both EMCs. The reads to EMCB_BASE go to EMC0TBD. Both EMC registers and IOBIST registers are accessed via the APB interface.

In single channel mode, EMC1 is not clocked or out of reset; therefore, register access to EMC1 might hang the APB bus.

There are three parts of software code access with MC/EMC registers: cold/warm boot (by either boot ROM or microboot), LP0/LP1 entry and LP1 exit, and DRAM DVFS sequence. It is also possible for another part of software to check the statistics registers of MC/EMC for testing, debugging, or performance monitoring.

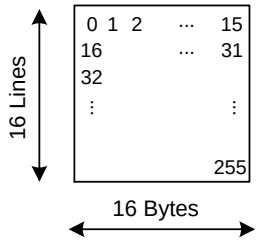
Cold boot and warm boot code are executed from the AVP, either off boot ROM or off microboot in IRAM. Warm boot is more sensitive to latency, so microboot is usually not a good option. Cold boot gets MC/EMC programming from the BCT table. Warm boot gets it from the PMC scratch registers, which contain a snapshot of MC/EMC register values stored by the Boot Loader, which is loaded to DRAM immediately after cold boot.

The DVFS sequence is in the OS kernel and run by the CPU off DRAM, so it is critical that the MC/EMC does not block traffic permanently at any time during the programming of this sequence.

20.10 Memory Tiling

The memory tiling format was originally proposed to decrease the latency for vertical accesses and to improve overall bandwidth utilization. Each tile is 256 bytes; the width of a tile is 16 bytes and height is 16 lines. Each tile entirely fits in a single DRAM page, often more than one per DRAM page. For example, 4 tiles will fit in a 1KB page. The addressing with in a tile is shown below and aligns with a macro-block pattern. This tiling fits well for video decoder and encoder needs. For clients that are inherently linear, tiling should have no effect for DRAM interfaces working on a 16-byte atom.

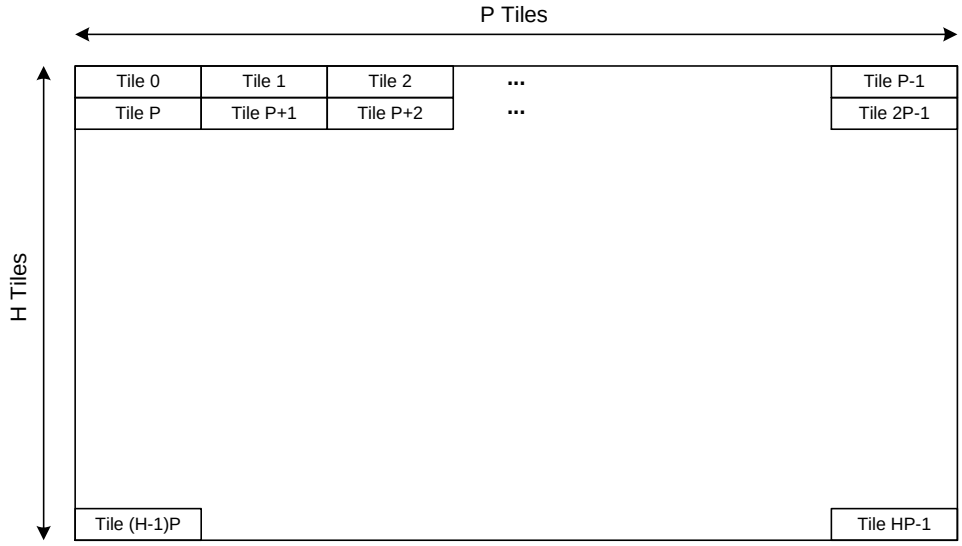
Figure 56: A Memory Tile



20.10.1 Tiling Pattern and Layout in Memory

Memory tiles are scan line ordered within tiled surface. Since each tile width is 16 bytes, height is 16 lines and the surface needs to be rectangular with integral number of tiles, it puts a restriction on the surface stride to be multiple of 16 bytes and height to be multiple of 16 lines. The diagram below shows how a typical surface of (PxH) tiles look like.

Figure 57: Tile Layout in a Surface



20.10.1.1 Tiled Address Calculation

For addressing a location in a tiled surface, the client has to provide the surface parameters - base address, pitch and pixel coordinate (x, y). The tiled address is calculated using the equation,

tiled_addr = base + (y/16) * 16 * pitch + (x/16) * 256 + (y%16) * 16 + x%16

where *base* is the surface base address in bytes, *y* is the vertical top-to-bottom offset of the pixel data in lines, *x* is the horizontal left-to-right offset of the pixel data in bytes, *pitch* is the surface padded pitch in bytes, and *tiled_addr* is the memory byte address after tiling.

20.10.1.2 Linear to Tiled Address Translation

Certain clients in the system are not able to provide (x, y) coordinates without disruptive hardware changes. In these cases, the client may choose to implement a linear-to-tiled address conversion mechanism that has reduced flexibility. By restricting the pitch *p* to the form

$p = k * 2^{(n + 6)}$

where *k* is an odd natural number and *n* is a natural number, a linear address can be converted to a tiled address requiring only the additional information of the surface base address and the surface pitch. This method reduces the width of the division operator required, thus reducing the latency impact of this operation.

The supported values of k are [1,3,5,7,9,11,13,15]; the supported values of n are [0,1,2,3,4,5,6]. For most surfaces with pitches of the restricted form, the resulting tiled address is exactly the same as would be computed by the normal (x, y) equation; surfaces where

$$(\text{linear} - \text{base}) > 2^{22}$$

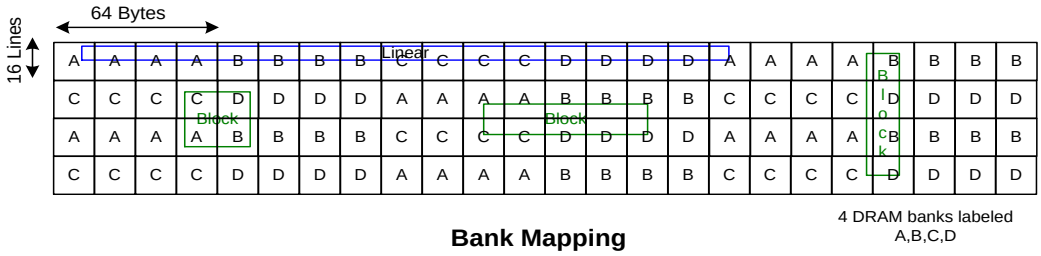
will result in incorrect tiled address. Certain surfaces that do not naturally align to a pitch of the form mentioned above will have wasted memory at the right and bottom edges of the surface.

20.10.2 Tiling Bank Layout

Even though tiling helps the block accesses to be in a single DRAM page, block accesses often fall in multiple tiles. For a typical DRAM, the penalty for closing the current page and opening a new page on the same bank is around 10 cycles; if the controller does not have to close the current page, this penalty drops to around 3 cycles. Penalty for closing and re-opening a page cannot be hidden in a single-client stream, so adjacent tiles should not be mapped to different row on the same bank. Penalty for opening a page on different bank can be hidden with the data transfer from different bank.

To balance the needs of linear clients and block clients, the bank interleaving must be chosen such that page-miss penalties are acceptable for both access patterns. The solution in Tegra 4 devices is to use byte address bits [11:10] as the bank bits to DRAM. For a typical 1KB-page DRAM, and assuming a 16-byte memory atom, this causes linear clients to switch banks every fourth access. The block clients also retain the benefits of page locality while still spreading their access patterns across enough banks to hide the page-open penalty.

Figure 58: Effects of Bank Address Mapping on Tile Layout



Bank Mapping

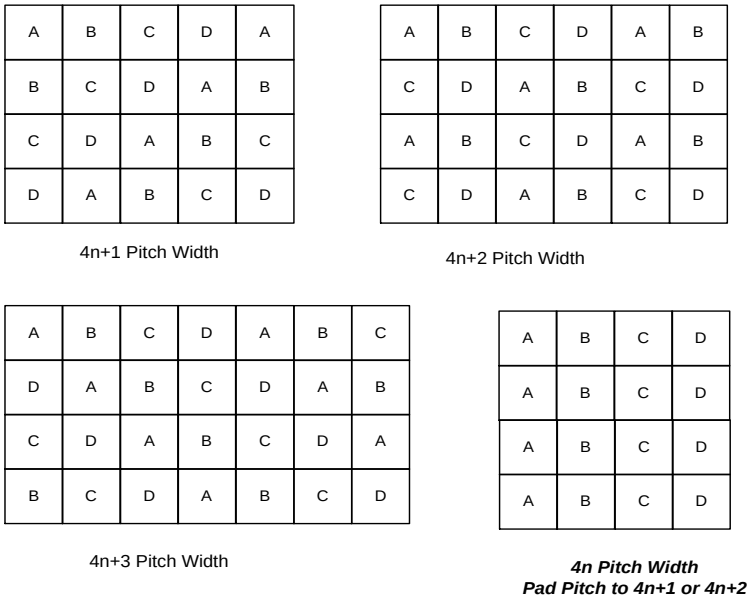
This bank mapping creates one problem, in that it reduces the inherent bank interleaving between different clients. The reordering aspects of the external memory arbiter should fairly handle contention between different clients; however the basic resource conflict still limits the available performance of the system.

20.10.2.1 Tiling Pitch Values and Padding

The figure below shows the bank ordering for different widths of surface. For pitch values which are in the form 4n+1, 4n+2, 4n+3, normal bank ordering provides bank interleaving for the vertical accesses. For 4n pitch, normal bank ordering is inefficient. To correct this, software should pad 4n pitch to 4n+1 or 4n+2 for better bank mapping for vertical accesses.

