Bit	Reset	Description
7	DISABLED	EMEM_ROW_MSB_ON_CS1: [PMC SECURE] Drive CS1 pin with address bit 15 0 = DISABLED 1 = ENABLED
0	N1	EMEM_NUMDEV: [PMC SECURE] Number of populated DRAM devices. 0 = N1 1 = N2

20.11.2.6 EMC_REFCTRL_0

Refresh Control Register

The REFCTRL register allows software to enable or disable the refresh controller.

REF_VALID should be enabled after the initialization sequence is completed.

Boot requirements

- If per-device DPD is used, the DEVICE_REFRESH_DISABLE field should be parameterized in the BCT and written by the Boot ROM during cold boot.
- If per-device DPD is used, the DEVICE_REFRESH_DISABLE field should be parameterized the scratch registers and restored by the Boot ROM during warm boot.
- REF_VALID field should always be set to ENABLED for normal use, no need to parameterize in BCT/scratch.

Offset: 0x20 | Read/Write: R/W | Reset: 0x00000000 (0b0xxxxxxxxxxxxxxxxxxxxxxxxxxxxx00)

Bit	Reset	Description
31	DISABLED	REF_VALID: Enable refresh controller. 0 = DISABLED 1 = ENABLED
1:0	0x0	DEVICE_REFRESH_DISABLE: Disables refresh to individual attached device (1 bit per DRAM chip select).

20.11.2.7 EMC_PIN_0

Controls State of Selected DRAM Pins

The PIN register allows software to control the state of the selected external DRAM pins.

Boot requirements

- Both fields in this register should be set to NORMAL during cold boot.
- Both fields in this register should be set to NORMAL during warm boot.

Offset: 0x24 | Read/Write: R/W | Reset: 0x00000100 (0bxxxxxxxxxxxxxxxxxxxxxxxx1xxx0xxx0)

Bit	Reset	Description
8	INACTIVE	PIN_RESET: Selects the level of the DDR3 RESET# pin. 0 = ACTIVE 1 = INACTIVE
4	NORMAL	PIN_DQM: Is used to always mask DRAM writes. This pin should only be used for initialization. Certain DRAM vendors require the DQM to be high during initialization. The register value should be set to NORMAL after the initialization sequence. 0 = NORMAL 1 = INACTIVE
0	POWERDOWN	PIN_CKE: Selects the level of the CKE pin. This can be used to place the DRAM in power down state. PIN_CKE value is applied all CKE pins. 0 = POWERDOWN 1 = NORMAL

20.11.2.8 EMC_TIMING_CONTROL_0

Triggers an Update of the Timing-Related Registers

The TIMING_CONTROL register is used by software to trigger parameter updates for timing parameter registers, RDQS/QUSE delay controls, and some DLL controls. Writing the TIMING_UPDATE field updates the active state of these registers with the programmed assembly state. The active state is updated during a safe interval determined by the EMC. If CLKCHANGE_REQ_ENABLE is enabled, the active value will automatically be updated on completion of the clock change.

> **Note:** Programming of this register does not trigger the shadow register update event immediately. To prevent shadow register programming issued after programming this register from being latched accidentally, always poll for TIMING_UPDATE_STALLED==0 after programming this register.

Boot Requirements

- Writing this register with 0x1 will trigger a timing update event, which should be used in both warm boot and cold boot sequences.

Offset: 0x28 | Read/Write: R/W | Reset: 0x0000000X (0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx)

Bit	Reset	Description
0	X	TIMING_UPDATE

20.11.2.9 EMC_RC_0

DRAM Timing Parameter

This register is shadowed: see usage note at top.

Boot Requirements

- This register should be parameterized in the BCT and written by the Boot ROM during cold boot.
- This register should be saved in the scratch registers and restored by the Boot ROM during warm boot.

Offset: 0x2c | Read/Write: R/W | Reset: 0x0000007f (0bxxxxxxxxxxxxxxxxxxxxxxxxxxx1111111)

Bit	Reset	Description
6:0	0x7f	RC: [PMC] Specifies the row cycle time. This is the minimum number of cycles between activate commands to the same bank. DDR3: max(0, ceil(tRC/tCK) - (CMD_2T_TIMING == 1 ? 2 : 1)) LPDDR2: ceil((tRASmin+tRPpb)/tCK) - 1

20.11.2.10 EMC_RFC_0

DRAM Timing Parameter

This register is shadowed: see usage note at top.

Boot Requirements

- This register should be parameterized in the BCT and written by the Boot ROM during cold boot.
- This register should be saved in the scratch registers and restored by the Boot ROM during warm boot.

Offset: 0x30 | Read/Write: R/W | Reset: 0x0000003f (0bxxxxxxxxxxxxxxxxxxxxxxxxx000111111)

Bit	Reset	Description
8:0	0x3f	RFC: [PMC] specifies the auto refresh cycle time. This is the minimum number of cycles between an auto refresh command and a subsequent auto refresh or activate command. DDR3: max(0, ceil(tRFC/tCK) - (CMD_2T_TIMING == 1 ? 2 : 1)) LPDDR2: ceil(tRFCab/tCK) - 1

20.11.2.11 EMC_RAS_0

DRAM Timing Parameter

This register is shadowed: see usage note at top.

Boot Requirements

- This register should be parameterized in the BCT and written by the Boot ROM during cold boot.
- This register should be saved in the scratch registers and restored by the Boot ROM during warm boot.

Offset: 0x34 | Read/Write: R/W | Reset: 0x0000003f (0bxxxxxxxxxxxxxxxxxxxxxxxxxxx111111)

Bit	Reset	Description
5:0	0x3f	RAS: [PMC] specifies the row active time. This is the minimum number of cycles between an activate command and a precharge command to the same bank. DDR3: max(0, ceil(tRASmin/tCK) - (CMD_2T_TIMING == 1 ? 2 : 1)) LPDDR2: max(3, ceil(tRASmin/tCK)) - 1

20.11.2.12 EMC_RP_0

DRAM Timing Parameter

This register is shadowed: see usage note at top.

Boot Requirements

- This register should be parameterized in the BCT and written by the Boot ROM during cold boot.
- This register should be saved in the scratch registers and restored by the Boot ROM during warm boot.

Offset: 0x38 | Read/Write: R/W | Reset: 0x0000003f (0bxxxxxxxxxxxxxxxxxxxxxxxxxxxx111111)

Bit	Reset	Description
5:0	0x3f	RP: [PMC] specifies the row precharge time. This is the minimum number of cycles between a precharge command and an activate command to the same bank. DDR3: max(0, ceil(tRP/tCK) - (CMD_2T_TIMING == 1 ? 2 : 1)) LPDDR2: max(3, ceil(tRP/tCK)) - 1

R2something and W2something registers are independent of burst length, and are relative to the last virtual CAS_ of a command. We start counting from the last data transfer as related to where CAS_ would be if BL = 4.

20.11.2.13 EMC_R2W_0

DRAM timing parameter

This register is shadowed: see usage note at top.

Boot requirements

- This register should be parameterized in the BCT and written by the Boot ROM during cold boot.
- This register should be saved in the scratch registers and restored by the Boot ROM during warm boot.

Offset: 0x3c | Read/Write: R/W | Reset: 0x0000001f (0bxxxxxxxxxxxxxxxxxxxxxxxxxxxx11111)

Bit	Reset	Description
4:0	0x1f	R2W: [PMC] specifies the minimum number of cycles from any read command to any write command, irrespective of bank. This parameter guarantees the read->write turn-around time on the bus. DDR3: RL - WL + 2 - (CMD_2T_TIMING == 1 ? 1 : 0) + (CTT_TERMINATION == 1 ? max(0, CTT + CTT_DURATION - RDV - 2) : (EMC2PMACRO_CFG_XM2DQS_E_STRPULL_DQS ? 1 : 0)) + (EMC2PMACRO_CFG_QUSE_MODE == ALWAYS_ON ? 1 : 0) LPDDR2: RL - WL + 1 + ceil(tDQSCKmax/tCK) + (EMC2PMACRO_CFG_XM2DQS_E_STRPULL_DQS ? 1 : 0) + (EMC2PMACRO_CFG_QUSE_MODE == ALWAYS_ON ? 1 : 0) Largest programming value is 29

20.11.2.14 EMC_W2R_0

DRAM timing parameter

This register is shadowed: see usage note at top.

Boot requirements

- This register should be parameterized in the BCT and written by the Boot ROM during cold boot.
- This register should be saved in the scratch registers and restored by the Boot ROM during warm boot.

Offset: 0x40 | Read/Write: R/W | Reset: 0x0000001f (0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxx11111)

Bit	Reset	Description
4:0	0x1f	W2R: [PMC] specifies the minimum number of cycles from a write command to a read command, irrespective of bank. DDR3 : WL + max(4, ceil(tWTR/tCK)) - (CMD_2T_TIMING == 1 ? 1 : 0) LPDDR2 : WL + 1 + ceil(tWTR/tCK) Largest programming value is 29.

20.11.2.15 EMC_R2P_0

DRAM timing parameter

This register is shadowed: see usage note at top.

Boot requirements

- This register should be parameterized in the BCT and written by the Boot ROM during cold boot.
- This register should be saved in the scratch registers and restored by the Boot ROM during warm boot.

Offset: 0x44 | Read/Write: R/W | Reset: 0x0000001f (0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxx11111)

Bit	Reset	Description
4:0	0x1f	R2P: [PMC] specifies the minimum number of cycles from a read command to a precharge command for the same bank. DDR3 : max(4, ceil(tRTP/tCK)) - (CMD_2T_TIMING == 1 ? 2 : 1) LPDDR2 : BL/2 + max(2, ceil(tRTP/tCK)) - 1 - (is-lpddr2-s2 ? 1 : 2). Here is-lpddr2-s2 is 1 if the LPDDR2 is S2, otherwise (S4) it is 0

20.11.2.16 EMC_W2P_0

DRAM timing parameter

This register is shadowed: see usage note at top.

Boot requirements

- This register should be parameterized in the BCT and written by the Boot ROM during cold boot.
- This register should be saved in the scratch registers and restored by the Boot ROM during warm boot.

Offset: 0x48 | Read/Write: R/W | Reset: 0x0000003f (0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxx111111)

Bit	Reset	Description
5:0	0x3f	W2P: [PMC] Specifies the minimum number of cycles from a write command to a precharge command for the same bank. DDR3 : WL + max(2, ceil(tWR/tCK)) - (CMD_2T_TIMING == 1 ? 1 : 0) LPDDR2: WL + max(3, TWR)

20.11.2.17 EMC_RD_RCD_0

DRAM timing parameter

This register is shadowed: see usage note at top.

Boot requirements

- This register should be parameterized in the BCT and written by the Boot ROM during cold boot.
- This register should be saved in the scratch registers and restored by the Boot ROM during warm boot.

Offset: 0x4c | Read/Write: R/W | Reset: 0x0000001f (0bxxxxxxxxxxxxxxxxxxxxxxxxxxxx011111)

Bit	Reset	Description
5:0	0x1f	RD_RCD: [PMC] Specifies the RAS to CAS delay. RD_RCD is the minimum number of cycles between an activate command and a read command to the same bank. DDR3 : ceil(tRCD/tCK) - (CMD_2T_TIMING == 1 ? 2 : 1) LPDDR2: max(3, ceil(tRCD/tCK)) - 1

20.11.2.18 EMC_WR_RCD_0

DRAM timing parameter

This register is shadowed: see usage note at top.

Boot requirements

- This register should be parameterized in the BCT and written by the Boot ROM during cold boot.
- This register should be saved in the scratch registers and restored by the Boot ROM during warm boot.

Offset: 0x50 | Read/Write: R/W | Reset: 0x0000001f (0bxxxxxxxxxxxxxxxxxxxxxxxxxxxx011111)

Bit	Reset	Description
5:0	0x1f	WR_RCD: [PMC] Minimum number of cycles between an activate command and a write command to the same bank. DDR3 : ceil(tRCD/tCK) - (CMD_2T_TIMING == 1 ? 2 : 1) LPDDR2: max(3, ceil(tRCD/tCK)) - 1

20.11.2.19 EMC_RRD_0

DRAM timing parameter

This register is shadowed: see usage note at top.

Boot requirements

- This register should be parameterized in the BCT and written by the Boot ROM during cold boot.
- This register should be saved in the scratch registers and restored by the Boot ROM during warm boot.

Offset: 0x54 | Read/Write: R/W | Reset: 0x0000000f (0bxxxxxxxxxxxxxxxxxxxxxxxxxxxx1111)

Bit	Reset	Description
3:0	0xf	RRD: [PMC] specifies the Bank X Act to Bank Y Act command delay. DDR3 : max(4, ceil(tRRD/tCK)) - (CMD_2T_TIMING == 1 ? 2 : 1) LPDDR2: max(2, ceil(tRRD/tCK)) - 1

20.11.2.20 EMC_REXT_0

DRAM timing parameter

This register is shadowed: see usage note at top.

Boot requirements

- This register should be parameterized in the BCT and written by the Boot ROM during cold boot.
- This register should be saved in the scratch registers and restored by the Boot ROM during warm boot.

Offset: 0x58 | Read/Write: R/W | Reset: 0x00000001 (0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx0001)

Bit	Reset	Description
3:0	0x1	REXT: [PMC] specifies the read to read delay for reads when multiple physical devices are present. DDR3: USE_PER_DEVICE_DLY_TRIM_IB == 1 ? 2 : 1 LPDDR2: ceil(3/tCK + 0.5) + USE_PER_DEVICE_DLY_TRIM_IB ? 1 : 0

20.11.2.21 EMC_WDV_0

DRAM timing parameter

This register is shadowed: see usage note at top.

Boot requirements

- This register should be parameterized in the BCT and written by the Boot ROM during cold boot.
- This register should be saved in the scratch registers and restored by the Boot ROM during warm boot.

Offset: 0x5c | Read/Write: R/W | Reset: 0x00000000 (0bxxxxxxxxxxxxxxxxxxxxxxxxxxxx0000)

Bit	Reset	Description
3:0	0x0	WDV: [PMC] the number of cycles to post (delay) write data from being asserted to the RAMs. DDR3 : WL - 1 LPDDR2 : WL 15 = MAX

20.11.2.22 EMC_QUSE_0

DRAM timing parameter

The QRST, QUSE, and RDV fields specify the delays from read to internal timing signals. These fields should be set as follows:

QUSE = CAS_LATENCY - 1 non-mobile SDRAM
= CAS_LATENCY - 2 for mobile SDRAM
QRST = CAS_LATENCY - 2
QSAFE >= RDV - QRST
RDV = CAS_LATENCY + 5
EINPUT = RDV - 7

Because SDRAM uses a tristating clock (the DQS), a method is needed to deal with the ambiguity of when DQS is tristated. Only one such method is supported: QUSE.

This register is shadowed: see usage note at top.

Boot requirements

- This register should be parameterized in the BCT and written by the Boot ROM during cold boot.
- This register should be saved in the scratch registers and restored by the Boot ROM during warm boot.

Offset: 0x60 | Read/Write: R/W | Reset: 0x00000002 (0bxxxxxxxxxxxxxxxxxxxxxxxxxxxx000010)

Bit	Reset	Description
5:0	0x2	QUSE: [PMC] Tells the chip when to look for read return data. LPDDR2/DDR3: obtained from characterization

20.11.2.23 EMC_QRST_0

DRAM timing parameter

This register is shadowed: see usage note at top.

Boot requirements

- This register should be parameterized in the BCT and written by the Boot ROM during cold boot.
- This register should be saved in the scratch registers and restored by the Boot ROM during warm boot.

Offset: 0x64 | Read/Write: R/W | Reset: 0x00000001 (0bxxxxxxxxxxxxxxxxxxxxxxxxxxx000001)

Bit	Reset	Description
5:0	0x1	QRST: [PMC] time from expiration of QSAFE until reset is issued. DDR3 : CL - 2 LPDDR2 : RL - 2

20.11.2.24 EMC_QSAFE_0

DRAM timing parameter

When PERIODIC_QRST is enabled, the QSAFE parameter is intended to guarantee that the QRSTs will not interfere with pending reads (e.g. the queue is empty). This field must be set to at least (RDV - QRST).

This register is shadowed: see usage note at top.

Boot requirements

- This register should be parameterized in the BCT and written by the Boot ROM during cold boot.
- This register should be saved in the scratch registers and restored by the Boot ROM during warm boot.

Offset: 0x68 | Read/Write: R/W | Reset: 0x00000007 (0bxxxxxxxxxxxxxxxxxxxxxxxxxxx00111)

Bit	Reset	Description
4:0	0x7	QSAFE: [PMC] Time from a read command to when it is safe to issue a QRST (delayed by the QRST parameter). LPDDR2/DDR3 QSAFE >= RDV - QRST

20.11.2.25 EMC_RDV_0

DRAM timing parameter

RDV is the read latency register. This register value is not negotiable; it will work with the right value and will not with the wrong value. It uses sequential timing, not combinational (i.e., maybe the silicon is fast enough type) timing.

This register is shadowed: see usage note at top.

Boot requirements

- This register should be parameterized in the BCT and written by the Boot ROM during cold boot.
- This register should be saved in the scratch registers and restored by the Boot ROM during warm boot.

Offset: 0x6c | Read/Write: R/W | Reset: 0x00000008 (0bxxxxxxxxxxxxxxxxxxxxxxxxxxxx001000)

Bit	Reset	Description
5:0	0x8	RDV: [PMC] Time from read command to latching the read data from the pad macros. DDR3 : RL + 6 + f_ceil(fly-by-time/tCK) - (DRAM-DLL-is-off ? 1 : 0) LPDDR2: RL + 6 + ceil((tDQSCKmax + fly-by-time)/tCK) fly-by-time is board routing dependent, which usually should be less than 1.5ns DRAM-DLL-is-off is true below 150 MHz where DRAM DLL has to be turned off 35 = MAX

20.11.2.26 EMC_REFRESH_0

DRAM timing parameter

The value of REFRESH is calculated using the following formula:

```
{REFRESH, REFRESH_LO} = max[(tREF/#_of_rows) / (emc_clk_period) - 64,
                            (tREF/#_of_rows) / (emc_clk_period) * 97%]
```

For example, if the clock frequency is 133 MHz, and the refresh requirement is 64 ms per 4096 rows. The programming value is 0x7e3.

This register is shadowed: see usage note at top.

Boot requirements

- This register should be parameterized in the BCT and written by the Boot ROM during cold boot.
- This register should be saved in the scratch registers and restored by the Boot ROM during warm boot.

Offset: 0x70 | Read/Write: R/W | Reset: 0x0000001f (0bxxxxxxxxxxxxxxxx0000000000011111)

Bit	Reset	Description
15:6	0x0	REFRESH: [PMC] specifies the interval between refresh requests.
5:0	0x1f	REFRESH_LO: [PMC]

20.11.2.27 EMC_BURST_REFRESH_NUM_0

DRAM timing parameter

BURST_REFRESH_NUM is used to specify the refresh burst count. The refresh controller will wait until BURST_REFRESH_NUM refreshes have been scheduled, then issue them all at once. This can result in a performance improvement in many cases.

Note: If tRAS(max) is less than the refresh interval (tREF/#_of_rows), tRAS(max) must be used instead of the refresh interval in the formula above. This is because refresh is used to satisfy tRAS(max) timing. Accordingly, BURST_REFRESH_NUM must be programmed in such a way that queuing up multiple refreshes does not violate tRAS(max) timing. Burst length = 2^BURST_REFRESH_NUM. Refreshes will be throttled to meet TREFBW limitation (8/window) if TREFBW > 0.

Note: Do not program this register to value non-zero unless for testing.

This register is shadowed: see usage note at top.

Boot requirements

- This register should be parameterized in the BCT and written by the Boot ROM during cold boot.
- This register should be saved in the scratch registers and restored by the Boot ROM during warm boot.

Offset: 0x74 | Read/Write: R/W | Reset: 0x00000000 (0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx0000)

Bit	Reset	Description
3:0	BR1	BURST_REFRESH_NUM: [PMC] Specify the refresh burst count. 0 = BR1 1 = BR2 2 = BR4 3 = BR8 4 = BR16 5 = BR32 6 = BR64 7 = BR128 8 = BR256 9 = BR512 9 = MAX

20.11.2.28 EMC_PDEX2WR_0

DRAM timing parameter

This register is shadowed: see usage note at top.

Boot requirements

- This register should be parameterized in the BCT and written by the Boot ROM during cold boot.
- This register should be saved in the scratch registers and restored by the Boot ROM during warm boot.

Offset: 0x78 | Read/Write: R/W | Reset: 0x0000003e (0bxxxxxxxxxxxxxxxxxxxxxxxxxxxx111110)

Bit	Reset	Description
5:0	0x3e	PDEX2WR: Specify the timing delay from exit of powerdown mode to a write command. DDR3 : max(3, ceil(tXP/tCK)) - (CMD_2T_TIMING == 1 ? 2 : 1) LPDDR2 : ceil(tXP/tCK) - 1 Note: on DDR3, if slow power down exit mode is used and ODT is enabled, use max(10, ceil(tXPDLL/tCK)) instead of max(3, ceil(tXP/tCK)) in the formula Largest allowed value is 62

20.11.2.29 EMC_PDEX2RD_0

DRAM timing parameter

This register is shadowed: see usage note at top.

Boot requirements

- This register should be parameterized in the BCT and written by the Boot ROM during cold boot.
- This register should be saved in the scratch registers and restored by the Boot ROM during warm boot.

Offset: 0x7c | Read/Write: R/W | Reset: 0x0000003e (0bxxxxxxxxxxxxxxxxxxxxxxxxxxxx111110)

Bit	Reset	Description
5:0	0x3e	PDEX2RD: Specify the timing delay from exit of powerdown mode to a read command. DDR3 : (use-slow-pd-exit-mode ? max(10, ceil(tXPDLL/tCK)) : max(3, ceil(tXP/tCK))) - (CMD_2T_TIMING == 1 ? 2 : 1) LPDDR2 : ceil(tXP/tCK) - 1 use-slow-pd-exit-mode is 1 if slow power down exit mode is used (MR0 bit 12 is 0). Largest allowed value is 62

20.11.2.30 EMC_PCHG2PDEN_0

DRAM timing parameter

This register is shadowed: see usage note at top.

Boot requirements

- This register should be parameterized in the BCT and written by the Boot ROM during cold boot.
- This register should be saved in the scratch registers and restored by the Boot ROM during warm boot.

Offset: 0x80 | Read/Write: R/W | Reset: 0x0000001f (0bxxxxxxxxxxxxxxxxxxxxxxxxxxx011111)

Bit	Reset	Description
5:0	0x1f	PCHG2PDEN: [PMC] Specify the timing delay from a precharge command to powerdown entry. DDR3 : 1 LPDDR2 : f_ceil(tRP]/tCK) - (CMD_2T_TIMING == 1 ? 1 : 0)

20.11.2.31 EMC_ACT2PDEN_0

[PMC] DRAM timing parameter

This register is shadowed: see usage note at top.

Boot requirements

- This register should be parameterized in the BCT and written by the Boot ROM during cold boot.
- This register should be saved in the scratch registers and restored by the Boot ROM during warm boot.

Offset: 0x84 | Read/Write: R/W | Reset: 0x0000001f (0bxxxxxxxxxxxxxxxxxxxxxxxxxxx011111)

Bit	Reset	Description
5:0	0x1f	ACT2PDEN: Specify the timing delay from an activate, MRS or EMRS command to power-down entry. DDR3/LPDDR2: 0

20.11.2.32 EMC_AR2PDEN_0

DRAM timing parameter

This register is shadowed: see usage note at top.

Boot requirements

- This register should be parameterized in the BCT and written by the Boot ROM during cold boot.
- This register should be saved in the scratch registers and restored by the Boot ROM during warm boot.

Offset: 0x88 | Read/Write: R/W | Reset: 0x0000001f (0bxxxxxxxxxxxxxxxxxxxxxxxxx000011111)

Bit	Reset	Description
8:0	0x1f	AR2PDEN: [PMC] Specify the timing delay from an autorefresh command to powerdown entry. DDR3 : max(7, ceil((tXPDLL - tXP)/tCK)) LPDDR2 : 1

20.11.2.33 EMC_RW2PDEN_0

DRAM timing parameter

This register is shadowed: see usage note at top.

Boot requirements

- This register should be parameterized in the BCT and written by the Boot ROM during cold boot.
- This register should be saved in the scratch registers and restored by the Boot ROM during warm boot.

Offset: 0x8c | Read/Write: R/W | Reset: 0x0000001f (0bxxxxxxxxxxxxxxxxxxxxxxxxxxxx011111)

Bit	Reset	Description
5:0	0x1f	RW2PDEN: [PMC] Specify the timing delay from a read/write command to powerdown entry. Auto-precharge timing must be taken into account when programming this field DDR3: max(RL+5, WL+4+TWR) - 1 LPDDR2: max(RL+BL/2+ceil((tDQSCKmax+1)/tCK)+1, WL+BL/2+1+ceil((tWR+1)/tCCK)) - 1

20.11.2.34 EMC_TXSR_0

DRAM timing parameter

This register is shadowed: see usage note at top.

Boot requirements

- This register should be parameterized in the BCT and written by the Boot ROM during cold boot.
- This register should be saved in the scratch registers and restored by the Boot ROM during warm boot.

Offset: 0x90 | Read/Write: R/W | Reset: 0x000003fe (0bxxxxxxxxxxxxxxxxxxxxxxxx1111111110)

Bit	Reset	Description
9:0	0x3fe	TXSR: [PMC] Cycles between self-refresh exit & first DRAM command that does not require a locked DLL. Largest allowed value is 0x3fe DDR3: max(5, ceil(tXSR/tCK)) LPDDR2: max(2, ceil(tXSR/tCK))

20.11.2.35 EMC_TCKE_0

DRAM timing parameter

This register is shadowed: see usage note at top.

Boot requirements

- This register should be parameterized in the BCT and written by the Boot ROM during cold boot.
- This register should be saved in the scratch registers and restored by the Boot ROM during warm boot.

Offset: 0x94 | Read/Write: R/W | Reset: 0x0000003e (0bxxxxxxxxxxxxxxxxxxxxxxxxxxxx111110)

Bit	Reset	Description
5:0	0x3e	TCKE: Specify the minimum CKE high pulse width. DDR3: Use-slow-pd-exit-mode ? max(10, ceil(max(tCKESR, uXPDLL)/tCK)) : max(4, ceil(max(tXP,tXP)/tCK)) LPDDR2: max(3, tCKE, ceil(tXP/tCK)) use-slow-pd-exit-mode is 1 if slow power down exit mode is used (MR0 bit 12 is 0

20.11.2.36 EMC_TFAW_0

DRAM timing parameter

This register is shadowed: see usage note at top.

Boot requirements

- This register should be parameterized in the BCT and written by the Boot ROM during cold boot.
- This register should be saved in the scratch registers and restored by the Boot ROM during warm boot.

Offset: 0x98 | Read/Write: R/W | Reset: 0x00000000 (0bxxxxxxxxxxxxxxxxxxxxxxxxxxx0000000)

Bit	Reset	Description
6:0	0x0	TFAW: [PMC] specify the width of the FAW (four-activate window) for 8-bank devices. Set to 0 to disable this timing check. Only 4 activates may occur within the rolling window. . DDR3/LPDDR2: ceil(tFAW/tCK)

20.11.2.37 EMC_TRPAB_0

DRAM timing parameter

This register is shadowed: see usage note at top.

Boot requirements

- This register should be parameterized in the BCT and written by the Boot ROM during cold boot.
- This register should be saved in the scratch registers and restored by the Boot ROM during warm boot.

Offset: 0x9c | Read/Write: R/W | Reset: 0x00000000 (0bxxxxxxxxxxxxxxxxxxxxxxxxxxx000000)

Bit	Reset	Description
5:0	0x0	TRPAB: [PMC] Specify precharge-all tRP allowance for 8-bank devices. Setting this field to 0 will cause EMC to use TRP.TRP for precharge-all. DDR3 : ceil(tRP/tCK) + 1 LPDDR2: max(3, ceil((tRPpb+3)/tCK

20.11.2.38 EMC_TCLKSTABLE_0

DRAM timing parameter

This register is shadowed: see usage note at top.

Boot requirements

- This register should be parameterized in the BCT and written by the Boot ROM during cold boot.
- This register should be saved in the scratch registers and restored by the Boot ROM during warm boot.

Offset: 0xa0 | Read/Write: R/W | Reset: 0x0000000f (0bxxxxxxxxxxxxxxxxxxxxxxxxxxx01111)

Bit	Reset	Description
4:0	0xf	TCLKSTABLE: [PMC] Specify minimum number of cycles of a stable clock period prior to exiting powerdown or self-refresh modes. DDR3 : max(5, ceil(tCKSRX/tCK)) - 1 LPDDR2: 2

20.11.2.39 EMC_TCLKSTOP_0

DRAM timing parameter

This register is shadowed: see usage note at top.

Boot requirements

- This register should be parameterized in the BCT and written by the Boot ROM during cold boot.
- This register should be saved in the scratch registers and restored by the Boot ROM during warm boot.

Offset: 0xa4 | Read/Write: R/W | Reset: 0x0000000f (0bxxxxxxxxxxxxxxxxxxxxxxxxxxx01111)

Bit	Reset	Description
4:0	0xf	TCLKSTOP: [PMC] Delay from last command to stopping the external clock to DRAM devices.

Bit	Reset	Description
		DDR3: max(5, ceil(tCKSRE/tCK)) - 1 LPDDR2: 2

20.11.2.40 EMC_TREFBW_0

DRAM timing parameter

This register is shadowed: see usage note at top.

Boot requirements

- This register should be parameterized in the BCT and written by the Boot ROM during cold boot.
- This register should be saved in the scratch registers and restored by the Boot ROM during warm boot.

Offset: 0xa8 | Read/Write: R/W | Reset: 0x00000000 (0bxxxxxxxxxxxxxxxxxx00000000000000)

Bit	Reset	Description
13:0	0x0	TREFBW: [PMC] specify the width of the burst-refresh window. If set to a non-zero value, only 8 refreshes will occur in this rolling window. Set to 0 to disable this timing check. DDR3: ceil(tREFI/tCK) LPDDR2: ceil(tREFBW/tCK)

20.11.2.41 EMC_QUSE_EXTRA_0

QUSE_EXTRA is combined with QUSE to add extra cycles to data return window. This is for use with DQS pulldowns in LPDDR2 where start of read preamble could vary by more than 1 cycle.

Example: To extend end of QUSE window by 1 cycle, set QUSE_EXTRA = QUSE + 1. To start the QUSE window earlier by 1 cycle, set QUSE_EXTRA = QUSE - 1. Disabled if QUSE_EXTRA = 0.

QUSE_PULLED_MORE_THAN_BL: The QUSE pulse width is equal to BL and can be extended with QUSE_EXTRA. If QUSE is pulled in more than the BL, this field needs to be set to 1.

QUSE_EXTENDED_MORE_THAN_BL: If QUSE is extended by more than the BL at the end, this field needs to be set to 1.

Only one of the QUSE_PULLED_MORE_THAN_BL or QUSE_EXTENDED_MORE_THAN_BL can be set 1 at any time because the QUSE window can be either pulled in or extended for any setting.

By default QUSE_PULLED_MORE_THAN_BL/QUSE_EXTENDED_MORE_THAN_BL should be set to 0.

This register is shadowed: see usage note at top.

Boot requirements

- This register should be parameterized in the BCT and written by the Boot ROM during cold boot.
- This register should be saved in the scratch registers and restored by the Boot ROM during warm boot.

Offset: 0xac | Read/Write: R/W | Reset: 0x00000000 (0bxxxxxxxxxxxxxxxxxxxxxxxx00xx000000)

Bit	Reset	Description
9	0x0	QUSE_EXTENDED_MORE_THAN_BL: [PMC]
8	0x0	QUSE_PULLED_MORE_THAN_BL: [PMC]
5:0	0x0	QUSE_EXTRA: [PMC2] DDR3/LPDDR2: (EMC2TMC_CFG_XM2DQS_E_SCHMT == 1) ? (QUSE + 1) : 0

20.11.2.42 EMC_ODT_WRITE_0

For DDR3, ODT may be enabled during writes and disabled during reads via control of ODT pin.

This register is shadowed: see usage note at top.

Boot requirements

- This register should be parameterized in the BCT and written by the Boot ROM during cold boot.
- This register should be saved in the scratch registers and restored by the Boot ROM during warm boot.

Offset: 0xb0 | Read/Write: R/W | Reset: 0x00000020 (0b00xxxxxxxxxxxxxxxxxx0000xx10x000

Bit	Reset	Description
31	0x0	ENABLE_ODT_DURING_WRITE: enables ODT to be turned on prior to issuing write to DRAM. [PMC] If ENABLE_ODT_DURING_WRITE = 1 and DISABLE_ODT_DURING_READ = 0, ODT will always be enabled after 1st write.
30	0x0	ODT_B4_WRITE: [PMC] If this field == 1, ODT is turned on ODT_WR_DELAY cycles prior to DRAM WRITE command. If this field == 0, ODT is turned on ODT_WR_DELAY cycles after DRAM WRITE command. Set ODT_B4_WRITE to 1 if (WL - ceiling(tAOND) - 2) < 0. This field is not used for DDR3.
11:8	0x0	ODT_WR_DURATION: [PMC] for LPDDR3, indicate how long to assert ODT by.
5	0x1	SHARE_ONE_ODT: [PMC] For LPDDR3 only. When enabled, ODT[1] is not used. The ODT for both ranks will be sharing the same ODT[0]. When disabled, ODT[0] is controlling rank0, ODT[1] is controlling rank1.
4	0x0	DRIVE_BOTH_ODT: [PMC] If this field = 0, only the ODT for the requested device will be asserted during write. If this field = 1, ODTs for both devices will be asserted during write.
2:0	0x0	ODT_WR_DELAY: [PMC] Set this field = ABS (WL - ceiling(tAOND) - 2). The valid programming range is 0 <= ODT_WR_DELAY <= 2, if ODT_B4_WRITE=0, 0 <= ODT_WR_DELAY <= 1, if ODT_B4_WRITE=1. For DDR3, this field = (WL - 3). For LPDDR3, this field = (WL - 2).

20.11.2.43 EMC_ODT_READ_0

This register is not used. Please keep it in reset value.

This register is shadowed: see usage note at top.

Boot requirements

- This register should be parameterized in the BCT and written by the Boot ROM during cold boot.
- This register should be saved in the scratch registers and restored by the Boot ROM during warm boot.

Offset: 0xb4 | Read/Write: R/W | Reset: 0x00000000 (0b00xxxxxxxxxxxxxxxxxxxxxxxxxxxx000)

Bit	Reset	Description
31	0x0	DISABLE_ODT_DURING_READ: enables ODT to be turned off prior to issuing read to DRAM. If this field == 0, ODT state will not be changed for reads. If this field == 1, Turn off ODT prior to READ command (has no effect if ODT ENABLE_ODT_DURING_WRITE == 0, as ODT will always be disabled). This field is not used for DDR3.
30	0x0	ODT_B4_READ: If this field == 1, ODT is turned off ODT_RD_DELAY cycles prior to DRAM READ command. If this field == 0, ODT is turned off ODT_RD_DELAY cycles after DRAM READ command. Set ODT_B4_READ to 1 if (RL - ceiling(tAOFD) - 2) < 0. This field is not used for DDR3.
2:0	0x0	ODT_RD_DELAY: Set this field = ABS (RL - ceiling(tAOFD) - 2). The valid programming range is 0 <= ODT_RD_DELAY <= 2 if ODT_B4_READ=0, 0 <= ODT_RD_DELAY <= 1 if ODT_B4_READ=1 This field is not used for DDR3.

20.11.2.44 EMC_WEXT_0

DRAM timing parameter

This register is shadowed: see usage note at top.

Boot requirements

- This register should be parameterized in the BCT and written by the Boot ROM during cold boot.
- This register should be saved in the scratch registers and restored by the Boot ROM during warm boot.

Offset: 0xb8 | Read/Write: R/W | Reset: 0x00000000 (0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx0000)

Bit	Reset	Description
3:0	0x0	WEXT: [PMC] specifies the write to write delay for writes when multiple physical devices are present. DDR3: max(0, (USE_PER_DEVICE_DLY_TRIM_OB == 1 ? 5 : 0) - (CMD_2T_TIMING == 1 ? 1 : 0)) LPDDR2: USE_PER_DEVICE_DLY_TRIM_OB == 1 ? 5 : 0

20.11.2.45 EMC_CTT_0

DRAM timing parameter

CTT controls timing of internal read terminations. Based on read latency (CTT must frame read data). Adding non-RDV linked timing control for flexibility. Has no effect unless CTT_TERMINATION == ENABLED || E_PUTERM_DQ == ENABLED It is sequential timing, not combinational (i.e., maybe the silicon is fast enough type) timing.

This register is shadowed: see usage note at top.

Boot requirements

- This register should be parameterized in the BCT and written by the Boot ROM during cold boot.

Offset: 0xbc | Read/Write: R/W | Reset: 0x00000008 (0bxxxxxxxxxxxxxxxxxxxxxxxxxx001000)

Bit	Reset	Description
5:0	0x8	CTT: [PMC] time from read command to CTT turn-on on DDR3 ? (CTT_TERMINATION == 1) ? CL + 7 : 0 LPDDR2: 0 35 = MAX

20.11.2.46 EMC_RFC_SLR_0

DRAM timing parameter

This register is shadowed: see usage note at top.

Boot requirements

- This register should be parameterized in the BCT and written by the Boot ROM during cold boot.
- This register should be saved in the scratch registers and restored by the Boot ROM during warm boot.

Offset: 0xc0 | Read/Write: R/W | Reset: 0x00000000 (0bxxxxxxxxxxxxxxxxxxxxxxxx000000000)

Bit	Reset	Description
8:0	0x0	RFC_SLR: [PMC] Specifies the stagger refresh cycle time between ranks. This is the minimum number of cycles between an auto refresh command to one rank and a subsequent auto refresh to another rank. A zero value indicates stagger refresh is disabled.

20.11.2.47 EMC_MRS_WAIT_CNT2_0

This register allows the delay between an MRS/EMRS/MRW/MRR command and the following DRAM command

Boot Requirements

- This register should be parameterized in the BCT and written by the Boot ROM during cold boot.

Offset: 0xc4 | Read/Write: R/W | Reset: 0x0208000f (0bxxxxxx1000001000xxxxxx0000001111) | Default: 0x03ff03ff

Bit	Reset	SW Default	Description
25:16	0x208	0x3ff	MRS_EXT2_WAIT_CNT: [PMC] Number of EMC clocks to wait before issuing any commands after sending an MRS ext2 command.
9:0	0xf	0x3ff	MRS_EXT1_WAIT_CNT: [PMC] Number of EMC clocks to wait before issuing any commands after sending an MRS ext1 command.

20.11.2.48 EMC_MRS_WAIT_CNT_0

This register allows the delay between an MRS/EMRS/MRW/MRR command and the following DRAM command.

Boot Requirements

- This register should be parameterized in the BCT and written by the Boot ROM during cold boot.

Offset: 0xc8 | Read/Write: R/W | Reset: 0x0208000f (0bxxxxxx1000001000xxxxxx0000001111)

Bit	Reset	SW Default	Description
25:16	0x208	0x3ff	MRS_LONG_WAIT_CNT: [PMC] Number of EMC clocks to wait before issuing any commands after sending an MRS long command.
9:0	0xf	0x3ff	MRS_SHORT_WAIT_CNT: [PMC] Number of EMC clocks to wait before issuing any commands after sending an MRS short command.

20.11.2.49 EMC_MRS_0

Command Trigger: MRS

The MRS register allows software to issue an MRS command.

BA0, BA1 are used to address MRS or EMRS registers in DRAM. Although this register can also program EMRS, use the EMRS register so that the hardware registers can shadow what is in the DRAM.

Boot requirements

- This register should be parameterized in the BCT and written by the Boot ROM during cold boot.

Offset: 0xcc | Read/Write: R/W | Reset: 0x00000000 (0b00xx00xxxx00xxxxxx00000000000000)

Bit	Reset	Description
31:30	0x0	MRS_DEV_SELECTN: [PMC] Active low chip-select, 0x0 applies command to both devices, 0x2 to for only dev0, 0x1 for only dev1.
27	0x0	USE_MRS_EXT_CNT: [PMC] 0 =USE_MRS_LONG_CNT will select between SHORT(0)/LONG(1), 1=USE_MRS_LONG_CNT will select between EXT1(0)/EXT2(1).
26	SHORT	USE_MRS_LONG_CNT: [PMC] Indicate to use long or short MRS wait count. 0 = SHORT 1 = LONG
21:20	0x0	MRS_BA: [PMC] Set to 0x0 for MRS.
13:0	0x0	MRS_ADR: [PMC] Mode-register data to be written.

20.11.2.50 EMC_EMRS_0

Command trigger: EMRS

The EMRS register allows software to issue an EMRS command.

Boot requirements

- This register should be parameterized in the BCT and written by the Boot ROM during cold boot.

Offset: 0xd0 | Read/Write: R/W | Reset: 0x00000000 (0b00xxx0xxxx00xxxxxx00000000000000)

Bit	Reset	Description
31:30	0x0	EMRS_DEV_SELECTN: [PMC] Active low chip-select, 0x0 applies command to both devices, 0x2 to for only dev0, 0x1 for only dev1.
27	0x0	USE_EMRS_EXT_CNT: [PMC] 0 = USE_MRS_LONG_CNT will select between SHORT(0)/LONG(1), 1 = USE_MRS_LONG_CNT will select between EXT1(0)/EXT2(1).
26	SHORT	USE_EMRS_LONG_CNT: [PMC] Indicate to use long or short MRS wait count. 0 = SHORT 1 = LONG
21:20	0x0	EMRS_BA: [PMC] Set to 0x1 for EMRS (and where applicable, 0x2 for EMRS2, and 0x3 for EMRS3).
13:0	0x0	EMRS_ADR: [PMC] Mode-register data to be written.

20.11.2.51 EMC_REF_0

Command Trigger: Refresh

Note: The REF register allows software to issue refresh commands. This is done to ensure proper DRAM initialization.
REF_NUM number of refreshes are issued to both devices regardless of the REF_DEV_SELECTN setting.

Boot requirements

- This register triggers a refresh command. REF_CMD should be written with 0x1 during cold boot to trigger refresh commands during DRAM initialization.

Offset: 0xd4 | Read/Write: R/W | Reset: 0x00000000 (0b00xxxxxxxxxxxxxx00000000xxxxxx00)

Bit	Reset	Description
31:30	0x0	REF_DEV_SELECTN: active low chip-select, 0x0 applies command to both devices, 0x2 to for only dev0, 0x1 for only dev1.
15:8	0x0	REF_NUM: perform (REF_NUM + 1) refresh cycles.
1	0x0	REF_NORMAL: 0 = execute first refresh immediately (this is use during DRAM initialization). 1 = execute refresh through normal refresh mechanism (this should be used in normal operation).
0	0x0	REF_CMD: causes the hardware to perform a REFRESH to all DRAM banks.

20.11.2.52 EMC_PRE_0

Command Trigger: Precharge-All

The PRE register allows software to issue a precharge all command. This command may be used to ensure proper DRAM initialization.

Boot requirements

- This register triggers a precharge-all command. PRE_CMD should be written with 0x1 during cold boot to trigger refresh commands during DRAM initialization.
- If per-device DPD is used, the PRE_DEV_SELECTN field should be parameterized in the BCT and written by the Boot ROM during cold boot.

Offset: 0xd8 | Read/Write: R/W | Reset: 0x00000000 (0b00xxxxxxxxxxxxxxxxxxxxxxxxxxxxxx0)

Bit	Reset	Description
31:30	0x0	PRE_DEV_SELECTN: active low chip-select, 0x0 applies command to both devices, 0x2 to for only dev0, 0x1 for only dev1.
0	0x0	PRE_CMD: causes the hardware to perform a PRECHARGE to all DRAM banks.

20.11.2.53 EMC_NOP_0

Command Trigger: NOP

The NOP register allows software to issue an explicit NOP command. This command may be used to ensure proper DRAM initialization.

Boot requirements

- This register triggers a no-operation command. NOP_CMD should be written with 0x1 during cold boot to trigger no-op commands during DRAM initialization.

Offset: 0xdc | Read/Write: R/W | Reset: 0b00xxxxxxxxxxxxxxxxxxxxxxxxxxxxx0

Bit	Reset	Description
31:30	0x0	NOP_DEV_SELECTN: active low chip-select, 0x0 applies command to both devices, 0x2 to for only dev0, 0x1 for only dev1.
0	0x0	NOP_CMD: causes the hardware to perform a NOP to all DRAM banks.

20.11.2.54 EMC_SELF_REF_0

Command Trigger: SELF REFRESH

The SELF_REF register allows software to issue self-refresh commands.

Do not program this register when a clock change sequence is on-going. Check the CLKCHANGE_COMPLETE_INT value if not sure.

Offset: 0xe0 | Read/Write: R/W | Reset: 0x00000000 (0b00xxxxxxxxxxxxxxxxxxxxxxxxxxxxxx0)

Bit	Reset	Description
31:30	0x0	SREF_DEV_SELECTN: active low chip-select, 0x0 applies command to both devices, 0x2 to for only dev0, 0x1 for only dev1, 0x3 for neither device.

Bit	Reset	Description
0	DISABLED	SELF_REF_CMD: causes the hardware to issue a SELF_REFRESH command. While CMD:ENABLED, the CKE pin is held deasserted. The CMD:ENABLED state will override the PIN:CKE setting. The DRAM will ignore all accesses until CMD:DISABLED. 0 = DISABLED 1 = ENABLED

20.11.2.55 EMC_DPD_0

Command Trigger: Deep Power Down

The DPD register allows software to issue a deep power down command.

Offset: 0xe4 | Read/Write: R/W | Reset: 0x00000000 (0b00xxxxxxxxxxxxxxxxxxxxxxxxxxxxxx0)

Bit	Reset	Description
31:30	0x0	DPD_DEV_SELECTN: active low chip-select, 0x0 applies command to both devices, 0x2 to for only dev0, 0x1 for only dev1.
0	DISABLED	DPD_CMD: causes the hardware to issue the deep power down command (Burst Terminate with cke low). While in DPD mode, the DRAM will not maintain data integrity. While CMD:ENABLED, the CKE pin is held deasserted. The CMD:ENABLED state will override the PIN:CKE setting. The DRAM will ignore all accesses until CMD:DISABLED. 0 = DISABLED 1 = ENABLED

20.11.2.56 EMC_MRW_0

Command Trigger: MRW

Mode Register Write: LPDDR2-only version of MRS/EMRS

Boot requirements

- This register triggers a mode register write command. Multiple mode-register writes may be required by the cold boot sequence. Such commands should be parameterized in the BCT and written by the Boot ROM during cold boot.

Offset: 0xe8 | Read/Write: R/W | Reset: 0x00000000 (0b00xx00xx00000000xxxxxxxx00000000

Bit	Reset	Description
31:30	0x0	MRW_DEV_SELECTN: [PMC] Active-low chip-select, 0x0 applies command to both devices, 0x2 to for only dev0, 0x1 for dev1.
27	0x0	USE_MRW_EXT_CNT: [PMC] 0 = USE_MRS_LONG_CNT will select between SHORT(0)/LONG(1), 1 = USE_MRS_LONG_CNT will select between EXT1(0)/EXT2(1).
26	SHORT	USE_MRW_LONG_CNT: [PMC] Indicate to use long or short MRS wait count.
23:16	0x0	MRW_MA: [PMC] Register address
7:0	0x0	MRW_OP: [PMC] Data to be written

20.11.2.57 EMC_MRR_0

Command Trigger: MRR

Mode Register Read: LPDDR2 only

Sequence

1. Read MRR until EMC_STATUS.MRR_DIVLD=0 (ok to skip if it is sure there are no pending MRR reads)

2. Write this register with the desired addr (MA) and device (DEV_SELECTN), device needs to be either DEV0 or DEV1: writing to both is illegal

3. Poll EMC_STATUS.MRR_DIVLD=1, or if using interrupt, wait for MRR_DIVLD_INT

4. Read back MRR. The value is in MRR_DATA field.

Note: It is okay to issue new MRR requests while there are on-going requests. e.g., to issue 3 MRR requests, follow these steps: 1,2,2,2,3,4,3,4,3,4. Data read back in step 4 is in the same order requested in step 2.

To make sure the EMC is available for new MRR requests, poll for EMC_STATUS.MRR_FIFO_SPACE > 0 before step 2.

If using 2 x16 DRAM, MRR_DATA[15:8] can be used to store MRR from 2nd DRAM on same CS (configured via CFG_2.MRR_BYTESEL_X16)

Offset: 0xec | Read/Write: R/W | Reset: 0x0000XXXX (0b00xx00xx00000000xxxxxxxxxxxxxxxx)

20.11.2.59 EMC_FBIO_CFG5_0

FBIO Configuration Register

The trimmer value may be overridden by setting using MULT==0 and OFFS = value << 4

The FBIO_CFG5 register controls the FBIO I/O cells.

The following fields are shadowed: DIFFERENTIAL_DQS, CTT_TERMINATION, DQS_PULLD, CMD_2T_TIMING.

Writes to these fields will not take effect until the active value is updated via TIMING_UPDATE or (if enabled) CLKCHANGE_REQ.

Boot requirements

- This register (except for field DISABLE_CONCURRENT_AUTOPRE) should be parameterized in the BCT and written by the Boot ROM during cold boot.
- This register (except for field DISABLE_CONCURRENT_AUTOPRE) should be saved in the scratch registers and restored by the Boot ROM during warm boot.

Offset: 0x104 | Read/Write: R/W | Reset: 0x0000a801 (0bxxxxxxxxxxxxxxxx01010100000xx0001)

Bit	Reset	Description

Bit	Reset	Description
7	DISABLED	DIFFERENTIAL_DQS: [PMC] Enables differential signaling on DQS strobes (LPDDR2/DDR2 options) 0 = DISABLED 1 = ENABLED
6	DISABLED	CFG_E_PUTERM_DQ: [PMC] Enables E_PUTERM_DQ mode in pads (DDR3 support). In the IOBRICK, the E_PUTERM_DQ mode overrides CTT_TERMINATION mode. 0 = DISABLED 1 = ENABLED
3:2	BURST4	DRAM_BURST: [PMC] Specifies the burst length to use for the attached device(s). ON_THE_FLY BC4/BL8 is only use for DDR3. 0 = BURST4 1 = BURST8 2 = ON_THE_FLY 3 = RESERVED
1:0	DDR1	DRAM_TYPE: [PMC] Specifies which DRAM protocol to use for the attached device(s). 0 = DDR3 1 = DDR1 2 = LPDDR2 3 = DDR2

20.11.2.60 EMC_FBIO_CFG6_0

FBIO Configuration Register

QUSE_LATE determines how much added delay FBIO should add to the QUSE path. QUSE needs to align (approximately) with the incoming DQS in order to qualify it, since the incoming DQS/feedback clock is not always valid.

DRAMC can position QUSE with m2clk granularity (2 bit times). QUSE_LATE provides finer granularity of 1/2 an M2CLK cycle (1/2 bit time). The amount of delay added is primarily a function of the round trip wire delay to/from the DRAM. Other portions of the delay (driver and receiver delay) are compensated for by delay through a non-bonded QUSE pad cell.

Additional delay can be added to QUSE vi XFORM_QUSEx_MULT and XFORM_QUSEx_OFFS (applied to DLL offset).

Boot requirements

- This register should be parameterized in the BCT and written by the Boot ROM during cold boot.
- This register should be saved in the scratch registers and restored by the Boot ROM during warm boot.

Offset: 0x114 | Read/Write: R/W | Reset: 0x00000002 (0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx010)

Bit	Reset	Description
2:0	0x2	CFG_QUSE_LATE: [PMC]

20.11.2.61 EMC_ACPD_CONTROL_0

Threshold for ACPD

Offset: 0x124 | Read/Write: R/W | Reset: 0x00000000 (0bxxxxxxxxxxxxxxxx0000000000000000)

Bit	Reset	Description
15:0	0x0	ACPD_THRESHOLD: [PMC] number of idle cycles to wait before allowing power-down entry

20.11.2.62 EMC_EMRS2_0

Command Trigger: EMRS2

The EMRS2 register allows software to issue an EMRS2 command.

Boot requirements

- This register should be parameterized in the BCT and written by the Boot ROM during cold boot.

Offset: 0x12c | Read/Write: R/W | Reset: 0x00000000 (0b00xx00xxxx00xxxxxx00000000000000)

Bit	Reset	Description
31:30	0x0	EMRS2_DEV_SELECTN: [PMC] active low chip-select, 0x0 applies command to both devices, 0x2 to for only dev0, 0x1 for only dev1.
27	0x0	USE_EMRS2_EXT_CNT: [PMC] 0=>USE_MRS_LONG_CNT will select between SHORT(0)/LONG(1), 1=>USE_MRS_LONG_CNT will select between EXT1(0)/EXT2(1).
26	SHORT	USE_EMRS2_LONG_CNT: [PMC] Indicate to use long or short MRS wait count. 0 = SHORT 1 = LONG
21:20	0x0	EMRS2_BA: [PMC] Set to 0x1 for EMRS (and where applicable, 0x2 for EMRS2, and 0x3 for EMRS3).
13:0	0x0	EMRS2_ADR: [PMC] mode-register data to be written.

20.11.2.63 EMC_EMRS3_0

Command Trigger: EMRS2

The EMRS3 register allows software to issue an EMRS3 command.

Boot requirements

- This register should be parameterized in the BCT and written by the Boot ROM during cold boot.

Offset: 0x130 | Read/Write: R/W | Reset: 0x00000000 (0b00xx00xxxx00xxxxxx00000000000000)

Bit	Reset	Description
31:30	0x0	EMRS3_DEV_SELECTN: [PMC] active low chip-select, 0x0 applies command to both devices, 0x2 to for only dev0, 0x1 for only dev1.
27	0x0	USE_EMRS3_EXT_CNT: [PMC] 0=>USE_MRS_LONG_CNT will select between SHORT(0)/LONG(1), 1=>USE_MRS_LONG_CNT will select between EXT1(0)/EXT2(1).
26	SHORT	USE_EMRS3_LONG_CNT: [PMC] Indicate to use long or short MRS wait count. 0 = SHORT 1 = LONG
21:20	0x0	EMRS3_BA: [PMC] Set to 0x1 for EMRS (and where applicable, 0x2 for EMRS2, and 0x3 for EMRS3).
13:0	0x0	EMRS3_ADR: [PMC] mode-register data to be written.

20.11.2.64 EMC_MRW2_0

Command Trigger: MRW2

Mode Register Write: LPDDR2-only version of MRS/EMRS

Boot requirements

This register triggers a mode register write command. Multiple mode-register writes may be required by the cold boot sequence. Such commands should be parameterized in the BCT and written by the Boot ROM during cold boot.

Offset: 0x134 | Read/Write: R/W | Reset: 0x00000000 (0b00xx00xx00000000xxxxxxxx00000000)

Bit	Reset	Description
31:30	0x0	MRW2_DEV_SELECTN: [PMC] active-low chip-select, 0x0 applies command to both devices, 0x2 to for only dev0, 0x1 for dev1.
27	0x0	USE_MRW2_EXT_CNT: [PMC] 0=>USE_MRS_LONG_CNT will select between SHORT(0)/LONG(1), 1=>USE_MRS_LONG_CNT will select between EXT1(0)/EXT2(1).
26	SHORT	USE_MRW2_LONG_CNT: [PMC] Indicate to use long or short MRS wait count. 0 = SHORT 1 = LONG
23:16	0x0	MRW2_MA: [PMC] register address
7:0	0x0	MRW2_OP: [PMC] data to be written

20.11.2.65 EMC_MRW3_0

Command Trigger: MRW3

Mode Register Write: LPDDR2-only version of MRS/EMRS

Boot requirements

This register triggers a mode register write command. Multiple mode-register writes may be required by the cold boot sequence. Such commands should be parameterized in the BCT and written by the Boot ROM during cold boot.

Offset: 0x138 | Read/Write: R/W | Reset: 0x00000000 (0b00xx00xx00000000xxxxxxxx00000000)

Bit	Reset	Description
31:30	0x0	MRW3_DEV_SELECTN: [PMC] active-low chip-select, 0x0 applies command to both devices, 0x2 to for only dev0, 0x1 for dev1.
27	0x0	USE_MRW3_EXT_CNT: [PMC] 0=>USE_MRS_LONG_CNT will select between SHORT(0)/LONG(1), 1=>USE_MRS_LONG_CNT will select between EXT1(0)/EXT2(1).
26	SHORT	USE_MRW3_LONG_CNT: [PMC] Indicate to use long or short MRS wait count. 0 = SHORT 1 = LONG
23:16	0x0	MRW3_MA: [PMC] register address
7:0	0x0	MRW3_OP: [PMC] data to be written

20.11.2.66 EMC_MRW4_0

Command Trigger: MRW4

Mode Register Write: LPDDR2-only version of MRS/EMRS

Boot requirements

This register triggers a mode register write command. Multiple mode-register writes may be required by the cold boot sequence. Such commands should be parameterized in the BCT and written by the Boot ROM during cold boot.

Offset: 0x13c | Read/Write: R/W | Reset: 0x00000000 (0b00xx00xx00000000xxxxxxxx00000000)

Bit	Reset	Description
31:30	0x0	MRW4_DEV_SELECTN: [PMC] active-low chip-select, 0x0 applies command to both devices, 0x2 to for only dev0, 0x1 for dev1.
27	0x0	USE_MRW4_EXT_CNT: [PMC] 0=>USE_MRS_LONG_CNT will select between SHORT(0)/LONG(1), 1=>USE_MRS_LONG_CNT will select between EXT1(0)/EXT2(1).
26	SHORT	USE_MRW4_LONG_CNT: [PMC] Indicate to use long or short MRS wait count. 0 = SHORT 1 = LONG
23:16	0x0	MRW4_MA: [PMC] register address
7:0	0x0	MRW4_OP: [PMC] data to be written

20.11.2.67 EMC_EINPUT_0

DRAM Timing Parameter

This register is shadowed: see usage note at top.

Boot requirements

- This register should be parameterized in the BCT and written by the Boot ROM during cold boot.
- This register should be saved in the scratch registers and restored by the Boot ROM during warm boot.

Offset: 0x14c | Read/Write: R/W | Reset: 0x00000000 (0bxxxxxxxxxxxxxxxxxxxxxxxxxxxx000000)

Bit	Reset	Description
5:0	0x0	EINPUT: [PMC] specifies when to assert EINPUT for a read, should normally be the same as QUSE.

20.11.2.68 EMC_EINPUT_DURATION_0

DRAM Timing Parameter

The minimum for EINPUT_DURATION is 4.

This register is shadowed: see usage note at top.

Boot requirements

- This register should be parameterized in the BCT and written by the Boot ROM during cold boot.
- This register should be saved in the scratch registers and restored by the Boot ROM during warm boot.

Offset: 0x150 | Read/Write: R/W | Reset: 0x00000004 (0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxx100)

Bit	Reset	Description
2:0	0x4	EINPUT_DURATION: [PMC] Specifies how long the EINPUT should be asserted.

20.11.2.69 EMC_PUTERM_EXTRA_0

DRAM Timing Parameter

PUTERM_EXTRA is used only when the DIRECT_QUSE mode is enabled to enable the dynamic puterm before the QUSE window.

PUTERM_PULLED_MORE_THAN_BL: The PUTERM pulse width is equal to BL+1 and can be extended with PUTERM_EXTRA. If PUTERM is pulled in more than BL, this field needs to be set to 1.

PUTERM_EXTENDED_MORE_THAN_BL: If PUTERM is extended by more than BL at the end, this field needs to be set to 1. Only one of the PUTERM_PULLED_MORE_THAN_BL or PUTERM_EXTENDED_MORE_THAN_BL can be set to 1 at any time because the PUTERM window can be either pulled in or extended for any setting. By default PUTERM_PULLED_MORE_THAN_BL/PUTERM_EXTENDED_MORE_THAN_BL should be set to 0.

This register is shadowed: see usage note at top.

Boot requirements

- This register should be parameterized in the BCT and written by the Boot ROM during cold boot.
- This register should be saved in the scratch registers and restored by the Boot ROM during warm boot.

Offset: 0x154 | Read/Write: R/W | Reset: 0x00010000 (0bxxxxxxxxxx000001xxxxxx00xx000000)

Bit	Reset	Description
21:16	0x1	PUTERM: [PMC] tells the chip when to assert dynamic PUTERM for read return data.
9	0x0	PUTERM_EXTENDED_MORE_THAN_BL: [PMC]
8	0x0	PUTERM_PULLED_MORE_THAN_BL: [PMC]
5:0	0x0	PUTERM_EXTRA: [PMC]

20.11.2.70 EMC_TCKESR_0

DRAM Timing Parameter

This register is shadowed: see usage note at top.

Boot requirements

- This register should be parameterized in the BCT and written by the Boot ROM during cold boot.
- This register should be saved in the scratch registers and restored by the Boot ROM during warm boot.

Offset: 0x158 | Read/Write: R/W | Reset: 0x0000003e (0bxxxxxxxxxxxxxxxxxxxxxxxxxxxx111110)

Bit	Reset	Description
5:0	0x3e	TCKESR: [PMC] Specify minimum low CKE pulse width for self-refresh mode.

20.11.2.71 EMC_TPD_0

DRAM Timing Parameter

This register is shadowed: see usage note at top.

Boot requirements

- This register should be parameterized in the BCT and written by the Boot ROM during cold boot.
- This register should be saved in the scratch registers and restored by the Boot ROM during warm boot.

Offset: 0x15c | Read/Write: R/W | Reset: 0x0000003e (0bxxxxxxxxxxxxxxxxxxxxxxxxxxxx111110)

Bit	Reset	Description
5:0	0x3e	TPD: [PMC] specify minimum low CKE pulse width for power-down mode.

20.11.2.72 EMC_AUTO_CAL_CONFIG_0

Auto-Calibration Settings for EMC Pads

Boot requirements

- This register (except for AUTOCAL_SLW_OVERRIDE and AUTO_CAL_START(trigger)) should be parameterized in the BCT and written by the Boot ROM during cold boot.
- This register (except for AUTOCAL_SLW_OVERRIDE and AUTO_CAL_START(trigger)) should be saved in the scratch registers and restored by the Boot ROM during warm boot.

Offset: 0x2a4 | Read/Write: R/W | Reset: 0x00f10000 (0b00000x001111x001xxx00000xxx00000

Bit	R/W	Reset	Description
31	RO	0x0	AUTO_CAL_START: [PMC] Writing a one to this bit starts the calibration state machine. This bit must be set even if the override is set in order to latch in the override value.
30	RW	0x0	AUTO_CAL_OVERRIDE: [PMC] 0 (normal operation): use AUTO_CAL_PU/PD_OFFSET as an offset to the calibration state machine setting 1 (override) : use AUTO_CAL_PU/PD_OFFSET register values directly
29	RW	DISABLED	AUTO_CAL_ENABLE: [PMC] 1 (normal operation): use EMC generated pullup/down (override or autocal) 0 (disabled): use emc2tmc_cfg* register settings for pullup/down 0 = DISABLED 1 = ENABLED
28	RW	0x0	AUTOCAL_SLW_OVERRIDE: [PMC] 0 (Normal operation) pad DRVDN/UP_SLWR/F tied to AUTO_CAL output DRDVDN/UP_SLWR/F[3:0] = AUTO_CAL_PULLDOWN/UP[4:1] 1 (override) use EMC2TMC_CFG*_DRVDN/UP_SLWR/F pins to control pad slew inputs
27	RW	0x0	AUTO_CAL_SLAVE_MODE: [PMC]. 0 master mode (used by channel connected to the comp pads). 1 slave mode (channel uses the PU/PD codes determined by the master)
25:20	RW	0xf	AUTO_CAL_E_CAL_UPDATE: [PMC] number of EMC clocks E_CAL_UPDATE is asserted
18:16	RW	0x1	AUTO_CAL_STEP: [PMC] calibration step interval (in microseconds)
12:8	RW	0x0	AUTO_CAL_PD_OFFSET: [PMC] 2's complement offset for the pull-down value
4:0	RW	0x0	AUTO_CAL_PU_OFFSET: [PMC] 2's complement offset for the DQ/DQS pull-up value

20.11.2.73 EMC_AUTO_CAL_INTERVAL_0

EMC Pad Calibration Interval

Boot requirements

- This register should be parameterized in the BCT and written by the Boot ROM during cold boot.
- This register should be saved in the scratch registers and restored by the Boot ROM during warm boot.

Offset: 0x2a8 | Read/Write: R/W | Reset: 0x00000000 (0bxxxxxxxxxxxx00000000000000000000)

Bit	Reset	Description
20:0	0x0	AUTO_CAL_INTERVAL: [PMC] 0: Calibrate once. Otherwise, auto-calibration occurs at intervals equivalent to the programmed number of microseconds.

20.11.2.74 EMC_AUTO_CAL_STATUS_0

EMC Pad Calibration Status

Offset: 0x2ac | Read/Write: RO | Reset: 0xXXXXXXXX (0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx)

Bit	Reset	Description
31	X	AUTO_CAL_ACTIVE: One when auto calibrate is active - valid only after auto calibrate sequence has completed (EMC_CAL_ACTIVE == 0)
28:24	X	AUTO_CAL_PULLDOWN_ADJ: Pull-down code sent to pads
20:16	X	AUTO_CAL_PULLUP_ADJ: Pull-up code sent to pads
12:8	X	AUTO_CAL_PULLDOWN: Pull-down code generated by auto-calibration
4:0	X	AUTO_CAL_PULLUP: Pull-up code generated by auto-calibration

20.11.2.75 EMC_REQ_CTRL_0

Request Status/Control

When either STALL_ALL_READS and/or STALL_ALL_WRITES is asserted, the stalling of read and/or write requests will not take effect until the status bit from EMC_STATUS register's NO_OUTSTANDING_TRANSACTIONS field is asserted.

Offset: 0x2b0 | Read/Write: R/W | Reset: 0x00000000 (0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx00)

Bit	Reset	Description
1	0x0	STALL_ALL_WRITES: Stall incoming write transactions
0	0x0	STALL_ALL_READS: Stall incoming read transactions

20.11.2.76 EMC_EMC_STATUS_0

EMC State-Machine Status

DRAM_IN_POWERDOWN, DRAM_IN_SELF_REFRESH, DRAM_IN_DPD: active high signal indicating current DRAM status for each of these modes, with 1 status bit per device, bit[0] = dev0 status, bit[1] = dev1 status.

Example: DRAM_IN_SELF_REFRESH = 0x3, both devices are in self-refresh, DRAM_IN_DPD= 0x2 would indicate only dev1 is in deep-power-down mode.

> **Note:** If EMC is reset or powered down, the actual DRAM state could be different than indicated by these status bits. These bits do not reflect manually entered/exited powerdown or self-refresh (via use of PIN_CKE).

Offset: 0x2b4 | Read/Write: RO | Reset: 0x0XXXXXXX (0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx

Bit	Reset	Description
27:26	X	ACPD_FSM_IDLE: Indicate dev[n] power-down FSM is idle.
25:24	X	DSR_FSM_IDLE: Indicate dev[n] dynamic self refresh FSM is idle.
23	X	TIMING_UPDATE_STALLED: Indicates timing update triggered by TIMING_CONTROL.TIMING_UPDATE is not yet completed.
22	X	ZQ_FSM_IDLE: Indicates auto ZQ state machine is idle.
21	X	CFG_ZQ_ACTIVE: Indicates ZQ configuration access is active.
20	X	MRR_DIVLD: MRR data available for reading
19:16	X	MRR_FIFO_SPACE: MRR FIFO space available

Bit	Reset	Description
13:12	X	DRAM_IN_DPD: dev[n] has been put into deep powerdown state
9:8	X	DRAM_IN_SELF_REFRESH: dev[n] has been put into self-refresh (will remain until SR exit cmd).
5:4	X	DRAM_IN_POWERDOWN: dev[n] has entered powerdown state (incoming req's will awaken if not stalled)
2	X	NO_OUTSTANDING_TRANSACTIONS: All non-stalled requests have completed
0	X	EMC_REQ_FIFO_EMPTY: Request FIFO is empty

20.11.2.77 EMC_CFG_2_0

EMC Configuration

Clock change sequencing: Once the divider is reprogrammed, CAR signals to EMC that a clock change is pending. If enabled, EMC stalls incoming requests, drains outstanding requests, and, if CLKCHANGE_(PD|SR)_ENABLE is enabled, puts DRAM into power-down (or self-refresh) before signalling to CAR that it is idle and ready for the change to happen. CAR will then change the divider/pll reprogramming. Once complete, EMC updates its shadow registers (assuming they may have been reprogrammed for new clock setting), unstalls requests, and resumes operation with new clock settings.

Boot requirements

- This register (except for fields DRAMC_PRE_B4_ACT, MRR_BYTESEL_X16, MRR_BYTESEL) should be parameterized in the BCT and written by the Boot ROM during cold boot.
- This register (except for fields DRAMC_PRE_B4_ACT, MRR_BYTESEL_X16, MRR_BYTESEL) should be saved in the scratch registers and restored by the Boot ROM during warm boot.
- If the OS needs the MRR_BYTESEL* fields set to non-default values to perform a mode-register read, it needs to correctly program these values before performing the MRR.

Offset: 0x2b8 | Read/Write: R/W | Reset: 0x00008047 (0b000000000000xx001000000001xxx111

Bit	Reset	Description
31	DISABLED	DRAMC_PRE_B4_ACT: [PMC] Reserved bit, gives priority to activates over precharges, determining which (precharge/activate) is processed first if both are pending and unblocked. 0 = DISABLED 1 = ENABLED
13	DISABLED	USE_PER_DEVICE_DLY_TRIM_OB: [PMC] Reserved bit. Allows using different outbound delay trim values per device. When enabled, WDV must be programmed to >= 2 and WEXT >=5. 0 = DISABLED 1 = ENABLED
12	DISABLED	USE_PER_DEVICE_DLY_TRIM_IB: [PMC] Reserved bit. Allows using different inbound delay trim values per device. When enabled, REXT/RDV/QUSE must be programmed to >= 2. 0 = DISABLED 1 = ENABLED
11	0x0	DIS_CNTR_WITH_CFG_TIMING_UPDATE: [PMC] Reserved bit. 1 = Disable reset of timing parameter counters with TIMING_CONTROL.TIMING_UPDATE.
9:8	LPDDR2	PIN_CONFIG: [PMC] Remaps address/command pins for LPDDR2_POP ball-out otherwise uses standard LPDDR2 pin configuration. 0 = LPDDR2 1 = LPDDR2_POP 2 = RESERVED
7	0x0	EARLY_TRFC_8_CLK: [PMC] Reserved bit. 1 = 8 clocks early, 0 = 16 clocks early.
6	0x1	DIS_STP_OB_CLK_DURING_NON_WR: [PMC] 1 = Disables stopping outbound data clock to I/O during non-write transactions.

Bit	Reset	Description
2	0x1	REF_AFTER_SREF: [PMC] 1 = Enables trigger of refresh after exiting self-refresh.
1	ENABLED	CLKCHANGE_PD_ENABLE: [PMC] Forces DRAM into power-down during CLKCHANGE. 0 = DISABLED 1 = ENABLED
0	ENABLED	CLKCHANGE_REQ_ENABLE: [PMC] Allows the EMC and CAR to handshake on PLL divider/source changes. 0 = DISABLED 1 = ENABLED

20.11.2.78 EMC_CFG_DIG_DLL_0

Configure Digital DLL

Controls for digital DLL's, which used to measure and maintain 1/4 cycle phase adjustment for RDQS strobes.

This register is shadowed: see usage note at top.

Boot requirements

- This register (except for field CFG_DLL_ALARM_DISABLE and DLL_RESET (trigger) and CFG_DLL_USE_OVERRIDE_UNTIL_LOCK(trigger)) should be parameterized in the BCT and written by the Boot ROM during cold boot.
- This register (except for field CFG_DLL_ALARM_DISABLE and DLL_RESET (trigger) and CFG_DLL_USE_OVERRIDE_UNTIL_LOCK(trigger)) should be saved in the scratch registers and restored by the Boot ROM during warm boot.

Offset: 0x2bc | Read/Write: R/W | Reset: 0xXX0000Xd (0bx0000x00000000000000000010x11x1

Bit	R/W	Reset	Description
31	RO	X	CFG_DLL_USE_OVERRIDE_UNTIL_LOCK: [PMC] Writing 1 to this register causes override_val to be used in place of DLL output until DLL_LOCK/DLL_LOCK_TIMEOUT is obtained. Takes effect on next shadow update.
30	RO	0x0	DLL_RESET: [PMC] Writing 1 to this register will send reset pulse to DLL's on next shadow update. Must reset DLLs when changing clock frequency by factor >= 2
29:28	RW	0x0	CFG_DLL_LOCK_LIMIT: [PMC] Reserved in case DLL has problems locking. DLL will be treated as locked after LIMIT µs. Counter is reset with DLL_RESET (from above) or with each periodic update (if using RUN_PERIODIC). Settings are: 00: LIMIT = 16 µs 01: LIMIT = 64 µs 10: LIMIT = 128 µs 11: LIMIT = 512 µs
27	RW	0x0	CFG_DLL_ALARM_DISABLE: [PMC] Reserved bit -- disable override of DLL logic when DLL_ALM is set (otherwise overrides DLI to 0x3FF).
26	RO	X	CFG_DLL_UPDATE_AT_NXT_REFRESH: Writing 1 to this register causes the DLCELL update to occur at the next REFRESH interval. Ordinarily, updates are only performed if the DLL value is updated. This mechanism allows updates to the XFORM_MULT/OFF to be taken at the next REFRESH.
25:16	RW	0x0	CFG_DLL_OVERRIDE_VAL: [PMC] Value to use in place of DLI output if CFG_DLL_OVERRIDE_EN is set or prior to lock in RUN_TIL_LOCK mode.
15	RW	0x0	CFG_DLL_TESTEN: [PMC] Enable DLL test mode
14	RW	0x0	CFG_DLL_QUSE_TESTOUT: [PMC] Enable DLL TESTOUT on QUSE pads
13:12	RW	0x0	CFG_DLL_TESTSEL: [PMC] Select DLL test output
11:8	RW	0x0	CFG_DLL_UDSET: [PMC] DLL Loop filter control (2^(udset+3)).

Bit	R/W	Reset	Description
7:6	RW	RUN_TIL_LOCK	CFG_DLL_MODE: [PMC] Controls how frequently DLL runs, as follows 0 = RUN_CONTINUOUS: DLL will run continuously. This option will consume the most power. Once LOCK/TIMEOUT occurs, trimmers will be updated at REFRESH or shadow update. 1 = RUN_TIL_LOCK: after DLL_RESET is set, DLL will run until it has locked/timed out, then be disabled. Trimmers updated at following REFRESH/shadow update. 2 = RUN_PERIODIC: after DLL_LOCK/TIMEOUT, DLL will be disabled and re-enabled after CFG_DLL_RUN_PERIOD µs to track delay changes (temperature/voltage). 3 = RESERVED
5	RW	0x0	CFG_DLL_LOWSPEED: [PMC] Enable DLL for use with low-speed EMCCLK operation (< 200 MHz).
4	RO	X	CFG_DLL_STALL_RW_UNTIL_LOCK: [PMC] Writing 1 to this register will cause the EMC to stall all RW traffic until the DLL locks. Takes effect on the next shadow update.
3	RW	0x1	CFG_DLL_STALL_ALL_TRAFFIC: [PMC] Enables stalling of all DRAM traffic while undergoing dll_stall condition;otherwise only block reads/writes are stalled during dll_stall
2	RW	ENABLED	CFG_DLL_OVERRIDE_EN: [PMC] Override DLL's DLI output with OVERRIDE_VAL (still uses mult/offset). 0 = DISABLED 1 = ENABLED
0	RW	ENABLED	CFG_DLL_EN: [PMC] Enables digital DLL 0 = DISABLED 1 = ENABLED

20.11.2.79 EMC_CFG_DIG_DLL_PERIOD_0

This register is shadowed: see usage note at top.

Offset: 0x2c0 | Read/Write: R/W | Reset: 0x00008000 (0bxxxxxxxxxxxxxxxx1000000000000000)

Bit	Reset	Description
15:0	0x8000	CFG_DLL_RUN_PERIOD: [PMC] If CFG_DLL_MODE == RUN_PERIODIC, this specifies the interval between runs in microseconds.

20.11.2.80 EMC_DIG_DLL_STATUS_0

Digital DLL Status

Digital DLL Status bits directly from the DLL

Offset: 0x2c8 | Read/Write: RO | Reset: 0x0000XXXX (0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx)

Bit	Reset	Description
15	X	DLL_LOCK
14	X	DLL_ALARM
13	X	DLL_LOCK_TIMEOUT
9:0	X	DLL_OUT

20.11.2.81 EMC_RDV_MASK_0

DRAM timing parameter

This register is shadowed: see usage note at top.

Boot requirements

- This register should be parameterized in the BCT and written by the Boot ROM during cold boot.
- This register should be saved in the scratch registers and restored by the Boot ROM during warm boot.

Offset: 0x2cc | Read/Write: R/W | Reset: 0x0000003f (0bxxxxxxxxxxxxxxxxxxxxxxxxxxx111111)

Bit	Reset	Description
5:0	0x3f	RDV_MASK: [PMC] This should be programmed to RDV.

20.11.2.82 EMC_WDV_MASK_0

DRAM timing parameter

This register is shadowed: see usage note at top.

Boot requirements

- This register should be parameterized in the BCT and written by the Boot ROM during cold boot.
- This register should be saved in the scratch registers and restored by the Boot ROM during warm boot.

Offset: 0x2d0 | Read/Write: R/W | Reset: 0x0000000f (0bxxxxxxxxxxxxxxxxxxxxxxxxxxxx1111)

Bit	Reset	Description
3:0	0xf	WDV_MASK: [PMC] This should be programmed to WDV.

20.11.2.83 EMC_CTT_DURATION_0

DRAM timing parameter

CTT_DURATION controls how long CTT remains enabled. If CTT + CTT_DURATION - RDV - 2 > 0, R2W must be increased by that amount.

Offset: 0x2d8 | Read/Write: R/W | Reset: 0x00000003 (0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxx011)

Bit	Reset	Description
2:0	0x3	CTT_DURATION: [PMC] Determines how long CTT remains enabled during reads. CTT determines when it will be enabled. DDR3: CTT_TERMINATION == 1 ? 4 : 0 LPDDR2: 0

20.11.2.84 EMC_CTT_TERM_CTRL_0

Configure CTT Termination Output Drive Strength

If CTT_TERMINATION is enabled, this controls the strength of the output drivers.

TERM_OVERRIDE forces use of EMC2TMC_CFG*_DRVDN_TERM, EMC2TMC_CFG*_DRVUP_TERM instead of using of AUTO_CAL DRVDN/DRVUP values with the following equation applied:

```
TERM_DRDN = (AUTO_CAL_DRVDN * TERM_SLOPE) / 4 + TERM_OFFSET
TERM_DRUP = (AUTO_CAL_DRVUP * TERM_SLOPE) / 4 + TERM_OFFSET
```

Recommended values for SLOPE/OFFSET:

100ohm CTT: TERM_SLOPE = 0x1, TERM_OFFSET = 0x4

50ohm CTT: TERM_SLOPE = 0x2, TERM_OFFSET = 0x8

Note: setting slope = 0 allows TERM_DRDN/DRVUP = TERM_OFFSET

setting slope > 2 is not supported

Boot requirements

- This register (except for fields TERM_DRVDN and TERM_DRVUP) should be parameterized in the BCT and written by the Boot ROM during cold boot.
- This register (except for fields TERM_DRVDN and TERM_DRVUP) should be saved in the scratch registers and restored by the Boot ROM during warm boot.

2:0	RW	0x2	TERM_SLOPE: [PMC]

ZQ Calibration Registers -- LPDDR2/DDR3

1. Periodic mode

Allows a ZQ calibration command to be sent periodically to DRAM. After ZCAL_INTERVAL, ZCAL_MRW_CMD will be sent to each DRAM, 1 at a time, followed by ZCAL_WAIT_CNT interval in which no other commands will be allowed to be sent to either DRAM. So if ZQ_MRW_DEV_SELECTN == 2'b00, it would send the MRW command to dev0, wait ZCAL_WAIT_CNT, send the command to dev1, wait ZCAL_WAIT_CNT, resume normal operation. It will then wait ZCAL_INTERVAL microseconds before repeating the procedure. The ZQ calibration command will not be sent to devices that are 1) unpopulated and 2) either in or about to enter self-refresh or DPD.

To enable periodic ZQ calibration, program ZCAL_INTERVAL and ZCAL_WAIT_CNT to be non-zero, as well as ZCAL_MRW_CMD to contain the command and device selection, followed by TIMING_CONTROL to latch those three registers.

Note that ZCAL_WAIT_CNT will be used instead of MRS_WAIT_CNT for delaying the subsequent DRAM commands after the ZQ calibration commands, even though in LPDDR2 a ZQ calibration command is also an MRW command.

Disable this feature by setting ZCAL_INTERVAL.ZCAL_REF_INTERVAL = 0, followed by TIMING_CONTROL to latch it.

2. One-shot mode

Allows ZQ calibration command to be sent to DRAM.

To send a one-shot command, keep ZCAL_INTERVAL and ZCAL_WAIT_CNT equal to zero, program ZCAL_MRW_CMD with only one device selected, then program TIMING_CONTROL to latch in those registers, and finally program ZCAL_ONE_SHOT to 1 to trigger the one-shot command. If more than one device needs to be calibrated, wait the ZQ calibration time and repeat the steps above with the other device selection bit enabled in ZCAL_MRW_CMD.

Do not send a one-shot ZQ calibration command when periodic mode is enabled.

20.11.2.85 EMC_ZCAL_INTERVAL_0

Configure ZQ Calibration

This register is shadowed: see usage note at top.

Boot requirements

- This register should be parameterized in the BCT and written by the Boot ROM during cold boot.
- This register should be saved in the scratch registers and restored by the Boot ROM during warm boot.

Offset: 0x2e0 | Read/Write: R/W | Reset: 0x00000000 (0bxxxxxxxx00000000000000000000000)

Bit	Reset	Description
23:10	0x0	ZCAL_INTERVAL_HI: [PMC] Combined with ZCAL_INTERVAL_LO specifies the number of microseconds to wait between issuance of ZCAL_MRW_CMD. If 0, ZCAL is disabled and internal counter will be reset.
9:0	0x0	ZCAL_INTERVAL_LO [PMC]

20.11.2.86 EMC_ZCAL_WAIT_CNT_0

Configure ZQ Calibration

This register is shadowed: see usage note at top.

Boot requirements

- This register should be parameterized in the BCT and written by the Boot ROM during cold boot.
- This register should be saved in the scratch registers and restored by the Boot ROM during warm boot.

Offset: 0x2e4 | Read/Write: R/W | Reset: 0x00000000 (0bxxxxxxxxxxxxxxxxxxxxxxxx0000000000)

Bit	Reset	Description
9:0	0x0	ZCAL_WAIT_CNT: [PMC] Number of EMC clocks to wait before issuing any commands after sending ZCAL_MRW_CMD.

20.11.2.87 EMC_ZCAL_MRW_CMD_0

Configure ZQ Calibration

This register is shadowed: see usage note at top.

(However it does not obey READ_MUX/WRITE_MUX non-default values.)

Boot requirements

- This register should be parameterized in the BCT and written by the Boot ROM during cold boot.
- This register should be saved in the scratch registers and restored by the Boot ROM during warm boot.

Offset: 0x2e8 | Read/Write: WO | Reset: 0x00000000 (0b00xxxxxx00000000xxxxxxxx00000000)

Bit	Reset	Description
31:30	0x0	ZQ_MRW_DEV_SELECTN: [PMC] Active-low chip-select, 0x0 applies command to both devices (will happen 1 at a time), 0x2 to for only dev0, 0x1 for dev1.
23:16	0x0	ZQ_MRW_MA: [PMC] MRW MA field to be sent after ZCAL_INTERVAL

Bit	Reset	Description
7:0	0x0	ZQ_MRW_OP: [PMC] MRW OP field to be sent after ZCAL_INTERVAL

20.11.2.88 EMC_ZQ_CAL_0

Trigger a Single ZQ Calibration

This register issues a ZQ calibration command for DDR3.

Offset: 0x2ec | Read/Write: R/W | Reset: 0x00000010 (0b00xxxxxxxxxxxxxxxxxxxxxxxxx1xxx0)

Bit	Reset	Description
31:30	0x0	ZQ_CAL_DEV_SELECTN: Active low chip-select, 0x0 applies command to both devices, 0x2 to for only dev0, 0x1 for only dev1, 0x3 for neither device (0x0, for both devices, is not allowed if the ZQ resister is shared between devices).
4	LONG	ZQ_CAL_LENGTH: Indicate short or long ZQ calibration. 0 = SHORT 1 = LONG
0	0x0	ZQ_CAL_CMD: Issues a ZQ calibration command (DDR3 only).

20.11.2.89 EMC_XM2CMDPADCTRL_0

Bit	Reset	Description
31:0	0x0	SCRATCH:

20.11.2.102 EMC_DLL_XFORM_DQS0_0

Configure Digital DLL

XFORM_DQSx_MULT and XFORM_DQSx_OFFS are a multiplier and offset, respectively, that can be used to modify the DLL output. Final products may be read out in DQS_TRIMMER_RD register. The default is multiply by 1 to keep the DLL's 1/4 cycle delay. Integer + fractional formats for multiplier and offset:

OFFS is 2's complement format, with bit [0] representing integer

The output of the XFORM is xform_out = (xform_in * MULT + OFFS*16)/ 16

Largest allowed MULT = 0x17

In the case of overflow, output is clamped according to these rules:

out >= 0x600, xform_out = 0x000

0x600 > out >= 0x400, xform_out = 0x3ff

That means clamping works within 50% above the maximum (0x3ff) DLL output or 50% below the minimum (0) DLL output.

To make sure that is always satisfied, conservatively program OFFS so that 0x600 < OFFS < (0x5ff – ((MULT * 0x3ff) >> 4)). The DLL output is effectively overridden by setting XFORM_*_MULT to 0 and programming XFORM_*_OFFS[8:1] to override value.

This register is shadowed: see usage note at top.

Boot requirements

- This register should be parameterized in the BCT and written by the Boot ROM during cold boot.
- This register should be saved in the scratch registers and restored by the Boot ROM during warm boot.

The DQS_CURRENT_TRIM_VAL_BYTE_x registers provide a way to observe the values being used by the trimmers

4:0	0x10	XFORM_DQS7_MULT: [PMC]

20.11.2.110 EMC_DLL_XFORM_QUSE0_0

Configure Digital DLL

XFORM_QUSEx_MULT and XFORM_QUSEx_OFFS are a multiplier and offset, respectively, that can be used to modify the DLL output. Final product may be read out in DQS_TRIMMER_RD register. The default is multiply by 1/2, to give 1/8 cycle delay.

OFFS is 2's complement format, with bit [0] representing integer. The output of the XFORM is xform_out = (xform_in * MULT + OFFS*16)/ 16

Largest allowed MULT = 0x17

In the case of overflow, output is clamped according to these rules:

out >= 0x600, xform_out = 0x000

0x600 > out >= 0x400, xform_out = 0x3ff

That means clamping works within 50% above the maximum (0x3ff) DLL output or 50% below the minimum (0) DLL output. To make sure that is always satisfied, conservatively program OFFS so that 0x600 < OFFS < (0x5ff – ((MULT * 0x3ff) >> 4)). The DLL output is effectively overridden by setting XFORM_*_MULT to 0 and programming XFORM_*_OFFS[8:1] to override value.

This register is shadowed: see usage note at top.

Boot requirements

- This register should be parameterized in the BCT and written by the Boot ROM during cold boot.
- This register should be saved in the scratch registers and restored by the Boot ROM during warm boot.

20.11.2.118 EMC_DLL_XFORM_DQ0_0

Configure Digital DLL

XFORM_DQx_MULT and XFORM_DQx_OFFS are a multiplier and offset, respectively, that can be used to modify the DLL output. XFORM_DQx_* applies to all DQ/DM bits in each byte x. Final products may be read out in the DQ_TRIMMER_RD register. The default is multiply by 1, providing 1/4 cycle skew to DQS to keep DLL's 1/4 cycle delay. Integer + fractional formats for multiplier & offset:

OFFS is 2's complement format, with bit [0] representing integer. The output of the XFORM is xform_out = (xform_in * MULT + OFFS*16)/ 16

Largest allowed MULT = 0x17

In the case of overflow, output is clamped according to these rules:

out >= 0x600, xform_out = 0x000

0x600 > out >= 0x400, xform_out = 0x3ff

That means clamping works within 50% above the maximum (0x3ff) DLL output or 50% below the minimum (0) DLL output. To make sure that is always satisfied, conservatively program OFFS so that 0x600 < OFFS < (0x5ff – ((MULT * 0x3ff) >> 4)).

This register is shadowed: see usage note at top.

Bit	Reset	Description
6:0	0x0	EMC2PMACRO_CFG_TXDQS7_DLI: [PMC]

Scheme to change controller timing parameters + SDRAM mode timing atomically.

1. Program the EMC controller timing registers (shadowed).
2. Pre-program the SDRAM mode registers.
    a. Write to whatever EMC registers you want to be execute after clock change request has been detected but before the actual clock change happens. For example, if you want to disable DLL in DDR3 mode, you can,
        i. Issue a write to SDRAM's MR1 register via EMC MRS register to disable DLL.
        ii. Issue a Self-refresh entry via EMC SELF_REF register.

    Note: If there's no need to execute any register access before clock change, simply skip step (a).

    b. Write 1 to STALL_THEN_EXE_AFTER_CLKCHANGE field which will prevent further config execution until after the actual clock change has happened.
    c. Write to whatever EMC registers you want to be executed after the clock change. Using the same example as (a), you will,
        i. Issue a Self-refresh exit via EMC SELF_REF register.
        ii. Issue writes to SDRAM's MRx register(s) to change read/write latencies and/or enable DLL

iii. Issue burst refreshes via EMC REF register.

Note: If there's no need to execute any register access after clock change, simply skip step (ii-iii); step (b) is still required.

3. Program the CAR to change either clock source and/or clock divider.

Note: In both sequences above, DYN_SELF_REF must be disabled off before the first step, then it can be restored after the last step.

The interval between two clock change sequences are recommended to be at least 20 µs apart

20.11.2.142 EMC_STALL_THEN_EXE_AFTER_CLKCHANGE_0

Write to this register will stall until after EMC timing registers are updated and that clock change has been completed. Once that happens, whatever register access follows this register write will be executed until UNSTALL_RW_AFTER_CLKCHANGE is encountered. At that point, normal memory read/write will be allowed to resume.

Offset: 0x3cc | Read/Write: RO | Reset: 0x00000000 (0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx0)

Bit	Reset	Description
0	0x0	STALL_THEN_EXE_AFTER_CLKCHANGE: Writing a one to this bit will stall subsequent register access.

20.11.2.143 EMC_AUTO_CAL_CLK_STATUS_0

EMC Pad Calibration Status

Offset: 0x3d4 | Read/Write: RO | Reset: 0xXXXXXXXX (0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx)

Bit	Reset	Description
28:24	X	AUTO_CAL_CLK_PULLDOWN_ADJ: Pull-down code sent to pads for MCLK pad.
20:16	X	AUTO_CAL_CLK_PULLUP_ADJ: Pull-up code sent to pads for MCLK pad.
12:8	X	AUTO_CAL_CLK_PULLDOWN: Pull-down code generated by auto-calibration for MCLK pad.
4:0	X	AUTO_CAL_CLK_PULLUP: Pull-up code generated by auto-calibration for MCLK pad.

20.11.2.144 EMC_SEL_DPD_CTRL_0

Configures Functional SEL_DPD Modes

Offset: 0x3d8 | Read/Write: R/W | Reset: 0x00040000 (0bxxxxxxxxxxxxxx100xxxxxx00xx0000xx)

Bit	Reset	Description
18:16	0x4	SEL_DPD_DLY: [PMC] number of cycles to wait before asserting SEL_DPD
9	DISABLED	QUSE_SEL_DPD_EN: [PMC] allow SEL_DPD assertion for QUSE pads 0 = DISABLED 1 = ENABLED

Bit	Reset	Description
4	DISABLED	RESET_SEL_DPD_EN: [PMC] assert SEL_DPD for reset pad 0 = DISABLED 1 = ENABLED
3	DISABLED	CA_SEL_DPD_EN: [PMC] allow SEL_DPD assertion for discrete command/address pads 0 = DISABLED 1 = ENABLED
2	DISABLED	CLK_SEL_DPD_EN: [PMC] allow SEL_DPD assertion for discrete clock pad 0 = DISABLED 1 = ENABLED

20.11.2.145 EMC_PRE_REFRESH_REQ_CNT_0

Offset: 0x3dc | Read/Write: R/W | Reset: 0x00000000 (0bxxxxxxxxxxxxxxxx0000000000000000)

Bit	Reset	Description
15:0	0x0	PRE_REF_REQ_CNT: [PMC] When the refresh counter reach this pre-refresh request count just before a burst refresh will be issued when it reach the {REFRESH,REFRESH_LO}, a pre-refresh request will be asserted to MC to close the banks/pages and flush its pipeline. A 0 value will disable this feature.

20.11.2.146 EMC_DYN_SELF_REF_CONTROL_0

Threshold for Dynamic Self-Refresh Entry

This register controls how dynamic self-refresh entry/exit is handled.

If ODT is enabled, the DSR_PER_DEVICE field must be set to DISABLED.

It is recommended to change the values of ODT_WRITE and DSR_PER_DEVICE with a clock change

To do it outside of a clock change sequence, one has to be aware that DSR enable/disable takes time to take effect. This is the sequence for disabling DSR_PER_DEVICE and enabling ODT outside of clock change:

1. DYN_SELF_REF <= DISABLED (DSR exit)
2. TIMING_UPDATE <= 1 (latch in the shadow value)
3. Read back and discard any EMC register such as INTSTATUS (ensure 1 and 2 have gone through)
4. Wait 2 µs for the last possible self-refresh entry
5. Poll for SDRAM_IN_SELF_REFRESH == 0 (ensure that self-refresh exits)
6. ODT_WRITE <= new value to turn on ODT

   DSR_PER_DEVICE <= DISABLED (turn off per-device DSR)

   DYN_SELF_REF <= ENABLED (re-enable DSR)
7. TIMING_UPDATE <= 1 (latch in the shadow values)

Offset: 0x3e0 | Read/Write: R/W | Reset: 0x00000000 (0b0xxxxxxxxxxxxxxx0000000000000000)

Bit	Reset	Description
31	DISABLED	DSR_PER_DEVICE: [PMC] controls whether dynamic self-refresh is done on a per-device basis. 0 = DISABLED 1 = ENABLED
15:0	0x0	DSR_THRESHOLD: [PMC] number of idle cycles to wait before allowing dynamic self-refresh entry

20.11.2.147 EMC_TXSRDLL_0

DRAM timing parameter

This register is shadowed: see usage note at top.

Boot requirements

- This register should be parameterized in the BCT and written by the Boot ROM during cold boot.
- This register should be saved in the scratch registers and restored by the Boot ROM during warm boot.

Note: If operating in non-DLL mode, this register needs to be updated with the non-DLL timing requirement.

Offset: 0x3e4 | Read/Write: R/W | Reset: 0x000007ff (0bxxxxxxxxxxxxxxxxxxxxx011111111111)

Bit	Reset	Description
11:0	0x7ff	TXSRDLL: [PMC] Cycles between self-refresh exit and first DRAM command requiring a locked DLL. For DDR3 only: READ (and RAP) and synchronous ODT commands. DDR3: 512. LPDDR2: TXSR (not used). Largest allowed value is 0xffe

20.11.2.148 EMC_CCFIFO_ADDR_0

CCFIFO_ADDR: This register contains the address offset of the EMC register that is intended to be executed during the clock change sequence.

Note: Before triggering a clock change sequence from the CAR, you must configure the pre-/post- clock change sequence by writing, multiple times, to the CCFIFO_DATA/CCFIFO_ADDR register pair. After the CCFIFO_ADDR register is written, Hardware will write the register offset and corresponding data into the 32-deep clock change FIFO (CCFIFO).

After the last CCFIFO_DATA/CCFIFO_ADDR register pair is written for a given clock change sequence, a dummy EMC register read (such as to the CCFIFO_ADDR register) should be executed to ensure the last clock change instruction gets written to the CCFIFO.

Offset: 0x3e8 | Read/Write: R/W | Reset: 0x00000000 (0bxxxxxxxxxxxxxxxx0000000000000000)

Bit	Reset	Description
15:0	0x0	CCFIFO_ADDR: clock change FIFO address register.

20.11.2.149 EMC_CCFIFO_DATA_0

CCFIFO_DATA: This register contains the 32-bit data of the EMC register that is intended to be written to or pointed at by CCFIFO_ADDR.

Offset: 0x3ec | Read/Write: R/W | Reset: 0x00000000 (0b00000000000000000000000000000000)

Bit	Reset	Description
31:0	0x0	CCFIFO_DATA: clock change FIFO data register.

20.11.2.150 EMC_CCFIFO_STATUS_0

Offset: 0x3f0 | Read/Write: RO | Reset: 0x000000XX (0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx)

Bit	Reset	Description
5:0	X	CCFIFO_COUNT

20.11.2.151 EMC_CDB_CNTL_1_0

CDB Control Register

Note: The controlling of CDB phase select is by the CDB_CNTL_1 register of each EMC0/1. The controlling of CDB clock gating is by EMC0's CDB_CNTL_2 register only. The EMC1 version of the CDB_CNTL_2 register is not used.

The following table lists the mapping for the SEL_PI_TAP bits in CDB Control Register 1.

Table 52: SEL_PI_TAP Mapping

CDB SEL_PI_TAP#	Which EMC?	Comment
CDB SEL_PI_TAP15	EMC0_EMC2PMACRO_SEL_PI_TAP7	channel 0, data byte 3

20.11.2.154 EMC_SWIZZLE_RANK0_BYTE_CFG_0

For byte swizzling, each SWZ_RANK*_BYTE*_SEL field indicates which SDRAM byte is mapped/connected to the corresponding byte of the chip.

The SWZ_RANK*_BYTE*_BIT*_SEL fields indicate which SDRAM data bit (0-7) within each byte is mapped/connected to the corresponding bit of the chip.

20.11.2.164 EMC_CA_TRAINING_START_0

Procedure for LPDDR3 CA Training

(1a) Configure data swizzling (if needed) through the DATA_SWIZZLE_RANK[0,1]_[0:7] registers.

(1b) Enable EMC2PMACRO_CFG_BYPASS_ADDRPIPE if needed. There's no need to enable EMC2PMACRO_CFG_BYPASS_DATAPIPE* for CA training purposes.

(1c) Follow the procedure on optimal trim setting into the CA bus clock trimmer below.

(2) Configure the CA training engine through the CA_TRAINING_[TIMING_CNTL1,TIMING_CNTL2, CA_LEAD_IN, CA, and CA_LEAD_OUT] registers.

(3) Software configures the CA training engine to use MR41 mode (through the CA_TRAINING_CFG register).