For 4n+1, 4n+3 mappings, even though banks in horizontal and vertical directions are different, the diagonals show inefficient bank orderings. Block accesses opening the same bank twice for these configurations will have some performance degradation. If this is not acceptable, the surfaces should be padded to a 4n+2 format.

Figure 59: Surface Pitch and Padding Examples



Impact of DRAM Configurations on Surface Pitch Alignment

Having 8 physical banks with the third bank-bit mapped low doubles the interval before a page-collision occurs (e.g., ABCDEFGH pattern) when using physical addressing. However, most applications are expected to use the virtual addressing via the SMMU, which translates the third bank-bit. Software SMMU allocation should be aware of this issue and attempt to page-color and pad accordingly.

Having two devices does not have any impact on tiling since the device bit is mapped high, and is translated.

Padding for Multiple Surfaces

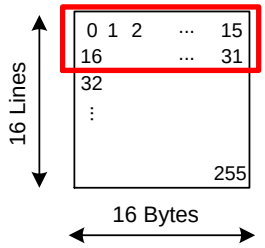
It is often the case that fetching from two surfaces which are tiled and switching buffers constantly. Good examples could be color and Z fetches, blending two surfaces, YUV surfaces, etc. In these cases it is quite possible that both the surfaces would keep accessing same bank and different rows, causing page-thrashing. This would create penalty in opening and closing the same bank multiple times. It must be noted that due to different consumption rates for different scenarios, it is impossible to avoid all page-thrashing. Efforts have been made to minimize page-thrashing in the MCCIF clients.

To reduce page-thrashing, software should program the base addresses of the surfaces staggered by the page size (usually 1KB), so that surfaces would start with a different bank. If the first surface is starting at address aligned to (4x) K bytes, the second surface should be aligned to (4x+1)K, (4x+2)K, or (4x+3)K.

20.10.3 Tiling with DRAM Atoms Larger than MSS Atoms

For situations where the DRAM fetches a minimum of 32 bytes per CAS command (DDR3), this tiling format produces an inherent 50% overfetch. Each memory access returns two lines of data, as shown in the figure below. For clients that issue request in macroblock order (MPE), or are natively working in 32 bytes (CPU caches, 3D engine) the MSS can coalesce two requests together late in the pipestage to take advantage of the overfetch. For clients that issue requests in horizontal linear order (Display, VI), the overfetch issue cannot be solved by MSS. Software should consider the overfetch inherent in linear clients into consideration when computing the overall bandwidth consumed for those clients touching tiled surfaces.

Figure 60: DDR3 Tiled Fetch



20.11 Memory Controller Registers

Refer to “Reading Register Tables” in the Introduction section for the register table protocol as well as recommendations for accessing registers.

20.11.1 MC Registers

USAGE NOTE: Many MC register fields are shadowed.

Writes to shadowed register fields update the shadow copy (this is default, assumes TIMING_CONTROL_DBG.WRITE_MUX==ASSEMBLY).

Reads to shadowed register fields return the currently-active copy (this is default, assumes TIMING_CONTROL_DBG.READ_MUX==ACTIVE).

This allows a new set of frequency-dependent timing parameters to be written to the shadow registers while memory traffic is ongoing, then when the parameters are completely written, the MC hardware can perform a timing-safe switch.

Such switches can be triggered via two methods: TIMING_CONTROL.TIMING_UPDATE (generally used during initialization), or the automatic CAR/EMC handshake on a clock-frequency or divider change (assuming TIMING_CONTROL_DBG.IGNORE_EMC_TRIGGERS==DISABLED).

Registers that are shadowed are marked by a comment:

> “This register is shadowed: see usage note at top”

USAGE NOTE: Many MC registers should be programmed by the Boot Loader as part of the warm boot (also known as "wake from LP0") and cold boot (also known as "power up") sequences. Suggested actions for the Boot ROM/Boot Loader are noted in comments labeled "Boot requirements: ...".

USAGE NOTE: Some MC registers may only be accessed by TrustZone-secured register transactions. See the Cortex-A15 documentation for information on how to handle security. Such registers are marked by a comment:

> “Access to this register is restricted to TrustZone-secured requestors.”

USAGE NOTE: The MC register fields to be stored in PMC scratch registers for warm boot must have "[PMC]" in their comments. After adding and removing such PMC flag, the tool warmboot_code_gen must be rerun to generate new boot ROM code.

20.11.1.1 MC_SMMU_CONFIG_0

Used for interrupt set/clear enums. When disabled, all transactions are untranslated. When enabled, transactions may be translated. See per-client and per-module enables in SMMU_* registers below.

This register can only be accessed by TrustZone-Secured accesses from the CPU.

Access to this register is restricted to TrustZone-secured requestors.

Boot requirements: This register should be saved to SDRAM registers and restored by the OS during warm boot.

SMMU Enable Register

Offset: 0x10 | Read/Write: R/W | Secure: Trust Zone Protected | Reset: 0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx0

Bit	Reset	Description
0	DISABLE	SMMU_ENABLE: 0 = DISABLE 1 = ENABLE

20.11.1.2 MC_SMMU_TLB_CONFIG_0

Translation Lookaside Buffer Config Register

Controls usage of the TLB.

Boot requirements: This register should be saved to SDRAM registers and restored by the OS during warm boot.

Offset: 0x14 | Read/Write: R/W | Reset: 0b001xxxxxxxxxxxxxxxxxxxxxxxx10000

Bit	Reset	Description
31	DISABLE	TLB_STATS_ENABLE: Enable TLB Hit and Miss counters 0 = DISABLE 1 = ENABLE
30	DISABLE	TLB_STATS_TEST: Set stats registers to all "1s" 0 = DISABLE 1 = ENABLE
29	ENABLE	TLB_HIT_UNDER_MISS: Allow hits to pass misses in the TLB. This value may not be changed on the fly. Ideally, this should be set before enabling the SMMU. At the very least, the TLB needs to be flushed and traffic through the SMMU stopped before changing this value. 0 = DISABLE 1 = ENABLE
4:0	0x10	TLB_ACTIVE_LINES: Set the number of active lines. Allows the TLB to be made "virtually smaller" to save power. "Inactive" lines will never hit and never hold data.

20.11.1.3 MC_SMMU_PTC_CONFIG_0

Controls usage of the PTC

Boot requirements: This register should be saved to SDRAM registers and restored by the OS during warm boot.

Page Table Cache Config Register

Offset: 0x18 | Read/Write: R/W | Reset: 0b001xxxxxxxxxxxxxxxxxxxxxxx111111

Bit	Reset	Description
31	DISABLE	PTC_STATS_ENABLE: Enable PTC Hit and Miss counters 0 = DISABLE 1 = ENABLE
30	DISABLE	PTC_STATS_TEST: Set stats registers to all "1s" 0 = DISABLE 1 = ENABLE
29	ENABLE	PTC_CACHE_ENABLE: Enable the PTC cache. 0 = DISABLE 1 = ENABLE
5:0	0x3f	PTC_INDEX_MAP: XOR pattern for tag generation

20.11.1.4 MC_SMMU_PTB_ASID_0

Page Table Bases (PTBs)

These pointers point to a 4KB-page aligned table of PDEs for each ASID. They also contain initial permission bits that are ANDed with those in the PDE and PTEs to determine the final permissions of accesses through this ASID.

The PTBs are stored in a RAM that is accessed indirectly though the SMMU_PTB_ASID and SMMU_PTB_DATA registers.

Boot requirements: This RAM should be saved to SDRAM and restored by the OS during warm boot.

Page Table Base ASID Register

This register selects which PTB is modified by the SMMU_PTB_DATA register.

Offset: 0x1c | Read/Write: R/W | Reset: 0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx

Bit	Reset	Description
1:0	X	CURRENT_ASID: ASID used to address SMMU_PTB register

20.11.1.5 MC_SMMU_PTB_DATA_0

Writes or reads to this register write or read the Page Table Base pointer for the ASID defined in the SMMU_PTB_ASID register.

This register is not TrustZone secure, but only a TrustZone secure access may alter the PTB for a secure ASID.

Secure ASIDs have additional privilege over other non-secure ASIDs - they may fetch page tables from secure memory and they can allow clients translated through them to make secure accesses if programmed to do so.

Attempts to write a secure ASID with a non-secure access will be ignored, and non-secure reads will return garbage.

Page Table Base Data Register

Offset: 0x20 | Read/Write: R/W | Reset: 0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx

Bit	Reset	Description
31	X	ASID_READABLE: if set, reads are allowed for this ASID
30	X	ASID_WRITABLE: if set, writes are allowed for this ASID
29	X	ASID_NONSECURE: if set, non-secure accesses are allowed for this ASID
19:0	X	ASID_PDE_BASE: Pointer to page of PDEs, bits [31:12] for this ASID

20.11.1.6 MC_SMMU_TLB_FLUSH_0

Software can write this register to flush a specific page group, 4MB section, entire ASID or the entire TLB. There is independent control over matching part or all of the VA and/or matching the ASID.

Note: The granularity of VA mapping here is at a page group, which is the number of PTEs that fit in a memory atom.

Translation Lookaside Buffer Flush Register

Offset: 0x30 | Read/Write: R/W | Reset: 0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx

Bit	Reset	Description
31	X	TLB_FLUSH_ASID_MATCH: If enabled, only entries matching TLB_FLUSH_ASID are flushed. 0 = DISABLE 1 = ENABLE
30:29	X	TLB_FLUSH_ASID: ASID to match when TLB_FLUSH_ASID_MATCH is ENABLED
19:2	X	TLB_FLUSH_VA_GROUP: Virtual address to match for group flushes, VA[31:14]
1:0	X	TLB_FLUSH_VA_MATCH: Controls flushing based on VA, one of ALL: Flush entire TLB SECTION: Flush all entries with a VA[31:22] that match TLB_FLUSH_VA_SECTION GROUP: Flush all entries with a VA[31:14] that match TLB_FLUSH_VA_GROUP 0 = ALL 2 = SECTION 3 = GROUP

20.11.1.7 MC_SMMU_PTC_FLUSH_0

Software can use this register to flush a specific PTE or PDE from the Page Table Cache (PTC) by writing the atom-aligned physical address of the PTE group. It can also flush the entire PTC via this register.