(4) Software starts the CA training engine (in the CA_TRAINING_START register) and waits for the CA training to finish (CA_TRAINING_BUSY).

(5) Software saves the result from the CA_TRAINING_RESULT* registers.

(6) Software repeats steps 3-5 but configures for MR48 mode.

(7) Software combines the results from MR41/MR48 modes to come up with a single trim setting and programs the CA bus clock trimmer (see below).

(8) Software issues MR42 to rank0.

(9) If desired, software can repeat steps 3-8 for rank1.

(10) Software combines the results from MR41/MR48 modes (if desired, results for rank1 as well) to come up with a single trim setting and programs the CA bus clock trimmer (see below).

(11) A separate CA training needs to be performed on channel-1 as well. Theoretically, CA training can be performed on both channels 0/1 in parallel to save training time.

Procedure to program the optimal trim setting into the CA bus clock trimmer

(A) Put CLKBUF0/CLKBUF2 into trimmer mode by setting EMC2TMC_CFG_XM2CMD_CLKBUF[0,2]_CONFIG = 001.

(B) Put XFORM_ADDR[0,2]_MULT field to 5'b0.

(C) Program bits [7:2] in the XFORM_ADDR[0,2]_OFFS field (11 bits) with the optimal trim result. The other XFORM_ADDR[0,2]_OFFS bits should remain at 0.

(D) Write a 1 into the TIMING_UPDATE field to load the above fields from shadow to active.

Below is what should be programmed into the CA_TRAINING_TIMING_CONTROL* registers.

CACKEL = tCACKEL + 15 clks

CAENT = tCAENT + 3 clks

CACD = tCACD + 5 clks

CACKEH = tCACKEH – 1 clk

CAEXT = tCAEXT – 1 clk

CA_DQ_RDV = CACD

20.11.2.181 EMC_DLL_XFORM_ADDR0_0

Configure Digital DLL for CMD/ADDR Group 0

XFORM_ADDRx_MULT and XFORM_ADDRx_OFFS are a multiplier and offset, respectively, that can be used to modify the DLL output. Final products may be read out in the ADDR_TRIMMER_RD register. The default is multiply by 1, to keep the DLL's 1/4 cycle delay. Integer + fractional formats for multiplier and offset:

OFFS is 2's complement format, with bit [0] representing integer

The output of the XFORM is xform_out = (xform_in * MULT + OFFS*16)/16

The largest allowed MULT = 0x17

In the case of overflow, the output is clamped according to these rules:

out >= 0x600, xform_out = 0x000

0x600 > out >= 0x400, xform_out = 0x3ff

That means clamping works within 50% above the maximum (0x3ff) DLL output or 50% below the minimum (0) DLL output.

To make sure that is always satisfied, conservatively program OFFS so that 0x600 < OFFS < (0x5ff - ((MULT * 0x3ff) >> 4))

The DLL output is effectively overridden by setting XFORM_*_MULT to 0 and programming XFORM_*_OFFS[8:1] to override the value

This register is shadowed: see usage note at the top.

Boot requirements

- This register should be parameterized in the BCT and written by the Boot ROM during cold boot.
- This register should be saved in the scratch registers and restored by the Boot ROM during warm boot.

The ADDR(0|1|2)_CURRENT_TRIM_VAL registers provide a way to observe the values being used by the trimmers.

20.11.2.188 EMC_ADDR_SWIZZLE_STACK1A_0

Address swizzling of the 3 ADDR/CNTL I/O stacks:

- Address stack1 (12 signals): BA[2:0], ADR[3:0], ADR[13:10], RESETN.
- Address stack2 (10 signals): ADR[9:4], ADR[14], CAS, RAS, WE.
- Address stack3 (6 signals): CS[1:0], CKE[1:0], ODT[1:0].

Note: The controlling of CDB phase select is by the CDB_CNTL_1 register of each EMC0/1.
The controlling of CDB clock gating is by EMC0's CDB_CNTL_2 register only. The EMC1 version of the CDB_CNTL_2 register is not used.
If LPDDRX_ADR_PIN_SWIZZLE_EN is enabled, it will get swizzled first before the ADDR/CNTL I/O stack swizzling.
For unused pins (such as BA0 pin in LPDDR2 mode), programming to anything other than the allowed enum will force that pin to be inactive or not-toggle

21.0 AHB

21.1 AHB Bus

The AHB Bus conforms to the *AMBA® Specification (Rev 2.0) Advanced High-performance Bus (AHB)* architecture as published by ARM®.

AHB is a 32-bit multi-master bus. Despite what its name implies, it is a second tier bus in the Tegra® 4 processor, slower and less flexible than the AXI bus used by the CPU, or the memory client interface used by the high-speed devices.

AHB clients in Tegra 4 processors include:

- The AHB memory controller slave, which is the interface between the AHB bus and the Memory Controller
- The AVP crossbar, both as a master and as a slave. This is the path to IRAM from AHB devices, and also the AVP and CPU path to AHB devices. Neither the CPU nor the AVP can access DRAM through this path.
- The APB DMA controller, used to provide data transfer between APB devices and memory.
- The USB2-OTG controllers
- The NAND flash controller
- The NOR/MIO controller
- The SD/MMC controllers
- The MIPI HSI controller
- The security engine (SE), both as a master and as a slave
- BSEA and BSEV bitstream engines
- The CoreSight™ debug controller.
- The deprecated AHB DMA controller master

AHB in the Tegra 4 processor supports secure access to memory, using the same secure bit mechanism used by the ARM Cortex™-A15 TrustZone security mechanism. This is supported by the SE, which can make secure accesses to memory.

21.2 AHB Bus Arbiter

The AHB Arbiter controls AHB bus master arbitration. This effectively forms a second level of arbitration for access to the memory controller through the AHB Slave Memory device, although AHB masters in some circumstances can use other AHB slaves, in particular they can access IRAM.

The controls presented here are largely for diagnostic purposes only. For suspect AHB performance problems, try disabling the other masters for the device with performance issues. In normal operation bus parking is usually enabled, and all the masters are enabled.

Also see the AHB slave interface registers, where the AHB pre-fetch logic can be configured to enhance performance for devices doing sequential read access from DRAM.

Each AHB master is assigned to either the high or low priority bin.

21.2.1 Arbitration Scheme

In every AHB Arbitration cycle, it is first decided whether a request from the high or low priority bin will be served. If there are only requests active for one of the bins, then that bin is served. When there are active requests from both bins, then the value from the AHB_PRIORITY_WEIGHT field is considered. There is a counter that is loaded with the AHB_PRIORITY_WEIGHT whenever the current count is 0 and someone wins an AHB arbitration. This counter is decremented anytime the count is

nonzero and the winner of AHB arbitration was from the high-priority bin. Whenever this counter is nonzero, then a high-priority bin request will win over any low-priority bin request. In a system where both high- and low- priority bin requests are constantly active, the AHB_PRIORITY_WEIGHT says how many high-priority requests will be served for every one low-priority request.

Within each bin, the arbitration algorithm is round robin. For example, after AHB Master 2 wins an arbitration, then Master 3 has precedence for winning the next (followed by Master 4, etc. while Master 2 is last). AHB Master ID's can be seen in the enumeration of AHB_MEM_PREFETCH_CFG* registers' "AHB_MST_ID" field.

21.2.2 AHB Arbiter Registers

Refer to "Reading Register Tables" in the Introduction section for the register table protocol as well as recommendations for accessing registers.

In Tegra 4 and prior generation processors, this location used to hold a configuration register for COP_CACHE, but COP_CACHE has been replaced with AVP_CACHE, which has a region in a different section. For software compatibility, this location is reserved.

21.2.2.1 AHB_ARBITRATION_DISABLE_0

The AHB arbitration control register allows user to tweak arbitration behavior of the AHB arbiter.

- Enable bus parking. This keeps the last serviced AHB master on the bus granted so that it can start another transaction faster. If bus parking is disabled, no AHB master will be able to start a new transaction until the arbitration is done and the master is granted the bus.
- Allows the user to specifically disable an AHB master from arbitrating on the AHB bus.

AHB Arbitration Controller

Offset: 0x4 │ Read/Write: R/W │ Reset: 0x00000000 (0b00xxxxxxxx0000000000000x00000000)

0	0x0	CPU: 1 = Disable CPU from arbitration. 0 = ENABLE 1 = DISABLE

21.2.2.2 AHB_ARBITRATION_PRIORITY_CTRL_0

The AHB arbiter implements a 2-level priority scheme. In the first level, arbitration is determined between the high and low priority group according to the priority weight; the higher the weight, the higher the winning rate of the high priority group.

In the second level, within each of the high/low priority group, arbitration is determined in a round-robin fashion.

AHB Arbitration Priority Control Register

Offset: 0x8 │ Read/Write: R/W │ Reset: 0x00000000 (0b00000000000000000000000000000000)

Bit	Reset	Description
31:29	0x0	AHB_PRIORITY_WEIGHT: AHB priority weight count. This 3-bit field is used to control the amount of attention (weight) given to the high priority group before switching to the low priority group.
28:0	0x0	AHB_PRIORITY_SELECT: 0 = low priority group.

21.2.2.3 AHB_ARBITRATION_USR_PROTECT_0

USR Protection Register

Offset: 0xc │ Read/Write: R/W │ Reset: 0x00000000 (0bxxxxxxxxxxxxxxxxxxxxxxxx000000000)

0	0x0	IRAMA: Abort on USR mode access to iRAMa memory space 0 = ABT_DIS 1 = ABT_EN

21.3 AHB “Gizmo”

AHB master/slave gizmos are essentially hardware layers used by many of the master/slave logic which need to connect to the AHB bus.

These hardware layers handle all the AHB bus protocols and convert the more complex AHB protocol into a much simpler IP interface/handshake.

Because the AHB master/slave gizmos interface with many IP logic with different characteristics varying in speed, latency, etc., the gizmos accept a number of static configuration bits. Depending on system speed, latency requirement, transfer direction, burst characteristic, etc., these static configuration bits can be pre-configured to give extra performance or improve bus efficiency.

21.3.1 AHB Gizmo Registers

Refer to “Reading Register Tables” in the Introduction section for the register table protocol as well as recommendations for accessing registers.

21.3.1.1 AHB_GIZMO_AHB_MEM_0

AHB Master/Slave Gizmo Register

Given below is a description of each configuration field, what they are used for and the pros and cons of using them.

> **Note:** These configuration bits are meant to be changed only when the particular gizmo you want to change is idle (not being used). Changing the configuration bits on-the-fly while that gizmo is active can hang the system.

AHB gizmo configuration bit definition:

(1) AHB Master Gizmo

1. MAX_AHB_BURSTSIZE: Controls the maximum burst size that this gizmo can generate on the AHB bus. For the current system, this field should be set to burst-of-8.
2. IMMEDIATE: Controls how quickly an AHB write request on the bus can start.
   - If 1, the gizmo will start an AHB write request once the IP side provides one beat of data of a burst. For IP that can provide quick continuous burst data, this setting provides parallelism between AHB request and IP data transfer. However, for IP that cannot provide quick burst data, this setting will force this gizmo to hold the AHB bus longer, reducing bus efficiency.
   - If 0, gizmo will wait until all beats of data of a burst are provided before starting an AHB write request. With this setting, AHB bus efficiency is realized but IP latency and efficiency may be reduced.
3. RD_DATA: Controls how read data will be returned from the gizmo to the IP side.
   - If 1, all beats of data of a burst have to be available before it indicates to the IP logic that read data is ready. This setting ensures there is no wait-state (bubble) between read data burst, but it will increase latency.
   - If 0, each beat of data of a burst will be sent from gizmo to the IP logic immediately. This setting will reduce latency, but can create non-consecutive data burst or bubble between data.
4. REQ_NEG_CNT: Provides a way to limit (in terms of number of AHB bus clock) how fast/often this master can request the AHB bus. The bigger the number, the slower the rate of AHB request.

(2) AHB Slave Gizmo

1. ENABLE_SPLIT: Controls enabling the split feature of the AHB bus.
   - If 1, the gizmo will always generate split response for a read. If ' DONT_SPLIT_AHB_WR' is set to 0, gizmo also generates split response if it cannot accept write request from the AHB master anymore. This setting can increase AHB bus utilization since it allows other AHB masters to talk to other AHB slaves while this original AHB slave is fetching read data. However, the flip side is that it takes longer time for the original AHB master to get the read data, because the original AHB master has to re-arbitrate for the AHB bus again in order to get to the data it asked for.

- If 0, the gizmo will not generate split response. Instead, it will hold on to the AHB bus until all the requested read data is returned back to the AHB master. This setting will reduce read latency to the master, but decrease AHB bus utilization.

2. FORCE_TO_AHB_SINGLE: Controls how the gizmo treats the AHB master's burst request.
   - If 1, the gizmo will break up the burst request internally into individual single word requests.
   - If 0, the gizmo will burst request internally as burst request.
3. ENB_FAST_REARBITRATE: Controls when the gizmo can allow the original read requested AHB master to re-arbitrate for the AHB bus again so the AHB master can retrieve the originally requested read data.
   - If 1, once first read data of a burst is in the slave gizmo's FIFO, it will allow the original AHB master to re-arbitrate, thus, allowing arbitration to happen in parallel with subsequent read data of a burst. However, if the data burst has wait-states or bubbles, then this setting will decrease AHB bus utilization because the slave gizmo will hold on to the AHB bus longer.
   - If 0, all read data of a burst must be in the slave gizmo's FIFO before it allows the original AHB master to re-arbitrate to retrieve the read data. This increases read data latency, and also increase AHB bus utilization.
4. IP_WR_REQ_IMMEDIATE: Controls when the gizmo will start write data request to the IP logic.
   - If 1, the gizmo will start write request to the IP logic once it gets one write data of a burst from the AHB side. This setting will create non-consecutive/bubbles in a write data burst.
   - If 0, the gizmo will start write request to the IP logic only when it gets all write data of a burst from the AHB side. This setting will create consecutive data burst (no bubbles or wait-states).
5. MAX_IP_BURSTSIZE: Controls the maximum burst size that this gizmo can generate to the IP logic.
6. ACCEPT_AHB_WR_ALWAYS: Controls how the slave gizmo will treat AHB write request.
   - If 1, the gizmo will always accept a write request without checking whether it's FIFOs can accept the write or not. This setting can reduce bus utilization, but can reduce the rate of AHB retry.
   - If 0, the gizmo will check its FIFOs to make sure they have room before accepting the AHB write request. This setting increase bus utilization, but can create a lot of AHB retry.
7. DONT_SPLIT_AHB_WR: Controls whether to split AHB write request when the slave gizmo determines it cannot accept the write request.
   - If 1 and when ENABLE_SPLIT=1, the gizmo will generate split for write if its FIFOs are not ready to accept the AHB write request or data. This setting can improve AHB bus utilization as there are no continuous AHB master retries on the bus.
   - If 0, the gizmo will generate retry response for write if its FIFOs are not ready to accept the AHB write request. Software should leave this bit at 0 since this feature has not been proven.

AHB Gizmo AHB-DMA/Memory Control Register

Offset: 0x10 │ Read/Write: R/W │ Reset: 0x00020081 (0b00000000xx0xx010xxxxxxx010xxx001)

Bit	Reset	Description
31:24	0x0	REQ_NEG_CNT: AHB master request negate count. This is an 8-bit counter used to indicate the minimum number of clock counts between requests from this AHB master.
21	0x0	CHANNEL_SPLIT_STALL: If enabled, AHB writes to a second MC channel will stall until all writes to the previous MC channel have completed. This prevents a later write from occurring before an earlier write to a different MC channel. 0 = DISABLE 1 = ENABLE

Bit	Reset	Description
18	0x0	IMMEDIATE: AHB master gizmo (AHB-DMA) – Start AHB write request immediately 1 = Start the AHB write request immediately as soon as the device has put one write data in the AHB gizmos queue. 0 = Start the AHB write request only when all the write data has transferred from the device to the AHB gizmos queue. 0 = DISABLE 1 = ENABLE
17:16	0x2	MAX_AHB_BURSTSIZE: AHB master gizmo (AHB-DMA) – Maximum allowed AHB burst size. 00 = single transfer 01 = burst-of-4 10 = burst-of-8 11 = burst-of-16 0 = DMA_BURST_1WORDS 1 = DMA_BURST_4WORDS 2 = DMA_BURST_8WORDS 3 = DMA_BURST_16WORDS
8	0x0	WR_WAIT_COMMIT_ON_1K: writes to ahbslv will only be issued to MC when all prior writes in different 1kB pages have reached the point of coherency. This is needed because the MC allows re-ordering of transactions. If this is not set, an entity which polls memory for a descriptor or flag to indicate some other memory has been written, may think something is available in memory when it is not. 0 = DISABLE 1 = ENABLE
7	0x1	DONT_SPLIT_AHB_WR: AHB slave gizmo (memory controller) – Do not split AHB write transaction 1 = Do not split AHB write transaction ever. 0 (and enable_split=1) = Allow AHB write transaction to be split. 0 = ENABLE 1 = DISABLE
6	0x0	ACCEPT_AHB_WR_ALWAYS: AHB slave gizmo (memory controller) - Accept AHB write request always. 1= Always accept AHB write request without checking whether there is room in the queue to store the write data. Bypass Memory Controller AHB slave gizmo write queue. 0 = Accept AHB write request only when there is enough room in the queue to store all the write data. Memory controller AHB slave gizmos write queue is used in this case. 0 = ACCEPT_ON_CHECK 1 = ACCEPT_ON_NOCHECK
2	0x0	ENB_FAST_REARBITRATE: AHB slave gizmo - Enable fast re-arbitration. 1 = Allow AHB master re-arbitration as soon as the device returns one read data into the gizmos queue. 0 = Allow AHB master re-arbitration only when the device returns all read data into the gizmos queue. 0 = DISABLE 1 = ENABLE

Bit	Reset	Description
1	0x0	FORCE_TO_AHB_SINGLE: AHB slave gizmo (memory controller) - Force all AHB transaction to single data request transaction 1 = Force to single data transaction always. 0 = Do not force to single data transaction. 0 = NOT_SINGLE_DATA 1 = SINGLE_DATA
0	0x1	ENABLE_SPLIT: AHB slave gizmo (memory controller) - Enable splitting AHB transaction. 0 = DISABLE 1 = ENABLE

21.4 AHB Memory Controller Slave

The AHB memory controller slave is the path used by AHB bus masters to access the Memory Controller. It provides access to DRAM from the AHB bus and can pre-fetch data.

21.4.1 AHB Memory Pre-Fetcher

The AHB memory controller slave contains a pre-fetcher block. This is intended to improve performance for AHB masters performing sequential reads from DRAM. Performance can be a problem because the AHB bus protocol only allows a single outstanding read request from a master, so the round trip latency limits bandwidth. As there are two level of arbitration, firstly on AHB and secondly within the memory controller, this latency can become large on a busy system.

There are eight such pre-fetchers, allowing this function to be active for up to eight AHB masters.

When the pre-fetcher is enabled, the first read request initiates a speculative read of up to 128 bytes, and subsequent linear reads will return the data directly to the AHB master without going through the memory controller to DRAM.

21.4.1.1 Pre-Fetch Invalidate

The pre-fetch buffer's contents are invalidated under any of the following conditions, in all cases a read refers to a DRAM read by the assigned HB master:

- The programmed time-out value is reached since the last read
- A read occurs which is not sequential with the previous read
- A read occurs which is not the same size as the previous read, unless the corresponding DISABLE_CHECK_SIZE_MASTERx bit is set.
- A read occurs which is past the end of the pre-fetch buffer (this will trigger a new fill of the buffer).
- The pre-fetcher is disabled. A momentary disable and then re-enable can be used to invalidate the buffer.

21.4.1.2 Pre-Fetch Buffer Coherency

As the pre-fetch buffer contains a copy of data in DRAM, there is an inherent coherency risk if the DRAM data is updated. The hardware invalidation mechanisms provide some protection here, but there remains risk of subtle problems arising from this hardware. If an AHB master shows errors that appear to arise from stale data then a reasonable experiment is to disable the pre-fetcher to see if that cures the problem. If so, the following guidelines may help.

Problems have been seen for control structures such as USB Transfer Descriptors.

Two approaches can resolve this problem:

1. Pad the data

As the pre-fetcher invalidates the buffer for any non-sequential read, placing some padding will prevent pre-fetch issues. A problem can be triggered by using something like this:

```
struct dtd { unsigned HW_descriptor[K] ; } ; struct dtd dtd_array[N] ;
```

This makes the hardware descriptors structures as read by the USB DMA sequential, and so pre-fetchable.
If the definition is modified as:

```
struct dtd { unsigned HW_descriptor[K] ; unsigned Padding ; } ; struct dtd dtd_array[N] ;
```

Then reads by USB DMA of consecutive hardware descriptors become **not** sequential and so there is no coherency issue as the pre-fetch buffer will be invalidated.

2. Invalidate the pre-fetch buffer

After updating a memory structure, the pre-fetch buffer can be invalidated by disabling the pre-fetcher and then immediately re-enabling it.

21.4.2 AHB Memory Controller Slave Registers

Refer to “Reading Register Tables” in the Introduction section for the register table protocol as well as recommendations for accessing registers.

21.4.2.5 AHB_AHB_MEM_PREFETCH_CFG_X_0

If DISABLE_CHECK_SIZE is 0, then only read requests that have the exact same size as the original read request that kick-started the prefetch process will cause a "hit". In addition, the address must be the exact next one in the sequence.

For instance, if the first request on a prefetch-enabled AHB Master arrives with SIZE=ONE_BYTE and ADDR[31:0]=0x3, then the next access must have SIZE=ONE_BYTE and ADDR[31:0]=0x4 in order to be considered a hit.

If DISABLE_CHECK_SIZE is 1, then a read request will hit as long as the incoming ADDR[31:4]matches the expected_ADDR[31:4]. expected_ADDR[31:4] is always either "last ADDR[31:4]" or "last ADDR[31:4] + 1", where last ADDR is the prior read request actually issued by the AHB Master(as opposed to the last request to the CIF, which could have been a speculative read).

expected_ADDR[31:4] is always "last ADDR[31:4]" unless "SIZE" field in the last request uses the last byte in the 16-byte CIF word.

NV_ahbslvmem prefetch

The NV_ahbslvmem prefetch feature is intended to reduce latency and improve overall bandwidth for AHB Masters doing reads to SDRAM. AHB only allows one outstanding read transaction at a time. When enabled, and kick-started by a first read request (which will "miss" since there would be nothing in the prefetch FIFO) the prefetcher makes speculative read requests to the memory controller in consecutive progression of linear address. Without this feature, an AHB Master will suffer roundtrip latency through the gizmo, PPCS, CIF, MC arbitration, and all the read data passing for every AHB transaction.

Address Boundaries for prefetching will stop the sequential prefetch process from making additional speculations. This is useful to help prevent coherency issues -- software needs ways to stop the prefetcher from prefetching data before the data has been written in memory. If an AHB master can be known to make 256 byte transfers that are aligned accesses, ADDR_BNDRY should be set to a value of 4.

INACTIVITY_TIMEOUT is intended to prevent coherency problems. If no read request from the prefetch-enabled master is observed after the number of cycles specified in the inactivity timeout counter, then any speculatively prefetched read data is invalidated.

There are eight AHB masters that can be enabled for prefetching. Each prefetch buffer can hold up to 8 entries (of 128 bits each entry) of prefetched data.

22.0 APB

22.1 APB Miscellaneous Registers

Refer to “Reading Register Tables” in the Introduction section for the register table protocol as well as recommendations for accessing registers.

This section describes a number of system control registers that are grouped together in the aptly named miscellaneous registers section. These registers are all present on the APB bus.

22.1.1 Strap Registers

This Boot Strapping register gets updated on power-on reset via the Pull-up/pull-down on the Strap I/Os. Based on strapping options set, the chip determines where to boot from. NOR FLASH WIDTH, MIO_WIDTH are also determined by Boot strap bits.

Some of these bits are used only during the design phase.

22.1.1.1 APB_MISC_PP_STRAPPING_OPT_A_0

Strapping Options Register

22.1.2.2 APB_MISC_PP_PINMUX_GLOBAL_0_0

Global Pinmux Control Register

When both CLAMP_INPUTS_WHEN_TRISTATED is set to ENABLE and the TRISTATE field is set to TRISTATE (1b1), the inputs to the core are clamped to zero. Software must set this bit before taking any controller using a pinmuxed pin out of reset.

Offset: 0x40 │ Read/Write: R/W │ Reset: 0x00000000 (0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx0)

Bit	Reset	Description
0	DISABLE	CLAMP_INPUTS_WHEN_TRISTATED: 0 = Do not clamp inputs when tristated; 1 = Clamp inputs when tristated 0 = DISABLE 1 = ENABLE

22.1.3 PULL_UP/PULL_DOWN Control Register

Controls the pull_up/pull_down inputs of the pads. Used to eliminate external components on interfaces that need pullup/pulldown. Those are weak internal pullup/pulldowns

- NORMAL setting means pad is neither pulled up (driving weak 1) or pulled down (driving weak 0)
- PULL_DOWN selection means pad is driving weak 0
- PULL_UP selection means pad is driving weak 1

WARNING! Driving an internal pull-up when the pad has an external pull-down and vice versa will cause a significant increase in power consumption.

Table 53: Cross Reference of Fields with Real Ball Names

Field Name	Controls Balls
XM2D_PU_PD	DDR_DQ0,DDR_DQ1,...,DDR_DQ31
XM2C_PU_PD	MIO_IORDY,DDR_DM0,..,DDR_DM3,DDR_DQS0,...,DDR_DQS3,DDR_A0,..,DDR_A13,DDR_BA0,DDR_BA1,DDR_CS0_,DDR_CS1_,DDR_CKE,DDR_RAS_,DDR_CAS_,DDR_WE_
DDRC_PU_PD	DDR_COMP_PU, DDR_COMP_PD

22.1.3.1 APB_MISC_PP_PULLUPDOWN_REG_C_0

Offset: 0xa8 │ Read/Write: R/W │ Reset: 0x00000000 (0b000000xxxxxxxxxxxxxxxxxxxxxxxx)

31:30	NORMAL	XM2C_PU_PD: 0 = NORMAL 1 = PULL_DOWN 2 = PULL_UP 3 = RSVD
29:28	NORMAL	XM2D_PU_PD: 0 = NORMAL 1 = PULL_DOWN 2 = PULL_UP 3 = RSVD
27:26	NORMAL	DDRC_PU_PD: 0 = NORMAL 1 = PULL_DOWN 2 = PULL_UP 3 = RSVD

22.1.3.2 APB_MISC_GP_HIDREV_0

Chip ID Revision Register

Offset: 0x804 │ Read/Write: RO │ Reset: 0x000XXXXX (0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx)

Bit	Reset	Description
19:16	X	MINORREV: Chip ID minor revision
15:8	X	CHIPID: Chip ID
7:4	X	MAJORREV: Chip ID major revision (0: Emulation, 1-15: Silicon) 0 = EMULATION 1 = A01
3:0	X	HIDFAM: Chip ID family register. 0 = GPU 1 = HANDHELD 2 = BR_CHIPS 3 = CRUSH 4 = MCP 5 = CK 6 = VAIO 7 = HANDHELD_SOC

22.1.4 Pad Control Registers

The registers below control pad behavior. For each digital pad, the following controls can be used to tune pad performance, functionality, and power consumption. The pads controlled by each pad group register can be found in the Pinmux section of this document.

- **HSM_EN** - High speed mode - active high, enables high speed mode for driver and receiver for better matching of the rise/fall delay in outbound and inbound paths. Use it for clocks and the high speed signaling where the matching timings are of importance.
- **SCHMT_EN** - Schmitt enable - active high, enables the Schmitt Trigger Type of I/P receiver. Default is Inverter Type of receiver.
- **LPMD** - Low power mode - select low power modes (different impedance and current value). The table depicts the function of low power mode

Table 54: Low Power Mode Functions

LPMD1	LPMD0	Power Mode Selected
0	0	X/8 Current Setting. Lowest Power or Current (8*Z ohm)
0	1	X/4 Current Setting (4*Z ohm)
1	0	X/2 Current Setting (2*Z ohm)
1	1	X Current Setting (Z ohm = 50 ohm). Highest Power or Current.

- CAL_DRVDN - drive down (falling edge) - Driver Output Pull-Down drive strength code.
- CAL_DRVUP - drive up (rising edge) - Driver Output Pull-Up drive strength code. Works with combination of LMPD bits. For lower power modes, higher drive strength are masked. See table below:

LPMD1	LPMD0	CAL_DRV*4	CAL_DRV*3	CAL_DRV*2	CAL_DRV*1	CAL_DRV*0
0	0	Masked to 0	Masked to 0	Masked to 0	Pass Code	Pass Code
0	1	Masked to 0	Masked to 0	Pass Code	Pass Code	Pass Code
1	0	Masked to 0	Pass Code	Pass Code	Pass Code	Pass Code
1	1	Pass Code	Pass Code	Pass Code	Pass Code	Pass Code

- DRVDN_SLWR - Driver Output Rising Edge Slew 2-bit control code.
  Code 11 is least slewing of signal, code 00 is highest slewing of the signal.
- DRVUP_SLWF -Driver Output Falling Edge Slew 2-bit control code.
  Code 11 is least slewing of signal, code 00 is highest slewing of the signal.

22.1.5 Pin Mux Selects

Refer to the MPIO/Pinmux section in this document for details on the Pinmux_aux registers.

22.2 APB DMA Controller

The APB DMA Controller is placed between the AHB Bus and the APB Bus and is a master on both buses.

The APB DMA Controller is used for block data transfers from a source location to the destination location. The source may be DRAM or IRAM, and the destination location could be devices placed on APB Bus; or vice versa. DMA transfers are done without any processor intervention other than register writes needed to program the parameters for a particular transfer, and accesses needed to handle any interrupts.

The APB DMA Controller has 32 fully programmable channels, which can all transfer data concurrently.

22.2.1 Features

Hardware Features

- DMA master for transfers between external/internal memory and peripheral devices on the APB Bus
- Two modes of operation: single transfer (once) or continuous
- Programmable burst sizes of 1, 4, or 8 words
- Maximum transfer size is 1 GB per channel, with the minimum size being one word
- Programmable APB Bus widths of 8, 16, and 32 bits
- Separate AHB and APB start addresses
- Per channel trigger and flow control mechanism support
- Channel to channel trigger support, i.e., ability to link up channels to start at the end of another channel's transfer, allowing scattering/gathering of physical memory.
- Interrupt generation at the completion of channel transfer
- Interrupts per channel can be routed to CPU or AVP
- Ability to hold processor until transfer is done
- Wrap mode supported for all channels in Once mode
- Ping-Pong feature supported in continuous mode
- Round-robin arbitration among channels at burst granularity
- Runs on APB clock. APB Clock generally runs at 1:2:2 or 1:2:3 clock ratios (sclk : hclk : pclk).

Software Features and Notes

- The AHB burst size and the FIFO trigger levels (in the modules) should be programmed so that they do not lead to an overflow/underflow of the FIFO.
- The DMA transfer size should be in multiples of 4 bytes only.
- A channel is programmed with the channel enable bit disabled. The channel enable bit should be set last.
- The Global enable bit is used to pause transfers for some time, and then resumes. This pauses transfers from all channels.
- If a channel is disabled while transfer is in progress, the transfer ends after ongoing burst is completed and an interrupt is generated if enabled.
- If the Channel_Pause bit of a particular channel is enabled during a data transfer, the data transfer is paused only on this channel after the completion of the current burst. It can be resumed by making this bit 0.
- Busy bit is set as soon as DMA channel is enabled and gets cleared after transfer is completed.
- Interrupts are "write 1 to clear".

- An interrupt is generated when the last data is accepted by the AHB slave while writing to the AHB bus and once the last data is placed on APB bus while reading from AHB bus. Note that completion of an AHB write does not guarantee the data is written to DRAM. Refer to the AHB section of this document to find out how to determine data is flushed from AHB to the MC for this master.
- When the address wrap feature is disabled, the addresses are incremented after each word transfer. This helps transfer data from/to contiguous locations.
- Usually, APB clients have a buffer of a fixed size. If the APB addresses were incrementing as in the case mentioned above, there is every possibility the address would cross the address limit of that client and go into the address range of another client. To avoid this, the wrap feature is used.
- With the address wrap feature enabled, the LS nibble of the address wraps back to 0 after completion of the programmed number of words instead of incrementing the address.

  Example: AHB burst size = 4 words, AHB start address = 0x4000_0000, AHB wrap on 32 words

  In this case, the AHB addresses would be:

  0x4000_0000, 0x4000_0004, 0x4000_0008, 0x4000_000C

  …….

  0x4000_0070, 0x4000_0074, 0x4000_0078, 0x4000_007C

  Note: Wrap does not occur in between bursts; it is only after completing a burst that the address wraps around. Wrap is possible for both AHB and APB addresses

- The default wrap around on the APB side is wrapping on 1 word. It prevents unnecessary address switching on the APB.
- The parameters of the channel should be programmed first (for example, base address, wrap-around). The control register of that channel should then be programmed. If the control register is programmed first, the current parameters of the DMA would be considered as the programmed values.
- If a burst of 8 is requested with the address that is not aligned to a 8-word boundary (addr [4:2] not zeros), the DMA does a single burst until it aligns itself to the 8-word boundary and then starts issuing burst requests (on AHB address).
- If a burst of 8 is requested and at any point of time the transfer size goes below 8 (less than 8 words left to transfer), the DMA completes the remaining transfers with a burst of 4 or 1, whichever is possible.
- If a burst of 4 is requested with the address that is not aligned to a 4-word boundary (addr [3:2] not zeros), the DMA does a single burst until it aligns itself to the 4-word boundary.
- If a burst of 4 is requested and at any point of time the transfer size goes below 4 (less than 4 words left to transfer), the DMA completes the remaining transfers with a burst of 1.

22.2.2 Functionality

There are 32 channels in APB DMA. An APB DMA channel can transfer specified portions of data from an AHB address space (can be iRAMs or DRAMs on the MC) to an APB address space. APB DMA follows a simple round robin arbitration scheme, starting with channel 0.

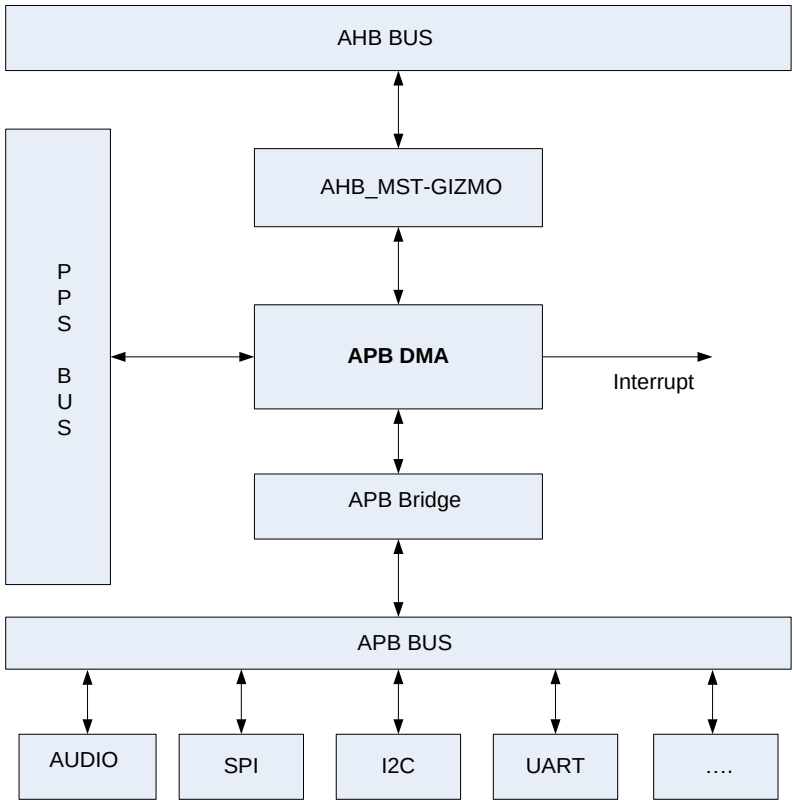
Each channel can have independent burst transfer sizes programmed to one word, four words, or eight words.

Each DMA channel supports:

- Enable bit: one for each channel and one global enable bit.
- Interrupt Enable at the end of transfer with ability to mask or route to desired processor.

- Ability to hold off a processor. The Processor that writes into this bit will be held until transfer is completed.
- Direction bit to determine the direction of transfer--AHB to APB or APB to AHB.
- Trigger and Flow selects. These are addition controls apart from channel enable, on which the transfer depends. Trigger is used to start a channel on some event to start the transfer and flow is used to proceed with every new burst transfer. These events are under either Software or Hardware control.
- Wrap feature wraps the LS nibble of the address back to ‘b0000 instead of incrementing to the next address if the required number of words has been transmitted.
- APB bus width is configurable whereas the AHB bus width is fixed to 32 bits. The APB bus can be 8, 16, or 32 bits wide . For an AHB burst of 8 (burst is always with regard to words) and an APB bus size of 16, there are: 8 words transferred to the APB side, or 16 "halfwords" transferred.
- Double Buffering Mode makes the APB DMA Burst Address reset to AHB Base Address after every even (2nd, 4th, 6th, etc.) APB DMA Transfer. This mode is used only along with continuous mode (once bit 0).
- Separate AHB start address and APB start address.
- Ability to delay the burst rate with the help of a global counter which can be programmed to desired value, which equals number of clocks delay required between each burst.

Figure 61: APB-DMA Block Diagram



22.2.3 Programming Guidelines

Follow these guidelines when programming the APB_DMA Controller:

1. All the registers of a channel should be programmed before the Channel Enable bit is set. To program each register:
   a. Program the AHB Starting Address and APB Starting address in *AHB_PTR and *APB_PTR Registers.

b. Program the required AHB BURST size, WRAP word window size and AHB_DATA_SWAP (byte swapping) option in *AHB_SWQ Register. The AHB BUS WIDTH is fixed to 32-bit Bus.
c. Program the required APB_BUS_WIDTH (as the peripheral), APB_DATA_SWAP (byte swapping) option and WRAP word window size in *APB_SEQ Register.
d. Program the Trigger and most significant 4 bits of DMA Count value in CHANNEL_*_CSRE Register.
e. Program the Interrupt option, Hold Processor option, DMA transfer direction, Transfer Mode, Flow Enable and DMA Count value in CHANNEL_*_CSR Register.
f. Program the Global Enable bit in APB_DMA Command Register. This should be done before programming any register of the channel; otherwise the channel register will not get programmed.
g. Whenever the Channel ENB bit is Enabled, the DMA starts the Data transfer.
h. Each channel status is observed by polling or interrupts status using APB_DMA Status Register.
i. The Tx/Rx Flow/Trigger requestors are programmed in APB-DMA Requestor Assignments Registers.

2. Clearing the Global Enable bit causes the transfers that are in progress to be paused. Setting the Global Enable resumes the transfers. If the Global Enable bit is disabled, then register access is not possible.
3. Setting the channel-Pause bit in CSRE register would pause data transfer on a channel.
4. If channel ENB is disabled independently while a transfer is in progress, the transfer ends after completing any burst sequence that is in progress.
5. Busy bit gets set as soon as a channel is enabled and is cleared after transfer is completed or when the channel is disabled
6. Interrupts are write-1-to-clear i.e., interrupt bit is cleared when the value of write data corresponding to the bit position of the interrupt bit is 1. It is best to read back the status register after the write-1-to-clear.
7. The APB burst size and the FIFO trigger levels (in the modules) need to be programmed such that they do not lead to an overflow/underflow of the FIFO.
8. The AHB wrap around needs to be programmed keeping in mind the address that is programmed in the AHB start address and the burst size.
9. If a burst of 8 is requested with the address that is not aligned to a 8-word boundary, the DMA would do a single burst till it aligns itself to the 8-word boundary and then starts issuing burst requests.
10. If a burst of 8 is requested and at any point of time the transfer size goes below 8, the DMA completes the remaining transfers with a burst of 4 or 1, whichever is possible.
11. If a burst of 4 is requested with the address that is not aligned to a 4-word boundary, the DMA does a single burst till it aligns itself to the 4-word boundary.

If a burst of 4 is requested and at any point of time the transfer size goes below 4, the DMA completes the remaining transfers with a burst of 1.

22.2.4 APB DMA Registers

Refer to “Reading Register Tables” in the Introduction section for the register table protocol as well as recommendations for accessing registers.

22.2.4.1 APBDMA_COMMAND_0

APB-DMA Command Register

The Global Enable bit in the command register enables the APB DMA. Clearing this bit causes active DMA transfers to be paused. Pending bus transactions (on going burst) will be completed and no new transactions will be initiated. Setting this bit again resumes the transfers. Disabling this bit will disable the channel register access.

Note that the power on reset value for the APB DMA Global Enable is 0. This bit must be written to 1 before any APB DMA transactions can begin.

Offset: 0x0 │Read/Write: R/W │ Reset: 0x00000000 (0b0xxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx)

Bit	Reset	Description
31	0x0	GEN: Enables Global APB-DMA 0 = DISABLE 1 = ENABLE

22.2.4.2 APBDMA_STATUS_0

APB-DMA Status Register

The Busy bits in the Status Register indicate which (if any) of the APB DMA channels have active pending APB DMA transfers. Note that APB DMA transfers that are started in continuous (repetitive) mode will have their busy bits active until the enable bit for the APB DMA channel is cleared to 0 (by the software). Read-only Flags set/cleared by hardware.

22.2.4.3 APBDMA_CNTRL_REG_0

APB-DMA Counter Register

The APB DMA Counter is used to slow down the request rates on some APB DMA channels. The APB DMA Channel Counter Enable register stores bits that configure which (if any) channel(s) should be throttled (bits [31:0] of channel counter enable register) correspond to APB DMA 32 channels.

The APB DMA Counter initial/reload count value is programmed in the APB DMA Counter Register (bits[15:0]).The APB DMA Counter is loaded with this initial/reload count value whenever the APB DMA Counter Register is written, and is re-loaded to this saved initial count value on a burst complete (programmable). The APB DMA Counter value will decrement whenever an APB DMA burst complete, and the current count value is non-zero, and any of the bits [31:16] are set.

Offset: 0x10 │ Read/Write: R/W │ Reset: 0x00000000 (0bxxxxxxxxxxxxxxxx0000000000000000)

Bit	Reset	Description

22.2.5 APB DMA Channel Registers

Refer to “Reading Register Tables” in the Introduction section for the register table protocol as well as recommendations for accessing registers.

Each of the 32 APB DMA channels has its own set of 8 APB DMA registers. Each channel has 32 bytes of address space. This subsection defines one complete set of APB DMA channel registers. The register spaces per APB DMA channel are listed in the table below.

Table 58: APB DMA Channel Register Mapping

Register Space	Channel Registers
0x0 – 0x1f	Channel 0 APB DMA Channel Registers
0x20 – 0x3f	Channel 1 APB DMA Channel Registers
0x40 – 0x5f	Channel 2 APB DMA Channel Registers
0x60 – 0x7f	Channel 3 APB DMA Channel Registers
0x80 – 0x9f	Channel 4 APB DMA Channel Registers

Register Space	Channel Registers
0xa0 – 0xbf	Channel 5 APB DMA Channel Registers
0xc0 – 0xcf	Channel 6 APB DMA Channel Registers
0xe0 – 0xff	Channel 7 APB DMA Channel Registers
0x100 – 0x11f	Channel 8 APB DMA Channel Registers
0x120 – 0x13f	Channel 9 APB DMA Channel Registers
0x140 – 0x15f	Channel 10 APB DMA Channel Registers
0x160 – 0x17f	Channel 11 APB DMA Channel Registers
0x180 – 0x19f	Channel 12 APB DMA Channel Registers
0x1a0 – 0x1bf	Channel 13 APB DMA Channel Registers
0x1c0 – 0x1df	Channel 14 APB DMA Channel Registers
0x1e0 – 0x1ff	Channel 15 APB DMA Channel Registers
0x200 – 0x21f	Channel 16 APB DMA Channel Registers
0x220 – 0x23f	Channel 17 APB DMA Channel Registers
0x240 – 0x25f	Channel 18 APB DMA Channel Registers
0x260 – 0x27f	Channel 19 APB DMA Channel Registers
0x280 – 0x29f	Channel 20 APB DMA Channel Registers
0x2a0 – 0x2bf	Channel 21 APB DMA Channel Registers
0x2c0 – 0x2df	Channel 22 APB DMA Channel Registers
0x2e0 – 0x2ff	Channel 23 APB DMA Channel Registers
0x300 – 0x31f	Channel 24 APB DMA Channel Registers
0x320 – 0x33f	Channel 25 APB DMA Channel Registers
0x340 – 0x35f	Channel 26 APB DMA Channel Registers
0x360 – 0x37f	Channel 27 APB DMA Channel Registers
0x380 – 0x39f	Channel 28 APB DMA Channel Registers
0x3a0 – 0x3bf	Channel 29 APB DMA Channel Registers
0x3c0 – 0x3df	Channel 30 APB DMA Channel Registers
0x3e0 – 0x3ff	Channel 31 APB DMA Channel Registers

22.2.5.1 APBDMACHAN_CHANNEL_n_CSR_0

APB-DMA-n Control Register

There are 32 APB DMA Channel Control Registers, one per channel (n = 0 through 31).

Writing a 1 to bit [31] of an APB DMA Channel Control Register will initiate the APB DMA transfer. Because this action will depend on some values programmed in the other registers, it is recommended that the registers in the address space in the required APB DMA channel be programmed before writing into the control register.

In "Once" mode, the channel is disabled after the APB DMA transfer has completed. When the channel's transfer completes, an interrupt will be sent if the IE.EOC bit is set. If the transfer requires a trigger or flow, then the corresponding trigger selected by the "TRIG_SEL" or "REQ_SEL" field must become active respectively before the channel can starts its transfer. If both Trigger and Flow bits are set, both conditions must be met before the channel starts each DMA burst.

Offset: 0x0 + (n * 0x20) │ Read/Write: R/W │ Reset: 0x00000000 (0b00000xxxxx00000000000000000000xx)

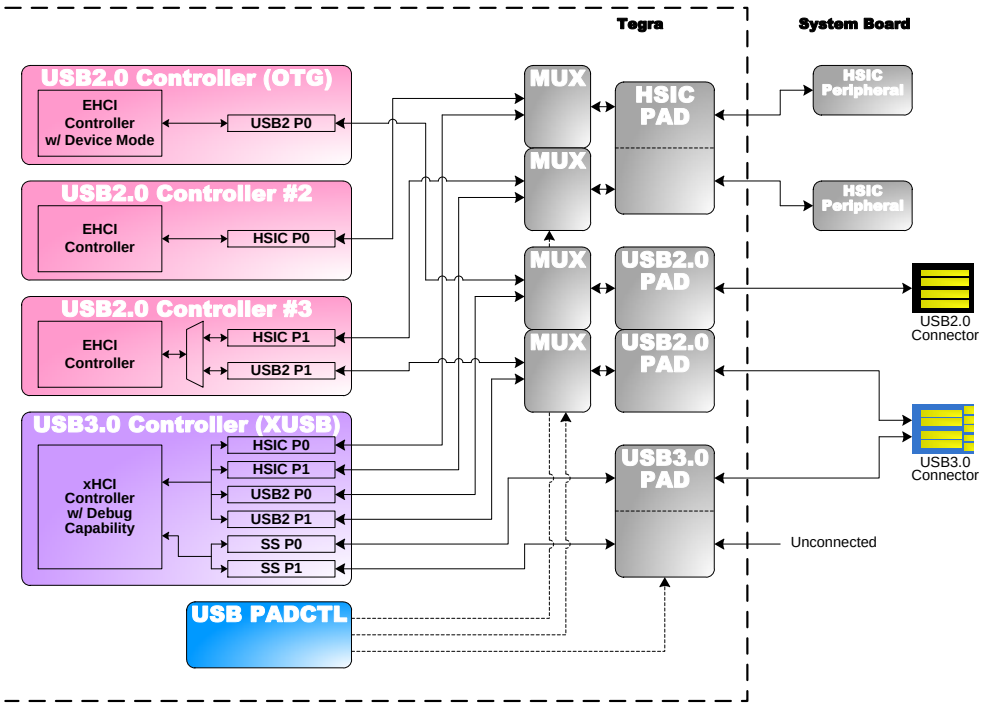
23.0 USB COMPLEX

Note: The ULPI functionality described in this section has been deprecated from Tegra® 4 devices, and is not supported by NVIDIA.

23.1 USB Overview

The Tegra 4 device has four USB controllers (USBOTG, USB2, USB3, and XUSB) and four USB interfaces (UTMIP, HSIC, HSIC1, and UTMIP1). The following diagram shows the relationship between the different USB controllers and interfaces.

Figure 62: Tegra 4 USB Controllers and Interfaces



Below is a summary of the key components in the USB complex:

- USBOTG and UTMIP: This is the primary USB port that supports OTG. USB recovery is also supported on this interface.
- USB2 and UHSIC: This interface allows connection of an HSIC peripheral/host on the PCB board.
- USB3 and UHSIC1: This interface allows connection of an HSIC peripheral/host on the PCB board.
- USB3 and UTMIP1: This interface allows an additional USB port. The primary purpose of this interface is to support host mode of operation.

On power-on-reset, USB2 defaults to unsupported UTMI mode, and USB3 defaults to UTMI mode.

USBOTG supports 16 bidirectional endpoints in device mode, where USB2 and USB3 should never be advised or programmed to support device mode. Endpoint 0 of USBOTG.is always a bidirectional control endpoint. All other endpoints can be programmed as one of Bulk, Interrupt, Isochronous or Control type in either direction. Control endpoints are always bidirectional and hence to program an endpoint as control type, both IN and OUT directions need to be programmed to control type. Conversely, if an endpoint has either IN or OUT direction programmed to be non-control type, the other direction also

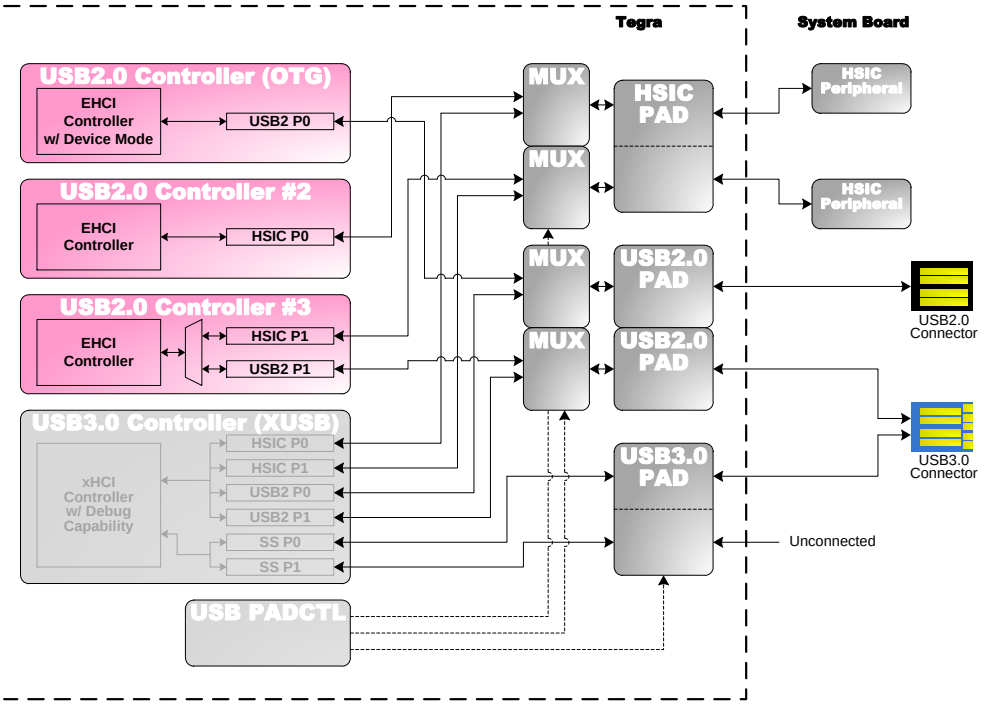
needs to be programmed to be non-control type. The maximum packet size supported on any endpoint is 1024 bytes in high-speed mode, for both device and host modes.

23.2 USB 2.0 Controllers and Interfaces

The USB 2.0 controllers in the Tegra 4 series of processors provide mechanisms for the processor to communicate with a PC as a peripheral or to communicate with USB 2.0 peripherals, such as keyboards, mouse devices, cameras, or storage devices, as a host using regular USB 2.0 ports. The USB 2.0 controllers also provide mechanisms for Tegra 4 devices to communicate with an on-board baseband controller with HSIC or regular interfaces. Each Tegra 4 device provides 3 USB 2.0 controllers with 4 USB interfaces: 2 regular USB ports and 2 HSICs.

The following figure illustrates the connection between USB 2.0 controllers and USB interfaces in a Tegra 4 device, where each USB 2.0 controller can be configured to support 1 USB interface.

Figure 63: Tegra 4 USB 2.0 Controllers and Interfaces



The Tegra 4 device supports peripheral and OTG functionalities with USB 2.0 controller #1, which implements VBUS and ID sensing capabilities and associated interrupt mechanisms to support for device, host, and OTG operations with the regular USB 2.0 port. Tegra 4 devices support battery charging charger detection capabilities and associated interrupt mechanisms that are compliant with USB Battery Charging specification version 1.2 with USB 2.0 controller #1. For both OTG and battery charging, software programming sequences are required to support the operations in response to hardware notifications from USB 2.0 controller #1.

All 3 USB 2.0 controllers support EHCI programming model for scheduling transactions and interface managements as hosts, with each USB 2.0 controller utilizes integrated transaction translator hub to support USB 1.1 transactions when its USB 2.0 interface connects to an USB 1.0 peripheral. USB 2.0 controller #1 supports EHCI-like programming models for scheduling responses to host requests.

Tegra 4 USB 2.0 controllers support L1 and L2 (suspend) link power managements. Tegra 4 USB 2.0 controllers support remote wakeup, wake on connect, wake on disconnect, and wake on overcurrent in all Tegra 4 power states, including deep sleep mode.

23.2.1 USB 2.0 Controller #1

USB 2.0 Controller #1 only connects to USB 2.0 Port #1, which is the primary USB 2.0 port on Tegra 4 devices. USB 2.0 Controller #1 shares the same USB 2.0 Port #1 pins with the USB 3.0 controller. The pinmux must be programmed prior to USB 2.0 Controller #1 using USB 2.0 Port #1.

USB 2.0 Controller #1 supports both USB 2.0 device and USB 2.0 host operations with OTG capabilities. USB recovery is supported only with USB 2.0 Controller #1 and USB 2.0 Port #1.

Wake-up from deep sleep mode is also supported on VBUS and accessory detect (ACCx_DETECT) pins. Power and Ground pins for USB1 and USB3 are shared.

23.2.2 USB 2.0 Controller #2

USB 2.0 Controller #2 must always be configured to Host mode and it can be configured to connect to HSIC Port #1. USB 2.0 Controller #2 can be configured to use HSIC interface that allows connection of an on-board peripheral supporting HSIC interface to Tegra 4 devices. HSIC can be used to support baseband controllers that support the HSIC interface.

23.2.3 USB 2.0 Controller #3

USB 2.0 Controller #3 must always be configured to Host mode, and it can be configured to connect to USB2.0 Port #2 or HSIC Port #2.

USB 2.0 Port

USB 2.0 Controller #3 can be configured to use regular USB 2.0 port. This is the second regular USB 2.0 port on Tegra 4 devices. USB 2.0 Controller #3 shares the same USB 2.0 Port #2 pins with the USB 3.0 controller. The pinmux must be programmed prior to USB 2.0 Controller #1 using USB 2.0 Port #2.

This USB 2.0 port only supports Host mode operations.

HSIC

USB 2.0 Controller #3 can be configured to use the HSIC interface that allows connection of an on-board peripheral supporting an HSIC interface to the Tegra 4 device. HSIC can be used to support baseband controllers that support an HSIC interface.

23.2.4 Interface Restrictions

Regular 2.0 port and HSIC are mutually exclusive for USB 2.0 controller #3, where only one of the interfaces can be used with a given board design.

On power-on-reset, the default interface for USB 2.0 controller #2 is the unsupported UTMIP interface, and the default interface of USB 2.0 controller #3 is regular USB 2.0 port.

23.2.5 AHB Interface

All 3 USB 2.0 controllers adapt AHB interface as masters and slaves for communicating with the other Tegra 4 devices. The following table lists the AHB interface numbers for each controller.

Table 59: AHB Master and Slave Numbers

Controller	AHB Master Number	AHB Slave Number
USB 2.0 Controller #1	6	6
USB 2.0 Controller #2	18	9
USB 2.0 Controller #3	17	11

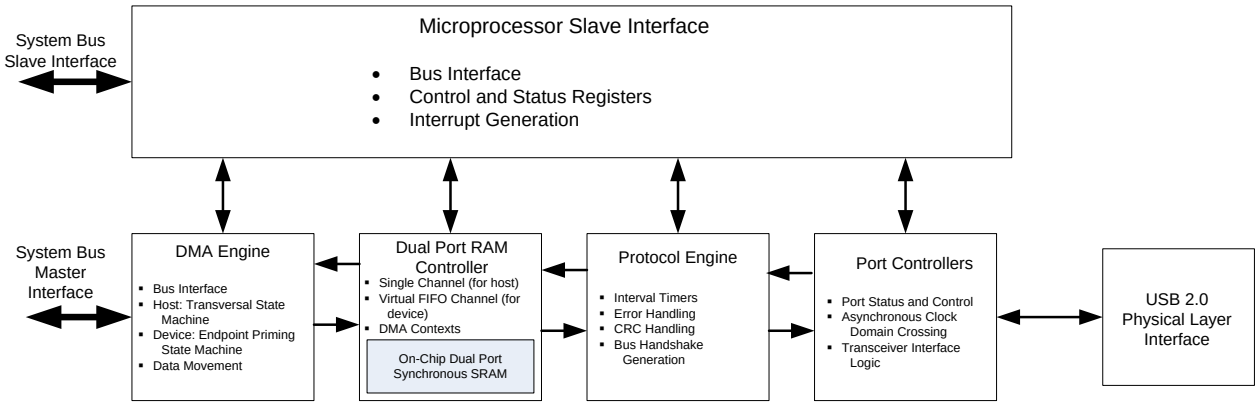
23.3 USB 2.0 Programming Interfaces

All 3 USB 2.0 controllers offer the same functionalities and may be configured to either host or device. However, due to interface restrictions, only USB 2.0 controller #1 should be configured to device mode, while USB 2.0 controller #2 and #3 must always be configured to host mode.

- Host controller registers and data structures are implemented as standard EHCI programming interface.
- Host controller supports USB 1.1 Full and Low speed devices via integrated transaction translator hub through EHCI standard data structures, instead of utilizing companion USB 1.1 host controller.
- Device controller registers and data structures are implemented as extensions to the EHCI programmers interface.

Figure 64 illustrates the control and datapaths block diagram of USB 2.0 controllers.

Figure 64: USB 2.0 Controller Block Diagram



23.3.1 Endpoint Capabilities

USB 2.0 controller #1 supports 16 IN and 16 OUT endpoints in device mode. Endpoint 0 is always a bidirectional control endpoint. All other endpoints can be configured as Bulk, Interrupt, Isochronous or Control endpoints in either direction. Control endpoints are always bidirectional. Hence for a control endpoint, the endpoints in both directions must be configured to be control endpoint. Conversely, if a particular endpoint number has either IN or OUT direction programmed to be a non-control endpoint, the other direction must also be configured as a non-control endpoint.

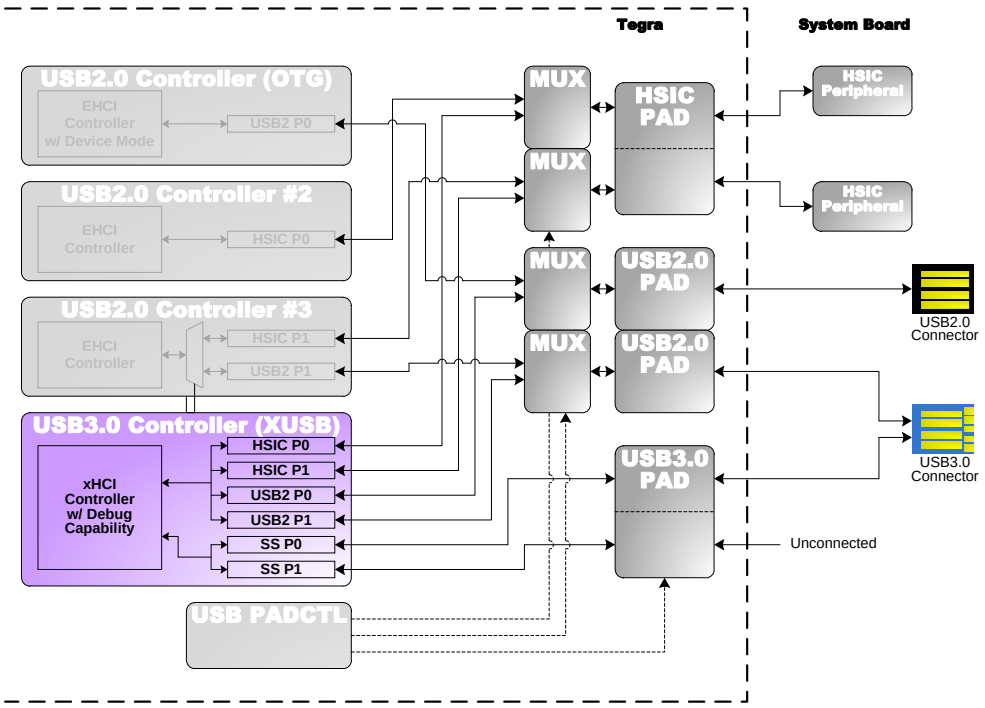
The maximum packet size supported on any endpoint is 1024 bytes in high-speed mode.

23.4 USB 3.0 Controller

The USB 3.0 Controller, also known as XUSB Controller, provides mechanisms for Tegra 4 devices to communicate with USB 2.0 peripherals, such as keyboards, mouse devices, and card readers, and USB 3.0 peripherals, such as cameras and storage devices, as a host using regular USB 3.0 ports. The Tegra 4 device provides 1 USB 3.0 controller that can support up to 2 regular USB 3.0 ports and their companion regular USB 2.0 ports.

The following figure illustrates the connection between USB 3.0 controllers and USB interfaces in Tegra 4 devices, where each USB 3.0 receptacle must encompass 1 USB 3.0 port and 1 USB 2.0 port from the USB 3.0 controller. USB 3.0 Controller shares the same USB 2.0 Port #1 and #2 pins with USB 2.0 controller #1 and #3. The pinmux must be programmed prior to USB 3.0 Controller using USB 2.0 Port #1 or #2.

Figure 65: Tegra 4 USB 3.0 Controller and Interfaces



The USB 3.0 controllers support the xHCI programming model for scheduling transactions and interface managements as a host that natively supports USB 3.0, USB 2.0, and USB 1.1 transactions with its USB 3.0 and USB 2.0 interfaces.

The Tegra 4 USB 3.0 controller supports USB 2.0 L1 and L2 (suspend) link power management and USB 3.0 U1, U2, and U3 (suspend) link power managements. The Tegra 4 USB 3.0 controller supports remote wakeup, wake on connect, wake on disconnect, and wake on overcurrent in all Tegra 4 power states, including deep sleep mode.

USB 2.0 Ports

Each USB 2.0 port operates in USB 2.0 High Speed mode when connecting directly to a USB 2.0 peripheral. Each USB 2.0 port operates in USB 1.1 Full and Low Speed modes when connecting directly to a USB 1.1 peripheral.

All USB 2.0 ports operating in High Speed mode share one High Speed Bus Instance, which means 480 Mb/s theoretical bandwidth is distributed across these ports. All USB 2.0 ports operating in Full or Low Speed modes share one Full/Low Speed Bus Instance, which means 12 Mb/s theoretical bandwidth is distributed across these ports.

USB 2.0 ports of the USB 3.0 controller support software initiated L1 and L2 (suspend) link power management. USB 2.0 ports of the USB 3.0 controller do not support hardware initiated L1 link power management.

USB 3.0 Ports

USB 3.0 ports only operate in USB 3.0 Super Speed mode. All USB 3.0 ports share one Super Speed Bus Instance, which means 5 Gb/s theoretical bandwidth is distributed across these ports.

USB 3.0 ports of the USB 3.0 controller support hardware initiated U1 and U2 link power management as well as software initiate U3 (suspend) link power management.

Falcon Microcontroller

The Tegra 4 USB 3.0 controller integrated an NVIDIA® Falcon microcontroller to perform the following tasks:

- Command ring processing
- Event ring management
- Endpoint scheduling
- Context save and restore

23.4.1 Interface Restrictions

A USB3.0 connector includes both USB2.0 and USB3.0 interface signals. The USB2.0 interface signals of a USB3.0 connector must be assigned to the USB3.0 controller for xHCI specification compliance.

Similarly, if the USB3.0 interface signals are used to connect to a peripheral on the system board, such as a USB3.0 hub, the USB2.0 signals connecting to that peripheral must be assigned to the USB3.0 controller.

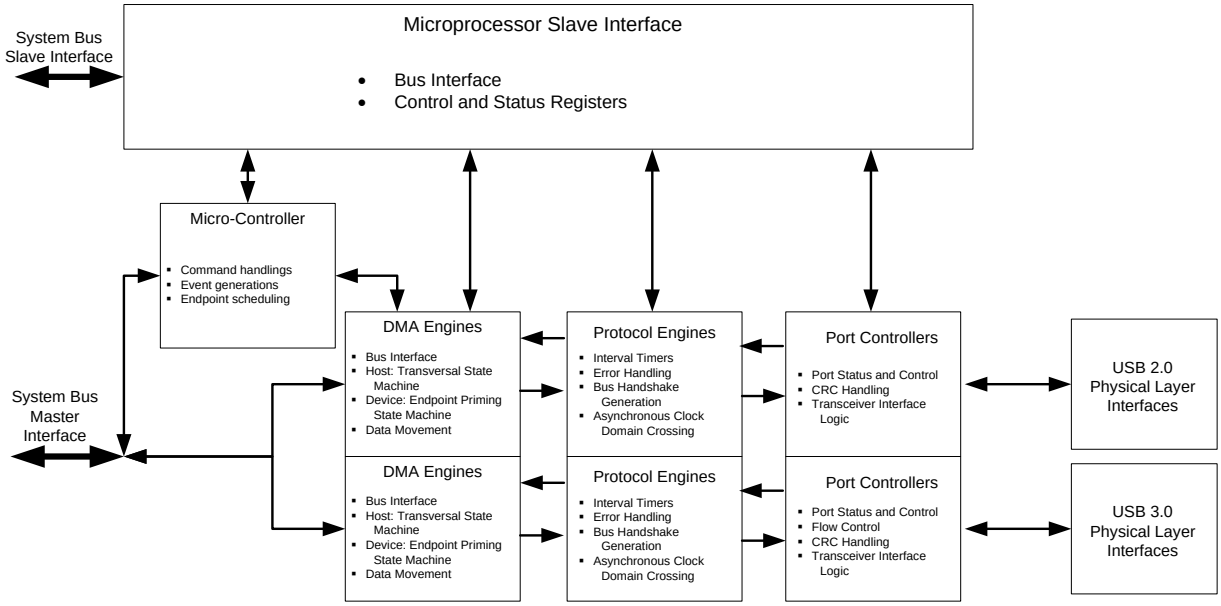
23.4.2 Host and Memory Access Interfaces

USB 3.0 controller adapts the APB interface as its host interface for configuration and memory-mapped I/O register accesses. USB 3.0 controller adapts direct memory as its memory interface for direct memory accesses.

23.5 USB 3.0 Programming Interface

The USB 3.0 Controller supports host functionality with host controller registers and data structures implemented as standard xHCI programming interface. Figure 66 illustrates the control and datapaths block diagram of the USB 3.0 controller.

Figure 66: USB 3.0 Controller Block Diagram



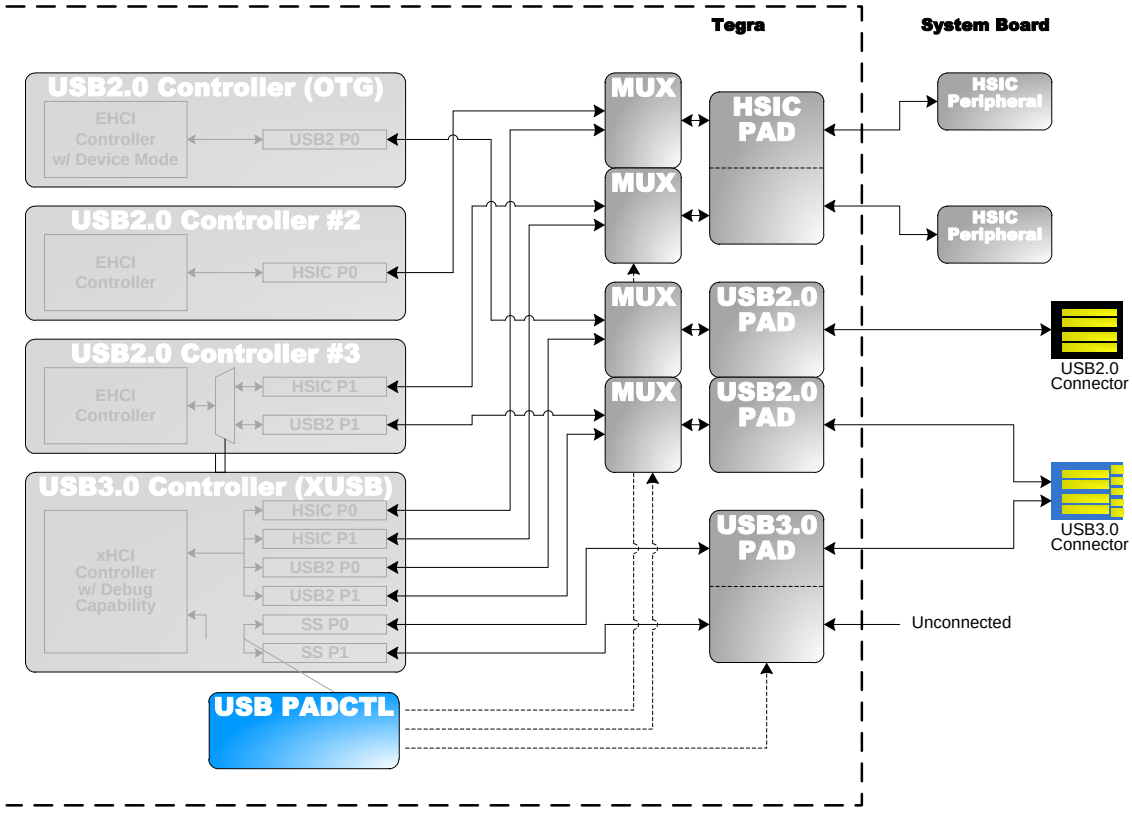
23.6 USB PADCTL

The USB PADCTL in Tegra 4 devices provides the programming interface to assign the USB 2.0 ports to either USB 2.0 controllers or the USB 3.0 controller. The USB PADCTL provides VBUS control and overcurrent mapping for all USB 2.0 controllers and the USB 3.0 controller.

The USB PADCTL also provides the programming interface to configure the pad parameters for the USB 3.0 pad and the USB 2.0 pad for the USB 2.0 port that is assigned to USB 3.0 controller.

The following figure illustrates the connection between USB PADCTL and USB interfaces in a Tegra 4 device.

Figure 67: Tegra 4 USB PADCTL and Interfaces



23.6.1 APB Interface

USB PADCTL adapts the APB interface as its host interface for configuration and memory-mapped I/O register accesses.

23.7 USB 2.0 Programming Guidelines

23.7.1 USB Device/Host Programming

Clock Initialization

After power-on-reset, the USB clocks are disabled. Software can enable the USB clocks by setting CLK_ENB_USBD in CLK_OUT_ENB_L register to ENABLE.

Also, USB stays in reset. So software should bring it out of reset by first setting the SWR_USBD_RST in RST_DEVICES_L register to ENABLE and then setting it to DISABLE.

There are some parameters in UTMIP that need to be programmed before bringing the UTMIP out of reset. Those need to be programmed every time USB is reset. The reset includes SWR_USBD_RST in RST_DEVICES_L register and RST in USB2D_USBCMD register.

After UTMIP is reset, the PHY clock takes some time to come up, so software must wait until the USB_PHY_CLK_VALID bit in the USB_SUSP_CTRL register becomes valid. This bit, if set to 1, also generates an interrupt if RSM_IE is set in the USB_SUSP_CTRL register.

23.7.1.1 ID and VBUS Connection

With Tegra 4 devices, you can use OTG_ID supported by the UTMIP/USB hardware, or use a GPIO for OTG_ID functions. If using an OTG_ID as a GPIO, the GPIO can be sampled to detect the presence of a micro-A or micro-B plug and the sampled value can be written to SW_ID bit in the PHY_VBUS_WAKEUP_ID_0 register. It is recommended that board design connects the OTG_ID pin on the Tegra 4 devices to the ID pin on the micro-AB connector even if the OTG_ID is connected to a GPIO.

Tegra 4 devices have a VBUS pin connected to UTMIP, and the VBUS pin from the connector should be connected to this pin even though VBUS from the connector is connected to a GPIO. It is not required that VBUS from the connector is directly connected to the VBUS pin of the Tegra 4 device. It is required that its voltage is above 3V when VBUS is on.

Both VBUS and ID are available as a wake-up event during DPD/LP0 state. USB bus D+/D- line wake events are also available in DPD/LP0 state. Please consult PMC programming guidelines for further recommendations.

23.7.1.2 Detection of USB Cable Insertion

The USB cable insertion event can be detected by a change in the ID or VBUS pin on the micro-AB connector. Initially, when the cable is not attached, the ID pin on the micro-AB connector is floating and is detected as 1 by the Tegra 4 devices because of the weak pull-up on this pin. This makes the Tegra 4 devices start up as a B-device, even though a cable is not connected (When the ID pin is seen as a 1 by Tegra 4 devices, there can be no-cable or micro-B connected).

When a user attaches the USB cable, one of the following two events occurs:

- The user connects the micro-A end of the cable to Tegra 4 devices. This changes the ID pin to 0. Hence software can detect the ID change and go to A-device mode. Software can then supply power to the USB and places the Tegra 4 devices in host mode.
- The user connects the micro-B (or mini-B) end of the cable to Tegra 4 devices. The other end of the cable can be either micro-A or standard-A and will be connected to a standard host, respectively. For both cases, the Host will start driving power on VBUS and software can detect the cable insertion event by checking the voltage on VBUS has gone above A_Sess_Vld level by reading the A_VBUS_VLD_STS bit in USB_PHY_VBUS_SENSORS register. Once this is seen, it can place the Tegra 4 device in the device mode.

Note: ID change can be detected by enabling the GPIO interrupt.
VBUS change can be detected by enabling the interrupt A_VBUS_VLD_INT_EN in USB_PHY_VBUS_SENSORS register.
USB controller and PHY clocks need not be turned on for this detection.
To detect these events during DPD/LP0 modes, use VBUS/ID wakeup events in the PMC.

23.7.1.3 PHY Clock Control

The PHY clock can be turned off using the SUSP_SET bit in the USB_SUSP_CTRL register. This bit must be pulsed by first writing a 1 and then writing a 0 to the bit.

To turn on the PHY clock, software should write to SUSP_CLR in USB_SUSP_CTRL register. This bit must be pulsed by first writing a 1 and then writing a 0 to the bit.

The current suspend status of the PHY can be checked by reading the bit SUSPENDED in USB_SUSP_CTRL register. If the PHY is placed in suspend, then this bit will be set to 1, else it will be set to 0. Also, if this bit is 1, PHY clock will be turned off and USB_PHY_CLK_VALID in USB_SUSP_CTRL register will be set to 0. If this bit is 0, USB_PHY_CLK_VALID bit can indicate whether the PHY clock is turned on or not.

The PHY clock can be turned on automatically on the events mentioned below. Set only the required wakeup enable bits based on the state of the USB as mentioned below. Do not set unnecessary wakeup enable bits. When the PHY clock wakes up under any such event, make sure that the wakeup enable bits are turned off as soon as possible.

An interrupt is generated whenever the PHY clock is turned on, which can be checked by checking the value of USB_PHY_CLK_VALID in the USB_SUSP_CTRL register to be 1. The interrupt can be enabled/disabled by setting the RSM_IE bit in USB_SUSP_CTRL to 1/0.

Note:	The PLLU_ENABLE bit in PLLU_BASE register should be always set to ENABLE. All the parameters for PLLU in PLLU_BASE and PLLU_MISC register should be set according to the oscillator frequency used. Not doing that will put the USB PHY PLL in a free-running mode, and can result in undesirable side effects. When the USB PHY is suspended, the PCLK should not be stopped. It can be reduced to 32 KHz, however. If the system clock is stopped, then it may not be possible to bring up the system on a wakeup event described below.

There are two cases to consider for controlling the PHY clocks.

Device Mode

The PHY clock can be turned off in two cases:

- When the USB cable is not connected
- When the USB Host puts the USB bus in suspend mode

When the USB cable is not connected, the VBUS signal is 0. In this case, the software needs to turn on the PHY clock on cable insertion. Follow the procedure described above in “Detection of USB Cable Insertion.”

When the USB cable is connected, the PHY clock can only be turned off when the bit SLI in USB2D_USBSTS register is set to 1 when the USB Host puts the USB bus in suspend mode. This bit can be used to generate an interrupt if the bit SLE in USB2D_USBINTR register if set to 1. In this case, software needs to set two bits in the USB_SUSP_CTRL register to turn on the PHY clock on a USB resume or a USB reset event from USB Host: WAKE_ON_DISCON_EN: Wake on Disconnect enable, and WK_RSM_EN - Wake on Resume enable.

If WK_RSM_EN (bit 8) in USB_SUSP_CTRL register is set to 1, the PHY clock can be turned on automatically on receiving USB resume event from USB Host. If WAKE_ON_DISCON_EN in USB_SUSP_CTRL register is set to 1, the PHY clock can be turned on automatically on receiving USB reset event from USB Host or if the USB cable is disconnected. These bits should only be turned on after the PHY clock is turned off. The method described above can be used to interrupt the processor when the PHY clock is turned on. Also, turn off these bits when coming out of suspend.

Host Mode

When a device is not connected, software can set the WKCN bit in USB2D_PORTSC1 register. Make sure that VBUS is also turned on. After this, it can stop the PHY clock by using the method described above. The PHY clock will resume automatically when a device is connected. The method described above can be used to interrupt the processor when the PHY clock is turned on.

With a device connected, software needs to put the USB system under suspend by setting the SUSP bit in the USB2D_PORTSC1 register. It needs to wait until this bit is set to 1 by the controller to make sure that the USB system actually went into suspend. It can enable WK_RSM_EN in the USB_SUSP_CTRL register and WK_DS in the USB2D_PORTSC1 register. Then it can stop the PHY clock as described above. The PHY clock will be turned on automatically if the USB device disconnects or it does a remote wakeup signaling. There will be an interrupt associated with this as described above.

If the software wants to wakeup USB system, then it needs to turn on the PHY clock as described above.

23.7.1.4 Charger Detection 1 (Non-compliant Chargers)

There can be 4 conditions for the different non-compliant chargers: SE1, FS-PU, LS-PU, SE0. You can have some hooks in software so that you can support any non-compliant charger by following the generic procedure below:

1. VBUS detection (by whatever means software does it; it does not matter)

2. Enable USB controller and PHY power and clocks

3. Wait until PHY_CLKVALID = 1.

4. Wait for 10 microseconds more. This gives time for any filtering to pass through so software does not read the wrong values.

5. Read the LS bits [11:10] in the PORTSC register.

- Case 1: LS = 2'b11: connected to charger_1.
- Case 2: LS = 2'b01: connected to charger_2.
- Case 3: LS = 2'b10: connected to charger_3.
- Case 4: LS = 2'b00: connected to either charger_4 or a PC host.

6. For case 1, 2, or 3, enable charging current as per that charger requirement. This could be different for every implementation.

7. For case 4, either you are connected to PC host or a charger_4 (which could be USB compliant charger as well). Go to step 10.

8. You can set the USB circuit on the Tegra 4 device to low-power mode now. Make sure the charger circuit does not change state.

9. VBUS disconnect. Go back to step 1.

10. Check if you are connected to a USB compliant charger by doing the charger detection from VBAT register. If yes, go back to step 8. If no, go to the next step.

11. Try to set the USB controller to device mode and enable by setting it to RUN mode. Wait for SOF.

12. If you do not see SOF after timeout, then you are connected to charger_4. Set the current limit as required for that charger. Go to Step 7.

23.7.1.5 Charger Detection 2 (Compliant Chargers)

This replaces step 10 from the previous section.

1. Make sure UTMIP_PD_CHRG in UTMIP_BAT_CHRG_CFG0 register is set to 0, so that charger detection circuit is on.

   Set the other register bits in UTMIP_BAT_CHRG_CFG0 register to the following values:

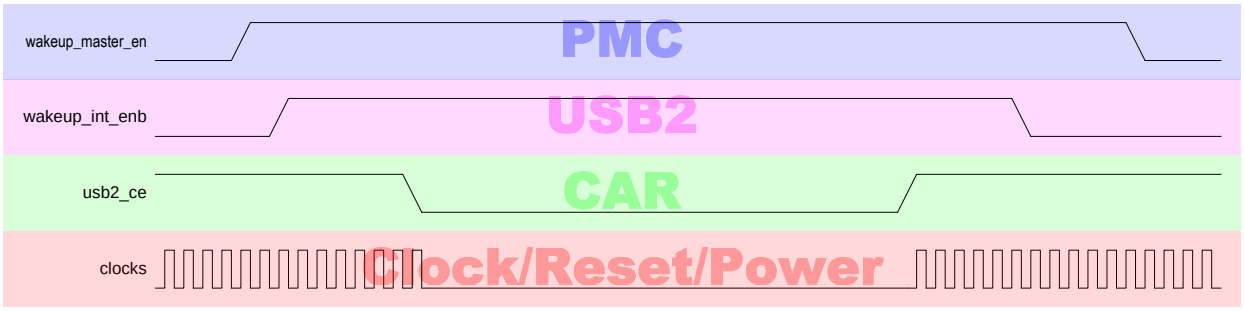
   - UTMIP_OP_I_SRC_EN = 1
2. Wait for about 10 microseconds to allow the battery charger detector to settle.
3. Now check the following bits in the register USB_PHY_VBUS_WAKEUP_ID.
   - VDCD_DET_CHG_DET bit is set, and VDCD_DET_STS indicates 1. Then you are connected to a USB compliant charger.
4. Set the registers bits in UTMIP_BAT_CHRG_CFG0 register to the following values:
   - UTMIP_OP_I_SRC_EN = 0
5. Set the other register bits in UTMIP_BAT_CHRG_CFG0_0 register to the following values:
   - UTMIP_OP_SRC_EN = 1
   - UTMIP_ON_SINK_EN = 1
   - UTMIP_OP_SINK_EN = 0

- UTMIP_ON_SRC_EN = 0

6. Wait for about 10 microseconds to allow the battery charger detector to settle.
7. Now check the following bits in the register USB_PHY_VBUS_WAKEUP_ID.
   - VDAT_DET_CHG_DET bit is set, and VDAT_DET_STS indicates 1. Then you are connected to a USB compliant charger.
8. If it is not set, then we are connected to a PC host.
9. Set the registers bits in UTMIP_BAT_CHRG_CFG0_0 register to the following values:
   - UTMIP_OP_SRC_EN = 0
   - UTMIP_ON_SINK_EN = 0
   - UTMIP_OP_SINK_EN = 0
   - UTMIP_ON_SRC_EN = 0
10. Now normal USB operation can continue if connected to PC host.

23.7.1.6 Controller Clock Gating

USB2 controllers support controller clock gating, where the port wakeup events are detected via the PMC sleepwalk logic. The following figure illustrates the signal sequences to enable USB2 controller clock gating wake event detection before its clocks are gated.



Enable Controller Clock Gating

Step 1

The System Power Management driver programs the PMC USB2.0 sleepwalk logic. This driver should enable the wake events according to the port states and Wake-on-Connect, Wake-on-Disconnect, and Wake-on-Over-Current settings of the USB2 ports accordingly.

> **Note:** The line wakeup event from the PMC is shared between the XUSB and USB2 controllers. There is no per controller masking for the line wake-up event, and when the sleepwalk logic triggers the event, both XUSB and USB2 controllers log the status even when they are not power gated or clock gated. Thus the system power management driver should ensure the wake status is cleared before enabling the sleepwalk logic.

Step 2

The System Power Management driver enables the USB2 controller wakeup interrupt.

Set the following USB2 register bits to '1' to enable the interrupt:

- USB2_UTMIP_PMC_WAKEUP0_0[UTMIP_LINE_WAKEUP_EVENT_INT_ENB] for USB2 #1
- UHSIC_PMC_WAKEUP0_0[UHSIC_LINE_WAKEUP_EVENT_INT_ENB] for USB2 #2

- UTMIP_PMC_WAKEUP0_0[UTMIP_LINE_WAKEUP_EVENT_INT_ENB] for USB2 #3
- UHSIC_PMC_WAKEUP0_0[UHSIC_LINE_WAKEUP_EVENT_INT_ENB] for USB2 #3

Step 3

The System Power Management driver disables the USB2 controller clocks.

Set the following CAR register bits to '1' to disable the clocks:

- CLK_RST_CONTROLLER_CLK_ENB_L_CLR_0[CLR_CLK_ENB_USBD] for USB2 #1
- CLK_RST_CONTROLLER_CLK_ENB_H_CLR_0[CLR_CLK_ENB_USB2] for USB2 #2
- CLK_RST_CONTROLLER_CLK_ENB_H_CLR_0[CLR_CLK_ENB_USB3] for USB2 #3

Step 4

The System Power Management driver puts UTMIPLL to IDDQ if all non-HSIC USB2.0 ports are assigned to USB2 controllers, and all these controllers are in reset or suspend states.

Set the following CAR register bit to '1' to put the PLL to IDDQ:

- CLK_RST_CONTROLLER_UTMIPLL_HW_PWRDN_CFG0_0[UTMIPLL_IDDQ_OVERRIDE_VALUE]

The System Power Management driver puts UTMIPLL IDDQ to under hardware control when some, but not all, non-HSIC USB2.0 ports are assigned to USB2 controllers, and all of these controllers are in reset or suspend states.

Set the following CAR register bits to '0' to enable UTMIPLL IDDQ hardware control:

- CLK_RST_CONTROLLER_UTMIPLL_HW_PWRDN_CFG0_0[UTMIPLL_IDDQ_PD_INCLUDE]
- CLK_RST_CONTROLLER_UTMIPLL_HW_PWRDN_CFG0_0[UTMIPLL_IDDQ_SWCTL]

Disable Controller Clock Gating

Step 1

The System Power Management driver brings UTMIPLL out of to IDDQ when all non-HSIC USB 2.0 ports are assigned to USB2 controllers and any these controllers are exiting reset or suspend states.

Set the following CAR register bit to '0' to put the PLL out of IDDQ:

- CLK_RST_CONTROLLER_UTMIPLL_HW_PWRDN_CFG0_0[UTMIPLL_IDDQ_OVERRIDE_VALUE]

The System Power Management driver puts UTMIPLL IDDQ to under software control when some, but not all, non-HSIC USB 2.0 ports are assigned to USB2 controllers, and any of these controllers are exiting reset or suspend states.

Set the following CAR register bits to '1' to disable IDDQ HW control:

- CLK_RST_CONTROLLER_UTMIPLL_HW_PWRDN_CFG0_0[UTMIPLL_IDDQ_PD_INCLUDE]
- CLK_RST_CONTROLLER_UTMIPLL_HW_PWRDN_CFG0_0[UTMIPLL_IDDQ_SWCTL]

Step 2

The System Power Management driver enables the USB2 controller clocks.

Set the following USB2 register bits to '1' to enable the clocks:

- CLK_RST_CONTROLLER_CLK_ENB_L_SET_0[SET_CLK_ENB_USBD] for USB2 #1
- CLK_RST_CONTROLLER_CLK_ENB_H_SET_0[SET_CLK_ENB_USB2] for USB2 #2
- CLK_RST_CONTROLLER_CLK_ENB_H_SET_0[SET_CLK_ENB_USB2] for USB2 #3

Step 3

The System Power Management driver disables the USB controller wake-up interrupt.

Set the following USB2 register bits to '0' to disable the interrupt:

- USB2_UTMIP_PMC_WAKEUP0_0[UTMIP_LINE_WAKEUP_EVENT_INT_ENB] for USB2 #1
- UHSIC_PMC_WAKEUP0_0[UHSIC_LINE_WAKEUP_EVENT_INT_ENB] for USB2 #2
- UTMIP_PMC_WAKEUP0_0[UTMIP_LINE_WAKEUP_EVENT_INT_ENB] for USB2 #3
- UHSIC_PMC_WAKEUP0_0[UHSIC_LINE_WAKEUP_EVENT_INT_ENB] for USB2 #3

Step 4

The System Power Management driver programs the PMC USB 2.0 sleepwalk logic to disable the sleepwalk logic.

23.7.2 LPM Support

Software should program the following register to set the duration the host keeps generating resume signaling when the host initiated exit from L1 based on system and device specific requirements:

USB2_CONTROLLER_USB2D_USBCMD_0.HIRD

The Errata to USB2 LPM renamed the field to BESL and revised the encoding value to extend the duration of host generated resume signaling that allows the device more time to wake up from deeper low power states. The hardware design is not revised to support these errata, where the following software walk-around is required to extend the resume signaling if required.

1. Move PAD out of Suspend

   USB1_IF_USB_SUSP_CTRL_0.USB_SUSP_CLR = SET (1)

2. Fake resume signaling

   USB3_UTMIP_MISC_CFG0_0.UTMIP_DPDM_OBSERVE = 1

   USB3_UTMIP_MISC_CFG0_0.UTMIP_DPDM_OBSERVE_SEL = 0xE

3. Wait required time following the encoding of the HIRD value in the errata
4. Enable hardware to drive the resume signaling

   USB2_CONTROLLER_USB2D_PORTSC1_0.FPR = Resume driven on port (1)

5. Disable fake resume signaling as hardware takes over

   USB3_UTMIP_MISC_CFG0_0.UTMIP_DPDM_OBSERVE = 0

6. Wait hardware finished driving resume signaling by check

   USB2_CONTROLLER_USB2D_PORTSC1_0.FPR = No resume driven on port (0)

7. Wait 50 µs
8. Enable hardware to start sending SOF and executing schedule

   USB2_CONTROLLER_USB2D_USBCMD_0.RS = RUN (1)

23.7.2.1 Software Initiated L1 Support

Software puts the bus to L1 or Suspend (L2) by setting the same SUSP bit in PORTSC1 register. The difference is to put the link to L1, software should first program the following registers:

USB2_CONTROLLER_USB2D_PORTSC1_0.DA = N, Device Address of the attached device

USB2_CONTROLLER_USB2D_HOSTPC1_DEVLC_0. EPLPM = 0

USB2_CONTROLLER_USB2D_PORTSC1_0.SLP = Suspend using L1 (1)

Software should then set the following register to initiate L1 entry

USB2_CONTROLLER_USB2D_PORTSC1_0.SUSP = 1

Software could check the following registers to ensure the link has entered L1

USB2_CONTROLLER_USB2D_PORTSC1_0.SUSP = Port in suspend state (1)

USB2_CONTROLLER_USB2D_PORTSC1_0.SSTS = L1STATE_ENTERED (0)

If L1 cannot be entered successfully, the bus would stay in L0. Hardware would generate port change interrupt when L1 entry failed, where software could check the following registers for the reason or the failed entry. Software could retry the L1 entry in a later time if the reason is NYET_PERIPH, where the peripheral indicates it's not ready to put the bus to L1.

USB2_CONTROLLER_USB2D_PORTSC1_0.SUSP = Port not in suspend state (0)

USB2_CONTROLLER_USB2D_PORTSC1_0.SSTS = NYET_PERIPH (1), or

= L1STATE_NOT_SUPPORTED (2),

= PERIPH_NORESP_ERR (3),

When the bus is in the L1 state, software could set the following register at any time to bring the link back to L0.

USB2_CONTROLLER_USB2D_PORTSC1_0.FPR = Resume driven on port (1)

23.7.2.2 Hardware Initiated L1 Support

Software could enable hardware to put the bus to L1 automatically. Software should first program the following registers, where X is the system specific idle threshold measured in number of SOFs with no activities in between:

USB2_CONTROLLER_USB2D_PORTSC1_0.DA = N, Device Address of the attached device

USB2_CONTROLLER_USB2D_HOSTPC1_DEVLC_0. EPLPM = 0

USB2_CONTROLLER_USB2D_HOSTPC1_DEVLC_0. LPMFRM = X.

Software should then set the following register to enabled hardware initiated L1 entry

USB2_CONTROLLER_USB2D_HOSTPC1_DEVLC_0. LPMX = 1

23.7.3 USB 2.0 Programming Sequence

The USB 2.0 controller supports the UHSIC interface. This interface is directly controlled through the USB2 register space.

23.7.3.1 Clock Initialization

After power-on-reset, USB2 clocks are disabled. Software can enable USB2 clocks by setting CLK_ENB_USB2 in CLK_RST_CLK_OUT_ENB_H register to ENABLE.

Also, USB2 stays in reset at power-on and software should bring it out of reset by first setting the SWR_USB2_RST bit in the RST_DEVICES_H register to ENABLE and then setting it to DISABLE.

After the clocks for USB2 are up, software can program any registers for USB2 required for proper configuration.

PLLU outputs a 480 MHz clock FO_UHSIC for the UHSIC interface. If using any of these interfaces, PLLU should be programmed appropriately.

Any time after USB2 is reset or the UHSIC PHY comes out of suspend, software needs to wait until the UHSIC PHY clock comes up. It can do that by checking the USB_PHY_CLK_VALID bit in USB2_IF_USB_SUSP_CTRL register. If this bit is 1, PHY clocks are up. There are interrupts associated with this bit: if USB_PHY_CLK_VALID_INT_ENB is set to ENABLE, USB_PHY_CLK_VALID_INT_STS will be set to SET whenever the PHY clock becomes valid. Software can write a 1 to USB_PHY_CLK_VALID_INT_STS to clear the interrupt status.

Before doing anything useful on USB2, one of its interfaces needs to be selected and configured.

23.7.3.2 Selection of UHSIC Interface

1. UHSIC I/O pad is in power-down state at power-on. Bring it out of power-down mode by writing PD_BG, PD_TX, PD_TRK, PD_RX, PD_ZI and RPD_DATA, RPD_STROBE fields in UHSIC_PADS_CFG1 register to 0.
2. Bring the tracking circuit out of power-down mode by clearing the PD_TRK bit.
3. Add a 25 µs delay to allow the calibration to complete.
4. Power down the tracking circuit by setting PD_TRK to 1.
5. Hold UHSIC In reset by writing 1 to UHSIC_RESET field in USB2_IF_USB_SUSP_CTRL register.
6. Program the PLLU parameters to enable UHSIC PLLU clock.
7. Select UHSIC interface by writing 1 to UHSIC_PHY_ENB field in USB2_IF_USB_SUSP_CTRL register.
8. Program the configuration parameters for UHSIC.
9. Release reset to UHSIC by writing 0 to UHSIC_RESET field in USB2_IF_USB_SUSP_CTRL register.
10. Set CM field in USB2D_USBMODE register to HOST mode.
11. Program the USB2 controller to use UHSIC PHY by writing 0 to PTS field in USB2_CONTROLLER_1_USB2D_HOSTPC1_DEVLC register.
12. Program the UHSIC_HS_POSTAMBLE_OUTPUT_ENABLE field in the UHSIC_TX_CFG0 register to “1”.
13. Wait until the PHY clock comes up by checking for the USB_PHY_CLK_VALID bit in the USB2_IF_USB_SUSP_CTRL register. Interrupt can be generated as explained above.

There is no VBUS or ID detection required for this interface because the UHSIC does not have these pins.

23.7.3.3 PHY Clock Control

The PHY clock can be turned off by writing 1 to the bit PHCD in USB2D_PORTSC1 register.

> **Note:** There is no need to pulse this bit as opposed to the USB1 (USBOTG) controller.

To turn on the PHY clock, software should write to USB_SUSP_CLR in USB2_IF_USB_SUSP_CTRL register. This bit must be pulsed by first writing a 1 and then writing a 0 to the bit.

Whenever the PHY is placed in suspend, PHY clock will be turned off and USB_PHY_CLK_VALID in USB2_IF_USB_SUSP_CTRL register will be set to 0. Software should make sure that PHY clock shuts down by polling this bit whenever it places the PHY into suspend. Software should make sure that PHY clock shuts down by polling this bit whenever it places the PHY into suspend.

The PHY clock can be turned on automatically on the events mentioned below. Set only the required wakeup enable bits based on the state of the USB as mentioned below. Do not set unnecessary wakeup enable bits. When the PHY clock wakes up under any such event, make sure that the wakeup enable bits are turned off as soon as possible.

To prevent the PHY clock from waking up on unnecessary glitches on the USB pins, software can set the USB_WAKEUP_DEBOUNCE_COUNT field in USB_SUSP_CTRL register to a non-zero value (between 1-7). This will allow the wakeup event to be debounced by the equivalent number of HCLK cycles.

An interrupt is generated whenever PHY is woken up from suspend, which can be verified by checking that the value of USB_WAKEUP_INT_STS in USB_SUSP_CTRL register is 1. The interrupt can be enabled/disabled by setting the bit USB_WAKEUP_INT_ENB in USB_SUSP_CTRL to 1/0.

An interrupt is generated whenever PHY clock is turned on, which can be verified by checking that the value of USB_PHY_CLK_VALID_INT_STS in USB_SUSP_CTRL register is 1. The interrupt can be enabled/disabled by setting the bit USB_PHY_CLK_VALID_INT_ENB in USB_SUSP_CTRL to 1/0.

To clear the interrupts USB_WAKEUP_INT_STS and USB_PHY_CLK_VALID_INT_STS, software can write a 1 to corresponding bits.

Generally, whenever PHY is woken up from suspend, first wakeup event is generated (USB_WAKEUP_INT_STS = 1) followed by PHY clock valid interrupt (USB_PHY_CLK_VALID_INT_STS = 1) when the PHY clock starts up.

When a device is not connected, software can set the WKCN bit in USB2D_PORTSC1 register. Make sure that VBUS is also turned on. After this, it can stop the PHY clock by using the method described above. The PHY clock will resume automatically when a device is connected. The method described above can be used to interrupt the processor when the PHY clock is turned on.

With a device connected, software needs to put the USB system under suspend by setting the bit SUSP in USB2D_PORTSC1 register. It needs to wait until this bit is set to 1 by the controller to make sure that the USB system actually went into suspend. It can enable the bits USB_WAKE_ON_RESUME_EN in USB2_IF_USB_SUSP_CTRL register and WK_DS in USB2D_PORTSC1 register. Then it can stop the PHY clock as described above. The PHY clock will be turned on automatically if the USB device disconnects or it does a remote wakeup signaling. There will be an interrupt associated with this as described above.

If the software wants to wake up the USB system, then it needs to turn on the PHY clock as described above.

23.7.3.4 Bus Signaling Procedure Changes for the UHSIC Interface

To support the UHSIC interface, some changes are required in the bus signaling procedure for USB2 controller (connect and bus reset sequences). These are described in the subsections below:

Host Mode - Bus Connect Sequence

The normal connect sequence assumes that port power has been enabled on a downstream port and the device has signaled a “Connect” on the bus. This will generate a port change interrupt and the software takes action from here. Standard EHCI connect interrupt can be used to detect the device connect.

Host Mode: Bus Reset Sequence

This is not the standard connect but rather a reconnect procedure without physically detaching the USB cable. This operation is demanded by software whenever it is necessary as it is the case when an unrecoverable anomaly takes place. It would then bring the bus, the port and the device into a well-known state.

1. Check if PortReset (PR bit in USB2D_PORTSC1 register) is NOT active – If by any means a bus reset is already taking place it must be stopped before proceeding. This is done by clearing the bit and polling until it goes LOW;
2. Enable the “PortReset” bit - Start the HSIC bus reset on a downstream port by activating the PR bit of the USB2D_PORTSC1 register;
3. Wait until the end of the reset – This wait time is defined by USB 2.0 spec and has the effect of holding the reset signaling on the HSIC bus;

4. Clear the PR bit – Stop the reset signaling by clearing the respective port reset bit;
5. Poll until the reset bit goes LOW – It is advised to guarantee that the reset bit is effectively cleared;
6. Poll until LineState is DPlus – This confirms that the reset signaling has really finished on the HSIC bus and that the USB2 controller is ready to connect again;
7. Proceed with step 2 of the “HOST Bus Connect Sequence” as described above. From here on, the procedure is the same as with an initial connect, instructing the USB2 controller to enter HS directly, skipping speed negotiation.
8. Standard EHCI reset interrupt can be used in Tegra 4 HSIC as native HSIC support in-built.

23.7.4 USB3 Programming Sequence

USB3 controller supports ICUSB and UTMIP3 interfaces. All of these interfaces are directly controlled through USB3 register space.

23.7.4.1 Clock Initialization

After power-on-reset, USB3 clocks are disabled. Software can enable USB3 clocks by setting CLK_ENB_USB3 in ARCLK_RST_CLK_OUT_ENB_H register to ENABLE.

Also, USB3 stays in reset at power-on and software should bring it out of reset by first setting SWR_USB3_RST in RST_DEVICES_H register to ENABLE and then set it to DISABLE.

After the clocks for USB3 are up, software can program any registers for USB3 required for proper configuration.

PLLU outputs a 60 MHz clock FO_ICUSB for ICUSB interface and a 12 MHz clock FO_USB for UTMIP3 interface. If using any of these interfaces, PLLU should be programmed appropriately.

After anytime USB3 is reset, or ICUSB/UTMIP3 PHY comes out of suspend, software needs to wait until ICUSB/UTMIP3 PHY clock comes up. It can do that by checking for USB_PHY_CLK_VALID bit in USB3_IF_USB_SUSP_CTRL register. If this bit is 1, PHY clocks are up, else they are not. There are interrupts associated with this bit: if USB_PHY_CLK_VALID_INT_ENB is set to ENABLE, USB_PHY_CLK_VALID_INT_STS will be set to SET whenever PHY clock becomes valid. Software can write a 1 to USB_PHY_CLK_VALID_INT_STS to clear the interrupt status.

Before doing anything useful on USB2, one of its interfaces needs to be selected and configured.

23.7.4.2 Selection of UTMIP3 Interface

1. UTMIP1 I/O pads are in power-down state at power-on. Bring them out of power-down mode by writing the following fields to 0:
2. FORCE_PD_POWERDOWN, FORCE_PD2_POWERDOWN, FORCE_PDZI_POWERDOWN fields in UTMIP_XCVR_CFG0 register.
3. OTGPD and BIASPD fields in UTMIP_BIAS_CFG0 register.
4. FORCE_PDDISC_POWERDOWN , FORCE_PDCHRP_POWERDOWN, FORCE_PDDR_POWERDOWN field in UTMIP_XCVR_CFG1 register.
5. Hold UTMIP1 PHY in reset by writing UTMIP_RESET bit in USB3_IF_USB_SUSP_CTRL register to 1.
6. Program the PLLU parameters to enable UTMIP3 PLLU clock.
7. Enable UTMIP1 interface by setting UTMIP_PHY_ENB in USB3_IF_USB_SUSP_CTRL register to 1.
8. Program the configuration parameters for UTMIP3.
9. Release reset to UTMIP1 by writing 0 to UTMIP_RESET field in USB3_IF_USB_SUSP_CTRL register.

10. Wait until PHY clock comes up by checking for USB_PHY_CLK_VALID bit in USB3_IF_USB_SUSP_CTRL register. Interrupt can be generated as explained above.
11. Set CM field in USB2D_USBMODE register to HOST mode.
12. Program the USB3 controller to use UTMIP3 PHY by setting the PTS field in USB2_CONTROLLER_2_USB2D_HOSTPC1_DEVLC register to UTMIP (2'b00).

23.7.4.3 Selection of UHSIC Interface

1. UHSIC1 I/O pad is in power-down state at power-on. Bring it out of power-down mode by writing PD_BG, PD_TX, PD_TRK, PD_RX, PD_ZI and RPD_DATA, RPD_STROBE fields in UHSIC_PADS_CFG1 register to 0.
2. Hold UHSIC1 In reset by writing 1 to UHSIC_RESET field in USB3_IF_USB_SUSP_CTRL register.
3. Program the PLLU parameters to enable UHSIC PLLU clock.
4. Select UHSIC interface by writing 1 to UHSIC_PHY_ENB field in USB3_IF_USB_SUSP_CTRL register.
5. Program the configuration parameters for UHSIC.
6. Release reset to UHSIC by writing 0 to UHSIC_RESET field in USB3_IF_USB_SUSP_CTRL register.
7. Set the CM field in the USB2D_USBMODE register to HOST mode.
8. Program the USB3 controller to use UHSIC PHY by writing 0 to PTS field in USB3_CONTROLLER_1_USB2D_HOSTPC1_DEVLC register.
9. Program the UHSIC_HS_POSTAMBLE_OUTPUT_ENABLE field in the UHSIC_TX_CFG0 register to "1".
10. Wait until the PHY clock comes up by checking for USB_PHY_CLK_VALID bit in USB3_IF_USB_SUSP_CTRL register. Interrupt can be generated as explained above.
11. There is no VBUS or ID detection required for this interface because these pins do not exist for UHSIC.

23.7.4.4 Detection of USB Cable Insertion

The USB cable insertion event can be detected by a change in the ID or VBUS pin on the micro-AB connector. Initially, when the cable is not attached, the ID pin on the micro-AB connector is floating and is detected as 1 by Tegra 4 devices because of the weak pull-up on this pin. This makes a Tegra 4 device start up as a B-device, even though a cable is not connected (when the ID pin is seen as a 1 by a Tegra 4 device, there can be no cable or micro-B connected).

When a user attaches the USB cable, one of the following two events occur:

- User connects micro-A end of the cable to the Tegra 4 device. This changes the ID pin to 0. Hence the software can detect the ID change and go to A-device mode. Software can then supply power to the USB and place the Tegra 4 device in host mode.
- User connects micro-B (or mini-B) end of the cable to the Tegra 4 device. The other end of the cable can be either micro-A or standard-A and will be connected to a standard host, respectively.

For both cases, the Host will start driving power on VBUS and software can detect the cable insertion event by checking the VBUS status on corresponding GPIO. Once this is seen, it can place the Tegra 4 device in the device mode.

Note: Both ID and VBUS changes can be detected by enabling the corresponding GPIO interrupts.
USB controller/PHY clocks do not need to be turned on for this detection as this is done using GPIOs.
To detect these events during DPD/LP0 modes, use VBUS/ID wakeup events in the PMC.

23.7.4.5 PHY Clock Control

The PHY clock can be turned off by writing 1 to the PHCD bit in the USB2D_PORTSC1 register.

Note:	There is no need to pulse this bit as opposed to the USB1 (USBOTG) controller.

To turn on the PHY clock, software should write to SUSP_CLR in USB3_IF_USB_SUSP_CTRL register. This bit must be pulsed by first writing a 1 and then writing a 0 to the bit.

The current suspend status of the PHY and thereby whether the PHY clock is running can be checked by reading the bit USB_PHY_CLK_VALID in USB_SUSP_CTRL register. If the PHY is placed in suspend, then this bit will be set to 0, else it will be set to 1. Software should make sure that PHY clock shuts down by polling this bit whenever it places the PHY into suspend.

The PHY clock can be turned on automatically on the events mentioned below. Set only the required wakeup enable bits based on the state of the USB as mentioned below. Do not set unnecessary wakeup enable bits. When the PHY clock wakes up under any such event, make sure that the wakeup enable bits are turned off as soon as possible.

To prevent the PHY clock from waking up on unnecessary glitches on the USB pins, software can set the USB_WAKEUP_DEBOUNCE_COUNT field in USB_SUSP_CTRL register to a non-zero value (between 1-7). This will allow the wakeup event to be debounced by the equivalent number of HCLK cycles.

An interrupt is generated whenever the PHY is woken up from suspend, which can be verified by checking that the value of USB_WAKEUP_INT_STS in USB_SUSP_CTRL register is 1. The interrupt can be enabled/disabled by setting the bit USB_WAKEUP_INT_ENB in USB_SUSP_CTRL to 1/0.

An interrupt is generated whenever PHY clock is turned on, which can be verified by checking that the value of USB_PHY_CLK_VALID_INT_STS in USB_SUSP_CTRL register is 1. The interrupt can be enabled/disabled by setting the bit USB_PHY_CLK_VALID_INT_ENB in USB_SUSP_CTRL to 1/0.

To clear the interrupts USB_WAKEUP_INT_STS and USB_PHY_CLK_VALID_INT_STS, software can write a 1 to the corresponding bits.

Generally, whenever PHY is woken up from suspend, first wakeup event is generated (USB_WAKEUP_INT_STS = 1) followed by PHY clock valid interrupt (USB_PHY_CLK_VALID_INT_STS = 1) when PHY clock starts up.

Note:	The PLLU_ENABLE bit in PLLU_BASE register should be always set to ENABLE. All the parameters for PLLU in PLLU_BASE and PLLU_MISC register should be set according to the oscillator frequency used. Not doing that will put the USB PHY PLL in a free-running mode, and can result in undesirable side-effects. When the USB PHY is suspended, the USB3 clock should not be stopped. It can be reduced to 32 KHz, however. If the system clock is stopped, then it may not be possible to bring up the system on a wakeup event described below. When USB3 is in suspend, AHB clocks to USB3 controller are turned off, and hence there should be no register access to USB2_CONTROLLER_2_* registers. All registers marked as ARUSB3_IF_* are accessible, and can be used to resume the UTMIP3 PHY clocks.

When a device is not connected, software can set the WKCN bit in USB2D_PORTSC1 register. Make sure that VBUS is also turned on. After this, it can stop the PHY clock by using the method described above. The PHY clock will resume automatically when a device is connected. The method described above can be used to interrupt the processor when the PHY clock is turned on.

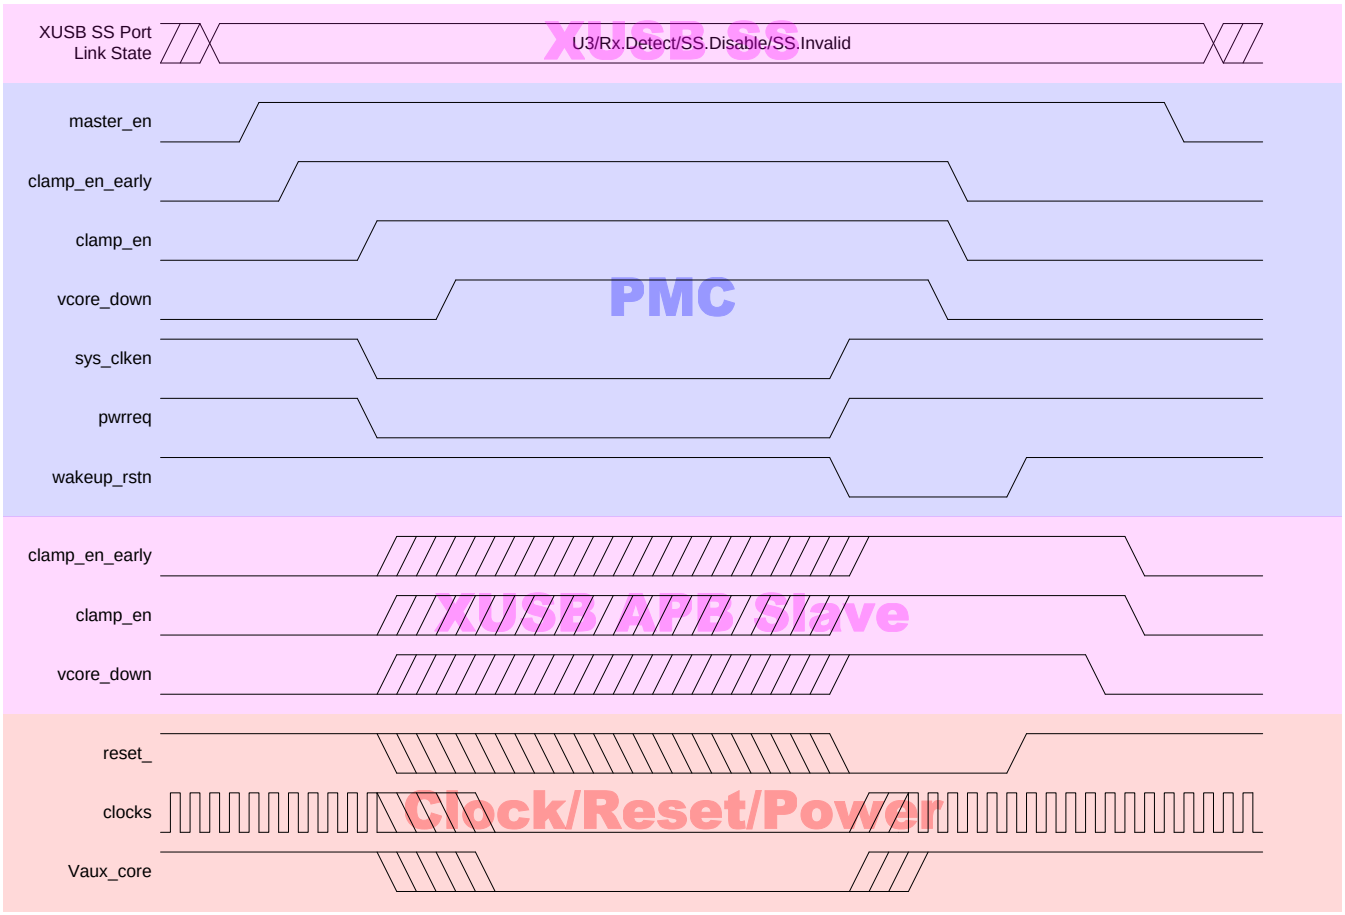
With a device connected, software needs to put the USB system under suspend by setting the bit SUSP in USB2D_PORTSC1 register. It needs to wait until this bit is set to 1 by the controller to make sure that the USB system actually went into suspend. It can enable the bits USB_WAKE_ON_RESUME_EN in USB_SUSP_CTRL register and WK_DS in USB2D_PORTSC1 register. Then it can stop the PHY clock as described above. The PHY clock will be turned on automatically if the USB device disconnects or it does a remote wakeup signaling. There will be an interrupt associated with this as described above.

If the software wants to wake up the USB system, it needs to turn on the PHY clock as described above.

23.7.5 XUSB Controller Power Gating

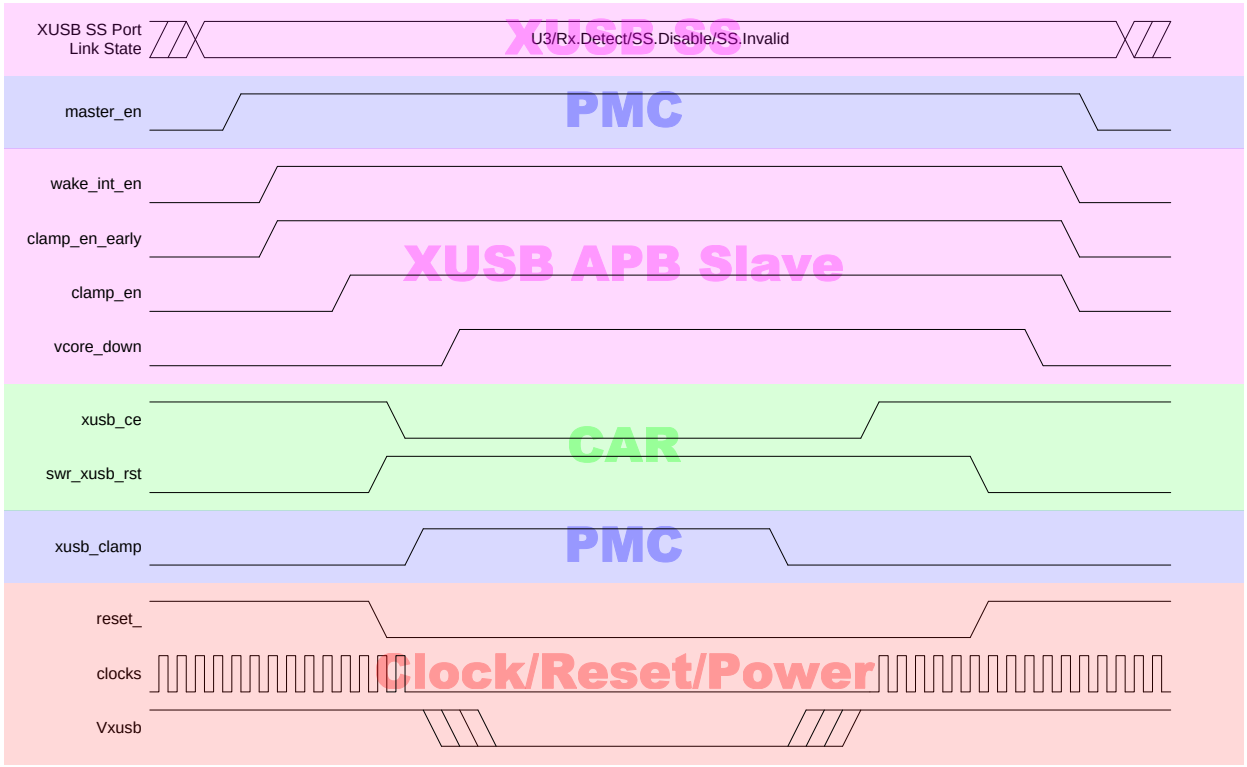
The following figure illustrates the signal sequences from the PMC that are used by XUSB SS Wake logic to enable its wake event detection.

LP0



PMC_1: APBDEV_PMC_UTMIP_UHSIC_SLEEP_CFG_0[UHSIC_MASTER_ENABLE_P0]
APBDEV_PMC_UTMIP_UHSIC_SLEEP_CFG_0[UTMIP_MASTER_ENABLE_P0]
APBDEV_PMC_UTMIP_UHSIC_SLEEP_CFG_0[UTMIP_MASTER_ENABLE_P2]
APBDEV_PMC_UTMIP_UHSIC2_SLEEP_CFG_0[UHSIC_MASTER_ENABLE_P1]
PMC_2: Sequence driven by PMC LP0 state machine

The next figure illustrates the signal sequences from the XUSB PADCTL block that are required to follow the same sequence as from PMC so XUSB SS Wake logic can enable its wake event detection.



XUSB has three partitions that can be selectively power-gated with the following use cases, where unlisted combinations are not supported:

XUSBC (Host/USB2.0)	XUSBB (Device)	XUSBA (SuperSpeed)	Use Case Descriptions
Powered	Powered	Powered	Both Host and Device modes in normal operations, with SuperSpeed links operational.
Powered	Powered	Power Gated	Both Host and Device modes in normal operations, with SuperSpeed links in low power states. SuperSpeed link wake events report through XUSB PADCTL.
Powered	Power Gated	Powered	Host mode in normal operations, with SuperSpeed links operational. Device mode power gated. Device mode SuperSpeed and USB2.0 link wake events report through XUSB PADCTL.
Powered	Power Gated	Power Gated	Host mode in normal operations, with SuperSpeed links in low power states. Device mode power gated. Host Mode SuperSpeed, and Device mode SuperSpeed and USB2.0 link wake events report through XUSB PADCTL.
Power Gated	Power Gated	Power Gated	Both Host and Device modes power gated, with SuperSpeed links in low power states. All Host and Device modes link wake events report through XUSB PADCTL.

23.7.5.1 All Partitions ELPG Entry

Step 1: xHCI driver performs context save operation. xHCI PEP driver performs XUSB_HOST specific context save operation. In case the SuperSpeed partition has already be power gated, xHCI FW and XUSB device mode driver should not save the

context of the SuperSpeed partition again. XUSB device mode driver performs XUSB_DEVICE specific context save operations. xHCI PEP driver and XUSB device mode driver performs XUSB IPFS specific context save operation.

- Read and store the value of the following registers:

  XUSB_{HOST,DEV}_MSI_BAR_SZ_0

  XUSB_{HOST,DEV}_MSI_AXI_BAR_ST_0

  XUSB_{HOST,DEV}_MSI_FPCI_BAR_ST_0

  XUSB_{HOST,DEV}_MSI_VEC0_0

  XUSB_{HOST,DEV}_MSI_EN_VEC0_0

  XUSB_{HOST,DEV}_FPCI_ERROR_MASKS_0

  XUSB_{HOST,DEV}_INTR_MASK_0

  XUSB_{HOST,DEV}_IPFS_INTR_ENABLE_0

  XUSB_{HOST,DEV}_UFPCI_CONFIG_0

  XUSB_{HOST,DEV}_CLKGATE_HYSTERESIS_0

  XUSB_{HOST,DEV}_XUSB_HOST_MCCIF_FIFOCTRL_0

Step 2: System Power Management driver programs the PMC USB2.0 sleepwalk logic for ports assigned to XUSB host mode and XUSB device mode.

System Power Management driver should enable the wake events according to the port states and Wake-on-Connect, Wake-on-Disconnect, and Wake-on-Over-Current settings of the USB2 ports accordingly.

> **Note:** The line wakeup event from PMC is shared between XUSB and USB2 controller. There is no per controller masking for the line wakeup event, and when the sleepwalk logic triggers the event, both XUSB and USB2 will log the status even when they are not power gated or clock gated. Thus the system power management driver should ensure the wake status is cleared before enabling the sleepwalk logic.

Step 3: xHCI PEP driver and XUSB device mode driver enable the XUSB wakeup interrupts for the SuperSpeed and USB2.0 ports assigned to host and device.

- Write ‘1’ to the following XUSB PADCTL register bits to clear the interrupt status.

  XUSB_PADCTL_ELPG_PROGRAM_0[SS_PORT0_WAKEUP_EVENT]

  XUSB_PADCTL_ELPG_PROGRAM_0[SS_PORT1_WAKEUP_EVENT]

  XUSB_PADCTL_ELPG_PROGRAM_0[USB2_PORT0_WAKEUP_EVENT]

  XUSB_PADCTL_ELPG_PROGRAM_0[USB2_PORT1_WAKEUP_EVENT]

  XUSB_PADCTL_ELPG_PROGRAM_0[USB2_HSIC_PORT0_WAKEUP_EVENT]

  XUSB_PADCTL_ELPG_PROGRAM_0[USB2_HSIC_PORT1_WAKEUP_EVENT]

- Set the following XUSB PADCTL register bits to ‘1’ to enable the interrupt.

  XUSB_PADCTL_ELPG_PROGRAM_0[SS_PORT0_WAKE_INTERRUPT_ENABLE]

  XUSB_PADCTL_ELPG_PROGRAM_0[SS_PORT1_WAKE_INTERRUPT_ENABLE]

  XUSB_PADCTL_ELPG_PROGRAM_0[USB2_PORT0_WAKE_INTERRUPT_ENABLE]

  XUSB_PADCTL_ELPG_PROGRAM_0[USB2_PORT1_WAKE_INTERRUPT_ENABLE]

  XUSB_PADCTL_ELPG_PROGRAM_0[USB2_HSIC_PORT0_WAKE_INTERRUPT_ENABLE]

XUSB_PADCTL_ELPG_PROGRAM_0[USB2_HSIC_PORT1_WAKE_INTERRUPT_ENABLE]

> **Note:** The interrupt status bit could also be set due to previous wake events reported for USB2 controllers, thus the status should be cleared before enabling the interrupt.

Step 4: xHCI PEP driver and XUSB device mode driver initiate the signal sequence to enable the XUSB SSwake detection logic for the SuperSpeed ports assigned to host and device.

- Write '1' to the following XUSB PADCTL register bit to assert the clamp_en_early signal.

  XUSB_PADCTL_ELPG_PROGRAM_0[SSP0_ELPG_CLAMP_EN_EARLY]

  XUSB_PADCTL_ELPG_PROGRAM_0[SSP1_ELPG_CLAMP_EN_EARLY]

- Write '1' to the following XUSB PADCTL register bit to assert the clamp_en signal.

  XUSB_PADCTL_ELPG_PROGRAM_0[SSP0_ELPG_CLAMP_EN]

  XUSB_PADCTL_ELPG_PROGRAM_0[SSP1_ELPG_CLAMP_EN]

- Wait 250 µs

> **Note:** These two writes must not be combined.

Step 5: System Power Management driver asserts reset to XUSB then disables its clocks.

- Set the following CAR register bits to '1' to assert reset to XUSB

  CLK_RST_CONTROLLER_RST_DEVICES_U_0[SWR_XUSB_HOST_RST] for host mode

  CLK_RST_CONTROLLER_RST_DEVICES_U_0[SWR_XUSB_DEV_RST] for device mode

  CLK_RST_CONTROLLER_RST_DEVICES_W_0[SWR_XUSB_SS_RST] for SuperSpeed ports

- Set the following CAR register bits to '1' to disable the clocks to individual XUSB partitions.

  CLK_RST_CONTROLLER_CLK_ENB_U_CLR_0[CLR_CLK_ENB_XUSB_HOST] for host mode

  CLK_RST_CONTROLLER_CLK_ENB_U_CLR_0[CLR_CLK_ENB_XUSB_DEV] for device mode

  CLK_RST_CONTROLLER_CLK_ENB_W_CLR_0[CLR_CLK_ENB_XUSB_SS] for SS ports

Step 6: System Power Management driver disables the XUSB power rails.

- Program the following PMC register bits to disable the power rail to XUSB host

  APBDEV_PMC_PWRGATE_TOGGLE_0[START] to 'disable'

  APBDEV_PMC_PWRGATE_TOGGLE_0[PARTID] to 'XUSBB'

- Program the following PMC register bits to disable the power rail to XUSB device

  APBDEV_PMC_PWRGATE_TOGGLE_0[START] to 'disable'

  APBDEV_PMC_PWRGATE_TOGGLE_0[PARTID] to 'XUSBC'

- Program the following PMC register bits to disable the power rail to XUSB SuperSpeed

  APBDEV_PMC_PWRGATE_TOGGLE_0[START] to 'disable'

  APBDEV_PMC_PWRGATE_TOGGLE_0[PARTID] to 'XUSBA'

> **Note:** Only one partition can be power gated at a time.

Step 7: xHCI PEP driver and XUSB device mode driver initiate the signal sequence to enable the XUSB SS wake detection logic for the SuperSpeed ports assigned to host and device.

- Write ‘1’ to the following XUSB PADCTL register bit to assert the vcore_off signal.

  XUSB_PADCTL_ELPG_PROGRAM_0[SSP0_ELPG_VCORE_DOWN]

  XUSB_PADCTL_ELPG_PROGRAM_0[SSP1_ELPG_VCORE_DOWN]

23.7.5.2 SuperSpeed Partition ELPG Entry

Step 1: xHCI FW and XUSB device mode driver perform SuperSpeed port specific context save operation.

Step 2: xHCI PEP driver and XUSB device mode driver enable the XUSB wakeup interrupts for the SuperSpeed and USB2.0 ports assigned to host and device.

Step 3: xHCI PEP driver and XUSB device mode driver initiate the signal sequence to enable the XUSB SSwake detection logic for the SuperSpeed ports assigned to host and device.

Step 4: System Power Management driver asserts reset to XUSB SuperSpeed partition then disables its clocks.

- Set the following CAR register bits to ‘1’ to assert reset to XUSB

  CLK_RST_CONTROLLER_RST_DEVICES_W_0[SWR_XUSB_SS_RST] for SuperSpeed ports

- Set the following CAR register bits to ‘1’ to disable the clocks to individual XUSB partitions.

  CLK_RST_CONTROLLER_CLK_ENB_W_CLR_0[CLR_CLK_ENB_XUSB_SS] for SS ports

Step 5: System Power Management driver disables the XUSB SuperSpeed partition power rails.

- Programming the following PMC register bits to disable the power rail to XUSB SuperSpeed

  APBDEV_PMC_PWRGATE_TOGGLE_0[START] to ‘disable’

  APBDEV_PMC_PWRGATE_TOGGLE_0[PARTID] to ‘XUSBA’

> **Note:** Only one partition can be power gated at a time.

Step 6: xHCI PEP driver and XUSB device mode driver initiate the signal sequence to enable the *XUSB* SS wake detection logic for the SuperSpeed ports assigned to host and device.

23.7.5.3 Device Mode Partition ELPG Entry

Step 1: XUSB device mode driver performs XUSB_DEVICE specific context save operations. XUSB device mode driver performs XUSB IPFS specific context save operation.

Step 2: System Power Management driver programs the PMC USB2.0 sleepwalk logic for ports assigned to XUSB device mode according to the PMC USB Wakeup Document.

System Power Management driver should enable the wake events according to the port states and Wake-on-Connect, Wake-on-Disconnect, and Wake-on-Over-Current settings of the USB2 ports accordingly.

> The line wakeup event from PMC is shared between XUSB and USB2 controller. There is no per controller masking for the line wakeup event, and when the sleepwalk logic triggers the event, both XUSB and USB2 will log the status even when they are not power gated or clock gated. Thus the system power management driver should ensure the wake status is cleared before enabling the sleepwalk logic.

Step 3: XUSB device mode driver enable the XUSB wakeup interrupts for the SuperSpeed and USB2.0 ports assigned to device as described in step 3 of section on “.All Partitions ELPG Entry” above.

Step 4: XUSB device mode driver initiate the signal sequence to enable the XUSB SSwake detection logic for the SuperSpeed ports assigned device as described in step 4 of section on “.All Partitions ELPG Entry” above..

Step 5: System Power Management driver asserts reset to XUSB then disables its clocks.

- Set the following CAR register bits to ‘1’ to assert reset to XUSB

  CLK_RST_CONTROLLER_RST_DEVICES_U_0[SWR_XUSB_DEV_RST] for device mode

- Set the following CAR register bits to ‘1’ to disable the clocks to individual XUSB partitions.

  CLK_RST_CONTROLLER_CLK_ENB_U_CLR_0[CLR_CLK_ENB_XUSB_DEV] for device mode

Step 6: System Power Management driver disables the XUSB power rails.

- Programming the following PMC register bits to disable the power rail to XUSB device

  APBDEV_PMC_PWRGATE_TOGGLE_0[START] to ‘disable’

  APBDEV_PMC_PWRGATE_TOGGLE_0[PARTID] to ‘XUSBC’

> **Note:** Only one partition can be power gated at a time.

Step 7: XUSB device mode driver initiate the signal sequence to enable the XUSB SS wake detection logic for the SuperSpeed ports assigned to device as described in step 7 of section on “.All Partitions ELPG Entry” above..

- Write ‘1’ to the following XUSB PADCTL register bit to assert the vcore_off signal.

  XUSB_PADCTL_ELPG_PROGRAM_0[SSP0_ELPG_VCORE_DOWN]

  XUSB_PADCTL_ELPG_PROGRAM_0[SSP1_ELPG_VCORE_DOWN]

23.7.5.4 All Partitions ELPG Exit

When the wake event is not generated by SuperSpeed ports, the SuperSpeed related programming should be skipped, where the SuperSpeed partition should exit ELPG due to wake events detected by SuperSpeed ports.

Step 1:

- System Power Management driver enables the XUSB power rails. Programming the following PMC register bits to enable the power rail to XUSB host

  APBDEV_PMC_PWRGATE_TOGGLE_0[START] to ‘enable’

  APBDEV_PMC_PWRGATE_TOGGLE_0[PARTID] to ‘XUSBB’

- Programming the following PMC register bits to disable the power rail to XUSB device

  APBDEV_PMC_PWRGATE_TOGGLE_0[START] to ‘enable’

  APBDEV_PMC_PWRGATE_TOGGLE_0[PARTID] to ‘XUSBC’

- Programming the following PMC register bits to disable the power rail to XUSB SuperSpeed

  APBDEV_PMC_PWRGATE_TOGGLE_0[START] to ‘enable’

  APBDEV_PMC_PWRGATE_TOGGLE_0[PARTID] to ‘XUSBA’

> **Note:** Only one partition can be power gated at a time.

Step 2: System Power Management driver enables XUSB clocks.

- Set the following CAR register bits to ‘1’ to enable the clocks to individual XUSB partitions.

  CLK_RST_CONTROLLER_CLK_ENB_U_SET_0[SET_CLK_ENB_XUSB_HOST] for host mode

  CLK_RST_CONTROLLER_CLK_ENB_U_SET_0[SET_CLK_ENB_XUSB_DEV] for device mode

  CLK_RST_CONTROLLER_CLK_ENB_W_SET_0[SET_CLK_ENB_XUSB_SS] for SS ports

Step 3: System Power Management driver deasserts reset to XUSB.

- Set the following CAR register bits to '0' to deassert reset to XUSB:

  CLK_RST_CONTROLLER_RST_DEVICES_U_0[SWR_XUSB_HOST_RST] for host mode

  CLK_RST_CONTROLLER_RST_DEVICES_U_0[SWR_XUSB_DEV_RST] for device mode

  CLK_RST_CONTROLLER_RST_DEVICES_W_0[SWR_XUSB_SS_RST] for SuperSpeed ports

- Wait 1 µs

Step 4: xHCI PEP driver and XUSB device mode driver disables the XUSB SS wakeup interrupts.

- Set the following XUSB PADCTL register bits to '0' to disable the interrupts:

  XUSB_PADCTL_ELPG_PROGRAM_0[SS_PORT0_WAKE_INTERRUPT_ENABLE]

  XUSB_PADCTL_ELPG_PROGRAM_0[SS_PORT1_WAKE_INTERRUPT_ENABLE]

  XUSB_PADCTL_ELPG_PROGRAM_0[USB2_PORT0_WAKE_INTERRUPT_ENABLE]

  XUSB_PADCTL_ELPG_PROGRAM_0[USB2_PORT1_WAKE_INTERRUPT_ENABLE]

  XUSB_PADCTL_ELPG_PROGRAM_0[USB2_HSIC_PORT0_WAKE_INTERRUPT_ENABLE]

  XUSB_PADCTL_ELPG_PROGRAM_0[USB2_HSIC_PORT1_WAKE_INTERRUPT_ENABLE]

Step 5: xHCI PEP driver and XUSB device mode driver initiate the signal sequence to disable the XUSB SS wake detection logic.

- Write '0' to the following XUSB PADCTL register bits to deassert the vcore_off signal:

  XUSB_PADCTL_ELPG_PROGRAM_0[SSP0_ELPG_VCORE_DOWN]

  XUSB_PADCTL_ELPG_PROGRAM_0[SSP1_ELPG_VCORE_DOWN]

- Write '0' to the following XUSB PADCTL register bits to deassert the clamp_en and clamp_en_early signals:

  XUSB_PADCTL_ELPG_PROGRAM_0[SSP0_ELPG_CLAMP_EN]

  XUSB_PADCTL_ELPG_PROGRAM_0[SSP1_ELPG_CLAMP_EN]

  XUSB_PADCTL_ELPG_PROGRAM_0[SSP0_ELPG_CLAMP_EN_EARLY]

  XUSB_PADCTL_ELPG_PROGRAM_0[SSP1_ELPG_CLAMP_EN_EARLY]

> **Note:** The write to clear vcore_off cannot be combined with the write to clear clamp_en and clamp_en_early.

Step 6: System Power Management driver programs the PMC USB2.0 sleepwalk logic for ports assigned to XUSB host mode and XUSB device mode to disable the sleepwalk logic.

Step 7: xHCI PEP driver and XUSB device mode driver perform XUSB IPFS specific context restore operation for registers listed in Step 1 of section on ".All Partitions ELPG Entry" above, then enables XUSB IPFS operation.

- Set the following XUSB IPFS register bit to '1':

  XUSB_{HOST,DEV}_CONFIGURATION_0[EN_FPCI]

xHCI PEP driver performs XUSB specific context restore operation. XUSB device mode driver performs XUSB_DEVICE specific context restore operation.

Step 8: xHCI PEP Driver loads XUSB firmware. Refer to the FW Boot Loader section. xHCI PEP Driver notifies XUSB firmware whether context of SuperSpeed Partition should be restored.

Step 9: xHCI driver performs context restore operation.

23.7.5.5 SuperSpeed Partition ELPG Exit

Step 1: System Power Management driver enables the XUSB power rails.

- Programming the following PMC register bits to disable the power rail to XUSB SuperSpeed

  APBDEV_PMC_PWRGATE_TOGGLE_0[START] to 'enable'

  APBDEV_PMC_PWRGATE_TOGGLE_0[PARTID] to 'XUSBA'

> **Note:** Only one partition can be un-power gated at a time.

Step 2: System Power Management driver enables XUSB clocks.

- Set the following CAR register bits to '1' to enable the clocks to individual XUSB partitions.

  CLK_RST_CONTROLLER_CLK_ENB_W_SET_0[SET_CLK_ENB_XUSB_SS] for SS ports

Step 3: xHCI PEP driver and XUSB device mode driver initiate the signal sequence to disable the XUSB SS wake detection logic for the SuperSpeed ports assigned to host and device as described in Step 3 of section on "All Partitions ELPG Exit" above.

Step 4: xHCI PEP driver and XUSB device mode driver disable the XUSB SS wakeup interrupts.

- Set the following XUSB PADCTL register bits to '0' to disable the interrupts.

  XUSB_PADCTL_ELPG_PROGRAM_0[SS_PORT0_WAKE_INTERRUPT_ENABLE]

  XUSB_PADCTL_ELPG_PROGRAM_0[SS_PORT1_WAKE_INTERRUPT_ENABLE]

Step 5: System Power Management driver deasserts reset to XUSB.

- Set the following *CAR* register bits to '0' to deassert reset to XUSB

  CLK_RST_CONTROLLER_RST_DEVICES_W_0[SWR_XUSB_SS_RST] for SuperSpeed ports

Step 6: xHCI FW and XUSB device mode driver performs their SuperSpeed port specific context restore operations.

23.7.5.6 Device Mode Partition ELPG Exit

Step 1: System Power Management driver enables the XUSB power rails.

- Programming the following PMC register bits to disable the power rail to XUSB device

  APBDEV_PMC_PWRGATE_TOGGLE_0[START] to 'enable'

  APBDEV_PMC_PWRGATE_TOGGLE_0[PARTID] to 'XUSBC'

> **Note:** Only one partition can be un-power gated at a time.

Step 2: System Power Management driver enables XUSB clocks.

- Set the following CAR register bits to '1' to enable the clocks to individual XUSB partitions.

  CLK_RST_CONTROLLER_CLK_ENB_U_SET_0[SET_CLK_ENB_XUSB_DEV] for device mode

Step 3: XUSB device mode driver initiate the signal sequence to disable the XUSB SS wake detection logic for the SuperSpeed ports assigned to device as described in Step 3 of section on "All Partitions ELPG Exit" above.

Step 4: XUSB device mode driver disables the XUSB SS wakeup interrupts for the ports assigned to device as described in Step 4 of section on "All Partitions ELPG Exit" above.

Step 5: System Power Management driver deasserts reset to XUSB.

- Set the following CAR register bits to '0' to deassert reset to XUSB

  CLK_RST_CONTROLLER_RST_DEVICES_U_0[SWR_XUSB_DEV_RST] for device mode

Step 6: System Power Management driver programs the PMC USB2.0 sleepwalk logic for ports assigned to XUSB device mode to disable the sleepwalk logic.

Step 7: XUSB device mode driver perform XUSB IPFS specific context restore operation for registers listed in Step 1 of the section on "All Partitions ELPG Entry" above, then enables XUSB IPFS operation.

- Set the following XUSB IPFS register bits to '1'

  XUSB_DEV_CONFIGURATION_0[EN_FPCI]

XUSB device mode driver performs XUSB_DEVICE specific context restore operation.

23.7.6 Initialization and Shutdown Procedure for USB

1. Bring up USB3 clocks by writing 1 to CLK_ENB_USB3 in ARCLK_RST_CLK_OUT_ENB_H register.
2. Set and clear the SWR_USB3_RST in RST_DEVICES_H register to bring the USB block out of reset.
3. Set the UTMIP_RESET bit in USB_SUSP_CTRL register to 1 to keep UTMIP3 PHY in reset.
4. Program UTMIP and PLLU parameters.
   - Set register UTMIP_MISC_CFG0 UTMIP_SUSPEND_EXIT_ON_EDGE (bit 22) to 0.
   - Set the PLLU_ENABLE to 1, and never ever de-assert it.
5. Set UTMIP_RESET bit in USB_SUSP_CTRL register to 0 to bring UTMIP3 out of reset.
   - Wait until PHY_CLKVALID is set to 1.
6. Set USB controller and PHY to suspend by writing 1 to PHCD in USB2D_PORTSC1 register. This will reduce the power consumption on USB3 controller and UTMIP3 PHY.
   - Wait until PHY_CLKVALID is set to 0.
7. Set all PD bits required to bring USB pads to low power mode.
   - UTMIP_OTGPD in UTMIP_BIAS_CFG0 is needed for VBUS detection, and so it should be set to 0.
   - If using VBUS_WAKEUP for VBUS detection, then UTMIP_BIASPD in UTMIP_BIAS_CFG0 can be set to 1 to save power. But if using A_SESS_VLD or any other VBUS sensor for VBUS detection, then this bit should be set to 0.
   - ID_PU in USB_PHY_VBUS_WAKEUP_ID should be set to 1 to enable ID detection.
   - UTMIP_IDPD_SEL in UTMIP_BIAS_CFG0 should be set to 0.
8. To interrupt the processor on VBUS or ID detection, software can set the following:
   - Enable appropriate VBUS interrupt enable, for example, I using A_SESS_VLD sensor for VBUS detection, set A_SESS_VLD_INT_EN in USB_PHY_VBUS_SENSORS register to 1.
   - Enable ID detection interrupt by setting ID_INT_EN in USB_PHY_VBUS_WAKEUP_ID register.
9. When (VBUS=1) or (ID=0) is detected, do the following:
   - Bring USB3 controller and PHY out of suspend by pulsing SUSP_CLR in USB_SUSP_CTRL register by first writing 1 and then writing 0.

10. Wait until PHY_CLKVALID is set to 1.
    - Clear the PD bits that are required for the normal operation.
11. From this point on, the driver can run the normal operations.
    - UTMIP should only be suspended by writing 1 to PHCD in USB2D_PORTSC1 register when USB cable is connected and only after USB bus is in suspend, for both device and host modes.
12. If a cable disconnect is detected (VBUS = 0) or (ID = 1), then go back to step 4.

23.7.7 Recommended PHY Settings

Contact your local NVIDIA representative for PHY settings specific to your design.

23.7.8 BIAS PAD Configuration

UTMIP BIAS pad is shared across USB_OTG and USB3 controllers and the below common bias pad settings need to be configured from USB1 controller only.

USB1_UTMIP_BIAS_CFG0_0:

- UTMIP_BIASPD
- UTMIP_HSCHIRP_LEVEL
- UTMIP_HSSQUELCH_LEVEL
- UTMIP_HSDISCON_LEVEL_MSB
- UTMIP_HSDISCON_LEVEL
- UTMIP_ACTIVE_TERM_OFFSET
- UTMIP_ACTIVE_PULLUP_OFFSET
- UTMIP_VBUS_LEVEL_LEVEL
- UTMIP_SESS_LEVEL_LEVEL

USB1_UTMIP_BIAS_CFG1_0:

- UTMIP_FORCE_PDTRK_POWERUP
- UTMIP_FORCE_PDTRK_POWERDOWN

Following is the sequence to configure above parameters of the BIAS pad.

1. Enable clock to USB1 controller
2. Set any of above parameters as required.
3. Disable clock to USB1 controller if it is not used.

23.7.9 BOOT ROM Initialization Sequence for USB Recovery

1. Program PLL_U.
    - Set the PLLU_BASE register fields, PLLU_DIVM, PLLU_DIVN, PLLU_VCO_FREQ, PLLU_BYPASS and PLLU_ENABLE fields as described in this document.
2. Configure USB
    a. Bring up USB1 (USB_OTG) clocks by writing 1 to CLK_ENB_USBD in CLK_OUT_ENB_L register.

b. Assert and deassert master USBD reset in CAR (SWR_USBD_RST in RST_DEVICES_L register) to bring USB1 out of reset.

c. Stop crystal clock by setting UTMIP_PHY_XTAL_CLOCKEN in UTMIP_MISC_CFG1 register to 0. This only stops the crystal clocks in the UTMIP units.

   Default value of the USB1_UTMIP_PHY_XTAL_CLOCKEN is 1, now changes to 0.

d. Programming automatic PLL start times.

   Setting USB1_IF_UTMIP_PLLU_ENABLE_DLY_COUNT, UTMIP_PLLU_STABLE_COUNT, UTMIP_PLL_ACTIVE_DLY_COUNT and UTMIP_XTAL_FREQ_COUNT as per the values given in the document.

e. Programming the tracking duration.

   Setting USB1_IF_UTMIP_BIAS_CFG1.UTMIP_BIAS_PDTRK_COUNT as per the values given in the document.

f. Program the debouncer length times.

   Setting UTMIP_DEBOUNCE_CFG0.UTMIP_BIAS_DEBOUNCE_A field.

g. Program various static parameters of the USB UTMIP1.

   Set UTMIP_TX_CFG0.UTMIP_FS_PREAMBLE_J to 0x1.

   Set UTMIP_BAT_CHRG_CFG0.UTMIP_PD_CHRG to 1.

   Set UTMIP_XCVR_CFG0.UTMIP_XCVR_LSBIAS_SEL to 0.

   Set third bit of UTMIP_SPARE_CFG0 to 1. i.e UTMIP_SPARE_CFG0 [3] to 1.

   Set UTMIP_HSRX_CFG0. UTMIP_IDLE_WAIT as per the values given in this document.

   Set UTMIP_HSRX_CFG0.UTMIP_ELASTIC_LIMIT to 16.

   Set UTMIP_HSRX_CFG1.UTMIP_HS_SYNC_START_DLY to 9

h. Restart the crystal clock by setting UTMIP_PHY_XTAL_CLOCKEN in UTMIP_MISC_CFG1 register to 1 for USB.

3. Wait for cable connect on USB UTMIP1 port. When cable is connected on USB UTMIP1 port, continue to the next step.
4. Bring UTMIP1 out of reset by writing 0 to UTMIP_RESET bit of USB1_IF_SUSP_CTRL register.
5. Wait until USB1_IF_USB_SUSP_CTRL.PHY_CLK_VALID is set to 1.
6. Then perform USB controller initialization.
   a. Reset the bus.
   b. Wait until the bus comes out of reset.
   c. Set the controller in device mode.
   d. Perform USB operations.

23.7.10 Performance Settings for USB Controllers

To meet USB's strict bandwidth/latency requirements, some AHB programming needs to be done. The following gives a guideline on the programming requirements to achieve maximum performance from USB:

- The burst size for USB controller should be programmed to 8 in the register USB2D_BURSTSIZE. Both TXPBURST and RXPBURST fields should be programmed to the same value of 8.
- The field ENB_FAST_REARBITRATE for AHB_MEM gizmo should be set to 1 in the register AHB_GIZMO_AHB_MEM.

- The field IMMEDIATE for USB gizmos should be set to 1 in the register AHB_GIZMO_USB, AHB_GIZMO_USB2 or AHB_GIZMO_USB3 depending on the controller in use.
- USB controllers should be set as high-priority masters on AHB by setting the bits corresponding to each USB controller to 1 in AHB_PRIORITY_SELECT field in the register AHB_ARBITRATION_PRIORITY_CTRL and setting the priority weight to 7 by setting the field AHB_PRIORITY_WEIGHT in the same register. USB master numbers are 6 for USB1, 18 for USB2 and 17 for USB3. The priority weight could be relaxed depending on requirements from other AHB masters in the system as required for different use cases.
- Prefetch engine needs to be setup correctly to enable prefetching of transmit data packets for USB masters. Each USB master needs one channel on the prefetch engine. There are 4 channels on the prefetch engine. If all 3 USB masters enable one channel at the same time, it would leave one more channel for another AHB master. Each prefetch channel is controlled by the register AHB_AHB_MEM_PREFETCH_CFG[NO] where NO=1,2,3,4. To enable prefetch for a USB controller on a channel, program AHB_MST_ID_USB, AHB_MST_ID_USB2 or AHB_MST_ID_USB3 in the field AHB_MST_ID for the register AHB_AHB_MEM_PREFETCH_CFG[NO]. The field ADDR_BNDRY should be set to log2 (buffer size) according to the buffer size required for the corresponding USB master. The field SPEC_THROTTLE should be set to 0, and the field INACTIVITY_TIMEOUT should be set to 0x800.
- When a particular USB controller is in Host mode, the field TXFIFOTHRES in the register USB2D_TXFILLTUNING (offset 0x154) should be set to 0x10.

All this programming need to be done before setting the RS bit in USB2D_USBCMD to RUN (1) for the corresponding USB controller.

23.7.11 USB Controller Handling of USB Resume Sequence

Following are the steps for how the USB controller handles a USB resume while the port is under PMC control:

1. PMC maintains suspend on the bus.
2. Auto resume happens, system starts restoring USB controller.
3. Set RUN bit from USB controller to start SOFs.
4. USB controller brought back to suspend state.
5. Switch USB bus from PMC to USB controller.
6. Wait until resume complete notified from USB controller. This is handled by the EHCI driver.
7. Further USB communication can start from here.

23.8 UTMIP Programming Guidelines

A Tegra 4 device has a total of 2 UTMI+ interfaces, where the second controller does not have a UTMI+ interface. This results in two cabled USB ports. These ports are not part of a multiport host configuration. They are completely independent ports and can be configured in any combination of device or host. Internally, these ports correspond to USB controllers 1 and 3, where controller 1 is often implicitly numbered. Externally, these are USB ports 0 and 1. All UTMI+ PHY interfaces are identical instances of the same design. All three controllers use latest edition of USB core controller.

23.8.1 Holding USB in Reset

It is important that most static configuration of the UTMIP (and USB) be done while the unit is held in reset. For example, holding reset ensures that PLL_U is disabled and can be reconfigured. It also ensures that transactions are not occurring on the USB interface. Holding reset in both a controller and its corresponding PHY can be achieved by using the RST bit of the USB2D_USBCMD register.

23.8.2 PLL_U Programming

The USB ports use a cascaded PLL scheme to guarantee a high clock quality. First there is a PLL_U, which is the source clock for both the USB PLLs that are dedicated to ports. PLL_U (of type CLKPLL960_USB) produces reference clocks for all forms of USB (HSIC USB, UTMIP, UHSIC). Table 60 describes the parameter settings that are dependent on the crystal clock reference frequency. The parameters are specified in decimal notation.

Table 60: 480 MHz PLL_U Output Frequency Fo = (Fi·N)÷(M· 2) With VCO_FREQ=0

Fi (MHz)	12.0MHz	13.0MHz	16.8MHz	19.2MHz	26.0MHz	38.4 MHz	48.0MHz
N (PLLU_DIVN)	960	960	400	200	960	200	960
M (PLLU_DIVM)	12	13	7	4	26	4	12

These parameters can be found in the PLLU_BASE register. The PLLU_OVERRIDE bit should be set to 0. PLLU_VCO_FREQ parameter must also be set to 0.

Note: PLL_U must be properly configured in the Boot ROM. DO NOT change the parameters of PLL_U while the unit is running. The same applies to the USB_PHY_PLL.

23.8.3 PLL_U and USB_PHY_PLL Automatic Startup Times

The PLL_U and USB_PHY_PLL automatic startup times are used in reset and suspend modes to kick start the PLLs. Software should not manually force the PLL up and down because it cannot do so rapidly enough to meet the protocol. The following table lists the start times, which must be set up in the Boot ROM.

Table 61: PLL Automated Start Times (Must be Set Up in the Boot ROM)

Crystal Frequency	12.0 MHz	13.0 MHz	16.8 MHZ	19.2 MHz	26.0 MHz	38.4 MHz	48.0 MHz
PLLU_ENABLE_DELAY_COUNT	2	2	3	3	4	5	6
PLLU_STABLE_COUNT	47	51	66	75	102	150	188
PLL_ACTIVE_DLY_COUNT	8	9	11	12	9	24	31
XTAL_FREQ_COUNT	118	127	165	188	254	375	469

PLLU_ENABLE_DLY_COUNT should be set for at least 1 microsecond, PLLU_STABLE_COUNT should be set for at least 1 ms, the PLL_ACTIVE_DLY_COUNT should be at least 10 ms, and the XTAL_FREQ_COUNT set for about 2.5 ms.

23.8.4 Fuse Programming

The Tegra 4 device incorporates fuses to account for process variation in high speed data eye swing. The high speed data eye is controlled through the SETUP[6:0] transceiver pad parameter of the USB control registers. To set this parameter via the fuses, set the UTMIP_SPARE_CFG0[3] bit on all USB ports. This must be done in the Boot ROM. The default is to maintain backward compatibility; which implies no fuses are used by default. The objective is to get the data eye swing as close as possible to 400mV without falling below the mark under typical operating conditions.

23.8.5 Programming the Tracking Length Time

The PD_TRK signal is used to power down the bias cell. After 25 microseconds of bias cell operation, the PD_TRK signal can be turned high to save power. This can be automated by programming a timing interval as given in the following table.

Table 62: 25 µs Timer on Bias Cell Tracking (for Set Up in the Boot ROM)

Crystal Frequency	12.0 MHz	13.0 MHz	16.8 MHZ	19.2 MHz	26.0 MHz	38.4 MHz	48.0 MHz
UTMIP_BIAS_PAD_TRK_COUNT (UTMIP_BIAS_CFG1[7:3])	5	6	7	8	11	15	19

All values in the table are decimal. This parameter must be set in the Boot ROM and while the crystal clock is stopped. To stop the crystal clock, lower the UTMIP_PHY_XTAL_CLOCKEN bit of register UTMIP_MISC_CFG1 and then re-enable it when done.

Because there is more than one UTMIP sharing the same bias cell, power down is done through a daisy chain, requiring power down across all ports.

23.8.6 Powering Down a USB Port Outside of Deep Power Down (DPD)

When a port is known to be disabled, there needs to be a mechanism to stop its power consumption for situations outside of DPD. This section addresses disabling a port while powered up.

Powering down of USB at times other than deep power down should be done by setting all specialized PLL and pad power down pins instead of using the global E_DPD pins of the USB analog components. It is safer to power down the cells through the traditional power down pins when the 3.3V and 1.2V supplies might still be on. This is achieved by setting the following pad controls from UTMIP register space. Before setting the power down bits; save previous registers values so that they may be restored. This type of power down should not be done in the Boot ROM.

Table 63: UTMIP Pad Controls

Pad Control	Analog Cell	Register Bit Settings
PD	Transceiver	UTMIP_FORCE_PD_POWER_DOWN=1
PD2	Transceiver	UTMIP_FORCE_PD2_POWER_DOWN=1
PD_ZI	Transceiver	UTMIP_FORCE_PDZI_POWER_DOWN=1
PD_DR	Transceiver	UTMIP_FORCE_PDDR_POWER_DOWN=1
PD_CHRP	Transceiver	UTMIP_FORCE_PDCHRP_POWER_DOWN=1
PD_DISC	Transceiver	UTMIP_FORCE_PDDISC_POWER_DOWN=1
PD_CHG	Transceiver	UTMIP_PD_CHG=1
PD	Bias	UTMIP_BIASPD=1
PD_TRK	Bias	UTMIP_FORCE_PDTRK_POWER_DOWN=1
OTG_PD	Bias	UTMIP_OTGPD=1
ID_PD	Bias	UTMIP_IDPD_SEL=1, UTMIP_IDPD_VAL=1
VBUS_WAKEUP_PD	Bias	UTMIP_VBUS_WAKEUP_POWER_DOWN=1
ENABLE	PHY PLL	UTMIP_FORCE_PLL_ENABLE_POWERDOWN=1
ACTIVE	PHY PLL	UTMIP_FORCE_PLL_ACTIVE_POWERDOWN=1
PD_SAMP_A/C	PHY_PLL	UTMIP_FORCE_PD_SAMP_A/C_POWERDOWN=1
ENABLE	PLL U	UTMIP_FORCE_PLLU_POWERDOWN=1
UTMIP	PHY	UTMIP_PHY_XTAL_CLOCKEN=0

23.8.7 Extending Debouncer Period Length

USB debouncers provide a programmable debounce to alleviate the software burden. This is done with the UTMIP_DEBOUNCE_TIME_SCALE parameter located at UTMIP_BIAS_CFG1[13:8]. The default implies a timescale factor of 1. The timescale should not be programmed at Boot ROM time. The timescale register field incremented by 1 multiplies the debounce duration for all debouncers.

In the Boot ROM, the A debounce period should be set to 10 ms. This is dependent on the crystal frequency scale. The following table shows how it is programmed.

Table 64: 10 ms Timer on the A Debounce Period

Crystal Frequency	12.0 MHz	13.0 MHz	16.8 MHZ	19.2 MHz	26.0 MHz	38.4 MHz	48.0 MHz
UTMIP_BIAS_DEBOUNCE_A	30000	32500	42000	48000	65000	96000	120000

To program values of 96000 and 120000 for crystal clock frequencies of 38.4 and 48 MHz, respectively, these steps must be followed:

1. In the debounce register, program 48000 for a 38.4 MHz crystal clock or 60000 for a 60 MHz clock.
2. Set UTMIP_BIAS_DEBOUNCE_TIMESCALE to 1 by writing into the USB2_UTMIP_BIAS_CFG1[1] register field.

23.8.8 Deep Power Down Behavior

Tegra 4 devices' deep power down behavior for USB wake-up events is controlled in the PMC via registers USB_DEBOUNCE_DLY, USB_AO and the WAKE_MASK (USB_EVENT field) of the PMC unit. These control the wake-up events, their debounce duration, and their debounce length while powered down. USB port 0 has a possible event on ID or VBUS detection. These can be configured at startup time. These registers take over from the UTMIP registers when the chip is powered down. The programming depends on the context of the chip. For example, if USB port 0 is a dedicated host port then the VBUS wake-up event should be kept powered down. Conversely, a dedicated device mode port may not want to wake-up on the detection of an ID connector and can chose to power down ID.

23.8.9 PHY Resets

Additional controls have been provided to stop the USB PHY (and its clocks) by issuing a reset to the PHY only (as opposed to a reset encompassing the controller and the PHY). This is akin to the Reset found in the UTMI+ standard. This is done in both controllers. See the UTMIP_RESET field of the USB_SUSP_CTRL register for more information.

23.8.10 Static Boot ROM Configuration for UTMIP

The boot ROM configuration for UTMIP should be done while the unit is held in Reset. For correct behavior, the following sequence MUST be followed:

1. Apply Reset to the USB controller (and UTMIP).
2. Run the crystal clock for approximately 5 microseconds while the UTMIP is in reset.
3. Stop the crystal clock by setting UTMIP_PHY_XTAL_CLOCKEN low. This only stops the crystal clocks in the UTMIP units.
4. Program PLL_U as described in the PLL_U programming section (section 3).
5. Program automatic PLL start times as described in the "PLL_U and USB_PHY_PLL Automatic Startup Times."
6. Remove power downs from USB_PHY_PLL ACTIVE/ENABLE/PD_SAMP_A/C and PLL_U.
7. Program the tracking duration as described in "Programming the Tracking Length Time." Remove the power downs from PD (Bias) and disable PD_TRK. After 25 µs (tracking time), enable PD_TRK by writing 0 into UTMIP_FORCE_PDTRK_POWER_DOWN.
8. Once PD (Bias) is disabled, disable OTG_PD after 1 µs.
9. Remove powerdowns from ID_PD and VBUS_WAKEUP_PD. This can be removed earlier, as there is no timing or sequential relation with other signals.
10. Once the PLL_U, USB_PHY_PLL, and Bias pad are ready, remove PD (Transceiver). After 400 ns, the USB pad is ready for HS/FS/LS operation.
11. There are other powerdowns which can be removed if needed (as such not needed for Boot ROM). These are PD / PD_ZI / PD_DR / PD_CHRP / PD_DISC / PD_CHG.

12. Program the debouncer length time as described in ”Extending Debouncer Period Length.”
13. Program various static parameters of the UTMIP as described in ”Miscellaneous Boot ROM Fields.”
14. Restart the crystal clock by setting UTMIP_PHY_XTAL_CLOCKEN.
15. Resume any previous USB programming work that falls outside of UTMIP and release reset.From the UTMIP perspective it does not matter when reset is released, as long as it is after step 8. It will take about 3.5 ms before the 60 MHz clock appears once reset is released.

From a UTMIP perspective, ensure that all the cabled USB port PHYs are configured similarly in the Boot ROM.

23.8.11 EHCI Deviations

- Embedded Transaction Translator – Allows direct attachment of FS and LS devices in host mode without the need for a companion controller.
- Embedded design interface – This core does not have a PCI Interface and therefore the PCI configuration registers described in the EHCI specification are not applicable.

Programmable Physical Interface Behavior

This design supports multiple Physical interfaces which can operate in differing modes when the core is configured with software programmable Physical Interface Modes. Software programmability allows the selection of the Physical interface part during the board design phase instead of during the chip design phase. The control bits for selecting the Physical Interface operating mode have been added to the HOSTPCx register providing a capability that is not defined by EHCI.

Port Reset

The port connect methods specified by EHCI require setting the port reset bit in the PORTSCx register for a minimum duration of 10ms. Due to the complexity required to support the attachment of devices that are not high speed, there are counter already present in the design that can count the 10ms reset pulse to alleviate the requirement of the software to measure this duration. The basic connection is then summarized as the following:

- [Port Change Interrupt] Port connect change occurs to notify the host controller driver that a device has attached.
- Software shall write a ‘1’ to the reset the device.
- Software shall write a ‘0’ to the reset the device after 10 ms.
- Driver needs to wait until port change interrupt is asserted and port reset is cleared

> **Note:** Should the EHCI host controller driver attempt to write a ‘0’ to the reset bit while a reset is in progress the write will be ignored and the reset will continue until completion.

- [Port Change Interrupt] Port enable change occurs to notify the host controller that the device is now operational and at this point the port speed has been determined.

Port Speed Detection

After the port change interrupt indicates that a port is enabled, the EHCI stack should determine the port speed. Unlike the EHCI implementation which will re-assign the port owner for any device that does not connect at High-Speed, this host controller supports direct attach of non High-Speed devices. Therefore, the following differences are important regarding port speed detection:

- Port Owner is read-only and always reads 0.

- A 2-bit Port Speed indicator (PSPD) has been added to HOSTPCx to provide the current operating speed of the port to the host controller driver.

Port Reset duration is 55 ms instead of 50 ms.

Port Suspend (PORTSC.Suspend) bit is set immediately after setting the bit. As per EHCI a 4 ms delay is expected for this bit to be set.

Tegra 4 devices also have the following cases that are not directly compliant to EHCI:

- USB controller/PHY interface initialization
- PHY Clock shutdown/wakeup procedure during suspend/resume/connect/disconnect
- For HSIC, connect process and bus reset process is not EHCI compliant – particularly no interrupts for connect.
- PMC logic use for special low power modes during suspend/LP0

23.9 USB Registers

Refer to “Reading Register Tables” in the Introduction section for the register table protocol as well as recommendations for accessing registers.

23.9.1 USB1 Controller Registers

23.9.1.1 USB2_CONTROLLER_USB2D_ID_0

USB2D Identification Register

Offset: 0x0 | Read/Write: RO |Reset: 0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx

Bit	Reset	Description
31:29	X	CIVERSION: Identifies the CI version
28:25	X	VERSION: Identifies the version of the core
24:21	X	REVISION: Revision number of the USB controller. This is set to 0x0.
20:16	X	TAG: Identifies the tag of the core
15:8	X	NID: One’s complement version of ID. This field is set to 0xF9.
7:0	X	ID: Configuration number. This field is set to 0x06

23.9.1.2 USB2_CONTROLLER_USB2D_HW_HOST_0

USB2D Hardware Host Register

Offset: 0x8 | Read/Write: RO | Reset: 0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx

Bit	Reset	Description
3:1	X	NPORT: VUSB_HS_NUM_PORT-1: This host controller has only 1 port. So this field will always be 0.
0	X	HC: VUSB_HS_HOST: Indicates support for host mode. Set to 1.

23.9.1.3 USB2_CONTROLLER_USB2D_HW_DEVICE_0

USB2D Hardware Device Register

Offset: 0xc | Read/Write: RO | Reset: 0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx

Bit	Reset	Description
5:1	X	DEVEP: VUSB_HS_DV_EP: Number of endpoints supported by this device controller. Set to 16. This includes control endpoint 0.
0	X	DC: Device capable: Set to 1 indicating support for device mode.

23.9.1.4 USB2_CONTROLLER_USB2D_HW_TXBUF_0

USB2D Hardware TX Buffer Register

Offset: 0x10 | Read/Write: RO | Reset: 0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx

Bit	Reset	Description
23:16	X	TXCHANADD: VUSB_HS_TX_CHAN_ADD: Total number of address bits for the transmit buffer of each transmit endpoint. Set to 7. Each transmit buffer is 128 words deep.
15:8	X	TXADD: VUSB_HS_TX_ADD: Total number of address bits for the transmit buffer. Set to 11. The total depth of the transmit buffer is 2048 words.
7:0	X	TCBURST: VUSB_HS_TX_BURST: Maximum burst size supported by the transmit endpoints for data transfers. Set to 8.

23.9.1.5 USB2_CONTROLLER_USB2D_HW_RXBUF_0

USB2D RX Buffer HW Parameters Register

Offset: 0x14 | Read/Write: RO | Reset: 0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx

Bit	Reset	Description
15:8	X	RXADD: VUSB_HS_RX_ADD: Total number of address bits for the receive buffer. Set to 7. The total depth of the receive buffer is 128 words
7:0	X	RXBURST: VUSB_HS_RX_BURST: Maximum burst size supported by the receive endpoints for data transfers. Set to 8.

23.9.1.6 USB2_CONTROLLER_USB2D_CAPLENGTH_0

USB2D Capability Register Length Register

Offset: 0x100 | Read/Write: RO | Reset: 0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx

Bit	Reset	Description
7:0	X	CAPLENGTH: Indicates which offset to add to the register base address at the beginning of the Operational Register. Set to 0x40.

23.9.1.7 USB2_CONTROLLER_USB2D_HCIVERSON_0

USB2D Host Interface Version Number Register

Offset: 0x102 | Read/Write: RO | Reset: 0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx

Bit	Reset	Description
15:0	X	HCIVERSION: Contains a BCD encoding of the EHCI revision number supported by this host controller. The most significant byte of this register represents a major revision and the least significant byte is the minor revision. This host controller supports EHCI revision 1.00.

23.9.1.8 USB2_CONTROLLER_USB2D_HCSPARAMS_0

USB2D Host Control Structural Parameters Register

Offset: 0x104 | Read/Write: RO | Reset: 0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx

Bit	Reset	Description
27:24	X	N_TT: Number of Transaction Translators: Indicates the number of embedded transaction translators associated with the USB2.0 host controller. This field is always set to 1 indicating only 1 embedded TT is implemented in this implementation. This is a non-EHCI field to support embedded TT.
23:20	X	N_PTT: Number of Ports per Transaction Translator: Indicates the number of ports assigned to each transaction translator within the USB2.0 host controller. Field always equals N_PORTS. This is a non-EHCI field to support embedded TT.
15:12	X	N_CC: Number of Companion Controller: Indicates the number of companion controllers. This field is set to 0.
11:8	X	N_PCC: Number of Ports per Companion Controller: Indicates the number of ports supported per internal companion controller. This field is set to 0.
4	X	PPC: Port Power Control: Indicates whether the host controller implementation includes port power control. 1 = Ports have port power switches 0= Ports do not have port power switches. This field affects the functionality of the port Power field in each port status and control register. This field is set to 1.
3:0	X	N_PORTS: Number of downstream ports. This field specifies the number of physical downstream ports implemented on this host controller. This field is fixed to 1, since this host controller only supports 1 port.

23.9.1.9 USB2_CONTROLLER_USB2D_HCCPARAMS_0

USB2D Host Control Capability Parameters Register

Offset: 0x108 | Read/Write: RO | Reset: 0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx

Bit	Reset	Description
18	X	PPC: Per-Port Change Event Capability - RO. Default = 1b. This field indicates the support for per-port change events. This field is related to the USBCMD PPE field, USBSTS PPCI field, and USBINTR PPCE field.
17	X	LEN: Link Power Management Capability - RO. Default = 1b. This field indicates the support for LPM L1 state. This field is related to USBCMD HIRD field, POSTSCx SSTS and DA fields and HOSTPCx LEN, BA, and EPLPM fields.
15:8	X	EECP: EHCI Extended Capabilities Pointer: Indicates a capabilities list exists. A value of 00h indicates no extended capabilities are implemented. For this implementation this field is always "0".
7:4	X	IST: Isochronous Scheduling Threshold. This field indicates, relative to the current position of the executing host controller, where software can reliably update the isochronous schedule. When bit [7] is zero, the value of the least significant 3 bits indicates the number of micro-frames a host controller can hold a set of isochronous data structures (one or more) before flushing the state. When bit [7] is a one, then host software assumes the host controller may cache an isochronous data structure for an entire frame. This field will always be "0".

Bit	Reset	Description
2	X	ASP: Asynchronous Schedule Park Capability. 1 = (Default) the host controller supports the park feature for high-speed queue heads in the Asynchronous Schedule. The feature can be disabled or enabled and set to a specific level by using the Asynchronous Schedule Park Mode Enable and Asynchronous Schedule Park Mode Count fields in the USBCMD register. This field is always 1.
1	X	PFL: Programmable Frame List Flag. 0 = System software must use a frame list length of 1024 elements with this host controller. The USBCMD register Frame List Size field is a read-only register and must be set to zero. 1 = System software can specify and use a smaller frame list and configure the host controller via the USBCMD register Frame List Size field. The frame list must always be aligned on a 4K-page boundary. This requirement ensures that the frame list is always physically contiguous. This field will always be "1".

23.9.1.10 USB2_CONTROLLER_USB2D_DCIVERSION_0

USB2D Device Interface Version Number Register

Offset: 0x120 | Read/Write: RO | Reset: 0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx

Bit	Reset	Description
15:0	X	DCIVERSION: The device controller interface conforms to the two-byte BCD encoding of the interface version number contained in this register.

23.9.1.11 USB2_CONTROLLER_USB2D_DCCPARAMS_0

USB2D Device Control Capabilities Register

Offset: 0x124 | Read/Write: RO | Reset: 0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx

Bit	Reset	Description
8	X	HC: Host Capable: 1 = This controller can operate as an EHCI compatible USB 2 0 host controller. This field is set to 1.
7	X	DC: Device Capable: 1 = Controller can operate as a USB 2.0 device. This field is set to 1.
5	X	LEN: Link Power Management Capability - RO. Default = 1b. This field indicates the support for LPM L1 state. This field is related to the DEVLCx ASUS, STL, BA, and NYT fields.
4:0	X	DEN: Device Endpoint Number: Number of endpoints built into the device controller. This is set to 16.

23.9.1.12 USB2_CONTROLLER_USB2D_EXTSTS_0

USB2D EXTSTS Register

Offset: 0x128 | Read/Write: R/W | Reset: 0bxxxxxxxxxxxxxxxxxxxxxxxxxxxx0000x

Bit	R/W	Reset	Description
4	RW	0x0	TI1: General Purpose Timer Interrupt 1 - RWC. Default = 0b. This bit is set when the counter in the GPTIMER1CTRL register transitions to zero. Writing a one to this bit will clear it.
3	RW	0x0	TI0: General Purpose Timer Interrupt 0 - RWC. Default = 0b. This bit is set when the counter in the GPTIMER1CTRL register transitions to zero. Writing a one to this bit will clear it.
2	RW	0x0	UPA: USB Host Periodic Interrupt (USBHSTPERINT) R/WC. This bit is set by the Host Controller when the cause of an interrupt is a completion of a USB transaction where the Transfer Descriptor (TD) has an interrupt on complete (IOC) bit set and the TD was from the periodic schedule. This bit is also set by the Host Controller when a short packet is detected AND the packet is on the periodic schedule. A short packet is when the actual number of bytes received was less than the expected number of bytes. This bit is not used by the device controller and will always be zero. 0 = DISABLE 1 = ENABLE

Bit	R/W	Reset	Description
1	RW	0x0	UAI: USB Host Asynchronous Interrupt (USBHSTASYNCINT) R/WC. This bit is set by the Host Controller when the cause of an interrupt is a completion of a USB transaction where the Transfer Descriptor (TD) has an interrupt on complete (IOC) bit set AND the TD was from the asynchronous schedule. This bit is also set by the Host when a short packet is detected AND the packet is on the asynchronous schedule. A short packet is when the actual number of bytes received was less than the expected number of bytes. This bit is not used by the device controller and will always be zero. 0 = DISABLE 1 = ENABLE
0	RO	X	NAKI: NAK Interrupt Bit Read Only. This bit is read only. It is set by hardware when for a particular endpoint both the TX/RX Endpoint NAK bit and the corresponding TX/RX Endpoint NAK Enable bit are set. This bit is automatically cleared by hardware when the all the enabled TX/RX Endpoint NAK bits are cleared. 0 = DISABLE 1 = ENABLE

23.9.1.13 USB2_CONTROLLER_USB2D_USBEXTINTR_0

USB2D EXTINTR Register

Offset: 0x12c | Read/Write: R/W | Reset: 0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxx00000

Bit	Reset	Description
4	0x0	TIE1: General Purpose Timer Interrupt Enable 1 - RWC. Default = 0b. When this bit is a one, and the TI1 bit in the EXTSTS register is a one, the controller will issue an interrupt. The interrupt is acknowledged by software clearing the TI1 bit.
3	0x0	TIE0: General Purpose Timer Interrupt Enable 0 - RWC. Default = 0b. When this bit is a one, and the TI1 bit in the EXTSTS register is a one, the controller will issue an interrupt. The interrupt is acknowledged by software clearing the TI1 bit.
2	0x0	UPIE: UPIE Interrupt Enable. 1 = USB controller issues an interrupt if the UPA bit in USBSTS register transitions. 0 = DISABLE 1 = ENABLE
1	0x0	UAIE: UAIE Interrupt Enable. 1 = USB controller issues an interrupt if the UAI bit in USBSTS register transitions. 0 = DISABLE 1 = ENABLE
0	0x0	NAKE: NAK Interrupt Enable. 1 = USB controller issues an interrupt if the NAKI bit in USBSTS register transitions. 0 = DISABLE 1 = ENABLE

23.9.1.14 USB2_CONTROLLER_USB2D_USBCMD_0

USB2D USB Command Register

Offset: 0x130 | Read/Write: R/W | Reset: 0bxxxx00000000010000000x1x11x0000000

Bit	R/W	Reset	Description
27:24	RW	0x0	HIRD: Host Initiated Resume Duration RW. Default = 0000b. This has the same behavior as bits 7:4 of the BA field of the HOSTPCx register. When writing to this field all BA[7:4] fields of all HOSTPCx registers will be set to this value. This field is used by system software to specify the minimum amount of time the host controller will drive the K-state during a host-initiated resume from an LPM state (e.g., L1), and is conveyed to each LPM-enabled device (via the HIRD bits within an LPM Tokens bmAttributes field) upon entry into a low-power state. Note the host controller is required to drive resume signaling for at least the amount of time specified in the HIRD value conveyed to the device during any proceeding host-initiated resume. Also note that the host controller is not required to observe this requirement during device-initiated resumes. Encoding for this field is identical to the definition for the similarly named HIRD field within an LPM Token, specifically: a value 0000b equals 50 µs and each additional increment adds 75 µs.

Bit	R/W	Reset	Description
			For example, the value 0001b equals 125 µs, and the value 1111b equals 1,175 µs (~1.2 ms).
23:16	RW	0x8	ITC: Interrupt Threshold Control .Read/Write. Default 08h. The system software uses this field to set the maximum rate at which the host/device controller will issue interrupts. ITC contains the maximum interrupt interval measured in micro-frames. Valid values are shown below. Value Maximum Interrupt Interval. 00h: Immediate (no threshold). 01h: 1 micro-frame. 02h: 2 micro-frames. 04h: 4 micro-frames. 08h: 8 micro-frames. 10h: 16 micro-frames. 20h: 32 micro-frames. 40h: 64 micro-frames 0 = IMMEDIATE 2 = ONE_MF 4 = TWO_MF 8 = EIGHT_MF 16 = SIXTEEN_MF 32 = THIRTY_TWO_MF 64 = SIXTY_FOUR_MF
15	RW	0x0	FS2: Bit 2 of Frame List Size.
14	RW	0x0	ATDTW: Add DTD Tripwire. This bit is used as a semaphore when a dTD is added to an active (primed) endpoint. This bit is set and cleared by software and will be cleared by hardware when a hazard exists such that adding a dTD to a primed endpoint may go unnoticed. 0 = CLEAR 1 = SET
13	RW	0x0	SUTW: Setup Tripwire. This bit is used as a semaphore when the 8 bytes of setup data read extracted by the firmware. If the setup lockout mode is off, then there exists a hazard when new setup data arrives and firmware is copying setup data from the QH for a previous setup packet. This bit is set and cleared by software and will be cleared by hardware when a hazard exists. 0 = CLEAR 1 = SET
11	RW	0x1	ASPE: Asynchronous Schedule Park mode Enable. Software uses this bit to enable or disable Park mode. When this bit is one, Park mode is enabled. When this bit is a zero, Park mode is disabled. This field is set to "1" in this implementation. 0 = DISABLE 1 = ENABLE
9:8	RW	0x3	ASP1_ASP0: Asynchronous Schedule Park Mode Count (OPTIONAL) Read/Write. If the Asynchronous Park Capability bit in the HCCPARAMS register is a one, then this field defaults to 3h and is R/W. Otherwise it defaults to zero and is RO. It contains a count of the number of successive transactions the host controller is allowed to execute from a high-speed queue head on the Asynchronous schedule before continuing traversal of the Asynchronous schedule. Valid values are 1h to 3h. Software must not write a zero to this bit when Park Mode Enable is a one as this will result in undefined behavior. This field is set to 3h in this implementation and is Read/Write capable.
7	RO	X	LR: Light Host/Device Controller Reset (OPTIONAL). Read Only. Not Implemented. This field will always be "0".
6	RW	0x0	IAA: Interrupt on Async Advance Doorbell. When the host controller has evicted all appropriate cached schedule states, it sets the Interrupt on Async Advance status bit in the USBSTS register. If the Interrupt on Sync Advance Enable bit in the USBINTR register is one, then the host controller will assert an interrupt at the next interrupt threshold. The host controller sets this bit to zero after it has set the Interrupt on Sync Advance status bit in the USBSTS register to one. Software should not write a one to this bit when the asynchronous schedule is inactive. Doing so will yield undefined results. This bit is only used in host mode. Writing a one to this bit when device mode is selected will have undefined results. 0 = CLEAR 1 = SET
5	RW	0x0	ASE: Asynchronous Schedule Enable. This bit controls whether the host controller skips processing the Asynchronous Schedule. 0 = Do not process the Asynchronous Schedule. 1 = Use the ASYNCLISTADDR register to access the Asynchronous Schedule. Only the host controller uses this bit. 0 = DISABLE 1 = ENABLE

Bit	R/W	Reset	Description
4	RW	0x0	PSE: Periodic Schedule Enable. This bit controls whether the host controller skips processing the Periodic Schedule. 0 = Do not process the Periodic Schedule 1 = Use the PERIODICLISTBASE register to access the Periodic Schedule. Only the host controller uses this bit. 0 = DISABLE 1 = ENABLE
3:2	RW	0x0	FS1_FS0: Frame List Size. (Read/Write). 000 = (Default). This field is Read/Write only if the Programmable Frame List Flag in the HCCPARAMS registers is set to one. Hence this field is Read/Write for this implementation. This field specifies the size of the frame list that controls which bits in the Frame Index Register should be used for the Frame List Current index. Note that this field is made up from USBCMD bits 15, 3, and 2. 000 = 1024 elements (4096 bytes) Default value 001 = 512 elements (2048 bytes) 010 = 256 elements (1024 bytes) 011 = 128 elements (512 bytes) 100 = 64 elements (256 bytes) 101 = 32 elements (128 bytes) 110 = 16 elements (64 bytes) 111 = 8 elements (32 bytes) Only the host controller uses this field.
1	RW	0x0	RST: Controller Reset. Software uses this bit to reset the controller. This bit is set to zero by the Host/Device Controller when the reset process is complete. Software cannot terminate the reset process early by writing a zero to this register. Host Controller: When software writes a one to this bit, the Host Controller resets its internal pipelines, timers, counters, state machines etc. to their initial value. Any transaction currently in progress on USB is immediately terminated. A USB reset is not driven on downstream ports. Software should not set this bit to a one when the HCHalted bit in the USBSTS register is a zero. Attempting to reset an actively running host controller results in undefined behavior. Device Controller: When software writes a one to this bit, the Device Controller resets its internal pipelines, timers, counters, state machines etc. to their initial value. Any transaction currently in progress on USB is immediately terminated. Writing a one to this bit in device mode is not recommended. 0 = CLEAR 1 = SET
0	RW	0x0	RS: Run/Stop: Host Controller: When set to a 1, the Host Controller proceeds with the execution of the schedule. The Host Controller continues execution as long as this bit is set to a one. When this bit is set to 0, the Host Controller completes the current transaction on the USB and then halts. The HCHalted bit in the status register indicates when the Host Controller has finished the transaction and has entered the stopped state. Software should not write a one to this field unless the host controller is in the Halted state (i.e., HCHalted in the USBSTS register is a one). Device Controller: Writing a one to this bit will cause the device controller to enable a pull-up on D+ and initiate an attach event. This control bit is not directly connected to the pull-up enable, as the pull-up will become disabled upon transitioning into high-speed mode. Software should use this bit to prevent an attach event before the device controller has been properly initialized. Writing a 0 to this will cause a detach event. 0 = STOP 1 = RUN

23.9.1.15 USB2_CONTROLLER_USB2D_USBSTS_0

USB2D USB Status Register

Offset: 0x134 | Read/Write: R/W | Reset: 0b00000000000000000x100x0000x0000

Bit	R/W	Reset	Description
31:16	RW	0x0	PPCI: Port-n Change Detect - RW. Default = 0000h. The definition for each bit is identical to the Port Change Detect field (bit 2 of this register) except these bits are specific to a given port, where bit 16 = Port 1, 17 = Port 2, etc. For example, if bit 17 is set to a one then a port change event was detected on Port 2. The N_PORTS field in HCSPARAMS specifies how many ports are exposed by the host controller and thus how many bits in this field are valid.

Bit	R/W	Reset	Description
15	RW	0x0	AS: Asynchronous Schedule Status. This bit reports the current real status of the Asynchronous Schedule. When set to zero the asynchronous schedule status is disabled and if set to one the status is enabled. The Host Controller is not required to immediately disable or enable the Asynchronous Schedule when software transitions the Asynchronous Schedule Enable bit in the USBCMD register. If AS = ASE: 1= Enable Asynchronous Schedule. 0= Disable Asynchronous Schedule. Only used by the host controller. 0 = DISABLE 1 = ENABLE
14	RW	0x0	PS: Periodic Schedule Status. This bit reports the current real status of the Periodic Schedule. When set to zero the periodic schedule is disabled, and if set to one the status is enabled. The Host Controller is not required to immediately disable or enable the Periodic Schedule when software transitions the Periodic Schedule Enable bit in the USBCMD register. If PS = PSE then: 1 = Periodic Schedule is enabled or 0 = Periodic Schedule is disabled. Only used by the host controller. 0 = DISABLE 1 = ENABLE
13	RO	X	RCL: Reclamation. This is a read-only status bit used to detect an empty asynchronous schedule. Only used by the host controller. 0 = DISABLE 1 = ENABLE
12	RW	0x1	HCH: HCHalted. 1 = Default. This bit is a zero whenever the Run/Stop bit is a one. The Host Controller sets this bit to one after it has stopped executing because of the Run/Stop bit being set to 0, either by software or by the Host Controller hardware (e.g., internal error). Only used by the host controller. 0 = UNHALTED 1 = HALTED
11	RW	0x0	UALT_INT: ULPI alt_int Interrupt. 0 = Default. This interrupt bit is set when an RXCMD is received through the ULPI interface with bit 7 set (alt_int).The alt_int itself is set when an unmasked event occurs on any bit in the Carkit Interrupt Latch Register, in the ULPI PHY The software should read the Carkit Interrupt Latch Register (Read to Clear) through the ULPI Viewport to check the source of the interrupt. Only present in designs where configuration constant VUSB_HS_PHY_ULPI = 1. 0 = NOT_ULPI_ALT_INT 1 = ULPI_ALT_INT
10	RW	0x0	ULPI_INT: ULPI Interrupt. This bit is set whenever an interrupt is received from ULPI PHY. Software writes 1 to clear it. 0 = NOT_ULPI_INT 1 = ULPI_INT
8	RW	0x0	SLI: DCSuspend. When a device controller enters a suspend state from an active state, this bit will be set to a 1. The device controller clears the bit upon exiting from a suspend state. Only used by the device controller. 0 = NOTSUSPEND 1 = SUSPENDED
7	RW	0x0	SRI: SOF Received. When the device controller detects a Start Of (micro) Frame, this bit will be set to a one. When an SOF is extremely late, the device controller will automatically set this bit to indicate that an SOF was expected. Therefore, this bit will be set roughly every 1 ms in device FS mode and every 125 µs in HS mode and will be synchronized to the actual SOF that is received. Since the device controller is initialized to FS before connect, this bit will be set at an interval of 1 ms during the prelude to the connect and chirp. In host mode, this bit will be set every 125 µs and can be used by the host controller driver as a time base. Software writes a 1 to this bit to clear it. This is a non-EHCI status bit. 0 = SOF_NOT_RCVD 1 = SOF_RCVD
6	RW	0x0	URI: USB Reset Received. When the device controller detects a USB Reset and enters the default state, this bit is set to a 1. Software can write a 1 to this bit to clear the USB Reset Received status bit. Only used by the device controller. 0 = NO_USB_RESET 1 = USB_RESET
5	RW	0x0	AAI: Interrupt and Asynchronous Advance. System software can force the host controller to issue an interrupt the next time the host controller advances the asynchronous schedule by writing a one to the Interrupt on Async Advance Doorbell bit in the USBCMD register. This status bit

Bit	R/W	Reset	Description
			indicates the assertion of that interrupt source. Only used by the host controller 0 = NOT_ADVANCED 1 = ADVANCED
4	RO	X	SEI: System Error. This bit is not used in this implementation and will always be set to "0". 0 = NO_ERROR 1 = ERROR
3	RW	0x0	FRI: Frame List Rollover. The Host Controller sets this bit to a 1 when the Frame List Index rolls over from its maximum value to 0. The exact value at which the rollover occurs depends on the frame list size. For example. If the frame list size (as programmed in the Frame List Size field of the USBCMD register) is 1024, the Frame Index Register rolls over every time FRINDEX [1 3] toggles. Similarly, if the size is 512, the Host Controller sets this bit to a 1 every time FHINDEX [12] toggles. Only used by the host controller. 0 = NO_ROLLOVER 1 = ROLLOVER
2	RW	0x0	PCI: Port Change Detect. The Host Controller sets this bit to a 1 when on any port a Connect Status occurs, a Port Enable/Disable Change occurs, or the Force Port Resume bit is set as the result of a J-K transition on the suspended port. The Device Controller sets this bit to a one when the port controller enters the full or high-speed operational state. When the port controller exits the full or high-speed operational states due to Reset or Suspend events, the notification mechanisms are the USB Reset Received bit and the DCSuspend bits, respectively. This bit is not EHCI compatible. 0 = NO_PORT_CHANGE 1 = PORT_CHANGE
1	RW	0x0	UEI: USB Error Interrupt. This bit gets set by the Host/Device controller when completion of a USB transaction results in an error condition. This bit is set along with the USBINT bit, if the TD on which the error interrupt occurred also had its interrupt on complete (IOC) bit set. 0 = NO_ERROR 1 = ERROR
0	RW	0x0	UI: USB Interrupt. This bit is set by the Host/Device Controller when the cause of an interrupt is a completion of a USB transaction where the Transfer Descriptor (TD) as an interrupt on complete (IOC) bit set. This bit is also set by the Host/Device Controller when a short packet is detected. A short packet is when the actual number of bytes received was less than the expected number of bytes. 0 = NO_INT 1 = INT

23.9.1.16 USB2_CONTROLLER_USB2D_USBINTR_0

USB2D USB Interrupt Enable Register

Offset: 0x138 | Read/Write: R/W | Reset: 0b0000000000000000xxxx00x000000000

Bit	Reset	Description
31:16	0x0	PPCE: Port-n Change Detect Enable - RW. Default = 0000h. The definition for each bit in this field is identical to bit 2 of this register (Port Change Interrupt Enable) except these bits are specific to a given port, where bit 16 = Port 1, 17 = Port 2, etc. For example, if bit 17 is set (1b) then a port change event was detected on Port 2. When a bit in this field is a one, and the corresponding Port-n Change Detect bit in the USBSTS register is a one, the host controller will issue an interrupt. The interrupt is acknowledged by software clearing the Port-n Change Detect bit.
11	0x0	UALTIE: ULPI alt_int Interrupt Enable. 1 = USB controller issues an interrupt if the ULPI_ALT_INT bit in the USBSTS register transitions. The interrupt is acknowledged by software by writing a 1 to the ULPI_ALT_INT bit. 0 = DISABLE 1 = ENABLE
10	0x0	ULPIE: ULPI Interrupt Enable. 1 = USB controller issues an interrupt if ULPI_INT bit in USBSTS register transitions. The interrupt is acknowledged by software by writing a 1 to the ULPI_INT bit. 0 = DISABLE 1 = ENABLE

Bit	Reset	Description
8	0x0	SLE: Sleep Enable. 1 = Device controller issues an interrupt if DCSuspend bit in USBSTS register transitions. The interrupt is acknowledged by software by writing a 1 to the DCSuspend bit. Only used by the device controller. 0 = DISABLE 1 = ENABLE
7	0x0	SRE: SOF Received Enable. 1 = Device controller issues an interrupt if SOF Received bit in USBSTS register = 1. The interrupt is acknowledged by software clearing the SOF Received bit. 0 = DISABLE 1 = ENABLE
6	0x0	URE: USB Reset Enable.1 = Device controller issues an interrupt if USB Reset Received bit in USBSTS register = 1. The interrupt is acknowledged by software clearing the USB Reset Received bit. Only used by the device controller. 0 = DISABLE 1 = ENABLE
5	0x0	AAE: Interrupt on Asynchronous Advance Enable. 1 = The host controller issues an interrupt at the next interrupt threshold if Interrupt on Async Advance bit in USBSTS register = 1. The interrupt is acknowledged by software clearing the Interrupt on Async Advance bit. Only used by the host controller. 0 = DISABLE 1 = ENABLE
4	0x0	SEE: System Error Enable. 1 = Host/device controller issues an interrupt if the System Error bit in USBSTS register = 1. The interrupt is acknowledged by software clearing the System Error bit. 0 = DISABLE 1 = ENABLE
3	0x0	FRE: Frame List Rollover Enable. 1 = Host controller issues an interrupt if Frame List Rollover bit in the USBSTS register = 1. The interrupt is acknowledged by software clearing the Frame List Rollover bit. Only used by the host controller. 0 = DISABLE 1 = ENABLE
2	0x0	PCE: Port Change Detect Enable. 1 = Host/device controller issues an interrupt if Port Change Detect bit in USBSTS register = 1. The interrupt is acknowledged by software clearing the Port Change Detect bit. 0 = DISABLE 1 = ENABLE
1	0x0	UEE: USB Error Interrupt Enable. 1 = Host controller issues an interrupt at the next interrupt threshold if the USBERRINT bit in USBSTS = 1. The interrupt is acknowledged by software clearing the USBERRINT bit in the USBSTS register. 0 = DISABLE 1 = ENABLE
0	0x0	UE: USB Interrupt Enable. 1 = Host/device issues an interrupt at the next interrupt threshold if the USBINT bit in USBSTS = 1. The interrupt is acknowledged by software clearing the USBINT bit. 0 = DISABLE 1 = ENABLE

23.9.1.17 USB2_CONTROLLER_USB2D_FRINDEX_0

USB2D USB Frame Index Register

Offset: 0x13c | Read/Write: RO | Reset: 0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx

Bit	Reset	Description
13:0	X	FRINDEX: Frame Index. The value in this register increments at the end of each time frame (micro-frame). Bits [N: 3] are used for the Frame List current index. Each location of the frame list is accessed 8 times (frames or micro-frames) before moving to the next index. The following illustrates values of N based on the value of the Frame List Size field in the USBCMD register, when used in host mode. USBCMD [Frame List Size] Number Elements N 000b (1024) 12 001b (512) 11 010b (256) 10

		011b	(128)	9
		100b	(64)	8
		101b	(32)	7
		110b	(16)	6
		111b	(8)	5
		In device mode, the value is the current frame number of the last frame transmitted. It is not used as an index. In either mode bits 2:0 indicate the current micro-frame.		

23.9.1.18 USB2_CONTROLLER_USB2D_PERIODICLISTBASE_0

USB2D Host Controller Frame List Base Address Register

Offset: 0x144 | Read/Write: R/W | Reset: 0b00000000000000000000xxxxxxxxxxxx

Bit	Reset	Description
31:25	0x0	USBADR: Device mode. The upper seven bits of this register represent the device address. After any controller reset or a USB reset, the device address is set to the default address (0). The default address will match all incoming addresses. Software shall reprogram the address after receiving a SET_ADDRESS request.
24	0x0	USBADRA: Device Address Advance. Default=0. When this bit is 0, any writes to USBADR are instantaneous. When this bit is written to a 1 at the same time or before USBADR is written, the write to the USBADR field is staged and held in a hidden register. After an IN occurs on endpoint 0 and is ACKed, USBADR will be loaded from the holding register. Hardware will automatically clear this bit on the following conditions: 1) IN is ACKed to endpoint 0. (USBADR is updated from staging register). 2) OUT/SETUP occur to endpoint 0. (USBADR is not updated). 3) Device Reset occurs (USBADR is reset to 0). Note: After the status phase of the SET_ADDRESS descriptor, the DCD has 2 ms to program the USBADR field. This mechanism will ensure this specification is met when the DCD cannot write of the device address within 2 ms from the SET_ADDRESS status phase. If the DCD writes the USBADR with USBADRA=1 after the SET_ADDRESS data phase (before the prime of the status phase), the USBADR will be programmed instantly at the correct time and meet the 2 ms USB requirement.
31:12	0x0	BASEADR: Host mode: This 32-bit register contains the beginning address of the Periodic Frame List in the system memory. The HCD loads this register prior to starting the schedule execution by the Host Controller. The memory structure referenced by this physical memory pointer is assumed to be 4-Kbyte aligned. The contents of this register are combined with the Frame Index Register (FRINDEX) to enable the Host Controller to step through the Periodic Frame List in sequence. Base Address (Low). These bits correspond to memory address signals [31:12], respectively. Only used by the host controller.

23.9.1.19 USB2_CONTROLLER_USB2D_ASYNCLISTADDR_0

USB2D Next Asynchronous List Address Register

Offset: 0x148 | Read/Write: R/W | Reset: 0b00000000000000000000000000xxxxx

Bit	Reset	Description
31:11	0x0	EPBASE: Device mode. This register contains the address of the top of the endpoint list in system memory. These bits correspond to memory address signals [31:11], respectively. This field will reference a list of up to 32 Queue Heads (QH). Only used by the device controller.
31:5	0x0	ASYBASE: Host mode. This 32-bit register contains the address of the next asynchronous queue head to be executed by the host. Link Pointer Low (LPL). These bits correspond to memory address signals [31:5], respectively. This field may only reference a Queue Head (OH). Only used by the host controller.

23.9.1.20 USB2_CONTROLLER_USB2D_ASYNCTTSTS_0

USB2D Asynchronous Buffer Status for Embedded TT Register

Offset: 0x14c | Read/Write: R/W | Reset: 0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx0x

Bit	R/W	Reset	Description
1	RW	0x0	TTAC: Embedded TT Async Buffers Clear. (Read/Write to set). This field will clear all pending transactions in the embedded TT Async Buffer(s). The clear will take as much time as necessary to clear buffer without interfering with a transaction in progress. TTAC will return to zero after being set by software only after the actual clear occurs.
0	RO	X	TTAS: Embedded TT Async Buffers Status. (Read Only). This read only bit will be 1 if one or more transactions are being held in the embedded TT Async. Buffers. When this bit is a zero, then all outstanding transactions in the embedded TT have been flushed.

23.9.1.21 USB2_CONTROLLER_USB2D_BURSTSIZE_0

USB2D Burst Size Register

Offset: 0x150 | Read/Write: R/W | Reset: 0bxxxxxxxxxxxxxxxx0000100000001000

Bit	Reset	Description
15:8	0x8	TXPBURST: Programmable TX Burst Length. (Read/Write). This register represents the maximum length of a burst in 32-bit words while moving data from system memory to the USB bus.
7:0	0x8	RXPBURST: Programmable RX Burst Length. (Read/Write). This register represents the maximum length of a burst in 32-bit words while moving data from the USB bus to system memory.

23.9.1.22 USB2_CONTROLLER_USB2D_TXFILLTUNING_0

USB2D Transmit Fill Tuning Register

Offset: 0x154 | Read/Write: R/W | Reset: 0bxxxxxxxxxx000010xxx0000000000000

Bit	Reset	Description
21:16	0x2	TXFIFOTHRES: FIFO Burst Threshold. (Read/Write). This register controls the number of data bursts that are posted to the TX latency FIFO in host mode before the packet begins on to the bus. The minimum value is 2 and this value should be a low as possible to maximize USB performance. A higher value can be used in systems with unpredictable latency and/or insufficient bandwidth where the FIFO may underrun because the data transferred from the latency FIFO to USB occurs before it can be replenished from system memory. This value is ignored if the Stream Disable bit in USBMODE register is set.
12:8	0x0	TXSCHHEALTH: Scheduler Health Counter. (Read/Write To Clear) [Default = 0] This register increments when the host controller fails to fill the TX latency FIFO to the level programmed by TXFIFOTHRES before running out of time to send the packet before the next Start-Of-Frame. This health counter measures the number of times this occurs to provide feedback to selecting a proper TXSCHOH. Writing to this register will clear the counter and this counter will max out at 31.
7:0	0x0	TXSCHOH: Scheduler Overhead. (Read/Write) [Default = 0] This register adds an additional fixed offset to the schedule time estimator described above as Tff. As an approximation, the value chosen for this register should limit the number of back-off events captured in the TXSCHHEALTH to less than 10 per second in a highly utilized bus. Choosing a value that is too high for this register is not desired as it can needlessly reduce USB utilization. The time unit represented in this register is 1.267 µs when a device is connected in High-Speed Mode. The time unit represented in this register is 6.333 µs when a device is connected in Low/Full Speed Mode

23.9.1.23 USB2_CONTROLLER_USB2D_ICUSB_CTRL_0

This register enables and controls the ICUSB FS/LS transceiver.