Note: The granularity of flushing is at the PTE group, which is the number of PTEs that fit in a memory atom.

Page Table Cache Flush Register

Offset: 0x34 | Read/Write: R/W | Reset: 0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx

Bit	Reset	Description
31:4	X	PTC_FLUSH_ADR: Physical address of PTE group to match for address flushes, PA[31:4]
0	X	PTC_FLUSH_TYPE: Controls flushing, one of ALL: Flush entire PTC ADR: Flush PTEs that are addressed by PTC_FLUSH_ADR 0 = ALL 1 = ADR

20.11.1.8 MC_SMMU_ASID_SECURITY_0

This register controls which ASIDs are considered "secure". Secure ASIDs cannot have their PTBs read or written by a non-secure access, nor can they be assigned as a module's ASID by a non-secure write.

ASIDs may also be enabled as "promoting", which allows modules mapped through them to inherit their secure status. If a secure ASID has its promotion bit enabled, modules mapped to this ASID may access the secure physical memory region.

> **Note:** All ASIDs, regardless of security, may access TrustZone-secure physical memory for page table accesses.

This register can only be accessed by TrustZone-Secured accesses from the CPU.

Boot requirements: This register should be saved to SDRAM and restored by the OS during warm boot.

ASID Security Register

Offset: 0x38 | Read/Write: R/W | Secure: Trust Zone Protected | Reset: 0bxxxxxxxxxxxx0000xxxxxxxxxxxx0000

Bit	Reset	Description
19:16	0x0	PROMOTING_ASIDS: If bit N in this field is set, clients that are mapped to ASID N may access the TrustZone-secure area of memory if ASID N is also marked as "secure".
3:0	0x0	SECURE_ASIDS: If bit N in this field is set, the PTB of ASID N cannot be read or written by a non-secure access, nor can this ASID be mapped to a module by a non-secure write.

20.11.1.9 MC_EMEM_CFG_0

Boot requirements:

- This register should be parameterized in the BCT and written by the Boot ROM during cold boot.
- This register should be saved in the scratch registers and restored by the Boot ROM during warm boot.
- During warm boot, this register may be derived from EMEM_ADR_CFG* register values.

External Memory Aperture Configuration

Offset: 0x50 | Read/Write: R/W | Reset: 0bxxxxxxxxxxxxxxxxxxxx0011111111111

Bit	Reset	Description
11:0	0x7ff	EMEM_SIZE_MB: Specify the external memory aperture size in megabytes. This field must be set to less than or equal to the available physical memory for proper operation. This value is used to check for decode errors; requests to addresses greater than or equal to EMEM_BOM+EMEM_SIZE_MB will result in an EMEM decode error.

20.11.1.10 MC_EMEM_ADR_CFG_0

The EMEM_ADR_CFG* registers are used to specify the DRAM density and geometry parameters. MC will use these parameters to derive device, row, bank, column addressing values to EMC.

> **Note:** The maximum size externally supported is dependent on pinout and address-map aperture limitations, and that it may be possible to configure the device/row/bank/column addresses in ways that exceed these limitations.

For each device attached [1..NUMDEV], the associated per-device address configuration must also be programmed, in the associated register EMEM_ADR_CFG_DEV{N-1}.

The maximum number of row bits carried internally is defined by NV_MC_EMEM_ROW_WIDTH.

The maximum number of address pins is defined by NV_MC_EMEM_ROWPIN_WIDTH.

If not being used to address a device, the chip-select pins may be re-used as row address pins for DDR3.

> **Note:** LPDDR2 only supports up to 15 row bits.

Valid settings for EMEM_ADR_CFG_DEV* registers should ensure device address width <= bank width + column width + NV_MC_EMEM_ROW_WIDTH

Boot requirements:

- This register should be parameterized in the BCT and written by the Boot ROM during cold boot.
- This register should be saved in the scratch registers and restored by the Boot ROM during warm boot.

External Memory Address Configuration, System

Offset: 0x54 | Read/Write: R/W | Reset: 0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx0

Bit	Reset	Description
0	N1	EMEM_NUMDEV: [PMC] number of populated DRAM devices. 0 = N1 1 = N2

20.11.1.11 MC_EMEM_ADR_CFG_DEV0_0

Configures the density and geometry of the first attached device.

Boot requirements:

- This register should be parameterized in the BCT and written by the Boot ROM during cold boot.
- This register should be saved in the scratch registers and restored by the Boot ROM during warm boot.

External Memory Address Configuration, Device 0

Offset: 0x58 | Read/Write: R/W | Reset: 0bxxxxxxxxxxxxx0100xxxxxx10xxxxx010

Bit	Reset	Description
19:16	D64MB	EMEM_DEV0_DEVSIZE: [PMC] density of the first attached DRAM device, used to generate width of row address. 2 = D16MB 3 = D32MB 4 = D64MB 5 = D128MB 6 = D256MB 7 = D512MB 8 = D1024MB 8 = D1GB 9 = D2048MB 9 = D2GB
9:8	W2	EMEM_DEV0_BANKWIDTH: [PMC] width of bank address of the first attached DRAM device. 2 = W2 3 = W3
2:0	W9	EMEM_DEV0_COLWIDTH: [PMC] width of column address of the first attached DRAM device. W8 maps to 1KB page size, W9 to 2KB, W10 to 4KB, etc. 1 = W8 2 = W9 3 = W10 4 = W11

20.11.1.12 MC_EMEM_ADR_CFG_DEV1_0

Configures the density and geometry of the second attached device, if a second device is populated.

To allow for 2 devices with different colwidth/bankwidth to be used without creating holes in the system-level address map, the DEVSIZE setting of the second device may be smaller than the others to allow for non-powers-of-2 attached memory sizes.

Boot requirements:

- This register should be parameterized in the BCT and written by the Boot ROM during cold boot.
- This register should be saved in the scratch registers and restored by the Boot ROM during warm boot.

External Memory Address Configuration, Device 1

Offset: 0x5c | Read/Write: R/W | Reset: 0bxxxxxxxxxxxxx0100xxxxxx10xxxxx010

Bit	Reset	Description
19:16	D64MB	EMEM_DEV1_DEVSIZE: [PMC] density of the second attached DRAM device, used to generate width of row address. 2 = D16MB 3 = D32MB 4 = D64MB 5 = D128MB 6 = D256MB 7 = D512MB 8 = D1024MB 8 = D1GB 9 = D2048MB 9 = D2GB
9:8	W2	EMEM_DEV1_BANKWIDTH: [PMC] width of bank address of the second attached DRAM device. 2 = W2 3 = W3
2:0	W9	EMEM_DEV1_COLWIDTH: [PMC] width of column address of the second attached DRAM device. W8 maps to 1KB page size, W9 to 2KB, W10 to 4KB, etc. 1 = W8 2 = W9 3 = W10 4 = W11

20.11.1.13 MC_SECURITY_CFG0_0

Security aperture: can be only accessed by TrustZone-Secured accesses from the secure clients. Access to this register is restricted to TrustZone-secured requestors.

Boot requirements: This security configuration register should be saved to SDRAM and restored by the OS during warm boot.

Generated from mc_clientsecurity.spec

The global memory client IDs with TrustZone-level security are as follows:

CLIENT	ID	ID(hex)	SWGROUP	MODULE	PARTITION	DESCRIPTION
csr_ppcsahbslvr	30	(0x1e)	ppcs	ppcs	ahb	AHB bus reads
csr_vdebsevr	34	(0x22)	vde	vde2x	vd	Video Decode (VDE) video bitstream engine reads
csr_mpcorelpr	38	(0x26)	mpcorelp	mpcorelp	a15lp	Reads from Cortex-A15 Shadow CPU core via the L2 cache
csr_mpcorer	39	(0x27)	mpcore	mpcore	pi	Reads from 4 Cortex-A15 CPU cores via the L2 cache

CLIENT	ID	ID(hex)	SWGROUP	MODULE	PARTITION	DESCRIPTION
csw_mpcorelpw	56	(0x38)	mpcorelp	mpcorelp	a15lp	Writes from Cortex-A15 Shadow CPU core via the L2 cache
csw_mpcorew	57	(0x39)	mpcore	mpcore	pi	Writes from 4 Cortex-A15 CPU cores via the L2 cache
csw_ppcsahbslvw	60	(0x3c)	ppcs	ppcs	ahb	AHB bus writes
csw_vdebsevw	62	(0x3e)	vde	vde2x	vd	Video Decode (VDE) video bitstream engine writes

Secure Region Configuration: Base

Offset: 0x70 | Read/Write: R/W | Secure: Trust Zone Protected | Reset: 0b100000000000xxxxxxxxxxxxxxxxxxxx

Bit	Reset	Description
31:20	0x800	SECURITY_BOM: SECURITY_BOM is the base of the secured region, limited to MB granularity. This must point to a region of the physical address map allocated to EMEM for it to be effective; MC cannot secure address space it does not own. (In other words, this is an absolute address, not an offset.) Above is the list of clients with the TrustZone-security access. Note that AXICIF clients will adhere to the standard AXI protocol "aprot[1]==0" indication for secure requests.

20.11.1.14 MC_SECURITY_CFG1_0

Access to this register is restricted to TrustZone-secured requestors.

Boot requirements:

This security configuration register should be saved to SDRAM and restored by the OS during warm boot.