USB2D ICUSB control register

Offset: 0x15c | Read/Write: R/W | Reset: 0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx0000

Bit	Reset	Description
3	0x0	IC_ENB1: ICUSB transceiver enable. This bit enables the ICUSB transceiver. To enable the interface, the bits PTS must be set to 11 in the PORTSCx. Writing a '1' to this bit selects the IC_USB interface. 0 = DISABLE 1 = ENABLE
2:0	0x0	IC_VDD1: ICUSB voltage select. It selects which voltage is being supplied to the ICUSB peripheral. 000 = No voltage 001 = 1.0V - reserved 010 = 1.2V - reserved 011 = 1.5V - reserved 100 = 1.8V 101 = 3.0V 110 = reserved 111 = reserved The Voltage negotiation should happen between enabling port power (PP) and asserting the run/stop bit in register.

23.9.1.24 USB2_CONTROLLER_USB2D_ULPI_VIEWPORT_0

This register provides indirect access to the ULPI PHY register set. Although the USB controller performs access to the ULPI PHY register set, there may be extraordinary circumstances where software may need direct access.

Note: WRITES TO THE ULPI THROUGH THE VIEWPORT CAN SUBSTANTIALLY HARM STANDARD USB OPERATIONS. CURRENTLY NO USAGE MODEL HAS BEEN DEFINED WHERE SOFTWARE SHOULD NEED TO EXECUTE WRITES DIRECTLY TO THE ULPI PHY. SEE EXCEPTION REGARDING OPTIONAL FEATURES BELOW.

Note: Executing read operations through the ULPI Viewport should have no harmful side effects to standard USB operations.

There are two operations that can be performed with the ULPI Viewport: wakeup and read /write operations.

The wakeup operation is used to put the ULPI interface into normal operation mode and reenable the clock if necessary. A wakeup operation is required before accessing the registers when the ULPI interface is operating in low power mode, serial mode, or carkit mode.

The ULPI state can be determined by reading the sync state bit (ULPI_SYNC_STATE). If this bit is a one, then ULPI interface is running in normal operation mode and can accept read/write operations. If the ULPI_SYNC_STATE indicates a 0 then then read/write operations will not be able to execute. Undefined behavior will result if ULPI_SYNC_STATE = 0 and a read or write operation is performed.

To execute a wakeup operation, write all 32-bits of the ULPI Viewport where ULPI_PORT is constructed appropriately and the ULPI_WAKEUP bit is a 1 and ULPI_RUN bit is a 0. Poll the ULPI Viewport until ULPI_WAKEUP is zero for the operation to complete.

To execute a read or write operation, write all 32 bits of the ULPI Viewport where ULPI_DATA_WR, ULPI_REG_ADDR, ULPI_PORT, ULPI_RD_WR are constructed appropriately and the ULPI_RUN bit is a 1. Poll the ULPI Viewport until ULPI_RUN is zero for the operation to complete. Once ULPI_RUN is zero, the ULPI_DATA_RD will be valid if the operation was a read.

The polling method above can be changed to interrupt driven using the ULPI interrupt defined in the USBSTS and USBINTR registers. When a wakeup or read/write operation is complete, the ULPI_INT interrupt will be set.

There are several optional features that may need to be enabled or disabled by system software as part of system configuration. These bits are contained in the Interface and OTG Control registers of the ULPI PHY register set. These registers also contain bits which are controlled by the link dynamically and therefore should be only modified by system software using the Set/Clear access method. Direct writes to these registers could have harmful side effects to the standard USB operations. The optional bits are as follows: Bits 3 through 7 in the Interface Control register and Bits 6 and 7 in the OTG Control register.

Please refer to the ULPI Specification Revision 1.1 for further information on the use of the optional features.

USB2D ULPI Viewport Register

Offset: 0x160 | Read/Write: R/W | Reset: 0b000xx00000000000xxxxxxxx00000000

Bit	R/W	Reset	Description
31	RW	0x0	ULPI_WAKEUP: ULPI Wakeup. Writing the 1 to this bit will begin the wakeup operation. The bit will automatically transition to 0 after the wakeup is complete. Once this bit is set, the driver cannot set it back to 0. Note: The driver must never execute a wakeup and a read/write operation at the same time. 0 = CLEAR 1 = SET
30	RW	0x0	ULPI_RUN: ULPI read/write Run. Writing the 1 to this bit will begin the read/write operation. The bit will automatically transition to 0 after the read/write is complete. Once this bit is set, the driver cannot set it back to 0. Note: The driver must never execute a wakeup and a read/write operation at the same time. 0 = CLEAR 1 = SET
29	RW	0x0	ULPI_RD_WR: ULPI read/write control. (0) Read; (1) Write. This bit selects between running a read or write operation. 0 = READ 1 = WRITE
27	RO	X	ULPI_SYNC_STATE: ULPI sync state. (1) Normal Sync. State. (0) In another state (i.e., carkit, serial, low power). This bit represents the state of the ULPI interface. 0 = NOT_NORMAL 1 = NORMAL
26:24	RW	0x0	ULPI_PORT: ULPI PHY port number. This field should be always written as 0.
23:16	RW	0x0	ULPI_REG_ADDR: ULPI PHY register address. When doing a read or write operation to the ULPI PHY, the address of the ULPI PHY register being accessed is written to this field.
15:8	RO	X	ULPI_DATA_RD: ULPI PHY data read. The data from the ULPI PHY register can be read from here after the read operation completes.
7:0	RW	0x0	ULPI_DATA_WR: ULPI PHY data write. The data to write to the ULPI PHY register is written here.

23.9.1.25 USB2_CONTROLLER_USB2D_PORTSC1_0

USB2D Port Status/Control 1 Register

Offset: 0x174 | Read/Write: R/W | Reset: 0b0000000xx0000000xxx1xx00x0xx010x

Bit	R/W	Reset	Description
31:25	RW	0x0	DA: Device Address - RW. Default = 0000000b. The 7-bit USB device address for the device attached to an immediately downstream of the associated root port. A value of zero indicates no device is present or software support for this feature is not present. This is used by the Controller when sending the LPM token. This field is only valid when the core is operating in host mode. If in device mode it will be read only and always equal to 0000000b.

Bit	R/W	Reset	Description
24:23	RO	X	SSTS: Suspend Status - RO. Default = 00b. These two bits are used by software to determine whether an L1-based suspend request was successful, specifically: 00b - L1 state entered with success. ACK received from peripheral. 01b - NYET received from peripheral. It was not able to enter L1 state this time. 10b - L1 state not supported by peripheral. STALL received. 11b - Peripheral did not respond or an error occurred. The value of this field is only valid when the port resides in the L0 state - that is, the meaning of these bits is invalid whenever bit 7 of this register (SUSP) is one. Ideally, the Controller driver should read this register if it receives an interrupt after issuing a suspend using L1 support. In case of a non-success a port change interrupt will be fired and this field should be checked for a possible L1 failure. This field is only valid when the core is operating in host mode. If in device mode, it will be always equal to 00b. 0 = L1STATE_ENTERED 1 = NYET_PERIPH 2 = L1STATE_NOT_SUPPORTED 3 = PERIPH_NORESP_ERR
22	RW	0x0	WKOC: Default = 0b. Wake on Over-current Enable: Writing this bit to a one enables the port to be sensitive to over-current conditions as wake-up events. This field is zero if Port Power (PP) is zero. This bit should only be used when operating in Host mode. Writing this bit to 1 while the controller is working in device mode can result in undefined behavior. 0 = DISABLE 1 = ENABLE
21	RW	0x0	WKDS: Wake on Disconnect Enable: Writing this bit to a one enables the port to be sensitive to device disconnects as wake-up events. This field is zero if Port Power (PP) is zero or in device mode. This bit should only be used when operating in Host mode. Writing this bit to 1 while the controller is working in device mode can result in undefined behavior. This bit should not be written to 1 if there is no device connected. After the device disconnect is detected, this bit should be cleared to 0. 0 = DISABLE 1 = ENABLE
20	RW	0x0	WKCN: Wake on Connect Enable: Writing this bit to a one enables the port to be sensitive to device connects as wake-up events. This field is zero if Port Power (PP) is zero or in device mode. This bit should only be used when operating in Host mode. Writing this bit to 1 while the controller is working in device mode can result in undefined behavior. This bit should not be written to 1 while the device is connected. After the device connection is detected, this bit should be cleared to 0. 0 = DISABLE 1 = ENABLE
19:16	RW	0x0	PTC: Port Test Control: Any value other than zero indicates that the port is operating in test mode. Value Specific Test. 0000b: Not enabled. 0001b: J_ STATE. 0010b: K_STATE. 0011b: SEQ_NAK. 0100b: Packet. 0101b: FORCE_ENABLE. 0110b to 1111b: Reserved. Refer to Chapter 7 of the USB Specification Revision 2.0 for details on each test mode. 0 = NORMAL_OP 1 = TEST_J 2 = TEST_K 3 = TEST_SE0_NAK 4 = TEST_PKT 5 = TEST_FORCE_ENABLE
15:14	RO	X	PIC: Port Indicator Control: This field is not supported in the current implementation. Please use a GPIO if you wish to use Port Indicators.
13	RO	X	PO: Port Owner. Port owner handoff is not implemented in this design; therefore this bit will always be 0.
12	RW	0x1	PP: Port Power: The function of this bit depends on the value of the Port Power Switching (PPC) field in the HCSPARAMS register. The behavior is as follows: PPC PP Operation 0b 0b Read Only. A device controller with no OTG capability does not have port power control switches. 1b 1b/0b RW. Host/OTG controller requires port power control switches. This bit represents the current setting of the switch (0=off, 1=on). When power is not available on a port (i.e., PP equals a 0), the port is non-functional and will not report attaches, detaches, etc. When an over-current condition is detected on a powered port and PPC is a one, the PP bit in each affected port may be transitioned by the host controller driver from a one to a zero (removing power from the port).

Bit	R/W	Reset	Description
			0 = NOT_POWERED 1 = POWERED
11:10	RO	X	LS: Line state. These bits reflect the current logical levels of the D+ (bit 10) and D- (bit 11) signal lines. The encoding of the bits is: 00b = SE0. 01b = J-state. 10b = K-state. 11b = Undefined. The value of this field is undefined if Port Power (PP) is zero in host mode. In host mode, the use of line-state by the host controller driver is not necessary (unlike EHCI), because the port controller state machine and the port routing manage the connection of LS and FS. In device mode, the use of line-state by the device controller driver is not necessary. 0 = SE0 1 = J_STATE 2 = K_STATE 3 = UNDEFINED
9	RW	0x0	SLP: Suspend using L1 - RW. Default = 0b. When this bit is set to '1' and a non-zero Device Address (DA) is specified, the Controller will instigate L1 entry during suspend (bit 7) and L1 exit during resume (bit 6). When this bit is set to zero, the Controller will use the legacy (L2) mechanism. Software should only set this bit when the device attached immediately downstream supports L1 transitions. When acting as device, this bit is read-only and set to '1' by the hardware when the Controller enters is L1 state (LPM token received and accepted). Note: HSP is redundant with PSPD[27:26]. This bit is not defined in the EHCI specification.
8	RW	0x0	PR: This field is zero if Port Power (PP) is zero. In Host Mode: Read/Write. 1=Port is in Reset. 0=Port is not in Reset. When software writes a one to this bit the bus-reset sequence as defined in the USB Specification Revision 2.0 is started. This bit will automatically change to zero after the reset sequence is complete. This behavior is different from EHCI where the host controller driver is required to set this bit to a zero after the reset duration is timed in the driver. In Device Mode: This bit is a read only status bit. Device reset from the USB bus is also indicated in the USBSTS register. 0 = NOT_USB_RESET 1 = USB_RESET
7	RO	X	SUSP: Port suspend. 1=Port in suspend state. 0=Port not in suspend state. In Host Mode: Read/Write. Port Enabled Bit and Suspend bit of this register define the port states as follows: Bits [Port Enabled, Suspend] Port State 0x Disable 10 Enable 11 Suspend. When in the suspend state, downstream propagation of data is blocked on this port, except for port reset. The blocking occurs at the end of the current transaction if a transaction was in progress when this bit was written to 1. In the suspend state, the port is sensitive to resume detection. Note that the bit status does not change until the port is suspended and that there may be a delay in suspending a port if there is a transaction currently in progress on the USB. The host controller will unconditionally set this bit to zero when software sets the Force Port Resume bit to zero. A write of zero to this bit is ignored by the host controller. If host software sets this bit to a one when the port is not enabled (i.e., Port enabled bit is a zero), the results are undefined. This field is zero if Port Power (PP) is zero in host mode. In Device Mode: Read Only. This bit is a read only status bit. 0 = NOT_SUSPEND 1 = SUSPEND

Bit	R/W	Reset	Description
6	RW	0x0	FPR: Force Port Resume. 1= Resume detected/driven on port. 0=No resume (K state) detected/driven on port. In Host Mode: Software sets this bit to one to drive resume signaling. The Host Controller sets this bit to one if a J-to-K transition is detected while the port is in the Suspend state. When this bit transitions to a one because a J-to-K transition is detected, the Port Change Detect bit in the USBSTS register is also set to one. This bit will automatically change to zero after the resume sequence is complete. This behavior is different from EHCI where the host controller driver is required to set this bit to a zero after the resume duration is timed in the driver. Note that when the Host controller owns the port, the resume sequence follows the defined sequence documented in the USB Specification Revision 2.0. The resume signaling (Full-speed 'K') is driven on the port as long as this bit remains a one. This bit remains a one until the port has switched to the high-speed idle. Writing a zero has no effect because the port controller will time the resume operation to clear the bit when the port control state switches to HS or FS idle. This field is zero if Port Power (PP) is zero in host mode. This bit is not-EHCI compatible. In Device mode: After the device has been in Suspend State for 5ms or more, software must set this bit to one to drive resume signaling before clearing. The Device Controller will set this bit to one if a J-to-K transition is detected while the port is in the Suspend state. The bit will be cleared when the device returns to normal operation. Also, when this bit transitions to a one because a J-to-K transition is detected, the Port Change Detect bit in the USBSTS register is also set to one. Software should ensure that the PHY clock is operational before writing a 1 to this bit to start the resume sequence. This is true for both Device and Host modes. 0 = NO_RESUME 1 = RESUME
5	RO	X	OCC: Over-current Change: Not supported 0 = NO_CHANGE 1 = CHANGE
4	RO	X	OCA: Over-current Active: Not supported 0 = NO_OVER_CURRENT 1 = OVER_CURRENT
3	RW	0x0	PEC: Port Enable/Disable Change: 1=Port enabled/disabled status has changed. 0=No change. In Host Mode: For the root hub, this bit gets set to a one only when a port is disabled due to disconnect on the port or due to the appropriate conditions existing at the EOF2 point (See Chapter 11 of the USB Specification). Software clears this by writing a one to it. This field is zero if Port Power (PP) is zero. In Device mode: The device port is always enabled. (This bit will be zero.) 0 = NO_CHANGE 1 = CHANGE
2	RW	0x1	PE: Port Enabled/Disabled: 1=Enable. 0=Disable (default). In Host Mode: Ports can only be enabled by the host controller as a part of the reset and enable. Software cannot enable a port by writing a one to this field. Ports can be disabled by either a fault condition (disconnect event or other fault condition) or by the host software. Note that the bit status does not change until the port state actually changes. There may be a delay in disabling or enabling a port due to other host controller and bus events. When the port is disabled, (0b) downstream propagation of data is blocked except for reset. This field is zero if Port Power (PP) is zero in host mode. In Device Mode: The device port is always enabled. (This bit will be one) 0 = PORT_DISABLED 1 = PORT_ENABLED
1	RW	0x0	CSC: Connect Status Change: 1 =Change in Current Connect Status. 0=No change (default) In Host Mode: Indicates a change has occurred in the port's Current Connect Status. The host/device controller sets this bit for all changes to the port device connect status, even if system software has not cleared an existing connect status change. For example, the insertion status changes twice before system software has cleared the changed condition, hub hardware will be 'setting' an already-set bit (i.e., the bit will remain set). Software clears this bit by writing a one to it. This field is zero if Port Power (PP) is zero in host mode. This bit is undefined in device controller mode 0 = NO_CHANGE 1 = CHANGE

Bit	R/W	Reset	Description
0	RO	X	CCS: Current Connect Status. In Host Mode: 1=Device is present on port. 0=No device is present (default). This value reflects the current state of the port, and may not correspond directly to the event that caused the Connect Status Change bit (Bit 1) to be set. This field is zero if Port Power (PP) is zero in host mode. In Device Mode: 1=Attached 0=Not Attached (default) A one indicates that the device successfully attached and is operating in either high speed or full speed as indicated by the High Speed Port bit in this register. A zero indicates that the device did not attach successfully or was forcibly disconnected by the software writing a zero to the Run bit in the USBCMD register. It does not state the device being disconnected or suspended. 0 = NOT_CONNECTED 1 = CONNECTED

23.9.1.26 USB2_CONTROLLER_USB2D_HOSTPC1_DEVLC_0

USB2D Device Mode LPM Behavior and Control Register

This register controls the LPM behavior and controls the behavior of each USB port. Only available in device mode. This register shares the same address with the HOSTPC1 register (which is used only in host mode).

USB2D Host Mode LPM Behavior and Control Register

This register controls the LPM behavior and controls the behavior of each USB port. Only available in host mode. This register shares the same address with the DEVLC register (which is used only in device mode).

Offset: 0x1b4 | Read/Write: R/W | Reset: 0b0000xxx0000000000000xxxxxxxxxxx0

Bit	R/W	Reset	Description
31:29	RW	0x0	PTS: Parallel transceiver select. This bit is not defined in the EHCI specification. 0 = UTMI 1 = RESERVED 2 = ULPI 3 = ICUSB_SER 4 = HSIC
28	RW	0x0	STS: Serial transceiver not selected. This is the only value supported. This bit is not defined in the EHCI specification. 0 = PARALLEL_IF 1 = SERIAL_IF
27	RO	X	PTW: Parallel Transceiver Width. Fixed to 0. This bit is not defined in the EHCI specification. 0 = EIGHT_BIT 1 = RESERVED
26:25	RO	X	PSPD: This register field indicates the speed at which the port is operating. 00 = Full Speed 01 = Low Speed 10 = High Speed. This bit is not defined in the EHCI specification. 0 = FULL_SPEED 1 = LOW_SPEED 2 = HIGH_SPEED 3 = RESERVED
24	RW	0x0	ALPD: Auto Low Power While Disconnect - RW. Default = 0b. If set, this feature will be enabled, and every time the port enters the disconnect state it will also enter low power state,disabling the transceiver clock. The behavior will be same as if the PHCD bit was enabled (in fact this bit will be set to 1 as soon as low power mode is enabled).When this field is set the WKCN field of PORTSCx register (Wake on Connect Enable) will also be set. This way the core will wake up in case a connect is detected. There will be a delay between the detection of a disconnect and actually enter in low power mode. This delay can be controlled by writing to the ALPDD field in the register USBMODE. 0 = DONT_AUTO_LOW_POWER_WHILE_DISCONNECT 1 = AUTO_LOW_POWER_WHILE_DISCONNECT

Bit	R/W	Reset	Description
23	RW	0x0	PFSC: Port Force Full Speed Connect - RW. Default = 0b. Writing this bit to a '1b' will force the port to only connect at Full Speed. It disables the chirp sequence that allows the port to identify itself as High Speed. This is useful for testing FS configurations with an HS host, hub or device. This bit is not defined in the EHCI specification. 0 = DONT_FORCE_FULL_SPEED 1 = FORCE_FULL_SPEED
22	RW	0x0	PHCD: PHY Low Power Suspend - Clock disable: Writing this bit to a 1 will disable the PHY clock. Write a 0 enables it. Reading this bit will indicate the status of the PHY clock. NOTE: The PHY clock cannot be disabled if it is being used as the system clock. In device mode, the PHY can be put into Low Power Clock Disable when the device is not running (USBCMD RS=0b) or the host has signaled suspend (PORTSCx SUSP=1b). Low Power Clock Disable will be cleared automatically when the host has signaled resume. Before forcing a resume from the device, the Controller driver must clear this bit. In host mode, the PHY can be put into Low Power Suspend Clock Disable when the downstream device has been put into suspend mode or when no downstream device is connected. Low Power Clock Disable is completely under the control of software. 0 = DISABLE 1 = ENABLE
21:20	RW	0x0	LPMX: Auto LPM set - RW. Default = 00b. This bit field is valid during Host Mode Only. For Device Mode, this bit is reserved. Value Meaning 00b Disables auto LPM. 01b If there is no activity for a certain number of SOFs the controller will send an LPM token, enter in suspend and issue a port change interrupt. 10b Same as above but without issuing an interrupt. 11b Reserved for futures LPM enhancements. The detection of no activity is based on the absence of response from the downstream device. Because of this limitation this feature should not be used if ISO OUT endpoints are being used (as no handshake is expected).
17	RW	0x0	ASUS: Auto Low Power - RW. Default = 0b. This bit field is valid during Device Mode Only. In Host Mode, it is part of the ELPM field. This bit is used to control the auto low power feature. If set, the auto low power feature will be enabled and every time the port enters in suspend state it will also enter in low power state, disabling the transceiver clock. The behavior will be the same as if the PHCD bit was enabled (in fact this bit will be set to '1' as soon as low power mode is enabled). 0 = DISABLE 1 = ENABLE
19:16	RW	0x0	EPLPM: Endpoint for LPM token - RW. Default = 0000b. This bit field is valid during Host Mode Only. For Device Mode, bits [19:18] are reserved and bit 17 is ASUS, while bit 16 is STL. This sets the endpoint number to which the LPM token will be sent. It will be directly mapped to the ENDP field in the LPM token with the EXT PID.
16	RW	0x0	STL: STALL reply to LPM token - RW. Default = 0b. This bit field is valid during Device Mode Only. In Host Mode, it is part of the ELPM field. When this bit is set to '1', the Controller will reply always with STALL to all incoming LPM tokens. This bit overrides the LPM NYET bit (NYT). 0 = DISABLE 1 = ENABLE
15:12	RW	0x0	LPMFRM: Auto LPM SOF Threshold - RW. Default = 0000b. This bit field is valid during Host Mode Only. For Device Mode, this field is reserved. This holds the SOF counter threshold. When the number of SOFs with no activity in between reaches this threshold and the auto LPM is enabled, an LPM token will be sent and the port will enter in suspend state. The SOF counter for this threshold is incremented each 125 µs, even if the port is not in HS operation.
11:1	RO	X	BA: bmAttributes - RO. Default = 00000000000b. This holds the bmAttributes field of the LPM sub-token received, after the EXT PID token.

Bit	R/W	Reset	Description
0	RW	0x0	NYT_ASUS: NYET reply to LPM token - RW. Default = 0b. This bit is NYT during Device Mode. Details follow: When this bit is to '1', the device controller will NYET all the LPM tokens. When this bit is set to '0', the Controller will ACK all the LPM tokens if the STALL bit (STL) is also set to '0'. This bit is ASUS in Host Mode. Details follow: This bit is used to control the auto low power feature. If set, the auto low power feature will be enabled and every time the port enters in suspend state it will also enter in low power state, disabling the transceiver clock. The behavior will be the same as if the PHCD bit was enabled (in fact this bit will be set to '1' as soon as low power mode is enabled). 0 = DISABLE 1 = ENABLE

23.9.1.27 USB2_CONTROLLER_USB2D_OTGSC_0

USB2D On-The-Go (OTG) Status and Control Register

Offset: 0x1f4 | Read/Write: R/W | Reset: 0bx0000000x0000000xxxxxxxxxx000x00

Bit	R/W	Reset	Description
30	RW	0x0	DPIE: Data Pulse Interrupt Enable. Setting this bit enables the Data pulse interrupt. 0 = DISABLE 1 = ENABLE
29	RW	0x0	ONEMSE: 1 millisecond timer Interrupt enable. Setting this bit enables the 1 millisecond timer interrupt. 0 = DISABLE 1 = ENABLE
28	RW	0x0	BSEIE: B Session End Interrupt Enable. Setting this bit enables the B session end interrupt 0 = DISABLE 1 = ENABLE
27	RW	0x0	BSVIE: B Session Valid Interrupt Enable. Setting this bit enables the B session valid interrupt 0 = DISABLE 1 = ENABLE
26	RW	0x0	ASVIE: A Session Valid Interrupt Enable. Setting this bit enables the A session valid interrupt 0 = DISABLE 1 = ENABLE
25	RW	0x0	AVVIE: A VBus Valid Interrupt Enable. Setting this bit enables the A VBus valid interrupt 0 = DISABLE 1 = ENABLE
24	RW	0x0	IDIE: USB ID Interrupt Enable. Setting this bit enables the USB ID interrupt 0 = DISABLE 1 = ENABLE
22	RW	0x0	DPIS: Data Pulse Interrupt Status. This bit is set when data bus pulsing occurs on DP or DM. Data bus pulsing is only detected when USBMODE.CM = Host (11) and PORTSC(0). PortPower = Off (0). Software writes a 1 to clear this bit. 0 = INT_CLEAR 1 = INT_SET
21	RW	0x0	ONEMSS: 1 millisecond timer Interrupt Status: This bit is set once every millisecond. Software writes a 1 to clear it. 0 = INT_CLEAR 1 = INT_SET
20	RW	0x0	BSEIS: B Session End Interrupt Status. This bit is set when VBus has fallen below the B session end threshold. Software writes a 1 to clear this bit . 0 = INT_CLEAR 1 = INT_SET
19	RW	0x0	BSVIS: B Session Valid Interrupt Status. This bit is set when VBus has either risen above or fallen below the B session valid threshold (0.8 VDC). Software writes a 1 to clear this bit. 0 = INT_CLEAR 1 = INT_SET

Bit	R/W	Reset	Description
18	RW	0x0	ASVIS: A Session Valid Interrupt Status. This bit is set when VBus has either risen above or fallen below the A session valid threshold (0.8 VDC). Software writes a one to clear this bit. 0 = INT_CLEAR 1 = INT_SET
17	RW	0x0	AVVIS: A VBus Valid Interrupt Status. This bit is set when VBus has either risen above or fallen below the VBus valid threshold (4.4 VDC) on an A device. Software writes a 1 to clear this bit. 0 = INT_CLEAR 1 = INT_SET
16	RW	0x0	IDIS: USB ID Interrupt Status. This bit is set when a change on the ID input has been detected. Software writes a 1 to clear this bit. 0 = INT_CLEAR 1 = INT_SET
14	RO	X	DPS: Data Bus Pulsing Status. A 1 indicates data bus pulsing is being detected on the port. 0 = STS_CLEAR 1 = STS_SET
13	RO	X	ONEMST: 1 millisecond timer toggle. This bit toggles once per millisecond 0 = STS_CLEAR 1 = STS_SET
12	RO	X	BSE: B session End. Indicates VBus is below the B session end threshold 0 = STS_CLEAR 1 = STS_SET
11	RO	X	BSV: B Session Valid. Indicates VBus is above the B session valid threshold 0 = STS_CLEAR 1 = STS_SET
10	RO	X	ASV: A Session Valid. Indicates VBus is above the A session valid threshold 0 = STS_CLEAR 1 = STS_SET
9	RO	X	AVV: A VBus Valid. Indicates VBus is above the A VBus valid threshold 0 = STS_CLEAR 1 = STS_SET
8	RO	X	ID: USB ID: 0 = A-device 1 = B-device 0 = A_DEV 1 = B_DEV
5	RW	0x0	IDPU: USB ID Pullup 0 = CLEAR 1 = SET
4	RW	0x0	DP: Data Pulsing. Setting this bit causes the pull-up on DP to be asserted for data pulsing during SRP. 0 = NO_DATA_PULSE 1 = DATA_PULSE
3	RW	0x0	OT: OTG Termination. This bit must be set when the OTG device is in device mode, this controls the pulldown on DM. 0 = NO_OTG_TERM 1 = OTG_TERM
1	RW	0x0	VC: VBUS Charge. Setting this bit causes the VBus line to be charged. This is used for VBus pulsing during SRP. 0 = NO_VBUS_CHRG 1 = VBUS_CHRG
0	RW	0x0	VD: VBUS_Discharge. Read/write. Setting this bit causes Vbus to discharge through a resistor. 0 = NO_VBUS_DISCHRG 1 = VBUS_DISCHRG

23.9.1.28 USB2_CONTROLLER_USB2D_USBMODE_0

USB2D USB Device Mode Register

Offset: 0x1f8 | Read/Write: R/W | Reset: 0b00000000000000000xxxxxxxxx0xxxxx

Bit	R/W	Reset	Description
31:16	RW	0x0	ALPDD: Auto Low Power While Disconnect Delay, Used when the ALPD field of the HOSTPCx register is set. Defines the delay between disconnect detection and entering in low power mode. The delay is <this register value>*64*100/3 in milliseconds. The maximum value is 65535*64*100/3 = 139,808 ms. The minimum value is 0. Only used in host mode.
15	RW	0x0	SRT: Shorten USB Reset Time. Software should never set this to 1.
5	RW	0x0	VBPS: VBUS Power Select This can be used by logic that selects between an on-chip Vbus power source (charge pump) and an off-chip source in systems when both are available. Only to be used in Host Mode. No functionality is implemented for this, so software should not use this bit.
4	RO	X	SDIS: Stream disable: 1: Streaming is disabled - helpful to avoid overruns/underruns when the system load is too high. 0 = STREAM_ENABLE 1 = STREAM_DISABLE
3	RO	X	SLOM: Setup Lockout Mode: In device mode, this bit controls the behavior of the setup lockout mechanism. 0: Setup lockout is ON (default). 1: Setup lockout is OFF. Firmware requires the use of setup tripwire semaphore in USB2D_USBCMD register. 0 = LOCKOUT_ON 1 = LOCKOUT_OFF
2	RO	X	ES: Endian Select: Note: For this implementation, this bit should be always set to 0 (little endian). 0 = LITTLE_ENDIAN 1 = RESERVED
1:0	RO	X	CM: Controller Mode: The controller mode will default to an idle state and will need to be initialized to the desired operating mode after reset. This register can only be written once after reset. If it is necessary to switch modes, software must reset the controller by writing to the RESET bit in the USBCMD register before reprogramming this register. 00 = Idle [Default]. 01 = Reserved. 10 = Device Controller. 11 = Host Controller. 0 = IDLE 1 = RESERVED 2 = DEVICE_MODE 3 = HOST_MODE

23.9.1.29 USB2_CONTROLLER_USB2D_ENDPTNAK_0

USB2D Endpoint NAK register

Offset: 0x200 | Read/Write: R/W | Reset: 0b00000000000000000000000000000000

Bit	Reset	Description
31:16	0x0	EPTN: TX Endpoint NAK R/WC. Each TX endpoint has 1 bit in this field. The bit is set when the device sends a NAK handshake on a received IN token for the corresponding endpoint. 0 = CLEAR 1 = SET
15:0	0x0	EPRN: RX Endpoint NAK R/WC. Each RX endpoint has 1 bit in this field. The bit is set when the device sends a NAK handshake on a received OUT or PING token for the corresponding endpoint. 0 = CLEAR 1 = SET

23.9.1.30 USB2_CONTROLLER_USB2D_ENDPTNAK_ENABLE_0

USB2D Endpoint NAK Enable Register

Offset: 0x204 | Read/Write: R/W | Reset: 0b00000000000000000000000000000000

Bit	Reset	Description
31:16	0x0	EPTNE: TX Endpoint NAK Enable R/W. Each bit is an enable bit for the corresponding TX Endpoint NAK bit. If this bit is set and the corresponding TX Endpoint NAK bit is set, the NAK Interrupt bit is set. 0 = DISABLE 1 = ENABLE
15:0	0x0	EPRNE: RX Endpoint NAK Enable R/W. Each bit is an enable bit for the corresponding RX Endpoint NAK bit. If this bit is set and the corresponding RX Endpoint NAK bit is set, the NAK Interrupt bit is set. 0 = DISABLE 1 = ENABLE

23.9.1.31 USB2_CONTROLLER_USB2D_ENDPTSETUPSTAT_0

USB2D Endpoint Setup Status Register

Offset: 0x208 | Read/Write: R/W | Reset: 0bxxxxxxxxxxxxxxxx0000000000000000

Bit	Reset	Description
15	0x0	ENDPTSETUPSTAT15: Endpoint 15 Setup Status: For every setup transaction that is received, this bit is set to 1. Software must clear or acknowledge the setup transfer by writing a 1 to it after it has read the setup data from Queue head. The response to a setup packet (as in the order of operations and total response time) is crucial to limit bus time-outs while the setup lock-out mechanism is engaged. This register is only used in device mode. 0 = NOT_RCVD 1 = SETUP_RCVD
14	0x0	ENDPTSETUPSTAT14: Endpoint 14 Setup Status: For every setup transaction that is received, this bit is set to 1. Software must clear or acknowledge the setup transfer by writing a 1 to it after it has read the setup data from Queue head. The response to a setup packet (as in the order of operations and total response time) is crucial to limit bus time-outs while the setup lock-out mechanism is engaged. This register is only used in device mode. 0 = NOT_RCVD 1 = SETUP_RCVD
13	0x0	ENDPTSETUPSTAT13: Endpoint 13 Setup Status: For every setup transaction that is received, this bit is set to 1. Software must clear or acknowledge the setup transfer by writing a 1 to it after it has read the setup data from Queue head. The response to a setup packet (as in the order of operations and total response time) is crucial to limit bus time-outs while the setup lock-out mechanism is engaged. This register is only used in device mode. 0 = NOT_RCVD 1 = SETUP_RCVD
12	0x0	ENDPTSETUPSTAT12: Endpoint 12 Setup Status: For every setup transaction that is received, this bit is set to 1. Software must clear or acknowledge the setup transfer by writing a 1 to it after it has read the setup data from Queue head. The response to a setup packet (as in the order of operations and total response time) is crucial to limit bus time-outs while the setup lock-out mechanism is engaged. This register is only used in device mode. 0 = NOT_RCVD 1 = SETUP_RCVD
11	0x0	ENDPTSETUPSTAT11: Endpoint 11 Setup Status: For every setup transaction that is received, this bit is set to 1. Software must clear or acknowledge the setup transfer by writing a 1 to it after it has read the setup data from Queue head. The response to a setup packet (as in the order of operations and total response time) is crucial to limit bus time-outs while the setup lock-out mechanism is engaged. This register is only used in device mode. 0 = NOT_RCVD 1 = SETUP_RCVD

Bit	Reset	Description
10	0x0	ENDPTSETUPSTAT10: Endpoint 10 Setup Status: For every setup transaction that is received, this bit is set to 1. Software must clear or acknowledge the setup transfer by writing a 1 to it after it has read the setup data from Queue head. The response to a setup packet (as in the order of operations and total response time) is crucial to limit bus time-outs while the setup lock-out mechanism is engaged. This register is only used in device mode. 0 = NOT_RCVD 1 = SETUP_RCVD
9	0x0	ENDPTSETUPSTAT9: Endpoint 9 Setup Status: For every setup transaction that is received, this bit is set to 1. Software must clear or acknowledge the setup transfer by writing a 1 to it after it has read the setup data from Queue head. The response to a setup packet (as in the order of operations and total response time) is crucial to limit bus time-outs while the setup lock-out mechanism is engaged. This register is only used in device mode. 0 = NOT_RCVD 1 = SETUP_RCVD
8	0x0	ENDPTSETUPSTAT8: Endpoint 8 Setup Status: For every setup transaction that is received, this bit is set to 1. Software must clear or acknowledge the setup transfer by writing a 1 to it after it has read the setup data from Queue head. The response to a setup packet (as in the order of operations and total response time) is crucial to limit bus time-outs while the setup lock-out mechanism is engaged. This register is only used in device mode. 0 = NOT_RCVD 1 = SETUP_RCVD
7	0x0	ENDPTSETUPSTAT7: Endpoint 7 Setup Status: For every setup transaction that is received, this bit is set to 1. Software must clear or acknowledge the setup transfer by writing a 1 to it after it has read the setup data from Queue head. The response to a setup packet (as in the order of operations and total response time) is crucial to limit bus time-outs while the setup lock-out mechanism is engaged. This register is only used in device mode. 0 = NOT_RCVD 1 = SETUP_RCVD
6	0x0	ENDPTSETUPSTAT6: Endpoint 6 Setup Status: For every setup transaction that is received, this bit is set to 1. Software must clear or acknowledge the setup transfer by writing a 1 to it after it has read the setup data from Queue head. The response to a setup packet (as in the order of operations and total response time) is crucial to limit bus time-outs while the setup lock-out mechanism is engaged. 23.9.1.33 USB2_CONTROLLER_USB2D_ENDPTFLUSH_0

USB2D Endpoint De-Initialization Register

Offset: 0x210 | Read/Write: R/W | Reset: 0b00000000000000000000000000000000

Bit	Reset	Description
31	0x0	FETB15: Flush Endpoint Transmit Buffer: Writing a one to this bit causes the associated endpoint to clear any primed buffers. If a packet is in progress for the associated endpoint that transfer will continue until completion. Hardware clears this register after the endpoint flush operation is successful. This is only used in device mode. 0 = DONT_FLUSH 1 = FLUSH
30	0x0	FETB14: Flush Endpoint Transmit Buffer: Writing a one to this bit causes the associated endpoint to clear any primed buffers. If a packet is in progress for the associated endpoint that transfer will continue until completion. Hardware clears this register after the endpoint flush operation is successful. This is only used in device mode. 0 = DONT_FLUSH 1 = FLUSH
29	0x0	FETB13: Flush Endpoint Transmit Buffer: Writing a one to this bit causes the associated endpoint to clear any primed buffers. If a packet is in progress for the associated endpoint that transfer will continue until completion. Hardware clears this register after the endpoint flush operation is successful. This is only used in device mode. 0 = DONT_FLUSH 1 = FLUSH
28	0x0	FETB12: Flush Endpoint Transmit Buffer: Writing a one to this bit causes the associated endpoint to clear any primed buffers. If a packet is in progress for the associated endpoint that transfer will continue until completion. Hardware clears this register after the endpoint flush operation is successful. This is only used in device mode. 0 = DONT_FLUSH 1 = FLUSH

Bit	Reset	Description
27	0x0	FETB11: Flush Endpoint Transmit Buffer: Writing a one to this bit causes the associated endpoint to clear any primed buffers. If a packet is in progress for the associated endpoint that transfer will continue until completion. Hardware clears this register after the endpoint flush operation is successful. This is only used in device mode. 0 = DONT_FLUSH 1 = FLUSH
26	0x0	FETB10: Flush Endpoint Transmit Buffer: Writing a one to this bit causes the associated endpoint to clear any primed buffers. If a packet is in progress for the associated endpoint that transfer will continue until completion. Hardware clears this register after the endpoint flush operation is successful. This is only used in device mode. 0 = DONT_FLUSH 1 = FLUSH
25	0x0	FETB9: Flush Endpoint Transmit Buffer: Writing a one to this bit causes the associated endpoint to clear any primed buffers. If a packet is in progress for the associated endpoint that transfer will continue until completion. Hardware clears this register after the endpoint flush operation is successful. This is only used in device mode. 0 = DONT_FLUSH 1 = FLUSH
24	0x0	FETB8: Flush Endpoint Transmit Buffer: Writing a one to this bit causes the associated endpoint to clear any primed buffers. If a packet is in progress for the associated endpoint that transfer will continue until completion. Hardware clears this register after the endpoint flush operation is successful. This is only used in device mode. 0 = DONT_FLUSH 1 = FLUSH
23	0x0	FETB7: Flush Endpoint Transmit Buffer: Writing a one to this bit causes the associated endpoint to clear any primed buffers. If a packet is in progress for the associated endpoint that transfer will continue until completion. Hardware clears this register after the endpoint flush operation is successful. This is only used in device mode. 0 = DONT_FLUSH 1 = FLUSH
22	0x0	FETB6: Flush Endpoint Transmit Buffer: Writing a one to this bit causes the associated endpoint to clear any primed buffers. If a packet is in progress for the associated endpoint that transfer will continue until completion. Hardware clears this register after the endpoint flush operation is successful. This is only used in device mode. 0 = DONT_FLUSH 1 = FLUSH
21	0x0	FETB5: Flush Endpoint Transmit Buffer: Writing a one to this bit causes the associated endpoint to clear any primed buffers. If a packet is in progress for the associated endpoint that transfer will continue until completion. Hardware clears this register after the endpoint flush operation is successful. This is only used in device mode. 0 = DONT_FLUSH 1 = FLUSH
20	0x0	FETB4: Flush Endpoint Transmit Buffer: Writing a one to this bit causes the associated endpoint to clear any primed buffers. If a packet is in progress for the associated endpoint that transfer will continue until completion. Hardware clears this register after the endpoint flush operation is successful. This is only used in device mode. 0 = DONT_FLUSH 1 = FLUSH
19	0x0	FETB3: Flush Endpoint Transmit Buffer: Writing a one to this bit causes the associated endpoint to clear any primed buffers. If a packet is in progress for the associated endpoint that transfer will continue until completion. Hardware clears this register after the endpoint flush operation is successful. This is only used in device mode. 0 = DONT_FLUSH 1 = FLUSH
18	0x0	FETB2: Flush Endpoint Transmit Buffer: Writing a one to this bit causes the associated endpoint to clear any primed buffers. If a packet is in progress for the associated endpoint that transfer will continue until completion. Hardware clears this register after the endpoint flush operation is successful. This is only used in device mode. 0 = DONT_FLUSH 1 = FLUSH

Bit	Reset	Description
17	0x0	FETB1: Writing a one to this bit causes the associated endpoint to clear any primed buffers. If a packet is in progress for the associated endpoint that transfer will continue until completion. Hardware clears this register after the endpoint flush operation is successful. This is only used in device mode. 0 = DONT_FLUSH 1 = FLUSH
16	0x0	FETB0: Writing a one to this bit causes the associated endpoint to clear any primed buffers. If a packet is in progress for the associated endpoint that transfer will continue until completion. Hardware clears this register after the endpoint flush operation is successful. This is only used in device mode. 0 = DONT_FLUSH 1 = FLUSH
15	0x0	FERB15: Flush Endpoint Receive Buffer: Writing a one to this bit causes the associated endpoint to clear any primed buffers. If a packet is in progress for the associated endpoint that transfer will continue until completion. Hardware clears this register after the endpoint flush operation is successful. This is only used in device mode. 0 = DONT_FLUSH 1 = FLUSH
14	0x0	FERB14: Flush Endpoint Receive Buffer: Writing a one to this bit causes the associated endpoint to clear any primed buffers. If a packet is in progress for the associated endpoint that transfer will continue until completion. Hardware clears this register after the endpoint flush operation is successful. This is only used in device mode. 0 = DONT_FLUSH 1 = FLUSH
13	0x0	FERB13: Flush Endpoint Receive Buffer: Writing a one to this bit causes the associated endpoint to clear any primed buffers. If a packet is in progress for the associated endpoint that transfer will continue until completion. Hardware clears this register after the endpoint flush operation is successful. This is only used in device mode. 0 = DONT_FLUSH 1 = FLUSH
12	0x0	FERB12: Flush Endpoint Receive Buffer: Writing a one to this bit causes the associated endpoint to clear any primed buffers. If a packet is in progress for the associated endpoint that transfer will continue until completion. Hardware clears this register after the endpoint flush operation is successful. This is only used in device mode. 0 = DONT_FLUSH 1 = FLUSH
11	0x0	FERB11: Flush Endpoint Receive Buffer: Writing a one to this bit causes the associated endpoint to clear any primed buffers. If a packet is in progress for the associated endpoint that transfer will continue until completion. Hardware clears this register after the endpoint flush operation is successful. This is only used in device mode. 0 = DONT_FLUSH 1 = FLUSH
10	0x0	FERB10: Flush Endpoint Receive Buffer: Writing a one to this bit causes the associated endpoint to clear any primed buffers. If a packet is in progress for the associated endpoint that transfer will continue until completion. Hardware clears this register after the endpoint flush operation is successful. This is only used in device mode. 0 = DONT_FLUSH 1 = FLUSH
9	0x0	FERB9: Flush Endpoint Receive Buffer: Writing a one to this bit causes the associated endpoint to clear any primed buffers. If a packet is in progress for the associated endpoint that transfer will continue until completion. Hardware clears this register after the endpoint flush operation is successful. This is only used in device mode. 0 = DONT_FLUSH 1 = FLUSH
8	0x0	FERB8: Flush Endpoint Receive Buffer: Writing a one to this bit causes the associated endpoint to clear any primed buffers. If a packet is in progress for the associated endpoint that transfer will continue until completion. Hardware clears this register after the endpoint flush operation is successful. This is only used in device mode. 0 = DONT_FLUSH 1 = FLUSH

Bit	Reset	Description
7	0x0	FERB7: Flush Endpoint Receive Buffer: Writing a one to this bit causes the associated endpoint to clear any primed buffers. If a packet is in progress for the associated endpoint that transfer will continue until completion. Hardware clears this register after the endpoint flush operation is successful. This is only used in device mode. 0 = DONT_FLUSH 1 = FLUSH
6	0x0	FERB6: Flush Endpoint Receive Buffer: Writing a one to this bit causes the associated endpoint to clear any primed buffers. If a packet is in progress for the associated endpoint that transfer will continue until completion. Hardware clears this register after the endpoint flush operation is successful. This is only used in device mode. 0 = DONT_FLUSH 1 = FLUSH
5	0x0	FERB5: Flush Endpoint Receive Buffer: Writing a one to this bit causes the associated endpoint to clear any primed buffers. If a packet is in progress for the associated endpoint that transfer will continue until completion. Hardware clears this register after the endpoint flush operation is successful. This is only used in device mode. 0 = DONT_FLUSH 1 = FLUSH
4	0x0	FERB4: Flush Endpoint Receive Buffer: Writing a one to this bit causes the associated endpoint to clear any primed buffers. If a packet is in progress for the associated endpoint that transfer will continue until completion. Hardware clears this register after the endpoint flush operation is successful. This is only used in device mode. 0 = DONT_FLUSH 1 = FLUSH
3	0x0	FERB3: Flush Endpoint Receive Buffer: Writing a one to this bit causes the associated endpoint to clear any primed buffers. If a packet is in progress for the associated endpoint that transfer will continue until completion. Hardware clears this register after the endpoint flush operation is successful. This is only used in device mode. 0 = DONT_FLUSH 1 = FLUSH
2	0x0	FERB2: Flush Endpoint Receive Buffer: Writing a one to this bit causes the associated endpoint to clear any primed buffers. If a packet is in progress for the associated endpoint that transfer will continue until completion. Hardware clears this register after the endpoint flush operation is successful. This is only used in device mode. 0 = DONT_FLUSH 1 = FLUSH
1	0x0	FERB1: Flush Endpoint Receive Buffer: Writing a one to this bit causes the associated endpoint to clear any primed buffers. If a packet is in progress for the associated endpoint that transfer will continue until completion. Hardware clears this register after the endpoint flush operation is successful. This is only used in device mode. 0 = DONT_FLUSH 1 = FLUSH
0	0x0	FERB0: Flush Endpoint Receive Buffer: Writing a one to this bit causes the associated endpoint to clear any primed buffers. This is only used in device mode. 0 = DONT_FLUSH 1 = FLUSH

23.9.1.34 USB2_CONTROLLER_USB2D_ENDPTSTATUS_0

USB2D Endpoint Status Register

Offset: 0x214 | Read/Write: RO | Reset: 0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx

Bit	Reset	Description
31	X	ETBR15: Endpoint Transmit Buffer Ready: One bit for each endpoint indicates status of the respective endpoint buffer. This bit is set to a one by the hardware as a response to receiving a command from a corresponding bit in the ENDPTPRIME register. There will always be a delay between setting a bit in the ENDPTPRIME register and endpoint indicating ready. This delay time varies based upon the current USB traffic and the number of bits set in the ENDPTPRIME register. Buffer ready is cleared by USB reset, by the USB DMA system, or through the ENDPTFLUSH register. This is only used in device mode. 0 = NOT_READY 1 = READY
30	X	ETBR14: Endpoint Transmit Buffer Ready: One bit for each endpoint indicates status of the respective endpoint buffer. This bit is set to a one by the hardware as a response to receiving a command from a corresponding bit in the ENDPTPRIME register. There will always be a delay between setting a bit in the ENDPTPRIME register and endpoint indicating ready. This delay time varies based upon the current USB traffic and the number of bits set in the ENDPTPRIME register. Buffer ready is cleared by USB reset, by the USB DMA system, or through the ENDPTFLUSH register. This is only used in device mode. 0 = NOT_READY 1 = READY
29	X	ETBR13: Endpoint Transmit Buffer Ready: One bit for each endpoint indicates status of the respective endpoint buffer. This bit is set to a one by the hardware as a response to receiving a command from a corresponding bit in the ENDPTPRIME register. There will always be a delay between setting a bit in the ENDPTPRIME register and endpoint indicating ready. This delay time varies based upon the current USB traffic and the number of bits set in the ENDPTPRIME register. Buffer ready is cleared by USB reset, by the USB DMA system, or through the ENDPTFLUSH register. This is only used in device mode. 0 = NOT_READY 1 = READY
28	X	ETBR12: Endpoint Transmit Buffer Ready: One bit for each endpoint indicates status of the respective endpoint buffer. This bit is set to a one by the hardware as a response to receiving a command from a corresponding bit in the ENDPTPRIME register. There will always be a delay between setting a bit in the ENDPTPRIME register and endpoint indicating ready. This delay time varies based upon the current USB traffic and the number of bits set in the ENDPTPRIME register. Buffer ready is cleared by USB reset, by the USB DMA system, or through the ENDPTFLUSH register. This is only used in device mode. 0 = NOT_READY 1 = READY
27	X	ETBR11: Endpoint Transmit Buffer Ready: One bit for each endpoint indicates status of the respective endpoint buffer. This bit is set to a one by the hardware as a response to receiving a command from a corresponding bit in the ENDPTPRIME register. There will always be a delay between setting a bit in the ENDPTPRIME register and endpoint indicating ready. This delay time varies based upon the current USB traffic and the number of bits set in the ENDPTPRIME register. Buffer ready is cleared by USB reset, by the USB DMA system, or through the ENDPTFLUSH register. This is only used in device mode. 0 = NOT_READY 1 = READY
26	X	ETBR10: Endpoint Transmit Buffer Ready: One bit for each endpoint indicates status of the respective endpoint buffer. This bit is set to a one by the hardware as a response to receiving a command from a corresponding bit in the ENDPTPRIME register. There will always be a delay between setting a bit in the ENDPTPRIME register and endpoint indicating ready. This delay time varies based upon the current USB traffic and the number of bits set in the ENDPTPRIME register. Buffer ready is cleared by USB reset, by the USB DMA system, or through the ENDPTFLUSH register. This is only used in device mode. 0 = NOT_READY 1 = READY
25	X	ETBR9: Endpoint Transmit Buffer Ready: One bit for each endpoint indicates status of the respective endpoint buffer. This bit is set to a one by the hardware as a response to receiving a command from a corresponding bit in the ENDPTPRIME register. There will always be a delay between setting a bit in the ENDPTPRIME register and endpoint indicating ready. This delay time varies based upon the current USB traffic and the number of bits set in the ENDPTPRIME register. Buffer ready is cleared by USB reset, by the USB DMA system, or through the ENDPTFLUSH register. This is only used in device mode. 0 = NOT_READY 1 = READY

Bit	Reset	Description
24	X	ETBR8: Endpoint Transmit Buffer Ready: One bit for each endpoint indicates status of the respective endpoint buffer. This bit is set to a one by the hardware as a response to receiving a command from a corresponding bit in the ENDPTPRIME register. There will always be a delay between setting a bit in the ENDPTPRIME register and endpoint indicating ready. This delay time varies based upon the current USB traffic and the number of bits set in the ENDPTPRIME register. Buffer ready is cleared by USB reset, by the USB DMA system, or through the ENDPTFLUSH register. This is only used in device mode. 0 = NOT_READY 1 = READY
23	X	ETBR7: Endpoint Transmit Buffer Ready: One bit for each endpoint indicates status of the respective endpoint buffer. This bit is set to a one by the hardware as a response to receiving a command from a corresponding bit in the ENDPTPRIME register. There will always be a delay between setting a bit in the ENDPTPRIME register and endpoint indicating ready. This delay time varies based upon the current USB traffic and the number of bits set in the ENDPTPRIME register. Buffer ready is cleared by USB reset, by the USB DMA system, or through the ENDPTFLUSH register. This is only used in device mode. 0 = NOT_READY 1 = READY
22	X	ETBR6: Endpoint Transmit Buffer Ready: One bit for each endpoint indicates status of the respective endpoint buffer. This bit is set to a one by the hardware as a response to receiving a command from a corresponding bit in the ENDPTPRIME register. There will always be a delay between setting a bit in the ENDPTPRIME register and endpoint indicating ready. This delay time varies based upon the current USB traffic and the number of bits set in the ENDPTPRIME register. Buffer ready is cleared by USB reset, by the USB DMA system, or through the ENDPTFLUSH register. This is only used in device mode. 0 = NOT_READY 1 = READY
21	X	ETBR5: Endpoint Transmit Buffer Ready: One bit for each endpoint indicates status of the respective endpoint buffer. This bit is set to a one by the hardware as a response to receiving a command from a corresponding bit in the ENDPTPRIME register. There will always be a delay between setting a bit in the ENDPTPRIME register and endpoint indicating ready. This delay time varies based upon the current USB traffic and the number of bits set in the ENDPTPRIME register. Buffer ready is cleared by USB reset, by the USB DMA system, or through the ENDPTFLUSH register. This is only used in device mode. 0 = NOT_READY 1 = READY
20	X	ETBR4: Endpoint Transmit Buffer Ready: One bit for each endpoint indicates status of the respective endpoint buffer. This bit is set to a one by the hardware as a response to receiving a command from a corresponding bit in the ENDPTPRIME register. There will always be a delay between setting a bit in the ENDPTPRIME register and endpoint indicating ready. This delay time varies based upon the current USB traffic and the number of bits set in the ENDPTPRIME register. Buffer ready is cleared by USB reset, by the USB DMA system, or through the ENDPTFLUSH register. This is only used in device mode. 0 = NOT_READY 1 = READY
19	X	ETBR3: Endpoint Transmit Buffer Ready: One bit for each endpoint indicates status of the respective endpoint buffer. This bit is set to a one by the hardware as a response to receiving a command from a corresponding bit in the ENDPTPRIME register. There will always be a delay between setting a bit in the ENDPTPRIME register and endpoint indicating ready. This delay time varies based upon the current USB traffic and the number of bits set in the ENDPTPRIME register. Buffer ready is cleared by USB reset, by the USB DMA system, or through the ENDPTFLUSH register. This is only used in device mode. 0 = NOT_READY 1 = READY
18	X	ETBR2: Endpoint Transmit Buffer Ready: One bit for each endpoint indicates status of the respective endpoint buffer. This bit is set to a one by the hardware as a response to receiving a command from a corresponding bit in the ENDPTPRIME register. There will always be a delay between setting a bit in the ENDPTPRIME register and endpoint indicating ready. This delay time varies based upon the current USB traffic and the number of bits set in the ENDPTPRIME register. Buffer ready is cleared by USB reset, by the USB DMA system, or through the ENDPTFLUSH register. This is only used in device mode. 0 = NOT_READY 1 = READY

Bit	Reset	Description

23.9.1.35 USB2_CONTROLLER_USB2D_ENDPTCOMPLETE_0

USB2D Endpoint Complete Register

Offset: 0x218 | Read/Write: R/W | Reset: 0b00000000000000000000000000000000

Bit	Reset	Description
31	0x0	ETCE15: Endpoint Transmit Complete Event: Each bit indicates a transmit event (IN/INTERRUPT) occurred and software should read the corresponding endpoint queue to determine the endpoint status. If the corresponding IOC bit is set in the Transfer Descriptor, then this bit will be set simultaneously with the USBINT. Writing a one clears the corresponding bit in this register. This is only used in device mode. 0 = NOT_COMPLETE 1 = COMPLETE
30	0x0	ETCE14: Endpoint Transmit Complete Event: Each bit indicates a transmit event (IN/INTERRUPT) occurred and software should read the corresponding endpoint queue to determine the endpoint status. If the corresponding IOC bit is set in the Transfer Descriptor, then this bit will be set simultaneously with the USBINT. Writing a one clears the corresponding bit in this register. This is only used in device mode. 0 = NOT_COMPLETE 1 = COMPLETE
29	0x0	ETCE13: Endpoint Transmit Complete Event: Each bit indicates a transmit event (IN/INTERRUPT) occurred and software should read the corresponding endpoint queue to determine the endpoint status. If the corresponding IOC bit is set in the Transfer Descriptor, then this bit will be set simultaneously with the USBINT. Writing a one clears the corresponding bit in this register. This is only used in device mode. 0 = NOT_COMPLETE 1 = COMPLETE

Bit	Reset	Description
28	0x0	ETCE12: Endpoint Transmit Complete Event: Each bit indicates a transmit event (IN/INTERRUPT) occurred and software should read the corresponding endpoint queue to determine the endpoint status. If the corresponding IOC bit is set in the Transfer Descriptor, then this bit will be set simultaneously with the USBINT. Writing a one clears the corresponding bit in this register. This is only used in device mode. 0 = NOT_COMPLETE 1 = COMPLETE
27	0x0	ETCE11: Endpoint Transmit Complete Event: Each bit indicates a transmit event (IN/INTERRUPT) occurred and software should read the corresponding endpoint queue to determine the endpoint status. If the corresponding IOC bit is set in the Transfer Descriptor, then this bit will be set simultaneously with the USBINT. Writing a one clears the corresponding bit in this register. This is only used in device mode. 0 = NOT_COMPLETE 1 = COMPLETE
26	0x0	ETCE10: Endpoint Transmit Complete Event: Each bit indicates a transmit event (IN/INTERRUPT) occurred and software should read the corresponding endpoint queue to determine the endpoint status. If the corresponding IOC bit is set in the Transfer Descriptor, then this bit will be set simultaneously with the USBINT. Writing a one clears the corresponding bit in this register. This is only used in device mode. 0 = NOT_COMPLETE 1 = COMPLETE
25	0x0	ETCE9: Endpoint Transmit Complete Event: Each bit indicates a transmit event (IN/INTERRUPT) occurred and software should read the corresponding endpoint queue to determine the endpoint status. If the corresponding IOC bit is set in the Transfer Descriptor, then this bit will be set simultaneously with the USBINT. Writing a one clears the corresponding bit in this register. This is only used in device mode. 0 = NOT_COMPLETE 1 = COMPLETE
24	0x0	ETCE8: Endpoint Transmit Complete Event: Each bit indicates a transmit event (IN/INTERRUPT) occurred and software should read the corresponding endpoint queue to determine the endpoint status. 23.9.2 USB1 Controller Interface Registers

These are used to generate the actual RTL registers for USB1 controller interface.

23.9.2.1 USB1_IF_USB_SUSP_CTRL_0

This register controls the suspend and resume behavior of USB controller/PHY.

USB Suspend Control Register

Offset: 0x400 | Read/Write: R/W | Reset: 0bxxxxx00xxxxxx000xxx01000xx000000

Bit	R/W	Reset	Description
26	RW	0x0	FAST_WAKEUP_RESP: Enable Fast Response from UTMIP PHY for a Remote Wakeup request from device. This is used only for cases where wakeup response needs to be within 1 ms of spec. Used for Host mode ONLY. 0 = DISABLE 1 = ENABLE
25	RW	0x0	UTMIP_SUSPL1_SET: Enable SuspendL1 for UTMIP PHY. Enabling this will only cut off clocks to the UTMIP logic. The USB PLLs, PllU and UTMIP PLL will still be running. 0 = DISABLE 1 = ENABLE
18:16	RW	0x0	USB_WAKEUP_DEBOUNCE_COUNT: USB PHY wakeup debounce counter. USB will debounce any wakeup event by the number of clocks programmed in this counter. A value of 0 results in no debounce.
12	RW	0x0	UTMIP_PHY_ENB: Enable UTMIP PHY mode. Set this to 1 if using UTMIP PHY. Otherwise set this to 0. 0 = DISABLE 1 = ENABLE
11	RW	0x1	UTMIP_RESET: Reset going to UTMIP PHY (active high). This should be set to 1 whenever programming the UTMIP config registers. It should be cleared to 0 after the programming of UTMIP config registers is done. UTMIP config registers should be programmed only once before doing any transactions on USB. The UTMIP PHY registers should be programmed while UTMIP is in reset. 0 = DISABLE 1 = ENABLE
10	RW	0x0	USB_SUSP_POL: Polarity of the suspend signal going to USB PHY. 0 = Active low (default). 1 = Active high. This should not be changed by software. 0 = ACTIVE_LOW 1 = ACTIVE_HIGH
9	RW	0x0	USB_PHY_CLK_VALID_INT_ENB: USB PHY clock valid interrupt enable. If this bit is enabled, interrupt is generated whenever USB clocks are resumed from a suspend. 0 = DISABLE 1 = ENABLE
8	RO	0x0	USB_PHY_CLK_VALID_INT_STS: USB PHY clock valid interrupt status. This bit is set whenever the USB PHY clock is woken up from suspend. Software must write a 1 to clear this bit. 0 = UNSET 1 = SET
7	RO	X	USB_PHY_CLK_VALID: USB PHY clock valid status. This bit indicates whether the USB PHY is generating a valid clock to the USB controller. If USB PHY clock is running, this bit is set to 1, else it is set to 0. 0 = UNSET 1 = SET
6	RO	X	USB_CLKEN: USB AHB clock enable status. Indicates whether the AHB clock to the USB controller is enabled or not. If AHB clock to USB controller is enabled, this bit is set to 1, else it is set to 0. NOTE: even when this is set to 0, all essential blocks that are required to resume USB clocks from suspend will be active and their AHB clock will not be suspended. 0 = UNSET 1 = SET

Bit	R/W	Reset	Description
5	RW	0x0	USB_SUSP_CLR: Suspend Clear. Software must write a 1 to this bit to bring the PHY out of suspend mode. This is used when the software stops the PHY clock during suspend and then wants to initiate a resume. Software should also write 0 to clear it. NOTE: It is required that software generate a positive pulse on this bit to guarantee proper operation. 0 = UNSET 1 = SET
4	RW	0x0	USB_WAKE_ON_DISCON_EN_DEV: Wake on Disconnect Enable (device mode). When enabled (1), the USB device will wake up from suspend on a disconnect event. This is only valid when USB controller is in device mode, it is not applicable when USB controller is in host mode. 0 = DISABLE 1 = ENABLE
3	RW	0x0	USB_WAKE_ON_CNNT_EN_DEV: Wake on Connect Enable (device mode). When enabled (1), USB device will wake up from suspend on a connect event. This is only valid when USB controller is in device mode, it is not applicable when USB controller is in host mode. 0 = DISABLE 1 = ENABLE
2	RW	0x0	USB_WAKE_ON_RESUME_EN: Wake on resume enable. If this bit is enabled, USB will wake up from suspend whenever a resume event is detected on USB. This is valid for both USB device and USB host modes. 0 = DISABLE 1 = ENABLE
1	RW	0x0	USB_WAKEUP_INT_ENB: USB wakeup interrupt enable. If this bit is enabled, interrupt is generated whenever USB wakeup event is generated. 0 = DISABLE 1 = ENABLE
0	RO	0x0	USB_WAKEUP_INT_STS: USB wakeup interrupt status. This bit is set whenever USB wakes up from suspend (a wakeup event is generated). Software must write a 1 to clear this bit. Note that during the wakeup sequence, PHY clocks will be resumed from suspend. Software can check when the PHY clocks are resumed by reading the bit USB_PHY_CLK_VALID. There is also a separate interrupt generated when PHY clock is resumed if USB_PHY_CLK_VALID_INT_EN is set. During the wakeup sequence, first USB_WAKEUP_INT_STS will be set, and it will take some time for the PHY clock to resume, which can be detected by checking USB_PHY_CLK_VALID. 0 = UNSET 1 = SET

23.9.2.2 USB1_IF_USB_PHY_VBUS_SENSORS_0

This register controls the OTG VBUS sensors in the USB PHY. There are 4 VBUS sensors:

- A_VBUS_VLD
- A_SESS_VLD
- B_SESS_VLD
- B_SESS_END

The debounced status of each sensor can be read from the corresponding _STS bit field of the sensor in this register. The _CHG_DET field is set to 1 whenever a change is detected in the value of the _STS bit field of the corresponding sensor. If _INT_EN is set, then an interrupt is generated to the processor. This interrupt can be routed to CPU/COP by appropriately writing the USBD bits in the interrupt controller registers.

In case software wants to override the value for a sensor, it can set the corresponding _SW_EN to 1, and set the corresponding sensor _SW_VALUE to 1 or 0 as per the requirement.

There are two debouncers for each sensor - DEBOUNCE_A and DEBOUNCE_B. The debounce values for them are controlled by the register UTMIP_DEBOUNCE_CFG0, fields UTMIP_BIAS_DEBOUNCE_A and UTMIP_BIAS_DEBOUNCE_B. For each sensor, we can select whether to use DEBOUNCE_A or DEBOUNCE_B by setting the field _DEB_SEL_B to the appropriate value (SEL_A or SEL_B).

Note: Do not set either UTMIP_BIAS_DEBOUNCE_A or UTMIP_BIAS_DEBOUNCE_B to 0x0. If not using one of the debouncers, keep it at the default value of 0xFFFF.

USB PHY VBUS SENSORS Control Register

Offset: 0x404 | Read/Write: R/W | Reset: 0bx0000x00x0000x00x0000x00x0000x00

Bit	R/W	Reset	Description
30	RW	0x0	A_VBUS_VLD_WAKEUP_EN: A_VBUS_VLD wakeup enable. If this bit is enabled, USB will wake up from suspend whenever a change is detected on A_VBUS_VLD. 0 = DISABLE 1 = ENABLE
29	RW	0x0	A_VBUS_VLD_DEB_SEL_B: A_VBUS_VLD debounce A/B select. Selects between the two debounce values UTMIP_BIAS_DEBOUNCE_A or UTMIP_BIAS_DEBOUNCE_B from the register UTMIP_DEBOUNCE_CFG0. 0 = SEL_A 1 = SEL_B
28	RW	0x0	A_VBUS_VLD_SW_VALUE: A_VBUS_VLD software value. Software should write the appropriate value (1/0) to set/unset the A_VBUS_VLD status. This is only valid when A_VBUS_VLD_SW_EN is set. 0 = UNSET 1 = SET
27	RW	0x0	A_VBUS_VLD_SW_EN: A_VBUS_VLD software enable. Enable Software Controlled A_VBUS_VLD. Software sets this bit to drive the value in A_VBUS_VLD_SW_VALUE to the USB controller. 0 = DISABLE 1 = ENABLE
26	RO	X	A_VBUS_VLD_STS: A_VBUS_VLD status. This is set to 1 whenever A_VBUS_VLD sensor output is 1. 0 = UNSET 1 = SET
25	RO	0x0	A_VBUS_VLD_CHG_DET: A_VBUS_VLD change detect. This field is set by hardware whenever a change is detected in the value of A_VBUS_VLD. software writes a 1 to clear it 0 = UNSET 1 = SET
24	RW	0x0	A_VBUS_VLD_INT_EN: A_VBUS_VLD interrupt enable. If this field is set to 1, an interrupt is generated whenever A_VBUS_VLD_CHG_DET is set to 1. 0 = DISABLE 1 = ENABLE
22	RW	0x0	A_SESS_VLD_WAKEUP_EN: A_SESS_VLD wakeup enable. If this bit is enabled, USB will wake up from suspend whenever a change is detected on A_SESS_VLD. 0 = DISABLE 1 = ENABLE
21	RW	0x0	A_SESS_VLD_DEB_SEL_B: A_SESS_VLD debounce A/B select. Selects between the two debounce values UTMIP_BIAS_DEBOUNCE_A or UTMIP_BIAS_DEBOUNCE_B from the register UTMIP_DEBOUNCE_CFG0. 0 = SEL_A 1 = SEL_B
20	RW	0x0	A_SESS_VLD_SW_VALUE: A_SESS_VLD software value. Software should write the appropriate value (1/0) to set/unset the A_SESS_VLD status. This is only valid when A_SESS_VLD_SW_EN is set. 0 = UNSET 1 = SET

Bit	R/W	Reset	Description
19	RW	0x0	A_SESS_VLD_SW_EN: A_SESS_VLD software enable. Enable Software Controlled A_SESS_VLD. Software sets this bit to drive the value in A_SESS_VLD_SW_VALUE to the USB controller. 0 = DISABLE 1 = ENABLE
18	RO	X	A_SESS_VLD_STS: A_SESS_VLD status. This is set to 1 whenever A_SESS_VLD sensor output is 1. 0 = UNSET 1 = SET
17	RO	0x0	A_SESS_VLD_CHG_DET: A_SESS_VLD change detect. This field is set by hardware whenever a change is detected in the value of A_SESS_VLD. software writes a 1 to clear it 0 = UNSET 1 = SET
16	RW	0x0	A_SESS_VLD_INT_EN: A_SESS_VLD interrupt enable. If this field is set to 1, an interrupt is generated whenever A_SESS_VLD_CHG_DET is set to 1. 0 = DISABLE 1 = ENABLE
14	RW	0x0	B_SESS_VLD_WAKEUP_EN: B_SESS_VLD wakeup enable. If this bit is enabled, USB will wake up from suspend whenever a change is detected on B_SESS_VLD. 0 = DISABLE 1 = ENABLE
13	RW	0x0	B_SESS_VLD_DEB_SEL_B: B_SESS_VLD debounce A/B select. Selects between the two debounce values UTMIP_BIAS_DEBOUNCE_A or UTMIP_BIAS_DEBOUNCE_B from the register UTMIP_DEBOUNCE_CFG0. 0 = SEL_A 1 = SEL_B
12	RW	0x0	B_SESS_VLD_SW_VALUE: B_SESS_VLD software value. Software should write the appropriate value (1/0) to set/unset the B_SESS_VLD status. This is only valid when B_SESS_VLD_SW_EN is set. 0 = UNSET 1 = SET
11	RW	0x0	B_SESS_VLD_SW_EN: B_SESS_VLD software enable. Enable Software Controlled B_SESS_VLD. Software sets this bit to drive the value in B_SESS_VLD_SW_VALUE to the USB controller. 0 = DISABLE 1 = ENABLE
10	RO	X	B_SESS_VLD_STS: B_SESS_VLD status. This is set to 1 whenever B_SESS_VLD sensor output is 1. 0 = UNSET 1 = SET
9	RO	0x0	B_SESS_VLD_CHG_DET: B_SESS_VLD change detect. This field is set by hardware whenever a change is detected in the value of B_SESS_VLD. software writes a 1 to clear it 0 = UNSET 1 = SET
8	RW	0x0	B_SESS_VLD_INT_EN: B_SESS_VLD interrupt enable. If this field is set to 1, an interrupt is generated whenever B_SESS_VLD_CHG_DET is set to 1. 0 = DISABLE 1 = ENABLE
6	RW	0x0	B_SESS_END_WAKEUP_EN: B_SESS_END wakeup enable. If this bit is enabled, USB will wake up from suspend whenever a change is detected on B_SESS_END. 0 = DISABLE 1 = ENABLE
5	RW	0x0	B_SESS_END_DEB_SEL_B: B_SESS_END debounce A/B select. Selects between the two debounce values UTMIP_BIAS_DEBOUNCE_A or UTMIP_BIAS_DEBOUNCE_B from the register UTMIP_DEBOUNCE_CFG0. 0 = SEL_A 1 = SEL_B

Bit	R/W	Reset	Description
4	RW	0x0	B_SESS_END_SW_VALUE: B_SESS_END software value. Software should write the appropriate value (1/0) to set/unset the B_SESS_END status. This is only valid when B_SESS_END_SW_EN is set. 0 = UNSET 1 = SET
3	RW	0x0	B_SESS_END_SW_EN: B_SESS_END software enable. Enable Software Controlled B_SESS_END Software sets this bit to drive the value in B_SESS_END_SW_VALUE to the USB controller. 0 = DISABLE 1 = ENABLE
2	RO	X	B_SESS_END_STS: B_SESS_END status. This is set to 1 whenever B_SESS_END sensor output is 1. 0 = UNSET 1 = SET
1	RO	0x0	B_SESS_END_CHG_DET: B_SESS_END change detect. This field is set by hardware whenever a change is detected in the value of B_SESS_END. software writes a 1 to clear it 0 = UNSET 1 = SET
0	RW	0x0	B_SESS_END_INT_EN: B_SESS_END interrupt enable. If this field is set to 1, an interrupt is generated whenever B_SESS_END_CHG_DET is set to 1. 0 = DISABLE 1 = ENABLE

23.9.2.3 USB1_IF_USB_PHY_VBUS_WAKEUP_ID_0

This register controls the battery charger (VDCD_DET, VDAT_DET), VBUS_WAKEUP and ID sensors. The following sensors are in this register:

- VBUS_WAKEUP
- ID
- VDAT_DET
- VDCD_DET

The debounced status of each sensor can be read from the corresponding _STS bit field of the sensor in this register. The _CHG_DET field is set to 1 whenever a change is detected in the value of the _STS bit field of the corresponding sensor. If _INT_EN is set, then an interrupt is generated to the processor. This interrupt can be routed to CPU/COP by appropriately writing the USBD bits in the interrupt controller registers.

In case software wants to override the value for a sensor, it can set the corresponding _SW_EN to 1, and set the corresponding sensor _SW_VALUE to 1 or 0 as per the requirement.

There are two debouncers for each sensor - DEBOUNCE_A and DEBOUNCE_B. The debounce values for them are controlled by the register UTMIP_DEBOUNCE_CFG0, fields UTMIP_BIAS_DEBOUNCE_A and UTMIP_BIAS_DEBOUNCE_B. For each sensor, we can select whether to use DEBOUNCE_A or DEBOUNCE_B by setting the field _DEB_SEL_B to the appropriate value (SEL_A or SEL_B).

Note: Do not set either UTMIP_BIAS_DEBOUNCE_A or UTMIP_BIAS_DEBOUNCE_B to 0x0. If not using one of the debouncers, keep it at the default value of 0xFFFF.

There are debouncers for VDAT_DET and VDCD_DET. These use separate debouncers -CHRG_DEBOUNCE_PERIOD_A and CHRG_DEBOUNCE_PERIOD_B. The debounce values for them are controlled by the register UTMIP_CHRG_DEB_CFG0, fields UTMIP_CHRG_DEBOUNCE_PERIOD_A and UTMIP_CHRG_DEBOUNCE_PERIOD_B. For each sensor, we can select whether to use CHRG_DEBOUNCE_PERIOD_A or CHRG_DEBOUNCE_PERIOD_B by setting the field _DEB_SEL_B to the appropriate value (SEL_A or SEL_B).

Note: Do not set either UTMIP_CHRG_DEBOUNCE_PERIOD_A or UTMIP_CHRG_DEBOUNCE_PERIOD_B to 0x0. If not using one of the debouncers, keep it at the default value of 0xFFFF.

USB PHY VBUS Wakeup and ID Control Register

Offset: 0x408 | Read/Write: R/W | Reset: 0bx0000x00xx000x00xx000x00x1000x00

Bit	R/W	Reset	Description
30	RW	0x0	VBUS_WAKEUP_WAKEUP_EN: VBUS_WAKEUP wakeup enable. If this bit is enabled, USB will wake up from suspend whenever a change is detected on VBUS_WAKEUP. 0 = DISABLE 1 = ENABLE
29	RW	0x0	VDCD_DET_DEB_SEL_B: VCDT_DET debounce A/B select. Selects the debounce value from UTMIP_CHRG_DEBOUNCE_PERIOD_A or UTMIP_CHRG_DEBOUNCE_PERIOD_B from the register UTMIP_CHRG_DEB_CFG0. 0 = SEL_A 1 = SEL_B
28	RW	0x0	VDCD_DET_SW_VALUE: VDCD_DET software value. Software should write the appropriate value (1/0) to set/unset the VDCD_DET status. This is only valid when VDCD_DET_SW_EN is set. 0 = UNSET 1 = SET
27	RW	0x0	VDCD_DET_SW_EN: VDCD_DET software enable. Enable Software Controlled VDCD_DET. Software sets this bit to drive the value in VDCD_DET_SW_VALUE to the USB controller 0 = DISABLE 1 = ENABLE
26	RO	X	VDCD_DET_STS: VDCD_DET status. This is set to 1 whenever VDCD_DET sensor output is 1. 0 = UNSET 1 = SET
25	RO	0x0	VDCD_DET_CHG_DET: VDCD_DET change detect. This field is set by hardware whenever a change is detected in the value of VDCD_DET. software writes a 1 to clear it 0 = UNSET 1 = SET
24	RW	0x0	VDCD_DET_INT_EN: VDCD_DET interrupt enable. If this field is set to 1, an interrupt is generated whenever VDCD_DET_CHG_DET is set to 1. 0 = DISABLE 1 = ENABLE
21	RW	0x0	VDAT_DET_DEB_SEL_B: VDAT_DET debounce A/B select. Selects between the two debounce values UTMIP_CHRG_DEBOUNCE_PERIOD_A or UTMIP_CHRG_DEBOUNCE_PERIOD_B from the register UTMIP_DEBOUNCE_CFG0. 0 = SEL_A 1 = SEL_B
20	RW	0x0	VDAT_DET_SW_VALUE: VDAT_DET software value. Software should write the appropriate value (1/0) to set/unset the VDAT_DET status. This is only valid when VDAT_DET_SW_EN is set. 0 = UNSET 1 = SET
19	RW	0x0	VDAT_DET_SW_EN: VDAT_DET software enable. Enable Software Controlled VDAT_DET. Software sets this bit to drive the value in VDAT_DET_SW_VALUE to the USB controller 0 = DISABLE 1 = ENABLE
18	RO	X	VDAT_DET_STS: VDAT_DET status. This is set to 1 whenever the VDAT_DET sensor output is 1. 0 = UNSET 1 = SET

Bit	R/W	Reset	Description
17	RO	0x0	VDAT_DET_CHG_DET: VDAT_DET change detect. This field is set by hardware whenever a change is detected in the value of VDAT_DET. software writes a 1 to clear it 0 = UNSET 1 = SET
16	RW	0x0	VDAT_DET_INT_EN: VDAT_DET interrupt enable. If this field is set to 1, an interrupt is generated whenever VDAT_DET_CHG_DET is set to 1. 0 = DISABLE 1 = ENABLE
13	RW	0x0	VBUS_WAKEUP_DEB_SEL_B: VBUS_WAKEUP debounce A/B select. Selects between the two debounce values UTMIP_BIAS_DEBOUNCE_A or UTMIP_BIAS_DEBOUNCE_B from the register UTMIP_DEBOUNCE_CFG0. 0 = SEL_A 1 = SEL_B
12	RW	0x0	VBUS_WAKEUP_SW_VALUE: VBUS wakeup software value. Software should write the appropriate value (1/0) to set/unset the VBUS_WAKEUP status. This is only valid when VBUS_WAKEUP_SW_EN is set. 0 = UNSET 1 = SET
11	RW	0x0	VBUS_WAKEUP_SW_EN: VBUS wakeup software enable. Enable Software Controlled VBUS_WAKEUP. Software sets this bit to drive the value in VBUS_WAKEUP_SW_VALUE to the USB controller. 0 = DISABLE 1 = ENABLE
10	RO	X	VBUS_WAKEUP_STS: VBUS wakeup status. This is set to 1 whenever VBUS_WAKEUP sensor output is 1. 0 = UNSET 1 = SET
9	RO	0x0	VBUS_WAKEUP_CHG_DET: VBUS wakeup change detect. This field is set by hardware whenever a change is detected in the value of VBUS_WAKEUP. software writes a 1 to clear it 0 = UNSET 1 = SET
8	RW	0x0	VBUS_WAKEUP_INT_EN: VBUS wakeup interrupt enable. If this field is set to 1, an interrupt is generated whenever VBUS_WAKEUP_CHG_DET is set to 1. 0 = DISABLE 1 = ENABLE

23.9.2.5 USB1_IF_USB_INTER_PKT_DELAY_CTRL_0

This controls the interpacket delay between two consecutive transmit packets in HS mode. This only applies to host mode as device never transmits two packets in a row.

Inter Packet Delay Control

Offset: 0x420 | Read/Write: R/W | Reset: 0bxxxxxxxxxxxxxxxxxxxxxxxxxxx0010010

Bit	Reset	Description
6:0	0x12	IP_DELAY_TX2TX_HS: HS Tx to Tx inter-packet delay. Software should not change this.

23.9.2.6 USB1_IF_USB_RSM_DLY_0

USB Controller Resume Signaling Delay

Offset: 0x490 | Read/Write: R/W | Reset: 0bxxxxxxxxxxxxxxxx0110100101111000

Bit	Reset	Description
15:0	0x6978	TIME_TO_RESUME: Send the resume back in number of 60 MHz cycles. Default gives 900 µs delay. Only applicable in host mode.

23.9.2.7 USB1_IF_SPARE_0

For ICUSB PADCTLS. Spare Register

Offset: 0x498 | Read/Write: R/W | Reset: 0b11111111111111110000000000000000

Bit	Reset	Description
31:16	0xffff	SPARE_HI: Spare register bits, defaulted to 1. SPARE_HI[0] - usb_port_reset_fix_en. Enable port-reset fix.
15:0	0x0	SPARE_LO: Spare register bits, defaulted to 0. SPARE_LO[4] - usb_hs_rsm_eop_fix_en, Enable HS_RESUME EOP fix. SPARE_LO[5] - usb_port_suspend_fix_en.

23.9.2.8 USB1_IF_USB1_NEW_CONTROL_0

For ULPI DIR Override

Offset: 0x4c0 | Read/Write: R/W | Reset: 0bxxxxxxxxxxxxxxxx00001111xxxxxx00

Bit	Reset	Description
15:8	0xf	REQUEST_EXPIRY_COUNTER: Time to wait for coalescing the request
1	0x0	MEM_ALIGNMENT_MUX_EN: Mux to select between Tegra 3 and Tegra 4 code 0 = DISABLE 1 = ENABLE
0	0x0	COHERENCY_EN: Enable fence mechanism. 0 = DISABLE 1 = ENABLE.

23.9.3 USB1 UTMIP Configuration Registers

Note: Current UTMIP configuration registers use settings that support NV software drivers and should NOT be modified. If designing custom drivers, consult your NV representative prior to modifying these registers

23.9.3.1 UTMIP REGISTER: PLL_CFG0

This register was used to configure PLL inside UTMIP block prior to Tegra 4 devices. This has been de-featured from UTMIP space and moved to CAR space. This register is used to configure the PHY PLL contained in the UTMIP module. Refer to the Clock and Reset Controller section for details on this register.

Note: This register has been moved to the Clock and Reset section of this document. PROGRAMMING THIS REGISTER HERE WILL HAVE NO EFFECT!

23.9.3.2 USB1_UTMIP_PLL_CFG1_0

UTMIP PLL and PLLU Configuration Register 1

Note: This register has been moved to the Clock and Reset section of this document. PROGRAMMING THIS REGISTER HERE WILL HAVE NO EFFECT!

This register was used to configure the PLL inside the UTMIP block prior to Tegra 4 devices. This register has been defeatured from UTMIP space and moved to CAR space. Refer to the Clock and Reset Controller section for details on this register.

23.9.3.3 USB1_UTMIP_XCVR_CFG0_0

UTMIP Transceiver Cell Configuration Register 0

Offset: 0x808 | Read/Write: R/W | Reset: 0b00100000001001010110010100000000

Bit	Reset	Description
31:25	0x10	UTMIP_XCVR_HSSLEW_MSB: Most significant bits of HS_SLEW.
24:22	0x0	UTMIP_XCVR_SETUP_MSB: Most significant bits of SETUP.
21	0x1	UTMIP_XCVR_LSBIAS_SEL: Low speed bias selection method for USB transceiver pad
20	0x0	UTMIP_XCVR_DISCON_METHOD: Disconnect method on the USB transceiver pad
19	0x0	UTMIP_FORCE_PDZI_POWERUP: Force PDZI input into power up.

Bit	Reset	Description
18	0x1	UTMIP_FORCE_PDZI_POWERDOWN: Force PDZI input into power down. (Overrides FORCE_PDZI_POWERUP.)
17	0x0	UTMIP_FORCE_PD2_POWERUP: Force PD2 input into power up.
16	0x1	UTMIP_FORCE_PD2_POWERDOWN: Force PD2 input into power down. (Overrides FORCE_PD2_POWERUP.)
15	0x0	UTMIP_FORCE_PD_POWERUP: Force PD input into power up.
14	0x1	UTMIP_FORCE_PD_POWERDOWN: Force PD input into power down. (Overrides FORCE_PD_POWERUP.)
13	0x1	UTMIP_XCVR_TERMEN: Enable HS termination.
12	0x0	UTMIP_XCVR_HSLOOPBACK: Internal loopback inside XCVR cell. Used for IOBIST.
11:10	0x1	UTMIP_XCVR_LSFSLEW: LS falling slew rate control.
9:8	0x1	UTMIP_XCVR_LSRSLEW: LS rising slew rate control.
7:6	0x0	UTMIP_XCVR_FSSLEW: FS slew rate control.
5:4	0x0	UTMIP_XCVR_HSSLEW: HS slew rate control. The two LSBs.
3:0	0x0	UTMIP_XCVR_SETUP: SETUP[3:0] input of XCVR cell. HS driver output control. 4 LSBs.

3	0x0	UTMIP_FLIP_FSLS_POLARITY
2	0x1	UTMIP_SUSPEND_TERMSEL
1:0	0x0	UTMIP_XCVRSEL3: Bit 0: 0: 0xa5 -> treat as KeepAlive 1: treat as regular packet Bit 1: 0: Turn on FS EOP detection 1: Turn off FS EOP detection

23.9.3.12 USB1_UTMIP_DEBOUNCE_CFG0_0

UTMIP Avalid and Bvalid Debounce

Debounce values IdDig, Avalid, Bvalid, VbusValid, VbusWakeUp, and SessEnd. Each of these signals has its own debouncer, and for each of those one out of 2 debouncing times can be chosen (BIAS_DEBOUNCE_A or BIAS_DEBOUNCE_B.)

The values of DEBOUNCE_A and DEBOUNCE_B are calculated as follows:

0xffff -> No debouncing at all

ms = *1000 / (1/19.2MHz) / 4

So to program a 1 ms debounce for BIAS_DEBOUNCE_A:

BIAS_DEBOUNCE_A[15:0] = 1000 * 19.2 / 4 = 4800 = 0x12c0

Offset: 0x82c | Read/Write: R/W | Reset: 0b11111111111111111111111111111111

Bit	Reset	Description
31:16	0xffff	UTMIP_BIAS_DEBOUNCE_B: simulation value -- Used for interrupts
15:0	0xffff	UTMIP_BIAS_DEBOUNCE_A: simulation value -- Used for interrupts

31:0	0x0	USB2D_QH: Queue Head for IN endpoint 1. This is used to store a local Queue Head data structure for either device mode or host mode. In device mode, it holds the Queue Head for IN endpoint 1.

23.9.3.25 USB2_QH_USB2D_QH_EP_2_OUT_0

USB2D Queue Head for OUT Endpoint 2

Offset: 0x1100 | Read/Write: R/W | Reset: 0b00000000000000000000000000000000

Bit	Reset	Description
31:0	0x0	USB2D_QH: Queue Head for OUT endpoint 2. This is used to store a local Queue Head data structure for either device mode or host mode. In device mode, it holds the Queue Head for OUT endpoint 2.

23.9.3.26 USB2_QH_USB2D_QH_EP_2_IN_0

USB2D Queue Head for IN Endpoint 2

Offset: 0x1140 | Read/Write: R/W | Reset: 0b00000000000000000000000000000000

Bit	Reset	Description
31:0	0x0	USB2D_QH: Queue Head for IN endpoint 2. This is used to store a local Queue Head data structure for either device mode or host mode. In device mode, it holds the Queue Head for IN endpoint 2.

23.9.3.27 USB2_QH_USB2D_QH_EP_3_OUT_0

USB2D Queue Head for OUT Endpoint 3

Offset: 0x1180 | Read/Write: R/W | Reset: 0b00000000000000000000000000000000

Bit	Reset	Description
31:0	0x0	USB2D_QH: Queue Head for OUT endpoint 3. This is used to store a local Queue Head data structure for either device mode or host mode. In device mode, it holds the Queue Head for OUT endpoint 3.

23.9.3.28 USB2_QH_USB2D_QH_EP_3_IN_0

USB2D Queue Head for IN Endpoint 3

Offset: 0x11c0 | Read/Write: R/W | Reset: 0b00000000000000000000000000000000

Bit	Reset	Description
31:0	0x0	USB2D_QH: Queue Head for IN endpoint 3. This is used to store a local Queue Head data structure for either device mode or host mode. In device mode, it holds the Queue Head for IN endpoint 3.

23.9.3.29 USB2_QH_USB2D_QH_EP_4_OUT_0

USB2D Queue Head for OUT Endpoint 4

Offset: 0x1200 | Read/Write: R/W | Reset: 0b00000000000000000000000000000000

Bit	Reset	Description
31:0	0x0	USB2D_QH: Queue Head for OUT endpoint 4. This is used to store a local Queue Head data structure for either device mode or host mode. In device mode, it holds the Queue Head for OUT endpoint 4.

23.9.3.30 USB2_QH_USB2D_QH_EP_4_IN_0

USB2D Queue Head for IN Endpoint 4

Offset: 0x1240 | Read/Write: R/W | Reset: 0b00000000000000000000000000000000

Bit	Reset	Description
31:0	0x0	USB2D_QH: Queue Head for IN endpoint 4. This is used to store a local Queue Head data structure for either device mode or host mode. In device mode, it holds the Queue Head for IN endpoint 4.

23.9.3.31 USB2_QH_USB2D_QH_EP_5_OUT_0

USB2D Queue Head for OUT Endpoint 5

Offset: 0x1280 | Read/Write: R/W | Reset: 0b00000000000000000000000000000000

Bit	Reset	Description
31:0	0x0	USB2D_QH: Queue Head for OUT endpoint 5. This is used to store a local Queue Head data structure for either device mode or host mode. In device mode, it holds the Queue Head for OUT endpoint 5.

23.9.3.32 USB2_QH_USB2D_QH_EP_5_IN_0

USB2D Queue Head for IN Endpoint 5

Offset: 0x12c0 | Read/Write: R/W | Reset: 0b00000000000000000000000000000000

Bit	Reset	Description
31:0	0x0	USB2D_QH: Queue Head for IN endpoint 5. This is used to store a local Queue Head data structure for either device mode or host mode. In device mode, it holds the Queue Head for IN endpoint 5.

23.9.3.33 USB2_QH_USB2D_QH_EP_6_OUT_0

USB2D Queue Head for OUT Endpoint 6

Offset: 0x1300 | Read/Write: R/W | Reset: 0b00000000000000000000000000000000

Bit	Reset	Description
31:0	0x0	USB2D_QH: Queue Head for OUT endpoint 6. This is used to store a local Queue Head data structure for either device mode or host mode. In device mode, it holds the Queue Head for OUT endpoint 6.

23.9.3.34 USB2_QH_USB2D_QH_EP_6_IN_0

USB2D Queue Head for IN Endpoint 6

Offset: 0x1340 | Read/Write: R/W | Reset: 0b00000000000000000000000000000000

Bit	Reset	Description
31:0	0x0	USB2D_QH: Queue Head for IN endpoint 6. This is used to store a local Queue Head data structure for either device mode or host mode. In device mode, it holds the Queue Head for IN endpoint 6.

23.9.3.35 USB2_QH_USB2D_QH_EP_7_OUT_0

USB2D Queue Head for OUT Endpoint 7

Offset: 0x1380 | Read/Write: R/W | Reset: 0b00000000000000000000000000000000

Bit	Reset	Description
31:0	0x0	USB2D_QH: Queue Head for OUT endpoint 7. This is used to store a local Queue Head data structure for either device mode or host mode. In device mode, it holds the Queue Head for OUT endpoint 7.

23.9.3.36 USB2_QH_USB2D_QH_EP_7_IN_0

USB2D Queue Head for IN Endpoint 7

Offset: 0x13c0 | Read/Write: R/W | Reset: 0b00000000000000000000000000000000

Bit	Reset	Description
31:0	0x0	USB2D_QH: Queue Head for IN endpoint 7. This is used to store a local Queue Head data structure for either device mode or host mode. In device mode, it holds the Queue Head for IN endpoint 7.

23.9.3.37 USB2_QH_USB2D_QH_EP_8_OUT_0

USB2D Queue Head for OUT Endpoint 8

Offset: 0x1400 | Read/Write: R/W | Reset: 0b00000000000000000000000000000000

Bit	Reset	Description
31:0	0x0	USB2D_QH: Queue Head for OUT endpoint 8. This is used to store a local Queue Head data structure for either device mode or host mode. In device mode, it holds the Queue Head for OUT endpoint 8.

23.9.3.38 USB2_QH_USB2D_QH_EP_8_IN_0

USB2D Queue Head for IN Endpoint 8

Offset: 0x1440 | Read/Write: R/W | Reset: 0b00000000000000000000000000000000

Bit	Reset	Description
31:0	0x0	USB2D_QH: Queue Head for IN endpoint 8. This is used to store a local Queue Head data structure for either device mode or host mode. In device mode, it holds the Queue Head for IN endpoint 8.

23.9.3.39 USB2_QH_USB2D_QH_EP_9_OUT_0

USB2D Queue Head for OUT Endpoint 9

Offset: 0x1480 | Read/Write: R/W | Reset: 0b00000000000000000000000000000000

Bit	Reset	Description
31:0	0x0	USB2D_QH: Queue Head for OUT endpoint 9. This is used to store a local Queue Head data structure for either device mode or host mode. In device mode, it holds the Queue Head for OUT endpoint 9.

23.9.3.40 USB2_QH_USB2D_QH_EP_9_IN_0

USB2D Queue Head for IN Endpoint 9

Offset: 0x14c0 | Read/Write: R/W | Reset: 0b00000000000000000000000000000000

Bit	Reset	Description
31:0	0x0	USB2D_QH: Queue Head for IN endpoint 9. This is used to store a local Queue Head data structure for either device mode or host mode. In device mode, it holds the Queue Head for IN endpoint 9.

23.9.3.41 USB2_QH_USB2D_QH_EP_10_OUT_0

USB2D Queue Head for OUT Endpoint 10

Offset: 0x1500 | Read/Write: R/W | Reset: 0b00000000000000000000000000000000

Bit	Reset	Description
31:0	0x0	USB2D_QH: Queue Head for OUT endpoint 10. This is used to store a local Queue Head data structure for either device mode or host mode. In device mode, it holds the Queue Head for OUT endpoint 10.

23.9.3.42 USB2_QH_USB2D_QH_EP_10_IN_0

USB2D Queue Head for IN Endpoint 10

Offset: 0x1540 | Read/Write: R/W | Reset: 0b00000000000000000000000000000000

Bit	Reset	Description
31:0	0x0	USB2D_QH: Queue Head for IN endpoint 10. This is used to store a local Queue Head data structure for either device mode or host mode. In device mode, it holds the Queue Head for IN endpoint 10.

23.9.3.43 USB2_QH_USB2D_QH_EP_11_OUT_0

USB2D Queue Head for OUT Endpoint 11

Offset: 0x1580 | Read/Write: R/W | Reset: 0b00000000000000000000000000000000

Bit	Reset	Description
31:0	0x0	USB2D_QH: Queue Head for OUT endpoint 11. This is used to store a local Queue Head data structure for either device mode or host mode. In device mode, it holds the Queue Head for OUT endpoint 11.

23.9.3.44 USB2_QH_USB2D_QH_EP_11_IN_0

USB2D Queue Head for IN Endpoint 11

Offset: 0x15c0 | Read/Write: R/W | Reset: 0b00000000000000000000000000000000

Bit	Reset	Description
31:0	0x0	USB2D_QH: Queue Head for IN endpoint 11. This is used to store a local Queue Head data structure for either device mode or host mode. In device mode, it holds the Queue Head for IN endpoint 11.

23.9.3.45 USB2_QH_USB2D_QH_EP_12_OUT_0

USB2D Queue Head for OUT Endpoint 12

Offset: 0x1600 | Read/Write: R/W | Reset: 0b00000000000000000000000000000000

Bit	Reset	Description
31:0	0x0	USB2D_QH: Queue Head for OUT endpoint 12. This is used to store a local Queue Head data structure for either device mode or host mode. In device mode, it holds the Queue Head for OUT endpoint 12.

23.9.3.46 USB2_QH_USB2D_QH_EP_12_IN_0

USB2D Queue Head for IN Endpoint 12

Offset: 0x1640 | Read/Write: R/W | Reset: 0b00000000000000000000000000000000

Bit	Reset	Description
31:0	0x0	USB2D_QH: Queue Head for IN endpoint 12. This is used to store a local Queue Head data structure for either device mode or host mode. In device mode, it holds the Queue Head for IN endpoint 12.

23.9.3.47 USB2_QH_USB2D_QH_EP_13_OUT_0

USB2D Queue Head for OUT Endpoint 13

Offset: 0x1680 | Read/Write: R/W | Reset: 0b00000000000000000000000000000000

Bit	Reset	Description
31:0	0x0	USB2D_QH: Queue Head for OUT endpoint 13. This is used to store a local Queue Head data structure for either device mode or host mode. In device mode, it holds the Queue Head for OUT endpoint 13.

23.9.3.48 USB2_QH_USB2D_QH_EP_13_IN_0

USB2D Queue Head for IN Endpoint 13

Offset: 0x16c0 | Read/Write: R/W | Reset: 0b00000000000000000000000000000000

Bit	Reset	Description
31:0	0x0	USB2D_QH: Queue Head for IN endpoint 13. This is used to store a local Queue Head data structure for either device mode or host mode. In device mode, it holds the Queue Head for IN endpoint 13.

23.9.3.49 USB2_QH_USB2D_QH_EP_14_OUT_0

USB2D Queue Head for OUT Endpoint 14

Offset: 0x1700 | Read/Write: R/W | Reset: 0b00000000000000000000000000000000

Bit	Reset	Description
31:0	0x0	USB2D_QH: Queue Head for OUT endpoint 14. This is used to store a local Queue Head data structure for either device mode or host mode. In device mode, it holds the Queue Head for OUT endpoint 14.

23.9.3.50 USB2_QH_USB2D_QH_EP_14_IN_0

USB2D Queue Head for IN Endpoint 14

Offset: 0x1740 | Read/Write: R/W | Reset: 0b00000000000000000000000000000000

Bit	Reset	Description
31:0	0x0	USB2D_QH: Queue Head for IN endpoint 14. This is used to store a local Queue Head data structure for either device mode or host mode. In device mode, it holds the Queue Head for IN endpoint 14.

23.9.3.51 USB2_QH_USB2D_QH_EP_15_OUT_0

USB2D Queue Head for OUT Endpoint 15

Offset: 0x1780 | Read/Write: R/W | Reset: 0b00000000000000000000000000000000

Bit	Reset	Description
31:0	0x0	USB2D_QH: Queue Head for OUT endpoint 15. This is used to store a local Queue Head data structure for either device mode or host mode. In device mode, it holds the Queue Head for OUT endpoint 15.

23.9.3.52 USB2_QH_USB2D_QH_EP_15_IN_0

USB2D Queue Head for IN Endpoint 15

Offset: 0x17c0 | Read/Write: R/W | Reset: 0b00000000000000000000000000000000

Bit	Reset	Description
31:0	0x0	USB2D_QH: Queue Head for IN endpoint 15. This is used to store a local Queue Head data structure for either device mode or host mode. In device mode, it holds the Queue Head for IN endpoint 15.

23.9.4 USB2 Controller Registers

23.9.4.1 USB2_CONTROLLER_1_USB2D_ID_0

USB2D Identification Register

Offset: 0x0 | Read/Write: RO | Reset: 0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx

Bit	Reset	Description
31:29	X	CIVERSION: Identifies the CI version
28:25	X	VERSION: Identifies the version of the core
24:21	X	REVISION: Revision number of the USB controller. This is set to 0x0.
20:16	X	TAG: Identifies the tag of the core
15:8	X	NID: One's complement version of ID. This field is set to 0xF9.
7:0	X	ID: Configuration number. This field is set to 0x06

23.9.4.2 USB2_CONTROLLER_1_USB2D_HW_HOST_0

USB2D Hardware Host Register

Offset: 0x8 | Read/Write: RO | Reset: 0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx

Bit	Reset	Description
3:1	X	NPORT: VUSB_HS_NUM_PORT-1: This host controller has only 1 port. So this field will always be 0.
0	X	HC: VUSB_HS_HOST: Indicates support for host mode. Set to 1.

23.9.4.3 USB2_CONTROLLER_1_USB2D_HW_DEVICE_0

USB2D Hardware Device Register

Offset: 0xc |Read/Write: RO | Reset: 0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx

Bit	Reset	Description
5:1	X	DEVEP: VUSB_HS_DV_EP: Number of endpoints supported by this device controller. Set to 16. This includes control endpoint 0.
0	X	DC: Device capable: Set to 1 indicating support for device mode.

23.9.4.4 USB2_CONTROLLER_1_USB2D_HW_TXBUF_0

USB2D Hardware TX Buffer Register

Offset: 0x10 | Read/Write: RO | Reset: 0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx

Bit	Reset	Description
23:16	X	TXCHANADD: VUSB_HS_TX_CHAN_ADD: Total number of address bits for the transmit buffer of each transmit endpoint. Set to 7. Each transmit buffer is 128 words deep.
15:8	X	TXADD: VUSB_HS_TX_ADD: Total number of address bits for the transmit buffer. Set to 11. The total depth of the transmit buffer is 2048 words.
7:0	X	TCBURST: VUSB_HS_TX_BURST: Maximum burst size supported by the transmit endpoints for data transfers. Set to 8.

23.9.4.5 USB2_CONTROLLER_1_USB2D_HW_RXBUF_0

USB2D RX Buffer HW Parameters Register

Offset: 0x14 | Read/Write: RO | Reset: 0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx

Bit	Reset	Description
15:8	X	RXADD: VUSB_HS_RX_ADD: Total number of address bits for the receive buffer. Set to 7. The total depth of the receive buffer is 128 words.
7:0	X	RXBURST: VUSB_HS_RX_BURST: Maximum burst size supported by the receive endpoints for data transfers. Set to 8.

23.9.4.6 USB2_CONTROLLER_1_USB2D_CAPLENGTH_0

USB2D Capability Register Length Register

Offset: 0x100 | Read/Write: RO | Reset: 0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx

Bit	Reset	Description
7:0	X	CAPLENGTH: Indicates which offset to add to the register base address at the beginning of the Operational Register. Set to 0x40.

23.9.4.7 USB2_CONTROLLER_1_USB2D_HCIVERSON_0

USB2D Host Interface Version Number Register

Offset: 0x102 | Read/Write: RO | Reset: 0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx

Bit	Reset	Description
15:0	X	HCIVERSION: Contains a BCD encoding of the EHCI revision number supported by this host controller. The most significant byte of this register represents a major revision and the least significant byte is the minor revision. This host controller supports EHCI revision 1.00.

23.9.4.8 USB2_CONTROLLER_1_USB2D_HCSPARAMS_0

USB2D Host Control Structural Parameters Register

Offset: 0x104 | Read/Write: RO | Reset: 0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx

Bit	Reset	Description
27:24	X	N_TT: Number of Transaction Translators: Indicates the number of embedded transaction translators associated with the USB2.0 host controller. This field is always set to 1 indicating only 1 embedded TT is implemented in this implementation. This is a non-EHCI field to support embedded TT.
23:20	X	N_PTT: Number of Ports per Transaction Translator: Indicates the number of ports assigned to each transaction translator within the USB2.0 host controller. Field always equals N_PORTS. This is a non-EHCI field to support embedded TT.
15:12	X	N_CC: Number of Companion Controller: Indicates the number of companion controllers. This field is set to 0.
11:8	X	N_PCC: Number of Ports per Companion Controller: Indicates the number of ports supported per internal companion controller. This field is set to 0.
4	X	PPC: Port Power Control: Indicates whether the host controller implementation includes port power control. 1 = Ports have port power switches 0= Ports do not have port power switches. This field affects the functionality of the port Power field in each port status and control register. This field is set to 1.
3:0	X	N_PORTS: Number of downstream ports. This field specifies the number of physical downstream ports implemented on this host controller. This field is fixed to 1, since this host controller only supports 1 port.

23.9.4.9 USB2_CONTROLLER_1_USB2D_HCCPARAMS_0

USB2D Host Control Capability Parameters Register

Offset: 0x108 | Read/Write: RO | Reset: 0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx

Bit	Reset	Description
18	X	PPC: Per-Port Change Event Capability. Default = 1b. This field indicates the support for per-port change events. This field is related to the USBCMD PPE field, USBSTS PPCI field, and USBINTR PPCE field.
17	X	LEN: Link Power Management Capability. Default = 1b. This field indicates the support for LPM L1 state. This field is related to the USBCMD HIRD field, POSTSCx SSTS and DA fields, and HOSTPCx LEN, BA, and EPLPM fields.
15:8	X	EECP: EHCI Extended Capabilities Pointer: Indicates a capabilities list exists. A value of 00h indicates no extended capabilities are implemented. For this implementation this field is always "0".
7:4	X	IST: Isochronous Scheduling Threshold. This field indicates, relative to the current position of the executing host controller, where software can reliably update the isochronous schedule. When bit [7] is zero, the value of the least significant 3 bits indicates the number of micro-frames a host controller can hold a set of isochronous data structures (one or more) before flushing the state. When bit [7] is a one, then host software assumes the host controller may cache an isochronous data structure for an entire frame. This field will always be "0".
2	X	ASP: Asynchronous Schedule Park Capability. 1 = (Default) the host controller supports the park feature for high-speed queue heads in the Asynchronous Schedule. The feature can be disabled or enabled and set to a specific level by using the Asynchronous Schedule Park Mode Enable and Asynchronous Schedule Park Mode Count fields in the USBCMD register. This field is always 1.
1	X	PFL: Programmable Frame List Flag. 0 = System software must use a frame list length of 1024 elements with this host controller. The USBCMD register Frame List Size field is a read-only register and must be set to zero. 1 = System software can specify and use a smaller frame list and configure the host controller via the USBCMD register Frame List Size field. The frame list must always be aligned on a 4K-page boundary. This requirement ensures that the frame list is always physically contiguous. This field will always be "1".

23.9.4.10 USB2_CONTROLLER_1_USB2D_DCIVERSION_0

USB2D Device Interface Version Number Register

Offset: 0x120 | Read/Write: RO | Reset: 0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx

Bit	Reset	Description
15:0	X	DCIVERSION: The device controller interface conforms to the two-byte BCD encoding of the interface version number contained in this register.

23.9.4.11 USB2_CONTROLLER_1_USB2D_DCCPARAMS_0

USB2D Device Control Capabilities Register

Offset: 0x124 | Read/Write: RO | Reset: 0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx

Bit	Reset	Description
8	X	HC: Host Capable: 1 = This controller is capable of operating as an EHCI compatible USB 2 0 host controller operating as an EHCI compatible USB 2.0 host controller. This field is set to 1.
7	X	DC: Device Capable: 1 = Controller is capable of operating as USB 2.0 device. This field is set to 1
5	X	LEN: Link Power Management Capability - RO. Default = 1b. This field indicates the support for LPM L1 state. This field is related to the DEVLCx ASUS, STL,BA and NYT fields.
4:0	X	DEN: Device Endpoint Number: Number of endpoints built into the device controller. This is set to 16.

23.9.4.12 USB2_CONTROLLER_1_USB2D_EXTSTS_0

USB2D EXTSTS Register

Offset: 0x128 | Read/Write: R/W | Reset: 0bxxxxxxxxxxxxxxxxxxxxxxxxxxxx0000x

Bit	R/W	Reset	Description
4	RW	0x0	TI1: General Purpose Timer Interrupt 1 - RWC. Default = 0b. This bit is set when the counter in the GPTIMER1CTRL register transitions to zero. Writing a one to this bit will clear it.
3	RW	0x0	TI0: General Purpose Timer Interrupt 0 - RWC. Default = 0b. This bit is set when the counter in the GPTIMER1CTRL register transitions to zero. Writing a one to this bit will clear it.
2	RW	0x0	UPA: USB Host Periodic Interrupt (USBHSTPERINT) R/WC. This bit is set by the Host Controller when the cause of an interrupt is a completion of a USB transaction where the Transfer Descriptor (TD) has an interrupt on complete (IOC) bit set and the TD was from the periodic schedule. This bit is also set by the Host Controller when a short packet is detected AND the packet is on the periodic schedule. A short packet is when the actual number of bytes received was less than the expected number of bytes. This bit is not used by the device controller and will always be zero. 0 = DISABLE 1 = ENABLE
1	RW	0x0	UAI: USB Host Asynchronous Interrupt (USBHSTASYNCINT) R/WC. This bit is set by the Host Controller when the cause of an interrupt is a completion of a USB transaction where the Transfer Descriptor (TD) has an interrupt on complete (IOC) bit set AND the TD was from the asynchronous schedule. This bit is also set by the Host when a short packet is detected AND the packet is on the asynchronous schedule. A short packet is when the actual number of bytes received was less than the expected number of bytes. This bit is not used by the device controller and will always be zero. 0 = DISABLE 1 = ENABLE
0	RO	X	NAKI: NAK Interrupt Bit Read Only. This bit is read only. It is set by hardware when for a particular endpoint both the TX/RX Endpoint NAK bit and the corresponding TX/RX Endpoint NAK Enable bit are set. This bit is automatically cleared by hardware when the all the enabled TX/RX Endpoint NAK bits are cleared. 0 = DISABLE 1 = ENABLE

23.9.4.13 USB2_CONTROLLER_1_USB2D_USBEXTINTR_0

USB2D EXTINTR Register

Offset: 0x12c | Read/Write: R/W | Reset: 0bxxxxxxxxxxxxxxxxxxxxxxxxxxxx00000

Bit	Reset	Description
4	0x0	TIE1: General Purpose Timer Interrupt Enable 1 - RWC. Default = 0b. When this bit is a one, and the TI1 bit in the EXTSTS register is a one, the controller will issue an interrupt. The interrupt is acknowledged by software clearing the TI1 bit.
3	0x0	TIE0: General Purpose Timer Interrupt Enable 0 - RWC. Default = 0b. When this bit is a one, and the TI1 bit in the EXTSTS register is a one, the controller will issue an interrupt. The interrupt is acknowledged by software clearing the TI1 bit.
2	0x0	UPIE: UPIE Interrupt Enable. 1 = USB controller issues an interrupt if the UPA bit in USBSTS register transitions. 0 = DISABLE 1 = ENABLE
1	0x0	UAIE: UAIE Interrupt Enable. 1 = USB controller issues an interrupt if the UAI bit in USBSTS register transitions. 0 = DISABLE 1 = ENABLE
0	0x0	NAKE: NAK Interrupt Enable. 1 = USB controller issues an interrupt if the NAKI bit in USBSTS register transitions. 0 = DISABLE 1 = ENABLE

23.9.4.14 USB2_CONTROLLER_1_USB2D_USBCMD_0

USB2D USB Command Register

Offset: 0x130 | Read/Write: R/W | Reset: 0bxxxx000000001000000x1x11x0000000

Bit	R/W	Reset	Description
27:24	RW	0x0	HIRD: Host Initiated Resume Duration RW. Default = 0000b. This has the same behavior as bits 7:4 of the BA field of the HOSTPCx register. When writing to this field all BA[7:4] fields of all HOSTPCx registers will be set to this value. This field is used by system software to specify the minimum amount of time the host controller will drive the K-state during a host-initiated resume from an LPM state (e.g., L1), and is conveyed to each LPM-enabled device (via the HIRD bits within an LPM Tokens bmAttributes field) upon entry into a low-power state. Note the host controller is required to drive resume signaling for at least the amount of time specified in the HIRD value conveyed to the device during any proceeding host-initiated resume. Also note that the host controller is not required to observe this requirement during device-initiated resumes. Encoding for this field is identical to the definition for the similarly named HIRD field within an LPM Token, specifically: a value 0000b equals 50µs and each additional increment adds 75µs. For example, the value 0001b equals 125µs, and a value 1111b equals 1,175µs (~1.2ms).
23:16	RW	0x8	ITC: Interrupt Threshold Control .Read/Write. Default 08h. The system software uses this field to set the maximum rate at which the host/device controller will issue interrupts. ITC contains the maximum interrupt interval measured in micro-frames. Valid values are shown below. Value Maximum Interrupt Interval 00h Immediate (no threshold) 01h 1 micro-frame 02h 2 micro-frames 04h 4 micro-frames 08h 8 micro-frames 10h 16 micro-frames 20h 32 micro-frames 40h 64 micro-frames 0 = IMMEDIATE 2 = ONE_MF

Bit	R/W	Reset	Description
			4 = TWO_MF 8 = EIGHT_MF 16 = SIXTEEN_MF 32 = THIRTY_TWO_MF 64 = SIXTY_FOUR_MF
15	RW	0x0	FS2: Bit 2 of Frame List Size.
14	RW	0x0	ATDTW: Add DTD Tripwire. This bit is used as a semaphore when a dTD is added to an active (primed) endpoint. This bit is set and cleared by software and will be cleared by hardware when a hazard exists such that adding a dTD to a primed endpoint may go unnoticed. 0 = CLEAR 1 = SET
13	RW	0x0	SUTW: Setup Tripwire. This bit is used as a semaphore when the 8 bytes of setup data read extracted by the firmware. If the setup lockout mode is off, then there exists a hazard when new setup data arrives and firmware is copying setup data from the QH for a previous setup packet. This bit is set and cleared by software and will be cleared by hardware when a hazard exists. 0 = CLEAR 1 = SET
11	RW	0x1	ASPE: Asynchronous Schedule Park mode Enable. Software uses this bit to enable or disable Park mode. When this bit is one, Park mode is enabled. When this bit is a zero, Park mode is disabled. This field is set to "1" in this implementation. 0 = DISABLE 1 = ENABLE
9:8	RW	0x3	ASP1_ASP0: Asynchronous Schedule Park Mode Count (OPTIONAL) Read/Write. If the Asynchronous Park Capability bit in the HCCPARAMS register is a one, then this field defaults to 3h and is R/W. Otherwise it defaults to zero and is RO. It contains a count of the number of successive transactions the host controller is allowed to execute from a high-speed queue head on the Asynchronous schedule before continuing traversal of the Asynchronous schedule. Valid values are 1h to 3h. Software must not write a zero to this bit when Park Mode Enable is a one as this will result in undefined behavior. This field is set to 3h in this implementation and is Read/Write capable.
7	RO	X	LR: Light Host/Device Controller Reset (OPTIONAL) . Read Only. Not Implemented. This field will always be "0".
6	RW	0x0	IAA: Interrupt on Async Advance Doorbell. When the host controller has evicted all appropriate cached schedule states, it sets the Interrupt on Async Advance status bit in the USBSTS register. If the Interrupt on Sync Advance Enable bit in the USBINTR register is one, then the host controller will assert an interrupt at the next interrupt threshold. The host controller sets this bit to zero after it has set the Interrupt on Sync Advance status bit in the USBSTS register to one. Software should not write a one to this bit when the asynchronous schedule is inactive. Doing so will yield undefined results. This bit is only used in host mode. Writing a one to this bit when device mode is selected will have undefined results. 0 = CLEAR 1 = SET
5	RW	0x0	ASE: Asynchronous Schedule Enable. This bit controls whether the host controller skips processing the Asynchronous Schedule. 0 = Do not process the Asynchronous Schedule. 1 = Use the ASYNCLISTADDR register to access the Asynchronous Schedule. Only the host controller uses this bit. 0 = DISABLE 1 = ENABLE
4	RW	0x0	PSE: Periodic Schedule Enable. This bit controls whether the host controller skips processing the Periodic Schedule. 0 = Do not process the Periodic Schedule 1 = Use the PERIODICLISTBASE register to access the Periodic Schedule. Only the host controller uses this bit. 0 = DISABLE 1 = ENABLE
3:2	RW	0x0	FS1_FS0: Frame List Size. (Read/Write). 000 = Default. This field is Read/Write only if Programmable Frame List Flag in the HCCPARAMS registers is set to one. Hence this field is Read/Write for this implementation. This field specifies the size of the frame list that controls which bits in the Frame Index Register should be used for the Frame List Current index. Note that this field is made up from USBCMD bits 15, 3, and 2. 000 = 1024 elements (4096 bytes) Default value 001 = 512 elements (2048 bytes)

Bit	R/W	Reset	Description
			010 = 256 elements (1024 bytes) 011 = 128 elements (512 bytes) 100 = 64 elements (256 bytes) 101 = 32 elements (128 bytes) 110 = 16 elements (64 bytes) 111 = 8 elements (32 bytes) Only the host controller uses this field.
1	RW	0x0	RST: Controller Reset. Software uses this bit to reset the controller. This bit is set to zero by the Host/Device Controller when the reset process is complete. Software cannot terminate the reset process early by writing a zero to this register. Host Controller: When software writes a one to this bit, the Host Controller resets its internal pipelines, timers, counters, state machines etc. to their initial value. Any transaction currently in progress on USB is immediately terminated. A USB reset is not driven on downstream ports. Software should not set this bit to a one when the HCHalted bit in the USBSTS register is a zero. Attempting to reset an actively running host controller results in undefined behavior. Device Controller: When software writes a one to this bit, the Device Controller resets its internal pipelines, timers, counters, state machines, etc. to their initial value. Any transaction currently in progress on USB is immediately terminated. Writing a one to this bit in device mode is not recommended. 0 = CLEAR 1 = SET
0	RW	0x0	RS: Run/Stop: Host Controller: When set to a 1, the Host Controller proceeds with the execution of the schedule. The Host Controller continues execution as long as this bit is set to a one. When this bit is set to 0, the Host Controller completes the current transaction on the USB and then halts. The HCHalted bit in the status register indicates when the Host Controller has finished the transaction and has entered the stopped state. Software should not write a one to this field unless the host controller is in the Halted state (i.e., HCHalted in the USBSTS register is a one). Device Controller: Writing a one to this bit will cause the device controller to enable a pull-up on D+ and initiate an attach event. This control bit is not directly connected to the pull-up enable, as the pull-up will become disabled upon transitioning into high-speed mode. Software should use this bit to prevent an attach event before the device controller has been properly initialized. Writing a 0 to this will cause a detach event. 0 = STOP 1 = RUN

23.9.4.15 USB2_CONTROLLER_1_USB2D_USBSTS_0

USB2D USB Status Register

Offset: 0x134 | Read/Write: R/W | Reset: 0b00000000000000000x100x0000x0000

Bit	R/W	Reset	Description
31:16	RW	0x0	PPCI: Port-n Change Detect - RW. Default = 0000h. The definition for each bit is identical to the Port Change Detect field (bit 2 of this register) except these bits are specific to a given port, where bit 16 = Port 1, 17 = Port 2, etc. For example, if bit 17 is set to a one then a port change event was detected on Port 2. The N_PORTS field in HCSPARAMS specifies how many ports are exposed by the host controller and thus how many bits in this field are valid.
15	RW	0x0	AS: Asynchronous Schedule Status. This bit reports the current status of the Asynchronous Schedule. When set to zero the asynchronous schedule status is disabled and if set to one the status is enabled. The Host Controller is not required to immediately disable or enable the Asynchronous Schedule when software transitions the Asynchronous Schedule Enable bit in the USBCMD register. If AS = ASE: 1= Enable Asynchronous Schedule. 0= Disable Asynchronous Schedule. Only used by the host controller. 0 = DISABLE 1 = ENABLE

Bit	R/W	Reset	Description
14	RW	0x0	PS: Periodic Schedule Status. This bit reports the current status of the Periodic Schedule. When set to zero the periodic schedule is disabled, and if set to one the status is enabled. The Host Controller is not required to immediately disable or enable the Periodic Schedule when software transitions the Periodic Schedule Enable bit in the USBCMD register. If PS = PSE:: 1 = Periodic Schedule is enabled. 0 = Periodic Schedule is disabled. Only used by the host controller. 0 = DISABLE 1 = ENABLE
13	RO	X	RCL: Reclamation. This is a read-only status bit used to detect an empty asynchronous schedule. Only used by the host controller. 0 = DISABLE 1 = ENABLE
12	RW	0x1	HCH: HCHalted. 1 = Default. This bit is a zero whenever the Run/Stop bit is a one. The Host Controller sets this bit to one after it has stopped executing because of the Run/Stop bit being set to 0, either by software or by the Host Controller hardware (e.g., internal error). Only used by the host controller. 0 = UNHALTED 1 = HALTED
11	RW	0x0	UALT_INT: ULPI alt_int Interrupt. 0 = Default. This interrupt bit is set when an RXCMD is received through the ULPI interface with bit 7 set (alt_int). The alt_int bit is set when an unmasked event occurs on any bit in the Carkit Interrupt Latch Register, in the ULPI PHY. The software should read the Carkit Interrupt Latch Register (Read to Clear) through the ULPI Viewport to check the source of the interrupt. Only present in designs where configuration constant VUSB_HS_PHY_ULPI = 1. 0 = NOT_ULPI_ALT_INT 1 = ULPI_ALT_INT
10	RW	0x0	ULPI_INT: ULPI Interrupt. This bit is set whenever an interrupt is received from ULPI PHY. Software writes 1 to clear it. 0 = NOT_ULPI_INT 1 = ULPI_INT
8	RW	0x0	SLI: DCSuspend. When a device controller enters a suspend state from an active state, this bit will be set to a 1. The device controller clears the bit upon exiting from a suspend state. Only used by the device controller. 0 = NOTSUSPEND 1 = SUSPENDED
7	RW	0x0	SRI: SOF Received. When the device controller detects a Start Of (micro) Frame, this bit will be set to a one. When an SOF is extremely late, the device controller will automatically set this bit to indicate that an SOF was expected. Therefore, this bit will be set roughly every 1ms in device FS mode and every 125 µs in HS mode and will be synchronized to the actual SOF that is received. Since device controller is initialized to FS before connect, this bit will be set at an interval of 1ms during the prelude to the connect and chirp. In host mode, this bit will be set every 125 µs and can be used by host controller driver as a time base. Software writes a 1 to this bit to clear it. This is a non-EHCI status bit. 0 = SOF_NOT_RCVD 1 = SOF_RCVD
6	RW	0x0	URI: USB Reset Received. When the device controller detects a USB Reset and enters the default state, this bit is set to a 1. Software can write a 1 to this bit to clear the USB Reset Received status bit. Only used by the device controller. 0 = NO_USB_RESET 1 = USB_RESET
5	RW	0x0	AAI: Interrupt and Asynchronous Advance. System software can force the host controller to issue an interrupt the next time the host controller advances the asynchronous schedule by writing a one to the Interrupt on Async Advance Doorbell bit in the USBCMD register. This status bit indicates the assertion of that interrupt source. Only used by the host controller. 0 = NOT_ADVANCED 1 = ADVANCED
4	RO	X	SEI: System Error. This bit is not used in this implementation and will always be set to "0". 0 = NO_ERROR 1 = ERROR

Bit	R/W	Reset	Description
3	RW	0x0	FRI: Frame List Rollover. The Host Controller sets this bit to a 1 when the Frame List Index rolls over from its maximum value to 0. The exact value at which the rollover occurs depends on the frame list size. For example. If the frame list size (as programmed in the Frame List Size field of the USBCMD register) is 1024, the Frame Index Register rolls over every time FRINDEX [1 3] toggles. Similarly, if the size is 512, the Host Controller sets this bit to a 1 every time FHINDEX [12] toggles. Only used by the host controller. 0 = NO_ROLLOVER 1 = ROLLOVER
2	RW	0x0	PCI: Port Change Detect. The Host Controller sets this bit to a 1 when on any port a Connect Status occurs, a Port Enable/Disable Change occurs, or the Force Port Resume bit is set as the result of a J-K transition on the suspended port. The Device Controller sets this bit to a one when the port controller enters the full or high-speed operational state. When the port controller exits the full or high-speed operational states due to Reset or Suspend events, the notification mechanisms are the USB Reset Received bit and the DCSuspend bits respectively. This bit is not EHCI compatible. 0 = NO_PORT_CHANGE 1 = PORT_CHANGE
1	RW	0x0	UEI: USB Error Interrupt. This bit gets set by the Host/Device controller when completion of a USB transaction results in an error condition. This bit is set along with the USBINT bit, if the TD on which the error interrupt occurred also ad its interrupt on complete (IOC) bit set. 0 = NO_ERROR 1 = ERROR
0	RW	0x0	UI: USB Interrupt. This bit is set by the Host/Device Controller when the cause of an interrupt is a completion of a USB transaction where the Transfer Descriptor (TD) as an interrupt on complete (IOC) bit set. This bit is also set by the Host/Device Controller when a short packet is detected. A short packet is when the actual number of bytes received was less than the expected number of bytes. 0 = NO_INT 1 = INT

23.9.4.16 USB2_CONTROLLER_1_USB2D_USBINTR_0

USB2D USB Interrupt Enable Register

Offset: 0x138 | Read/Write: R/W | Reset: 0b0000000000000000xxxx00x000000000

Bit	Reset	Description
31:16	0x0	PPCE: Port-n Change Detect Enable - RW. Default = 0000h. The definition for each bit in this field is identical to bit 2 of this register (Port Change Interrupt Enable) except these bits are specific to a given port, where bit 16 = Port 1, 17 = Port 2, etc. For example, if bit 17 is set (1b) then a port change event was detected on Port 2. When a bit in this field is a one, and the corresponding Port-n Change Detect bit in the USBSTS register is a one, the host controller will issue an interrupt. The interrupt is acknowledged by software clearing the Port-n Change Detect bit.
11	0x0	UALTIE: ULPI alt_int Interrupt Enable. 1 = USB controller issues an interrupt if the ULPI_ALT_INT bit in the USBSTS register transitions. The interrupt is acknowledged by software writing a 1 to the ULPI_ALT_INT bit. 0 = DISABLE 1 = ENABLE
10	0x0	ULPIE: ULPI Interrupt Enable. 1 = USB controller issues an interrupt if ULPI_INT bit in USBSTS register transitions. The interrupt is acknowledged by software by writing a 1 to the ULPI_INT bit. 0 = DISABLE 1 = ENABLE
8	0x0	SLE: Sleep Enable. 1 = Device controller issues an interrupt if DCSuspend bit in USBSTS register transitions. The interrupt is acknowledged by software by writing a 1 to the DCSuspend bit. Only used by the device controller. 0 = DISABLE 1 = ENABLE

Bit	Reset	Description
7	0x0	SRE: SOF Received Enable. 1 = Device controller issues an interrupt if SOF Received bit in USBSTS register = 1. The interrupt is acknowledged by software clearing the SOF Received bit. 0 = DISABLE 1 = ENABLE
6	0x0	URE: USB Reset Enable.1 = Device controller issues an interrupt if USB Reset Received bit in USBSTS register = 1. The interrupt is acknowledged by software clearing the USB Reset Received bit. Only used by the device controller. 0 = DISABLE 1 = ENABLE
5	0x0	AAE: Interrupt on Asynchronous Advance Enable. 1 = the host controller issues an interrupt at the next interrupt threshold if the Interrupt on Async Advance bit in the USBSTS register = 1. The interrupt is acknowledged by software clearing the Interrupt on Async Advance bit. Only used by the host controller. 0 = DISABLE 1 = ENABLE
4	0x0	SEE: System Error Enable. 1 = Host/device controller issues an interrupt if the System Error bit in the USBSTS register = 1. The interrupt is acknowledged by software clearing the System Error bit. 0 = DISABLE 1 = ENABLE
3	0x0	FRE: Frame List Rollover Enable. 1 = Host controller issues an interrupt if the Frame List Rollover bit in the USBSTS register = 1. The interrupt is acknowledged by software clearing the Frame List Rollover bit. Only used by the host controller. 0 = DISABLE 1 = ENABLE
2	0x0	PCE: Port Change Detect Enable. 1 = Host/device controller issues an interrupt if Port Change Detect bit in USBSTS register = 1. The interrupt is acknowledged by software clearing the Port Change Detect bit. 0 = DISABLE 1 = ENABLE
1	0x0	UEE: USB Error Interrupt Enable. 1 = Host controller issues an interrupt at the next interrupt threshold if the USBERRINT bit in USBSTS = 1. The interrupt is acknowledged by software clearing the USBERRINT bit in the USBSTS register. 0 = DISABLE 1 = ENABLE
0	0x0	UE: USB Interrupt Enable. 1 = Host/device issues an interrupt at the next interrupt threshold if the USBINT bit in USBSTS = 1. The interrupt is acknowledged by software clearing the USBINT bit. 0 = DISABLE 1 = ENABLE

23.9.4.17 USB2_CONTROLLER_1_USB2D_FRINDEX_0

USB2D USB Frame Index Register

Offset: 0x13c | Read/Write: RO | Reset: 0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx

Bit	Reset	Description
13:0	X	FRINDEX: Frame Index. The value in this register increments at the end of each time frame (micro-frame). Bits [N: 3] are used for the Frame List current index. Each location of the frame list is accessed 8 times (frames or micro-frames) before moving to the next index. The following illustrates values of N based on the value of the Frame List Size field in the USBCMD register, when used in host mode. USBCMD [Frame List Size] Number Elements N 000b (1024) 12 001b (512) 11 010b (256) 10 011b (128) 9 100b (64) 8 101b (32) 7 110b (16) 6 111b (8) 5 In device mode, the value is the current frame number of the last frame transmitted. It is not used as an index. In either mode, bits 2:0 indicate the current micro-frame.

23.9.4.18 USB2_CONTROLLER_1_USB2D_PERIODICLISTBASE_0

USB2D Host Controller Frame List Base Address Register

Offset: 0x144 | Read/Write: R/W | Reset: 0b00000000000000000000xxxxxxxxxxxx

Bit	Reset	Description
31:25	0x0	USBADR: Device mode. The upper seven bits of this register represent the device address. After any controller reset or a USB reset, the device address is set to the default address (0). The default address will match all incoming addresses. Software shall reprogram the address after receiving a SET_ADDRESS request.
24	0x0	USBADRA: Device Address Advance. Default=0. When this bit is 0, any writes to USBADR are instantaneous. When this bit is written to a 1 at the same time or before USBADR is written, the write to the USBADR field is staged and held in a hidden register. After an IN occurs on endpoint 0 and is ACKed, USBADR will be loaded from the holding register. Hardware will automatically clear this bit on the following conditions: 1) IN is ACKed to endpoint 0. (USBADR is updated from staging register). 2) OUT/SETUP occur to endpoint 0. (USBADR is not updated). 3) Device Reset occurs (USBADR is reset to 0). Note: After the status phase of the SET_ADDRESS descriptor, the DCD has 2 ms to program the USBADR field. This mechanism will ensure this specification is met when the DCD cannot write of the device address within 2ms from the SET_ADDRESS status phase. If the DCD writes the USBADR with USBADRA=1 after the SET_ADDRESS data phase (before the prime of the status phase), the USBADR will be programmed instantly at the correct time and meet the 2ms USB requirement.
31:12	0x0	BASEADR: Host mode: This 32-bit register contains the beginning address of the Periodic Frame List in the system memory. HCD loads this register prior to starting the schedule execution by the Host Controller. The memory structure referenced by this physical memory pointer is assumed to be 4-Kbyte aligned. The contents of this register are combined with the Frame Index Register (FRINDEX) to enable the Host Controller to step through the Periodic Frame List in sequence. Base Address (Low). These bits correspond to memory address signals [31:12], respectively. Only used by the host controller.

23.9.4.19 USB2_CONTROLLER_1_USB2D_ASYNCLISTADDR_0

USB2D Next Asynchronous List Address Register

Offset: 0x148 | Read/Write: R/W | Reset: 0b00000000000000000000000000xxxxx

Bit	Reset	Description
31:11	0x0	EPBASE: Device mode. This register contains the address of the top of the endpoint list in system memory. These bits correspond to memory address signals [31:11], respectively. This field will reference a list of up to 32 Queue Heads (QH). Only used by the device controller.
31:5	0x0	ASYBASE: Host mode. This 32-bit register contains the address of the next asynchronous queue head to be executed by the host. Link Pointer Low (LPL). These bits correspond to memory address signals [31:5], respectively. This field may only reference a Queue Head (OH). Only used by the host controller.

23.9.4.20 USB2_CONTROLLER_1_USB2D_ASYNCTTSTS_0

USB2D Asynchronous Buffer Status for Embedded TT Register

Offset: 0x14c | Read/Write: R/W | Reset: 0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx0x

Bit	R/W	Reset	Description
1	RW	0x0	TTAC: Embedded TT Async Buffers Clear. (Read/Write to set). This field will clear all pending transactions in the embedded TT Async Buffer(s). The clear will take as much time as necessary to clear buffer without interfering with a transaction in progress. TTAC will return to zero after being set by software only after the actual clear occurs.
0	RO	X	TTAS: Embedded TT Async Buffers Status. (Read Only). This read-only bit will be 1 if one or more transactions are being held in the embedded TT Async. Buffers. When this bit is a zero, then all outstanding transactions in the embedded TT have been flushed.

23.9.4.21 USB2_CONTROLLER_1_USB2D_BURSTSIZE_0

USB2D Burst Size register

Offset: 0x150 | Read/Write: R/W | Reset: 0bxxxxxxxxxxxxxxxx0000100000001000

Bit	Reset	Description
15:8	0x8	TXPBURST: Programmable TX Burst Length. (Read/Write). This register represents the maximum length of a burst in 32-bit words while moving data from system memory to the USB bus.
7:0	0x8	RXPBURST: Programmable RX Burst Length. (Read/Write). This register represents the maximum length of a burst in 32-bit words while moving data from the USB bus to system memory.

23.9.4.22 USB2_CONTROLLER_1_USB2D_TXFILLTUNING_0

USB2D Transmit Fill Tuning Register

Offset: 0x154 | Read/Write: R/W | Reset: 0bxxxxxxxxxx000010xxx0000000000000

Bit	Reset	Description
21:16	0x2	TXFIFOTHRES: FIFO Burst Threshold. (Read/Write). This register controls the number of data bursts that are posted to the TX latency FIFO in host mode before the packet begins on to the bus. The minimum value is 2, and this value should be a low as possible to maximize USB performance. A higher value can be used in systems with unpredictable latency and/or insufficient bandwidth where the FIFO may underrun because the data transferred from the latency FIFO to USB occurs before it can be replenished from system memory. This value is ignored if the Stream Disable bit in USBMODE register is set.

Bit	Reset	Description
12:8	0x0	TXSCHHEALTH: Scheduler Health Counter. (Read/Write To Clear) [Default = 0] This register increments when the host controller fails to fill the TX latency FIFO to the level programmed by TXFIFOTHRES before running out of time to send the packet before the next Start-Of-Frame. This health counter measures the number of times this occurs to provide feedback to selecting a proper TXSCHOH. Writing to this register will clear the counter and this counter will max out at 31.
7:0	0x0	TXSCHOH: Scheduler Overhead. (Read/Write) [Default = 0] This register adds an additional fixed offset to the schedule time estimator described above as Tff. As an approximation, the value chosen for this register should limit the number of back-off events captured in the TXSCHHEALTH to less than 10 per second in a highly utilized bus. Choosing a value that is too high for this register is not desired as it can needlessly reduce USB utilization. The time unit represented in this register is 1.267 µs when a device is connected in High-Speed Mode. The time unit represented in this register is 6.333 µs when a device is connected in Low/Full Speed Mode

23.9.4.23 USB2_CONTROLLER_1_USB2D_ICUSB_CTRL_0

USB2D ICUSB Control Register

This register enables and controls the ICUSB FS/LS transceiver.

Offset: 0x15c | Read/Write: R/W | Reset: 0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx0000

Bit	Reset	Description
3	0x0	IC_ENB1: ICUSB transceiver enable. This bit enables the ICUSB transceiver. To enable the interface, the bits PTS must be set to 11 in the PORTSCx. Writing a '1' to this bit selects the IC_USB interface. 0 = DISABLE 1 = ENABLE
2:0	0x0	IC_VDD1: ICUSB voltage select. It selects which voltage is being supplied to the ICUSB peripheral. 000= No voltage 001 = 1.0V - reserved 010= 1.2V - reserved 011= 1.5V - reserved 100 = 1.8V 101 = 3.0V 110 = reserved 111 = reserved The Voltage negotiation should happen between enabling port power (PP) and asserting the run/stop bit in register.

23.9.4.24 USB2_CONTROLLER_1_USB2D_ULPI_VIEWPORT_0

This register provides indirect access to the ULPI PHY register set. Although the USB controller performs access to the ULPI PHY register set, there may be extraordinary circumstances where software may need direct access.

Note: WRITES TO THE ULPI THROUGH THE VIEWPORT CAN SUBSTANTIALLY HARM STANDARD USB OPERATIONS. CURRENTLY NO USAGE MODEL HAS BEEN DEFINED WHERE SOFTWARE SHOULD NEED TO EXECUTE WRITES DIRECTLY TO THE ULPI PHY. SEE EXCEPTION REGARDING OPTIONAL FEATURES BELOW.

Note: EXECUTING READ OPERATIONS THROUGH THE ULPI VIEWPORT SHOULD HAVE NO HARMFUL SIDE EFFECTS TO STANDARD USB OPERATIONS.

There are two operations that can be performed with the ULPI Viewport-- wakeup and read /write operations.

The wakeup operation is used to put the ULPI interface into normal operation mode and re-enable the clock if necessary. A wakeup operation is required before accessing the registers when the ULPI interface is operating in low power mode, serial mode, or Carkit mode.

The ULPI state can be determined by reading the sync state bit (ULPI_SYNC_STATE). If this bit is a one, then ULPI interface is running in normal operation mode and can accept read/write operations. If the ULPI_SYNC_STATE indicates a 0 then then

read/write operations will not be able to execute. Undefined behavior will result if ULPI_SYNC_STATE = 0 and a read or write operation is performed.

To execute a wakeup operation, write all 32 bits of the ULPI Viewport where ULPI_PORT is constructed appropriately and the ULPI_WAKEUP bit is a 1 and ULPI_RUN bit is a 0. Poll the ULPI Viewport until ULPI_WAKEUP is zero for the operation to complete.

To execute a read or write operation, write all 32 bits of the ULPI Viewport where ULPI_DATA_WR, ULPI_REG_ADDR, ULPI_PORT, ULPI_RD_WR are constructed appropriately and the ULPI_RUN bit is a 1. Poll the ULPI Viewport until ULPI_RUN is zero for the operation to complete. Once ULPI_RUN is zero, the ULPI_DATA_RD will be valid if the operation was a read.

The polling method above can be changed to interrupt driven using the ULPI interrupt defined in the USBSTS and USBINTR registers. When a wakeup or read/write operation is complete, the ULPI_INT interrupt will be set.

There are several optional features that may need to be enabled or disabled by system software as part of system configuration. These bits are contained in the Interface and OTG Control registers of the ULPI PHY register set. These registers also contain bits which are controlled by the link dynamically and therefore should be only modified by system software using the Set/Clear access method. Direct writes to these registers could have harmful side effects to the standard USB operations. The optional bits are as follows: Bits 3 through 7 in the Interface Control register and Bits 6 and 7 in the OTG Control register.

Please refer to the ULPI Specification Revision 1.1 for further information on the use of the optional features.

USB2D ULPI Viewport Register

Offset: 0x160 | Read/Write: R/W | Reset: 0b000xx00000000000xxxxxxxx00000000

Bit	R/W	Reset	Description
31	RW	0x0	ULPI_WAKEUP: ULPI Wakeup. Writing the 1 to this bit will begin the wakeup operation. The bit will automatically transition to 0 after the wakeup is complete. Once this bit is set, the driver cannot set it back to 0. Note: The driver must never execute a wakeup and a read/write operation at the same time. 0 = CLEAR 1 = SET
30	RW	0x0	ULPI_RUN: ULPI read/write Run. Writing the 1 to this bit will begin the read/write operation. The bit will automatically transition to 0 after the read/write is complete. Once this bit is set, the driver cannot set it back to 0. Note: The driver must never execute a wakeup and a read/write operation at the same time. 0 = CLEAR 1 = SET
29	RW	0x0	ULPI_RD_WR: ULPI read/write control. (0) Read; (1) Write. This bit selects between running a read or write operation. 0 = READ 1 = WRITE
27	RO	X	ULPI_SYNC_STATE: ULPI sync state. (1) Normal Sync. State. (0) In another state (i.e., Carkit, serial, low power). This bit represents the state of the ULPI interface. 0 = NOT_NORMAL 1 = NORMAL
26:24	RW	0x0	ULPI_PORT: ULPI PHY port number. This field should be always written as 0.
23:16	RW	0x0	ULPI_REG_ADDR: ULPI PHY register address. When doing a read or write operation to the ULPI PHY, the address of the ULPI PHY register being accessed is written to this field.
15:8	RO	X	ULPI_DATA_RD: ULPI PHY data read. The data from the ULPI PHY register can be read from here after the read operation completes.
7:0	RW	0x0	ULPI_DATA_WR: ULPI PHY data write. The data to write to the ULPI PHY register is written here.

23.9.4.25 USB2_CONTROLLER_1_USB2D_PORTSC1_0

USB2D Port Status/Control 1 Register

Offset: 0x174 | Read/Write: R/W | Reset: 0b0000000xx0000000xxx1xx00x0xx010x

Bit	R/W	Reset	Description
31:25	RW	0x0	DA: Device Address. Default = 0000000b. The 7-bit USB device address for the device attached to an immediately downstream of the associated root port. A value of zero indicates no device is present or software support for this feature is not present. This is used by the Controller when sending the LPM token. This field is only valid when the core is operating in host mode. If in device mode it will be read only and always equal to 0000000b.
24:23	RO	X	SSTS: Suspend Status. Default = 00b. These two bits are used by software to determine whether an L1-based suspend request was successful, specifically: 00b - L1 state entered with success. ACK received from peripheral. 01b - NYET received from peripheral. It was not able to enter L1 state this time. 10b - L1 state not supported by peripheral. STALL received. 11b - Peripheral did not respond or an error occurred. The value of this field is only valid when the port resides in the L0 state - that is, the meaning of these bits is invalid whenever bit 7 of this register (SUSP) is one. Ideally, the Controller driver should read this register if it receives an interrupt after issuing a suspend using L1 support. In case of a non-success a port change interrupt will be fired and this field should be checked for a possible L1 failure. This field is only valid when the core is operating in host mode. If in device mode it will be always equal to 00b. 0 = L1STATE_ENTERED 1 = NYET_PERIPH 2 = L1STATE_NOT_SUPPORTED 3 = PERIPH_NORESP_ERR
22	RW	0x0	WKOC: Default = 0b. Wake on Over-current Enable: Writing this bit to a one enables the port to be sensitive to over-current conditions as wake-up events. This field is zero if Port Power (PP) is zero. This bit should only be used when operating in Host mode. Writing this bit to 1 while the controller is working in device mode can result in undefined behavior. 0 = DISABLE 1 = ENABLE
21	RW	0x0	WKDS: Wake on Disconnect Enable: Writing this bit to a one enables the port to be sensitive to device disconnects as wake-up events. This field is zero if Port Power (PP) is zero or in device mode. This bit should only be used when operating in Host mode. Writing this bit to 1 while the controller is working in device mode can result in undefined behavior. This bit should not be written to 1 if there is no device connected. After the device disconnect is detected, this bit should be cleared to 0. 0 = DISABLE 1 = ENABLE
20	RW	0x0	WKCN: Wake on Connect Enable: Writing this bit to a one enables the port to be sensitive to device connects as wake-up events. This field is zero if Port Power (PP) is zero or in device mode. This bit should only be used when operating in Host mode. Writing this bit to 1 while the controller is working in device mode can result in undefined behavior. This bit should not be written to 1 while the device is connected. After the device connection is detected, this bit should be cleared to 0. 0 = DISABLE 1 = ENABLE
19:16	RW	0x0	PTC: Port Test Control: Any value other than zero indicates that the port is operating in test mode. Value — Specific Test. 0000b — Not enabled. 0001b — J_ STATE. 0010b — K_STATE. 0011b — SEQ_NAK. 0100b Packet. 0101b — FORCE_ENABLE. 0110b to 1111b — Reserved. Refer to Chapter 7 of the USB Specification Revision 2.0 for details on each test mode.

Bit	R/W	Reset	Description
			0 = NORMAL_OP 1 = TEST_J 2 = TEST_K 3 = TEST_SE0_NAK 4 = TEST_PKT 5 = TEST_FORCE_ENABLE
15:14	RO	X	PIC: Port Indicator Control: This field is not supported in the current implementation. Please use a GPIO if you wish to use Port Indicators.
13	RO	X	PO: Port Owner. Port owner handoff is not implemented in this design, therefore this bit will always be 0.
12	RW	0x1	PP: Port Power: The function of this bit depends on the value of the Port Power Switching (PPC) field in the HCSPARAMS register. The behavior is as follows: PPC PP Operation 0b 0b Read Only. A device controller with no OTG capability does not have port power control switches. 1b 1b/0b RW. Host/OTG controller requires port power control switches. This bit represents the current setting of the switch (0=off, 1=on). When power is not available on a port (i.e., PP equals a 0), the port is non-functional and will not report attaches, detaches, etc. When an over-current condition is detected on a powered port and PPC is a one, the PP bit in each affected port may be transitioned by the host controller driver from a one to a zero (removing power from the port). 0 = NOT_POWERED 1 = POWERED
11:10	RO	X	LS: Line state. These bits reflect the current logical levels of the D+ (bit 10) and D- (bit 11) signal lines. The encoding of the bits is: 00b = SE0 01b = J-state 10b = K-state 11b = Undefined The value of this field is undefined if Port Power (PP) is zero in host mode. In host mode, the use of line-state by the host controller driver is not necessary (unlike EHCI), because the port controller state machine and the port routing manage the connection of LS and FS. In device mode, the use of line-state by the device controller driver is not necessary. 0 = SE0 1 = J_STATE 2 = K_STATE 3 = UNDEFINED
9	RW	0x0	SLP: Suspend using L1 - RW. Default = 0b. When this bit is set to '1' and a non-zero Device Address (DA) is specified Controller will instigate L1 entry during suspend (bit 7) and L1 exit during resume (bit 6). When set to zero the Controller will use the legacy (L2) mechanism. Software should only set this bit when the device attached immediately downstream supports L1 transitions. When acting as device, this bit is read-only and set to '1' by the hardware when the Controller enters is L1 state (LPM token received and accepted). Note: HSP is redundant with PSPD(27:26). This bit is not defined in the EHCI specification.
8	RW	0x0	PR: This field is zero if Port Power (PP) is zero. In Host Mode: Read/Write. 1=Port is in Reset. 0=Port is not in Reset. When software writes a one to this bit, the bus-reset sequence as defined in the USB Specification Revision 2.0 is started. This bit will automatically change to zero after the reset sequence is complete. This behavior is different from EHCI where the host controller driver is required to set this bit to a zero after the reset duration is timed in the driver. In Device Mode: This bit is a read-only status bit. Device reset from the USB bus is also indicated in the USBSTS register. 0 = NOT_USB_RESET 1 = USB_RESET

Bit	R/W	Reset	Description
7	RO	X	SUSP: Port suspend. 1=Port in suspend state. 0=Port not in suspend state. In Host Mode: Read/Write. Port Enabled bit and Suspend bit of this register define the port states as follows: Bits [Port Enabled, Suspend] Port State 0x Disable 10 Enable 11 Suspend When in the suspend state, downstream propagation of data is blocked on this port, except for port reset. The blocking occurs at the end of the current transaction if a transaction was in progress when this bit was written to 1. In the suspend state, the port is sensitive to resume detection. Note that the bit status does not change until the port is suspended and that there may be a delay in suspending a port if there is a transaction currently in progress on the USB. The host controller will unconditionally set this bit to zero when software sets the Force Port Resume bit to zero. A write of zero to this bit is ignored by the host controller. If host software sets this bit to a one when the port is not enabled (i.e., Port enabled bit is a zero), the results are undefined. This field is zero if Port Power (PP) is zero in host mode. In Device Mode: Read Only. This bit is a read-only status bit. 0 = NOT_SUSPEND 1 = SUSPEND
6	RW	0x0	FPR: Force Port Resume. 1= Resume detected/driven on port. 0=No resume (K state) detected/driven on port. In Host Mode: Software sets this bit to one to drive resume signaling. The Host Controller sets this bit to one if a J-to-K transition is detected while the port is in the Suspend state. When this bit transitions to a one because a J-to-K transition is detected, the Port Change Detect bit in the USBSTS register is also set to one. This bit will automatically change to zero after the resume sequence is complete. This behavior is different from EHCI where the host controller driver is required to set this bit to a zero after the resume duration is timed in the driver. Note that when the Host controller owns the port, the resume sequence follows the defined sequence documented in the USB Specification Revision 2.0. The resume signaling (Full-speed 'K') is driven on the port as long as this bit remains a one. This bit remains a one until the port has switched to the high-speed idle. Writing a zero has no effect because the port controller will time the resume operation to clear the bit when the port control state switches to HS or FS idle. This field is zero if Port Power (PP) is zero in host mode. This bit is not-EHCI compatible. In Device mode: After the device has been in Suspend State for 5 ms or more, software must set this bit to one to drive resume signaling before clearing. The Device Controller will set this bit to one if a J-to-K transition is detected while the port is in the Suspend state. The bit will be cleared when the device returns to normal operation. Also, when this bit transitions to a one because a J-to-K transition is detected, the Port Change Detect bit in the USBSTS register is also set to one. Software should ensure that the PHY clock is operational before writing a 1 to this bit to start the resume sequence. This is true for both Device and Host modes. 0 = NO_RESUME 1 = RESUME
5	RO	X	OCC: Over-current Change: Not supported 0 = NO_CHANGE 1 = CHANGE
4	RO	X	OCA: Over-current Active: Not supported 0 = NO_OVER_CURRENT 1 = OVER_CURRENT
3	RW	0x0	PEC: Port Enable/Disable Change: 1=Port enabled/disabled status has changed. 0=No change. In Host Mode: For the root hub, this bit gets set to a one only when a port is disabled due to disconnect on the port or due to the appropriate conditions existing at the EOF2 point (See Chapter 11 of the USB Specification). Software clears this by writing a one to it. This field is zero if Port Power (PP) is zero. In Device mode: The device port is always enabled. (This bit will be zero) 0 = NO_CHANGE 1 = CHANGE
2	RW	0x1	PE: Port Enabled/Disabled: 1=Enable. 0=Disable (default) In Host Mode: Ports can only be enabled by the host controller as a part of the reset and enable. Software cannot enable a port by writing a one to this field. Ports can be disabled by either a fault condition (disconnect event or other fault condition) or by the host software. Note that the bit status does not change until the port state actually changes. There may be a delay in disabling or enabling a port due to other host controller and bus events. When the port is disabled, (0b)

Bit	R/W	Reset	Description
			downstream propagation of data is blocked except for reset. This field is zero if Port Power (PP) is zero in host mode. In Device Mode: The device port is always enabled. (This bit will be one) 0 = PORT_DISABLED 1 = PORT_ENABLED
1	RW	0x0	CSC: Connect Status Change: 1 =Change in Current Connect Status. 0=No change (default) In Host Mode: Indicates a change has occurred in the port's Current Connect Status. The host/device controller sets this bit for all changes to the port device connect status, even if system software has not cleared an existing connect status change. For example, the insertion status changes twice before system software has cleared the changed condition, hub hardware will be 'setting' an already-set bit (i.e., the bit will remain set). Software clears this bit by writing a one to it. This field is zero if Port Power (PP) is zero in host mode. This bit is undefined in device controller mode. 0 = NO_CHANGE 1 = CHANGE
0	RO	X	CCS: Current Connect Status. In Host Mode: 1=Device is present on port. 0=No device is present (default). This value reflects the current state of the port, and may not correspond directly to the event that caused the Connect Status Change bit (Bit 1) to be set. This field is zero if Port Power (PP) is zero in host mode. In Device Mode: 1=Attached. 0=Not Attached (default). A one indicates that the device successfully attached and is operating in either high speed or full speed as indicated by the High Speed Port bit in this register. A zero indicates that the device did not attach successfully or was forcibly disconnected by the software writing a zero to the Run bit in the USBCMD register. It does not state the device being disconnected or suspended. 0 = NOT_CONNECTED 1 = CONNECTED

23.9.4.26 USB2_CONTROLLER_1_USB2D_HOSTPC1_DEVLC_0

USB2D Device Mode LPM Behav and Control Register

This register controls the LPM behavior and controls the behavior of each USB port. Only available when in device mode. This register shares the same address with the HOSTPC1 register (which is used only in host mode).

USB2D Host Mode LPM Behav and Control Register

This register controls the LPM behavior and controls the behavior of each USB port. Only available when in host mode. This register shares the same address with the DEVLC register (which is used only in device mode).

Offset: 0x1b4 | Read/Write: R/W | Reset: 0b0000xxx0000000000000xxxxxxxxxxx0

Bit	R/W	Reset	Description
31:29	RW	0x0	PTS: Parallel transceiver select. This bit is not defined in the EHCI specification. 0 = UTMI 1 = RESERVED 2 = ULPI 3 = ICUSB_SER 4 = HSIC
28	RW	0x0	STS: Serial transceiver not selected. This is the only value supported. This bit is not defined in the EHCI specification. 0 = PARALLEL_IF 1 = SERIAL_IF
27	RO	X	PTW: Parallel Transceiver Width. Fixed to 0. This bit is not defined in the EHCI specification. 0 = EIGHT_BIT 1 = RESERVED

Bit	R/W	Reset	Description
26:25	RO	X	PSPD: This register field indicates the speed at which the port is operating. 00 = Full Speed 01 = Low Speed 10 = High Speed. This bit is not defined in the EHCI specification. 0 = FULL_SPEED 1 = LOW_SPEED 2 = HIGH_SPEED 3 = RESERVED
24	RW	0x0	ALPD: Auto Low Power While Disconnect - RW. Default = 0b. If set, this feature will be enabled, and every time the port enters the disconnect state, it will also enter in low power state, disabling the transceiver clock. The behavior will be same as if the PHCD bit was enabled (in fact this bit will be set to 1 as soon as low power mode is enabled).When this field is set the WKCN field of PORTSCx register (Wake on Connect Enable) will also be set. This way the core will wake up in case a connect is detected. There will be a delay between the detection of a disconnect and actually enter in low power mode. This delay can be controlled by writing to the ALPDD field in the register USBMODE 0 = DONT_AUTO_LOW_POWER_WHILE_DISCONNECT 1 = AUTO_LOW_POWER_WHILE_DISCONNECT
23	RW	0x0	PFSC: Port Force Full Speed Connect - RW. Default = 0b. Writing this bit to a '1b' will force the port to only connect at Full Speed. It disables the chirp sequence that allows the port to identify itself as High Speed. This is useful for testing FS configurations with an HS host, hub or device. This bit is not defined in the EHCI specification. 0 = DONT_FORCE_FULL_SPEED 1 = FORCE_FULL_SPEED
22	RW	0x0	PHCD: PHY Low Power Suspend - Clock disable: Writing this bit to a 1 will disable the PHY clock. Writing a 0 enables it. Reading this bit will indicate the status of the PHY clock. NOTE: The PHY clock cannot be disabled if it is being used as the system clock. In device mode, the PHY can be put into Low Power Clock Disable when the device is not running (USBCMD RS=0b) or the host has signaled suspend (PORTSCx SUSP=1b). Low Power Clock Disable will be cleared automatically when the host has signaled resume. Before forcing a resume from the device, the Controller driver must clear this bit. In host mode, the PHY can be put into Low Power Suspend Clock Disable when the downstream device has been put into suspend mode or when no downstream device is connected. Low Power Clock Disable is completely under the control of software. 0 = DISABLE 1 = ENABLE
21:20	RW	0x0	LPMX: Auto LPM set - RW. Default = 00b. This bit field is **valid during Host Mode Only**. For Device Mode this is reserved. Value Meaning 00b Disables auto LPM. 01b If there is no activity for a certain number of SOFs the controller will send an LPM token, enter in suspend and issue a port change interrupt. 10b Same as above but without issuing an interrupt. 11b Reserved for futures LPM enhancements. The detection of no activity is based on the absence of response from the downstream device. Because of this limitation this feature should not be used if ISO OUT endpoints are being used (as no handshake is expected).
17	RW	0x0	ASUS: Auto Low Power - RW. Default = 0b. This bit field is **valid during Device Mode Only**. In Host Mode it is part of ELPM field. This bit is used to control the auto low power feature. If set, the auto low power feature will be enabled and every time the port enters in suspend state it will also enter in low power state, disabling the transceiver clock. The behavior will be the same as if the PHCD bit was enabled (in fact this bit will be set to '1' as soon as low power mode is enabled). 0 = DISABLE 1 = ENABLE
19:16	RW	0x0	EPLPM: Endpoint for LPM token - RW. Default = 0000b. This bit field is **valid during Host Mode Only**. For Device Mode [19:18] is reserved and 17 is ASUS, while 16 is STL. This sets the endpoint number to which the LPM token will be sent. It will be directly mapped to the ENDP field in the LPM token with the EXT PID.
16	RW	0x0	STL: STALL reply to LPM token - RW. Default = 0b. This bit field is **valid during Device Mode Only**. In Host Mode it is a part of ELPM field. When this bit is set to '1', the Controller will reply always with STALL to all incoming LPM tokens. This bit overrides the LPM NYET bit (NYT). 0 = DISABLE 1 = ENABLE

Bit	R/W	Reset	Description
15:12	RW	0x0	LPMFRM: Auto LPM SOF Threshold - RW. Default = 0000b. This bit field is **valid during Host Mode Only**. For Device Mode this is reserved. This holds the SOF counter threshold. When the number of SOF with no activity in between reaches this threshold and the auto LPM is enabled, an LPM token will be sent and the port will enter in suspend state. The SOF counter for this threshold is incremented each 125 µs, even if the port is not in HS operation.
11:1	RO	X	BA: bmAttributtes - RO. Default = 00000000000b. This holds the bmAttributes field of the LPM sub-token received, after the EXT PID token.
0	RW	0x0	NYT_ASUS: NYET reply to LPM token - RW. Default = 0b. This bit is NYT during Device Mode. Details follow: When this bit is '1', the device controller will NYET all the LPM tokens. When this bit is set to '0', the Controller will ACK all the LPM tokens if the STALL bit (STL) is also set to '0'. This bit is ASUS in Host Mode. Details follow: This bit is used to control the auto low power feature. If set, the auto low power feature will be enabled and every time the port enters in suspend state it will also enter in low power state, disabling the transceiver clock. The behavior will be the same as if the PHCD bit was enabled (in fact this bit will be set to '1' as soon as low power mode is enabled). 0 = DISABLE 1 = ENABLE

23.9.4.27 USB2_CONTROLLER_1_USB2D_OTGSC_0

USB2D On-The-Go (OTG) Status and Control Register

Offset: 0x1f4 | Read/Write: R/W | Reset: 0bx0000000x0000000xxxxxxxxxx000x00

Bit	R/W	Reset	Description
30	RW	0x0	DPIE: Data Pulse Interrupt Enable. Setting this bit enables the Data pulse interrupt. 0 = DISABLE 1 = ENABLE
29	RW	0x0	ONEMSE: 1 millisecond timer Interrupt enable. Setting this bit enables the 1 millisecond timer interrupt. 0 = DISABLE 1 = ENABLE
28	RW	0x0	BSEIE: B Session End Interrupt Enable. Setting this bit enables the B session end interrupt 0 = DISABLE 1 = ENABLE
27	RW	0x0	BSVIE: B Session Valid Interrupt Enable. Setting this bit enables the B session valid interrupt 0 = DISABLE 1 = ENABLE
26	RW	0x0	ASVIE: A Session Valid Interrupt Enable. Setting this bit enables the A session valid interrupt 0 = DISABLE 1 = ENABLE
25	RW	0x0	AVVIE: A VBus Valid Interrupt Enable. Setting this bit enables the A VBus valid interrupt 0 = DISABLE 1 = ENABLE
24	RW	0x0	IDIE: USB ID Interrupt Enable. Setting this bit enables the USB ID interrupt 0 = DISABLE 1 = ENABLE
22	RW	0x0	DPIS: Data Pulse Interrupt Status. This bit is set when data bus pulsing occurs on DP or DM. Data bus pulsing is only detected when USBMODE.CM = Host (11) and PORTSC(0).PortPower = Off (0). Software writes a 1 to clear this bit. 0 = INT_CLEAR 1 = INT_SET
21	RW	0x0	ONEMSS: 1 millisecond timer Interrupt Status: This bit is set once every millisecond. Software writes a 1 to clear it. 0 = INT_CLEAR 1 = INT_SET

Bit	R/W	Reset	Description
20	RW	0x0	BSEIS: B Session End Interrupt Status. This bit is set when VBus has fallen below the B session end threshold. Software writes a 1 to clear this bit. 0 = INT_CLEAR 1 = INT_SET
19	RW	0x0	BSVIS: B Session Valid Interrupt Status. This bit is set when VBus has either risen above or fallen below the B session valid threshold (0.8 VDC). Software writes a 1 to clear this bit. 0 = INT_CLEAR 1 = INT_SET
18	RW	0x0	ASVIS: A Session Valid Interrupt Status. This bit is set when VBus has either risen above or fallen below the A session valid threshold (0.8 VDC). Software writes a one to clear this bit. 0 = INT_CLEAR 1 = INT_SET
17	RW	0x0	AVVIS: A VBus Valid Interrupt Status. This bit is set when VBus has either risen above or fallen below the VBus valid threshold (4.4 VDC) on an A device. Software writes a 1 to clear this bit. 0 = INT_CLEAR 1 = INT_SET
16	RW	0x0	IDIS: USB ID Interrupt Status. This bit is set when a change on the ID input has been detected. Software writes a 1 to clear this bit. 0 = INT_CLEAR 1 = INT_SET
14	RO	X	DPS: Data Bus Pulsing Status. A 1 indicates data bus pulsing is being detected on the port. 0 = STS_CLEAR 1 = STS_SET
13	RO	X	ONEMST: 1 millisecond timer toggle. This bit toggles once per millisecond 0 = STS_CLEAR 1 = STS_SET
12	RO	X	BSE: B session End. Indicates VBus is below the B session end threshold 0 = STS_CLEAR 1 = STS_SET
11	RO	X	BSV: B Session Valid. Indicates VBus is above the B session valid threshold 0 = STS_CLEAR 1 = STS_SET
10	RO	X	ASV: A Session Valid. Indicates VBus is above the A session valid threshold 0 = STS_CLEAR 1 = STS_SET
9	RO	X	AVV: A VBus Valid. Indicates VBus is above the A VBus valid threshold 0 = STS_CLEAR 1 = STS_SET
8	RO	X	ID: USB ID: 0 = A-device 1 = B-device 0 = A_DEV 1 = B_DEV
5	RW	0x0	IDPU: USB ID Pullup 0 = CLEAR 1 = SET
4	RW	0x0	DP: Data Pulsing. Setting this bit causes the pull-up on DP to be asserted for data pulsing during SRP. 0 = NO_DATA_PULSE 1 = DATA_PULSE
3	RW	0x0	OT: OTG Termination. This bit must be set when the OTG device is in device mode, this controls the pulldown on DM. 0 = NO_OTG_TERM 1 = OTG_TERM
1	RW	0x0	VC: VBUS Charge. Setting this bit causes the VBus line to be charged. This is used for VBus pulsing during SRP. 0 = NO_VBUS_CHRG 1 = VBUS_CHRG

Bit	R/W	Reset	Description
0	RW	0x0	VD: VBUS_Discharge. Read/write. Setting this bit causes Vbus to discharge through a resistor. 0 = NO_VBUS_DISCHRG 1 = VBUS_DISCHRG

23.9.4.28 USB2_CONTROLLER_1_USB2D_USBMODE_0

USB2D USB Device Mode Register

Offset: 0x1f8 | Read/Write: R/W | Reset: 0b00000000000000000xxxxxxxxx0xxxxx

Bit	R/W	Reset	Description
31:16	RW	0x0	ALPDD: Auto Low Power While Disconnect Delay. Used when the ALPD field of the HOSTPCx register is set. Defines the delay between disconnect detection and entering in low power mode. The delay is <this register value>*64*100/3 in milliseconds. The maximum value is 65535*64*100/3 = 139,808 ms. The minimum value is 0. Only used in Host mode.
15	RW	0x0	SRT: Shorten USB Reset Time. Software should never set this to 1.
5	RW	0x0	VBPS: VBUS Power Select This can be used by logic that selects between an on-chip Vbus power source (charge pump) and an off-chip source in systems when both are available. Only to be used in Host Mode. Software should not use this.
4	RO	X	SDIS: Stream disable: 1 Streaming is disabled - helpful to avoid overruns/underruns when system load is too high. 0 = STREAM_ENABLE 1 = STREAM_DISABLE
3	RO	X	SLOM: Setup Lockout Mode: In device mode, this bit controls the behavior of the setup lockout mechanism. 0 - Setup lockout is ON (default) 1 Setup lockout is OFF. Firmware requires the use of setup tripwire semaphore in USB2D_USBCMD register. 0 = LOCKOUT_ON 1 = LOCKOUT_OFF
2	RO	X	ES: Endian Select: Note: For this implementation, this should be always set to 0 (little endian). 0 = LITTLE_ENDIAN 1 = RESERVED
1:0	RO	X	CM: Controller Mode: The controller mode will default to an idle state and will need to be initialized to the desired operating mode after reset. This register can only be written once after reset. If it is necessary to switch modes, software must reset the controller by writing to the RESET bit in the USBCMD register before reprogramming this register. 00 = Idle [Default]. 01 = Reserved. 10 = Device Controller. 11 = Host Controller. 0 = IDLE 1 = RESERVED 2 = DEVICE_MODE 3 = HOST_MODE

23.9.4.29 USB2_CONTROLLER_1_USB2D_ENDPTNAK_0

USB2D Endpoint NAK register

Offset: 0x200 | Read/Write: R/W | Reset: 0b00000000000000000000000000000000

Bit	Reset	Description
31:16	0x0	EPTN: TX Endpoint NAK R/WC. Each TX endpoint has 1 bit in this field. The bit is set when the device sends a NAK handshake on a received IN token for the corresponding endpoint. 0 = CLEAR 1 = SET
15:0	0x0	EPRN: RX Endpoint NAK R/WC. Each RX endpoint has 1 bit in this field. The bit is set when the device sends a NAK handshake on a received OUT or PING token for the corresponding endpoint. 0 = CLEAR 1 = SET

23.9.4.30 USB2_CONTROLLER_1_USB2D_ENDPTNAK_ENABLE_0

USB2D Endpoint NAK Enable Register

Offset: 0x204 | Read/Write: R/W | Reset: 0b00000000000000000000000000000000

Bit	Reset	Description
31:16	0x0	EPTNE: TX Endpoint NAK Enable R/W. Each bit is an enable bit for the corresponding TX Endpoint NAK bit. If this bit is set and the corresponding TX Endpoint NAK bit is set, the NAK Interrupt bit is set. 0 = DISABLE 1 = ENABLE
15:0	0x0	EPRNE: RX Endpoint NAK Enable R/W. Each bit is an enable bit for the corresponding RX Endpoint NAK bit. If this bit is set and the corresponding RX Endpoint NAK bit is set, the NAK Interrupt bit is set. 0 = DISABLE 1 = ENABLE

Bit	Reset	Description
16	0x0	FETB0: Writing a one to this bit causes the associated endpoint to clear any primed buffers. If a packet is in progress for the associated endpoint that transfer will continue until completion. Hardware clears this register after the endpoint flush operation is successful. This is only used in device mode. 0 = DONT_FLUSH 1 = FLUSH
15	0x0	FERB15: Flush Endpoint Receive Buffer: Writing a one to this bit causes the associated endpoint to clear any primed buffers. If a packet is in progress for the associated endpoint that transfer will continue until completion. Hardware clears this register after the endpoint flush operation is successful. This is only used in device mode. 0 = DONT_FLUSH 1 = FLUSH
14	0x0	FERB14: Flush Endpoint Receive Buffer: Writing a one to this bit causes the associated endpoint to clear any primed buffers. If a packet is in progress for the associated endpoint that transfer will continue until completion. Hardware clears this register after the endpoint flush operation is successful. This is only used in device mode. 0 = DONT_FLUSH 1 = FLUSH
13	0x0	FERB13: Flush Endpoint Receive Buffer: Writing a one to this bit causes the associated endpoint to clear any primed buffers. If a packet is in progress for the associated endpoint that transfer will continue until completion. Hardware clears this register after the endpoint flush operation is successful. This is only used in device mode. 0 = DONT_FLUSH 1 = FLUSH
12	0x0	FERB12: Flush Endpoint Receive Buffer: Writing a one to this bit causes the associated endpoint to clear any primed buffers. If a packet is in progress for the associated endpoint that transfer will continue until completion. Hardware clears this register after the endpoint flush operation is successful. This is only used in device mode. 0 = DONT_FLUSH 1 = FLUSH
11	0x0	FERB11: Flush Endpoint Receive Buffer: Writing a one to this bit causes the associated endpoint to clear any primed buffers. If a packet is in progress for the associated endpoint that transfer will continue until completion. Hardware clears this register after the endpoint flush operation is successful. This is only used in device mode. 0 = DONT_FLUSH 1 = FLUSH
10	0x0	FERB10: Flush Endpoint Receive Buffer: Writing a one to this bit causes the associated endpoint to clear any primed buffers. If a packet is in progress for the associated endpoint that transfer will continue until completion. Hardware clears this register after the endpoint flush operation is successful. This is only used in device mode. 0 = DONT_FLUSH 1 = FLUSH
9	0x0	FERB9: Flush Endpoint Receive Buffer: Writing a one to this bit causes the associated endpoint to clear any primed buffers. If a packet is in progress for the associated endpoint that transfer will continue until completion. Hardware clears this register after the endpoint flush operation is successful. This is only used in device mode. 0 = DONT_FLUSH 1 = FLUSH
8	0x0	FERB8: Flush Endpoint Receive Buffer: Writing a one to this bit causes the associated endpoint to clear any primed buffers. If a packet is in progress for the associated endpoint that transfer will continue until completion. Hardware clears this register after the endpoint flush operation is successful. This is only used in device mode. 0 = DONT_FLUSH 1 = FLUSH
7	0x0	FERB7: Flush Endpoint Receive Buffer: Writing a one to this bit causes the associated endpoint to clear any primed buffers. If a packet is in progress for the associated endpoint that transfer will continue until completion. Hardware clears this register after the endpoint flush operation is successful. This is only used in device mode. 0 = DONT_FLUSH 1 = FLUSH

Bit	Reset	Description
6	0x0	FERB6: Flush Endpoint Receive Buffer: Writing a one to this bit causes the associated endpoint to clear any primed buffers. If a packet is in progress for the associated endpoint that transfer will continue until completion. Hardware clears this register after the endpoint flush operation is successful. This is only used in device mode. 0 = DONT_FLUSH 1 = FLUSH
5	0x0	FERB5: Flush Endpoint Receive Buffer: Writing a one to this bit causes the associated endpoint to clear any primed buffers. If a packet is in progress for the associated endpoint that transfer will continue until completion. Hardware clears this register after the endpoint flush operation is successful. This is only used in device mode. 0 = DONT_FLUSH 1 = FLUSH
4	0x0	FERB4: Flush Endpoint Receive Buffer: Writing a one to this bit causes the associated endpoint to clear any primed buffers. If a packet is in progress for the associated endpoint that transfer will continue until completion. Hardware clears this register after the endpoint flush operation is successful. This is only used in device mode. 0 = DONT_FLUSH 1 = FLUSH
3	0x0	FERB3: Flush Endpoint Receive Buffer: Writing a one to this bit causes the associated endpoint to clear any primed buffers. If a packet is in progress for the associated endpoint that transfer will continue until completion. Hardware clears this register after the endpoint flush operation is successful. This is only used in device mode. 0 = DONT_FLUSH 1 = FLUSH
2	0x0	FERB2: Flush Endpoint Receive Buffer: Writing a one to this bit causes the associated endpoint to clear any primed buffers. If a packet is in progress for the associated endpoint that transfer will continue until completion. Hardware clears this register after the endpoint flush operation is successful. This is only used in device mode. 0 = DONT_FLUSH 1 = FLUSH
1	0x0	FERB1: Flush Endpoint Receive Buffer: Writing a one to this bit causes the associated endpoint to clear any primed buffers. If a packet is in progress for the associated endpoint that transfer will continue until completion. Hardware clears this register after the endpoint flush operation is successful. This is only used in device mode. 0 = DONT_FLUSH 1 = FLUSH
0	0x0	FERB0: Flush Endpoint Receive Buffer: Writing a one to this bit causes the associated endpoint to clear any primed buffers. If a packet is in progress for the associated endpoint that transfer will continue until completion. Hardware clears this register after the endpoint flush operation is successful. This is only used in device mode. 0 = DONT_FLUSH 1 = FLUSH

23.9.4.34 USB2_CONTROLLER_1_USB2D_ENDPTSTATUS_0

USB2D Endpoint Status Register

Offset: 0x214 | Read/Write: RO | Reset: 0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx

Bit	Reset	Description
31	X	ETBR15: Endpoint Transmit Buffer Ready: One bit for each endpoint indicates status of the respective endpoint buffer. This bit is set to a one by the hardware as a response to receiving a command from a corresponding bit in the ENDPTPRIME register. There will always be a delay between setting a bit in the ENDPTPRIME register and endpoint indicating ready. This delay time varies based upon the current USB traffic and the number of bits set in the ENDPTPRIME register. Buffer ready is cleared by USB reset, by the USB DMA system, or through the ENDPTFLUSH register. This is only used in device mode. 0 = NOT_READY 1 = READY

Bit	Reset	Description
30	X	ETBR14: Endpoint Transmit Buffer Ready: One bit for each endpoint indicates status of the respective endpoint buffer. This bit is set to a one by the hardware as a response to receiving a command from a corresponding bit in the ENDPTPRIME register. There will always be a delay between setting a bit in the ENDPTPRIME register and endpoint indicating ready. This delay time varies based upon the current USB traffic and the number of bits set in the ENDPTPRIME register. Buffer ready is cleared by USB reset, by the USB DMA system, or through the ENDPTFLUSH register. This is only used in device mode. 0 = NOT_READY 1 = READY
29	X	ETBR13: Endpoint Transmit Buffer Ready: One bit for each endpoint indicates status of the respective endpoint buffer. This bit is set to a one by the hardware as a response to receiving a command from a corresponding bit in the ENDPTPRIME register. There will always be a delay between setting a bit in the ENDPTPRIME register and endpoint indicating ready. This delay time varies based upon the current USB traffic and the number of bits set in the ENDPTPRIME register. Buffer ready is cleared by USB reset, by the USB DMA system, or through the ENDPTFLUSH register. This is only used in device mode. 0 = NOT_READY 1 = READY
28	X	ETBR12: Endpoint Transmit Buffer Ready: One bit for each endpoint indicates status of the respective endpoint buffer. This bit is set to a one by the hardware as a response to receiving a command from a corresponding bit in the ENDPTPRIME register. There will always be a delay between setting a bit in the ENDPTPRIME register and endpoint indicating ready. This delay time varies based upon the current USB traffic and the number of bits set in the ENDPTPRIME register. Buffer ready is cleared by USB reset, by the USB DMA system, or through the ENDPTFLUSH register. This is only used in device mode. 0 = NOT_READY 1 = READY
27	X	ETBR11: Endpoint Transmit Buffer Ready: One bit for each endpoint indicates status of the respective endpoint buffer. This bit is set to a one by the hardware as a response to receiving a command from a corresponding bit in the ENDPTPRIME register. There will always be a delay between setting a bit in the ENDPTPRIME register and endpoint indicating ready. This delay time varies based upon the current USB traffic and the number of bits set in the ENDPTPRIME register. Buffer ready is cleared by USB reset, by the USB DMA system, or through the ENDPTFLUSH register. This is only used in device mode. 0 = NOT_READY 1 = READY
26	X	ETBR10: Endpoint Transmit Buffer Ready: One bit for each endpoint indicates status of the respective endpoint buffer. This bit is set to a one by the hardware as a response to receiving a command from a corresponding bit in the ENDPTPRIME register. There will always be a delay between setting a bit in the ENDPTPRIME register and endpoint indicating ready. This delay time varies based upon the current USB traffic and the number of bits set in the ENDPTPRIME register. 23.9.4.35 USB2_CONTROLLER_1_USB2D_ENDPTCOMPLETE_0

USB2D Endpoint Complete Register

Offset: 0x218 | Read/Write: R/W | Reset: 0b00000000000000000000000000000000

Bit	Reset	Description
31	0x0	ETCE15: Endpoint Transmit Complete Event: Each bit indicates a transmit event (IN/INTERRUPT) occurred and software should read the corresponding endpoint queue to determine the endpoint status. If the corresponding IOC bit is set in the Transfer Descriptor, then this bit will be set simultaneously with the USBINT. Writing a one clears the corresponding bit in this register. This is only used in device mode. 0 = NOT_COMPLETE 1 = COMPLETE
30	0x0	ETCE14: Endpoint Transmit Complete Event: Each bit indicates a transmit event (IN/INTERRUPT) occurred and software should read the corresponding endpoint queue to determine the endpoint status. If the corresponding IOC bit is set in the Transfer Descriptor, then this bit will be set simultaneously with the USBINT. Writing a one clears the corresponding bit in this register. This is only used in device mode. 0 = NOT_COMPLETE 1 = COMPLETE
29	0x0	ETCE13: Endpoint Transmit Complete Event: Each bit indicates a transmit event (IN/INTERRUPT) occurred and software should read the corresponding endpoint queue to determine the endpoint status. If the corresponding IOC bit is set in the Transfer Descriptor, then this bit will be set simultaneously with the USBINT. Writing a one clears the corresponding bit in this register. This is only used in device mode. 0 = NOT_COMPLETE 1 = COMPLETE
28	0x0	ETCE12: Endpoint Transmit Complete Event: Each bit indicates a transmit event (IN/INTERRUPT) occurred and software should read the corresponding endpoint queue to determine the endpoint status. If the corresponding IOC bit is set in the Transfer Descriptor, then this bit will be set simultaneously with the USBINT. Writing a one clears the corresponding bit in this register. This is only used in device mode. 0 = NOT_COMPLETE 1 = COMPLETE

Bit	Reset	Description
27	0x0	ETCE11: Endpoint Transmit Complete Event: Each bit indicates a transmit event (IN/INTERRUPT) occurred and software should read the corresponding endpoint queue to determine the endpoint status. If the corresponding IOC bit is set in the Transfer Descriptor, then this bit will be set simultaneously with the USBINT. Writing a one clears the corresponding bit in this register. This is only used in device mode. 0 = NOT_COMPLETE 1 = COMPLETE
26	0x0	ETCE10: Endpoint Transmit Complete Event: Each bit indicates a transmit event (IN/INTERRUPT) occurred and software should read the corresponding endpoint queue to determine the endpoint status. If the corresponding IOC bit is set in the Transfer Descriptor, then this bit will be set simultaneously with the USBINT. Writing a one clears the corresponding bit in this register. This is only used in device mode. 0 = NOT_COMPLETE 1 = COMPLETE
25	0x0	ETCE9: Endpoint Transmit Complete Event: Each bit indicates a transmit event (IN/INTERRUPT) occurred and software should read the corresponding endpoint queue to determine the endpoint status. If the corresponding IOC bit is set in the Transfer Descriptor, then this bit will be set simultaneously with the USBINT. Writing a one clears the corresponding bit in this register. This is only used in device mode. 0 = NOT_COMPLETE 1 = COMPLETE
24	0x0	ETCE8: Endpoint Transmit Complete Event: Each bit indicates a transmit event (IN/INTERRUPT) occurred and software should read the corresponding endpoint queue to determine the endpoint status. If the corresponding IOC bit is set in the Transfer Descriptor, then this bit will be set simultaneously with the USBINT. Writing a one clears the corresponding bit in this register. This is only used in device mode. 0 = NOT_COMPLETE 1 = COMPLETE
23	0x0	ETCE7: Endpoint Transmit Complete Event: Each bit indicates a transmit event (IN/INTERRUPT) occurred and software should read the corresponding endpoint queue to determine the endpoint status. If the corresponding IOC bit is set in the Transfer Descriptor, then this bit will be set simultaneously with the USBINT. Writing a one clears the corresponding bit in this register. This is only used in device mode. 0 = NOT_COMPLETE 1 = COMPLETE
22	0x0	ETCE6: Endpoint Transmit Complete Event: Each bit indicates a transmit event (IN/INTERRUPT) occurred and software should read the corresponding endpoint queue to determine the endpoint status. 23.9.5 USB2 Controller Interface Registers

These are used to generate the actual RTL registers for USB2 controller interface.

ULPIS2S resets to be used as follows:

- Assert ULPIS2S_SLV0_CLAMP_XMIT to ensure that the signals between SLV0 and the line simulator are clean.
- Assert ULPIS2S_SLV0_RESET
- Do a functional asynchronous reset of the ChipIdea controller
- Deassert ULPIS2S_SLV0_RESET
- Deassert ULPIS2S_SLV0_CLAMP_XMIT

NULPI_SLV1_RESET should be used in the same way if there is some explicit way to reset the external ULPI controller (which is not necessarily the case). There is usually no reason to assert ULPIS2S_LINE_RESET.

23.9.5.1 USB2_IF_USB_SUSP_CTRL_0

This register controls the suspend and resume behavior of the USB controller/PHY.

USB Suspend Control Register

Offset: 0x400 | Read/Write: R/W | Reset: 0bxxxxx00111110000x1001000xx000000

Bit	R/W	Reset	Description
26	RW	0x0	FAST_WAKEUP_RESP: Enable Fast Response from UTMIP PHY for a Remote Wakeup request from device. This is used only for cases where wakeup response needs to be within 1ms of spec. Used for Host mode ONLY. 0 = DISABLE 1 = ENABLE
25	RW	0x0	UTMIP_SUSPL1_SET: Enable SuspendL1 for UTMIP PHY Enabling this will only cutoff clocks to the UTMIP logic. The USB PLLs, PllU and UTMIP PLL will still be running. 0 = DISABLE 1 = ENABLE
24	RW	0x1	ULPI_PADS_CLKEN_RESET: Async reset for the synchronizers that are used in the external and loopback ULPI 60 MHz clock. 0 = DISABLE 1 = ENABLE
23	RW	0x1	ULPI_PADS_RESET: Async reset for trimmers and line state logic that is implemented in the pad macros. 0 = DISABLE 1 = ENABLE
22	RW	0x1	ULPIS2S_LINE_RESET: Async reset of the line simulator logic that sits between the two virtual PHYs (active high). The ULPI PHY registers should be programmed while ULPI is in reset. 0 = DISABLE 1 = ENABLE
21	RW	0x1	ULPIS2S_SLV1_RESET: Async reset of the SLV1 ULPI logic. This corresponds to resetting the virtual PHY that is connected to the internal ULPI controller (active high). The ULPI PHY registers should be programmed while ULPI is in reset. 0 = DISABLE 1 = ENABLE
20	RW	0x1	ULPIS2S_SLV0_RESET: Async reset of the SLV0 ULPI logic. This corresponds to resetting the virtual PHY that is connected to the external ULPI controller. (active high). The ULPI PHY registers should be programmed while ULPI is in reset. 0 = DISABLE 1 = ENABLE

Bit	R/W	Reset	Description
19	RW	0x0	UHSIC_PHY_ENB: Enable UHSIC PHY mode. Set this to 1 if using UHSIC PHY. Otherwise set this to 0. 0 = DISABLE 1 = ENABLE
18:16	RW	0x0	USB_WAKEUP_DEBOUNCE_COUNT: USB PHY wakeup debounce counter USB will debounce any wakeup event by the number of clocks programmed in this counter. A value of 0 results in no debounce.
14	RW	0x1	UHSIC_RESET: Reset going to UHSIC PHY (active high). This should be set to 1 whenever programming the UHSIC config registers. It should be cleared to 0 after the programming of UHSIC config registers is done. UHSIC config registers should be programmed only once before doing any transactions on UHSIC. The UHSIC PHY registers should be programmed while UHSIC is in reset. 0 = DISABLE 1 = ENABLE
13	RW	0x0	ULPI_PHY_ENB: Enable ULPI PHY mode. Set this to 1 if using null or link ULPI PHY. Otherwise set this to 0. 0 = DISABLE 1 = ENABLE
12	RW	0x0	UTMIP_PHY_ENB: Enable UTMIP PHY mode Set this to 1 if using UTMIP PHY. Otherwise set this to 0. 0 = DISABLE 1 = ENABLE
11	RW	0x1	UTMIP_RESET: Reset going to UTMIP PHY (active high). This should be set to 1 whenever programming the UTMIP config registers. It should be cleared to 0 after the programming of UTMIP config registers is done. UTMIP config registers should be programmed only once before doing any transactions on UTMIP. The UTMIP PHY registers should be programmed while UTMIP is in reset. 0 = DISABLE 1 = ENABLE
10	RW	0x0	USB_SUSP_POL: Polarity of the suspend signal going to UHSIC PHY. 0 = Active low (default) 1 = Active high This should not be changed by software. 0 = ACTIVE_LOW 1 = ACTIVE_HIGH
9	RW	0x0	USB_PHY_CLK_VALID_INT_ENB: USB PHY clock valid interrupt enable. If this bit is enabled, interrupt is generated whenever USB clocks are resumed from a suspend. 0 = DISABLE 1 = ENABLE
8	RO	0x0	USB_PHY_CLK_VALID_INT_STS: USB PHY clock valid interrupt status. This bit is set whenever USB PHY clock is woken up from suspend. Software must write a 1 to clear this bit. 0 = UNSET 1 = SET
7	RO	X	USB_PHY_CLK_VALID: USB PHY clock valid status. This bit indicates whether the USB PHY is generating a valid clock to the USB controller. If USB PHY clock is running, this bit is set to 1, else it is set to 0. 0 = UNSET 1 = SET
6	RO	X	USB_CLKEN: USB AHB clock enable status. Indicates whether the AHB clock to the USB controller is enabled or not. If AHB clock to USB controller is enabled, this bit is set to 1, else it is set to 0. NOTE: even when this is set to 0, all essential blocks that are required to resume USB clocks from suspend will be active and their AHB clock will not be suspended. 0 = UNSET 1 = SET
5	RW	0x0	USB_SUSP_CLR: Suspend Clear Software must write a 1 to this bit to bring the PHY out of suspend mode. This is used when the software stops the PHY clock during suspend and then wants to initiate a resume. Software should also write 0 to clear it. NOTE: It is required that software generate a positive pulse on this bit to guarantee proper operation. 0 = UNSET 1 = SET

Bit	R/W	Reset	Description
4	RW	0x0	USB_WAKE_ON_DISCON_EN_DEV: Wake on Disconnect Enable (device mode). When enabled (1), USB device will wake up from suspend on a disconnect event. This is only valid when USB controller is in device mode, it is not applicable when USB controller is in host mode. 0 = DISABLE 1 = ENABLE
3	RW	0x0	USB_WAKE_ON_CNNT_EN_DEV: Wake on Connect Enable (device mode). When enabled (1), USB device will wake up from suspend on a connect event. This is only valid when USB controller is in device mode, it is not applicable when USB controller is in host mode. 0 = DISABLE 1 = ENABLE
2	RW	0x0	USB_WAKE_ON_RESUME_EN: Wake on resume enable. If this bit is enabled, the USB will wake up from suspend whenever a resume event is detected on USB. This is valid for both USB device and USB host modes. 0 = DISABLE 1 = ENABLE
1	RW	0x0	USB_WAKEUP_INT_ENB: USB wakeup interrupt enable. If this bit is enabled, interrupt is generated whenever USB wakeup event is generated. 0 = DISABLE 1 = ENABLE
0	RO	0x0	USB_WAKEUP_INT_STS: USB wakeup interrupt status. This bit is set whenever the USB wakes up from suspend (a wakeup event is generated). Software must write a 1 to clear this bit. Note that during the wakeup sequence, PHY clocks will be resumed from suspend. Software can check when the PHY clocks are resumed by reading the bit USB_PHY_CLK_VALID. There is also a separate interrupt generated when PHY clock is resumed if USB_PHY_CLK_VALID_INT_EN is set. During the wakeup sequence, first USB_WAKEUP_INT_STS will be set, and it will take some time for the PHY clock to resume, which can be detected by checking USB_PHY_CLK_VALID. 0 = UNSET 1 = SET

23.9.5.2 USB2_IF_USB_ULPIS2S_CTRL_0

This register is used to set up parameters for ULPI null PHY mode.

Note: Current ULPI configuration registers use settings that support NV software drivers and should NOT be modified. If designing custom drivers, consult your NV representative prior to modifying these registers

ULPI NULL PHY Control Register

Offset: 0x418 | Read/Write: R/W | Reset: 0bxxxxxxxx0000xx0000000000xxxx0000

Bit	Reset	Description
23:20	0x0	ULPIS2S_CLAMP_LINE_DRIVE: The line drive value that should be sent into the line simulator during transmit clamping. The suggested value is 0x1: tri-state.
17	0x0	ULPIS2S_SLV1_CLAMP_XMIT: When set to 1, the outputs of the SLV1 transmit state machine are clamped to 0. This bit should be set before the SLV0 async reset is asserted to prevent meta-stability issues in the line simulator.
16	0x0	ULPIS2S_SLV0_CLAMP_XMIT: When set to 1, the outputs of the SLV0 transmit state machine are clamped to 0. This bit should be set before the SLV0 async reset is asserted to prevent meta-stability issues in the line simulator.
15	0x0	ULPIS2S_DISABLE_STP_PU: When set to 1 and in ULPIS2S mode, the pullup on the STP pin will NOT be active, even if the remote LINK asks to do so. In this case, an external pullup resistor would be required to ensure valid levels when the remote link is not powered.
14	0x0	ULPIS2S_SUPPORT_HS_KEEP_ALIVE: When enabled, the PHY will support HS KeepAlive packets. In that case, this would be the only thing that is supported in Opmode3. All other Opmode3 generate packets are not supported under any circumstances. 0 = DISABLE 1 = ENABLE

Bit	Reset	Description
13	0x0	ULPIS2S_DISCON_DONT_CHECK_SE0: When enabled, the disconnect detection logic will only check that that the other side is 'driving' tri-state. It will not check whether or not the local side is driving SE0. 0 = DISABLE 1 = ENABLE
12	0x0	ULPIS2S_FORCE_ULPI_CLK_OUT: When enabled and ULPIS2S_ENA is ENABLED, the external ULPI_CLOCK pad will always carry the internal 60MHz clock, even if the interface is in shutdown mode. 0 = DISABLE 1 = ENABLE
11:8	0x0	ULPIS2S_SPARE: Reserved bits.
3	0x0	ULPIS2S_PLLU_MASTER_BLASTER60: When enabled, the PLLU 60MHz clock will be forced on. 0 = DISABLE 1 = ENABLE
2	0x0	ULPIS2S_SUPPORT_DISCONNECT: When disabled, the PHY will never detect a Disconnect. 0 = DISABLE 1 = ENABLE
1	0x0	ULPIS2S_SLV1_FORCE_DEVICE: When disabled, the slave port that is connected to the pins can be programmed to be host or a device depending on the value of the DpPulldown and DmPulldown bits in the OTG_CTRL ULPI register. When enabled, the values of those bits in the OTG_CTRL register is ignored and the port will always behave like a device. 0 = DISABLE 1 = ENABLE
0	0x0	ULPIS2S_ENA: When enabled, the ULPI link interface coming out of the USB2 controller enters a NULL PHY with two slaves. As a result the external pins will have a slave ULPI interface. When disabled, the ULPI link interface coming out of the USB2 controller go straight to the pins. 0 = DISABLE 1 = ENABLE

23.9.5.3 USB2_IF_USB_ULPIS2S_SLV1_ID_0

This register controls the product and vendor ID fields for ULPI null PHY presented to external ULPI master.

Note: Current ULPI configuration registers use settings that support NV software drivers and should NOT be modified. If designing custom drivers, consult your NV representative prior to modifying these registers

Offset: 0x41c | Read/Write: R/W | Reset: 0b00000000000000000000000000000000

Bit	Reset	Description
31:16	0x0	ULPIS2S_SLV1_VENDOR_ID: PHY vendor_id as seen by the external ULPI master
15:0	0x0	ULPIS2S_SLV1_PRODUCT_ID: PHY product_id as seen by the external ULPI master

23.9.5.4 USB2_IF_USB_INTER_PKT_DELAY_CTRL_0

Inter Packet Delay Control

This register controls the interpacket delay between two consecutive transmit packets in HS mode. This only applies to host mode as device never transmits two packets in a row.

Offset: 0x420 | Read/Write: R/W | Reset: 0bxxxxxxxxxxxxxxxxxxxxxxxxxxx0010010

Bit	Reset	Description
6:0	0x12	IP_DELAY_TX2TX_HS: HS Tx to Tx inter-packet delay. This is valid only for UHSIC PHY. Software should not change this.

23.9.5.5 USB2_IF_USB_RSM_DLY_0

USB Controller Resume Signalling Delay

Offset: 0x490 | Read/Write: R/W | Reset: 0bxxxxxxxxxxxxxxxx0110100101111000

Bit	Reset	Description
15:0	0x6978	TIME_TO_RESUME: Send the resume back in number of 60 MHz cycles. Default gives 900 µs delay. Only applicable in host mode.

23.9.5.6 USB2_IF_SPARE_0

For ICUSB PADCTLS

Spare Register

Offset: 0x498 | Read/Write: R/W | Reset: 0b11111111111111110000000000000000

Bit	Reset	Description
31:16	0xffff	SPARE_HI: Spare register bits, defaulted to 1. SPARE_HI[0] - usb_port_reset_fix_en. Enable port-reset fix SPARE_HI[1] - hsic_conn_det_feature_enable. enable HSIC connect detection
15:0	0x0	SPARE_LO: Spare register bits, defaulted to 0. SPARE_LO[4] - usb_hs_rsm_eop_fix_en. Enable HS_RESUME EOP fix SPARE_LO[5] - usb_port_suspend_fix_en

23.9.5.7 USB2_IF_ULPI_DIR_OVERRIDE_0

ULPI Override

Offset: 0x49c | Read/Write: R/W | Reset: 0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx1

Bit	Reset	Description
0	0x1	ULPI_DIR_OVERRIDE: By default, this bit is set. This will override ulpi_dir; i.e., when this bit is set, ulpi_dir is always asserted. Software needs to explicitly clear this bit, once slv1 Lp0 context is restored.

23.9.5.8 USB2_IF_USB2_NEW_CONTROL_0

USB Coherency and Memory Alignment Controls

Offset: 0x4c0 | Read/Write: R/W | Reset: 0bxxxxxxxxxxxxxxxx00001111xxxxxx00

Bit	Reset	Description
15:8	0xf	REQUEST_EXPIRY_COUNTER: Time to wait for coalescing the request.
1	0x0	MEM_ALIGNMENT_MUX_EN: Mux to select between Tegra 3 and Tegra 4 code 0 = DISABLE 1 = ENABLE
0	0x0	COHERENCY_EN: Enable fence mechanism. 0 = DISABLE 1 = ENABLE

23.9.6 UHSIC Configuration Registers

Note: Current HSIC configuration registers use settings that support NV software drivers and should NOT be modified. If designing custom drivers, consult your NV representative prior to modifying these registers

23.9.6.1 USB2_UHSIC_PLL_CFG0_0

UHSIC PHY PLL Configuration Register 0

This register is used to configure the PHY PLL contained in the UHSIC module.

Offset: 0xc00 | Read/Write: R/W | Reset: 0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx0

Bit	Reset	Description
0	0x0	UHSIC_PLL_SPARE: Reserved

23.9.6.2 USB2_UHSIC_PLL_CFG1_0

UHSIC PLL and PLLU Configuration Register 1

PLL CONFIGURATION and PARAMETERS

In normal operation, the following clock generators are in play for USB:

Crystal clock -> enters PLLU to generate 12 MHz clock -> enters USB_PHY PLL to generate 480/60 MHz clock

The following parameters control the bring-up of the PLLs:

Coming out of reset or suspend

PllUOnState: start pllu_enable_count and pll_lock_count

Wait ~1 µs to actually enable the PLLU (pllu_enable_count == ClkXtal * PLLU_ENABLE_DLY_COUNT * 8)

Wait ~1ms until PLLU is actually stable (pll_lock_count == ClkXtal * PLLU_STABLE_COUNT * 256) => USB_PHY PLL_ENABLE

Number for a 19.2MHz crystal clock

- PLLU_ENABLE_DLY_COUNT[4:0] = 1 * 19.2 / 8 = 2.4 = 3 = 0x03
- PLLU_STABLE_COUNT[11:0] = 1000 * 19.2 / 256 = 75 = 0x4b (Note: currently defaults to 0x600)
- XTAL_FREQ_COUNT[11:0] = 2500 * 19.2 / 256 = 187 = 0xbb

This register is used to configure the PHY PLL contained in the UHSIC module as well as the PLLU power up and down.