Secure Region Configuration: Bound

Offset: 0x74 | Read/Write: R/W | Secure: Trust Zone Protected | Reset: 0bxxxxxxxxxxxxxxxxxxxx000000000000

Bit	Reset	Description
11:0	0x0	SECURITY_SIZE_MB: SECURITY_SIZE_MB is the size, in megabytes, of the secured region. If set to 0, the security check in MC is disabled.

20.11.1.15 MC_SECURITY_CFG2_0

Protected/Carveout apertures: If enabled, certain memory clients are restricted to using SMMU-translated pages or the carveout aperture, they cannot access the protected aperture.

The protected region can be used to prevent hardware engines from accessing the operating system.

The protected region is always [EMEM_BOM..CARVEOUT_BOM).

The carveout region is always [CARVEOUT_BOM..EMEM_TOM].

Access to this register is restricted to TrustZone-secured requestors.

Boot requirements:

This security configuration register should be saved to SDRAM and restored by the OS during warm boot.

The global memory client IDs allowed access to the protected region are as follows:

CLIENT	ID	ID(hex)	SWGROUP	MODULE	PARTITION	DESCRIPTION
csr_ptcr	0	(0x00)	ptc			Misses from System Memory Management Unit (SMMU) Page Table Cache (PTC)
csr_avpcarm7r	15	(0x0f)	avpc	avpc	avp	ARM7 Audio-Video Processor (AVP) reads via the avp_cache
csr_ppcsahbslvr	30	(0x1e)	ppcs	ppcs	ahb	AHB bus reads
csr_vdebsevr	34	(0x22)	vde	vde2x	vd	Video Decode (VDE) video bitstream engine reads
csr_mpcorelpr	38	(0x26)	mpcorelp	mpcorelp	a15lp	Reads from Cortex-A15 Shadow CPU core via the L2 cache
csr_mpcorer	39	(0x27)	mpcore	mpcore	pi	Reads from 4 Cortex-A15 CPU cores via the L2 cache
csw_avpcarm7w	50	(0x32)	avpc	avpc	avp	ARM7 Audio-Video Processor (AVP) writes via the avp_cache
csw_mpcorelpw	56	(0x38)	mpcorelp	mpcorelp	a15lp	Writes from Cortex-A15 Shadow CPU core via the L2 cache
csw_mpcorew	57	(0x39)	mpcore	mpcore	pi	Writes from 4 Cortex-A15 CPU cores via the L2 cache
csw_ppcsahbslvw	60	(0x3c)	ppcs	ppcs	ahb	AHB bus writes
csw_vdebsevw	62	(0x3e)	vde	vde2x	vd	Video Decode (VDE) video bitstream engine writes

Protected Region Configuration: Bound

Offset: 0x78 | Read/Write: R/W | Secure: Trust Zone Protected | Reset: 0b100000000000

Bit	Reset	Description
31:20	0x800	CARVEOUT_BOM: CARVEOUT_BOM is the megabyte-aligned starting address of the carveout region. (In other words, this is an absolute address, not an offset.) If CARVEOUT_BOM is set to <=NV_ADDRESS_MAP_EMEM_BASE, this security check in MC is disabled.

20.11.1.16 MC_EMEM_ARB_CFG_0

General configuration of the External Memory Arbiter.

Boot requirements:

- This register should be parameterized in the BCT and written by the Boot ROM during cold boot.
- This arbitration configuration register should be saved to SDRAM and restored by the OS during warm boot.
- During Boot ROM warm boot, this register may be derived from the emcclk and a standard tick-value.

This register is shadowed: see usage note at top.

External Memory Arbitration Configuration

Offset: 0x90 | Read/Write: R/W | Reset: 0b00000xxxxxxx000001000

Bit	Reset	Description
20:16	0x0	EXTRA_TICKS_PER_UPDATE: The number of extra ticks to add every deadline timer update. Used to keep cycles-per-tick constant when the mcclk period is less than the chosen wall-clock granularity for the deadline counter. If =0, then every tick increments the deadline counter by 1; if =1, then every tick increments the deadline counter by 2, etc. Assuming a target of 30ns-per-tick, some example programming (assumes DIV=2): 10MHz emcclk => 5MHz mcclk => would need to increment deadline counter by 6.67 if using 1 cycle-per-tick => or update by 20 every 3 cycles => 3 cycles-per-tick and 19 extra-ticks-per-update. Since performance is not critical at such slow speeds, rounding errors may be deemed acceptable, so the previous example may be simpler to program as 1 cycle-per-tick and 5 extra-ticks-per-update. Another example, the slowest supported clock speed using a 30ns tick that doesn't distort the tick is: 1.04MHz mcclk => with 31 extra-ticks-per-update and updating every cycle.
8:0	0x8	CYCLES_PER_UPDATE: The number of mcclk cycles per deadline timer update. The target wall-clock granularity ("tick") for the deadline counter should be fixed for the design, then the CYCLES_PER_UPDATE should be used to convert the wall-time value into mcclk cycles. All client latency allowances are also expressed in units of "ticks". Of all deadline-related controls, only the CYCLES_PER_UPDATE and EXTRA_TICKS_PER_UPDATE values need to be updated on a clock-change event. Assuming a target of 30ns-per-tick, some example programming (assumes DIV=2): 667MHz emcclk => 333MHz mcclk => 10 cycles-per-tick; 400MHz emcclk => 200MHz mcclk => 6 cycles-per-tick. Note that value 0x0 is illegal.

20.11.1.17 MC_EMEM_ARB_OUTSTANDING_REQ_0

This register can be used to limit the number of outstanding requests in the arbiter and monitor the count.

If outstanding transaction is greater than the maximum, requests are throttled based on MC_EMEM_ARB_RING1_THROTTLE_0 register

Boot requirements:

- This register should be parameterized in the BCT and written by the Boot ROM during cold boot.
- This arbitration configuration register should be saved to SDRAM and restored by the OS during warm boot.
- During Boot ROM section of warm boot, this register may be derived from other MC settings.

This register is shadowed: see usage note at top.

External Memory Arbitration Configuration: Outstanding Request Limiter

Offset: 0x94 | Read/Write: R/W | Reset: 0b10xxxxxxxxxxxxxxxxxxxxx010000000

Bit	R/W	Reset	Description
31	RW	ENABLE	LIMIT_OUTSTANDING: when ENABLED, the total number of requests in the arbiter is limited to the value in ARB_MAX_OUTSTANDING 0 = DISABLE 1 = ENABLE
30	RW	DISABLE	LIMIT_DURING_HOLDOFF_OVERRIDE: when DISABLED, override the limiting of transactions during hold-off to let requests flow freely 0 = DISABLE 1 = ENABLE
24:16	RO	X	ARB_OUTSTANDING_COUNT: Current number of outstanding requests
8:0	RW	0x80	ARB_MAX_OUTSTANDING: The maximum number of requests allowed in the arbiter when LIMIT_OUTSTANDING is set to ENABLE.

20.11.1.18 MC_EMEM_ARB_TIMING_RCD_0

Boot requirements:

- This register should be parameterized in the BCT and written by the Boot ROM during cold boot.
- This arbitration configuration register should be saved to SDRAM and restored by the OS during warm boot.
- During Boot ROM section of warm boot, this register may be derived from EMC settings using the given equations.

This register is shadowed: see usage note at top.

External Memory Arbitration Configuration: DRAM Timing : tRCD

Offset: 0x98 | Read/Write: R/W | Reset: 0bxxxxxxxxxxxxxxxxxxxxxxxxxxxx111111

Bit	Reset	Description
5:0	0x3f	RCD: The minimum number of cycles between activate commands to the same bank. Program to max (1,ceil(max(EMC.WR_RCD,EMC.RD_RCD)/DIV)-1-1). Note that value 0x0 is illegal.

20.11.1.19 MC_EMEM_ARB_TIMING_RP_0

Boot requirements:

- This register should be parameterized in the BCT and written by the Boot ROM during cold boot.
- This arbitration configuration register should be saved to SDRAM and restored by the OS during warm boot.
- During Boot ROM section of warm boot, this register may be derived from EMC settings using the given equations.

This register is shadowed: see usage note at top.

External Memory Arbitration Configuration: DRAM Timing : tRP

Offset: 0x9c | Read/Write: R/W | Reset: 0bxxxxxxxxxxxxxxxxxxxxxxxxxxx1111111

Bit	Reset	Description
6:0	0x7f	RP: The minimum number of cycles between an internal precharge command and an activate command to the same bank. Program to ceil (EMC.RP/DIV)-1+SFA. The combined value of RAP2PRE+RP 0x0 is illegal; the combined value of WAP2PRE+RP 0x0 is illegal.

20.11.1.20 MC_EMEM_ARB_TIMING_RC_0

Boot requirements

- This register should be parameterized in the BCT and written by the Boot ROM during cold boot.
- This arbitration configuration register should be saved to SDRAM and restored by the OS during warm boot.
- During Boot ROM section of warm boot, this register may be derived from EMC settings using the given equations.

This register is shadowed: see usage note at top.

External Memory Arbitration Configuration: DRAM Timing : tRC

Offset: 0xa0 | Read/Write: R/W | Reset: 0bxxxxxxxxxxxxxxxxxxxxxxxxxxx1111111

Bit	Reset	Description
6:0	0x7f	RC: This is the minimum number of cycles between activate commands to the same bank. Program to ceil (max(EMC.RC,(EMC.RAS+EMC.RP))/DIV)-1.

20.11.1.21 MC_EMEM_ARB_TIMING_RAS_0

Boot requirements:

- This register should be parameterized in the BCT and written by the Boot ROM during cold boot.
- This arbitration configuration register should be saved to SDRAM and restored by the OS during warm boot.
- During Boot ROM section of warm boot, this register may be derived from EMC settings using the given equations.

This register is shadowed: see usage note at top.

External Memory Arbitration Configuration: DRAM Timing: tRAS

Offset: 0xa4 | Read/Write: R/W | Reset: 0bxxxxxxxxxxxxxxxxxxxxxxxxxxxx111111

Bit	Reset	Description
5:0	0x3f	RAS: This is the minimum number of cycles between an activate command and a precharge command to the same bank. Program to ceil (EMC.RAS/DIV)-1-1.

20.11.1.22 MC_EMEM_ARB_TIMING_FAW_0

Boot requirements:

- This register should be parameterized in the BCT and written by the Boot ROM during cold boot.
- This arbitration configuration register should be saved to SDRAM and restored by the OS during warm boot.
- During Boot ROM section of warm boot, this register may be derived from EMC settings using the given equations.

This register is shadowed: see usage note at top.

External Memory Arbitration Configuration: DRAM Timing: tFAW

Offset: 0xa8 | Read/Write: R/W | Reset: 0bxxxxxxxxxxxxxxxxxxxxxxxxxx1111111

Bit	Reset	Description
5:0	0x3f	FAW: For 8-bank devices: Only 4 activates may occur within this rolling window. Program to ceil (EMC.TFAW/DIV)-1. Programming this to 0x0 or not programming a device to 4 banks will turn off this check.

20.11.1.23 MC_EMEM_ARB_TIMING_RRD_0

Boot requirements:

- This register should be parameterized in the BCT and written by the Boot ROM during cold boot.
- This arbitration configuration register should be saved to SDRAM and restored by the OS during warm boot.
- During Boot ROM section of warm boot, this register may be derived from EMC settings using the given equations.

This register is shadowed: see usage note at top of spec file.

External Memory Arbitration Configuration: DRAM Timing: tRRD

Offset: 0xac | Read/Write: R/W | Reset: 0bxxxxxxxxxxxxxxxxxxxxxxxxxxxx1111

Bit	Reset	Description
3:0	0xf	RRD: The minimum number of cycles between an activate command and an activate command to a different bank. Program to ceil (EMC.RRD/DIV)-1.

20.11.1.24 MC_EMEM_ARB_TIMING_RAP2PRE_0

Boot requirements:

- This register should be parameterized in the BCT and written by the Boot ROM during cold boot.
- This arbitration configuration register should be saved to SDRAM and restored by the OS during warm boot.
- During Boot ROM section of warm boot, this register may be derived from EMC settings using the given equations.

This register is shadowed: see usage note at top.

External Memory Arbitration Configuration: DRAM Timing : tRAP2PRE

Offset: 0xb0 | Read/Write: R/W | Reset: 0bxxxxxxxxxxxxxxxxxxxxxxxxxxxx111111

Bit	Reset	Description
5:0	0x3f	RAP2PRE: The number of cycles between a read command with auto-precharge and the internal precharge command generated by the DRAM. Program to ceil (EMC_R2P/DIV). Note that: the combined value of RAP2PRE+RP 0x0 is illegal.

20.11.1.25 MC_EMEM_ARB_TIMING_WAP2PRE_0

Boot requirements:

- This register should be parameterized in the BCT and written by the Boot ROM during cold boot.
- This arbitration configuration register should be saved to SDRAM and restored by the OS during warm boot.
- During Boot ROM section of warm boot, this register may be derived from EMC settings using the given equations.

This register is shadowed: see usage note at top.

External Memory Arbitration Configuration: DRAM Timing: tWAP2PRE

Offset: 0xb4 | Read/Write: R/W | Reset: 0bxxxxxxxxxxxxxxxxxxxxxxxxxxx1111111

Bit	Reset	Description
6:0	0x7f	WAP2PRE: The number of cycles between a write command with auto-precharge and the internal precharge command generated by the DRAM. Program to ceil (EMC_W2P/DIV). Note that: the combined value of WAP2PRE+RP 0x0 is illegal.

20.11.1.26 MC_EMEM_ARB_TIMING_R2R_0

Boot requirements:

- This register should be parameterized in the BCT and written by the Boot ROM during cold boot.
- This arbitration configuration register should be saved to SDRAM and restored by the OS during warm boot.
- During Boot ROM section of warm boot, this register may be derived from EMC settings using the given equations.

This register is shadowed: see usage note at top.

External Memory Arbitration Configuration: DRAM Timing: tR2R

Offset: 0xb8 | Read/Write: R/W | Reset: 0bxxxxxxxxxxxxxxxxxxxxxxxxxxxx11111

Bit	Reset	Description
4:0	0x1f	R2R: The number of cycles between consecutive read commands to different devices (different chip selects). Program to ceil (EMC.REXT/DIV)-1+OTFA+SFA.

20.11.1.27 MC_EMEM_ARB_TIMING_W2W_0

Boot requirements:

- This register should be parameterized in the BCT and written by the Boot ROM during cold boot.
- This arbitration configuration register should be saved to SDRAM and restored by the OS during warm boot.
- During Boot ROM section of warm boot, this register may be derived from EMC settings using the given equations.

This register is shadowed: see usage note at top.

External Memory Arbitration Configuration: DRAM Timing: tW2W

Offset: 0xbc | Read/Write: R/W | Reset: 0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx11111

Bit	Reset	Description
4:0	0x1f	W2W: The number of cycles between consecutive write commands to different devices (different chip selects). Program to ceil (EMC.WEXT/DIV)-1+SFA.

20.11.1.28 MC_EMEM_ARB_TIMING_R2W_0

Boot requirements:

- This register should be parameterized in the BCT and written by the Boot ROM during cold boot.
- This arbitration configuration register should be saved to SDRAM and restored by the OS during warm boot.
- During Boot ROM section of warm boot, this register may be derived from EMC settings using the given equations.

This register is shadowed: see usage note at top.

External Memory Arbitration Configuration: DRAM Timing: tR2W

Offset: 0xc0 | Read/Write: R/W | Reset: 0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx111111

Bit	Reset	Description
5:0	0x3f	R2W: The number of cycles to turn the bus from reads to writes. Program to ceil (EMC.R2W/DIV)-1+OTFA+SFA.

20.11.1.29 MC_EMEM_ARB_TIMING_W2R_0

Boot requirements:

- This register should be parameterized in the BCT and written by the Boot ROM during cold boot.
- This arbitration configuration register should be saved to SDRAM and restored by the OS during warm boot.
- During Boot ROM section of warm boot, this register may be derived from EMC settings using the given equations.

This register is shadowed: see usage note at top.

External Memory Arbitration Configuration: DRAM Timing: tW2R

Offset: 0xc4 | Read/Write: R/W | Reset: 0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx111111

Bit	Reset	Description
5:0	0x3f	W2R: The number of cycles to turn the bus from reads to writes. Program to ceil (EMC.W2R/DIV)-1+SFA.

20.11.1.30 MC_EMEM_ARB_DA_TURNS_0

The direction arbiter attempts to choose the highest efficiency (i.e. lowest bubbles) direction to open pages next. While programming this register incorrectly may lower performance, it should never cause chip-hangs since the EMC always controls the final DRAM timing decisions. This register should be reprogrammed after clock-change events to bring the computed values back in alignment with EMC's register values. These turn costs are deliberately not computed in hardware to provide better flexibility to tweak arbiter performance.

The configuration registers for turns for DA are separate from the timing registers to allow for flexibility in the programming.

Boot requirements:

- This arbitration configuration register should be saved to SDRAM and restored by the OS during warm boot.
- During Boot ROM section of warm boot, this register may be derived from MC settings using the given equations.

This register is shadowed: see usage note at top.

External Memory Arbitration Configuration: Direction Arbiter: Turns

Offset: 0xd0 | Read/Write: R/W | Reset: 0b00001111000011110000001000000101

Bit	Reset	Description
31:24	0xf	W2R_TURN: Bubbles produced by a write to read bus turn. Approximately MC_EMEM_ARB_TIMING_W2R.
23:16	0xf	R2W_TURN: Bubbles produced by a read to write bus turn. Approximately MC_EMEM_ARB_TIMING_R2W.
15:8	0x2	W2W_TURN: Bubbles produced by a write to write (other device) bus turn. Approximately MC_EMEM_ARB_TIMING_W2W.
7:0	0x5	R2R_TURN: Bubbles produced by a read to read (other device) bus turn. Approximately MC_EMEM_ARB_TIMING_R2R.

20.11.1.31 MC_EMEM_ARB_DA_COVERS_0

The direction arbiter attempts to choose the highest efficiency (i.e., lowest bubbles) direction to open pages next. While programming this register incorrectly may lower performance, it should never cause chip-hangs since the EMC always controls the final DRAM timing decisions. This register should be reprogrammed after clock-change events to bring the computed values back in alignment with EMC's register values. These cover costs are deliberately not computed in hardware to provide better flexibility to tweak arbiter performance.

Boot requirements:

- This arbitration configuration register should be saved to SDRAM and restored by the OS during warm boot.
- During Boot ROM section of warm boot, this register may be derived from MC settings using the given equations.

This register is shadowed: see usage note at top.

External Memory Arbitration Configuration: Direction Arbiter: Covers

Offset: 0xd4 | Read/Write: R/W | Reset: 0bxxxxxxxx00001111000001111000011111

Bit	Reset	Description
23:16	0xf	RCD_W_COVER: Cost to cover the activate-to-write delay. Approximately ceil ((EMC.RTP + EMC.RP + EMC.RD_RCD)/DIV)-1.
15:8	0xf	RCD_R_COVER: Cost to cover the activate-to-read delay. Approximately ceil ((EMC.WTP + EMC.RP + EMC.WR_RCD)/DIV)-1.

Bit	Reset	Description
7:0	0xf	RC_COVER: Cost to cover the activate-to-activate delay. Approximately MC_EMEM_ARB_TIMING_RC.