Offset: 0xc04 | Read/Write: R/W | Reset: 0bxxxxxxxxxxxxxx0001100000011000000

Bit	Reset	Description
18:14	0x3	UHSIC_PLLU_ENABLE_DLY_COUNT: 1 µs / (1/19.2MHz) = 19 / 8 = 2.36 = 3
13	0x0	UHSIC_FORCE_PLLU_POWERUP
12	0x0	UHSIC_FORCE_PLLU_POWERDOWN
11:0	0xc0	UHSIC_XTAL_FREQ_COUNT: 2.5ms / (1/19.2MHz) = 48000 / 256 = 187 = 0xBB

23.9.6.3 USB2_UHSIC_HSRX_CFG0_0

UHSIC High Speed Receive Config 0

Offset: 0xc08 | Read/Write: R/W | Reset: 0bxxxxxxxxxxxxxx0010100111000111000

Bit	Reset	Description
18	0x0	UHSIC_NO_STRIPPING: Do not strip incoming data
17:13	0xa	UHSIC_IDLE_WAIT: Number of idle cycles to declare IDLE.
12:8	0xe	UHSIC_ELASTIC_OVERRUN_LIMIT
7	0x0	UHSIC_ELASTIC_OVERRUN_DISABLE: Do not declare overrun errors until overflow of FIFO
6:2	0xe	UHSIC_ELASTIC_UNDERRUN_LIMIT
1	0x0	UHSIC_ELASTIC_UNDERRUN_DISABLE: Do not declare underrun errors
0	0x0	UHSIC_PASS_FEEDBACK: Pass through the feedback, do not block it.

23.9.6.4 USB2_UHSIC_HSRX_CFG1_0

UHSIC High speed receive config 1

Offset: 0xc0c | Read/Write: R/W | Reset: 0bxxxxxxxx10001000001010010010011

Bit	Reset	Description
23:20	0x8	UHSIC_TX_BLOCK_CNT: Controls how long after the end of transmission the receive path is blocked
19:14	0x20	UHSIC_RX_STROBE_DLY_TRIMMER: Number of delays cells between UH_RX_STROBE and RxStrobeClk in zero cycle path
13:9	0x14	UHSIC_INPUT_FIFO_DEPTH: Depth of the 2-bit wide input FIFO. Maximum depth is 20. Can be tuned
8	0x1	UHSIC_LINE_STATE_RESUME_FAKE_SE0: When enabled, send an SE0 for 2 LS symbols at the end of ResumeK
7	0x0	UHSIC_LINE_STATE_BYPASS: Bypass Line State reclocking logic
6	0x0	UHSIC_EARLY_LINE_STATE_FILTER: Assumes line state filtering table is inclusive, not exclusive
5:1	0x9	UHSIC_HS_SYNC_START_DLY: How long to wait before start of sync launches RxActive
0	0x1	UHSIC_HS_ALLOW_KEEP_ALIVE: Allow Keep Alive packets

23.9.6.5 USB2_UHSIC_TX_CFG0_0

UHSIC Transmit Config Signals

Offset: 0xc10 | Read/Write: R/W | Reset: 0bxxxxxxxxxxxxxxxxxxxxxxxx1000000000

Bit	Reset	Description
9	0x1	UHSIC_HS_READY_WAIT_FOR_VALID
8	0x0	UHSIC_PACKET_INVERT_DATA: Invert data during a regular packet
7	0x0	UHSIC_PACKET_FORCE_STROBE_LOW: Force STROBE low during a regular instead of toggling it
6	0x0	UHSIC_HS_POSTAMBLE_OUTPUT_ENABLE: output enable turns off after 1 cycle
5	0x0	UHSIC_SIE_RESUME_ON_LINESTATE: SIE, not macrocell, detects LineState change to resume
4	0x0	UHSIC_SOF_ON_NO_STUFF: SOF when OpMode 3 -- perhaps, when sending controller made packets
3	0x0	UHSIC_SOF_ON_NO_ENCODE: SOF when OpMode 2 -- not likely, for Chirp

Bit	Reset	Description
2	0x0	UHSIC_NO_STUFFING: No bit stuffing, static programming
1	0x0	UHSIC_NO_ENCODING: No encoding, static programming
0	0x0	UHSIC_NO_SYNC_NO_EOP: Do not send SYNC or EOP

23.9.6.6 USB2_UHSIC_MISC_CFG0_0

UHSIC Miscellaneous Configurations

Offset: 0xc14 | Read/Write: R/W | Reset: 0bxxxxxxxxxxxx00100010011101000111 10

Bit	Reset	Description
20	0x0	UHSIC_DISABLE_BUSRESET: When 1, the PHY will not send out BusReset during XcvrSelect0, TermSelect0 and Opmode2. It will send out a non-bit-stuffed, non-encoded packet instead.
19	0x0	UHSIC_FORCE_TERMSEL: Value to be forced on TermSelect when FORCE_XCVR_MODE is set.
18	0x1	UHSIC_EXTEND_BK_ACTIVE: Drive bus keeper one cycle longer when going out of IDLE
17:16	0x0	UHSIC_FORCE_XCVRSEL: Value to be forced on XcvrSelect when FORCE_XCVR_MODE is set.
15	0x0	UHSIC_FORCE_XCVR_MODE: 1: Force the values of XcvrSelect and TermSelect via config bits instead of via the controller
14	0x1	UHSIC_SYMMETRIC_CONNECT_DATA 0: DATA goes high before STROBE goes low and low before STROBE goes high. 1: DATA goes high before STROBE goes low and goes low *after* STROBE goes high.
13	0x0	UHSIC_ASYNC_CONNECT_DATA 0: DATA keeps setup and hold requirements during CONNECT. 1: DATA moves together with STROBE
12	0x0	UHSIC_LONG_CONNECT_STROBE 0: STROBE is 2 periods long during connect. 1: STROBE is 3 periods long during connect
11	0x1	UHSIC_ACTIVE_BK_DRIVE_RX: 1: Use RX state (EOP, etc.) to determine starting time to drive bus keeper instead of waiting for IDLE detection.
10	0x1	UHSIC_ACTIVE_BK_DRIVE_TX: 1: Use TX state to determine starting time to drive bus keeper instead of waiting for IDLE detection.
9	0x1	UHSIC_DETECT_SHORT_IDLE 0: Use 3 edges (negative and positive) to detect an idle state on the line. 1: use 4 edges.
8	0x0	UHSIC_DETECT_SHORT_CONNECT 0: Use 3 edges (negative and positive) to detect a connect state on the line. 1: Use 4 edges.
7	0x1	UHSIC_SUSPEND_EXIT_ON_EDGE: Suspend exit requires edge or simply a value.
6:5	0x0	UHSIC_INJECT_ERROR_TYPE: Force error insertion into RX path. (Used for IOBIST.) 0 = DISABLE 1 = BIT_ERR 2 = RX_ERR 3 = BIT_RX_ERR
4:2	0x3	UHSIC_STABLE_COUNT: Number of crystal clock cycles of signal not changing to consider stable.
1	0x1	UHSIC_STABLE_ALL: Determines if all signals need to be stable to not change a config.
0	0x0	UHSIC_COMB_TERMS: Use combinational terminations or synced through CLKXTAL

23.9.6.7 USB2_UHSIC_MISC_CFG1_0

UHSIC Miscellaneous Configurations

Offset: 0xc18 | Read/Write: R/W | Reset: 0bxxxxxxxxxxxxxxx100001100000000010

Bit	Reset	Description
17	0x1	UHSIC_PHY_XTAL_CLOCKEN: Selects whether or not to enable the crystal clock in the module.
16:15	0x0	UHSIC_OBS_SEL: Selects which one of 4 observation vectors is presented on the observation bus
14	0x0	UHSIC_FORCE_IOBIST_CLK_ON: Always enable IoBist CLK60. This is required when you want to use RX_ERROR_CNT_EN.
13:2	0x600	UHSIC_PLLU_STABLE_COUNT: PLLU frequency lock delay.
1	0x1	UHSIC_RX_ERROR_CNT_CLR: Clear IOBST RxError counter.
0	0x0	UHSIC_RX_ERROR_CNT_EN: Enable IOBIST RxError counter when not in IOBIST mode. Allows one to read out the number of errors via JTAG during normal operation

23.9.6.8 USB2_UHSIC_PADS_CFG0_0

UHSIC Pads settings

Offset: 0xc1c | Read/Write: R/W | Reset: 0b00000000100010001000100010001000

Bit	Reset	Description
31:24	0x0	UHSIC_HSIC_OPT: Spare config bits
23:20	0x8	UHSIC_TX_SLEWN: Output slew rate (fall time) adjustment
19:16	0x8	UHSIC_TX_SLEWP: Output slew rate (rise time) adjustment
15:12	0x8	UHSIC_TX_RTUNEN: Fine tuned 50 ohm termination resistor for NMOS driver
11:8	0x8	UHSIC_TX_RTUNEP: Fine tuned 50 ohm termination resistor for PMOS driver
7:4	0x8	UHSIC_TX_RTERMN: Output impedance adjustment for NMOS driver
3:0	0x8	UHSIC_TX_RTERMP: Output impedance adjustment for PMOS driver

23.9.6.9 USB2_UHSIC_PADS_CFG1_0

UHSIC Pads Settings

Offset: 0xc20 | Read/Write: R/W | Reset: 0bxxxxxxxxxxxxxxxxxxxx0011001111101

Bit	Reset	Description
12	0x0	UHSIC_RPU_STROBE: Enable pull up on IO_STROBE
11	0x0	UHSIC_RPU_DATA: Enable pull up on IO_DATA
10	0x1	UHSIC_RPD_STROBE: Enable pull down on IO_STROBE
9	0x1	UHSIC_RPD_DATA: Enable pull down on IO_DATA
8	0x0	UHSIC_LPBK: Internal digital loopback
7	0x0	UHSIC_RX_SEL 0: Differential read buffers 1: Single-ended buffers
6	0x1	UHSIC_PD_ZI: Power-down single ended receiver
5	0x1	UHSIC_PD_RX: Power-down receiver

Bit	Reset	Description
4	0x1	UHSIC_PD_TRK: Power down tracking circuit
3	0x1	UHSIC_PD_TX: Power-down transmitter
2	0x1	UHSIC_PD_BG: Power-down band-gap and bias generator
1	0x0	UHSIC_IDDQ: Shut down analog blocks for IDDQ testing
0	0x1	UHSIC_AUTO_RTERM_EN: Enable auto-termination

23.9.6.10 USB2_UHSIC_CMD_CFG0_0

Determine startup behavior.

When AUTO_NEGOTIATE == 0

- Firmware is supposed to take care of things.

HOST

if Opmode1: do not drive anything

else

Initial power up:

- Asynchronously drive 00
- After a few crystal clocks, enable bus keepers

Offset: 0xc24 | Read/Write: R/W | Reset: 0bxxxxxxxxxxxxxxxxxxxxxxxxxxx0000101

Bit	Reset	Description
6	0x0	UHSIC_FORCE_ACTIVATED: Force PHY into activated state without connect handshake (both host and device)
5	0x0	UHSIC_PRETEND_CONNECT_DETECT: While in HOST mode, act as if the input stage has seen a CONNECT pulse from the external PHY
4	0x0	UHSIC_FORCE_RESET: While in HOST mode, force global state machine into RESET state
3	0x0	UHSIC_FORCE_CONNECT: Upon rising value of this bit, force device to send connect. Only useful when AUTO_CONNECT is disabled.
2	0x1	UHSIC_AUTO_CONNECT: As device, automatically send Connect during activation.
1	0x0	UHSIC_FORCE_ACTIVATE: Upon rising value of this bit, instruct state machine to go into activation mode. Only useful when AUTO_ACTIVATE is disabled.
0	0x1	UHSIC_AUTO_ACTIVATE: Upon power up, automatically move to activation mode and start going through the connect procedure.

23.9.6.11 USB2_UHSIC_STAT_CFG0_0

Offset: 0xc28 | Read/Write: R/W | Reset: 0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx0

Bit	R/W	Reset	Description
31:16	RO	X	UHSIC_CALIOUT
15:8	RO	X	UHSIC_SPARE_STATUS
2:1	RO	X	UHSIC_BUS_STATE

23.9.6.13 USB2_UHSIC_MISC_STS0_0

UHSIC SPARE Fuse Value

Offset: 0xc30 | Read/Write: RO | Reset: 0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx

Bit	Reset	Description
0	X	UHSIC_TX_HS_VLD: Indicates when the controller is driving on the bus

23.9.6.14 USB2_UHSIC_PMC_WAKEUP0_0

UHSIC PMC Wakeup Value

Offset: 0xc34 | Read/Write: R/W | Reset: 0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx0

Bit	R/W	Reset	Description
1	RO	X	UHSIC_LINE_WAKEUP_EVENT_INT_STS: Indicates the status of the PMC wakeup event
0	RW	0x0	UHSIC_LINE_WAKEUP_EVENT_INT_ENB: Interrupt mask for the PMC wakeup event

23.9.6.15 USB2_QH_USB2D_QH_EP_0_OUT_0

USB2D Queue Head for OUT Endpoint 0

Offset: 0x1000 | Read/Write: R/W | Reset: 0b00000000000000000000000000000000

Bit	Reset	Description
31:0	0x0	USB2D_QH: Queue Head for OUT endpoint 0. This is used to store a local Queue Head data structure for either device mode or host mode. In device mode, it holds the Queue Head for OUT endpoint 0.

23.9.6.16 USB2_QH_USB2D_QH_EP_0_IN_0

USB2D Queue Head for IN Endpoint 0

Offset: 0x1040 | Read/Write: R/W | Reset: 0b00000000000000000000000000000000

Bit	Reset	Description
31:0	0x0	USB2D_QH: Queue Head for IN endpoint 0. This is used to store a local Queue Head data structure for either device mode or host mode. In device mode, it holds the Queue Head for IN endpoint 0.

23.9.6.17 USB2_QH_USB2D_QH_EP_1_OUT_0

USB2D Queue Head for OUT Endpoint 1

Offset: 0x1080 | Read/Write: R/W | Reset: 0b00000000000000000000000000000000

Bit	Reset	Description
31:0	0x0	USB2D_QH: Queue Head for OUT endpoint 1. This is used to store a local Queue Head data structure for either device mode or host mode. In device mode, it holds the Queue Head for OUT endpoint 1.

23.9.6.18 USB2_QH_USB2D_QH_EP_1_IN_0

USB2D Queue Head for IN Endpoint 1

Offset: 0x10c0 | Read/Write: R/W | Reset: 0b00000000000000000000000000000000

Bit	Reset	Description
31:0	0x0	USB2D_QH: Queue Head for IN endpoint 1. This is used to store a local Queue Head data structure for either device mode or host mode. In device mode, it holds the Queue Head for IN endpoint 1.

23.9.6.19 USB2_QH_USB2D_QH_EP_2_OUT_0

USB2D Queue Head for OUT Endpoint 2

Offset: 0x1100 | Read/Write: R/W | Reset: 0b00000000000000000000000000000000

Bit	Reset	Description
31:0	0x0	USB2D_QH: Queue Head for OUT endpoint 2. This is used to store a local Queue Head data structure for either device mode or host mode. In device mode, it holds the Queue Head for OUT endpoint 2.

23.9.6.20 USB2_QH_USB2D_QH_EP_2_IN_0

USB2D Queue Head for IN Endpoint 2

Offset: 0x1140 | Read/Write: R/W | Reset: 0b00000000000000000000000000000000

Bit	Reset	Description
31:0	0x0	USB2D_QH: Queue Head for IN endpoint 2. This is used to store a local Queue Head data structure for either device mode or host mode. In device mode, it holds the Queue Head for IN endpoint 2.

23.9.6.21 USB2_QH_USB2D_QH_EP_3_OUT_0

USB2D Queue Head for OUT Endpoint 3

Offset: 0x1180 | Read/Write: R/W | Reset: 0b00000000000000000000000000000000

Bit	Reset	Description
31:0	0x0	USB2D_QH: Queue Head for OUT endpoint 3. This is used to store a local Queue Head data structure for either device mode or host mode. In device mode, it holds the Queue Head for OUT endpoint 3.

23.9.6.22 USB2_QH_USB2D_QH_EP_3_IN_0

USB2D Queue Head for IN Endpoint 3

Offset: 0x11c0 | Read/Write: R/W | Reset: 0b00000000000000000000000000000000

Bit	Reset	Description
31:0	0x0	USB2D_QH: Queue Head for IN endpoint 3. This is used to store a local Queue Head data structure for either device mode or host mode. In device mode, it holds the Queue Head for IN endpoint 3.

23.9.6.23 USB2_QH_USB2D_QH_EP_4_OUT_0

USB2D Queue Head for OUT Endpoint 4

Offset: 0x1200 | Read/Write: R/W | Reset: 0b00000000000000000000000000000000

Bit	Reset	Description
31:0	0x0	USB2D_QH: Queue Head for OUT endpoint 4. This is used to store a local Queue Head data structure for either device mode or host mode. In device mode, it holds the Queue Head for OUT endpoint 4.

23.9.6.24 USB2_QH_USB2D_QH_EP_4_IN_0

USB2D Queue Head for IN Endpoint 4

Offset: 0x1240 | Read/Write: R/W | Reset: 0b00000000000000000000000000000000

Bit	Reset	Description
31:0	0x0	USB2D_QH: Queue Head for IN endpoint 4. This is used to store a local Queue Head data structure for either device mode or host mode. In device mode, it holds the Queue Head for IN endpoint 4.

23.9.6.25 USB2_QH_USB2D_QH_EP_5_OUT_0

USB2D Queue Head for OUT Endpoint 5

Offset: 0x1280 | Read/Write: R/W | Reset: 0b00000000000000000000000000000000

Bit	Reset	Description
31:0	0x0	USB2D_QH: Queue Head for OUT endpoint 5. This is used to store a local Queue Head data structure for either device mode or host mode. In device mode, it holds the Queue Head for OUT endpoint 5.

23.9.6.26 USB2_QH_USB2D_QH_EP_5_IN_0

USB2D Queue Head for IN Endpoint 5

Offset: 0x12c0 | Read/Write: R/W | Reset: 0b00000000000000000000000000000000

Bit	Reset	Description
31:0	0x0	USB2D_QH: Queue Head for IN endpoint 5. This is used to store a local Queue Head data structure for either device mode or host mode. In device mode, it holds the Queue Head for IN endpoint 5.

23.9.6.27 USB2_QH_USB2D_QH_EP_6_OUT_0

USB2D Queue Head for OUT Endpoint 6

Offset: 0x1300 | Read/Write: R/W | Reset: 0b00000000000000000000000000000000

Bit	Reset	Description
31:0	0x0	USB2D_QH: Queue Head for OUT endpoint 6. This is used to store a local Queue Head data structure for either device mode or host mode. In device mode, it holds the Queue Head for OUT endpoint 6.

23.9.6.28 USB2_QH_USB2D_QH_EP_6_IN_0

USB2D Queue Head for IN Endpoint 6

Offset: 0x1340 | Read/Write: R/W | Reset: 0b00000000000000000000000000000000

Bit	Reset	Description
31:0	0x0	USB2D_QH: Queue Head for IN endpoint 6. This is used to store a local Queue Head data structure for either device mode or host mode. In device mode, it holds the Queue Head for IN endpoint 6.

23.9.6.29 USB2_QH_USB2D_QH_EP_7_OUT_0

USB2D Queue Head for OUT Endpoint 7

Offset: 0x1380 | Read/Write: R/W | Reset: 0b00000000000000000000000000000000

Bit	Reset	Description
31:0	0x0	USB2D_QH: Queue Head for OUT endpoint 7. This is used to store a local Queue Head data structure for either device mode or host mode. In device mode, it holds the Queue Head for OUT endpoint 7.

23.9.6.30 USB2_QH_USB2D_QH_EP_7_IN_0

USB2D Queue Head for IN Endpoint 7

Offset: 0x13c0 | Read/Write: R/W | Reset: 0b00000000000000000000000000000000

Bit	Reset	Description
31:0	0x0	USB2D_QH: Queue Head for IN endpoint 7. This is used to store a local Queue Head data structure for either device mode or host mode. In device mode, it holds the Queue Head for IN endpoint 7.

23.9.6.31 USB2_QH_USB2D_QH_EP_8_OUT_0

USB2D Queue Head for OUT Endpoint 8

Offset: 0x1400 | Read/Write: R/W | Reset: 0b00000000000000000000000000000000

Bit	Reset	Description
31:0	0x0	USB2D_QH: Queue Head for OUT endpoint 8. This is used to store a local Queue Head data structure for either device mode or host mode. In device mode, it holds the Queue Head for OUT endpoint 8.

23.9.6.32 USB2_QH_USB2D_QH_EP_8_IN_0

USB2D Queue Head for IN Endpoint 8

Offset: 0x1440 | Read/Write: R/W | Reset: 0b00000000000000000000000000000000

Bit	Reset	Description
31:0	0x0	USB2D_QH: Queue Head for IN endpoint 8. This is used to store a local Queue Head data structure for either device mode or host mode. In device mode, it holds the Queue Head for IN endpoint 8.

23.9.6.33 USB2_QH_USB2D_QH_EP_9_OUT_0

USB2D Queue Head for OUT Endpoint 9

Offset: 0x1480 | Read/Write: R/W | Reset: 0b00000000000000000000000000000000

Bit	Reset	Description
31:0	0x0	USB2D_QH: Queue Head for OUT endpoint 9. This is used to store a local Queue Head data structure for either device mode or host mode. In device mode, it holds the Queue Head for OUT endpoint 9.

23.9.6.34 USB2_QH_USB2D_QH_EP_9_IN_0

USB2D Queue Head for IN Endpoint 9

Offset: 0x14c0 | Read/Write: R/W | Reset: 0b00000000000000000000000000000000

Bit	Reset	Description
31:0	0x0	USB2D_QH: Queue Head for IN endpoint 9. This is used to store a local Queue Head data structure for either device mode or host mode. In device mode, it holds the Queue Head for IN endpoint 9.

23.9.6.35 USB2_QH_USB2D_QH_EP_10_OUT_0

USB2D Queue Head for OUT Endpoint 10

Offset: 0x1500 | Read/Write: R/W | Reset: 0b00000000000000000000000000000000

Bit	Reset	Description
31:0	0x0	USB2D_QH: Queue Head for OUT endpoint 10. This is used to store a local Queue Head data structure for either device mode or host mode. In device mode, it holds the Queue Head for OUT endpoint 10.

23.9.6.36 USB2_QH_USB2D_QH_EP_10_IN_0

USB2D Queue Head for IN Endpoint 10

Offset: 0x1540 | Read/Write: R/W | Reset: 0b00000000000000000000000000000000

Bit	Reset	Description
31:0	0x0	USB2D_QH: Queue Head for IN endpoint 10. This is used to store a local Queue Head data structure for either device mode or host mode. In device mode, it holds the Queue Head for IN endpoint 10.

23.9.6.37 USB2_QH_USB2D_QH_EP_11_OUT_0

USB2D Queue Head for OUT Endpoint 11

Offset: 0x1580 | Read/Write: R/W | Reset: 0b00000000000000000000000000000000

Bit	Reset	Description
31:0	0x0	USB2D_QH: Queue Head for OUT endpoint 11. This is used to store a local Queue Head data structure for either device mode or host mode. In device mode, it holds the Queue Head for OUT endpoint 11.

23.9.6.38 USB2_QH_USB2D_QH_EP_11_IN_0

USB2D Queue Head for IN Endpoint 11

Offset: 0x15c0 | Read/Write: R/W | Reset: 0b00000000000000000000000000000000

Bit	Reset	Description
31:0	0x0	USB2D_QH: Queue Head for IN endpoint 11. This is used to store a local Queue Head data structure for either device mode or host mode. In device mode, it holds the Queue Head for IN endpoint 11.

23.9.6.39 USB2_QH_USB2D_QH_EP_12_OUT_0

USB2D Queue Head for OUT Endpoint 12

Offset: 0x1600 | Read/Write: R/W | Reset: 0b00000000000000000000000000000000

Bit	Reset	Description
31:0	0x0	USB2D_QH: Queue Head for OUT endpoint 12. This is used to store a local Queue Head data structure for either device mode or host mode. In device mode, it holds the Queue Head for OUT endpoint 12.

23.9.6.40 USB2_QH_USB2D_QH_EP_12_IN_0

USB2D Queue Head for IN Endpoint 12

Offset: 0x1640 | Read/Write: R/W | Reset: 0b00000000000000000000000000000000

Bit	Reset	Description
31:0	0x0	USB2D_QH: Queue Head for IN endpoint 12. This is used to store a local Queue Head data structure for either device mode or host mode. In device mode, it holds the Queue Head for IN endpoint 12.

23.9.6.41 USB2_QH_USB2D_QH_EP_13_OUT_0

USB2D Queue Head for OUT Endpoint 13

Offset: 0x1680 | Read/Write: R/W | Reset: 0b00000000000000000000000000000000

Bit	Reset	Description
31:0	0x0	USB2D_QH: Queue Head for OUT endpoint 13. This is used to store a local Queue Head data structure for either device mode or host mode. In device mode, it holds the Queue Head for OUT endpoint 13.

23.9.6.42 USB2_QH_USB2D_QH_EP_13_IN_0

USB2D Queue Head for IN Endpoint 13

Offset: 0x16c0 | Read/Write: R/W | Reset: 0b00000000000000000000000000000000

Bit	Reset	Description
31:0	0x0	USB2D_QH: Queue Head for IN endpoint 13. This is used to store a local Queue Head data structure for either device mode or host mode. In device mode, it holds the Queue Head for IN endpoint 13.

23.9.6.43 USB2_QH_USB2D_QH_EP_14_OUT_0

USB2D Queue Head for OUT Endpoint 14

Offset: 0x1700 | Read/Write: R/W | Reset: 0b00000000000000000000000000000000

Bit	Reset	Description
31:0	0x0	USB2D_QH: Queue Head for OUT endpoint 14. This is used to store a local Queue Head data structure for either device mode or host mode. In device mode, it holds the Queue Head for OUT endpoint 14.

23.9.6.44 USB2_QH_USB2D_QH_EP_14_IN_0

USB2D Queue Head for IN Endpoint 14

Offset: 0x1740 | Read/Write: R/W | Reset: 0b00000000000000000000000000000000

Bit	Reset	Description
31:0	0x0	USB2D_QH: Queue Head for IN endpoint 14. This is used to store a local Queue Head data structure for either device mode or host mode. In device mode, it holds the Queue Head for IN endpoint 14.

23.9.6.45 USB2_QH_USB2D_QH_EP_15_OUT_0

USB2D Queue Head for OUT Endpoint 15

Offset: 0x1780 | Read/Write: R/W | Reset: 0b00000000000000000000000000000000

Bit	Reset	Description
31:0	0x0	USB2D_QH: Queue Head for OUT endpoint 15. This is used to store a local Queue Head data structure for either device mode or host mode. In device mode, it holds the Queue Head for OUT endpoint 15.

23.9.6.46 USB2_QH_USB2D_QH_EP_15_IN_0

USB2D Queue Head for IN Endpoint 15

Offset: 0x17c0 | Read/Write: R/W | Reset: 0b00000000000000000000000000000000

Bit	Reset	Description
31:0	0x0	USB2D_QH: Queue Head for IN endpoint 15. This is used to store a local Queue Head data structure for either device mode or host mode. In device mode, it holds the Queue Head for IN endpoint 15.

23.9.7 USB3 Controller Registers

23.9.7.1 USB2_CONTROLLER_2_USB2D_ID_0

USB2D Identification Register

Offset: 0x0 | Read/Write: RO | Reset: 0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx

Bit	Reset	Description
31:29	X	CIVERSION: Identifies the CI version
28:25	X	VERSION: Identifies the version of the core
24:21	X	REVISION: Revision number of the USB controller. This is set to 0x0.
20:16	X	TAG: Identifies the tag of the core
15:8	X	NID: One's complement version of ID. This field is set to 0xF9.
7:0	X	ID: Configuration number. This field is set to 0x06

23.9.7.2 USB2_CONTROLLER_2_USB2D_HW_HOST_0

USB2D Hardware Host Register

Offset: 0x8 | Read/Write: RO | Reset: 0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx

Bit	Reset	Description
3:1	X	NPORT: VUSB_HS_NUM_PORT-1: This host controller has only 1 port. So this field will always be 0.
0	X	HC: VUSB_HS_HOST: Indicates support for host mode. Set to 1.

23.9.7.3 USB2_CONTROLLER_2_USB2D_HW_DEVICE_0

USB2D Hardware Device Register

Offset: 0xc | Read/Write: RO | Reset: 0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx

Bit	Reset	Description
5:1	X	DEVEP: VUSB_HS_DV_EP: Number of endpoints supported by this device controller. Set to 16. This includes control endpoint 0.
0	X	DC: Device capable: Set to 1 indicating support for device mode.

23.9.7.4 USB2_CONTROLLER_2_USB2D_HW_TXBUF_0

USB2D Hardware TX Buffer Register

Offset: 0x10 | Read/Write: RO | Reset: 0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx

Bit	Reset	Description
23:16	X	TXCHANADD: VUSB_HS_TX_CHAN_ADD: Total number of address bits for the transmit buffer of each transmit endpoint. Set to 7. Each transmit buffer is 128 words deep.
15:8	X	TXADD: VUSB_HS_TX_ADD: Total number of address bits for the transmit buffer. Set to 11. The total depth of the transmit buffer is 2048 words.
7:0	X	TCBURST: VUSB_HS_TX_BURST: Maximum burst size supported by the transmit endpoints for data transfers. Set to 8.

23.9.7.5 USB2_CONTROLLER_2_USB2D_HW_RXBUF_0

USB2D RX Buffer HW Parameters Register

Offset: 0x14 | Read/Write: RO | Reset: 0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx

Bit	Reset	Description
15:8	X	RXADD: VUSB_HS_RX_ADD: Total number of address bits for the receive buffer. Set to 7. The total depth of the receive buffer is 128 words.
7:0	X	RXBURST: VUSB_HS_RX_BURST: Maximum burst size supported by the receive endpoints for data transfers. Set to 8.

23.9.7.6 USB2_CONTROLLER_2_USB2D_CAPLENGTH_0

USB2D Capability Register Length Register

Offset: 0x100 | Read/Write: RO | Reset: 0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx

Bit	Reset	Description
7:0	X	CAPLENGTH: Indicates which offset to add to the register base address at the beginning of the Operational Register. Set to 0x40.

23.9.7.7 USB2_CONTROLLER_2_USB2D_HCIVERSON_0

USB2D Host Interface Version Number Register

Offset: 0x102 | Read/Write: RO | Reset: 0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx

Bit	Reset	Description
15:0	X	HCIVERSION: Contains a BCD encoding of the EHCI revision number supported by this host controller. The most significant byte of this register represents a major revision and the least significant byte is the minor revision. This host controller supports EHCI revision 1.00.

23.9.7.8 USB2_CONTROLLER_2_USB2D_HCSPARAMS_0

USB2D Host Control Structural Parameters Register

Offset: 0x104 | Read/Write: RO | Reset: 0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx

Bit	Reset	Description
27:24	X	N_TT: Number of Transaction Translators: Indicates the number of embedded transaction translators associated with the USB2.0 host controller. This field is always set to 1 indicating only 1 embedded TT is implemented in this implementation. This is a non-EHCI field to support embedded TT.
23:20	X	N_PTT: Number of Ports per Transaction Translator: Indicates the number of ports assigned to each transaction translator within the USB2.0 host controller. Field always equals N_PORTS. This is a non-EHCI field to support embedded TT.
15:12	X	N_CC: Number of Companion Controller: Indicates the number of companion controllers. This field is set to 0.
11:8	X	N_PCC: Number of Ports per Companion Controller: Indicates the number of ports supported per internal companion controller. This field is set to 0.
4	X	PPC: Port Power Control: Indicates whether the host controller implementation includes port power control. 1 = Ports have port power switches 0= Ports do not have port power switches. This field affects the functionality of the port Power field in each port status and control register. This field is set to 1.
3:0	X	N_PORTS: Number of downstream ports. This field specifies the number of physical downstream ports implemented on this host controller. This field is fixed to 1, since this host controller only supports 1 port.

23.9.7.9 USB2_CONTROLLER_2_USB2D_HCCPARAMS_0

USB2D Host Control Capability Parameters Register

Offset: 0x108 | Read/Write: RO | Reset: 0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx

Bit	Reset	Description
18	X	PPC: Per-Port Change Event Capability - RO. Default = 1b. This field indicates the support for per-port change events. This field is related to the USBCMD PPE field, USBSTS PPCI field, and USBINTR PPCE field.
17	X	LEN: Link Power Management Capability - RO. Default = 1b. This field indicates the support for LPM L1 state. This field is related to the USBCMD HIRD field, POSTSCx SSTS and DA fields, and HOSTPCx LEN, BA, and EPLPM fields.
15:8	X	EECP: EHCI Extended Capabilities Pointer: Indicates a capabilities list exists. A value of 00h indicates no extended capabilities are implemented. For this implementation this field is always "0".
7:4	X	IST: Isochronous Scheduling Threshold. This field indicates, relative to the current position of the executing host controller, where software can reliably update the isochronous schedule. When bit [7] is zero, the value of the least significant 3 bits indicates the number of micro-frames a host controller can hold a set of isochronous data structures (one or more) before flushing the state. When bit [7] is a one, then host software assumes the host controller may cache an isochronous data structure for an entire frame. This field will always be "0".
2	X	ASP: Asynchronous Schedule Park Capability. 1 = (Default) the host controller supports the park feature for high-speed queue heads in the Asynchronous Schedule. The feature can be disabled or enabled and set to a specific level by using the Asynchronous Schedule Park Mode Enable and Asynchronous Schedule Park Mode Count fields in the USBCMD register. This field is always 1.
1	X	PFL: Programmable Frame List Flag. 0 = System software must use a frame list length of 1024 elements with this host controller. The USBCMD register Frame List Size field is a read-only register and must be set to zero. 1 = System software can specify and use a smaller frame list and configure the host controller via the USBCMD register Frame List Size field. The frame list must always be aligned on a 4K-page boundary. This requirement ensures that the frame list is always physically contiguous. This field will always be "1".

23.9.7.10 USB2_CONTROLLER_2_USB2D_DCIVERSION_0

USB2D Device Interface Version Number Register

Offset: 0x120 | Read/Write: RO | Reset: 0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx

Bit	Reset	Description
15:0	X	DCIVERSION: The device controller interface conforms to the two-byte BCD encoding of the interface version number contained in this register.

23.9.7.11 USB2_CONTROLLER_2_USB2D_DCCPARAMS_0

USB2D Device Control Capabilities Register

Offset: 0x124 | Read/Write: RO | Reset: 0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx

Bit	Reset	Description
8	X	HC: Host Capable: 1 = This controller is capable of operating as an EHCI compatible USB 2.0 host controller. This field is set to 1.
7	X	DC: Device Capable: 1 = Controller is capable of operating as USB 2.0 device. This field is set to 1.

Bit	Reset	Description
5	X	LEN: Link Power Management Capability - RO. Default = 1b. This field indicates the support for LPM L1 state. This field is related to the DEVLCx ASUS, STL, BA, and NYT fields.
4:0	X	DEN: Device Endpoint Number: Number of endpoints built into the device controller. This is set to 16.

23.9.7.12 USB2_CONTROLLER_2_USB2D_EXTSTS_0

USB2D EXTSTS Register

Offset: 0x128 | Read/Write: R/W | Reset: 0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxx0000x

Bit	R/W	Reset	Description
4	RW	0x0	TI1: General Purpose Timer Interrupt 1 - RWC. Default = 0b. This bit is set when the counter in the GPTIMER1CTRL register transitions to zero. Writing a one to this bit will clear it.
3	RW	0x0	TI0: General Purpose Timer Interrupt 0 - RWC. Default = 0b. This bit is set when the counter in the GPTIMER1CTRL register transitions to zero. Writing a one to this bit will clear it.
2	RW	0x0	UPA: USB Host Periodic Interrupt (USBHSTPERINT) R/WC. This bit is set by the Host Controller when the cause of an interrupt is a completion of a USB transaction where the Transfer Descriptor (TD) has an interrupt on complete (IOC) bit set and the TD was from the periodic schedule. This bit is also set by the Host Controller when a short packet is detected AND the packet is on the periodic schedule. A short packet is when the actual number of bytes received was less than the expected number of bytes. This bit is not used by the device controller and will always be zero. 0 = DISABLE 1 = ENABLE
1	RW	0x0	UAI: USB Host Asynchronous Interrupt (USBHSTASYNCINT) R/WC. This bit is set by the Host Controller when the cause of an interrupt is a completion of a USB transaction where the Transfer Descriptor (TD) has an interrupt on complete (IOC) bit set AND the TD was from the asynchronous schedule. This bit is also set by the Host when a short packet is detected AND the packet is on the asynchronous schedule. A short packet is when the actual number of bytes received was less than the expected number of bytes. This bit is not used by the device controller and will always be zero. 0 = DISABLE 1 = ENABLE
0	RO	X	NAKI: NAK Interrupt Bit Read Only. This bit is read only. It is set by hardware when for a particular endpoint both the TX/RX Endpoint NAK bit and the corresponding TX/RX Endpoint NAK Enable bit are set. This bit is automatically cleared by hardware when the all the enabled TX/RX Endpoint NAK bits are cleared. 0 = DISABLE 1 = ENABLE

23.9.7.13 USB2_CONTROLLER_2_USB2D_USBEXTINTR_0

USB2D EXTINTR Register

Offset: 0x12c | Read/Write: R/W | Reset: 0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxx00000

Bit	Reset	Description
4	0x0	TIE1: General Purpose Timer Interrupt Enable 1 - RWC. Default = 0b. When this bit is a one, and the TI1 bit in the EXTSTS register is a one, the controller will issue an interrupt. The interrupt is acknowledged by software clearing the TI1 bit.
3	0x0	TIE0: General Purpose Timer Interrupt Enable 0 - RWC. Default = 0b. When this bit is a one, and the TI1 bit in the EXTSTS register is a one, the controller will issue an interrupt. The interrupt is acknowledged by software clearing the TI1 bit.
2	0x0	UPIE: UPIE Interrupt Enable. 1 = USB controller issues an interrupt if UPA bit in USBSTS register transitions. 0 = DISABLE 1 = ENABLE

Bit	Reset	Description
1	0x0	UAIE: UAIE Interrupt Enable. 1 = USB controller issues an interrupt if UAI bit in USBSTS register transitions. 0 = DISABLE 1 = ENABLE
0	0x0	NAKE: NAK Interrupt Enable. 1 = USB controller issues an interrupt if NAKI bit in USBSTS register transitions. 0 = DISABLE 1 = ENABLE

23.9.7.14 USB2_CONTROLLER_2_USB2D_USBCMD_0

USB2D USB Command Register

Offset: 0x130 | Read/Write: R/W | Reset: 0bxxxx00000000010000000x1x11x0000000

Bit	R/W	Reset	Description
27:24	RW	0x0	HIRD: Host Initiated Resume Duration RW. Default = 0000b. This has the same behavior as bits 7:4 of the BA field of the HOSTPCx register. When writing to this field all BA[7:4] fields of all HOSTPCx registers will be set to this value. This field is used by system software to specify the minimum amount of time the host controller will drive the K-state during a host-initiated resume from an LPM state (e.g., L1), and is conveyed to each LPM-enabled device (via the HIRD bits within an LPM Tokens bmAttributes field) upon entry into a low-power state. Note the host controller is required to drive resume signaling for at least the amount of time specified in the HIRD value conveyed to the device during any proceeding host-initiated resume. Also note that the host controller is not required to observe this requirement during device-initiated resumes. Encoding for this field is identical to the definition for the similarly named HIRD field within an LPM Token, specifically: a value 0000b equals 50 µs and each additional increment adds 75 µs. For example, the value 0001b equals 125 µs, and a value 1111b equals 1,175 µs (~1.2ms).
23:16	RW	0x8	ITC: Interrupt Threshold Control .Read/Write. Default 08h. The system software uses this field to set the maximum rate at which the host/device controller will issue interrupts. ITC contains the maximum interrupt interval measured in micro-frames. Valid values are shown below. Value Maximum Interrupt Interval 00h = Immediate (no threshold) 01h = 1 micro-frame 02h = 2 micro-frames 04h = 4 micro-frames 08h = 8 micro-frames 10h = 16 micro-frames 20h = 32 micro-frames 40h = 64 micro-frames 0 = IMMEDIATE 2 = ONE_MF 4 = TWO_MF 8 = EIGHT_MF 16 = SIXTEEN_MF 32 = THIRTY_TWO_MF 64 = SIXTY_FOUR_MF
15	RW	0x0	FS2: Bit 2 of Frame List Size.
14	RW	0x0	ATDTW: Add DTD Tripwire. This bit is used as a semaphore when a dTD is added to an active (primed) endpoint. This bit is set and cleared by software and will be cleared by hardware when a hazard exists such that adding a dTD to a primed endpoint may go unnoticed. 0 = CLEAR 1 = SET
13	RW	0x0	SUTW: Setup Tripwire. This bit is used as a semaphore when the 8 bytes of setup data read extracted by the firmware. If the setup lockout mode is off, then there exists a hazard when new setup data arrives and firmware is copying setup data from the QH for a previous setup packet. This bit is set and cleared by software and will be cleared by hardware when a hazard exists. 0 = CLEAR 1 = SET

Bit	R/W	Reset	Description
11	RW	0x1	ASPE: Asynchronous Schedule Park mode Enable. Software uses this bit to enable or disable Park mode. When this bit is one, Park mode is enabled. When this bit is a zero, Park mode is disabled. This field is set to "1" in this implementation. 0 = DISABLE 1 = ENABLE
9:8	RW	0x3	ASP1_ASP0: Asynchronous Schedule Park Mode Count (OPTIONAL) Read/Write. If the Asynchronous Park Capability bit in the HCCPARAMS register is a one, then this field defaults to 3h and is R/W. Otherwise it defaults to zero and is RO. It contains a count of the number of successive transactions the host controller is allowed to execute from a high-speed queue head on the Asynchronous schedule before continuing traversal of the Asynchronous schedule. Valid values are 1h to 3h. Software must not write a zero to this bit when Park Mode Enable is a one as this will result in undefined behavior. This field is set to 3h in this implementation.
7	RO	X	LR: Light Host/Device Controller Reset (OPTIONAL). Not Implemented. This field will always be "0".
6	RW	0x0	IAA: Interrupt on Async Advance Doorbell. When the host controller has evicted all appropriate cached schedule states, it sets the Interrupt on Async Advance status bit in the USBSTS register. If the Interrupt on Sync Advance Enable bit in the USBINTR register is one, then the host controller will assert an interrupt at the next interrupt threshold. The host controller sets this bit to zero after it has set the Interrupt on Sync Advance status bit in the USBSTS register to one. Software should not write a one to this bit when the asynchronous schedule is inactive. Doing so will yield undefined results. This bit is only used in Host mode. Writing a one to this bit when device mode is selected will have undefined results. 0 = CLEAR 1 = SET
5	RW	0x0	ASE: Asynchronous Schedule Enable. This bit controls whether the host controller skips processing the Asynchronous Schedule. 0 = Do not process the Asynchronous Schedule. 1 = Use the ASYNCLISTADDR register to access the Asynchronous Schedule. Only the host controller uses this bit. 0 = DISABLE 1 = ENABLE
4	RW	0x0	PSE: Periodic Schedule Enable. This bit controls whether the host controller skips processing the Periodic Schedule. 0 = Do not process the Periodic Schedule 1 = Use the PERIODICLISTBASE register to access the Periodic Schedule. Only the host controller uses this bit. 0 = DISABLE 1 = ENABLE
3:2	RW	0x0	FS1_FS0: Frame List Size 000 = Default. This field is Read/Write only if Programmable Frame List Flag in the HCCPARAMS registers is set to one. Hence this field is Read/Write for this implementation. This field specifies the size of the frame list that controls which bits in the Frame Index Register should be used for the Frame List Current index. Note that this field is made up from USBCMD bits 15, 3, and 2. 000 = 1024 elements (4096 bytes) Default value 001 = 512 elements (2048 bytes) 010 = 256 elements (1024 bytes) 011 = 128 elements (512 bytes) 100 = 64 elements (256 bytes) 101 = 32 elements (128 bytes) 110 = 16 elements (64 bytes) 111 = 8 elements (32 bytes) Only the host controller uses this field.
1	RW	0x0	RST: Controller Reset. Software uses this bit to reset the controller. This bit is set to zero by the Host/Device Controller when the reset process is complete. Software cannot terminate the reset process early by writing a zero to this register. Host Controller: When software writes a one to this bit, the Host Controller resets its internal pipelines, timers, counters, state machines etc. to their initial value. Any transaction currently in progress on USB is immediately terminated. A USB reset

Bit	R/W	Reset	Description
			is not driven on downstream ports. Software should not set this bit to a one when the HCHalted bit in the USBSTS register is a zero. Attempting to reset an actively running host controller results in undefined behavior. Device Controller: When software writes a one to this bit, the Device Controller resets its internal pipelines, timers, counters, state machines, etc. to their initial value. Any transaction currently in progress on USB is immediately terminated. Writing a one to this bit in device mode is not recommended. 0 = CLEAR 1 = SET
0	RW	0x0	RS: Run/Stop: Host Controller: When set to a 1, the Host Controller proceeds with the execution of the schedule. The Host Controller continues execution as long as this bit is set to a one. When this bit is set to 0, the Host Controller completes the current transaction on the USB and then halts. The HCHalted bit in the status register indicates when the Host Controller has finished the transaction and has entered the stopped state. Software should not write a one to this field unless the host controller is in the Halted state (i.e., HCHalted in the USBSTS register is a one). Device Controller: Writing a one to this bit will cause the device controller to enable a pull-up on D+ and initiate an attach event. This control bit is not directly connected to the pull-up enable, as the pull-up will become disabled upon transitioning into high-speed mode. Software should use this bit to prevent an attach event before the device controller has been properly initialized. Writing a 0 to this will cause a detach event. 0 = STOP 1 = RUN

23.9.7.15 USB2_CONTROLLER_2_USB2D_USBSTS_0

USB2D USB Status Register

Offset: 0x134 | Read/Write: R/W | Reset: 0b00000000000000000x100x0000x0000

Bit	R/W	Reset	Description
31:16	RW	0x0	PPCI: Port-n Change Detect - RW. Default = 0000h. The definition for each bit is identical to the Port Change Detect field (bit 2 of this register) except these bits are specific to a given port, where bit 16 = Port 1, 17 = Port 2, etc. For example, if bit 17 is set to a one then a port change event was detected on Port 2. The N_PORTS field in HCSPARAMS specifies how many ports are exposed by the host controller and thus how many bits in this field are valid.
15	RW	0x0	AS: Asynchronous Schedule Status. This bit reports the current real status of the Asynchronous Schedule. When set to zero the asynchronous schedule status is disabled and if set to one the status is enabled. The Host Controller is not required to immediately disable or enable the Asynchronous Schedule when software transitions the Asynchronous Schedule Enable bit in the USBCMD register. If AS = ASE: 1= Enable Asynchronous Schedule 0= Disable Asynchronous Schedule Only used by the host controller. 0 = DISABLE 1 = ENABLE
14	RW	0x0	PS: Periodic Schedule Status. This bit reports the current real status of the Periodic Schedule. When set to zero the periodic schedule is disabled, and if set to one the status is enabled. The Host Controller is not required to immediately disable or enable the Periodic Schedule when software transitions the Periodic Schedule Enable bit in the USBCMD register. If PS = PSE: 1 = Periodic Schedule is enabled 0 = Periodic Schedule is disabled Only used by the host controller. 0 = DISABLE 1 = ENABLE
13	RO	X	RCL: Reclamation. This is a read-only status bit used to detect an empty asynchronous schedule. Only used by the host controller. 0 = DISABLE 1 = ENABLE

Bit	R/W	Reset	Description
12	RW	0x1	HCH: HCHalted. 1 = Default. This bit is a zero whenever the Run/Stop bit is a one. The Host Controller sets this bit to one after it has stopped executing because of the Run/Stop bit being set to 0, either by software or by the Host Controller hardware (e.g., internal error). Only used by the host controller. 0 = UNHALTED 1 = HALTED
11	RW	0x0	UALT_INT: ULPI alt_int Interrupt. 0 = Default. This interrupt bit is set when an RXCMD is received through the ULPI interface with bit 7 set (alt_int). The alt_int itself is set when an unmasked event occurs on any bit in the Carkit Interrupt Latch Register, in the ULPI PHY. The software should read the Carkit Interrupt Latch Register (Read to Clear) through the ULPI Viewport to check the source of the interrupt. Only present in designs where configuration constant VUSB_HS_PHY_ULPI = 1. 0 = NOT_ULPI_ALT_INT 1 = ULPI_ALT_INT
10	RW	0x0	ULPI_INT: ULPI Interrupt. This bit is set whenever an interrupt is received from ULPI PHY. Software writes 1 to clear it. 0 = NOT_ULPI_INT 1 = ULPI_INT
8	RW	0x0	SLI: DCSuspend. When a device controller enters a suspend state from an active state, this bit will be set to a 1. The device controller clears the bit upon exiting from a suspend state. Only used by the device controller. 0 = NOTSUSPEND 1 = SUSPENDED
7	RW	0x0	SRI: SOF Received. When the device controller detects a Start Of (micro) Frame, this bit will be set to a one. When an SOF is extremely late, the device controller will automatically set this bit to indicate that an SOF was expected. Therefore, this bit will be set roughly every 1ms in device FS mode and every 125 µs in HS mode and will be synchronized to the actual SOF that is received. Since device controller is initialized to FS before connect, this bit will be set at an interval of 1ms during the prelude to the connect and chirp. In host mode, this bit will be set every 125 µs and can be used by host controller driver as a time base. Software writes a 1 to this bit to clear it. This is a non-EHCI status bit. 0 = SOF_NOT_RCVD 1 = SOF_RCVD
6	RW	0x0	URI: USB Reset Received. When the device controller detects a USB Reset and enters the default state, this bit is set to a 1. Software can write a 1 to this bit to clear the USB Reset Received status bit. Only used by the device controller. 0 = NO_USB_RESET 1 = USB_RESET
5	RW	0x0	AAI: Interrupt and Asynchronous Advance. System software can force the host controller to issue an interrupt the next time the host controller advances the asynchronous schedule by writing a one to the Interrupt on Async Advance Doorbell bit in the USBCMD register. This status bit indicates the assertion of that interrupt source. Only used by the host controller 0 = NOT_ADVANCED 1 = ADVANCED
4	RO	X	SEI: System Error. This bit is not used in this implementation and will always be set to "0". 0 = NO_ERROR 1 = ERROR
3	RW	0x0	FRI: Frame List Rollover. The Host Controller sets this bit to a 1 when the Frame List Index rolls over from its maximum value to 0. The exact value at which the rollover occurs depends on the frame list size. For example. If the frame list size (as programmed in the Frame List Size field of the USBCMD register) is 1024, the Frame Index Register rolls over every time FRINDEX [1 3] toggles. Similarly, if the size is 512, the Host Controller sets this bit to a 1 every time FHINDEX [12] toggles. Only used by the host controller. 0 = NO_ROLLOVER 1 = ROLLOVER

Bit	R/W	Reset	Description
2	RW	0x0	PCI: Port Change Detect. The Host Controller sets this bit to a 1 when on any port a Connect Status occurs, a Port Enable/Disable Change occurs, or the Force Port Resume bit is set as the result of a J-K transition on the suspended port. The Device Controller sets this bit to a one when the port controller enters the full or high-speed operational state. When the port controller exits the full or high-speed operational states due to Reset or Suspend events, the notification mechanisms are the USB Reset Received bit and the DCSuspend bits respectively. This bit is not EHCI compatible. 0 = NO_PORT_CHANGE 1 = PORT_CHANGE
1	RW	0x0	UEI: USB Error Interrupt. This bit gets set by the Host/Device controller when completion of a USB transaction results in an error condition. This bit is set along with the USBINT bit, if the TD on which the error interrupt occurred also ad its interrupt on complete (IOC) bit set. 0 = NO_ERROR 1 = ERROR
0	RW	0x0	UI: USB Interrupt. This bit is set by the Host/Device Controller when the cause of an interrupt is a completion of a USB transaction where the Transfer Descriptor (TD) as an interrupt on complete (IOC) bit set. This bit is also set by the Host/Device Controller when a short packet is detected. A short packet is when the actual number of bytes received was less than the expected number of bytes. 0 = NO_INT 1 = INT

23.9.7.16 USB2_CONTROLLER_2_USB2D_USBINTR_0

USB2D USB Interrupt Enable Register

Offset: 0x138 | Read/Write: R/W | Reset: 0b00000000000000000xxxx00x000000000

Bit	Reset	Description
31:16	0x0	PPCE: Port-n Change Detect Enable - RW. Default = 0000h. The definition for each bit in this field is identical to bit 2 of this register (Port Change Interrupt Enable) except these bits are specific to a given port, where bit 16 = Port 1, 17 = Port 2, etc. For example, if bit 17 is set (1b) then a port change event was detected on Port 2. When a bit in this field is a one, and the corresponding Port-n Change Detect bit in the USBSTS register is a one, the host controller will issue an interrupt. The interrupt is acknowledged by software clearing the Port-n Change Detect bit.
11	0x0	UALTIE: ULPI alt_int Interrupt Enable. 1 = USB controller issues an interrupt if ULPI_ALT_INT bit in USBSTS register transitions. The interrupt is acknowledged by software by writing a 1 to the ULPI_ALT_INT bit. 0 = DISABLE 1 = ENABLE
10	0x0	ULPIE: ULPI Interrupt Enable. 1 = USB controller issues an interrupt if ULPI_INT bit in USBSTS register transitions. The interrupt is acknowledged by software by writing a 1 to the ULPI_INT bit. 0 = DISABLE 1 = ENABLE
8	0x0	SLE: Sleep Enable. 1 = Device controller issues an interrupt if DCSuspend bit in USBSTS register transitions. The interrupt is acknowledged by software by writing a 1 to the DCSuspend bit. Only used by the device controller. 0 = DISABLE 1 = ENABLE
7	0x0	SRE: SOF Received Enable. 1 = Device controller issues an interrupt if SOF Received bit in USBSTS register = 1. The interrupt is acknowledged by software clearing the SOF Received bit. 0 = DISABLE 1 = ENABLE
6	0x0	URE: USB Reset Enable.1 = Device controller issues an interrupt if USB Reset Received bit in USBSTS register = 1. The interrupt is acknowledged by software clearing the USB Reset Received bit. Only used by the device controller. 0 = DISABLE 1 = ENABLE

Bit	Reset	Description
5	0x0	AAE: Interrupt on Asynchronous Advance Enable. 1 = the host controller issues an interrupt at the next interrupt threshold if Interrupt on Async Advance bit in USBSTS register = 1. The interrupt is acknowledged by software clearing the Interrupt on Async Advance bit. Only used by the host controller. 0 = DISABLE 1 = ENABLE
4	0x0	SEE: System Error Enable. 1 = Host/device controller issues an interrupt if the System Error bit in USBSTS register = 1. The interrupt is acknowledged by software clearing the System Error bit. 0 = DISABLE 1 = ENABLE
3	0x0	FRE: Frame List Rollover Enable. 1 = Host controller issues an interrupt if Frame List Rollover bit in the USBSTS register = 1. The interrupt is acknowledged by software clearing the Frame List Rollover bit. Only used by the host controller. 0 = DISABLE 1 = ENABLE
2	0x0	PCE: Port Change Detect Enable. 1 = Host/device controller issues an interrupt if Port Change Detect bit in USBSTS register = 1. The interrupt is acknowledged by software clearing the Port Change Detect bit. 0 = DISABLE 1 = ENABLE
1	0x0	UEE: USB Error Interrupt Enable. 1 = Host controller issues an interrupt at the next interrupt threshold if the USBERRINT bit in USBSTS = 1. The interrupt is acknowledged by software clearing the USBERRINT bit in the USBSTS register. 0 = DISABLE 1 = ENABLE
0	0x0	UE: USB Interrupt Enable. 1 = Host/device issues an interrupt at the next interrupt threshold if the USBINT bit in USBSTS = 1. The interrupt is acknowledged by software clearing the USBINT bit. 0 = DISABLE 1 = ENABLE

23.9.7.17 USB2_CONTROLLER_2_USB2D_FRINDEX_0

USB2D USB Frame Index Register

Offset: 0x13c | Read/Write: RO | Reset: 0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx

Bit	Reset	Description
13:0	X	FRINDEX: Frame Index. The value in this register increments at the end of each time frame (micro-frame). Bits [N: 3] are used for the Frame List current index. Each location of the frame list is accessed 8 times (frames or micro-frames) before moving to the next index. The following illustrates values of N based on the value of the Frame List Size field in the USBCMD register, when used in host mode. USBCMD [Frame List Size] Number Elements N 000b (1024) 12 001b (512) 11 010b (256) 10 011b (128) 9 100b (64) 8 101b (32) 7 110b (16) 6 111b (8) 5 In device mode, the value is the current frame number of the last frame transmitted. It is not used as an index. In either mode, bits 2:0 indicate the current micro-frame.

23.9.7.18 USB2_CONTROLLER_2_USB2D_PERIODICLISTBASE_0

USB2D Host Controller Frame List Base Address Register

Offset: 0x144 | Read/Write: R/W | Reset: 0b00000000000000000000xxxxxxxxxxxx

Bit	Reset	Description
31:25	0x0	USBADR: Device mode. The upper seven bits of this register represent the device address. After any controller reset or a USB reset, the device address is set to the default address (0). The default address will match all incoming addresses. Software shall reprogram the address after receiving a SET_ADDRESS request.
24	0x0	USBADRA: Device Address Advance. Default=0. When this bit is 0, any writes to USBADR are instantaneous. When this bit is written to a 1 at the same time or before USBADR is written, the write to the USBADR field is staged and held in a hidden register. After an IN occurs on endpoint 0 and is ACKed, USBADR will be loaded from the holding register. Hardware will automatically clear this bit on the following conditions: 1) IN is ACKed to endpoint 0. (USBADR is updated from staging register). 2) OUT/SETUP occur to endpoint 0. (USBADR is not updated). 3) Device Reset occurs (USBADR is reset to 0). Note: After the status phase of the SET_ADDRESS descriptor, the DCD has 2 ms to program the USBADR field. This mechanism will ensure this specification is met when the DCD cannot write of the device address within 2 ms from the SET_ADDRESS status phase. If the DCD writes the USBADR with USBADRA=1 after the SET_ADDRESS data phase (before the prime of the status phase), the USBADR will be programmed instantly at the correct time and meet the 2ms USB requirement.
31:12	0x0	BASEADR: Host mode: This 32-bit register contains the beginning address of the Periodic Frame List in the system memory. HCD loads this register prior to starting the schedule execution by the Host Controller. The memory structure referenced by this physical memory pointer is assumed to be 4-Kbyte aligned. The contents of this register are combined with the Frame Index Register (FRINDEX) to enable the Host Controller to step through the Periodic Frame List in sequence. Base Address (Low). These bits correspond to memory address signals [31:12], respectively. Only used by the host controller.

23.9.7.19 USB2_CONTROLLER_2_USB2D_ASYNCLISTADDR_0

USB2D Next Asynchronous List Address Register

Offset: 0x148 | Read/Write: R/W | Reset: 0b00000000000000000000000000xxxxx

Bit	Reset	Description
31:11	0x0	EPBASE: Device mode. This register contains the address of the top of the endpoint list in system memory. These bits correspond to memory address signals [31:11], respectively. This field will reference a list of up to 32 Queue Heads (QH). Only used by the device controller.
31:5	0x0	ASYBASE: Host mode. This 32-bit register contains the address of the next asynchronous queue head to be executed by the host. Link Pointer Low (LPL). These bits correspond to memory address signals [31:5], respectively. This field may only reference a Queue Head (OH). Only used by the host controller.

23.9.7.20 USB2_CONTROLLER_2_USB2D_ASYNCTTSTS_0

USB2D Asynchronous Buffer Status for Embedded TT Register

Offset: 0x14c | Read/Write: R/W | Reset: 0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx0x

Bit	R/W	Reset	Description
1	RW	0x0	TTAC: Embedded TT Async Buffers Clear. (Read/Write to set). This field will clear all pending transactions in the embedded TT Async Buffer(s). The clear will take as much time as necessary to clear buffer without interfering with a transaction in progress. TTAC will return to zero after being set by software only after the actual clear occurs.
0	RO	X	TTAS: Embedded TT Async Buffers Status. (Read Only). This read only bit will be 1 if one or more transactions are being held in the embedded TT Async. Buffers. When this bit is a zero, then all outstanding transactions in the embedded TT have been flushed.

23.9.7.21 USB2_CONTROLLER_2_USB2D_BURSTSIZE_0

USB2D Burst Size Register

Offset: 0x150 | Read/Write: R/W | Reset: 0bxxxxxxxxxxxxxxxx0000100000001000

Bit	Reset	Description
15:8	0x8	TXPBURST: Programmable TX Burst Length. (Read/Write). This register represents the maximum length of a burst in 32-bit words while moving data from system memory to the USB bus.
7:0	0x8	RXPBURST: Programmable RX Burst Length. (Read/Write). This register represents the maximum length of a burst in 32-bit words while moving data from the USB bus to system memory.

23.9.7.22 USB2_CONTROLLER_2_USB2D_TXFILLTUNING_0

USB2D Transmit Fill Tuning Register

Offset: 0x154 | Read/Write: R/W | Reset: 0bxxxxxxxxxx000010xxx0000000000000

Bit	Reset	Description
21:16	0x2	TXFIFOTHRES: FIFO Burst Threshold. (Read/Write). This register controls the number of data bursts that are posted to the TX latency FIFO in host mode before the packet begins on to the bus. The minimum value is 2 and this value should be a low as possible to maximize USB performance. A higher value can be used in systems with unpredictable latency and/or insufficient bandwidth where the FIFO may underrun because the data transferred from the latency FIFO to USB occurs before it can be replenished from system memory. This value is ignored if the Stream Disable bit in USBMODE register is set.
12:8	0x0	TXSCHHEALTH: Scheduler Health Counter. (Read/Write To Clear) [Default = 0]. This register increments when the host controller fails to fill the TX latency FIFO to the level programmed by TXFIFOTHRES before running out of time to send the packet before the next Start-Of-Frame. This health counter measures the number of times this occurs to provide feedback to selecting a proper TXSCHOH. Writing to this register will clear the counter and this counter will max out at 31.
7:0	0x0	TXSCHOH: Scheduler Overhead. (Read/Write) [Default = 0]. This register adds an additional fixed offset to the schedule time estimator described above as Tff. As an approximation, the value chosen for this register should limit the number of back-off events captured in the TXSCHHEALTH to less than 10 per second in a highly utilized bus. Choosing a value that is too high for this register is not desired as it can needlessly reduce USB utilization. The time unit represented in this register is 1.267 µs when a device is connected in High-Speed Mode. The time unit represented in this register is 6.333 µs when a device is connected in Low/Full Speed Mode.

23.9.7.23 USB2_CONTROLLER_2_USB2D_ICUSB_CTRL_0

USB2D ICUSB Control Register

This register enables and controls the ICUSB FS/LS transceiver.

Offset: 0x15c | Read/Write: R/W | Reset: 0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx0000

Bit	Reset	Description
3	0x0	IC_ENB1: ICUSB transceiver enable. This bit enables the ICUSB transceiver. To enable the interface, the bits PTS must be set to 11 in the PORTSCx. Writing a '1' to this bit selects the IC_USB interface. 0 = DISABLE 1 = ENABLE
2:0	0x0	IC_VDD1: ICUSB voltage select. It selects which voltage is being supplied to the ICUSB peripheral. 000 = No voltage 001 = 1.0V – reserved 010 = 1.2V - reserved 011 = 1.5V - reserved 100 = 1.8V 101 = 3.0V

Bit	Reset	Description
		110 = reserved 111 = reserved The Voltage negotiation should happen between enabling port power (PP) and asserting the run/stop bit in register.

23.9.7.24 USB2_CONTROLLER_2_USB2D_ULPI_VIEWPORT_0

USB2D ULPI Viewport Register

This register provides indirect access to the ULPI PHY register set. Although the USB controller performs access to the ULPI PHY register set, there may be extraordinary circumstances where software may need direct access.

Note: WRITES TO THE ULPI THROUGH THE VIEWPORT CAN SUBSTANTIALLY HARM STANDARD USB OPERATIONS. CURRENTLY NO USAGE MODEL HAS BEEN DEFINED WHERE SOFTWARE SHOULD NEED TO EXECUTE WRITES DIRECTLY TO THE ULPI PHY. SEE EXCEPTION REGARDING OPTIONAL FEATURES BELOW.

Note: EXECUTING READ OPERATIONS THROUGH THE ULPI VIEWPORT SHOULD HAVE NO HARMFUL SIDE EFFECTS TO STANDARD USB OPERATIONS.

There are two operations that can be performed with the ULPI Viewport: wakeup and read /write operations.

The wakeup operation is used to put the ULPI interface into normal operation mode and re-enable the clock, if necessary. A wakeup operation is required before accessing the registers when the ULPI interface is operating in low power mode, serial mode, or Carkit mode.

The ULPI state can be determined by reading the sync state bit (ULPI_SYNC_STATE). If this bit is a one, then ULPI interface is running in normal operation mode and can accept read/write operations. If the ULPI_SYNC_STATE indicates a 0 then then read/write operations will not be able to execute. Undefined behavior will result if ULPI_SYNC_STATE = 0 and a read or write operation is performed.

To execute a wakeup operation, write all 32 bits of the ULPI Viewport where ULPI_PORT is constructed appropriately and the ULPI_WAKEUP bit is a 1 and ULPI_RUN bit is a 0. Poll the ULPI Viewport until ULPI_WAKEUP is zero for the operation to complete.

To execute a read or write operation, write all 32 bits of the ULPI Viewport where ULPI_DATA_WR, ULPI_REG_ADDR, ULPI_PORT, ULPI_RD_WR are constructed appropriately and the ULPI_RUN bit is a 1. Poll the ULPI Viewport until ULPI_RUN is zero for the operation to complete. Once ULPI_RUN is zero, the ULPI_DATA_RD will be valid if the operation was a read.

The polling method above can be changed to interrupt driven using the ULPI interrupt defined in the USBSTS and USBINTR registers. When a wakeup or read/write operation is complete, the ULPI_INT interrupt will be set.

There are several optional features that may need to be enabled or disabled by system software as part of system configuration. These bits are contained in the Interface and OTG Control registers of the ULPI PHY register set. These registers also contain bits which are controlled by the link dynamically and therefore should be only modified by system software using the Set/Clear access method. Direct writes to these registers could have harmful side effects to the standard USB operations. The optional bits are as follows: Bits 3 through 7 in the Interface Control register and Bits 6 and 7 in the OTG Control register.

Refer to the ULPI Specification Revision 1.1 for further information on the use of the optional features.

Offset: 0x160 | Read/Write: R/W | Reset: 0b000xx00000000000xxxxxxxx00000000

Bit	R/W	Reset	Description
31	RW	0x0	ULPI_WAKEUP: ULPI Wakeup. Writing the 1 to this bit will begin the wakeup operation. The bit will automatically transition to 0 after the wakeup is complete. Once this bit is set, the driver cannot set it back to 0. Note: The driver must never execute a wakeup and a read/write operation at the same time. 0 = CLEAR 1 = SET
30	RW	0x0	ULPI_RUN: ULPI read/write Run. Writing the 1 to this bit will begin the read/write operation. The bit will automatically transition to 0 after the read/write is complete. Once this bit is set, the driver cannot set it back to 0. Note: The driver must never execute a wakeup and a read/write operation at the same time. 0 = CLEAR 1 = SET
29	RW	0x0	ULPI_RD_WR: ULPI read/write control. (0) Read; (1) Write. This bit selects between running a read or write operation. 0 = READ 1 = WRITE
27	RO	X	ULPI_SYNC_STATE: ULPI sync state. (1) Normal Sync. State. (0) In another state (i.e., Carkit, serial, low power). This bit represents the state of the ULPI interface. 0 = NOT_NORMAL 1 = NORMAL
26:24	RW	0x0	ULPI_PORT: ULPI PHY port number. This field should be always written as 0.
23:16	RW	0x0	ULPI_REG_ADDR: ULPI PHY register address. When doing a read or write operation to the ULPI PHY, the address of the ULPI PHY register being accessed is written to this field.
15:8	RO	X	ULPI_DATA_RD: ULPI PHY data read. The data from the ULPI PHY register can be read from here after the read operation completes.
7:0	RW	0x0	ULPI_DATA_WR: ULPI PHY data write. The data to write to the ULPI PHY register is written here.

23.9.7.25 USB2_CONTROLLER_2_USB2D_PORTSC1_0

USB2D Port Status/Control 1 Register

Offset: 0x174 | Read/Write: R/W | Reset: 0b0000000xx0000000xxx1xx00x0xx010x

Bit	R/W	Reset	Description
31:25	RW	0x0	DA: Device Address. Default = 0000000b. The 7-bit USB device address for the device attached to an immediately downstream of the associated root port. A value of zero indicates no device is present or software support for this feature is not present. This is used by the Controller when sending the LPM token. This field is only valid when the core is operating in host mode. If in device mode, it will be read only and always equal to 0000000b.

Bit	R/W	Reset	Description
24:23	RO	X	SSTS: Suspend Status. Default = 00b. These two bits are used by software to determine whether an L1-based suspend request was successful, specifically: 00b - L1 state entered with success. ACK received from peripheral. 01b - NYET received from peripheral. It was not able to enter L1 state this time. 10b - L1 state not supported by peripheral. STALL received. 11b - Peripheral did not respond or an error occurred. The value of this field is only valid when the port resides in the L0 state - that is, the meaning of these bits is invalid whenever bit 7 of this register (SUSP) is one. Ideally, the Controller driver should read this register if it receives an interrupt after issuing a suspend using L1 support. In case of a non-success a port change interrupt will be fired and this field should be checked for a possible L1 failure. This field is only valid when the core is operating in host mode. If in device mode it will be always equal to 00b. 0 = L1STATE_ENTERED 1 = NYET_PERIPH 2 = L1STATE_NOT_SUPPORTED 3 = PERIPH_NORESP_ERR
22	RW	0x0	WKOC: Default = 0b. Wake on Over-current Enable: Writing this bit to a one enables the port to be sensitive to over-current conditions as wake-up events. This field is zero if Port Power (PP) is zero. This bit should only be used when operating in Host mode. Writing this bit to 1 while the controller is working in device mode can result in undefined behavior. 0 = DISABLE 1 = ENABLE
21	RW	0x0	WKDS: Wake on Disconnect Enable: Writing this bit to a one enables the port to be sensitive to device disconnects as wake-up events. This field is zero if Port Power (PP) is zero or in device mode. This bit should only be used when operating in Host mode. Writing this bit to 1 while the controller is working in device mode can result in undefined behavior. This bit should not be written to 1 if there is no device connected. After the device disconnect is detected, this bit should be cleared to 0. 0 = DISABLE 1 = ENABLE
20	RW	0x0	WKCN: Wake on Connect Enable: Writing this bit to a one enables the port to be sensitive to device connects as wake-up events. This field is zero if Port Power (PP) is zero or in device mode. This bit should only be used when operating in Host mode. Writing this bit to 1 while the controller is working in device mode can result in undefined behavior. This bit should not be written to 1 while the device is connected. After the device connection is detected, this bit should be cleared to 0. 0 = DISABLE 1 = ENABLE
19:16	RW	0x0	PTC: Port Test Control: Any value other than zero indicates that the port is operating in test mode. Value Specific Test. 0000b: Not enabled. 0001b: J_ STATE. 0010b: K_STATE. 0011b: SEQ_NAK. 0100b: Packet. 0101b: FORCE_ENABLE. 0110b to 1111b: Reserved. Refer to Chapter 7 of the USB Specification Revision 2.0 for details on each test mode. 0 = NORMAL_OP 1 = TEST_J 2 = TEST_K 3 = TEST_SE0_NAK 4 = TEST_PKT 5 = TEST_FORCE_ENABLE
15:14	RO	X	PIC: Port Indicator Control: This field is not supported in the current implementation. Please use a GPIO if you wish to use Port Indicators.
13	RO	X	PO: Port Owner. Port owner handoff is not implemented in this design, therefore this bit will always be 0.

Bit	R/W	Reset	Description
12	RW	0x1	PP: Port Power: The function of this bit depends on the value of the Port Power Switching (PPC) field in the HCSPARAMS register. The behavior is as follows: PPC PP Operation 0b 0b Read Only. A device controller with no OTG capability does not have port power control switches. 1b 1b/0b RW. Host/OTG controller requires port power control switches. This bit represents the current setting of the switch (0=off, 1=on). When power is not available on a port (i.e., PP equals a 0), the port is non-functional and will not report attaches, detaches, etc. When an over-current condition is detected on a powered port and PPC is a one, the PP bit in each affected port may be transitioned by the host controller driver from a one to a zero (removing power from the port). 0 = NOT_POWERED 1 = POWERED
11:10	RO	X	LS: Line state. These bits reflect the current logical levels of the D+ (bit 10) and D- (bit 11) signal lines. The encoding of the bits is: 00b = SE0 01b = J-state 10b = K-state 11b = Undefined The value of this field is undefined if Port Power (PP) is zero in host mode. In host mode, the use of line-state by the host controller driver is not necessary (unlike EHCI), because the port controller state machine and the port routing manage the connection of LS and FS. In device mode, the use of line-state by the device controller driver is not necessary. 0 = SE0 1 = J_STATE 2 = K_STATE 3 = UNDEFINED
9	RW	0x0	SLP: Suspend using L1 - RW. Default = 0b. When this bit is set to '1' and a non-zero Device Address (DA) is specified Controller will instigate L1 entry during suspend (bit 7) and L1 exit during resume (bit 6). When set to zero the Controller will use the legacy (L2) mechanism. Software should only set this bit when the device attached immediately downstream supports L1 transitions. When acting as device, this bit is read-only and set to '1' by the hardware when the Controller enters is L1 state (LPM token received and accepted). Note: HSP is redundant with PSPD(27:26). This bit is not defined in the EHCI specification.
8	RW	0x0	PR: This field is zero if Port Power (PP) is zero. In Host Mode: Read/Write. 1=Port is in Reset. 0=Port is not in Reset. When software writes a one to this bit the bus-reset sequence as defined in the USB Specification Revision 2.0 is started. This bit will automatically change to zero after the reset sequence is complete. This behavior is different from EHCI where the host controller driver is required to set this bit to a zero after the reset duration is timed in the driver. In Device Mode: This bit is a read only status bit. Device reset from the USB bus is also indicated in the USBSTS register. 0 = NOT_USB_RESET 1 = USB_RESET

Bit	R/W	Reset	Description
7	RO	X	SUSP: Port suspend. 1=Port in suspend state. 0=Port not in suspend state. In Host Mode: Read/Write. Port Enabled Bit and Suspend bit of this register define the port states as follows: Bits [Port Enabled, Suspend] Port State 0x Disable 10 Enable 11 Suspend When in suspend state, downstream propagation of data is blocked on this port, except for port reset. The blocking occurs at the end of the current transaction if a transaction was in progress when this bit was written to 1. In the suspend state, the port is sensitive to resume detection. Note that the bit status does not change until the port is suspended and that there may be a delay in suspending a port if there is a transaction currently in progress on the USB. The host controller will unconditionally set this bit to zero when software sets the Force Port Resume bit to zero. A write of zero to this bit is ignored by the host controller. If host software sets this bit to a one when the port is not enabled (i.e., Port enabled bit is a zero) the results are undefined. This field is zero if Port Power (PP) is zero in host mode. In Device Mode: Read Only. This bit is a read only status bit. 0 = NOT_SUSPEND 1 = SUSPEND
6	RW	0x0	FPR: Force Port Resume. 1= Resume detected/driven on port. 0=No resume (K state) detected/driven on port. In Host Mode: Software sets this bit to one to drive resume signaling. The Host Controller sets this bit to one if a J-to-K transition is detected while the port is in the Suspend state. When this bit transitions to a one because a J-to-K transition is detected, the Port Change Detect bit in the USBSTS register is also set to one. This bit will automatically change to zero after the resume sequence is complete. This behavior is different from EHCI where the host controller driver is required to set this bit to a zero after the resume duration is timed in the driver. Note that when the Host controller owns the port, the resume sequence follows the defined sequence documented in the USB Specification Revision 2.0. The resume signaling (Full-speed 'K') is driven on the port as long as this bit remains a one. This bit remains a one until the port has switched to the high-speed idle. Writing a zero has no effect because the port controller will time the resume operation to clear the bit when the port control state switches to HS or FS idle. This field is zero if Port Power (PP) is zero in host mode. This bit is not-EHCI compatible. In Device mode: After the device has been in Suspend State for 5ms or more, software must set this bit to one to drive resume signaling before clearing. The Device Controller will set this bit to one if a J-to-K transition is detected while the port is in the Suspend state. The bit will be cleared when the device returns to normal operation. Also, when this bit transitions to a one because a J-to-K transition is detected, the Port Change Detect bit in the USBSTS register is also set to one. Software should ensure that the PHY clock is operational before writing a 1 to this bit to start the resume sequence. This is true for both Device and Host modes. 0 = NO_RESUME 1 = RESUME
5	RO	X	OCC: Over-current Change: Not supported 0 = NO_CHANGE 1 = CHANGE
4	RO	X	OCA: Over-current Active: Not supported 0 = NO_OVER_CURRENT 1 = OVER_CURRENT
3	RW	0x0	PEC: Port Enable/Disable Change: 1=Port enabled/disabled status has changed. 0=No change. In Host Mode: For the root hub, this bit gets set to a one only when a port is disabled due to disconnect on the port or due to the appropriate conditions existing at the EOF2 point (See Chapter 11 of the USB Specification). Software clears this by writing a one to it. This field is zero if Port Power (PP) is zero. In Device mode: The device port is always enabled. (This bit will be zero) 0 = NO_CHANGE 1 = CHANGE
2	RW	0x1	PE: Port Enabled/Disabled: 1=Enable. 0=Disable (default) In Host Mode: Ports can only be enabled by the host controller as a part of the reset and enable. Software cannot enable a port by writing a one to this field. Ports can be disabled by either a fault condition (disconnect event or other fault condition) or by the host software. Note that the bit status does not change until the port state actually changes. There may be a delay in disabling or enabling a port due to other host controller and bus events. When the port is disabled, (0b)

Bit	R/W	Reset	Description
			downstream propagation of data is blocked except for reset. This field is zero if Port Power (PP) is zero in host mode. In Device Mode: The device port is always enabled. (This bit will be one) 0 = PORT_DISABLED 1 = PORT_ENABLED
1	RW	0x0	CSC: Connect Status Change: 1 =Change in Current Connect Status. 0=No change (default). In Host Mode: Indicates a change has occurred in the port's Current Connect Status. The host/device controller sets this bit for all changes to the port device connect status, even if system software has not cleared an existing connect status change. For example, the insertion status changes twice before system software has cleared the changed condition, hub hardware will be 'setting' an already-set bit (i.e., the bit will remain set). Software clears this bit by writing a one to it. This field is zero if Port Power (PP) is zero in host mode. This bit is undefined in device controller mode. 0 = NO_CHANGE 1 = CHANGE
0	RO	X	CCS: Current Connect Status: In Host Mode: 1=Device is present on port. 0=No device is present (default). This value reflects the current state of the port, and may not correspond directly to the event that caused the Connect Status Change bit (Bit 1) to be set. This field is zero if Port Power (PP) is zero in host mode. In Device Mode: 1=Attached 0=Not Attached (default) A one indicates that the device successfully attached and is operating in either high speed or full speed as indicated by the High Speed Port bit in this register. A zero indicates that the device did not attach successfully or was forcibly disconnected by the software writing a zero to the Run bit in the USBCMD register. It does not state the device being disconnected or suspended. 0 = NOT_CONNECTED 1 = CONNECTED

23.9.7.26 USB2_CONTROLLER_2_USB2D_HOSTPC1_DEVLC_0

USB2D Device Mode LPM Behavior and Control Register

This register controls the LPM behavior and controls the behavior of each USB port in device mode only. This register shares the same address with the HOSTPC1 register (which is used only in host mode).

USB2D Host Mode LPM Behavior and Control Register

This register controls the LPM behavior and controls the behavior of each USB port in host mode only. This register shares the same address with the DEVLC register (which is used only in device mode).

Offset: 0x1b4 | Read/Write: R/W | Reset: 0b0000xxx0000000000000xxxxxxxxxxx0

Bit	R/W	Reset	Description
31:29	RW	0x0	PTS: Parallel transceiver select. This bit is not defined in the EHCI specification. 0 = UTMI 1 = RESERVED 2 = ULPI 3 = ICUSB_SER 4 = HSIC
28	RW	0x0	STS: Serial transceiver not selected. This is the only value supported. This bit is not defined in the EHCI specification. 0 = PARALLEL_IF 1 = SERIAL_IF
27	RO	X	PTW: Parallel Transceiver Width. Fixed to 0. This bit is not defined in the EHCI specification. 0 = EIGHT_BIT 1 = RESERVED

Bit	R/W	Reset	Description
26:25	RO	X	PSPD: This register field indicates the speed at which the port is operating. 00 = Full Speed 01 = Low Speed 10 = High Speed. This bit is not defined in the EHCI specification. 0 = FULL_SPEED 1 = LOW_SPEED 2 = HIGH_SPEED 3 = RESERVED
24	RW	0x0	ALPD: Auto Low Power While Disconnect - RW. Default = 0b. If set, this feature will be enabled and every time the port enters the disconnect state it will also enter in low power state, disabling the transceiver clock. The behavior will be same as if the PHCD bit was enabled(in fact this bit will be set to 1 as soon as low power mode is enabled).When this field is set the WKCN field of PORTSCx register(Wake on Connect Enable) will also be set. This way the core will wake up in case a connect is detected. There will be a delay between the detection of a disconnect and actually enter in low power mode. This delay can be controlled by writing to the ALPDD field in the USBMODE register. 0 = DONT_AUTO_LOW_POWER_WHILE_DISCONNECT 1 = AUTO_LOW_POWER_WHILE_DISCONNECT
23	RW	0x0	PFSC: Port Force Full Speed Connect - RW. Default = 0b. Writing this bit to a '1b' will force the port to only connect at Full Speed. It disables the chirp sequence that allows the port to identify itself as High Speed. This is useful for testing FS configurations with an HS host, hub or device. This bit is not defined in the EHCI specification. 0 = DONT_FORCE_FULL_SPEED 1 = FORCE_FULL_SPEED
22	RW	0x0	PHCD: PHY Low Power Suspend - Clock disable: Writing this bit to a 1 will disable the PHY clock. Write a 0 enables it. Reading this bit will indicate the status of the PHY clock. NOTE: The PHY clock cannot be disabled if it is being used as the system clock. In device mode, the PHY can be put into Low Power Clock Disable when the device is not running (USBCMD RS=0b) or the host has signaled suspend (PORTSCx SUSP=1b). Low Power Clock Disable will be cleared automatically when the host has signaled resume. Before forcing a resume from the device, the Controller driver must clear this bit. In host mode, the PHY can be put into Low Power Suspend Clock Disable when the downstream device has been put into suspend mode or when no downstream device is connected. Low Power Clock Disable is completely under the control of software. 0 = DISABLE 1 = ENABLE
21:20	RW	0x0	LPMX: Auto LPM set. Default = 00b. This bit field is valid during Host Mode Only. For Device Mode, this is reserved. Value Meaning 00b Disables auto LPM. 01b If there is no activity for a certain number of SOFs the controller will send an LPM token, enter in suspend and issue a port change interrupt. 10b Same as above but without issuing an interrupt. 11b Reserved for futures LPM enhancements. The detection of no activity is based on the absence of response from the downstream device. Because of this limitation this feature should not be used if ISO OUT endpoints are being used (as no handshake is expected).
17	RW	0x0	ASUS: Auto Low Power. Default = 0b. This bit field is valid during Device Mode Only. In Host Mode it is part of ELPM field. This bit is used to control the auto low power feature. If set, the auto low power feature will be enabled and every time the port enters the suspend state, it will also enter the low power state, disabling the transceiver clock. The behavior will be the same as if the PHCD bit was enabled (in fact this bit will be set to '1' as soon as low power mode is enabled). 0 = DISABLE 1 = ENABLE
19:16	RW	0x0	EPLPM: Endpoint for LPM token. Default = 0000b. This bit field is valid during Host Mode only. For Device Mode, bits [19:18] are reserved and bit 17 is ASUS, while bit 16 is STL. This sets the endpoint number to which the LPM token will be sent. It will be directly mapped to the ENDP field in the LPM token with the EXT PID.

Bit	R/W	Reset	Description
16	RW	0x0	STL: STALL reply to LPM token. Default = 0b. This bit field is valid during Device Mode only. In Host Mode it is a part of ELPM field. When this bit is set to '1', the Controller will reply always with STALL to all incoming LPM tokens. This bit overrides the LPM NYET bit (NYT). 0 = DISABLE 1 = ENABLE
15:12	RW	0x0	LPMFRM: Auto LPM SOF Threshold. Default = 0000b. This bit field is valid during Host Mode only. For Device Mode, this is reserved. This holds the SOF counter threshold. When the number of SOF with no activity in between reaches this threshold and the auto LPM is enabled, an LPM token will be sent and the port will enter in suspend state. The SOF counter for this threshold is incremented each 125 µs, even if the port is not in HS operation.
11:1	RO	X	BA: BmAttributes . Default = 00000000000b. This holds the bmAttributes field of the LPM sub-token received, after the EXT PID token.
0	RW	0x0	NYT_ASUS: NYET reply to LPM token. Default = 0b. This bit is NYT during Device Mode. Details follow: When this bit is to '1', the device controller will NYET all the LPM tokens. When this bit is set to '0', the Controller will ACK all the LPM tokens if the STALL bit (STL) is also set to '0'. This bit is ASUS in Host Mode. Details follow: This bit is used to control the auto low power feature. If set, the auto low power feature will be enabled and every time the port enters in suspend state it will also enter in low power state, disabling the transceiver clock. The behavior will be the same as if the PHCD bit was enabled (in fact this bit will be set to '1' as soon as low power mode is enabled). 0 = DISABLE 1 = ENABLE

23.9.7.27 USB2_CONTROLLER_2_USB2D_OTGSC_0

USB2D On-The-Go (OTG) Status and Control Register

Offset: 0x1f4 | Read/Write: R/W | Reset: 0bx0000000x0000000xxxxxxxxxx000x00

Bit	R/W	Reset	Description
30	RW	0x0	DPIE: Data Pulse Interrupt Enable. Setting this bit enables the Data pulse interrupt. 0 = DISABLE 1 = ENABLE
29	RW	0x0	ONEMSE: 1 millisecond timer Interrupt enable. Setting this bit enables the 1 millisecond timer interrupt. 0 = DISABLE 1 = ENABLE
28	RW	0x0	BSEIE: B Session End Interrupt Enable. Setting this bit enables the B session end interrupt 0 = DISABLE 1 = ENABLE
27	RW	0x0	BSVIE: B Session Valid Interrupt Enable. Setting this bit enables the B session valid interrupt 0 = DISABLE 1 = ENABLE
26	RW	0x0	ASVIE: A Session Valid Interrupt Enable. Setting this bit enables the A session valid interrupt 0 = DISABLE 1 = ENABLE
25	RW	0x0	AVVIE: A VBus Valid Interrupt Enable. Setting this bit enables the A VBus valid interrupt 0 = DISABLE 1 = ENABLE
24	RW	0x0	IDIE: USB ID Interrupt Enable. Setting this bit enables the USB ID interrupt 0 = DISABLE 1 = ENABLE
22	RW	0x0	DPIS: Data Pulse Interrupt Status. This bit is set when data bus pulsing occurs on DP or DM. Data bus pulsing is only detected when USBMODE.CM = Host (11) and PORTSC(0).PortPower = Off (0). Software writes a 1 to clear this bit. 0 = INT_CLEAR 1 = INT_SET

Bit	R/W	Reset	Description
21	RW	0x0	ONEMSS: 1 millisecond timer Interrupt Status: This bit is set once every millisecond. Software writes a 1 to clear it. 0 = INT_CLEAR 1 = INT_SET
20	RW	0x0	BSEIS: B Session End Interrupt Status. This bit is set when VBus has fallen below the B session end threshold. Software writes a 1 to clear this bit . 0 = INT_CLEAR 1 = INT_SET
19	RW	0x0	BSVIS: B Session Valid Interrupt Status. This bit is set when VBus has either risen above or fallen below the B session valid threshold (0.8 VDC). Software writes a 1 to clear this bit. 0 = INT_CLEAR 1 = INT_SET
18	RW	0x0	ASVIS: A Session Valid Interrupt Status. This bit is set when VBus has either risen above or fallen below the A session valid threshold (0.8 VDC). Software writes a one to clear this bit. 0 = INT_CLEAR 1 = INT_SET
17	RW	0x0	AVVIS: A VBus Valid Interrupt Status. This bit is set when VBus has either risen above or fallen below the VBus valid threshold (4.4 VDC) on an A device. Software writes a 1 to clear this bit. 0 = INT_CLEAR 1 = INT_SET
16	RW	0x0	IDIS: USB ID Interrupt Status. This bit is set when a change on the ID input has been detected. Software writes a 1 to clear this bit. 0 = INT_CLEAR 1 = INT_SET
14	RO	X	DPS: Data Bus Pulsing Status. A 1 indicates data bus pulsing is being detected on the port. 0 = STS_CLEAR 1 = STS_SET
13	RO	X	ONEMST: 1 millisecond timer toggle. This bit toggles once per millisecond 0 = STS_CLEAR 1 = STS_SET
12	RO	X	BSE: B session End. Indicates VBus is below the B session end threshold 0 = STS_CLEAR 1 = STS_SET
11	RO	X	BSV: B Session Valid. Indicates VBus is above the B session valid threshold 0 = STS_CLEAR 1 = STS_SET
10	RO	X	ASV: A Session Valid. Indicates VBus is above the A session valid threshold 0 = STS_CLEAR 1 = STS_SET
9	RO	X	AVV: A VBus Valid. Indicates VBus is above the A VBus valid threshold 0 = STS_CLEAR 1 = STS_SET
8	RO	X	ID: USB ID: 0 = A-device 1 = B-device 0 = A_DEV 1 = B_DEV
5	RW	0x0	IDPU: USB ID Pullup 0 = CLEAR 1 = SET
4	RW	0x0	DP: Data Pulsing. Setting this bit causes the pull-up on DP to be asserted for data pulsing during SRP. 0 = NO_DATA_PULSE 1 = DATA_PULSE
3	RW	0x0	OT: OTG Termination. This bit must be set when the OTG device is in device mode, this controls the pulldown on DM. 0 = NO_OTG_TERM 1 = OTG_TERM

Bit	R/W	Reset	Description
1	RW	0x0	VC: VBUS Charge. Setting this bit causes the VBus line to be charged. This is used for VBus pulsing during SRP. 0 = NO_VBUS_CHRG 1 = VBUS_CHRG
0	RW	0x0	VD: VBUS_Discharge. Read/write. Setting this bit causes Vbus to discharge through a resistor. 0 = NO_VBUS_DISCHRG 1 = VBUS_DISCHRG

23.9.7.28 USB2_CONTROLLER_2_USB2D_USBMODE_0

USB2D USB Device Mode Register

Offset: 0x1f8 | Read/Write: R/W | Reset: 0b00000000000000000xxxxxxxxx0xxxxx

Bit	R/W	Reset	Description
31:16	RW	0x0	ALPDD: Auto Low Power While Disconnect Delay, Used when the ALPD field of the HOSTPCx register is set. Defines the delay between disconnect detection and entering in low power mode. The delay is <this register value>*64*100/3 in milliseconds. The maximum value is 65535*64*100/3 = 139,808 ms. The minimum value is 0. Only used in host mode.
15	RW	0x0	SRT: Shorten USB Reset Time. Software should never set this bit to 1.
5	RW	0x0	VBPS: VBUS Power Select This can be used by logic that selects between an on-chip Vbus power source (charge pump) and an off-chip source in systems when both are available. Only to be used in Host Mode. No functionality is implemented for this, so software should not use this.
4	RO	X	SDIS: Stream disable: 1 Streaming is disabled - helpful to avoid overruns/underruns when system load is too high. 0 = STREAM_ENABLE 1 = STREAM_DISABLE
3	RO	X	SLOM: Setup Lockout Mode: In device mode, this bit controls the behavior of the setup lockout mechanism. 0 - Setup lockout is ON (default) 1 - Setup lockout is OFF. Firmware requires the use of setup tripwire semaphore in USB2D_USBCMD register. 0 = LOCKOUT_ON 1 = LOCKOUT_OFF
2	RO	X	ES: Endian Select: Note: For this implementation, this should be always set to 0 (little endian). 0 = LITTLE_ENDIAN 1 = RESERVED
1:0	RO	X	CM: Controller Mode: The controller mode will default to an idle state and will need to be initialized to the desired operating mode after reset. This register can only be written once after reset. If it is necessary to switch modes, software must reset the controller by writing to the RESET bit in the USBCMD register before reprogramming this register. 00 = Idle [Default] 01 = Reserved 10 = Device Controller 11 = Host Controller. 0 = IDLE 1 = RESERVED 2 = DEVICE_MODE 3 = HOST_MODE

23.9.7.29 USB2_CONTROLLER_2_USB2D_ENDPTNAK_0

USB2D Endpoint NAK Register

Offset: 0x200 | Read/Write: R/W | Reset: 0b00000000000000000000000000000000

Bit	Reset	Description
31:16	0x0	EPTN: TX Endpoint NAK R/WC. Each TX endpoint has 1 bit in this field. The bit is set when the device sends a NAK handshake on a received IN token for the corresponding endpoint. 0 = CLEAR 1 = SET
15:0	0x0	EPRN: RX Endpoint NAK R/WC. Each RX endpoint has 1 bit in this field. The bit is set when the device sends a NAK handshake on a received OUT or PING token for the corresponding endpoint. 0 = CLEAR 1 = SET

23.9.7.30 USB2_CONTROLLER_2_USB2D_ENDPTNAK_ENABLE_0

USB2D Endpoint NAK Enable Register

Offset: 0x204 | Read/Write: R/W | Reset: 0b00000000000000000000000000000000

Bit	Reset	Description
31:16	0x0	EPTNE: TX Endpoint NAK Enable R/W. Each bit is an enable bit for the corresponding TX Endpoint NAK bit. If this bit is set and the corresponding TX Endpoint NAK bit is set, the NAK Interrupt bit is set. 0 = DISABLE 1 = ENABLE
15:0	0x0	EPRNE: RX Endpoint NAK Enable R/W. Each bit is an enable bit for the corresponding RX Endpoint NAK bit. If this bit is set and the corresponding RX Endpoint NAK bit is set, the NAK Interrupt bit is set. 0 = DISABLE 1 = ENABLE

23.9.7.31 USB2_CONTROLLER_2_USB2D_ENDPTSETUPSTAT_0

USB2D Endpoint Setup Status Register

Offset: 0x208 | Read/Write: R/W | Reset: 0bxxxxxxxxxxxxxxxx0000000000000000

Bit	Reset	Description
15	0x0	ENDPTSETUPSTAT15: Endpoint 15 Setup Status: For every setup transaction that is received, this bit is set to 1. Software must clear or acknowledge the setup transfer by writing a 1 to it after it has read the setup data from Queue head. The response to a setup packet (as in the order of operations and total response time) is crucial to limit bus time-outs while the setup lock-out mechanism is engaged. This register is only used in device mode. 0 = NOT_RCVD 1 = SETUP_RCVD
14	0x0	ENDPTSETUPSTAT14: Endpoint 14 Setup Status: For every setup transaction that is received, this bit is set to 1. Software must clear or acknowledge the setup transfer by writing a 1 to it after it has read the setup data from Queue head. The response to a setup packet (as in the order of operations and total response time) is crucial to limit bus time-outs while the setup lock-out mechanism is engaged. This register is only used in device mode. 0 = NOT_RCVD 1 = SETUP_RCVD
13	0x0	ENDPTSETUPSTAT13: Endpoint 13 Setup Status: For every setup transaction that is received, this bit is set to 1. Software must clear or acknowledge the setup transfer by writing a 1 to it after it has read the setup data from Queue head. The response to a setup packet (as in the order of operations and total response time) is crucial to limit bus time-outs while the setup lock-out mechanism is engaged. This register is only used in device mode. 0 = NOT_RCVD 1 = SETUP_RCVD

Bit	Reset	Description
12	0x0	ENDPTSETUPSTAT12: Endpoint 12 Setup Status: For every setup transaction that is received, this bit is set to 1. Software must clear or acknowledge the setup transfer by writing a 1 to it after it has read the setup data from Queue head. The response to a setup packet (as in the order of operations and total response time) is crucial to limit bus time-outs while the setup lock-out mechanism is engaged. This register is only used in device mode. 0 = NOT_RCVD 1 = SETUP_RCVD
11	0x0	ENDPTSETUPSTAT11: Endpoint 11 Setup Status: For every setup transaction that is received, this bit is set to 1. Software must clear or acknowledge the setup transfer by writing a 1 to it after it has read the setup data from Queue head. The response to a setup packet (as in the order of operations and total response time) is crucial to limit bus time-outs while the setup lock-out mechanism is engaged. This register is only used in device mode. 0 = NOT_RCVD 1 = SETUP_RCVD
10	0x0	ENDPTSETUPSTAT10: Endpoint 10 Setup Status: For every setup transaction that is received, this bit is set to 1. Software must clear or acknowledge the setup transfer by writing a 1 to it after it has read the setup data from Queue head. The response to a setup packet (as in the order of operations and total response time) is crucial to limit bus time-outs while the setup lock-out mechanism is engaged. This register is only used in device mode. 0 = NOT_RCVD 1 = SETUP_RCVD
9	0x0	ENDPTSETUPSTAT9: Endpoint 9 Setup Status: For every setup transaction that is received, this bit is set to 1. 23.9.7.34 USB2_CONTROLLER_2_USB2D_ENDPTSTATUS_0

USB2D Endpoint Status Register

Offset: 0x214 | Read/Write: RO | Reset: 0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx

Bit	Reset	Description
31	X	ETBR15: Endpoint Transmit Buffer Ready: One bit for each endpoint indicates status of the respective endpoint buffer. This bit is set to a one by the hardware as a response to receiving a command from a corresponding bit in the ENDPTPRIME register. There will always be a delay between setting a bit in the ENDPTPRIME register and endpoint indicating ready. This delay time varies based upon the current USB traffic and the number of bits set in the ENDPTPRIME register. Buffer ready is cleared by USB reset, by the USB DMA system, or through the ENDPTFLUSH register. This is only used in device mode. 0 = NOT_READY 1 = READY
30	X	ETBR14: Endpoint Transmit Buffer Ready: One bit for each endpoint indicates status of the respective endpoint buffer. This bit is set to a one by the hardware as a response to receiving a command from a corresponding bit in the ENDPTPRIME register. There will always be a delay between setting a bit in the ENDPTPRIME register and endpoint indicating ready. This delay time varies based upon the current USB traffic and the number of bits set in the ENDPTPRIME register. Buffer ready is cleared by USB reset, by the USB DMA system, or through the ENDPTFLUSH register. This is only used in device mode. 0 = NOT_READY 1 = READY
29	X	ETBR13: Endpoint Transmit Buffer Ready: One bit for each endpoint indicates status of the respective endpoint buffer. This bit is set to a one by the hardware as a response to receiving a command from a corresponding bit in the ENDPTPRIME register. There will always be a delay between setting a bit in the ENDPTPRIME register and endpoint indicating ready. This delay time varies based upon the current USB traffic and the number of bits set in the ENDPTPRIME register. Buffer ready is cleared by USB reset, by the USB DMA system, or through the ENDPTFLUSH register. This is only used in device mode. 0 = NOT_READY 1 = READY
28	X	ETBR12: Endpoint Transmit Buffer Ready: One bit for each endpoint indicates status of the respective endpoint buffer. This bit is set to a one by the hardware as a response to receiving a command from a corresponding bit in the ENDPTPRIME register. There will always be a delay between setting a bit in the ENDPTPRIME register and endpoint indicating ready. This delay time varies based upon the current USB traffic and the number of bits set in the ENDPTPRIME register. Buffer ready is cleared by USB reset, by the USB DMA system, or through the ENDPTFLUSH register. This is only used in device mode. 0 = NOT_READY 1 = READY
27	X	ETBR11: Endpoint Transmit Buffer Ready: One bit for each endpoint indicates status of the respective endpoint buffer. This bit is set to a one by the hardware as a response to receiving a command from a corresponding bit in the ENDPTPRIME register. There will always be a delay between setting a bit in the ENDPTPRIME register and endpoint indicating ready. This delay time varies based upon the current USB traffic and the number of bits set in the ENDPTPRIME register. Buffer ready is cleared by USB reset, by the USB DMA system, or through the ENDPTFLUSH register. This is only used in device mode. 0 = NOT_READY 1 = READY
26	X	ETBR10: Endpoint Transmit Buffer Ready: One bit for each endpoint indicates status of the respective endpoint buffer. This bit is set to a one by the hardware as a response to receiving a command from a corresponding bit in the ENDPTPRIME register. There will always be a delay between setting a bit in the ENDPTPRIME register and endpoint indicating ready. This delay time varies based upon the current USB traffic and the number of bits set in the ENDPTPRIME register. Buffer ready is cleared by USB reset, by the USB DMA system, or through the ENDPTFLUSH register. This is only used in device mode. 0 = NOT_READY 1 = READY

Bit	Reset	Description
25	X	ETBR9: Endpoint Transmit Buffer Ready: One bit for each endpoint indicates status of the respective endpoint buffer. This bit is set to a one by the hardware as a response to receiving a command from a corresponding bit in the ENDPTPRIME register. 23.9.8 USB3 Controller Interface Registers

These are used to generate the actual RTL registers for the USB3 controller interface.