20.11.1.32 MC_EMEM_ARB_MISC0_0

BC2AA_HOLDOFF: In the case where the currently-open pages have more work pending than the time it would take to open another page, it is better to hold off opening that page until it is truly needed. The Best-bank Cache computes the pending work and compares it to this threshold and advises the Activation Arbiter to hold-off.

Priority Inversion: In general, if the arbiter is working on a lower-priority request that blocks a higher-priority request, these thresholds are used to limit the number of low-priority requests we will service before the arbiter will interrupt the lower-priority traffic to start servicing the higher-priority traffic.

The priority classes are (in increasing priority order): Low (! expired), High (expired), HighIso.

There are three ways priority can be inverted: Bank Activation, Bus Direction, and Refresh:

Bank Activation: If an unexpired request to bank A, row R currently holds the page open, and a request to bank A, row S expires, the Transaction Arbiter must make a decision whether to finish out the work for row R or to interrupt that transfer to immediately service row S. The TA makes this decision based on the remaining work for row R and whether row S is for an isochronous client, and the two PRIORITY_INVERSION thresholds.

Bus Direction: If the Transaction Arbiter is currently working on expired requests in direction P, and requests are also expired (or expired-iso) in direction Q, the Transaction Arbiter must make a decision whether to continue working in direction P or switch the bus to direction Q. The Transaction Arbiter will service at maximum PRIORITY_INVERSION_THRESHOLD (or _INVERSION_ISO_THRESHOLD) requests in direction P before switching to direction Q.

Refresh: If the Transaction Arbiter is currently working on requests, and EMC asks to inject a refresh, the Transaction Arbiter must decide whether it is more efficient (overall) to close the pages immediately or to finish the pages and then close them. Depending on the setting of the REFRESH_ACK_THRESHOLD_USAGE configuration bit (in EMEM_ARB_MISC1 register, below), the Transaction Arbiter will either choose to close the page immediately (NONE), close the page immediately if its length is over the iso threshold (ISO), or close the page immediately if its length is over the normal threshold (NORMAL). If the length is less than the chosen threshold, the Transaction Arbiter will service all remaining requests to the page before acknowledging the EMC refresh request.

When in DDR3 coalesce-for-performance mode, the arbiters will monitor the traffic patterns and may halve the priority inversion thresholds if they detect the current traffic is not coalescing efficiently. When in MC_EMC_SAME_FREQ mode, the priority inversion thresholds should be set to half of their non-same-frequency values.

Boot requirements:

- This register should be parameterized in the BCT and written by the Boot ROM during cold boot.
- The MC_EMC_SAME_FREQ field should be saved to scratch registers and restored by the Boot ROM during warm boot.
- The other fields of this register should be saved to SDRAM and restored by the OS during warm boot.
- During Boot ROM section of warm boot, this register may be derived from other settings.

This register is shadowed: see usage note at top.

External Memory Arbitration Configuration: Miscellaneous Thresholds (0)

Offset: 0xd8 | Read/Write: R/W | Reset: 0bx111001000001010x100000000010000

Bit	Reset	Description
30:28	0x7	ATOMS_PER_DVFS_PULSE: The MC will toggle the sys_stats_mon outputs for every 2^(atoms_per_dvfs_pulse+1) atoms of traffic, where an atom is defined as NV_MC_EMEM_WD=16 bytes. The maximum atoms_per_dvfs_pulse setting supported is the reset value, also known as NV_MC_EMEM_DVFS_CNTR_CFG_RESET.
27	DISABLE	MC_EMC_SAME_FREQ: [PMC] Used in conjunction with EMEM_ARB_MISC1.COALESCE_FOR_PERFORMANCE to configure how often MC can send EMC a data request, should be configured to mirror CAR's CLK_SOURCE_EMC.MC_EMC_SAME_FREQ. If configured to DIV=2 BL=4, then MC can send a data request every cycle. If configured to DIV=1 BL=4, then MC can send a data request every other cycle. If configured to DIV=2 BL!=4, then MC can send a data request every other cycle. If configured to DIV=1 BL!=4, then MC can send a data request once every four cycles. 0 = MC is 1/2 the frequency of EMC (DIV=2). 1 = MC is the same frequency of EMC (DIV=1). 0 = DISABLE 1 = ENABLE
26:21	0x10	EXPIRING_SOON_SLACK_THRESHOLD: Slack threshold below which an isochronous request is considered to be expiring "soon". Used to de-assert mc2emc_idle signal early to wake EMC out of power-down or self-refresh. If using EMC's Dynamic Self Refresh features, set this to the ticks needed to cover exit self-refresh delay; otherwise, if using EMC's ACPD feature, set to the ticks needed to cover exit power-down delay; if neither power-saving feature is being used, the programming of this threshold should have no effect.
20:16	0xa	PRIORITY_INVERSION_ISO_THRESHOLD: Bank Activation: maximum number of unexpired or expired-but-not-isochronous requests that can be serviced before switching to expired isochronous traffic. Bus Direction: maximum number of requests in direction P that can be serviced before switching to expired-isochronous traffic in direction Q. Refresh: maximum number of requests that can be serviced before refresh is sent. Values <= 0x2 disable the feature. Values < 0x6 should be avoided if coalescing for performance.
14:8	0x40	PRIORITY_INVERSION_THRESHOLD: Bank Activation: maximum number of unexpired requests that can be serviced before switching to expired traffic. Bus Direction: maximum number of requests in direction P that can be serviced before switching to expired traffic in direction Q. Refresh: maximum number of requests that can be serviced before refresh is sent. Values <= 0x2 disable the feature. Values < 0x6 should be avoided if coalescing for performance.
7:0	0x10	BC2AA_HOLDOFF_THRESHOLD: If the pending work is greater than this value, hold off on activations. Generally should be set to match the page-opening cost: MC_EMEM_ARB_TIMING_RC+1.

20.11.1.33 MC_EMEM_ARB_MISC1_0

Boot requirements:

- This register should be parameterized in the BCT and written by the Boot ROM during cold boot.
- The COALESCE_FOR_PERFORMANCE field should be saved to scratch registers and restored by the Boot ROM during warm boot. It may also be derived from EMC settings.
- The other fields of this register should be saved to SDRAM and restored by the OS during warm boot.

External Memory Arbitration Configuration: Miscellaneous Thresholds (1)

Offset: 0xdc | Read/Write: R/W | Reset: 0b10000x0010101xxxxxxxxxxxxxxxxxxx

Bit	Reset	Description
31:28	0x8	DEADLOCK_PREVENTION_SLACK_THRESHOLD: If the slack at the head of any bank-queue, or any of the slacks in the hit-under-miss FIFO is less than -(2^threshold), backpressure the input to the arbiter until the violating slack values have been arbitrated. This is intended to: (a) avoid deadline-wrapping in heavily backpressured corner-cases and (b) quickly get such cases back into high-efficiency arbitration. Value of 0x0 disables the feature. The reset value is NV_MC_EMEM_DL_WIDTH-1. Behavior with values >= NV_MC_EMEM_DL_WIDTH is UNDEFINED. If the threshold is reached, ARBITRATION_EMEM_INT will fire.
27	DISABLE	COALESCE_FOR_PERFORMANCE: If EMC has BL=8 or BL=4_or_8_on_the_fly, tell the arbiter to coalesce for performance reasons. While MC/EMC will functionally work without this bit, performance will be significantly better if MC knows it should coalesce. 0 = DISABLE 1 = ENABLE
25:24	NORMAL	REFRESH_ACK_THRESHOLD_USAGE: Determines which thresholds (if any) the refresh-acknowledge signal will use to determine how to close all pages after EMC has requested a refresh. 0 = NORMAL : Use priority-inversion threshold 1 = ISO : Use priority-inversion-iso threshold 2 = NONE : Force a precharge immediately to close the page

20.11.1.34 MC_EMEM_ARB_RING1_THROTTLE_0

Ring1 Snap Arbiter Throttle - Inserts some number of stall cycles at Ring1 after every request.

Throttle cycle count varies whether outstanding_request count is below (LOW) or above (HIGH) the max_outstanding threshold.

Boot requirements: During Boot ROM section of warm boot, this register may be derived from other settings.

This register is shadowed: see usage note at top.

External Memory Arbitration Configuration: Snap Arbiter Throttle

Offset: 0xe0 | Read/Write: R/W | Reset: 0bxxxxxxxxxxxx11111xxxxxxxxxxx00000

Bit	Reset	Description
20:16	0x1f	RING1_THROTTLE_CYCLES_HIGH: Cycles of throttle after each request when outstanding transaction count is greater than or equal to threshold.
4:0	0x0	RING1_THROTTLE_CYCLES_LOW: Cycles of throttle after each request when outstanding transaction count is below threshold. Suggested programming: (DIV==1)? 1 : 0.

20.11.1.35 MC_EMEM_ARB_RING3_THROTTLE_0

Ring3 Snap Arbiter Throttle - Inserts some number of stall cycles at Ring3 after every request

Boot requirements: This register should be saved in the SDRAM and restored by the OS during warm boot.

This register is shadowed: see usage note at top.

External Memory Arbitration Configuration: Snap Arbiter Throttle

Offset: 0xe4 | Read/Write: R/W | Reset: 0bxxxxxxxxxxxx00000xxxxxxxxxxx00000

Bit	Reset	Description
4:0	0x0	RING3_THROTTLE_CYCLES: Cycles of throttle after each request.

20.11.1.36 MC_CLIENT_HOTRESET_CTRL_0

Writing FLUSH_ENABLE to a bit in this register causes a flush to be performed on all of the clients for the selected swname. The status of the flush (done/in progress) can be monitored in the CLIENT_HOTRESET_STATUS register.

A proper client reset sequence is as follows:

1. Set the appropriate FLUSH_ENABLE bit in the CLIENT_HOTRESET_CTRL register to block further access by the client, and start the flush process.
2. Poll the CLIENT_HOTRESET_STATUS register until the appropriate bit returns FLUSH_DONE.
3. Clear module bit in the CLK_RST_CONTROLLER_RST_DEVICES_* register to reset the module.
4. Set module bit in the CLK_RST_CONTROLLER_RST_DEVICES_* register to release the module reset.
5. Clear the appropriate FLUSH_ENABLE bit in the CLIENT_HOTRESET_CTRL register to allow transactions to flow.

Memory Client Hot Reset Control Register

Offset: 0x200 | Read/Write: R/W | Reset: 0bxxxxxxxxx0000x00x0x000000000000x

Bit	Reset	Description
17	DISABLE	VI_FLUSH_ENABLE: 0 = DISABLE 1 = ENABLE 0 = DISABLED 1 = ENABLED

20.11.1.62 MC_SMMU_VI_ASID_0

Enables or disables SMMU translation for the module and if enabled sets the ASID for translation.

This register is not TrustZone secure, but non-secure writes to this register will be dropped if either the current or new value of the ASID field is for a secure ASID (regardless of the current or new value of the SMMU_ENABLE field.

SMMU VI ASID Assignment Register

Offset: 0x280 | Read/Write: R/W | Reset: 0b0xxxxxxxxxxxxxxxxxxxxxxxxxxxxx00

Bit	Reset	Description
31	DISABLE	VI_SMMU_ENABLE: if set, translation is enabled for this module 0 = DISABLE 1 = ENABLE
1:0	0x0	VI_ASID: ASID to use for translation, if enabled

20.11.1.63 MC_A9LP_EXTRA_SNAP_LEVELS_0

Each additional level provides an extra request to the snap arbiter. For n requesters, each will get 1/n of the bandwidth. Adding a second level for one client will give that client 2/n+1 of the bandwidth.

Note that a value of 0 means no 'additional' requests, the client still has 1 request.

Additional Snap Arbiter Levels for Partition Client a9lp

Offset: 0x29c | Read/Write: R/W | Reset: 0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx00

Bit	Reset	Description
1:0	0x0	SNAP_LEVELS_A9LP

20.11.1.64 MC_AHB_EXTRA_SNAP_LEVELS_0

Each additional level provides an extra request to the snap arbiter. For n requesters, each will get 1/n of the bandwidth. Adding a second level for one client will give that client 2/n+1 of the bandwidth.

Note that a value of 0 means no 'additional' requests; the client still has 1 request.

Additional snap arbiter levels for partition client AHB

Offset: 0x2a0 | Read/Write: R/W | Reset: 0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx00

Bit	Reset	Description
1:0	0x0	SNAP_LEVELS_AHB

20.11.1.65 MC_APB_EXTRA_SNAP_LEVELS_0

Each additional level provides an extra request to the snap arbiter. For n requesters, each will get 1/n of the bandwidth. Adding a second level for one client will give that client 2/n+1 of the bandwidth.

Note that a value of 0 means no 'additional' requests, the client still has 1 request.

Additional Snap Arbiter Levels for Partition Client APB

Offset: 0x2a4 | Read/Write: R/W | Reset: 0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx00

Bit	Reset	Description
1:0	0x0	SNAP_LEVELS_APB

20.11.1.66 MC_AVP_EXTRA_SNAP_LEVELS_0

Each additional level provides an extra request to the snap arbiter. For n requesters, each will get 1/n of the bandwidth. Adding a second level for one client will give that client 2/n+1 of the bandwidth.

Note that a value of 0 means no 'additional' requests, the client still has 1 request.

Additional Snap Arbiter Levels for Partition Client AVP

Offset: 0x2a8 | Read/Write: R/W | Reset: 0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx00

Bit	Reset	Description
1:0	0x0	SNAP_LEVELS_AVP

20.11.1.67 MC_DIS_EXTRA_SNAP_LEVELS_0

Each additional level provides an extra request to the snap arbiter. For n requesters, each will get 1/n of the bandwidth. Adding a second level for one client will give that client 2/n+1 of the bandwidth.

Note that a value of 0 means no 'additional' requests; the client still has 1 request.

Additional Snap Arbiter Levels for Partition Client DIS

Offset: 0x2ac | Read/Write: R/W | Reset: 0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx11

Bit	Reset	Description
1:0	0x3	SNAP_LEVELS_DIS

20.11.1.68 MC_HEG_EXTRA_SNAP_LEVELS_0

Each additional level provides an extra request to the snap arbiter. For n requesters, each will get 1/n of the bandwidth. Adding a second level for one client will give that client 2/n+1 of the bandwidth.

Note that a value of 0 means no 'additional' requests; the client still has 1 request.

Additional Snap Arbiter Levels for Partition Client HEG

Offset: 0x2b0 | Read/Write: R/W | Reset: 0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx00

Bit	Reset	Description
1:0	0x0	SNAP_LEVELS_HEG

20.11.1.69 MC_ME_EXTRA_SNAP_LEVELS_0

Each additional level provides an extra request to the snap arbiter. For n requesters, each will get 1/n of the bandwidth. Adding a second level for one client will give that client 2/n+1 of the bandwidth.

Note that a value of 0 means no 'additional' requests, the client still has 1 request.

Additional Snap Arbiter Levels for Partition Client ME

Offset: 0x2b4 | Read/Write: R/W | Reset: 0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx00

Bit	Reset	Description
1:0	0x0	SNAP_LEVELS_ME

20.11.1.70 MC_PCX_EXTRA_SNAP_LEVELS_0

Each additional level provides an extra request to the snap arbiter. For n requesters, each will get 1/n of the bandwidth. Adding a second level for one client will give that client 2/n+1 of the bandwidth.

Note that a value of 0 means no 'additional' requests, the client still has 1 request.

Additional Snap Arbiter Levels for Partition Client PCX

Offset: 0x2b8 | Read/Write: R/W | Reset: 0b00

Bit	Reset	Description
1:0	0x0	SNAP_LEVELS_PCX

20.11.1.71 MC_PI_EXTRA_SNAP_LEVELS_0

Each additional level provides an extra request to the snap arbiter. For n requesters, each will get 1/n of the bandwidth. Adding a second level for one client will give that client 2/n+1 of the bandwidth.

Note that a value of 0 means no 'additional' requests, the client still has 1 request.

20.11.1.115 MC_PTSA_GRANT_DECREMENT_0

The amount that the PTSA DDAs are decremented each cycle there is a grant should be programmed to the fraction of total memory bandwidth / maximum total memory bandwidth.

Offset: 0x960 | Read/Write: R/W | Reset: 0bxxxxxxxxxxxxxxxxxxxxxxxx100000000

Bit	Reset	Description
8	0x1	PTSA_GRANT_DECREMENT_INT: Integer portion (0 or 1)
7:0	0x0	PTSA_GRANT_DECREMENT_FRAC: Fractional portion

20.11.2 EMC Registers

> **Note:** Please use EMC_WINCR definition to specify incr1/incr4 based on the project defines.

USAGE NOTE: Many EMC register fields are shadowed:

- Writes to shadowed register fields update the shadow copy (this is default, assumes DBG.WRITE_MUX==ASSEMBLY).
- Reads to shadowed register fields return the currently-active copy (this is default, assumes DBG.READ_MUX==ACTIVE).

This allows a new set of frequency-dependent timing parameters to be written to the shadow registers while memory traffic is ongoing, then when the parameters are completely written, the EMC hardware can perform a timing-safe switch.

Such switches can be triggered via two methods: TIMING_CONTROL.TIMING_UPDATE (generally used during initialization), or the automatic CAR/EMC handshake on a clock-frequency or divider change (assuming CFG_2.CLKCHANGE_REQ_ENABLE==ENABLED).

Registers that are shadowed are marked by a comment:

```
// This register is shadowed: see usage note at top.
```

Occasionally, only certain fields in the register will be shadowed, if so they are noted after the above comment.

USAGE NOTE: Many EMC registers play crucial roles in warm boot (also known as "wake from LP0") and cold boot (also known as "power up") sequences. Suggested actions for the Boot ROM/Bootloader are noted in comments labelled "Boot requirements: ...".

USAGE NOTE: The EMC register fields to be stored in the PMC must have "[PMC]", "[PMC2]", or "[PMC3]".in their comments. ([PMC2] registers are packed/unpacked after [PMC] register group in software code. [PMC3] is even later.) The fields that need to be stored in PMC Secure Scratch registers must have [PMC_SECURE] in their comments.

20.11.2.1 EMC_INTSTATUS_0

Interrupt Status Register

Clear on 1-write. Init value is clear.

Offset: 0x0 | Read/Write: R/W | Reset: 0x00000000 (0bxxxxxxxxxxxxxxxxxxxxxxxx0000000x0x)

Bit	Reset	Description
9	CLEAR	DLL_LOCK_TIMEOUT_INT: Indicates a DLL lock timeout has occurred. 0 = CLEAR 1 = SET
8	CLEAR	CCFIFO_OVERFLOW_INT: Clock change FIFO overflow. 0 = CLEAR 1 = SET
7	CLEAR	DLL_ALARM_INT: Indicates a DLL alarm has been set 0 = CLEAR 1 = SET
6	CLEAR	ACCESS_TO_SR_DPD_DEV_INT: Indicates a system attempt to access a self-refresh/deep-powered-down device. 0 = CLEAR 1 = SET
5	CLEAR	MRR_DIVLD_INT: LPDDR2 MRR data is available to be read. 0 = CLEAR 1 = SET
4	CLEAR	CLKCHANGE_COMPLETE_INT: CAR/EMC clock-change handshake complete. 0 = CLEAR 1 = SET
3	CLEAR	REFRESH_OVERFLOW_INT: Refresh request overflow timeout. 0 = CLEAR 1 = SET
1	CLEAR	EXT_INTR_IN_INT: External interrupt input (from the next EMC) 0 = CLEAR 1 = SET

20.11.2.2 EMC_INTMASK_0

Interrupt Mask Register

Init value is masked.