23.9.8.1 USB3_IF_USB_SUSP_CTRL_0

USB Suspend Control Register

This register controls the suspend and resume behavior of the USB controller/PHY.

Offset: 0x400 | Read/Write: R/W | Reset: 0bxxxxx00xxxxx000001001000xx000000

Bit	R/W	Reset	Description
26	RW	0x0	FAST_WAKEUP_RESP: Enable Fast Response from UTMIP PHY for a Remote Wakeup request from device. This is used only for cases where wakeup response needs to be within 1 ms of spec. Used for Host mode ONLY. 0 = DISABLE 1 = ENABLE
25	RW	0x0	UTMIP_SUSPL1_SET: Enable SuspendL1 for UTMIP PHY. Enabling this will only cut off clocks to the UTMIP logic. The USB PLLs, PllU and UTMIP PLL will still be running. 0 = DISABLE 1 = ENABLE
19	RW	0x0	UHSIC_PHY_ENB: Enable UHSIC PHY mode. Set this to 1 if using the UHSIC PHY. Otherwise set this to 0. 0 = DISABLE 1 = ENABLE
18:16	RW	0x0	USB_WAKEUP_DEBOUNCE_COUNT: USB PHY wakeup debounce counter. The USB will debounce any wakeup event by the number of clocks programmed in this counter. A value of 0 results in no debounce.
15	RW	0x0	ICUSB_MOD_CLK_ENB: ICUSB module clock enable. Enables transceiver clock to USB controller when in ICUSB mode. After setting ICUSB_PHY_ENB, software needs to wait until PLLU output is stable before setting ICUSB_MOD_CLK_ENB to ENABLE. This will be reset to DISABLE whenever ICUSB is in suspend. Software needs to enable it after ICUSB comes out of suspend after waiting for PLLU output to be stable again. 0 = DISABLE 1 = ENABLE
14	RW	0x1	UHSIC_RESET: Reset going to UHSIC PHY (active high). This should be set to 1 whenever programming the UHSIC config registers. It should be cleared to 0 after the programming of UHSIC config registers is done. UHSIC config registers should be programmed only once before doing any transactions on UHSIC. The UHSIC PHY registers should be programmed while the UHSIC is in reset. 0 = DISABLE 1 = ENABLE
13	RW	0x0	ICUSB_PHY_ENB: Enable ICUSB PHY mode. Setting this will enable the PLLU output clock when ICUSB is not in suspend mode. 0 = DISABLE 1 = ENABLE
12	RW	0x0	UTMIP_PHY_ENB: Enable UTMIP PHY mode. Set this to 1 if using UTMIP PHY. Otherwise set this to 0. 0 = DISABLE 1 = ENABLE
11	RW	0x1	UTMIP_RESET: Reset going to UTMIP PHY (active high). This should be set to 1 whenever programming the UTMIP config registers. It should be cleared to 0 after the programming of UTMIP config registers is done. UTMIP config registers should be programmed only once before doing any transactions on USB. The UTMIP PHY registers should be programmed while UTMIP is in reset. 0 = DISABLE 1 = ENABLE

Bit	R/W	Reset	Description
10	RW	0x0	USB_SUSP_POL: Polarity of the suspend signal going to the USB PHY. 0 = Active low (default), 1 = Active high. This should not be changed by software. 0 = ACTIVE_LOW 1 = ACTIVE_HIGH
9	RW	0x0	USB_PHY_CLK_VALID_INT_ENB: USB PHY clock valid interrupt enable. If this bit is enabled, interrupt is generated whenever USB clocks are resumed from a suspend. 0 = DISABLE 1 = ENABLE
8	RO	0x0	USB_PHY_CLK_VALID_INT_STS: USB PHY clock valid interrupt status. This bit is set whenever the USB PHY clock is woken up from suspend. Software must write a 1 to clear this bit. 0 = UNSET 1 = SET
7	RO	X	USB_PHY_CLK_VALID: USB PHY clock valid status. This bit indicates whether the USB PHY is generating a valid clock to the USB controller. If USB PHY clock is running, this bit is set to 1, else it is set to 0. 0 = UNSET 1 = SET
6	RO	X	USB_CLKEN: USB AHB clock enable status. Indicates whether the AHB clock to the USB controller is enabled or not. If AHB clock to USB controller is enabled, this bit is set to 1, else it is set to 0. NOTE: Even when this is set to 0, all essential blocks that are required to resume USB clocks from suspend will be active and their AHB clock will not be suspended. 0 = UNSET 1 = SET
5	RW	0x0	USB_SUSP_CLR: Suspend Clear. Software must write a 1 to this bit to bring the PHY out of suspend mode. This is used when the software stops the PHY clock during suspend and then wants to initiate a resume. Software should also write 0 to clear it. NOTE: It is required that software generate a positive pulse on this bit to guarantee proper operation. 0 = UNSET 1 = SET
4	RW	0x0	USB_WAKE_ON_DISCON_EN_DEV: Wake on Disconnect Enable (device mode). When enabled (1), USB device will wake up from suspend on a disconnect event. This is only valid when USB controller is in device mode, it is not applicable when USB controller is in host mode. 0 = DISABLE 1 = ENABLE
3	RW	0x0	USB_WAKE_ON_CNNT_EN_DEV: Wake on Connect Enable (device mode). When enabled (1), USB device will wake up from suspend on a connect event. This is only valid when USB controller is in device mode, it is not applicable when USB controller is in host mode. 0 = DISABLE 1 = ENABLE
2	RW	0x0	USB_WAKE_ON_RESUME_EN: Wake on resume enable. If this bit is enabled, USB will wake up from suspend whenever a resume event is detected on USB. This is valid for both USB device and USB host modes. 0 = DISABLE 1 = ENABLE
1	RW	0x0	USB_WAKEUP_INT_ENB: USB wakeup interrupt enable. If this bit is enabled, interrupt is generated whenever USB wakeup event is generated. 0 = DISABLE 1 = ENABLE
0	RO	0x0	USB_WAKEUP_INT_STS: USB wakeup interrupt status. This bit is set whenever USB wakes up from suspend (a wakeup event is generated). Software must write a 1 to clear this bit. Note that during the wakeup sequence, PHY clocks will be resumed from suspend. Software can check when the PHY clocks are resumed by reading the bit USB_PHY_CLK_VALID. There is also a separate interrupt generated when PHY clock is resumed if USB_PHY_CLK_VALID_INT_EN is set. During the wakeup sequence, first USB_WAKEUP_INT_STS will be set, and it will take some time for the PHY clock to resume, which can be detected by checking USB_PHY_CLK_VALID. 0 = UNSET 1 = SET

23.9.8.2 USB3_IF_USB_PHY_VBUS_SENSORS_0

USB PHY VBUS SENSORS Control Register

This register controls the OTG VBUS sensors in the USB PHY. There are 4 VBUS sensors:

- A_VBUS_VLD
- A_SESS_VLD
- B_SESS_VLD
- B_SESS_END

The debounced status of each sensor can be read from the corresponding _STS bit field of the sensor in this register. The _CHG_DET field is set to 1 whenever a change is detected in the value of the _STS bit field of the corresponding sensor. If _INT_EN is set, then an interrupt is generated to the processor. This interrupt can be routed to CPU/COP by appropriately writing the USBD bits in the interrupt controller registers.

In case software wants to override the value for a sensor, it can set the corresponding _SW_EN to 1, and set the corresponding sensor _SW_VALUE to 1 or 0 as per the requirement.

There are two debouncers for each sensor - DEBOUNCE_A and DEBOUNCE_B. The debounce values for them are controlled by the register UTMIP_DEBOUNCE_CFG0, fields UTMIP_BIAS_DEBOUNCE_A and UTMIP_BIAS_DEBOUNCE_B. For each sensor, we can select whether to use DEBOUNCE_A or DEBOUNCE_B by setting the field _DEB_SEL_B to the appropriate value (SEL_A or SEL_B).

Note: Do not set either UTMIP_BIAS_DEBOUNCE_A or UTMIP_BIAS_DEBOUNCE_B to 0x0. If not using one of the debouncers, keep it at the default value of 0xFFFF.

Offset: 0x404 | Read/Write: R/W | Reset: 0bx0000x00x0000x00x0000x00x0000x00

Bit	R/W	Reset	Description
30	RW	0x0	A_VBUS_VLD_WAKEUP_EN: A_VBUS_VLD wakeup enable. If this bit is enabled, USB will wake up from suspend whenever a change is detected on A_VBUS_VLD. 0 = DISABLE 1 = ENABLE
29	RW	0x0	A_VBUS_VLD_DEB_SEL_B: A_VBUS_VLD debounce A/B select. Selects between the two debounce values UTMIP_BIAS_DEBOUNCE_A or UTMIP_BIAS_DEBOUNCE_B from the register UTMIP_DEBOUNCE_CFG0. 0 = SEL_A 1 = SEL_B
28	RW	0x0	A_VBUS_VLD_SW_VALUE: A_VBUS_VLD software value. Software should write the appropriate value (1/0) to set/unset the A_VBUS_VLD status. This is only valid when A_VBUS_VLD_SW_EN is set. 0 = UNSET 1 = SET
27	RW	0x0	A_VBUS_VLD_SW_EN: A_VBUS_VLD software enable. Enable Software Controlled A_VBUS_VLD. Software sets this bit to drive the value in A_VBUS_VLD_SW_VALUE to the USB controller. 0 = DISABLE 1 = ENABLE

0	RW	0x0	B_SESS_END_INT_EN: B_SESS_END interrupt enable. If this field is set to 1, an interrupt is generated whenever B_SESS_END_CHG_DET is set to 1. 0 = DISABLE 1 = ENABLE

23.9.8.3 USB3_IF_USB_PHY_VBUS_WAKEUP_ID_0

USB PHY VBUS Wakeup and ID Control Register

This register controls the battery charger (VDCD_DET, VDAT_DET), VBUS_WAKEUP, and ID sensors. The following sensors are in this register:

- VBUS_WAKEUP
- ID
- VDAT_DET
- VDCD_DET

The debounced status of each sensor can be read from the corresponding _STS bit field of the sensor in this register. The _CHG_DET field is set to 1 whenever a change is detected in the value of the _STS bit field of the corresponding sensor. If _INT_EN is set, then an interrupt is generated to the processor. This interrupt can be routed to CPU/COP by appropriately writing the USBD bits in the interrupt controller registers.

In case software wants to override the value for a sensor, it can set the corresponding _SW_EN to 1, and set the corresponding sensor _SW_VALUE to 1 or 0 as per the requirement.

There are two debouncers for each sensor - DEBOUNCE_A and DEBOUNCE_B. The debounce values for them are controlled by the register UTMIP_DEBOUNCE_CFG0, fields UTMIP_BIAS_DEBOUNCE_A and UTMIP_BIAS_DEBOUNCE_B. For each sensor, we can select whether to use DEBOUNCE_A or DEBOUNCE_B by setting the field _DEB_SEL_B to the appropriate value (SEL_A or SEL_B).

Note: Do not set either UTMIP_BIAS_DEBOUNCE_A or UTMIP_BIAS_DEBOUNCE_B to 0x0. If not using one of the debouncers, keep it at the default value of 0xFFFF.

There are debouncers for VDAT_DET and VDCD_DET. These use separate debouncers - CHRG_DEBOUNCE_PERIOD_A and CHRG_DEBOUNCE_PERIOD_B. The debounce values for them are controlled by the register UTMIP_CHRG_DEB_CFG0, fields UTMIP_CHRG_DEBOUNCE_PERIOD_A and UTMIP_CHRG_DEBOUNCE_PERIOD_B. For each sensor, we can select whether to use HRG_DEBOUNCE_PERIOD_A or CHRG_DEBOUNCE_PERIOD_B by setting the field _DEB_SEL_B to the appropriate value (SEL_A or SEL_B).

Note: Do not set either UTMIP_CHRG_DEBOUNCE_PERIOD_A or UTMIP_CHRG_DEBOUNCE_PERIOD_B to 0x0. If not using one of the debouncers, keep it at the default value of 0xFFFF.

23.9.9 XUSB Host Registers

23.9.9.1 XUSB_HOST_AXI_BAR0_SZ_0

Offset: 0x0 | Read/Write: R/W | Reset: 0x00000008 (0bxxxxxxxxxxxx00000000000000001000)

Bit	Reset	Description
19:0	0x8	AXI_BAR0_SIZE: The size of the address range associated with BARi is in 4K increments. Value of 0 signifies BARi is not used.

23.9.9.2 XUSB_HOST_AXI_BAR1_SZ_0

Offset: 0x4 | Read/Write: R/W | Reset: 0x00000000 (0bxxxxxxxxxxxx00000000000000000000)

Bit	Reset	Description
19:0	0x0	AXI_BAR1_SIZE: The size of the address range associated with BARi is in 4K increments. Value of 0 signifies BARi is not used.

23.9.9.3 XUSB_HOST_AXI_BAR2_SZ_0

Offset: 0x8 | Read/Write: R/W | Reset: 0x00000000 (0bxxxxxxxxxxxx00000000000000000000)

Bit	Reset	Description
19:0	0x0	AXI_BAR2_SIZE: The size of the address range associated with BARi is in 4K increments. Value of 0 signifies BARi is not used.

23.9.9.4 XUSB_HOST_AXI_BAR3_SZ_0

Offset: 0xc | Read/Write: R/W | Reset: 0x00000000 (0bxxxxxxxxxxxx00000000000000000000)

Bit	Reset	Description
19:0	0x0	AXI_BAR3_SIZE: The size of the address range associated with BARi is in 4K increments. Value of 0 signifies BARi is not used.

23.9.9.5 XUSB_HOST_AXI_BAR0_START_0

Offset: 0x40 | Read/Write: R/W | Reset: 0x70090000 (0b01110000000010010000xxxxxxxxxxxx)

Bit	Reset	Description
31:12	0x70090	AXI_BAR0_START: The start of the AXI address space for BARi. The AXI target address is compared to start/size for each BAR to determine if the access is to that BAR.

23.9.9.6 XUSB_HOST_AXI_BAR1_START_0

Offset: 0x44 | Read/Write: R/W | Reset: 0x00000000 (0b00000000000000000000xxxxxxxxxxxx)

Bit	Reset	Description
31:12	0x0	AXI_BAR1_START: The start of AXI address space for BARi. The AXI target address is compared to start/size for each BAR to determine if the access is to that BAR.

23.9.9.7 XUSB_HOST_AXI_BAR2_START_0

Offset: 0x48 | Read/Write: R/W | Reset: 0x00000000 (0b00000000000000000000xxxxxxxxxxxx)

Bit	Reset	Description
31:12	0x0	AXI_BAR2_START: The start of the AXI address space for BARi. The AXI target address is compared to start/size for each BAR to determine if the access is to that BAR.

23.9.9.8 XUSB_HOST_AXI_BAR3_START_0

Offset: 0x4c | Read/Write: R/W | Reset: 0x00000000 (0b00000000000000000000xxxxxxxxxxxx)

Bit	Reset	Description
31:12	0x0	AXI_BAR3_START: The start of the AXI address space for BARi. The AXI target address is compared to start/size for each BAR to determine if the access is to that BAR.

23.9.9.9 XUSB_HOST_FPCI_BAR0_0

Offset: 0x80 | Read/Write: R/W | Reset: 0x00700901 (0b00000000011100000000010010000xxx1)

Bit	Reset	Description
31:4	0x70090	FPCI_BAR0_START: The start of the FPCI address space mapped into the BARi range of PCI memory space. The 40-bit FPCI address is determined by a 12-bit left shift of the value of this register.
0	0x1	FPCI_BAR0_ACCESS_TYPE: Indicates if the address region is memory mapped versus configuration or I/O space. 0 = memory-mapped access (PW only) 1 = I/O or config access (NPW only)

23.9.9.10 XUSB_HOST_FPCI_BAR1_0

Offset: 0x84 | Read/Write: R/W | Reset: 0x00000001 (0b00000000000000000000000000000xxx1)

Bit	Reset	Description
31:4	0x0	FPCI_BAR1_START: The start of FPCI address space mapped into the BARi range of PCI memory space. The 40-bit FPCI address is determined by a 12-bit left shift of the value of this register.
0	0x1	FPCI_BAR1_ACCESS_TYPE: Indicates if the address region is memory mapped versus configuration or I/O space. 0 = Memory-mapped access (PW only) 1 = I/O or config access (NPW only)

23.9.9.11 XUSB_HOST_FPCI_BAR2_0

Offset: 0x88 | Read/Write: R/W | Reset: 0x00000001 (0b00000000000000000000000000000xxx1)

Bit	Reset	Description
31:4	0x0	FPCI_BAR2_START: The start of FPCI address space mapped into the BARi range of PCI memory space. The 40-bit FPCI address is determined by a 12-bit left shift of the value of this register.
0	0x1	FPCI_BAR2_ACCESS_TYPE: Indicates if the address region is memory mapped versus configuration or I/O space. 0 = Memory-mapped access (PW only) 1 = I/O or config access (NPW only)

23.9.9.12 XUSB_HOST_FPCI_BAR3_0

Offset: 0x8c | Read/Write: R/W | Reset: 0x00000001 (0b00000000000000000000000000000xxx1)

Bit	Reset	Description
31:4	0x0	FPCI_BAR3_START: The start of FPCI address space mapped into the BARi range of PCI memory space. The 40-bit FPCI address is determined by a 12-bit left shift of the value of this register.
0	0x1	FPCI_BAR3_ACCESS_TYPE: Indicates if the address region is memory mapped versus configuration or I/O space. 0 = Memory-mapped access (PW only) 1 = I/O or config access (NPW only)

23.9.9.13 XUSB_HOST_MSI_BAR_SZ_0

MSI BAR SIZE

Offset: 0xc0 | Read/Write: R/W | Reset: 0x00000000 (0bxxxxxxxxxxxxx00000000000000000000)

Bit	Reset	Description
19:0	0x0	MSI_BAR_SIZE: The size of the address range associated with MSI BAR is in 4K increments. Value of 0 signifies BAR is not used.

23.9.9.14 XUSB_HOST_MSI_AXI_BAR_ST_0

MSI AXI BAR START

Offset: 0xc4 | Read/Write: R/W | Reset: 0x00000000 (0b00000000000000000000xxxxxxxxxxxx)

Bit	Reset	Description
31:12	0x0	MSI_AXI_BAR_START: The start of the upstream AXI address space for MSI BAR. The upstream FPCI address is compared to start/1KB range for the MSI BAR to determine if the access is MSI. Bits 31:12 of MSI BAR start correspond to AXI address bits 31:12.

23.9.9.15 XUSB_HOST_MSI_FPCI_BAR_ST_0

MSI FPCI BAR START

Offset: 0xc8 | Read/Write: R/W | Reset: 0x00000000 (0b00000000000000000000000000000xxxx)

Bit	Reset	Description
31:4	0x0	MSI_FPCI_BAR_START: The start of the upstream FPCI address space for MSI BAR. The upstream FPCI address is compared to start/1KB range for MSI BAR to determine if the access is MSI. Bits 31:4 of MSI BAR start correspond to UFPCI address bits 39:12.

23.9.9.16 XUSB_HOST_MSI_VEC0_0

MSI VECTORi, i in [0,7]

Offset: 0x100 | Read/Write: R/W | Reset: 0x00000000 (0b00000000000000000000000000000000)

Bit	Reset	Description
31:0	0x0	MSI_VECTOR0: Each vector register corresponds to 32 of the possible 256 MSI vectors.VECTOR0 corresponds to MSI vectors 31-0. Vector7 corresponds to MSI vectors 255-223.When an upstream MSI is sent, the bit corresponding to the MSI vector is set to 1 by hardware if the corresponding enable bit is 1.The bit is set to 0 if a 1 is written to its location.

23.9.9.17 XUSB_HOST_MSI_VEC1_0

Offset: 0x104 | Read/Write: R/W | Reset: 0x00000000 (0b00000000000000000000000000000000)

Bit	Reset	Description
31:0	0x0	MSI_VECTOR1: Each vector register corresponds to 32 of the possible 256 MSI vectors.VECTOR0 corresponds to MSI vectors 31-0. Vector7 corresponds to MSI vectors 255-223.When an upstream MSI is sent, the bit corresponding to the MSI vector is set to 1 by hardware if the corresponding enable bit is 1.The bit is set to 0 if a 1 is written to its location.

23.9.9.18 XUSB_HOST_MSI_VEC2_0

Offset: 0x108 | Read/Write: R/W | Reset: 0x00000000 (0b00000000000000000000000000000000)

Bit	Reset	Description
31:0	0x0	MSI_VECTOR2: Each vector register corresponds to 32 of the possible 256 MSI vectors.VECTOR0 corresponds to MSI vectors 31-0. Vector7 corresponds to MSI vectors 255-223.When an upstream MSI is sent, the bit corresponding to the MSI vector is set to 1 by hardware if the corresponding enable bit is 1.The bit is set to 0 if a 1 is written to its location.

23.9.9.19 XUSB_HOST_MSI_VEC3_0

Offset: 0x10c | Read/Write: R/W | Reset: 0x00000000 (0b00000000000000000000000000000000)

Bit	Reset	Description
31:0	0x0	MSI_VECTOR3: Each vector register corresponds to 32 of the possible 256 MSI vectors.VECTOR0 corresponds to MSI vectors 31-0. Vector7 corresponds to MSI vectors 255-223.When an upstream MSI is sent, the bit corresponding to the MSI vector is set to 1 by hardware if the corresponding enable bit is 1.The bit is set to 0 if a 1 is written to its location.

23.9.9.20 XUSB_HOST_MSI_VEC4_0

Offset: 0x110 | Read/Write: R/W | Reset: 0x00000000 (0b00000000000000000000000000000000)

Bit	Reset	Description
31:0	0x0	MSI_VECTOR4: Each vector register corresponds to 32 of the possible 256 MSI vectors.VECTOR0 corresponds to MSI vectors 31-0. Vector7 corresponds to MSI vectors 255-223.When an upstream MSI is sent, the bit corresponding to the MSI vector is set to 1 by hardware if the corresponding enable bit is 1.The bit is set to 0 if a 1 is written to its location.

23.9.9.21 XUSB_HOST_MSI_VEC5_0

Offset: 0x114 | Read/Write: R/W | Reset: 0x00000000 (0b00000000000000000000000000000000)

Bit	Reset	Description
31:0	0x0	MSI_VECTOR5: Each vector register corresponds to 32 of the possible 256 MSI vectors.VECTOR0 corresponds to MSI vectors 31-0. Vector7 corresponds to MSI vectors 255-223.When an upstream MSI is sent, the bit corresponding to the MSI vector is set to 1 by hardware if the corresponding enable bit is 1.The bit is set to 0 if a 1 is written to its location.

23.9.9.22 XUSB_HOST_MSI_VEC6_0

Offset: 0x118 | Read/Write: R/W | Reset: 0x00000000 (0b00000000000000000000000000000000)

Bit	Reset	Description
31:0	0x0	MSI_VECTOR6: Each vector register corresponds to 32 of the possible 256 MSI vectors.VECTOR0 corresponds to MSI vectors 31-0. Vector7 corresponds to MSI vectors 255-223.When an upstream MSI is sent, the bit corresponding to the MSI vector is set to 1 by hardware if the corresponding enable bit is 1.The bit is set to 0 if a 1 is written to its location.

23.9.9.23 XUSB_HOST_MSI_VEC7_0

Offset: 0x11c | Read/Write: R/W | Reset: 0x00000000 (0b00000000000000000000000000000000)

Bit	Reset	Description
31:0	0x0	MSI_VECTOR7: Each vector register corresponds to 32 of the possible 256 MSI vectors.VECTOR0 corresponds to MSI vectors 31-0. Vector7 corresponds to MSI vectors 255-223.When an upstream MSI is sent, the bit corresponding to the MSI vector is set to 1 by hardware if the corresponding enable bit is 1.The bit is set to 0 if a 1 is written to its location.

23.9.9.24 XUSB_HOST_MSI_EN_VEC0_0

MSI ENABLE VECTORi, i in [0,7], RW

Offset: 0x140 | Read/Write: R/W | Reset: 0x00000000 (0b00000000000000000000000000000000)

Bit	Reset	Description
31:0	0x0	MSI_ENABLE_VECTOR0: Each vector register corresponds to the enable bit for 32 of the possible 256 MSI vectors. ENABLE VECTOR0 corresponds to enable bits for MSI vectors 31-0. Vector7 corresponds to enable bits for MSI vectors 255-223.When an upstream MSI is sent, the bit corresponding to the MSI vector is set to 1 by hardware if the corresponding enable bit is 1.

23.9.9.25 XUSB_HOST_MSI_EN_VEC1_0

Offset: 0x144 | Read/Write: R/W | Reset: 0x00000000 (0b00000000000000000000000000000000)

Bit	Reset	Description
31:0	0x0	MSI_ENABLE_VECTOR1: Each vector register corresponds to the enable bit for 32 of the possible 256 MSI vectors. ENABLE VECTOR0 corresponds to enable bits for MSI vectors 31-0. Vector7 corresponds to enable bits for MSI vectors 255-223.When an upstream MSI is sent, the bit corresponding to the MSI vector is set to 1 by hardware if the corresponding enable bit is 1.

23.9.9.26 XUSB_HOST_MSI_EN_VEC2_0

Offset: 0x148 | Read/Write: R/W | Reset: 0x00000000 (0b00000000000000000000000000000000)

Bit	Reset	Description
31:0	0x0	MSI_ENABLE_VECTOR2: Each vector register corresponds to the enable bit for 32 of the possible 256 MSI vectors. ENABLE VECTOR0 corresponds to enable bits for MSI vectors 31-0. Vector7 corresponds to enable bits for MSI vectors 255-223.When an upstream MSI is sent, the bit corresponding to the MSI vector is set to 1 by hardware if the corresponding enable bit is 1.

23.9.9.27 XUSB_HOST_MSI_EN_VEC3_0

Offset: 0x14c | Read/Write: R/W | Reset: 0x00000000 (0b00000000000000000000000000000000)

Bit	Reset	Description
31:0	0x0	MSI_ENABLE_VECTOR3: Each vector register corresponds to the enable bit for 32 of the possible 256 MSI vectors. ENABLE VECTOR0 corresponds to enable bits for MSI vectors 31-0. Vector7 corresponds to enable bits for MSI vectors 255-223.When an upstream MSI is sent, the bit corresponding to the MSI vector is set to 1 by hardware if the corresponding enable bit is 1.

23.9.9.28 XUSB_HOST_MSI_EN_VEC4_0

Offset: 0x150 | Read/Write: R/W | Reset: 0x00000000 (0b00000000000000000000000000000000)

Bit	Reset	Description
31:0	0x0	MSI_ENABLE_VECTOR4: Each vector register corresponds to the enable bit for 32 of the possible 256 MSI vectors. ENABLE VECTOR0 corresponds to enable bits for MSI vectors 31-0. Vector7 corresponds to enable bits for MSI vectors 255-223.When an upstream MSI is sent, the bit corresponding to the MSI vector is set to 1 by hardware if the corresponding enable bit is 1.

23.9.9.29 XUSB_HOST_MSI_EN_VEC5_0

Offset: 0x154 | Read/Write: R/W | Reset: 0x00000000 (0b00000000000000000000000000000000)

Bit	Reset	Description
31:0	0x0	MSI_ENABLE_VECTOR5: Each vector register corresponds to the enable bit for 32 of the possible 256 MSI vectors. ENABLE VECTOR0 corresponds to enable bits for MSI vectors 31-0. Vector7 corresponds to enable bits for MSI vectors 255-223.When an upstream MSI is sent, the bit corresponding to the MSI vector is set to 1 by hardware if the corresponding enable bit is 1.

23.9.9.30 XUSB_HOST_MSI_EN_VEC6_0

Offset: 0x158 | Read/Write: R/W | Reset: 0x00000000 (0b00000000000000000000000000000000)

Bit	Reset	Description
31:0	0x0	MSI_ENABLE_VECTOR6: Each vector register corresponds to the enable bit for 32 of the possible 256 MSI vectors. ENABLE VECTOR0 corresponds to enable bits for MSI vectors 31-0. Vector7 corresponds to enable bits for MSI vectors 255-223.When an upstream MSI is sent, the bit corresponding to the MSI vector is set to 1 by hardware if the corresponding enable bit is 1.

23.9.9.31 XUSB_HOST_MSI_EN_VEC7_0

Offset: 0x15c | Read/Write: R/W | Reset: 0x00000000 (0b00000000000000000000000000000000)

Bit	Reset	Description
31:0	0x0	MSI_ENABLE_VECTOR7: Each vector register corresponds to the enable bit for 32 of the possible 256 MSI vectors. ENABLE VECTOR0 corresponds to enable bits for MSI vectors 31-0. Vector7 corresponds to enable bits for MSI vectors 255-223.When an upstream MSI is sent, the bit corresponding to the MSI vector is set to 1 by hardware if the corresponding enable bit is 1.

23.9.9.32 XUSB_HOST_CONFIGURATION_0

Configuration

Offset: 0x180 | Read/Write: R/W | Reset: 0x800X8X00 (0b1xxxxxxxxxxxxxxx10xxxxxx00000000)

Bit	R/W	Reset	Description
31	RW	0x1	CLKEN_OVERRIDE: This can override the clock enable in case of a malfunction.
18	RO	X	INITIATOR_READ_IDLE: This read-only bit provides status reads on AFI upstream A value of 1b indicates there are no outstanding reads to the initiator.
17	RO	X	INITIATOR_WRITE_IDLE: This read-only bit provides status writes on AFI upstream A value of 1b indicates there are no outstanding writes to the initiator.
15	RW	0x1	WDATA_LEAD_CYA: Used to en(dis)able the handling of write data ahead of requests on IPFS AXI target.
14	RW	0x0	WR_INTRLV_CYA: Used to en(dis)able the handling of interleaved write requests on IPFS AXI target.

Bit	R/W	Reset	Description
11	RO	X	TARGET_READ_IDLE: This read-only bit provides status reads to IPFS target. A value of 1b indicates there are no outstanding reads to the downstream FPCI.
10	RO	X	TARGET_WRITE_IDLE: This read-only bit provides status writes to IPFS target. A value of 1b indicates there are no outstanding writes to the downstream FPCI.
9	RO	X	MSI_VEC_EMPTY: This read-only bit provides status on whether MSI Vector registers have any active bits valid or not.
7	RW	0x0	UFPCI_DUAL_CHANNEL_BLOCK: Input to the upstream requests 1 = Enable dual-channel blocking 0 = Disable dual-channel blocking
6	RW	0x0	UFPCI_PWPASSPW: Input to the upstream FPCI 1 = Whenever write is ready, send it. 0 = Write goes only when outstanding PWs outside of new write's region are retired (default).
5	RW	0x0	UFPCI_PASSPW: Input to the upstream FPCI. Allows the upstream FPCI reads to pass writes.
4	RW	0x0	UFPCI_PWPASSNPW: Used for the upstream FPCI. Allows the upstream FPCI PWs to pass NPWs.
3	RW	0x0	DFPCI_PWPASSNPW: Used for the downstream FPCI. Allows the downstream FPCI PWs to pass NPWs.
2	RW	0x0	DFPCI_RSPPASSPW: Input to the downstream FPCI. Allows the downstream FPCI responses to pass writes
1	RW	0x0	DFPCI_PASSPW: Input to the downstream FPCI. Allow the downstream FPCI reads to pass writes.
0	RW	0x0	EN_FPCI: When the IPFS device block is disabled, it is completely invisible on the IPFS bus; i.e., it does not even process IPFS configuration accesses.

23.9.9.33 XUSB_HOST_FPCI_ERROR_MASKS_0

FPCI Error Masks

Offset: 0x184 | Read/Write: R/W | Reset: 0x00000000 (0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx000)

Bit	Reset	Description
2	0x0	MASK_FPCI_MASTER_ABORT: This bit allows an FPCI error to be forwarded to an AXI response when the FPCI error response indicates a Master Abort. 1 = Forward error 0 = Return AXI OKAY response (2'b0)
1	0x0	MASK_FPCI_DATA_ERROR: This bit allows an FPCI error to be forwarded to an AXI response when the FPCI error response indicates a Data Error. 1 = Forward error 0 = Return AXI OKAY response (2'b0)
0	0x0	MASK_FPCI_TARGET_ABORT: This bit allows an FPCI error to be forwarded to an AXI response when FPCI error response indicates a Target Abort. This bit also covers a decode error generated when there is no devsel received. 1 = Forward error 0 = Return AXI OKAY response (2'b0)

23.9.9.34 XUSB_HOST_INTR_MASK_0

Interrupt Masks

Offset: 0x188 | Read/Write: R/W | Reset: 0x00000000 (0bxxxxxxxxxxxxxxxx0xxxxxxx0xxxxxxx0)

Bit	Reset	Description
16	0x0	IP_INT_MASK: IP (SATA/AZA) interrupt to the Cortex™-A15 MPCore™ gated by the mask.
8	0x0	MSI_MASK: MSI to the Cortex-A15 MPCore gated by the mask.
0	0x0	INT_MASK: Interrupt to the Cortex-A15 MPCore gated by the mask.

23.9.9.35 XUSB_HOST_INTR_CODE_0

Interrupt Control

Offset: 0x18c | Read/Write: R/W | Reset: 0x00000000 (0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxx00000)

Bit	Reset	Description
4:0	0x0	INT_CODE: Eight interrupt codes. If the code is 0, logging of the next interrupt is enabled 0 = INT_CODE_CLEAR : Clear interrupt code 1 = INT_CODE_INI_SLVERR: Interrupt code for MPCore AXI SLVERR response to IPFS 2 = INT_CODE_INI_DECERR: Interrupt code for MPCore AXI DECERR response to IPFS 3 = INT_CODE_TGT_SLVERR: Interrupt code for PCIe endpoint FPCI target abort or data error response to IPFS 4 = INT_CODE_TGT_DECERR: Interrupt code for PCIe2 FPCI master abort response to IPFS 5 = INT_CODE_TGT_WRERR: Interrupt code for bufferable write to non-posted write address region 6 = RSVD1: Reserved 7 = INT_CODE_DFPCI_DECERR: Interrupt code for PCIe2 response to downstream request when downstream FPCI address does not fall in a claimable downstream region 8 = INT_CODE_AXI_DECERR: Interrupt code for IPFS response to downstream request when AXI target AXI address does not fall in any IPFS downstream BARs 9 = INT_CODE_FPCI_TIMEOUT: Interrupt code for FPCI Timeout 10 = RSVD2: Reserved for future expansion 11 = RSVD3 12 = RSVD4 13 = RSVD5 14 = RSVD6 15 = INT_CODE_SM_FATAL_ERROR: Interrupt code for SM fatal error 16 = INT_CODE_SM_NON_FATAL_ERROR: Interrupt code for SM non-fatal error

23.9.9.36 XUSB_HOST_INTR_SIGNATURE_0

Interrupt Signature

Offset: 0x190 | Read/Write: R/W | Reset: 0x00000000 (0b00000000000000000000000000000x0)

Bit	Reset	Description
31:2	0x0	INT_INFO: For interrupt codes 1-5/7-8, this field contains address bits [31:2], either in FPCI memory space or AXI space. For FPCI generated errors, the field contains the FPCI address. For AXI/IPFS generated errors, the field contains the AXI address.
0	0x0	DIR: Indicates the direction of the AXI/FPCI transaction. 1=RD/0=WRIF signature type is 6 (sideband message), this field is 1. 0 = WRITE: Interrupt due to a write transaction 1 = READ: Interrupt due to a read transaction

23.9.9.37 XUSB_HOST_UPPER_FPCI_ADDR_0

Upper FPCI Address

Offset: 0x194 | Read/Write: R/W | Reset: 0x00000000 (0bxxxxxxxxxxxxxxxxxxxxxxxx00000000)

Bit	Reset	Description
7:0	0x0	INT_INFO_UPPER: These 8 bits are the upper byte of the captured FPCI address (bits [39:32]) when the interrupt code is 3, 4, or 7. These bits determine the region in the Hypertransport Address Map that was accessed.

23.9.9.38 XUSB_HOST_IPFS_INTR_ENABLE_0

IPFS Interrupt Enable

Offset: 0x198 | Read/Write: R/W | Reset: 0x00000000 (0bxxxxxxxxxxxxxxxxxx00xxxx00000000)

Bit	Reset	Description
13	0x0	EN_SM_NON_FATAL_ERROR: Enable bit for interrupt code 15
12	0x0	EN_SM_FATAL_ERROR: Enable bit for interrupt code 14
7	0x0	EN_FPCI_TIMEOUT: Enable bit for interrupt code 9
6	0x0	EN_AXI_DECERR: Enable bit for interrupt code 8
5	0x0	EN_DFPCI_DECERR: Enable bit for interrupt code 7
4	0x0	EN_TGT_WRERR: Enable bit for interrupt code 5

23.9.9.39 XUSB_HOST_UFPCI_CONFIG_0

Upstream FPCI Configuration

Offset: 0x19c | Read/Write: R/W | Reset: 0x0000000a (0bxxxxxxxxxxxxxxxxxxxxxxxxxxxx01010)

Bit	Reset	Description
4:0	0xa	UNITID_T0C0: Upstream FPCI Unit ID for controller 0. HyperTransport, upstream FPCI request

23.9.9.40 XUSB_HOST_CFG_REVID_0

CFG_REVID Register

Offset: 0x1a0 | Read/Write: R/W | Reset: 0x000X10XX (0bxxxxxxxxxxxxxxxxxx0100xxxxxxx1xx)

Bit	R/W	Reset	Description
19	RO	X	DEV2SM_NONISO_REQUEST_PEND: This bit indicates if there is a non-ISO request pending. 0 = NO 1 = YES
18	RO	X	DEV2SM_ISO_REQUEST_PEND: This bit indicates if there is an ISO request pending. 0 = NO 1 = YES

Bit	R/W	Reset	Description
13:12	RW	0x1	STRAP_CPU_MODE: MCP: Mode to send MSI. It can be programmable. 0 = NB_INTEL 1 = NB_AMD 2 = AMD 3 = TMTA
11	RW	0x0	CFG_REVID_WRITE_ENABLE: MCP: The enable to override the rev ID. It can be programmable. 0 = CLEAR 1 = SET
10	RW	0x0	CFG_REVID_OVERRIDE: MCP: Provides a way to override the current revision ID. It can be programmable. 0 = DISABLE 1 = ENABLE
4	RO	X	DEV2LEG_NONCOH_REQUEST_PEND: MCP: Tells the leg block that a non-coherent request is pending. 0 = NO 1 = YES
3	RO	X	DEV2LEG_COH_REQUEST_PEND: MCP comment: Tells the leg block that a coherent request is pending. 0 = NO 1 = YES
2	RW	0x1	SM2DEV_FPCI_TIMEOUT_EN: FPCI timeout enable bit for Controller 0 = DISABLE 1 = ENABLE

23.9.9.41 XUSB_HOST_FPCI_TIMEOUT_0

FPCI_TIMEOUT Register

Offset: 0x1a4 | Read/Write: R/W | Reset: 0x000f0000 (0bxxxxxxxxxxxxx11110000000000000000)

Bit	Reset	Description
19:0	0xf0000	SM2ALL_FPCI_TIMEOUT_THRESH: This field sets the timeout threshold value for the FPCI bus. It starts counting for each queue (ISO/NISO- RD/WR) with a pending request in the FPCI wrapper, the count resets when the requests are popped.

23.9.9.42 XUSB_HOST_TOM_0

Top of Memory Limit

Offset: 0x1a8 | Read/Write: R/W | Reset: 0x3fff0fff (0bxx11111111111111xxxx111111111111)

Bit	Reset	Description
29:16	0x3fff	LEG2ALL_TOM2: Top of Memory Limit 2.
11:0	0xfff	LEG2ALL_TOM1: Top of Memory Limit 1.

23.9.9.43 XUSB_HOST_INITIATOR_ISO_PW_RESP_PENDING_0

Initiator ISO PW Response Pending

Offset: 0x1ac | Read/Write: RO | Reset: 0x000000XX (0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx)

Bit	Reset	Description
7:0	X	NUM_INITIATOR_ISO_PW_RESP_PEND: Number of pending initiator ISO PW responses

23.9.9.44 XUSB_HOST_INITIATOR_NISO_PW_RESP_PENDING_0

Initiator Non-ISO PW Response Pending

Offset: 0x1b0 | Read/Write: RO | Reset: 0x000000XX (0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx)

Bit	Reset	Description
7:0	X	NUM_INITIATOR_NISO_PW_RESP_PEND: Number of pending initiator NISO PW responses

23.9.9.45 XUSB_HOST_INTR_STATUS_0

IPFS Interrupt Status

Offset: 0x1b4 | Read/Write: RO | Reset: 0x0000000X (0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx)

Bit	Reset	Description
2	X	IP_INTR_STATUS: Status of IP (SATA/AZA) interrupt
1	X	MSI_INTR_STATUS: Status of MSI interrupt
0	X	IPFS_INTR_STATUS: Status of IPFS interrupt

23.9.9.46 XUSB_HOST_DFPCI_BEN_0

Downstream FPCI Byte Enables

Offset: 0x1b8 | Read/Write: R/W | Reset: 0x00000000 (0b0xxxxxxxxxxxxxxxxxxxxxxxxxxx0000)

Bit	Reset	Description
31	0x0	EN_DFPCI_BEN: Enable bit for BEN. When set, the programmed BE is sent on the DFPCI bus
3:0	0x0	DFPCI_BYTE_ENABLE_N: Active low byte enables

23.9.9.47 XUSB_HOST_CLKGATE_HYSTERESIS_0

Offset: 0x1bc | Read/Write: R/W | Reset: 0x00000014 (0bxxxxxxxxxxxxxxxxxxxxxxxx00010100)

Bit	Reset	Description
7:0	0x14	CLK_DISABLE_CNT: Number of IPFS clock cycles to wait after clock gating criteria are met to disable IPFS/FPCI clocks

23.9.9.48 XUSB_HOST_XUSB_HOST_MCCIF_FIFOCTRL_0

Memory Client Interface FIFO Control Register

Note: The FIFO timing aspects of this register are no longer supported, but are retained for software compatibility.

The clock enable fields of this register control the second-level clock gating for the MC side of the MCCIF.

A '1' written to the override field will result in that clock reverting to the legacy mode of operation (where the msc*clk is on whenever the client clk is enabled.

Offset: 0x1dc | Byte Offset: 0x770 | Read/Write: R/W | Reset: 0x00000000 (0bxxxxxxxxxxxxxx00xxxxxxxxxxx0000)

23.9.11.3 T_XUSB_CFG_2

PCI Revision ID and Class Code Register

Offset: 0x08 | Read/Write: R

Bits	Reset	R/W	Description
31:24	Ch	R	T_XUSB_CFG_2_BASE_CLASS: The CLASS_CODE bits identify the generic function of the device and (in some cases) a specific register-level programming interface. The register is broken into three byte-size fields. The upper byte (at offset 0BH) is a base class code which broadly classifies the type of function the device performs. The middle-byte (at offset 0BH) is a sub-class code which identifies more specifically the function of the device. The lower byte (at offset 09H) identifies a specific register-level programming interface (if any) so that device independent software can interact with the device. The Class Code and Revision ID are defined by parameters per block. Ch: BASE_CLASS_SBC (default)
23:16	3h	R	T_XUSB_CFG_2_SUB_CLASS: 3h: SUB_CLASS_XUSB (default)
15:8	30h	R	T_XUSB_CFG_2_PROG_IF: 30h: PROG_IF_XHCI (default)
7:0	A1h	R	T_XUSB_CFG_2_REVISION_ID: The REVISION_ID bits specify a device specific revision identifier. The value is chosen by the vendor. Zero is an acceptable value. This field should be viewed as a vendor defined extension to the DEVICE_ID. A1h: REVISION_ID_VAL (default) A1h: REVISION_ID_A01

23.9.11.4 T_XUSB_CFG_3

PCI Configuration Register

Offset: 0x0C | Read/Write: R

Bits	Reset	R/W	Description
31:24	0	R	Reserved
23	0	R	T_XUSB_CFG_3_HEADER_TYPE_FUNC: 0h: HEADER_TYPE_FUNC_SINGLE (default) 1h: HEADER_TYPE_FUNC_MULTI
22:16	0	R	T_XUSB_CFG_3_HEADER_TYPE_DEVICE: The HEADER_TYPE bits identify the layout of the bytes 10h through 3Fh in configuration space and also whether or not the device contains multiple functions. Bit 7 in this register is used to identify a multi-function device. If the bit is 0, then the device is single function. If the bit is 1, then the device has multiple functions. Bits 6 through 0 specify the layout of bytes 10h through 3Fh. The LATENCY_TIMER and HEADER_TYPE are defined by parameters per block. 0h: HEADER_TYPE_DEVICE_NON_BRIDGE (default) 1h: HEADER_TYPE_DEVICE_P2P_BRIDGE
15:11	0	R	T_XUSB_CFG_3_LATENCY_TIMER:

Bits	Reset	R/W	Description
			The LATENCY_TIMER bits contain, in units of PCI bus clocks, the value of the Latency Timer for this PCI bus master. This register must be implemented as writable by any master that can burst more than two data phases. This register may be implemented as read-only for devices that burst two or fewer data phases, but the hardwired value must be limited to 16 or less. A typical implementation would be to build the five high-order bits (leaving the bottom three as read-only), resulting in a timer granularity of eight clocks. At reset, the register should be set to 0 (if programmable). LATENCY_TIMER bits are writable. 0h: LATENCY_TIMER_0_CLOCKS (default) 1h: LATENCY_TIMER_8_CLOCKS 1Eh: LATENCY_TIMER_240_CLOCKS 1Fh: LATENCY_TIMER_248_CLOCKS
10:8	0	R	Reserved
7:0	0	R	T_XUSB_CFG_3_CACHE_LINE_SIZE: 0h: CACHE_LINE_SIZE_0 (default) 20h: CACHE_LINE_SIZE_32 40h: CACHE_LINE_SIZE_64

23.9.11.5 T_XUSB_CFG_4

PCI Configuration Register

Offset: 0x10 | Read/Write: R/W

Bits	Reset	R/W	Description
31:15	0	R/W	T_XUSB_CFG_4_BASE_ADDRESS: The BASE_ADDRESS bits contain the base address of the device. The number of upper bits that a device actually implements depends on how much of the address space the device will respond to. A device that wants a 1 MB memory address space (using a 32-bit base address register) would build the top 12 bits of the address register, hardwiring the other bits to 0. Power-up software can determine how much address space the device required by writing a value of all 1's to the register and then reading the value back. The device will return 0's in all don't-care address bits, effectively specifying the address space required. 0h: BASE_ADDRESS_DEFAULT (default)
14:4	0	R	T_XUSB_CFG_4_BAR_SIZE_32KB: 0h: BAR_SIZE_32KB_RSVD (default)
3	1h	R	T_XUSB_CFG_4_PREFETCHABLE: 0h: PREFETCHABLE_NOT 1h: PREFETCHABLE_MERGABLE (default)
2:1	2h	R	T_XUSB_CFG_4_ADDRESS_TYPE: The ADDRESS_TYPE bits contain the type of the Base Address. It can be 32 bits, 20 bits, or 64 bits wide. 0h: ADDRESS_TYPE_32_BIT 2h: ADDRESS_TYPE_64_BIT (default)
0	0	R	T_XUSB_CFG_4_SPACE_TYPE: The SPACE_TYPE bit indicates whether the register maps into Memory or I/O space. 0h: SPACE_TYPE_MEMORY (default) 1h: SPACE_TYPE_IO

31:0	0	R	T_XUSB_CFG_6_RSVD: 0h: RSVD_00 (default)

23.9.11.8 T_XUSB_CFG_11

PCI Configuration Register

The SUBSYSTEM_VENDOR_ID bits and SUBSYSTEM_ID bits are used to uniquely identify the add-in board or subsystem where the device resides. When the device is on the motherboard, there is no serial ROM and the registers both initialize to NONE. The motherboard BIOS must set the values of the Subsystem ID and Subsystem Vendor ID by writing the proper values to the SUBSYSTEM_VENDOR_ID and SUBSYSTEM_ID bits in the PCI_T_16 register (NOT PCI_T_11).

Offset: 0x2c | Read/Write: R

Bits	Reset	R/W	Description
31:16	0	R	T_XUSB_CFG_11_SUBSYSTEM_ID: 0h: SUBSYSTEM_ID_NONE (default)

Bits	Reset	R/W	Description
31:0	0	R	T_XUSB_CFG_12_RESERVED: 0h: RESERVED_0 (default)

23.9.11.10 T_XUSB_CFG_13

PCI Capability Pointer Register

Offset: 0x34 | Read/Write: R

Bits	Reset	R/W	Description
31:8	0	R	Reserved
7:0	44h	R	T_XUSB_CFG_13_CAP_PTR: The CAP_PTR bits indicate the offset into configuration space where the capabilities list begins. This always points to 0x44 where at least the PCI-PM registers are expected to reside. 44h: CAP_PTR_PMCAP C0h: CAP_PTR_MSI 70h: CAP_PTR_MSIX DCh: CAP_PTR_MMAP 44h: CAP_PTR_DEFAULT (default)

23.9.11.11 T_XUSB_CFG_14

PCI Configuration Register

Offset: 0x38 | Read/Write: R

Bits	Reset	R/W	Description
31:0	0	R	T_XUSB_CFG_14_RESERVED: 0h: RESERVED_0 (default)

23.9.11.12 T_XUSB_CFG_15

PCI Configuration Register

Offset: 0x3c | Read/Write: R/W

Bits	Reset	R/W	Description
31:24	0	R	T_XUSB_CFG_15_MAX_LAT: The MAX_LAT bits contain the maximum time the device requires to gain access to the CPI bus. This read-only register is used to specify the device's desired settings for Latency Timer values. The value specifies a period of time in units of 1/4 microseconds. Values of 0 indicate that the device has no major requirements for the settings of Latency Timers. MAX_LAT is nonzero. The INTR_PIN, MIN_GNT, and MAX_LAT are configurable per block. For a 64-byte buffer with two 32-byte sections, the maximum tolerable latency for the XHCI once a large XUSB ISO transaction has begun is about 23 µs. The latency timer is hardwired to 20 µs. This value only applies in External PCI operation. 0h: MAX_LAT_NO_REQUIREMENTS (default) 14h: MAX_LAT_5US 50h: MAX_LAT_20US
23:16	0	R	T_XUSB_CFG_15_MIN_GNT: The MIN_GNT bits contain the length of the burst period a device needs assuming a clock rate of 33 MHz. This read-only register is used to specify the device's desired settings for Latency Timer values. The value specifies a period of time in units of 1/4 microsecond. Values of 0 indicate that the device has no major requirements for the settings of Latency Timers. MIN_GNT is nonzero. 0h: MIN_GNT_NO_REQUIREMENTS (default) 1h: MIN_GNT_240NS
15:8	1h	R	T_XUSB_CFG_15_INTR_PIN: The INTR_PIN bits contain the interrupt pin the device (or device function) uses. A value of 1 corresponds to INTA#. A value of 2 corresponds to INTB#. A value of 3 corresponds to INTC#. A value of 4 corresponds to INTD#. Devices (or device functions) that do not use an interrupt pin must put a 0 in this register. 0h: INTR_PIN_NONE 1h: INTR_PIN_INTA (default) 2h: INTR_PIN_INTB 3h: INTR_PIN_INTC 4h: INTR_PIN_INTD
7:0	0	R/W	T_XUSB_CFG_15_INTR_LINE: The INTR_LINE bits contain the interrupt routing information. The register is read/write and must be implemented by any device (or device function) that uses an interrupt pin. POST software will write the routing information into this register as it initializes and configures the system. The value in this register tells which input of the system interrupt controller(s) the device's interrupt pin is connected to. Device drivers and operating systems can use this information to determine priority and vector information. INTR_LINE is initialized to 0xff (no connection) at reset. Some PCI BIOS' cannot handle aliased INTR_LINEs. Some PCI BIOS' cannot handle INTR_LINE initialized to 0xff. 0h: INTR_LINE_IRQ0 (default) 1h: INTR_LINE_IRQ1 Fh: INTR_LINE_IRQ15 FFh: INTR_LINE_UNKNOWN

13:8	20h	R/W	T_XUSB_CFG_24_FLADJ: Frame Length Adjustment Register. This register is in the auxiliary power well. This feature is used to adjust any offset from the clock source that generates the clock that drives the SOF counter. When a new value is written into these six bits,

Bits	Reset	R/W	Description
			the length of the frame is adjusted. Its initial programmed value is system dependent based on the accuracy of hardware USB clock and is initialized by system BIOS. This register should only be modified when the HChalted bit in the USBSTS register is a one. Changing value of this register while the host controller is operating yields undefined results. It should not be reprogrammed by USB system software unless the default or BIOS programmed values are incorrect, or the system is restoring the register while returning from a suspended state. 20h: FLADJ_VALUE (default)
7:0	30h	R	T_XUSB_CFG_24_SBRN: Serial Bus Release Number Register. This register contains the release of the Universal Serial Bus Specification with which this Universal Serial Bus Host Controller module is compliant. 30h: SBRN_VALUE

23.9.11.17 T_XUSB_CFG_EMU_RSVD

MSIX is not part of Tegra 4 devices.

The PCIE and HT capabilities are not required. PCIE capability will be trapped by the emulation only IP - the emulation only IP put the PCIE capability at 80h ~ BBh, and uses BCh ~ BFh, so these regions are reserved for the emulation only IP. (The emulation only IP will mask the pointers to insert the PCIE capability to the config space of the unit.)

MSI Message Control and Capability Register B0h

MSI_CTRL is the main control register for MSI support.

Offset: 0xc0 | Read/Write: R/W

Bits	Reset	R/W	Description
31:25	0	R	Reserved
24	0	R	T_XUSB_MSI_CTRL_VECTOR_MASK_CAP: The VECTOR_MASK_CAP field indicates whether or not the controller supports MSI-per-vector masking. 0h: VECTOR_MASK_CAP_DIS 1h: VECTOR_MASK_CAP_EN 0h: VECTOR_MASK_CAP_DEFAULT (default)
23	1h	R	T_XUSB_MSI_CTRL_64_ADDR_CAP: The 64_ADDR_CAP field indicates whether or not the controller is capable of generating a 64-bit message address. A value of 1 means the controller is capable of generating a 64-bit message address. 0h: 64_ADDR_CAP_DIS 1h: 64_ADDR_CAP_EN 1h: 64_ADDR_CAP_DEFAULT (default)

Bits	Reset	R/W	Description
22:20	0	R/W	T_XUSB_MSI_CTRL_MULT_MSG_ENABLE: System software writes to this field to indicate the number of allocated vectors (less than or equal to the number of vectors requested). The number of vectors is aligned as a power of two. When MSI is enabled, the controller will be allocated at least one vector. 0h: MULT_MSG_ENABLE_1 1h: MULT_MSG_ENABLE_2 2h: MULT_MSG_ENABLE_4 3h: MULT_MSG_ENABLE_8 4h: MULT_MSG_ENABLE_16 5h: MULT_MSG_ENABLE_32 0h: MULT_MSG_ENABLE_DEFAULT (default)
19:17	0	R	T_XUSB_MSI_CTRL_MULT_MSG_CAP: System software reads this field to determine the number of requested vectors. The number of requested vectors must be aligned to a power of two. Values of 6 and 7 in this field are reserved. 0h: MULT_MSG_CAP_1 1h: MULT_MSG_CAP_2 2h: MULT_MSG_CAP_4 3h: MULT_MSG_CAP_8 4h: MULT_MSG_CAP_16 5h: MULT_MSG_CAP_32 0h: MULT_MSG_CAP_DEFAULT (default)
16	0	R/W	T_XUSB_MSI_CTRL_MSI_ENABLE: The MSI_ENABLE field enables the MSI capability. If MSI_ENABLE is written to a 1, the controller is permitted to use MSI to request service and is prohibited from using the legacy interrupt. System configuration software sets this bit to enable MSI. A device driver is prohibited from writing this bit to mask the controller's service request. If this bit is written to a 0, the controller is prohibited from using MSI to request service. 0h: MSI_ENABLE_OFF 1h: MSI_ENABLE_ON 0h: MSI_ENABLE_DEFAULT (default)
15:8	E0h	R	T_XUSB_MSI_CTRL_NEXT_PTR: The NEXT_PTR field identifies the next item in the capabilities list. It is a read-only field. 70h: NEXT_PTR_MSIX DCh: NEXT_PTR_MMAP 44h: NEXT_PTR_PMCAP 0h: NEXT_PTR_NULL E0h: NEXT_PTR_MAILBOX E0h: NEXT_PTR_DEFAULT (default)
7:0	5h	R	T_XUSB_MSI_CTRL_CAP_ID: The CAP_ID field identifies this capability block as the MSI capability block. This is read-only as 0x5. 5h: CAP_ID_MSI (default)

23.9.11.19 T_XUSB_MSI_ADDR1

MSI Message Address Register 84h

MSI_ADDR1 specifies the lower 32 bits to which an MSI memory write transaction should occur.

Offset: 0xc4 | Read/Write: R/W

Bits	Reset	R/W	Description
31:2	0	R/W	T_XUSB_MSI_ADDR1_MSG_ADDR: System-specified message address. When MSI is enabled, this field specifies the Dword-aligned address for the MSI memory write transaction. 0h: MSG_ADDR_DEFAULT (default)
1:0	0	R	Reserved

23.9.11.20 T_XUSB_MSI_ADDR2

MSI Message Upper Address Register 88h

MSI_ADDR2 specifies the upper 32 bits to which an MSI memory write transaction should occur.

Offset: 0xc8 | Read/Write: R/W

Bits	Reset	R/W	Description
31:0	0	R/W	T_XUSB_MSI_ADDR2_MSG_ADDR: System-specified message address. When MSI is enabled, this field specifies the upper 32 bits of the address for the MSI memory write transaction. The contents of this register only apply when T_XUSB_CFG_MSI_CTRL_64_ADDR_CAP bit is set. 0h: MSG_ADDR_DEFAULT (default)

23.9.11.21 T_XUSB_MSI_DATA

MSI Message Data Register 8Ch

The MSI_DATA register contains the system-specified message.

Offset: 0xcc | Read/Write: R/W

Bits	Reset	R/W	Description
31:16	0	R	Reserved
15:0	0	R/W	T_XUSB_MSI_DATA_MSG_DATA: System-specified message When MSI is enabled, the message data is driven onto the lower 16 bits of the MSI memory write. The MULT_MSG_ENABLE field in configuration register 80h specifies the number of low-order message data bits that the XHCI is permitted to modify to generate its system software allocated vectors. 0h: MSG_DATA_DEFAULT (default)

23.9.13 USB3 UTMIP Configuration Registers

Note: Current UTMIP configuration registers use settings that support NV software drivers and should NOT be modified. If designing custom drivers, consult your NV representative prior to modifying these registers

23.9.13.1 USB3_UTMIP_PLL_CFG0_0

USB_PHY PLL Configuration Register 0

Note: This register has been moved to the Clock and Reset section of this document. PROGRAMMING THIS REGISTER HERE WILL HAVE NO EFFECT!

This register was used to configure the PLL inside UTMIP block prior to Tegra 4 devices. This has been defeatured from UTMIP space and moved to Clock and Reset (CAR) space. Refer to the UTMIP_PLL register descriptions in the Clock and Reset Controller section.

23.9.13.2 USB3_UTMIP_PLL_CFG1_0

UTMIP PLL and PLLU Configuration Register 1

Note: This register has been moved to the Clock and Reset section of this document. PROGRAMMING THIS REGISTER HERE WILL HAVE NO EFFECT!

This register was used to configure the PLL inside the UTMIP block prior to Tegra 4 devices. This has been defeatured from UTMIP space and moved to CAR space. Refer to the UTMIP_PLL register descriptions in the Clock and Reset Controller section.

23.9.13.3 USB3_UTMIP_XCVR_CFG0_0

UTMIP Transceiver Cell Configuration Register 0

Offset: 0x808 | Read/Write: R/W | Reset: 0b00100000001001010110010100000000

Bit	Reset	Description
31:25	0x10	UTMIP_XCVR_HSSLEW_MSB: Most significant bits of HS_SLEW.
24:22	0x0	UTMIP_XCVR_SETUP_MSB: Most significant bits of SETUP.
21	0x1	UTMIP_XCVR_LSBIAS_SEL: Low speed bias selection method for usb transceiver pad
20	0x0	UTMIP_XCVR_DISCON_METHOD: Disconnect method on the usb transceiver pad
19	0x0	UTMIP_FORCE_PDZI_POWERUP: Force PDZI input into power up.
18	0x1	UTMIP_FORCE_PDZI_POWERDOWN: Force PDZI input into power down. (Overrides FORCE_PDZI_POWERUP.)

Bit	Reset	Description
17	0x0	UTMIP_FORCE_PD2_POWERUP: Force PD2 input into power up.
16	0x1	UTMIP_FORCE_PD2_POWERDOWN: Force PD2 input into power down. (Overrides FORCE_PD2_POWERUP.)
15	0x0	UTMIP_FORCE_PD_POWERUP: Force PD input into power up.
14	0x1	UTMIP_FORCE_PD_POWERDOWN: Force PD input into power down. (Overrides FORCE_PD_POWERUP.)
13	0x1	UTMIP_XCVR_TERMEN: Enable HS termination.
12	0x0	UTMIP_XCVR_HSLOOPBACK: Internal loopback inside XCVR cell. Used for IOBIST.
11:10	0x1	UTMIP_XCVR_LSFSLEW: LS falling slew rate control.
9:8	0x1	UTMIP_XCVR_LSRSLEW: LS rising slew rate control.
7:6	0x0	UTMIP_XCVR_FSSLEW: FS slew rate control.
5:4	0x0	UTMIP_XCVR_HSSLEW: HS slew rate control. The two LSBs.
3:0	0x0	UTMIP_XCVR_SETUP: SETUP[3:0] input of XCVR cell. HS driver output control. 4 LSBs.

23.9.13.4 USB3_UTMIP_BIAS_CFG0_0

23.9.13.22 USB3_ UHSIC_PLL_CFG1_0

UHSIC PLL and PLLU Configuration Register 1

This register is used to configure the PHY PLL contained in the UHSIC module as well as the PLLU power up and down.

PLL CONFIGURATION and PARAMETERS

In normal operation, the following clock generators are in play for USB:

Crystal clock -> enters PLLU to generate 12 MHz clock -> enters USB_PHY PLL to generate 480/60 MHz clock

The following parameters control the bring-up of the PLLs:

Coming out of reset or suspend

PllUOnState: start pllu_enable_count and pll_lock_count

Wait ~1 µs to enable the PLL_U (pllu_enable_count == ClkXtal * PLLU_ENABLE_DLY_COUNT * 8)

Wait ~1 ms until PLLU is stable (pll_lock_count == ClkXtal * PLLU_STABLE_COUNT * 256) => USB_PHY PLL_ENABLE

Numbers for a 19.2 MHz crystal clock

- PLLU_ENABLE_DLY_COUNT[4:0] = 1 * 19.2 / 8 = 2.4 = 3 = 0x03
- PLLU_STABLE_COUNT[11:0] = 1000 * 19.2 / 256 = 75 = 0x4b (Note: currently defaults to 0x600)
- XTAL_FREQ_COUNT[11:0] = 2500 * 19.2 / 256 = 187 = 0xbb

6	0x0	UHSIC_HS_POSTAMBLE_OUTPUT_ENABLE: output enable turns off 1 cycle after
5	0x0	UHSIC_SIE_RESUME_ON_LINESTATE: SIE, not macrocell, detects Line State change to resume
4	0x0	UHSIC_SOF_ON_NO_STUFF: SOF when OpMode 3 -- perhaps, when the sending controller made packets
3	0x0	UHSIC_SOF_ON_NO_ENCODE: SOF when OpMode 2 -- not likely, for Chirp
2	0x0	UHSIC_NO_STUFFING: No bit stuffing, static programming
1	0x0	UHSIC_NO_ENCODING: No encoding, static programming
0	0x0	UHSIC_NO_SYNC_NO_EOP: Do not send SYNC or EOP

23.9.13.26 USB3_ UHSIC_MISC_CFG0_0

UHSIC Miscellaneous Configurations

Offset: 0xc14 | Read/Write: R/W | Reset: 0bxxxxxxxxxxx00100010011110100011110

Bit	Reset	Description
20	0x0	UHSIC_DISABLE_BUSRESET: When 1, the PHY will not send out BusReset during XcvrSelect0, TermSelect0, and Opmode2. It will send out a non-bit-stuffed, non-encoded packet instead.
19	0x0	UHSIC_FORCE_TERMSEL: Value to be forced on TermSelect when FORCE_XCVR_MODE is set.
18	0x1	UHSIC_EXTEND_BK_ACTIVE: Drive the bus keeper one cycle longer when going out of IDLE
17:16	0x0	UHSIC_FORCE_XCVRSEL: Value to be forced on XcvrSelect when FORCE_XCVR_MODE is set.
15	0x0	UHSIC_FORCE_XCVR_MODE: 1: Force the values of XcvrSelect and TermSelect via config bits instead of via the controller
14	0x1	UHSIC_SYMMETRIC_CONNECT_DATA 0: DATA goes high before STROBE goes low and low before STROBE goes high. 1: DATA goes high before STROBE goes low and goes low *after* STROBE goes high.
13	0x0	UHSIC_ASYNC_CONNECT_DATA 0: DATA keeps setup and hold requirements during CONNECT. 1: DATA moves together with STROBE
12	0x0	UHSIC_LONG_CONNECT_STROBE 0: STROBE is 2 periods long during connect. 1: STROBE is 3 periods long during connect
11	0x1	UHSIC_ACTIVE_BK_DRIVE_RX: 1: Use RX state (EOP, etc.) to determine starting time to drive bus keeper instead of waiting for IDLE detection.
10	0x1	UHSIC_ACTIVE_BK_DRIVE_TX: 1: Use TX state to determine starting time to drive bus keeper instead of waiting for IDLE detection.
9	0x1	UHSIC_DETECT_SHORT_IDLE 0: Use 3 edges (negative and positive) to detect an idle state on the line. 1: Use 4 edges.
8	0x0	UHSIC_DETECT_SHORT_CONNECT: 0: Use 3 edges (negative and positive) to detect a connect state on the line. 1: Use 4 edges.
7	0x1	UHSIC_SUSPEND_EXIT_ON_EDGE: Suspend exit requires edge or simply a value.
6:5	0x0	UHSIC_INJECT_ERROR_TYPE: Force error insertion into RX path. (Used for IOBIST.) 0 = DISABLE 1 = BIT_ERR 2 = RX_ERR 3 = BIT_RX_ERR
4:2	0x3	UHSIC_STABLE_COUNT: Number of crystal clock cycles of signal not changing to consider stable.
1	0x1	UHSIC_STABLE_ALL: Determines if all signals need to be stable to not change a config.
0	0x0	UHSIC_COMB_TERMS: Use combinational terminations or synced through CLKXTAL

23.9.13.27 USB3_ UHSIC_MISC_CFG1_0

UHSIC Miscellaneous Configurations

Offset: 0xc18 | Read/Write: R/W | Reset: 0bxxxxxxxxxxxxxxx100001100000000010

Bit	Reset	Description
17	0x1	UHSIC_PHY_XTAL_CLOCKEN: Selects whether to enable the crystal clock in the module.
16:15	0x0	UHSIC_OBS_SEL: Select which one of 4 observation vectors is presented on the observation bus
14	0x0	UHSIC_FORCE_IOBIST_CLK_ON: Always enable IoBist CLK60. This would be required when you want to use RX_ERROR_CNT_EN.
13:2	0x600	UHSIC_PLLU_STABLE_COUNT: PLLU frequency lock delay.
1	0x1	UHSIC_RX_ERROR_CNT_CLR: Clear IOBST RxError counter
0	0x0	UHSIC_RX_ERROR_CNT_EN: Enable IOBIST RxError counter when not in IOBIST mode. Allows one to read out the number of errors via JTAG during normal operation

Bit	Reset	Description
12	0x0	UHSIC_RPU_STROBE: Enable pull up on IO_STROBE
11	0x0	UHSIC_RPU_DATA: Enable pull up on IO_DATA
10	0x1	UHSIC_RPD_STROBE: Enable pull down on IO_STROBE
9	0x1	UHSIC_RPD_DATA: Enable pull down on IO_DATA
8	0x0	UHSIC_LPBK: Internal digital loopback
7	0x0	UHSIC_RX_SEL: 0: Differential read buffers, 1: Single-ended buffers
6	0x1	UHSIC_PD_ZI: Power down single ended receiver
5	0x1	UHSIC_PD_RX: Power down receiver
4	0x1	UHSIC_PD_TRK: Power down tracking circuit

Bit	Reset	Description
3	0x1	UHSIC_PD_TX: Power down transmitter
2	0x1	UHSIC_PD_BG: Power down band-gap and bias generator
1	0x0	UHSIC_IDDQ: Shut down analog blocks for IDDQ testing
0	0x1	UHSIC_AUTO_RTERM_EN: Enable auto-termination

23.9.13.30 USB3_ UHSIC_CMD_CFG0_0

Determine start-up behavior.

When AUTO_NEGIOTIATE == 0

- Firmware is supposed to take care of things.

HOST

if Opmode1: do not drive anything

else

Initial power up:

- Asynchronously drive 00
- After a few crystal clocks, enable bus keepers

Offset: 0xc24 | Read/Write: R/W | Reset: 0bxxxxxxxxxxxxxxxxxxxxxxxxxxx0000101

Bit	Reset	Description
6	0x0	UHSIC_FORCE_ACTIVATED: Force PHY into activated state without connect handshake (both host and device)
5	0x0	UHSIC_PRETEND_CONNECT_DETECT: While in HOST mode, act as if the input stage has seen a CONNECT pulse from the external PHY
4	0x0	UHSIC_FORCE_RESET: While in HOST mode, force global state machine into RESET state
3	0x0	UHSIC_FORCE_CONNECT: Upon rising value of this bit, force device to send connect. Only useful when AUTO_CONNECT is disabled.
2	0x1	UHSIC_AUTO_CONNECT: As device, automatically send Connect during activation.
1	0x0	UHSIC_FORCE_ACTIVATE: Upon rising value of this bit, instruct state machine to go into activation mode. Only useful when AUTO_ACTIVATE is disabled.
0	0x1	UHSIC_AUTO_ACTIVATE: Upon power up, automatically move to activation mode and start going through connect procedure.

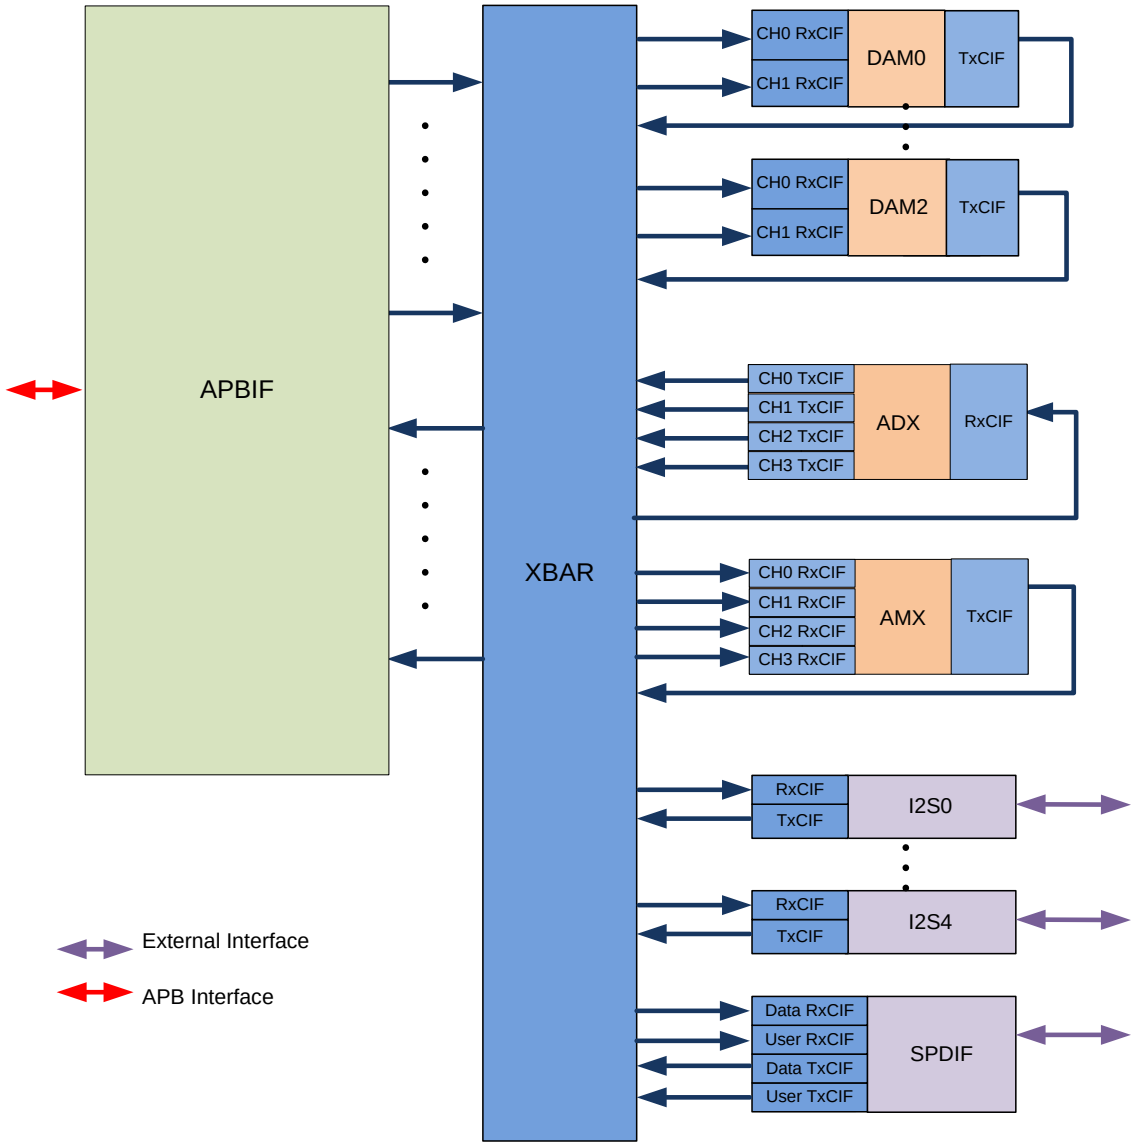
24.0 AUDIO HUB (AHUB)

Tegra® 4 processors support multiple interfaces to the audio devices in the system cellular baseband; different audio codecs; digital audio that is synthesized or decoded by the AVP audio coprocessor or CPU; Bluetooth modules; FM receivers; HDMI audio to a TV or home theater; etc. AHUB can cater to the different interface, protocol, and signal quality requirements of these audio devices.

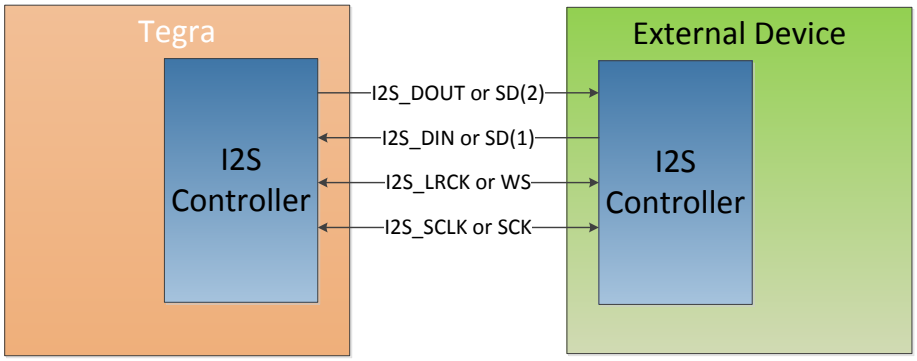
Figure 68: Audio Hub Functional Block Diagram



The Audio Hub (AHUB) consists of

- 5 I^2S controllers and 1 S/PDIF controller to interface with external devices
- A multi-channel DMA unit (APBIF) to interface with memory and internal modules.
- 3 Digital Audio sample-rate conversion and Mixing blocks (DAMs), 1 Audio Multiplexer (AMX), and 1 Audio Demultiplexer (ADX) for audio processing.
- A crossbar switch (XBAR) matrix interconnects all the above modules in any configuration as desired using a CIF interface. CIF interface is an NVIDIA proprietary interface that enables one module in AHUB to send/receive data to/from another module in AHUB.

24.1 I²S Controller



The I²S controller implements full-duplex and bidirectional and single direction point-to-point serial interfaces. It can interface with I2S-compatible products, such as compact disc players, digital audio tape devices, digital sound processors, modems, Bluetooth chips, etc. The I²S controller can operate both as master and slave.

The I²S controller streams synchronous serial audio data between the Tegra 4 device and an external audio device. The controller supports the I²S Left Justified Mode, Right Justified Mode, and DSP mode formats.

The I²S controller also supports the PCM, telephony (network), and Time Division Multiplex (TDM) modes of data transfer. Pulse Code Modulation (PCM) is a standard method used to digitize audio (particularly voice) patterns for transmission over digital communication channels. The Telephony or Network mode is used to transmit and receive data to/from an external mono codec in a slot-based scheme of time-division multiplexing. TDM mode is same as network mode, but in TDM mode, all or any of the slots are active. All of these modes are synced up by a frame-sync signal, much the same as the left-right-channel-clock LRCK in the case of normal I²S communication.

This controller is indirectly connected to the APB bus through the APBIF, and can trigger the APB-bridge DMA to transfer data to and from its FIFOs. Refer to the APBIF section of this document for further details.

Features

- PCM, Network, and TDM mode support
- Can operate in both Master and Slave modes
- Supports I²S, RJM, LJM, and DSP mode data formats
- Supports non- 50:50 mark-space ratio in both Master and Slave modes of I2S, RJM, and LJM
- Contains two FIFOs and control logic. In I2S basic modes, both FIFOs can be configured for Tx or Rx. In PCM/Network mode; FIFO-1 acts as Tx FIFO and FIFO-2 as Rx FIFO
- Buffer memory optimized for peripheral bus utilization, allowing multiple sets of data being stored for both incoming and outgoing data stream per slot (Data-Packed mode in both FIFOs)
- Supports PCM-mode mono and Network mode with independent slot selection for Tx and Rx
- PCM mode supports short and long FSYNC. Long FSYNC can be only 2 clocks wide in Master mode and any number of clocks in slave mode
- Same LRCK/FSYNC for both transmission and reception of data
- Network mode with independent slot selection for both Tx and Rx
- TDM mode with flexibility in number of slots and slot(s) selection
- Capability to drive out a High-Z outside the prescribed slot for transmission
- 6-bit clock divisor to support single- and double-speed for the following rates: 8 KHz, 32 KHz, 44.1 KHz, 48 KHz, 96 KHz, and 128 KHz
- Maximum frequency of the device clock supported is 24 MHz

- The number of slots can be programmed from 1 to a maximum of 8 in TDM mode
- Can transmit and receive word lengths of 8, 16, 24, and 32
- Supports u-Law and A-Law compression/decompression

The I^2S controller supports bidirectional audio streams. It can operate in full-duplex or single directional mode; that is, it can transmit or receive data on both the I2S_DIN and I2S_DOUT pins, based on the register-configuration. The I^2S controller supports input word lengths of 16, 20, 24, or 32 bits. In TDM mode, the word length can be supported in multiples of 4, starting from 8 bits.

In Master mode, the I^2S controller signals the synchronization of all I^2S data transactions. In Master mode, the I^2S controller module generates the SCLK bit clock (I2S_SCLK) and Left-Right channel clock LRCK (I2S_LRC) to the A/D or D/A converter. The A/D or D/A converter synchronizes the input or output audio data based on these clock signals.

In Slave mode, the external A/D or D/A converter provides the synchronization clocks, bit clock (I2S_SCLK) and Left-Right channel clock (I2S_LRCK) to the I^2S controller. The I^2S controller synchronizes the input/output audio data to these clocks.

24.1.1 External Signaling

The I2S interface consists of 4 signals--FSYNC, BITCLK, SDATA1 and SDATA2-- all defined as bidirectional. SDATA1 and SDATA2 associate themselves to FIFO-1 and FIFO-2, respectively. In I2S mode, the SDATA1 and SDATA2 can be configured to be either input or output based on the configuration of the corresponding FIFO.

24.1.1.1 Data Formats in Basic I2S Mode

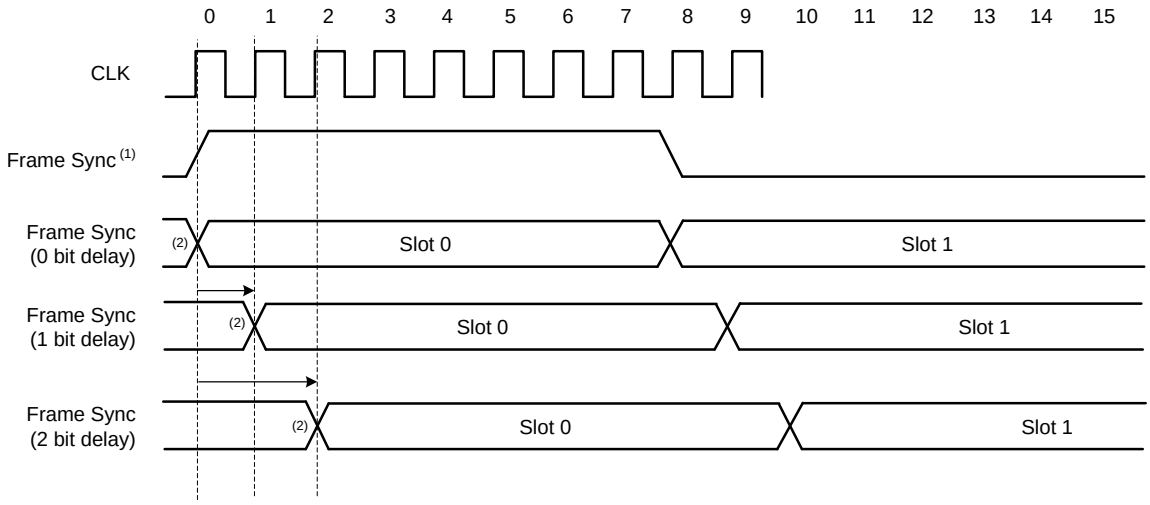
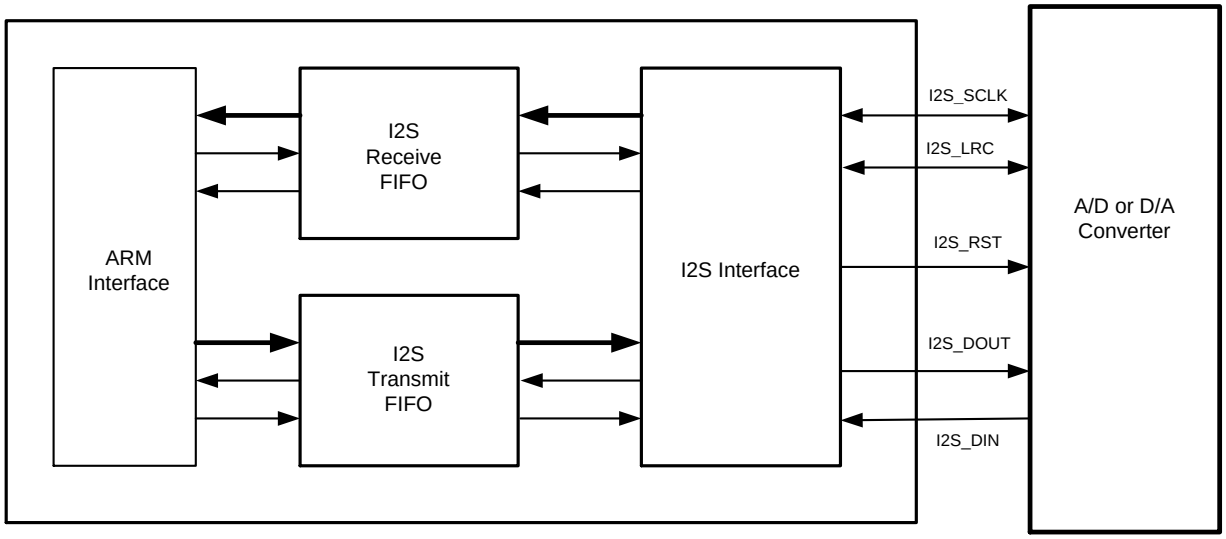
1. FS duration of a slot is shown. FS duration of a single bit is also supported.



1. FS duration of a slot is shown. FS duration of a single bit is also supported.
2. Last bit of the last slot of the previous frame. No gap is allowed between this bit and the first bit of slot 0.

24.1.2 I2S Functionality

Figure 76: I2S Functional Block Diagram



24.1.3 I2S Programming Guidelines

24.1.3.1 Module Initialization

Reset the controller (not mandatory after a POR) and enable the clocks to the controller.

24.1.3.2 I2S Sampling Rate Selection

For LRCK mode, the channel_bit_cnt can be calculated using this equation:

```
Channel_bit_cnt = (frequency of bit_clk) / (2 * required sampling rate) - 1
```

For FSYNC mode, the channel_bit_cnt can be calculated using this equation:

```
Channel_bit_cnt = (frequency of bit_clk) / (required sampling rate) - 1
```

If the above calculation returns a fractional value, the non-symmetry feature of the controller should be used to attain the required sampling rate. In that case, the channel_bit_cnt value should be programmed with an integer that is closest to the fraction, but less than the fraction.

The table below shows some examples for common sampling rates, with CLK_SOURCE_I2S = 24 MHz

Table 65: Common Sampling Rates (CLK_Source_I2S = 24 MHz)

Sampling Rate	I2S_NEW_TIMING[12:00] (mark-space ratio:: Left_channel : Right_channel)				
	CLK_DIVISOR=0 BIT_CLK=24 MHz	CLK_DIVISOR=1 BIT_CLK=12 MHz	CLK_DIVISOR=3 BIT_CLK=6 MHz	CLK_DIVISOR=5 BIT_CLK=4 MHz	CLK_DIVISOR=7 BIT_CLK=3 MHz
8 KHz	0x05DB	0x02ED	0x0176	0x00F9	0x10BB
	(1500:1500)	(750:750)	(375:375)	(250:250)	(187:188)
32 KHz	0x0176	0x10BB	Not supported	0x103E	Not supported
	(375:375)	(187:188)		(62:63)	
44.1 KHz	0x010F	0x0087	0x0043	0x002C	0x0021
	(272:272)	(136:136)	(68:68)	(45:45)	(34:34)
48 KHz	0x00F9	0x007C	0x103E	Not supported	Not supported
	(250:250)	(125:125)	(62:63)		
96 KHz	0x007C	0x103E	0x101F	Not supported	Not supported
	(125:125)	(62:63)	(31:32)		

Note: Ideally, any sampling rate can be generated, either accurately or approximately with any clk_src selected for I2S, if the clk_divisor and the channel_bit_cnt are programmed accordingly.

NON_SYM.EN feature is meant to create the sampling rates approximately, by realizing an odd bit rate with a non-50:50 mark/space ratio. However, if the bit rate (2*channel_bit_cnt) itself is a fraction, the resultant sampling rate will not be accurate. The entries shown as not supported in the above table are attributed to such a deviation.

When the channel_bit_cnt is less than 32, the bit_size should be programmed to be less than channel_bit_cnt.

24.1.3.3 Transmit/Receive Data Flow for I2S Basic, LJM, and RJM Modes

After the module initialization (reset and clock programming), program the corresponding bits of the following registers, preferably in the same sequence:

- **I2S_CTRL:** Set I2S_CTRL[31] = 1/0 to enable/disable I2S Tx mode and I2S_CTRL[30] = 1/0 to enable/disable I2S Rx mode.
- **I2S_CTRL:** Set I2S_CTRL[14:12] = 0 for LRCK mode
- **I2S_OFFSET_0:** Set I2S_OFFSET_0[26:16] = RX_DATA_OFFSET and I2S_OFFSET_0[10:0]= TX_DATA_OFFSET. Settings for this register will decide whether I2S basic, LJM, or RJM mode is selected.
- **I2S_TIMING:** Set I2S_TIMING [10:0] = CHANNEL_BIT_CNT. This is the channel bit count referred to in the “I2S Sampling Rate Selection**”** section.

24.1.3.4 Network, DSP, TDM, and PCM Modes

When in Network, DSP, TDM, or PCM mode, to get the correct fsync, program the following control register bits:

- **I2S_TIMING**: Set I2S_CTRL [10:0] = CHANNEL_BIT_CNT. Refer to the “I2S Sampling Rate Selection**”** section

- **I2S_CTRL:** Set I2S_CTRL[31]=1/0 to enable/disable I2S Tx mode and I2S_CTRL[30]=1/0 to enable/disable I2S Rx mode.
- **I2S_CTRL**: Set I2S_CTRL[14:12]=1 for FSYNC mode
- **I2S_CTRL**: Set I2S_CTRL [9] = 1 to set LRCK_POLARITY as HIGH.
- **I2S_SLOT_CTRL_0**: Set I2S_SLOT_CTRL_0[3:0] = number of slots in a frame - 1.
- **I2S_SLOT_CTRL2_0**: Set I2S_SLOT_CTRL2_0[31:16] for Rx slot enable. Set I2S_SLOT_CTRL2_0[15:0] for Tx slot enable. Each bit represents a slot.

  For example, if bits 17 and 16 are set, it means slot 0 and 1 have been enabled for the Rx path. Similarly, if bit 0 is enabled, it means only slot 0 is enabled for the Tx path.

24.2 Crossbar

Tegra 4 processors have an MxN full crossbar switch with unidirectional data flow, where M and N are the number of TX and RX clients, respectively. A TX client can send audio data to multiple RX clients, while an RX client can receive data from only one TX at a time. A session is created by binding a transmitting TX client and a receiving RX client. At any point, a TX or RX client can be bound to no more than one session. Multiple sessions can be active at a time and work independent of each other.

24.2.1 Clocking

When multiple sessions are in progress, the AHUB clock should be fast enough to support the session with the highest data rate. If a session is used for sending an 8 kHz 16-bit stereo stream, the AHUB clock should be at least 256 kHz. While a faster clock is better for data transmission, it is not necessarily good for power consumption. Using the clock directly from the crystal without going through PLLs is recommended for typical audio applications like MP3 music playback. Depending on the applications, you can program the clock registers to satisfy the requirement of clock frequency. The following table shows the various clock frequencies for AHUB.

Table 66: AHUB Clock Frequencies

Clock Frequency	Description
64 kHz	Slowest clock to carry 8-bit mono voice data in 8 kHz sampling
1.4112 MHz	Clock to carry 16-bit stereo audio data in 44.1 kHz sampling
1.536 MHz	Clock to carry 16-bit stereo audio data in 48 kHz sampling
4.608 MHz	Clock to carry 24-bit stereo audio data in 96 kHz sampling or 16 bit 6 channel audio data in 48 kHz sampling
12 MHz	Minimum crystal frequency
18.432 MHz	Clock to carry 24-bit 8 channel audio data in 96 kHz sampling
36.864 MHz	Clock to carry 24-bit 8 channel audio data in 192 kHz sampling (HDMI maximum)

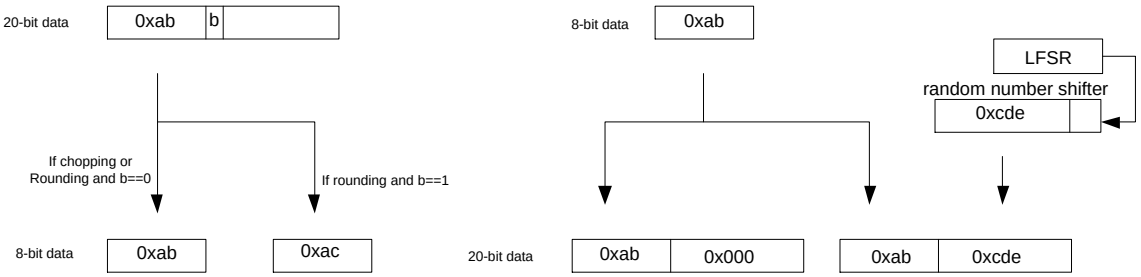
24.2.2 AHUBCIF

The main function of AHUBCIF (generic term for TxCIFs, RxCIFs) is to serialize an audio sample to a serial data stream or deserialize a serial data stream to be an audio sample. The configuration register is programmed to specify the bit width and the number of channels for parsing incoming stream or serializing outgoing stream.

Besides serialization/deserialization, other common format conversions performed in AHUBCIF optionally by the register configuration include data width conversion and channel conversion.

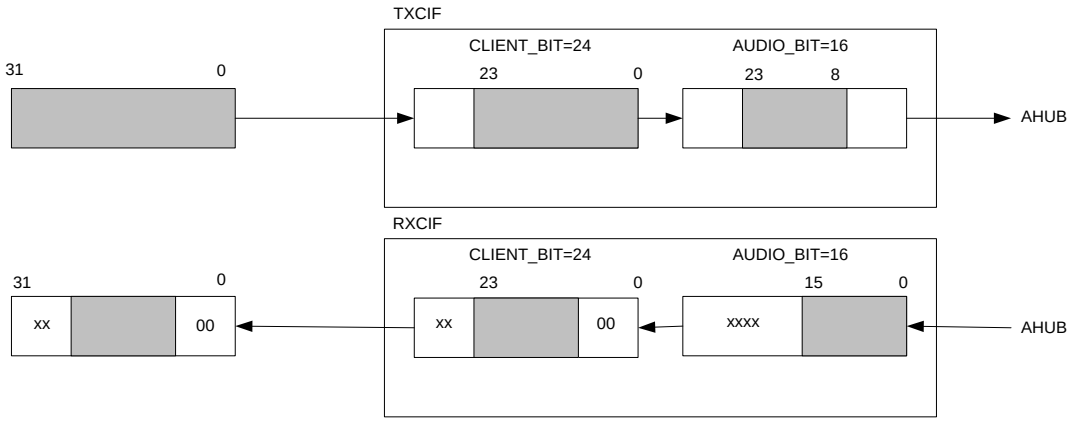
AHUB and AHUBCIF support 8-, 16-, 24-, and 32-bit wide data. When converting from a larger width to a smaller width, a configuration option is provided to chop off the least significant bits and a randomly generated bit can be added to the least significant bit to make audio stream sound more natural. When converting a smaller width to a larger width, the blank region can be either filled with 0’s or 1’s or randomly generated numbers.

Figure 77: Data Format Conversion



AHUBCIF supports mono-to-stereo and stereo-to-mono conversion. Mono data is converted to stereo by duplicating the data into the second channel. The stereo to mono conversion has the following options: copying the first channel data into the mono channel, copying the second channel data into the mono channel, or averaging two channel data, (L + R)/2.

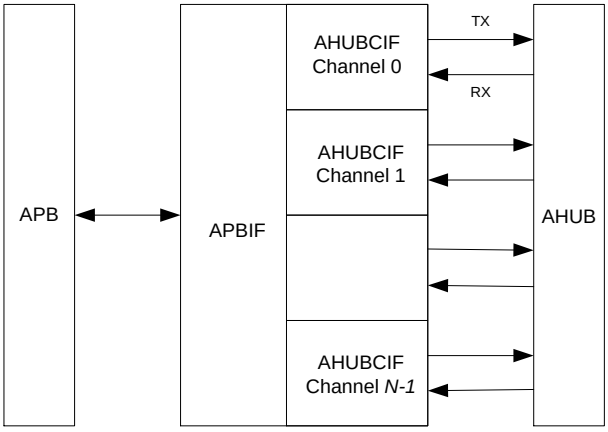
The bit width of audio sample on the Audio HUB side is specified by AUDIO_BITS field. The bit width of audio samples in the client domain is specified by the CLIENT_BITS field. Since AHUBCIF has a 32-bit data interface, the maximum value of CLIENT_BITS and AUDIO_BITS is 32. When the bus is defined to be DATA[31:0], CLIENT_BITS specifies how many bits are valid from LSB in the client. If CLIENT_BITS=24, DATA[23:0] is valid, while DATA[31:24] may be unused. If the client data is serialized with AUDIO_BITS=24, all 24 bits of the client data are transmitted or received through AHUB. However, if AHUB_BITS is less than CLIENT_BITS (for example AHUB_BITS=16), the lower 8 bits are discarded for transmission and only DATA[23:8] will be transmitted to AHUB. The figure below shows the conversion.



24.3 APBIF

APBIF is the agent for the APB control flow and DMA operation, which sends or receives data from/to Memory. APBIF is composed of *N* instances of AHUBIF and APB interface as shown in the figure below.