Offset: 0x4 | Read/Write: R/W | Reset: 0x00000000 (0bxxxxxxxxxxxxxxxxxxxxxxxx0000000x0x)

Bit	Reset	Description
9	MASKED	DLL_LOCK_TIMEOUT_INTMASK: Mask for DLL lock timeout interrupt. 0 = MASKED 1 = UNMASKED
8	MASKED	CCFIFO_OVERFLOW_INTMASK: Mask for clock change FIFO overflow. 0 = MASKED 1 = UNMASKED
7	MASKED	DLL_ALARM_INTMASK: Mask for DLL alarm 0 = MASKED 1 = UNMASKED
6	MASKED	ACCESS_TO_SR_DPD_DEV_INTMASK: Mask for access a self-refresh/deep-powered-down device interrupt. 0 = MASKED 1 = UNMASKED
5	MASKED	MRR_DIVLD_INTMASK: Mask for MRR data available. 0 = MASKED 1 = UNMASKED
4	MASKED	CLKCHANGE_COMPLETE_INTMASK: Mask for CAR/EMC clock-change handshake complete. 0 = MASKED 1 = UNMASKED
3	MASKED	REFRESH_OVERFLOW_INTMASK: Mask for refresh request overflow timeout. 0 = MASKED 1 = UNMASKED
1	MASKED	EXT_INTR_IN_INTMASK: Mask for external interrupt input 0 = MASKED 1 = UNMASKED

20.11.2.3 EMC_DBG_0

Debug Register

The DBG register is used to reconfigure the EMC during debug or chip testing.

Boot Requirements

- This register should be parameterized in the BCT and written by the Boot ROM during cold boot.
- This register should be saved in the scratch registers and restored by the Boot ROM during warm boot.

Offset: 0x8 | Read/Write: R/W | Reset: 0x01000400 (0bxxxxxxx1xxxxxxxxxx00x10xxxxx0000)

Bit	Reset	Description
24	ENABLED	CFG_PRIORITY: determines the priority of cfg accesses to the DRAM. Setting this register to ENABLED gives DRAM config cycles (refresh, mrs, emrs, etc.) higher priority over real time requestors. The DISABLED setting gives the real time requestors higher priority than DRAM config cycles. Do not program to DISABLED unless for debugging. 0 = DISABLED 1 = ENABLED
13	DISABLED	SUPPRESS_WRITE_CMD: suppress write command sent to DRAM

Bit	Reset	Description
		0 = DISABLED 1 = ENABLED
12	DISABLED	SUPPRESS_READ_CMD: suppress read command sent to DRAM 0 = DISABLED 1 = ENABLED
10	ENABLED	AP_REQ_BUSY_CTRL: determines whether the busy signal from the auto-precharge cancellation (APC) FIFO is allowed to stall requests to the EMC. This field should usually be set to ENABLED 0 = DISABLED 1 = ENABLED
9	MANAGED	READ_DQM_CTRL: If set to MANAGED, EMC only turns them on when necessary. If set to ALWAYS_ON, the DQM signals are enabled during non-write operation. This field should usually be set to MANAGED 0 = MANAGED 1 = ALWAYS_ON
2	DISABLED	FORCE_UPDATE: causes the active state to get updated with the assembly state immediately upon setting this register. 0 = DISABLED 1 = ENABLED
1	ASSEMBLY	WRITE_MUX: controls whether writes to the configuration registers are done from the assembly or active state. 0 = ASSEMBLY 1 = ACTIVE
0	ACTIVE	READ_MUX: controls whether reads to the configuration registers are done from the assembly or active state. 0 = ACTIVE 1 = ASSEMBLY

20.11.2.4 EMC_CFG_0

Configuration Register

The CFG register is used to configure the external memory interface.

Note: For each EMC2PMACRO_CFG_BYPASS_DATAPIPE*=0, the timing parameters (WDV, RDV, CTT, PUTERM, PUTERM_EXTRA,QUSE, QUSE_EXTRA, QRST, EINPUT, IBDLY) must be subtracted by 1 to compensate. In other words, if both *_BYPASS_DATAPIPE* are set to 0, the above timing parameters need to be subtracted by 2.

For EMC2PMACRO_CFG_BYPASS_ADDRPIPE=0, the above timing parameters need to be added by 1.

Boot Requirements

- This register should be parameterized in the BCT and written by the BootROM during cold boot.
- This register should be saved in the scratch registers and restored by the BootROM during warm boot.

Offset: 0xc | Read/Write: R/W | Reset: 0x03c0000e (0b0000xx11110000xxxxxxxxxx000111x)

Bit	Reset	Description
31	DISABLED	DRAM_CLKSTOP_PD: [PMC] clock stop is only allowed to happen if the DRAM is in active/precharge powerdown (for all CKE bits associated with clock) 0 = DISABLED 1 = ENABLED
30	DISABLED	DRAM_CLKSTOP_SR: [PMC] clockstop is only allowed to happen if the DRAM is in self-refresh (for all CKE bits associated with clock) 0 = DISABLED 1 = ENABLED

Bit	Reset	Description
29	NO_POWERDOWN	DRAM_ACPD: [PMC] allows the DRAM controller to perform opportunistic active powerdown control using the CKE pin on the DRAM. The behavior of the powerdown control logic is controlled by the PDEX2* and *2PDEN registers. The value of DRAM_ACPD should only be changed when CKE is low, e.g., during software-controlled self-refresh or before DRAM initialization. 0 = NO_POWERDOWN 1 = ACTIVE_POWERDOWN
28	DISABLED	DYN_SELF_REF: [PMC] 0 = DISABLED 1 = ENABLED
25	ENABLED	AUTO_PRE_WR: [PMC] enable using MC auto-precharge indication for writes. This bits, when set to DISABLE, will override the settings in the MC register (EMC ignore the auto-precharge indication from MC). Otherwise, they permit clients to make either auto or explicit precharge requests depend on the state of MAN_PRE_WR. 0 = DISABLED 1 = ENABLED
24	ENABLED	AUTO_PRE_RD: [PMC] enable using MC auto-precharge indication for reads. This bits, when set to DISABLE, will override the settings in the MC register (EMC ignores the auto-precharge indication from MC). Otherwise, they permit clients to make either auto or explicit precharge requests depend on the state of MAN_PRE_RD. 0 = DISABLED 1 = ENABLED
23	ENABLED	MAN_PRE_WR: [PMC] enable explicit-precharge in the EMC for writes. When this bit is enabled (and AUTO_PRE_WR=enable), EMC will issue an explicit precharge command after the memory write command. If this bit is disabled (and AUTO_PRE_WR=enable), EMC will issue an auto-precharge with the memory write command. 0 = DISABLED 1 = ENABLED
22	ENABLED	MAN_PRE_RD: [PMC] enable explicit-precharge in the EMC for reads. When this bit is enabled (and AUTO_PRE_RD=enable), EMC will issue an explicit precharge command after the memory read command. If this bit is disabled (and AUTO_PRE_RD=enable), EMC will issue an auto-precharge with the memory read command. 0 = DISABLED 1 = ENABLED
21	DISABLED	PERIODIC_QRST: [PMC] specifies whether or not to periodic reset the FBIO read-data FIFO during normal operation. The periodic resets can be used for graceful recovery from an intermittent failure condition; only the initial reset is absolutely required. Note: For LPDDRx and MRR (if ever used), this bit should be set to enable. 0 = DISABLED 1 = ENABLED
20	DISABLED	EN_DYNAMIC_PUTERM: [PMC] enable dynamic puterm. 0 = DISABLED 1 = ENABLED
19	DISABLED	DLY_WR_DQ_HALF_CLOCK: [PMC] 1 = delay write data by 1/2 clock. 0 = DISABLED 1 = ENABLED
18	DISABLED	DSR_VTTGEN_DRV_EN: [PMC] enable VTTGEN controls (via DSR_VTTGEN_DRV/TXDSRVTTGEN registers) during DSR. 0 = DISABLED 1 = ENABLED
6	0x0	INVERT_DQM: [PMC] 1 = invert DQM polarity.
5	0x0	WAIT_FOR_DISPLAYB_READY_B4_CC: [PMC] 1 = wait for displayb ready event to be asserted before acknowledging clock change.
4	0x0	WAIT_FOR_DISPLAY_READY_B4_CC: [PMC] 1 = wait for display ready event to be asserted before acknowledging clock change.

Bit	Reset	Description
3	0x1	EMC2PMACRO_CFG_BYPASS_DATAPIPE2: [PMC] 1 = bypass data pipeline stage2 (closer to I/O) between EMC and data pad-macro.
2	0x1	EMC2PMACRO_CFG_BYPASS_DATAPIPE1: [PMC] 1 = bypass data pipeline stage1 (closer to core) between EMC and data pad-macro.
1	0x1	EMC2PMACRO_CFG_BYPASS_ADDRPIPE: [PMC] 1 = bypass address pipeline stage between EMC and address pad-macro.

20.11.2.5 EMC_ADR_CFG_0

External Memory Address Configuration, System

The ADR_CFG register is used to specify the number of DRAM devices. DRAM density and geometry parameters are specified by the EMEM_ADR_CFG* registers in MC.

Boot requirements:

- This register should be parameterized in the BCT and written by the Boot ROM during cold boot.
- This register should be saved in the scratch registers and restored by the Boot ROM during warm boot.

Offset: 0x10 | Read/Write: R/W | Reset: 0x00000000 (0bxxxxxxxxxxxxxxxxxxxxxxxxxxx0xxxxxx0)