Figure 78: AHUB Crossbar Switch and Clients



Features

- Separate APB DMA operations for all AHUB clients
- Each channel is bidirectional and needs one TX and one RX AHUBCIF.
- Scalable *N* channel design
- Maintain interrupt registers for AHUB clients

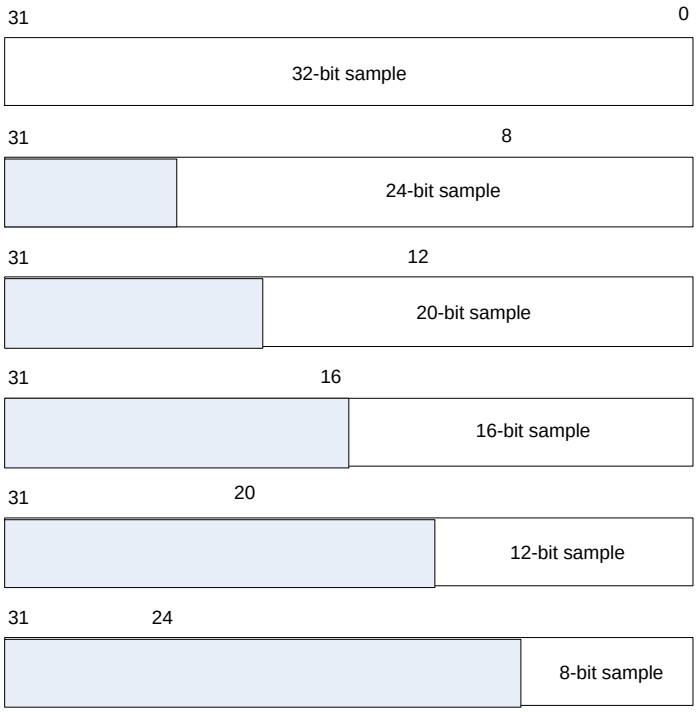
24.3.1 APBIF Functionality

24.3.1.1 Number of Channels

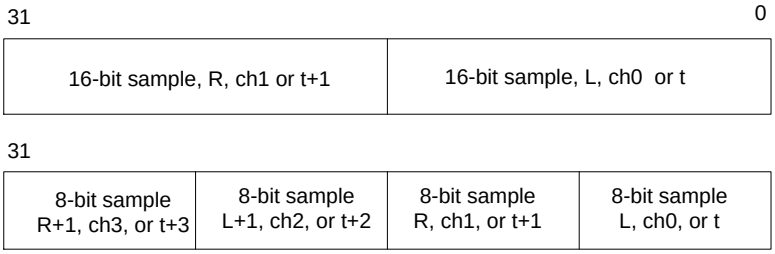
Tegra 4 devices support 10 full-duplex DMA channels. Channels 0-3 reside in the APBIF register space, and Channels 4-9 reside in the APBIF2 register space.

24.3.1.2 Data Packing

When an audio sample is saved in the memory, it is right justified in a Dword configuration, regardless of its bit width. The next figure shows how a sample is stored in the memory without packing.



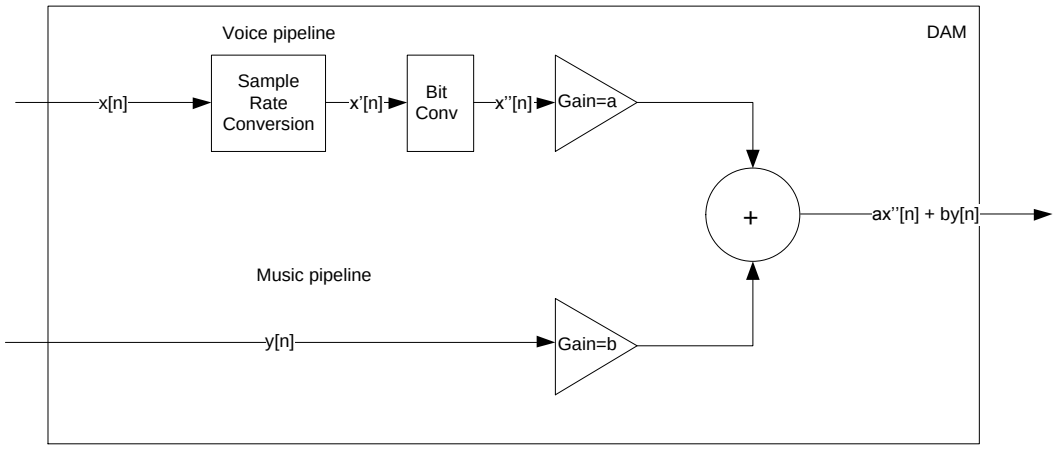
APBIF supports two types of packing, 2x16 bits and 4x8 bits on a Dword boundary. The figure shows the packing modes. When the samples are packed, the sample in the LSB is either the first channel sample (channel 0) or the earlier sample (time T) compared to T+1, T+2 etc. In case of a 4x8 bit configuration, the one in the LSB is the earlier left channel sample or the earliest sample in case of single channel stream.



24.4 Digital Audio Mixer (DAM)

The DAMs have the capability of mixing two input PCM streams of different sampling frequencies and word lengths into one PCM stream. Appropriate gain values can be applied to the individual stream before mixing. The mixing is supported for mono and stereo inputs. A conceptual block diagram of the DAM is shown below.

Figure 79: DAM Block Diagram



In the above figure, the output signals sampling rate and word length will match that of y[n]. The following table shows the possible sample rate conversions.

x[n] \ x'[n]	8 KHz	16 KHz	44.1 KHz	48 KHz
8 KHz	No	Yes	Yes	Yes
16 KHz	Yes	No	Yes	Yes
44.1 KHz	Yes	Yes	No	No
48 KHz	Yes	Yes	No	No

Gain Controller

The gain controller supports a 16-bit volume level and performs a multiply with its input. The gain value is specified in the Q12 unsigned fractional format.

With this format, 0x1000 means 1 in linear gain, while 0x0800 means 0.5 in linear gain. Note that the 24-bit input data is signed data, while the gain value is unsigned.

The accumulator output is shifted right 14 bits to generate a normalized output.

24.4.1 DAM Programming Guidelines

1. Enable APBIF, DAM, and AUDIO clocks and by programing the CLK_RST_CONTROLLER_CLK_OUT_ENB_U register.
2. Enable clocks of other audio modules if DAM is interacting with them.
3. Deassert DAM0 and AUDIO reset by programming CLK_RST_CONTROLLER_RST_DEVICES_U register
4. Deassert reset of other audio modules by similar programming of registers

5. Wait for resets to happen before proceeding further.
6. Start AUDIO programming to connecting CIFs of the Audio Modules involved in the transactions. For example program AUDIO registers AUDIO_I2S0_RX and AUDIO_DAM0_RX to connect the CIFs of I2S and DAM
7. Program Start, high, and low threshold values on I^2S flow control.
8. Start DAM programming
    a. Configure Audio CIF control registers for both the input channels (Rx CIFs) DAM_AUDIOCIF_CH0_CTRL and DAM_AUDIOCIF_CH1_CTRL respectively. Parameters to be configured are MONO_CONV, TRUNCATE, DIRECTION, REPLICATE, STEREO_CONV, EXPAND, CLIENT_BITS, CIF_BITS, CLIENT_CHANNELS, CIF_CHANNELS, and FIFO_THRESHOLD.
    b. Configure the Audio CIF control register DAM_AUDIOCIF_OUT_CTRL for the Tx CIF by the same parameters cited for Rx CIFs.
    c. Set the input FsIn by programming DAM_CH0_CTRL for channel 0 and DAM_CH1_CTRL for channel 1.
    d. Set the Gain for both the channels by setting DAM_CH0_CONV and DAM_CH1_CONV for both channel 0 and channel 1, respectively
    e. Enable DAM output by setting FsOut into the DAM_CTRL register
    f. If the use case involves sample rate conversion either from 44.1 KHz to some frequency or from some frequency to 44.1 KHz, then enable the farrow filter by configuring the DAM_FARROW_PARAM register.
    g. For channel mixing, DATA_SYNC field in both DAM_CH0_CTRL and DAM_CH1_CTRL have to be configured correctly to have mixing in 4 available modes.
        - Ch0 wait on Ch1
        - Ch1 wait on Ch0
        - Both channels wait on each other (Preferred option)
        - Channels don’t wait
    h. Enable DAM by setting the ENABLE bit in DAM_CTRL
9. Program other audio modules by configuring their programmable registers before starting any transactions.

24.5 S/PDIF

The S/PDIF controller supports both input and output in serial audio digital interface format. The input controller can digitally recover a clock from the received stream. The S/PDIF controller is also used to generate the embedded audio for the HDMI output channel.

The controller conforms to the AES/EBU IEC 60958 standard.

The S/PDIF controller consists of two major modules:

- The **S/PDIF Output module**, responsible for sending data to the "spdifout" port in IEC 60958-3 biphase-mark code format
- The **S/PDIF Input module**, responsible for retrieving data to the "spdifin" port in IEC 60958-3 biphase-mark code format

When used for other purposes, this interface is primarily intended to carry audio data coded other than as linear PCM coded audio samples. Provisions are also made to allow the interface to carry data related to computer software or signals coded using non-linear PCM. The format specification for these applications is not part of this standard.

Features

- Fully implements IEC-958 standard interface
- Provides mono and stereo support for sampling frequencies 32 kHz, 44.1 kHz, and 48 kHz

- Supports the following data formats:
  - 16-bit
  - 20-bit
  - 24-bit
  - Raw
  - 16-bit packed
- Supports “autolock” mode to automatically detect the “spdifin” sample rate and lock onto the data stream.
- Supports “override” mode to provide a manual control to sample the “spdifin” data stream.
- Provides a loopback mode to route the “spdifout” back to “spdifin” for self-testing.
- S/PDIF Output (transmitter)
  - 16-word data FIFO for storage of outgoing audio data
  - 4-word user FIFO for storage of outgoing user data
  - 6-word page buffer for storage of outgoing channel status
- S/PDIF Input (receiver)
  - 16-word data FIFO for storage of incoming audio data
  - 4-word user FIFO for storage of incoming user data
  - 6-word page buffer for storage of incoming channel status
- Maximum device clock of 50 MHz

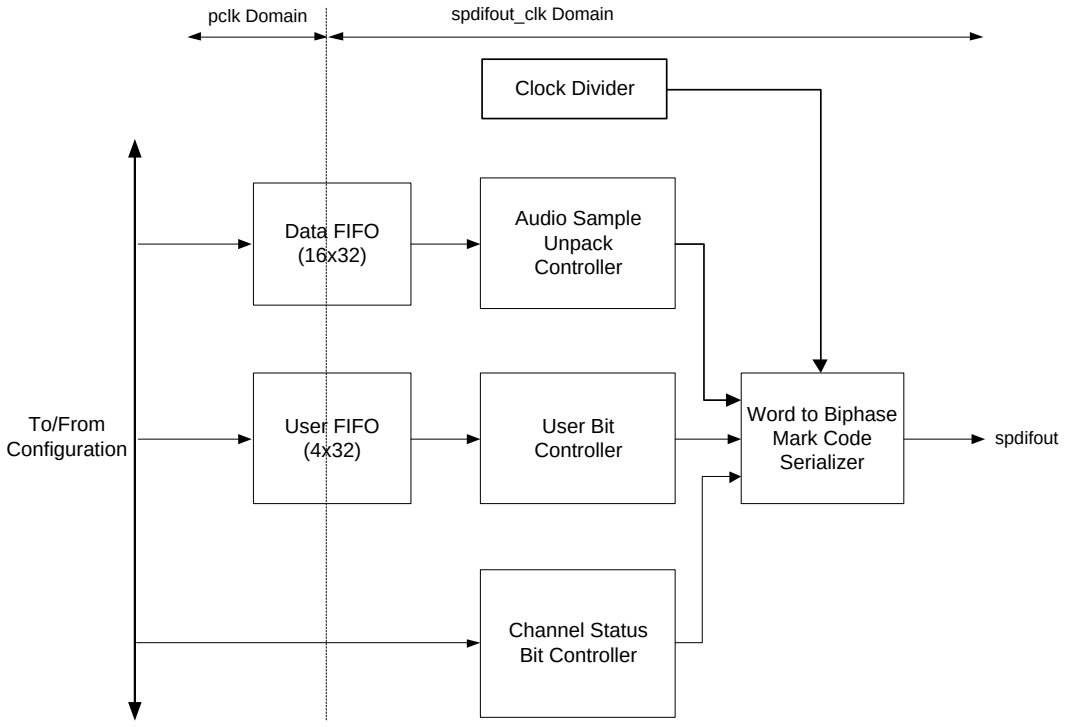
24.5.1 S/PDIF Functionality

24.5.1.1 SPDIFOUT

The S/PDIF Output module contains the following sub-blocks:

- A clock divider
- A 16-word data FIFO
- An audio sample unpack controller
- A 4-word user FIFO
- A user bit controller
- A channel status bit controller
- A word to biphase mark code serializer

Figure 80: SPDIFOUT Block Diagram



Data FIFO

This 16-word deep FIFO is used to store audio samples written by the system in raw mode. It also stores non-audio data such as parity, channel status, user, validity, and preamble bits. This FIFO also serves as a bridge between the 'pclk' and 'spdifout_clk' domains.

Audio Sample Unpack Controller

Based on the PACK register field, this controller either breaks up the packed data from the data FIFO, or lets the Data FIFO's data flow through unmodified to the "word to bi-phase mark code serializer" module. This also controls when to pop an entry out of the data FIFO.

User FIFO

This 4-word deep FIFO is used to store user data written by the system. In raw mode, data from this FIFO is not used. This FIFO also serves as a bridge between the 'pclk' and 'spdifout_clk' domains.

User Bit Controller

When in 16-bit, 20-bit, 24-bit, or pack mode (PACK = 1 or BIT.MODE ≠11) and user data transmit is enabled (TXU.E = 1), this controller temporarily stores an entry out of the user FIFO and feeds user data at the rate of one bit per subframe to the "word to bi-phase mark code serializer" module. This controller also handles when to pop an entry out of the user FIFO. If user data transmit is disabled (TXU.E = 0), the user bit is forced to 0.

Channel Status Bit Controller

When in 16-, 20-, 24-bit, or pack mode (PACK = 1 or BIT.MODE ≠ 11) and channel status transmit is enabled (**TXC.E** = 1), this controller will temporary store an entry out of the channel data TX page buffer and feed channel status, one bit per frame, to

the “word to biphase mark code serializer” module. Also, it provides control to advance the channel data TX page buffer pointer to the next entry. If channel status transmit is disabled (TXC.E = 0), the channel status bit will be forced to 0.

Word to Biphase Mark Code Serializer

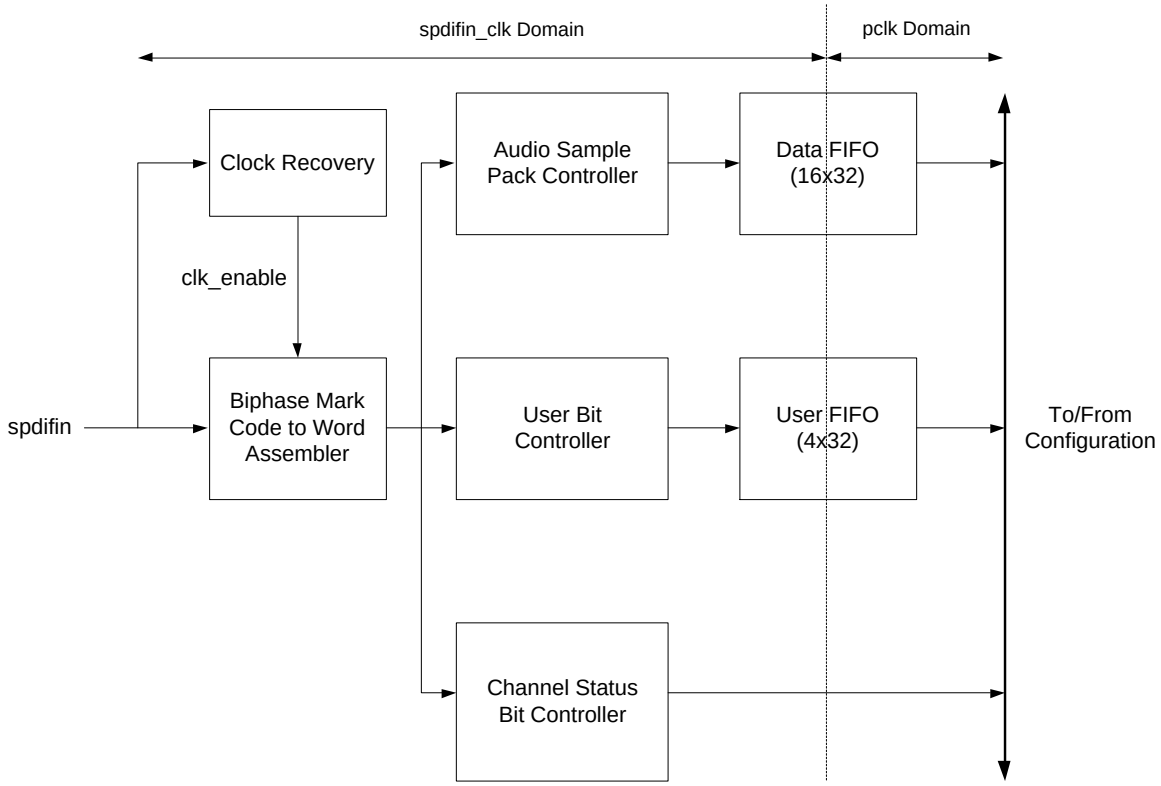
Based on the PACK and BIT.MODE register fields, this controller assembles a 32-bit word from the “Audio sample unpack controller” module, “User bit controller” module, and/or “channel status bit controller” module. This 32-bit word will then be converted to the IEC 60958-3 biphase-mark code format and is sent out through the ‘spdifout’ signal. This controller also provides various status signals (e.g., end of transmitting a subframe) back to the “unpack”, “user”, and “channel status” controllers.

24.5.1.2 SPDIFIN

The S/PDIF Input module contains the following sub-blocks:

- A bi-phase mark code to word assembler
- An audio sample pack controller
- A 16-word data FIFO
- A user bit controller
- A 4-word user FIFO
- A channel status bit controller
- A clock recovery

Figure 81: SPDIFIN Block Diagram



Biphase Mark Code to Word Assembler

Based on the clock enable pulse from the "clock recovery" module, this controller reads the 'spdifin' data stream in IEC 60958-3 biphase mark code format and converts/assembles bit data into a 32-bit word. This 32-bit word is then read by the "audio sample pack controller", "user bit controller", and "channel status bit controller" modules for further processing. This controller also provides various status signals (e.g., end of receiving a subframe) to the "pack", "user", and "channel status" controllers.

Audio Sample Pack Controller

Based on the PACK register field, this controller either combines two audio data or lets the audio data flow through unmodified from the "biphase mark code to word assembler" module to the data FIFO. This also controls when to push an entry into the data FIFO.

Data FIFO

This 16-word deep FIFO is used to store audio samples written by the "audio sample pack controller" module. In 16-bit, 20-bit, 24-bit, or pack mode, it also stores non-audio data such as parity, channel status, user, validity, and preamble bits. This FIFO also serves as a bridge between the 'spdifin_clk' and 'pclk' domains.

User Bit Controller

This controller saves the user bits from each subframe and assembles them into a 32-bit word before pushing an entry into the user FIFO.

User FIFO

This 4-word deep FIFO is used to store user data written by the "user bit controller" module. This FIFO also serves as a bridge between the 'spdifin_clk' and 'pclk' domains.

Channel Status Bit Controller

This controller handles saving the channel status bits from channel A (subframe 1) and assembles them into a 32-bit word before writing into the 6-word channel status page buffer. The channel status page buffer also resides within this controller.

24.5.2 S/PDIF Programming Guidelines

24.5.2.1 16-, 20-, 24-bit Modes

During transmission, the audio data is taken from the TX data FIFO, the channel status bit is taken from the TX channel status page buffer, and the user status bit is from the TX user FIFO. The preamble bits are generated by the hardware. The Valid bit is always zero.

During reception, the audio data is stored in the RX data FIFO, the channel status bit is stored in the RX channel status page buffer and the user status bit is stored in the RX user FIFO.

In addition to storing the audio data, the RX data FIFO also stores the preamble bits, channel status bit, user status bit and the valid bit. The reception of the channel bits start after the B-preamble is detected.

The audio-data sample has 16, 20, or 24 bits of data. Firmware has to transmit 16-, 20-, or 24-bit data and read 16-, 20-, or 24-bit data.

24.5.2.2 Raw Mode

During transmission, the audio data, the preamble bits, channel status bits, the user bits, and the valid bits are transmitted from the RX data FIFO. The firmware has to provide the correct preamble bits for the receiving device to synchronize with the transmitter. The firmware has to provide preambles according to the following table:

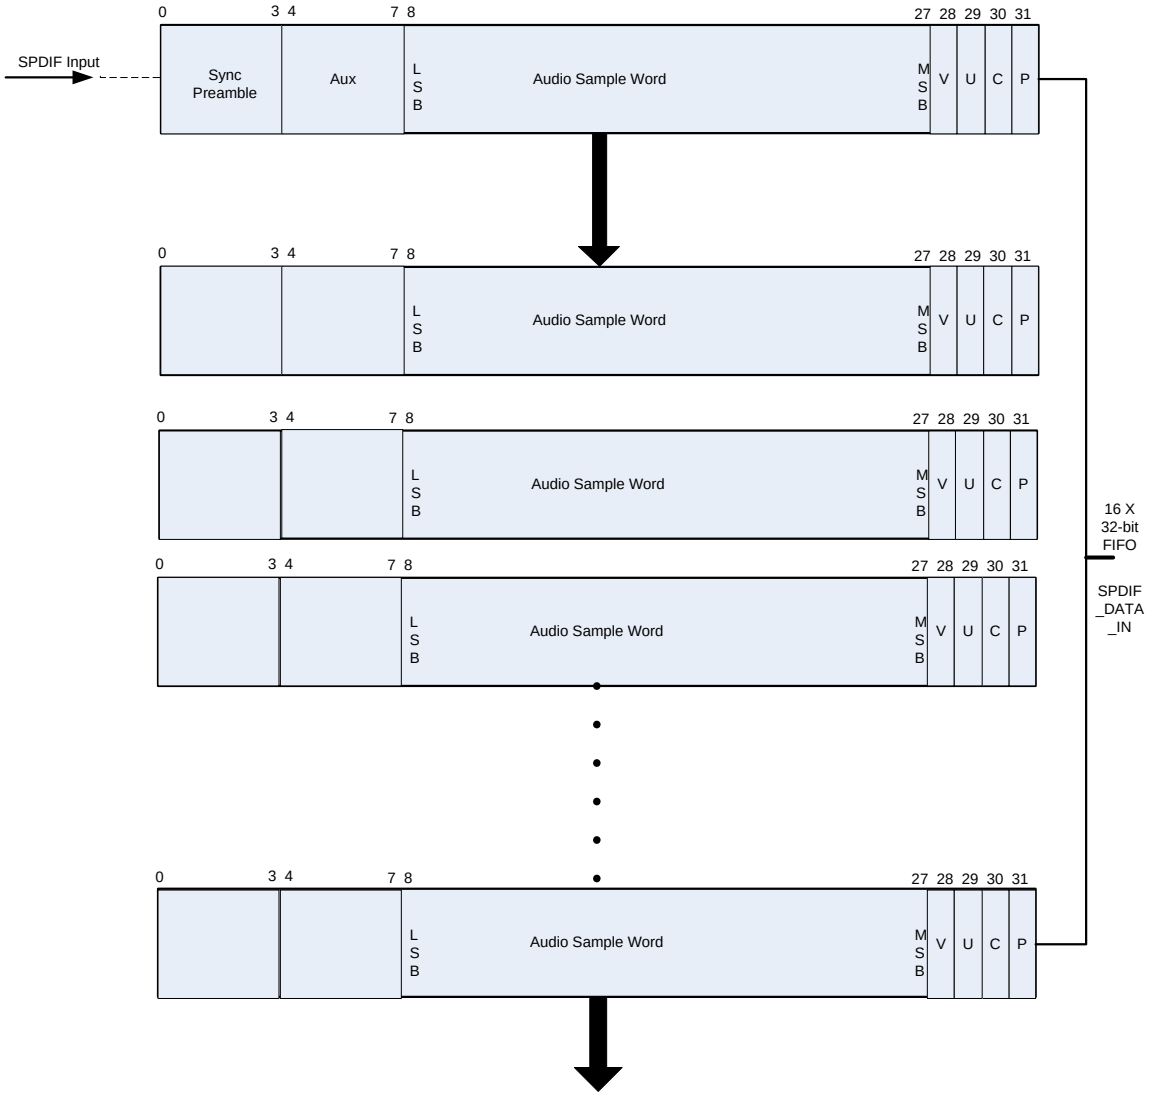
Preceding State in the Parity Bit: 0/1

Table 67: Preamble Bits

Symbol	Preamble Code	Channel Coding	Description
“B” (or “Z”)	0001/0001	11101000/00010111	Start of a block.
“M” (or “X”)	0010/0010	11100010/00011101	Start of sub-frame 1.
“W” (or “Y”)	0011/0011	11100100/00011011	Start of sub-frame 2.

During reception, the audio-data, the preamble bits, channel status bits, the user bits and the valid bits are stored in the RX data FIFO. The user bit is also stored in the RX user FIFO. The channel bit is also stored in the RX channel status page buffer. But the channel status bits are stored in the RX channel status page buffer only after the B-preamble is detected.

Figure 82: S/PDIF Data Format for Raw Mode



24.5.2.3 Pack Mode

During transmission, audio data is taken from TX data FIFO, which contains two 16-bit data (the upper 16 bits are for channel B or sub-frame 2, the lower 16 bits are for channel A or sub-frame 1), the channel status bits are taken from TX channel status page buffer and user status bits taken from TX user FIFO. The preamble bits are generated by the hardware. The valid bit is always zero.

During reception, audio data is stored in the RX data FIFO which contains two 16-bit data (the upper 16 bits are channel B data and the lower 16 bits are channel A data), the channel status bits are stored in the RX channel status page buffer and the user status bits stored in the RX user FIFO. The reception of the channel bits starts after the B-preamble is detected.

24.5.2.4 Module Reset

The application may initialize or reset the S/PDIF module via the clock and reset (CAR) control's RST_DEVICES_L_0 register.

24.5.2.5 Clock Source/Divider Control

The SPDIFOUT clock source/divider can be selected by programming CAR's CLK_SOURCE_SPDIF register. Refer to the S/PDIF registers below for the needed input frequency for the desire output audio sample rate.

The SPDIFIN clock source/divider can be selected by programming CAR's CLK_SOURCE_SPDIF register. Refer to the SPDIF registers below for the needed oversample frequency.

24.5.2.6 Clock Enable Control

The application may enable the S/PDIF clocks by programming CAR's CLK_OUT_ENB_L_0 register.

24.5.2.7 Detecting Incoming Sampling Rate

The SPDIFIN is capable of detecting and locking onto the 'spdifin' data stream regardless of the sample rate. It achieves this by using an oversampling technique.

In addition to reading the sampling rate from the channel status information, one can also read the PERIOD field in the STROBE_CTRL_0 register to estimate the incoming sample rate. The last two digits of PERIOD indicate the fractional clock period.

Sample rate ≈ ('spdifin' clock frequency * 1000) / (PERIOD * 128)

If using the PERIOD method, it is better to read this field toward the end of the song or just before turning off the SPDIFIN. Although the hardware can lock onto the SPDIFIN data stream in as little as 2 subframes of time, the hardware is actually constantly re-adjusting itself (due to jitter, synchronization loss, etc. in the data stream) to provide the strobe point to the center of the biphase data stream. Over time, the strobe point will vary less and less because the hardware has already adjusted to all the variations seen in the data stream.

24.5.2.8 S/PDIF Transmit Data Flow

Make sure that the TX_FIFO is filled before enabling the transmission by setting TX_EN field of CTRL_0 register. Never allow the TX_FIFO to go empty at any time during transmission. The interrupt is generated when the Tx Data FIFO empty count is greater than the Tx DATA attention value (TX_ATN_LVL field of DATA_FIFO_CSR_0 register) if the Tx interrupt enable is set.

24.5.2.9 S/PDIF Receive Data Flow

To enable the reception of RX_FIFO, set the RX_EN field of the CTRL_0 register. Never allow the RX_FIFO to become full at any time during reception. The interrupt is generated when Rx Data FIFO data count is greater than the Rx DATA attention value (RX_ATN_LVL field of the DATA_FIFO_CSR register), if the Rx interrupt enable bit is set.

24.5.2.10 Method of Filling/Retrieve Data from TX/RX User/Data FIFO

Use the DMA method by programming the APB-DMA and APBIF registers. With this method, the FIFO attention levels need to be set in APBIF just like in method 2. But instead of enabling interrupts when the FIFO attention level is reached, one should program the APBDMA registers. Now, every time the attention level is reached, a DMA request will be generated by the APBIF to the APBDMA and the APBDMA will perform the data moving task from/to APBIF FIFOs to the AHB bus.

24.5.3 Clock Rates

The table below shows the clock rates required by each sub-controller for the given sample rate.

Table 68: S/PDIF Clock Rates

Sample Rate (KHz)	S/PDIF Output Clock Frequency (exact frequency MHz)	Period (ns)	S/PDIF Input Clock Frequency (min. frequency but <= 100 MHz)
32.0	4.0960	244.141	16.3840 (48 MHz typical)
44.1	5.6448	177.154	22.5790 (48 MHz typical)
48.0	6.1440	162.760	24.5760 (48 MHz typical)
88.2	11.2896	88.577	45.1584 (72 MHz typical)
96.0	12.2880	81.380	49.1520 (72 MHz typical)
176.4	22.5792	44.289	90.3168 (108 MHz typical)
192.0	24.5760	40.690	98.3040 (108 MHz typical)

24.6 Audio Multiplexer Block (AMX)

The AMX operates in two modes which differ from each other when multiplexing begins:

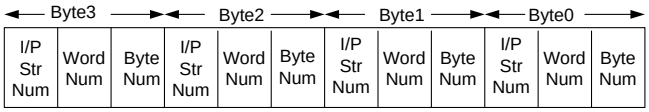
- Mode 0: At the beginning wait for all enabled input streams to have data before forming the very first frame.
- Mode 1: Start whenever data is available in any one of the enabled input streams.

  In either mode, once the first output frame is sent out, the AMX always waits for all active streams to have data available before forming and sending subsequent frames.

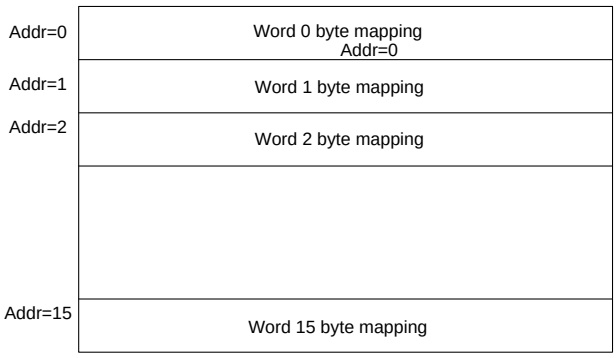
24.6.1 AMX Byte RAM Map

Each byte in the output frame is uniquely mapped to a byte in one of the four input frames. The mapping information is software configurable and is stored in a Byte Map RAM as shown in the figure below.

Figure 83: Byte Map RAM for AMX



Byte mapping for each word in the output frame (for example, Word 0)



Byte Map RAM

The maximum frame size supported is 16 words (or slots) with each word being 32 bits long. The contents of each word in RAM are described in the table below. There are three parameters stored in Byte Map RAM that specify the input source for each output byte.

1. Stream Number: Specifies one of the four input streams that sources the output byte
2. Word number: Specifies the word number within the input stream (as specified in #1 above) frame.
3. Byte number: The byte number within the word specified in #2 above

Table 69: Word Content in RAM

Field	Bits	Description
InputStrNum for output Byte3	31:30	The source stream number of the byte 3.
WordNum for output Byte3	29:26	The word number within source stream specified in bits 31:30
ByteNum for output Byte3	25:24	The byte number within the input frame word specified in 25:24
InputStrNum for output Byte2	23:22	The source stream number of the byte 2.
WordNum for output Byte2	21:18	The word number within source stream specified in bits 21:18
ByteNum for output Byte2	17:16	The byte number within the input frame word specified in 17:16
ChNum for output Byte1	15:14	The source stream number of the byte 1.
WordNum for output Byte1	13:10	The word number within source stream specified in bits 15:14
ByteNum for output Byte1	8:9	The byte number within the input frame word specified in 13:10
InputStrNum for Byte0	7:6	The source stream number of the byte 0.
WordNum for output Byte0	5:2	The word number within source stream specified in bits 5:2
ByteNum for output Byte0	1:0	The byte number within the input frame word specified in 1:0

A few important things to note:

- Input bytes cannot be mapped to output bytes out of order in any stream. This means that word zero in the input frame appears first in the output frame, followed by word 1 and so on.
- Not all bytes within an input frame need be mapped to an output byte.

- Not all output frame bytes need be enabled. Each output byte has a byte enable (software configurable). If a particular byte within output frame is not enabled, the corresponding mapping in the Byte Map RAM is ignored and that byte is populated with zeros

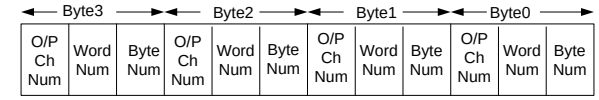
24.6.2 AMX Programming Guidelines

1. Configure Audio CIF control registers for all the four input channels (Rx CIFs) AMX_AUDIOCIF_CH0_CTRL, AMX_AUDIOCIF_CH1_CTRL, AMX_AUDIOCIF_CH2_CTRL and AMX_AUDIOCIF_CH3_CTRL respectively. Parameters to be configured are MONO_CONV, TRUNCATE, DIRECTION, REPLICATE, STEREO_CONV, EXPAND, CLIENT_BITS, AUDIO_BITS, CLIENT_CHANNELS, AUDIO_CHANNELS, and FIFO_THRESHOLD.
2. Configure the **AMX_CTRL_0** register for the **CH_DE**P parameter field which determines whether we need to wait for all enabled channels to have data before transfer or start sending the data when any one of the input channels have data (**WT_ON_ALL & WT_ON_ANY**).
3. Configure the **MSTR_CH_NUM** register for designated master channel, so that if the data is available on particular channel we can send the output.
4. Configure the Audio CIF control register **AMX_AUDIOCIF_OUT_CTRL** for the Tx CIF by the same parameters cited for Rx CIFs.
5. Enable AMX Output by setting **BYTE_EN** in **AMX_OUT_BYTE_EN0** and **AMX_OUT_BYTE_EN1** respectively.
6. Byte RAMCTL programming:
   - For programming RAM with the **HW_ADR_EN** bit unset in the **AMX_AUDIORAMCTL_AMX_CTRL** register, set RAM offset in the **RAM_ADR** field of the **AMX_AUDIORAMCTL_AMX_CTRL** register and sets data in the **DATA** field in **AMX_AUDIORAMCTL_AMX_DATA**.
   - For Programming RAM with the HW_ADR_EN bit set in the **AMX_AUDIORAMCTL_AMX_CTRL** register, set RAM offset in the **RAM_ADR** field of the **AMX_AUDIORAMCTL_AMX_CTRL** register to 0 and set data in the **DATA** field in **AMX_AUDIORAMCTL_AMX_DATA**. Hardware auto-increments **RAM_ADR** after each write.

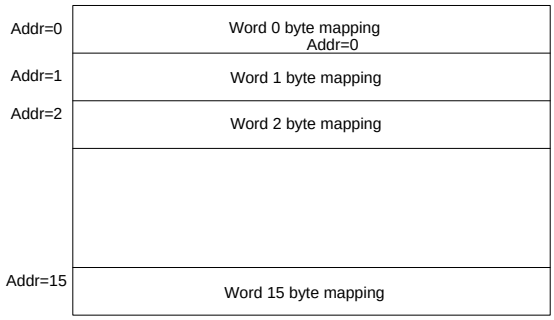
24.7 Demultiplexer Block (ADX)

The demultiplexer block (ADX) takes an input frame and demultiplexes into four audio output channels. Here the functionality is the inverse of the AMX block. Therefore, the Byte Map RAM structure is identical to that of AMX. Each output byte is uniquely mapped to an input channel (unless it is disabled, in which case it will not be used).

Figure 84: Byte Map RAM for ADX



Byte mapping for each word in the output frame (say, Word 0)



Byte Map RAM

Field	Bits	Description
OutputStrNum for output Byte3	31:30	The destination stream number of the byte 3.
WordNum for output Byte3	29:26	The word number within destination stream specified in bits 31:30
ByteNum for output Byte3	25:24	The byte number within the output frame word specified in bits 25:24
OutputStrNum for output Byte2	23:22	The destination stream number of the byte 2.
WordNum for output Byte2	21:18	The word number within destination stream specified in bits 21:18
ByteNum for output Byte2	17:16	The byte number within the output frame word specified in bits 17:16
ChNum for output Byte1	15:14	The destination stream number of the byte 1.
WordNum for output Byte1	13:10	The word number within the destination stream specified in bits 15:14
ByteNum for output Byte1	8:9	The byte number within the output frame word specified in bits 13:10
OutputStrNum for Byte0	7:6	The destination stream number of the byte 0.
WordNum for output Byte0	5:2	The word number within the destination stream specified in bits 5:2
ByteNum for output Byte0	1:0	The byte number within the output frame word specified in bits 1:0

24.7.1 ADX Programming Guidelines

1. Configure Audio CIF control registers for one input channel (Rx CIF) **ADX_AUDIOCIF_IN_CTRL** register. Parameters to be configured are MONO_CONV, TRUNCATE, DIRECTION, REPLICATE, STEREO_CONV, EXPAND, CLIENT_BITS, AUDIO_BITS, CLIENT_CHANNELS, AUDIO_CHANNELS, and FIFO_THRESHOLD.
2. Configure Audio CIF control registers for four output channels **ADX_AUDIOCIF_CH0_CTRL, ADX_AUDIOCIF_CH1_CTRL, ADX_AUDIOCIF_CH2_CTRL** and **ADX_AUDIOCIF_CH3_CTRL** for the Tx CIFs by the same parameters cited for Rx CIF.
3. Configure **ADX_OUT_CH_CTRL_0** for enabling or disabling four output channels.
4. Enable ADX input by setting **BYTE_EN** in **ADX_IN_BYTE_EN0** and **ADX_IN_BYTE_EN1** respectively.
5. Byte RAMCTL:
   - For programming RAM with HW_ADR_EN bit unset in the ADX_AUDIORAMCTL_ADX_CTRL register, set RAM offset in RAM_ADR field of ADX_AUDIORAMCTL_ADX_CTRL register and set data in DATA field in ADX_AUDIORAMCTL_ADX_DATA.
   - For programming RAM with the HW_ADR_EN bit set in the ADX_AUDIORAMCTL_ADX_CTRL register, set RAM offset in RAM_ADR field of ADX_AUDIORAMCTL_ADX_CTRL register to 0 and set data in DATA field in ADX_AUDIORAMCTL_ADX_DATA. Hardware auto-increments the RAM_ADR after each write.

24.8 Audio Hub Registers

Refer to “Reading Register Tables” in the Introduction section for the register table protocol as well as recommendations for accessing registers.

Control Register for AUDIOCIF for both TX and RX

MONO_CONV : Convert mono to stereo

ZERO -> zero out the second channel
COPY -> copy the first channel to the second channel
valid only in 1 channel to 2 channels conversion

TRUNCATE : rounding method on LSB when deleting lower bits

CHOP -> chop off the lower bits; if 1, just chop off lower bits (truncate)

ROUND -> if immediate lower bit is 1, add 1 to the significant bits

ROUND should be chosen for signed numbers because rounding is toward positive infinite. Also, in case of the max positive number, the lower bits are just chopped off.

For example with 8 -> 4 bit rounding for signed numbers

0x7F -> 0x7

0x0F -> 0x1

0xFF -> 0x0

0x8F -> 0x9

DIRECTION : Direction of CIF

TXCIF -> TX port to AUDIO

RXCIF -> RX port from AUDIO

REPLICATE : When FIFO underflows, if replicate bit is set then previous frame is repeated.

In Tegra 4 devices, only replicating for mono and stereo frames is supported due to the FIFO size limitation. If there are more than 2 channels, the samples in the FIFO are used to fill other multi-channels.

DISABLE -> Disable replication. All zeros will be used.

ENABLE -> Previous frame is repeated.

STEREO_CONV : Convert stereo to mono

CH0 -> pick the first channel

CH1 -> pick the second channel

AVG -> (ch0 + ch1) / 2

valid only in 2 channel to 1 channel conversion

EXPAND : Expand the additional bits with the following method

ZERO -> zero out the expanded field

ONE -> fill the expanded field with 1's

LSFR -> fill the expanded field with a random number

CLIENT_BITS : The number of bits in a sample in the client side

CIF_BITS : The number of bits in a sample in the AUDIO side

CLIENT_CHANNELS : The number of channels in the client side

the actual channels = CLIENT_CHANNELS + 1, i.e., 0 -> 1 channel

CIF_CHANNELS : The number of channels in the AUDIO side

the actual channels = CIF_CHANNELS + 1, i.e., 0 -> 1 channel

FIFO_THRESHOLD : This specifies the number of words that need to be present in the FIFO before a CIF starts transfers.

0 : start transfer when 1 word is received.

1 : start transfer when 2 words are received.

i : start transfer when i words are received.

For example, if FIFO_THRESHOLD is set to 3, then the Rx CIF gives rd_req to the I2S/SPDIF/DAM core only after 4 words have been written into the FIFO. It is recommended that a non-zero value be set only for rx_cifs of I2S and S/PDIF. For all other cases, the default value of zero is the appropriate setting.

24.8.1 APBIF Registers

24.8.1.1 APBIF_CHANNEL0_CTRL_0

Offset: 0x0 | Read/Write: R/W | Reset: 0x00000000 (0b000xxxxx00000000000000000x000x000)

Bit	Reset	Description

24.8.1.36 APBIF_I2S_INT_MASK_0

Because the config registers of the AUDIO clients are daisy-chained, their read latency can be high. To avoid unnecessary latency, the clients provide signals to APBI, mostly interrupt signals so that CPU/AVP can access them promptly.

These registers should be detailed further with AUDIO clients.

Interrupt Mask and Status for AUDIO Clients

24.8.2 APBIF2 Registers

Audio channels 4 through 9 have their own set of 7 APBIF2 registers. Each channel has 32 bytes of address space. This subsection defines one complete set of APBIF2 registers. The register spaces per APBIF2 channel are listed in the table below.

Table 70: APBIF2 Channel Register Mapping

Register Space	Channel Registers
0x0 – 0x1f	Channel 4 APBIF2 Channel Registers
0x20 – 0x3f	Channel 5 APBIF2 Channel Registers
0x40 – 0x5f	Channel 6 APBIF2 Channel Registers
0x60 – 0x7f	Channel 7 APBIF2 Channel Registers
0x80 – 0x9f	Channel 8 APBIF2 Channel Registers
0xa0 – 0x17f	Channel 9 APBIF2 Channel Registers

24.8.2.1 APBIF2_CHANNELn_CTRL_0

There are 6 APBIF2 Channel Control Registers, one per channel (n = 4 through 9).

Offset: 0x0 + (n * 0x20) | Read/Write: R/W | Reset: 0x00000000 (0b000xxxxx0000000000000000x000x000)

Bit	Reset	Description
31	0x0	TX_ENABLE: Enable TX channel to AUDIO. 0 = DISABLE 1 = ENABLE
30	0x0	RX_ENABLE: Enable RX channel to AUDIO. 0 = DISABLE 1 = ENABLE
29	0x0	LOOPBACK: Debug mode. The RX CIF is directly hooked up to the TX CIF. 0 = DISABLE 1 = ENABLE
23:16	0x0	TX_THRESHOLD. Trigger threshold level, number of free slots - 1. DMA request is triggered when the number of free slots is > TX_THRESHOLD. For example, If a DMA request needs to be generated when 4 free slots are available, this field needs to be set to 3.
15:8	0x0	RX_THRESHOLD: Trigger threshold level, # of data DWords - 1. DMA request is triggered when the number of DWords in the FIFO is > RX_THRESHOLD. For example, if a DMA request needs to be generated when 4 DWords are available, this field needs to be set to 3.
6	0x0	TX_PACK_EN: Enable packed data. 0 = DISABLE 1 = ENABLE
5:4	0x0	TX_PACK: 0 = NOP 1 = RSVD 2 = PACK8_4 3 = PACK16
2	0x0	RX_PACK_EN: Enable packed data. 0 = DISABLE 1 = ENABLE
1:0	0x0	RX_PACK: 0 = NOP 1 = RSVD 2 = PACK8_4 3 = PACK16

24.8.2.2 APBIF2_CHANNELn_CLEAR_0

There are 6 APBIF2 Channel Clear Registers, one per channel (n = 4 through 9).

Offset: 0x4 + (n * 0x20) | Read/Write: R/W | Reset: 0x00000000 (0b00xxxxxxxxxxxxxxxxxxxxxxxxxxxxxx)

Bit	Reset	Description
31	0x0	TX_SOFT_RESET: 0 = DISABLE 1 = ENABLE
30	0x0	RX_SOFT_RESET: 0 = DISABLE 1 = ENABLE

24.8.2.3 APBIF2_CHANNELn_STATUS_0

There are 6 APBIF2 Channel Status Registers, one per channel (n = 4 through 9).

Offset: 0x8 + (n * 0x20) | Read/Write: RO | Reset: 0xXXXX000X (0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx)

Bit	Reset	Description
31:24	X	TX_FREE_COUNT: Number of free slots in the TX FIFO.
23:16	X	RX_FREE_COUNT: Number of free slots in the RX FIFO.
1	X	TX_TRIG: TX FIFO threshold. 0 = DISABLE 1 = ENABLE
0	X	RX_TRIG: RX FIFO threshold. 0 = DISABLE 1 = ENABLE

24.8.2.4 APBIF2_CHANNELn_TXFIFO_0

There are 6 APBIF2 Channel TX FIFO Registers, one per channel (n = 4 through 9).

Offset: 0xc + (n * 0x20) | Read/Write: R/W | Reset: 0xXXXXXXXX (0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx)

Bit	Reset	Description
31:0	X	DATA

24.8.2.5 APBIF2_CHANNELn_RXFIFO_0

There are 6 APBIF2 Channel RX FIFO Registers, one per channel (n = 4 through 9).

Offset: 0x10 + (n * 0x20) | Read/Write: R/W | Reset: 0xXXXXXXXX (0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx)

Bit	Reset	Description
31:0	X	DATA

24.8.2.6 APBIF2_AUDIOCIF_TXn_CTRL_0

There are 6 APBIF2 Audio CIF TX Control Registers, one per channel (n = 4 through 9).

When packed mode is enabled for a transmit channel, data is unpacked based on the APBIF2 TX channel CLIENT_BITS field.

- CLIENT_BITS = 0: Reserved. Do not use because 4 bit mode is not supported by the audio cluster.
- CLIENT_BITS = 1: (8 bit mode) : Four 8-bit samples are packed into one 32 bit word.
- CLIENT_BITS = 2: (12 bit mode): Two 12-bit samples are packed into one 32 bit word.

- CLIENT_BITS = 3: (16 bit mode): Two 16-bit samples are packed into one 32 bit word.
- CLIENT_BITS > 3: Packing is not possible.

24.8.3 Audio Registers

24.8.3.1 AUDIO_APBIF_RX0_0

The following macro defines a register for each RX port. No more than one field can be 1 in a register because an RX port can receive from only one TX port.

Example:

```
reg DAM0_RX0 incr4
0:0          DAM0_TX0          rw        i=0
1:1          I2S0_TX0          rw        i=0
2:2          I2S1_TX0          rw        i=0
;
```

24.8.5 I2S Registers

The I^2S Controller is designed to transport streaming audio-data between the system memory and an audio-codec. The controller supports I^2S format, Left Justified Mode format, Right Justified Mode format, and DSP mode format, as defined in the Philips inter-IC-sound (I^2S) bus specification.

The controller also supports the PCM and telephony (network) mode of data-transfer. Pulse-Code-Modulation (PCM) is a standard method used to digitize audio (particularly voice) patterns for transmission over digital communication channels.

The Telephony (network) mode is used to transmit and receive data to/from an external mono codec in a slot-based scheme of time-division multiplexing.

The controller has one transmit and one receive interface. The controller can be configured to operate either as a master or a slave.

24.8.5.1 I2S_CTRL_0

The I2S control register is used to configure bit formats (I2S, LJM, RJM, DSP, PCM, NW, TDM), bit sizes (8, 16, 20, 24 and 32), FIFO formats, Master/slave selection, LR polarity, and error interrupt enables.

24.8.5.2 I2S_TIMING_0

The CHANNEL_BIT_CNT field of this register is used to program the number of bit-clocks per channel of LRCK (sampling rate) that the I^2S controller needs to send out in Master mode. This value is interpreted as follows:

- DSP mode: - Number of bit clocks (sclk) within (LEFT +RIGHT) channel width.
- Basic/LJM/RJM modes:- Number of bit clocks (sclk) within each individual channel width (LEFT or RIGHT).
- PCM/NW/TDM modes:- Number of bit clocks (sclk) per frame

The NON_SYM.EN can be used to program the I2S Controller to output a non-50:50 mark-space ratio on to the I2S bus. When the NON_SYM.EN Bit[12] is enabled, the Controller sends out exactly the programmed number of clock cycles on the left channel and one bit clock greater on the right channel. . This is used in Basic/LJM/RJM modes.

When NON_SYM.EN is enabled, the channel-bit-count should be programmed with the number of bit-clocks required in left-channel. This will ensure that the non-50:50 mark-space ratio is achieved with R_BCLK = L_BCLK + 1

The PCM/NW/TDM modes channel_bit_cnt can be calculated using the equation:

```
Channel_bit_cnt  = (frequency of bit_clk) / (2 * required sampling rate) -1;
```

If this calculation returns a fractional value, the non-symmetry feature of the controller should be used to attain the required sampling rate.

I2S Timing Register

Offset: 0x4 | Read/Write: R/W | Reset: 0x0000001f (0bxxxxxxxxxxxxxxxxxxxx0x00000011111)

Bit	Reset	Description
12	0x0	NON_SYM_EN: To enable non-symmetry mode. 0 = DISABLE 1 = ENABLE

24.8.5.8 I2S_FLOWCTL_0

This register controls the flow control mechanism and is valid only with the TX mode. The flow control is only useful when the input stream to I^2S/SPDIF is already real-time spaced such as a live stream from Baseband through another I2S_RX. If the input stream is from DMA directly, the flow control should be disabled.

FLOWCTRL

Offset: 0x1c │ Read/Write: R/W │ Reset: 0x80000XXX (0b10xxxxxxxxxxxxxxxxxxxxxxxxxxxxxx)

Bit	Reset	Description
31	QUAD	FILTER: Use linear or quadratic filter. Tegra 4 devices support quadratic filter only. 0 = LINEAR 1 = QUAD
30	DISABLE	DUMMY_WR_EN: Insert a dummy frame when enabled 0 = DISABLE 1 = ENABLE
11:8	X	START_THRESHOLD: Flow control should wait for FIFO filled N-1, 0 means actual threshold = 1
7:4	X	HIGH_THRESHOLD: High-threshold for HIGH state N-1, 0 means actual threshold = 1
3:0	X	LOW_THRESHOLD: Low-threshold for LOW state N-1, 0 means actual threshold = 1

24.8.5.9 I2S_TX_STEP_0

Offset: 0x20 │ Read/Write: R/W │ Reset: 0x00008000 (0bxxxxxxxxxxxxxxxx1000000000000000)

Bit	Reset	Description
15:0	0x8000	STEP_SIZE: This is a compensation value for the clock difference between input and output. To catch up the clock difference quickly, this value is supposed to be bigger than clock

Bit	Reset	Description
		difference in terms of STEP_SIZE; however, to avoid sound quality degradation, it should not be much greater than the clock difference. For example, the input frame sampling rate is 44.095 kHz and the output frame sampling rate is 44.100 kHz, the clock error rate is (44100 - 44095) / 44100 = 0.000113. The step size used in the linear interpolation is 0x8000 (32768) step_size = 0.000113 * 32768 = 3.7. A threshold of 4 is recommended. If the value is less than 3 in the above example, the adjusted step size will not be able to catch up. The flow control FIFO will eventually become empty, leading to either NULL or replication of the last sample.

24.8.5.10 I2S_FLOW_STATUS_0

When the flow controller is used, the step size should be properly chosen depending on the clock frequency difference. The step size should be small enough not to degrade sound quality, but big enough to converge the FIFO depth.

If the step size is not big enough, the FIFO depth will either increase or decrease, which will cause FIFO overflow/underflow eventually. The flow controller monitor and counter can be used to fine-tune the step size. When the flow controller is enabled and a proper step size is chosen, the FIFO depth should be in [threshold -1 : threshold + 1].

When the flow controller monitor is enabled and the FIFO depth is deviated from the range, either FLOW_OVERFLOW or FLOW_UNDERFLOW will be set. Also, the interrupt signal will be asserted, if MONITOR_INT_EN is enabled. MONITOR_CLR clears the FLOW_OVERFLOW/UNDERFLOW as well as the interrupt signal to APBIF.

When the flow controller counter is enabled, it records how many samples are processed and how many times the step size is applied to either lower or raise the time step. In case of stereo samples, it counts as 1.

- FLOW_NORMAL - the total number of samples (only count left channel samples).
- FLOW_OVER - the number of samples with adding STEP_SIZE to the time step.
- FLOW_UNDER - the number of samples with subtracting STEP_SIZE from the time step.

Flow Controller Monitor/Counter

Offset: 0x24 │ Read/Write: R/W │ Reset: 0x0000000X (0b00xxxxxxxxxxxxxxxxxxxxxxxxxx0xx00)

24.8.6.7 SPDIF_CH_STA_RX_A_0

This 6-word receive channel data page buffer holds a block (192 frames) of channel status information. The order of receive is from LSB bit to MSB bit, and from CH_STA_RX_A to CH_STA_RX_F and back to CH_STA_RX_A.

Note: Only channel status bits from channel A (subframe 1) will be saved into this page buffer.

SPDIF Channel Status Rx Page Buffer Register

Offset: 0x18 | Read/Write: RO | Reset: 0xXXXXXXXX (0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx)

Bit	Reset	Description
31:0	X	RX_C31_RX_C0: Channel status bits [31:0]; one bit per audio sample

31:0	X	RX_C191_RX_C160: Channel status bits [191:160]; one bit per audio sample

24.8.6.13 SPDIF_CH_STA_TX_A_0

This 6-word transmit channel data page buffer holds a block (192 frames) of channel status information. The order of transmission is from LSB bit to MSB bit, and from CH_STA_TX_A to CH_STA_TX_F and back to CH_STA_TX_A.

Note: The channel status data from this page buffer will be used only when PACK=1, or when BIT_MODE=00/01/10.
Each channel status bit will be sent out to "both" subframes.

24.8.6.19 SPDIF_FLOWCTL_CTRL_0

This register controls the flow control mechanism and is valid only with the TX mode. The flow control is only useful when the input stream to I2S/SPDIF is already real-time spaced such as a live stream from Baseband through another I2S_RX. If the input stream is from DMA directly, the flow control should be disabled.

Offset: 0x70 | Read/Write: R/W | Reset: 0x80000XXX (0b10xxxxxxxxxxxxxxxxxxxxxxxxxxxxxx)

Bit	Reset	Description
31	QUAD	FILTER: to use linear or quadratic filter. Tegra 4 devices support quadratic filter only. 0 = LINEAR 1 = QUAD
30	DISABLE	DUMMY_WR_EN: Insert a dummy frame when enabled 0 = DISABLE 1 = ENABLE
11:8	X	START_THRESHOLD: Flow control should wait for FIFO filled N-1, 0 means actual

Bit	Reset	Description
		threshold 1
7:4	X	HIGH_THRESHOLD: High-threshold for HIGH state N-1, 0 means actual threshold 1
3:0	X	LOW_THRESHOLD: Low-threshold for LOW state N-1, 0 means actual threshold 1

24.8.6.20 SPDIF_TX_STEP_0

Offset: 0x74 │ Read/Write: R/W │ Reset: 0x00008000 (0bxxxxxxxxxxxxxxxx1000000000000000)

Bit	Reset	Description
15:0	0x8000	STEP_SIZE: This is a compensation value for the clock difference between input and output. To catch up the clock difference quickly, this value is supposed to be bigger than clock difference in terms of STEP_SIZE, but to avoid the sound quality degradation it should not be much greater than the clock difference. For example, the input frame sampling rate is 44.095 kHz, the output frame sampling rate is 44.100 kHz, and the clock error rate is (44100 - 44095) / 44100 = 0.00011.3 The step size used in the linear interpolation is 0x8000 (32768) step_size = 0.000113 * 32768 = 3.7. A threshold of 4 is recommended. If the value is less than 3 in the above example, the adjusted step size will not be able to catch up. The flow control FIFO will eventually become empty, leading to either NULL or replication of the last sample.

24.8.6.21 SPDIF_FLOW_STATUS_0

When the flow controller is used, the step size should be properly chosen depending on the clock frequency difference. The step size should be small enough not to degrade sound quality, but big enough to converge the FIFO depth. If the step size is not big enough, the FIFO depth will either increase or decrease, which will cause FIFO overflow/underflow eventually.

The flow controller monitor and counter can be used to fine-tune the step size. When the flow controller is enabled and a proper step size is chosen, the FIFO depth should be in [threshold -1 : threshold + 1].

When the flow controller monitor is enabled and the FIFO depth is deviated from the range, either FLOW_OVERFLOW or FLOW_UNDERFLOW will be set. Also, the interrupt signal will be asserted, if MONITOR_INT_EN is enabled. MONITOR_CLR clears the FLOW_OVERFLOW/UNDERFLOW as well as the interrupt signal to APBIF.

When the flow controller counter is enabled, it records how many samples are processed and how many times the step size is applied to either lower or raise the time step. In case of stereo samples, it counts as 1.

- FLOW_NORMAL - the total number of samples (only count left channel samples).
- FLOW_OVER - the number of samples with adding STEP_SIZE to the time step.
- FLOW_UNDER - the number of samples with subtracting STEP_SIZE from the time step.

Flow Controller Monitor/Counter

25.0 DISPLAY CONTROLLER

The Tegra® 4 architecture has two entirely independent display controllers. They are intended to support two independent display devices, typically a local display panel and an external HDMI TV. Other configurations are possible such as two local panels. Each display controller can run at a different clock rate and drive a different resolution panel.

The Tegra 4 display controllers are significantly more efficient in the way they fetch from memory compared with prior Tegra devices. They use line buffers to store scan lines required for re-use, to avoid redundant fetches when scaling or using a tiled surface format.

25.1 Features

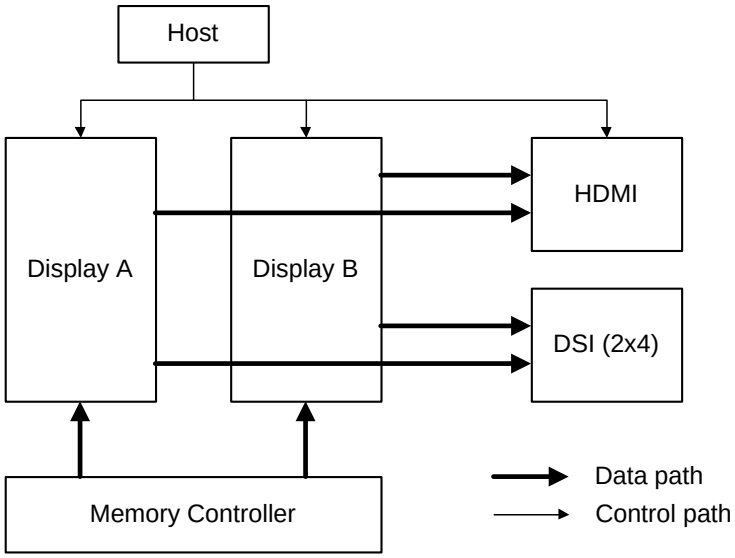
Specific enhancements include:

- Use of line buffering to avoid refetching data from memory on subsequent lines
- Efficient fetch for scaling
- Support for 32-byte memory atoms
- Improved handling of display buffer underflow
- Support for high-quality scaling/filtering across all windows
- Support up to Quad-HD resolution
- Support for Image Rotation in hardware
- Extending the cursor size to 256x256 with full color and alpha-blending
- Display Color Management unit (based on a LUT and CSC in the output path)

Features removed:

- Analog TV Out
- LCD parallel interface

Figure 85: Display Controller Top-Level Block Diagram



25.1.1 Output Capabilities

- 1 or 2 captive panels on two 4-lane DSI channels, operating either independently for 1 or 2 panels, or ganged together as 2x4 for a single panel.
  - Maximum panel size of 2560x1600 @ 60 Hz using 2x 4-lane ganged DSI channels
  - Independent resolution and pixel clock when not ganged
- 1 External Display
  - On HDMI. Maximum 1920x1080p @ 60 Hz (stereo or not)
  - On HDMI. Maximum 4096x2160p @ 30 Hz
  - With HDCP and multi-channel audio

25.1.2 Color Management Unit (CMU)

- Gamma (tone curve) conversion
- Color gamut conversion
- Allow conversion of sRGB content for a non-sRGB panel, for predictable colors (color matching)
- Enhanced PRISM display for these panels, as the PRISM algorithm assumes sRGB gamma
- Enable TCON and panels with non sRGB response
- Allows color calibrated displays, and enables end-to-end Camera / ISP -> Display color quality

25.1.3 Window A/B/C

- Data Formats
  - B4G4R4A4
  - B5G5R5A, AB5G5R5, B5G6R5
  - B8G8R8A8, R8G8B8A8
  - YCbCr420P , YCbCr422P, YCbCr422RP (planar format)
  - YCbCr422 (packed format)
  - Palletized format limited to 8-bit mode.
- Three 256x8-bit RAMs (color palette) used for gamma correction.
- Horizontal and Vertical Flip
- Horizontal and Vertical Scaling
  - Horizontal scale-down by up to 4x, subject to clock speed limitations
  - Vertical scale-down by up to 4x for 2Bpp or 2x for 4Bpp, again subject to clock speed limitations
  - Scale-up by up to 4000x
- Filtering
  - 6-tap, 16-phase programmable H filter
  - 2-tap, 16-phase programmable V filter
- YCbCr to RGB color space converter
- Digital Vibrance (8-level)

The table below describes a breakdown of features for a Tegra 4 Display on a window basis.

Head	Maximum Resolution	Window	Scaling	Planar Rotation	Packed Rotation
A INTERNAL	2560x1600	A	**Y**	**Y**	**Y**
		B	**Y**	**N**	**Y**
		C	**Y**	**N**	**Y**
B EXTERNAL	Quad-HD (4096x2160)	A	**Y**	**N**	**N**
		B	**Y**	**N**	**N**
		C	**Y**	**N**	**N**

25.2 Block Diagrams

Figure 86: Display Controller Front End Block Diagram

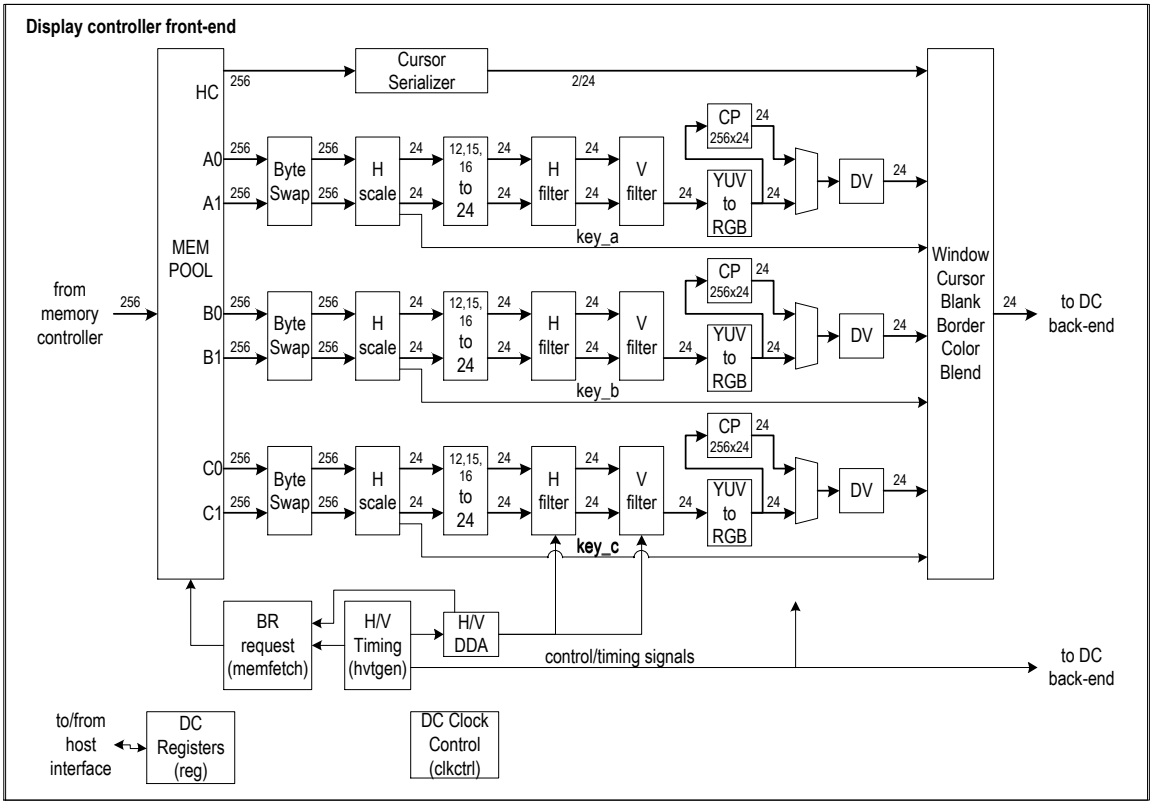


Figure 87: Display Controller Back End Block Diagram

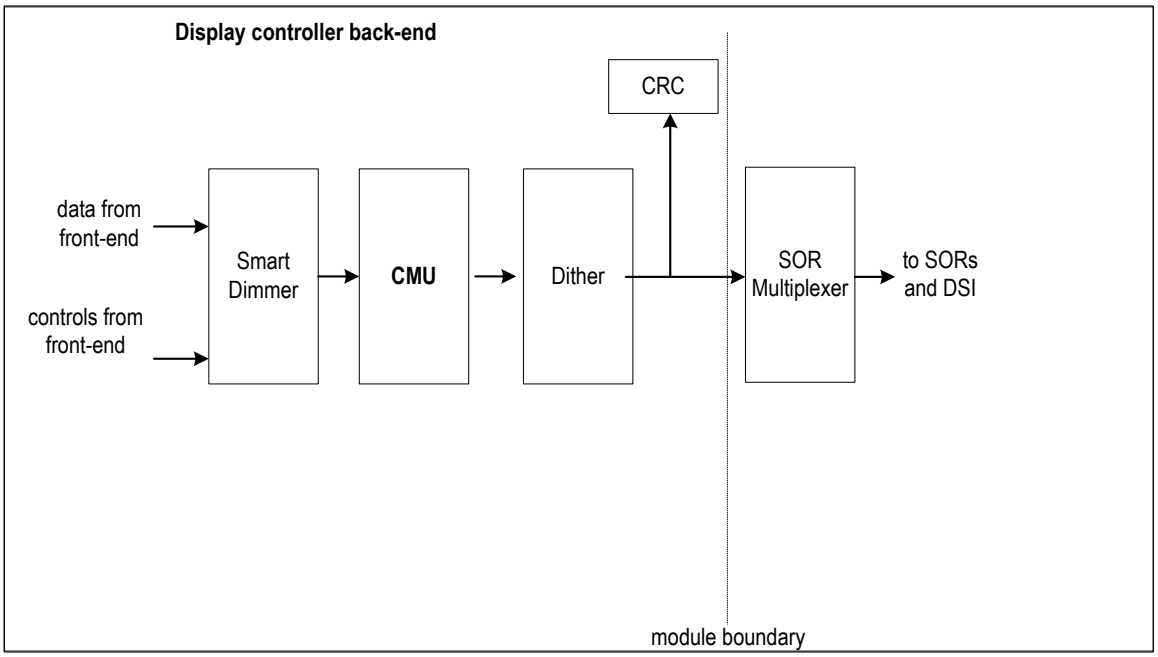


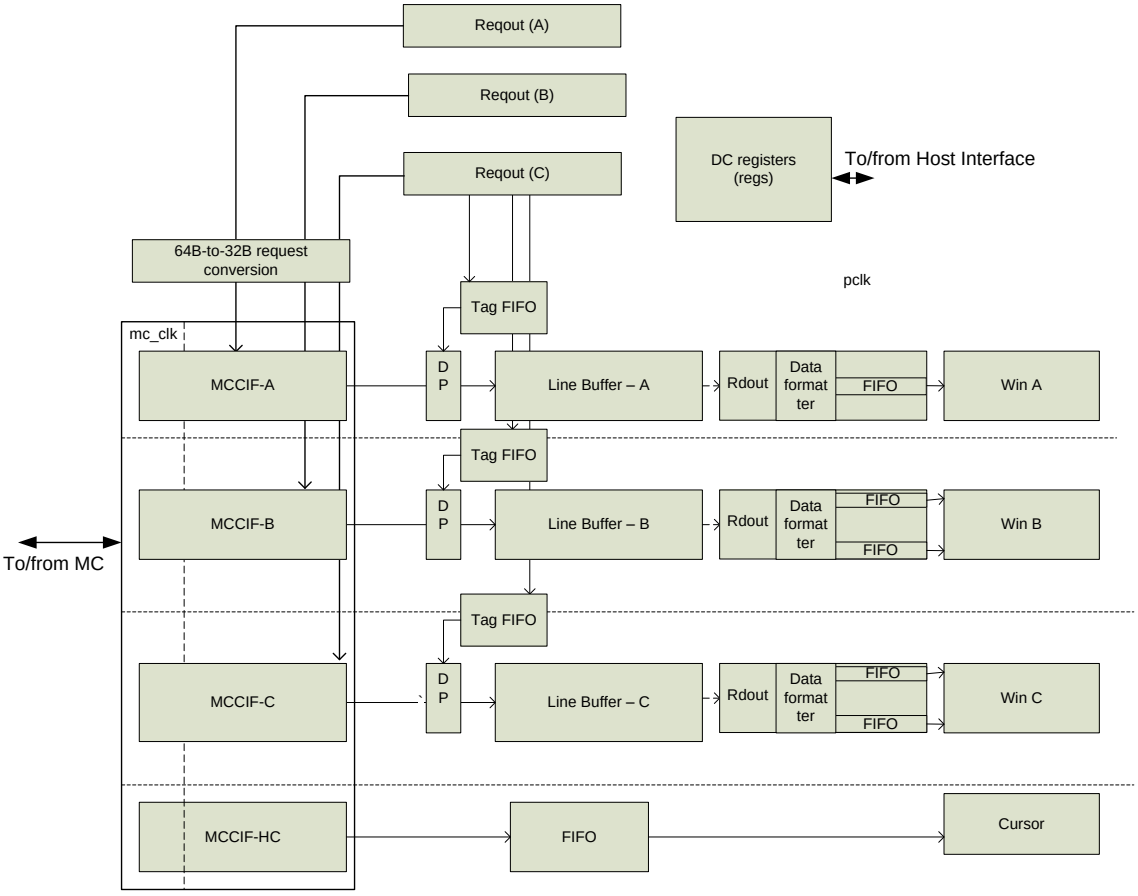
25.3 Display Controller Description

25.3.1 MEMFETCH

The top-level block diagram of the display memory interface for Tegra 4 devices is given in Figure 88. The diagram shows 3 memory fetch engines associated with the 3 windows in the display controller. Each window memory fetch engine has a line buffer and MCCIF.

Requests are issued to the memory and data is returned via MCCIF to the window line buffer. Data from the line buffer is subsequently read out, unpacked and passed to the window scaler and filter units. The cursor fetch engine does not contain line buffers.

Figure 88: Memfetch Block Diagram



25.3.1.1 Request Engine

The request engine is responsible for fetching the window image from memory. Logic to translate the X, Y coordinates to a linear memory address is used to make 32B requests to memory. This logic previously resided in the MCCIF.

A pulse signal is sent to the request engine from the display timing generator at the beginning of the vertical blanking period to alert the request engine to start requesting the image data. Tagged 32B requests are sent to the MCCIF. The thread ID specifying the line location of the return data is passed to the tag FIFO between the request and response engines. The thread ID is read by the data packer block when the return data is received and the data is steered to the appropriate line(s) in the line buffer.

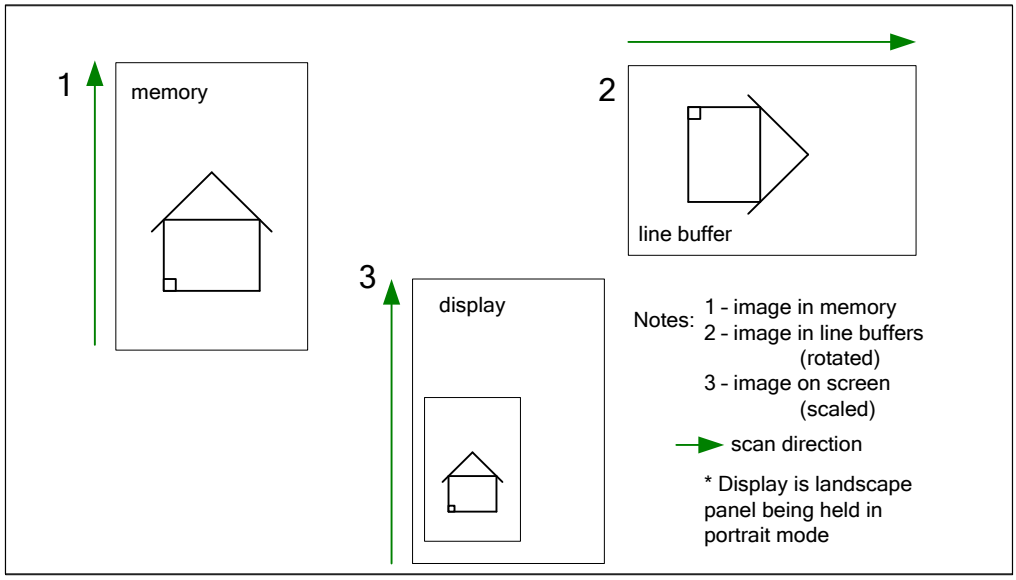
The request engine must handle the following surface formats:

- Pitched linear surface
- Tiled surface – 16B x 16 line
  - 16B x 2 line – subset with incrementing X (non-rotated)
  - 16B x 2 line – subset with incrementing Y (rotated surface)

Rotation Support

Previous versions of display support 0° or 180° rotation or image flip. Tablet use of portrait mode has now made rotation (90° or 270°) a common use-case. To support rotation the memfetch unit will rotate the data at the input to the line buffers. Put simply memfetch will walk the Y axis and store these columns in memory as rows to the display. The figure below illustrates the image orientation and shape at different stages in the pipeline for rotation.

Figure 89: Example Rotation Use-Case



Memfetch only supports rotation in tiled mode. This is due to the amount of horizontal pixel data read in pitched linear versus tiled format. For pitched linear 32B of horizontal data is fetched compared to tiled format where only 16B of horizontal data is fetched using the 16B x 4 line block linear mode. Since rotation switches rows and columns the 4 horizontal pixels become 4 rows in the line buffer. Therefore the minimum number of lines when rotation is enabled is 4. The number of lines grows to 5 when scaling is enabled.

The request for 16Bx4 tiled format must be communicated to MCCIF via addressing bits 6 and 7. Memfetch will increment the Y instead of X coordinate for subsequent accesses and after reaching maximum Y will reset the coordinates to (X+16B, 0) for the next fetch of columns from memory.

An additional bit (SCAN_COLUMN) is defined to indicate if the image needs to be scanned out row by row or column by column. When this bit is enabled display need to scan out lines column by column. This will provide the required 90°/270° rotated images. To achieve 90° or 270° rotation, software must use a combination of H_DIR, V_DIR and SCAN_COLUMN as shown in the table below. It illustrates how the image is scanned in to display by the memfetch unit for each combination of (SCAN_COLUMN, H_DIR, V_DIR).

SCAN_COLUMN	H_DIR	V_DIR	Orientation
0	0	0	0 degrees
0	0	1	N/A – vertical flip
0	1	0	N/A – horizontal flip
0	1	1	180 degrees
1	0	0	N/A – vertical flip followed by rotation
1	0	1	90 degrees
1	1	0	N/A – horizontal flip followed by rotation
1	1	1	270 degrees

The window dimension registers start to get confusing when rotation is introduced. Therefore it's important to note which registers apply to pre-rotation and which to post rotation.

The following registers apply to pre-rotation:

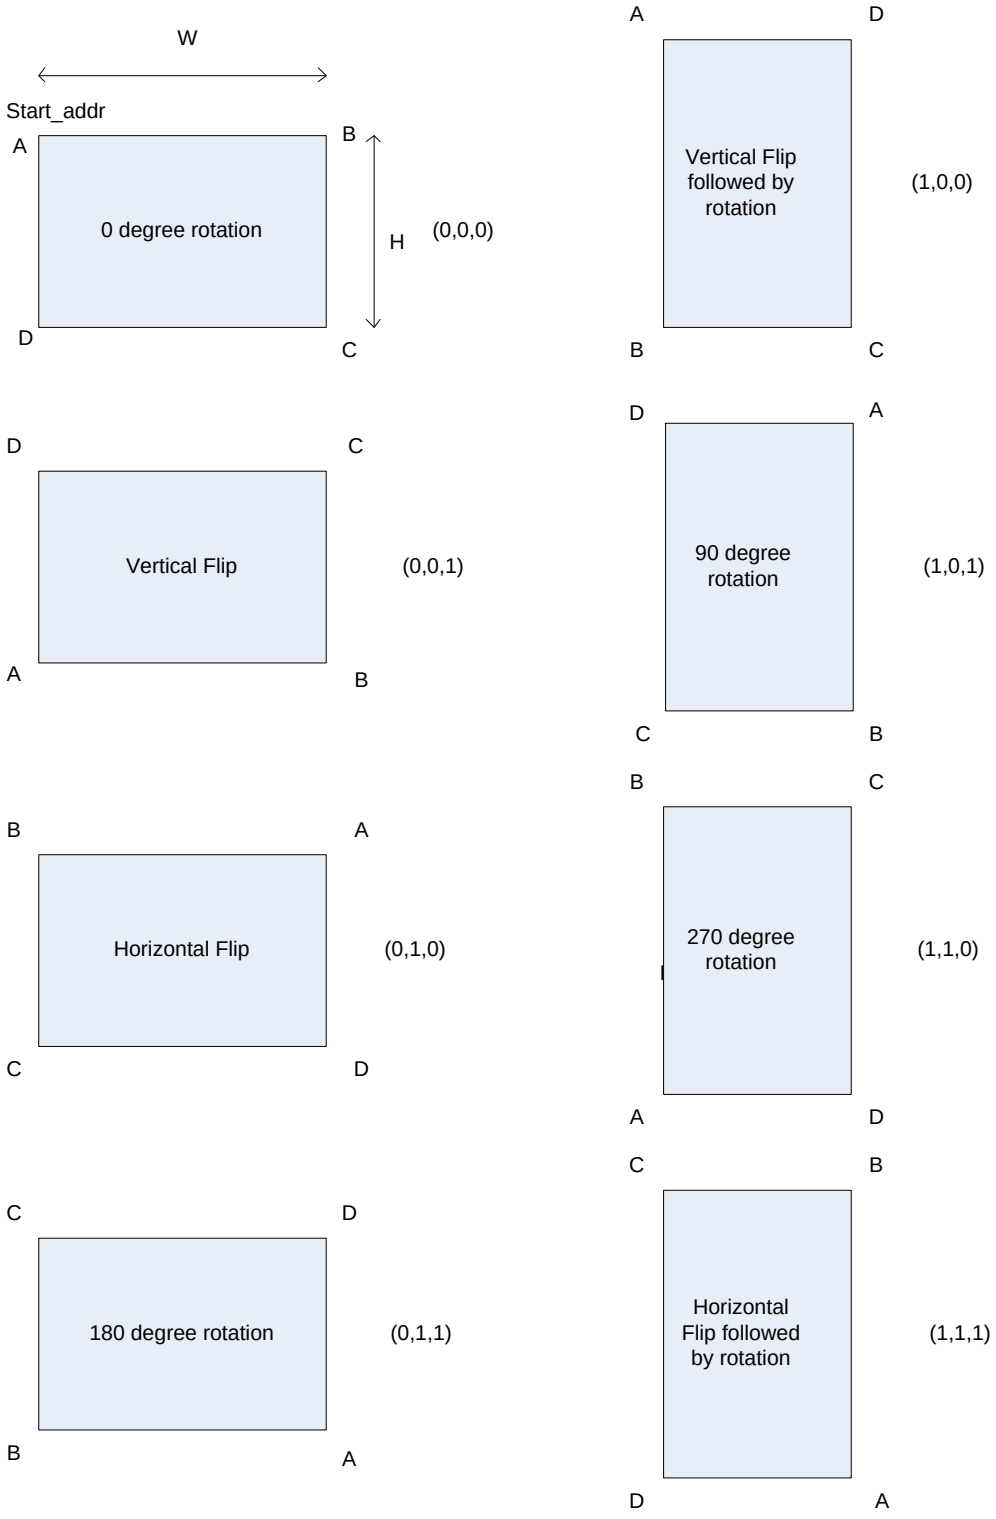
- B_WIN_OPTIONS
  - H_DIR
  - V_DIR
  - SCAN_COLUMN
- B_LINE_STRIDE
- B_START_ADDR_*
- B_ ADDR_H_OFFSET_*
- B_ ADDR_V_OFFSET_*

The following registers apply to post rotation:

- B_WIN_OPTIONS
  - H_FILTER*
  - V_FILTER*
  - SCAN_COLUMN
- B_PRESCALED_SIZE
- B_SIZE
- B*_INITIAL_DDA
- B_DDA_INCREMENT

Because the memfetch unit is essentially walking the Y axis in memory the majority of the window registers and its associated logic remain unchanged. Therefore except for B_ADDR_H/V_OFFSET horizontal and vertical directions are with respect to post rotation.

Figure 90: Rotation Combinations



25.3.1.2 Line Buffer

The memfetch line buffer allows the display controller to retain one or more scan line of window data locally so that no further reading of the scan line is required from memory. The scenarios where this is required are:

- Vertical scaling and filtering
  - Requires 3 scan lines of data for non-rotated memory fetches
  - Requires 5 scan lines of data for rotated memory fetches of packed data
- Reading tiled data
  - Data is sent in 2 scan lines for non-rotated memory fetches
  - Data is sent in 4 scan lines for rotated memory fetches

Data is received from the memory interface and steered to the proper location in the line buffer. Data is read out of the line buffer and unpacked based on the pixel format. These pixels are sent to the window scaler logic in the display pipe.

In the vertical scaling and filtering scenario, up to five scan lines of data are required for the vertical scaler engine for it to generate the proper scaled output. In the tiled mode scenario, only a single scan-line is output but the 32B returned data contains portions of two scan lines. To ensure adequate storage of RGB packed data format and steady bandwidth consumption to the display controller line buffers will be deep enough to hold up to five lines of maximum width of packed pixel data based on the maximum use-case supported by the given window.

Support for YUV planar rotation when reading data in 16Bx2 format requires a larger amount of data storage. Each plane of data will return 16B per color component. Due to scaling it is required to keep a scan line of data in the buffer when fetching the next block of 16. This will require an additional byte of data. Therefore the buffer requirements for YUV planar are:

- Number of bytes per plane = 17B
  - Minimum data fetch size = 16B
  - Scaling requires additional scan-line remain
  - Pixel component depth per plane = 1B
- Number of planes = 3
- Line buffer width = 2560 pixels – Tegra 4 maximum width
- Line buffer size = 17 bytes/plane* 3 planes/pixel * 2560 pixels per line
  - 130560 bytes

Since the line buffer storage requirement for YUV planar is close to three times (3X) the RGB packed format, the Tegra 4 display only supports buffering support for YUV planar rotation on 1 window. This restriction applies to YUV422 packed data as well due to the implementation of expanding the data to YUV444 in the line buffer. The other two windows will contain buffering to support non YUV planar rotation (51200 bytes).

Below are the equations used to calculate buffer requirements for a given rotated video image.

- YUV444 (packed):
  - Scaling – 5 lines*4Bpp*width
  - No scaling – 4 lines*4Bpp*width
- YUV422 (packed):
  - Scaling – 9 lines*4Bpp(as data is expanded)*width
  - No scaling – 8 lines*4Bpp(as data is expanded)*width
- YUV420 (planar):
  - Scaling: 3 (number of surfaces)*17*width (17 lines @ 1B/line)
  - No scaling: 3 (number of surfaces)*16*width (16 lines @ 1B/line)

As previously stated the purpose of the line buffer is to prevent re-fetch of data from memory. The line buffer size requirement to prevent re-fetch depends on the use-case. Based on the use case and method of packing/unpacking pixels stored in the line buffer there will be an inherent pixel latency associated with the buffer. The memory controller can take advantage of this latency to temporarily stop sending pixel data to display for cases such as changing the memory clock frequency.

Note that the line buffer can be written or read either with single or multiple lines per clock. For non-rotation use cases, line buffers can be loaded either one or two lines at a time corresponding to pitched linear or tiled data formats. For rotation use cases, line buffers load up to 16 lines at a time based on pixel format. Line buffers are read one or two lines at a time based on vertical scaling. The following tables and figures illustrate the line buffer size as well as inherent latency for various use cases for packed ARGB formats (4Bpp). For rotation use-case only tiled formats are supported. Tiled format is 16Bx16 lines.

Table 71: Non-Rotation Use Cases

Scenario	Vertical Scaling Enabled	Data Format	Line buffer size required to avoid re-fetch	Pixel Latency of Line Buffer
A	NO	Pitched-linear	0	0
B	NO	Tiled	1 line	0 - 1 line
C	YES	Pitched-linear	1 line	0
D	YES	Tiled	3 lines	1 line

Table 72: Rotation Use Cases

Scenario	Vertical Scaling Enabled	Data Format	Line buffer size required to avoid re-fetch	Pixel Latency of Line Buffer
A	NO	Tiled	4 line	1 - 4 lines
B	YES	Tiled	5 lines	2 - 5 lines
C	NO	YUV Planer	16 line	1 - 16 lines
D	YES	YUV Planer	17 lines	2 - 17 lines

The pixel latency refers to the number of lines available in the line buffer when the line buffer is full between when a given pixel is written to and read from the line buffer. For some of these use cases, there is a relatively long period of time after a pixel is written to the buffer before it is needed in the scan line. However it is important to note that in every case where a scan line or more of data exists the scan lines are being written at a rate of ½ or ¼ of the pixel clock rate since either 2 or 4 scan lines are being read at once from memory at a rate of 1 pixel per clock.

The fixed size of the Tegra 4 display buffers is given below. Each buffer size has a corresponding “maximum use-case” scenario from those listed above. For those scenarios that are not “maximum use-case”, the portion of the line buffer beyond what the scenario required can be used as latency buffering. Indeed, even the “maximum use-case” scenario can use a portion of the pixel latency as latency buffering.

Table 73: Tegra 4 Display Line Buffer Sizes

Line Buffer Size (KB)	Maximum Use-Case	Maximum Resolution
128	Rotation – Scenario C	2560x1600
50	Rotation – Scenario B	2560x1600
48	Non-Rotation – Scenario D	Quad-HD (4096x2160)

To take advantage of the portion of the line buffer dedicated for handling latency MEMFETCH will send flags to MC indicating when a programmable threshold is crossed. For each scenario, software must calculate the portion of the line buffer that can be used for latency buffering and set the threshold accordingly. Below are is a list of the flags MEMFETCH will generate:

- SPOOLUP
  - Signal name: csr_display0a2mc_spool_up
  - Active from when data is requested during Vblank until active space
  - Active space starts with 1st pixel of window sent to display pipe
- DVFS buffering

- Requires HWM threshold
- Signal name: csr_display0a2mc_ready_for_latency_event
- Active when:
    - Buffer exceeds HWM threshold
    - Window is disabled
    - From the time all data is read for current frame until data is requested for subsequent frame
- Deactivated with occurrence of underflow for the remainder of the frame

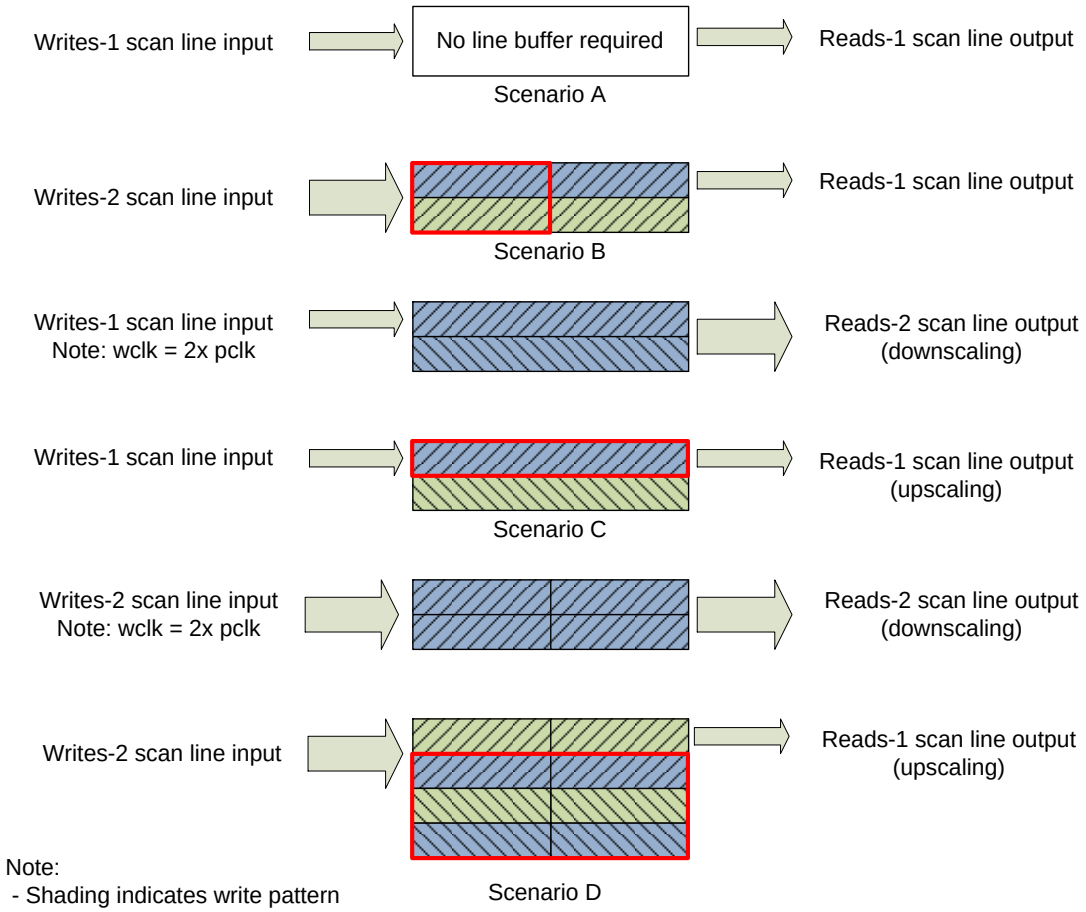
- LATENCY ALLOWANCE SCALE FACTOR buffering
    - Requires HWM/LWM thresholds
    - Signal names:
        - csr_display0a2mc_la_th_above_hi = level > HWM
            - deactivate with occurrence of underflow for remainder of frame
            - activate when window is disabled
        - csr_display0a2mc_la_th_below_lo = level < LWM
            - activate with occurrence of underflow for remainder of frame
            - deactivate when window is disabled

The programmable threshold will simply keep a running count of the number of bytes in the buffer and compare that value against the one in the threshold register.

Line buffering for planer YUV requires separate storage per plane. Each line is read by sending 1KB of Y requests followed by IKB of U then 1KB of V requests. This is maintained until the entire line of YUV is read. Subsequent line requests are not issued for any component until all component requests have been issued for the current line. MEMFETCH does allow for changing the weights of the given requests per plane to help control the behavior of the requests per plane.

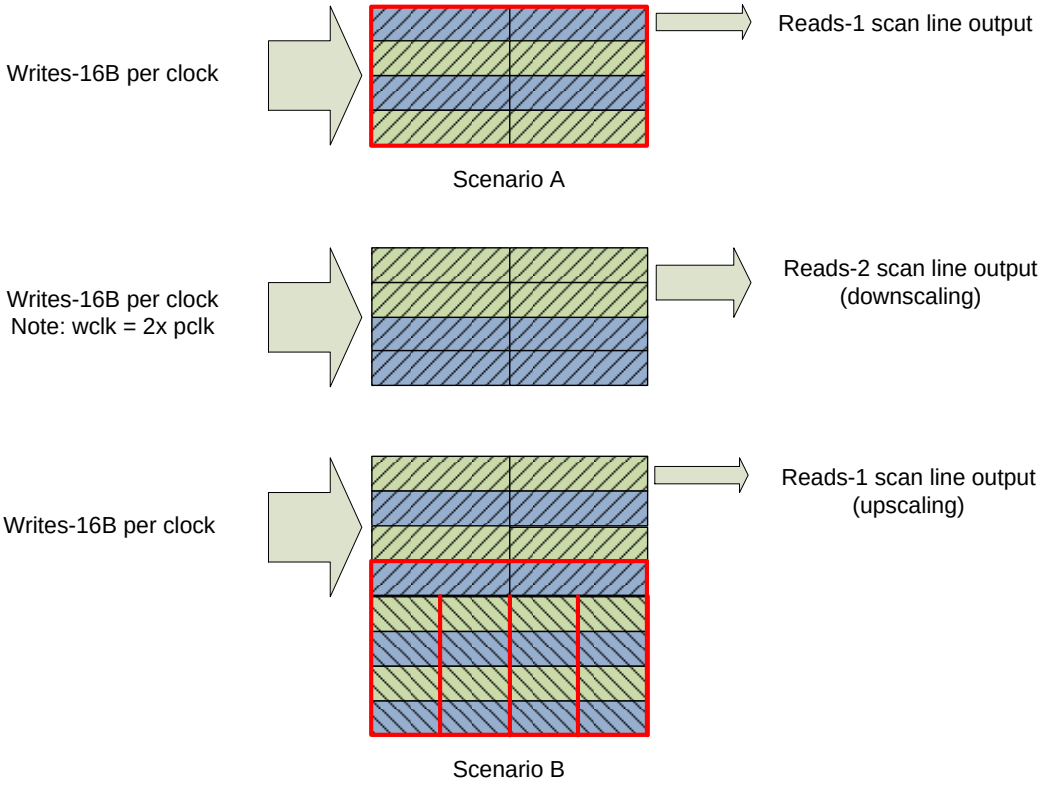
For non-rotated YUV planer use cases, the size of the line buffer is less than that of 4B ARGB since the pixel format is only 1.5B/pixel. However, rotated planer YUV requires storage of 16B for each line per plane. Contact your NVIDIA AE should you need further support on this.

Figure 91: Non-Rotation Line Buffer Use Cases



Note:
- Shading indicates write pattern
- Color indicates read pattern
- Red box indicates line buffer max size to avoid re-fetch

Figure 92: Rotation Line Buffer Use Cases



Note:
- Shading indicates write pattern
- Color indicates read pattern
- Red boxes indicate line buffer size needed to avoid refetch
- Red lines indicate progress of filling line buffer as scan lines are read

25.3.1.3 Handling of Underflow

Display is an isochronous client that requires a steady bandwidth allocation. If data is not returned at a fairly constant rate and the line buffers run dry then data will not appear on the screen at the proper time. Eventually when data does start to flow to the display controller the image will appear shifted and there is no way for the image data to catch up to where it should be on the screen. This undesirable lack of guaranteed data is called underflow and it can happen in 2 forms:

- Short term underflow – pixels worth of missing data
- Long term underflow – scan-lines worth of missing data

For short term underflow it is possible for the display controller to catch up to the correct pixel by the start of the next scan-line by reading pixels during the horizontal blanking period. Short term underflow is being managed by Tegra display controller in this manner. For long term underflow it would be impossible for the display controller to throw out that much data. Short term underflow may arise when the memory controller is over-taxed based on a momentary surge in memory client requests. Long term underflow may happen when memory controller frequency changes are being made.

Tegra 4 display windows will address short term underflow similar to what is done in Tegra 3. Long term underflow is also handled in a manner similar to Tegra 3 during the active frame portion. Below is a description of Tegra 4 Underflow recovery improvements:

- Underflow recovery within a frame

- Similar to Tegra 3:
    - Start counter of underflow pixels when underflow occurs
    - Last valid pixel is held at the beginning at the display pipeline for duration of the underflow
    - Underflow pixels that eventually return to display are stored in line buffer and immediately read/discarded
    - Operation continues (even during HBlank) until all underflow pixels have been discarded
    - Once valid pixel is present at display pipe input memfetch operations return to normal mode
- Limit requests issued at the end of a frame if window is in underflow using the following method:
    - For cases when underflow continues to the end of the frame
    - Add threshold counter (B_UFLOW_THRESHOLD)
    - Track prescaled scanout
    - Stop issuing frame requests when
        - prescaled scanout + threshold is > prescaled size

- Underflow recovery between frames
    - Add a FIFO before DP logic to determine which of the responses that are coming back are for the previous frame
    - Drop pixels from previous frame at 64B/pclk rate
    - Within display pipe, reset the underflowed pixel counters
    - Limit requests issued at the end of a frame if window is in underflow using method described above

The Tegra 4 display handles cursor underflow in the following manner:

- Interface between memfetch and display pipeline will sense when underflow occurs.
- When underflow occurs display pipeline will drive cursor alpha value of 0 for the remainder of the underflow period. This could be until the end of 1 or more scan-lines.
- Memfetch will not drive valid to display pipeline until the start of the scan-line when data is available.
- Display pipeline will not assert ready to memfetch until the beginning of the scan-line when data is available and memfetch is driving valid.
- Memfetch keeps track of number of clocks of missing data and when data does appear it reads out the data until the end of the scan line is reached.

It is important to highlight underflows for debug purposes. Current display units raise an interrupt to indicate that underflow has occurred. The Tegra 4 display continues to drive an interrupt when an underflow is detected. To further assist with highlighting underflows memfetch drives a solid color from the window that experiences an underflow if the associated enable bit is active.

25.3.2 Surface/Color Formats

In general, the Tegra 4 display supports the same pixel and surface formats used in Tegra 3. These pixel formats are not supported by the Tegra 4 display controller:

- P1 – 1bpp palletized
- P2 – 2bpp palletized
- P4 – 4bpp palletized
- RGB666
- YUV422RA

Below is a list of the surface and pixel formats supported by the Tegra 4 display controller. Formats are lsb-to-msb.

Surface formats:

- Pitched linear – scan-line data
- Tiled – 16B x 16 line

Pixel formats:

- RGB packed
  - P8 – 8bpp palletized
  - B4G4R4A4 - 16bpp
  - B5G5R5A- 16bpp
  - AB5G5R5 - 16bpp
  - B5G6R5 - 16bpp
  - B8G8R8A8- 32bpp
  - R8G8B8A8- 32bpp
- YUV packed
  - YCbCr422 – packed CbYCrYCbYCrY…
  - YUV422 – like YCbCr422 but with “True” YUV
- YUV planar
  - YCbCr422P (3 surfaces)
  - YCbCr422R (3 surfaces, rotated - U and V are same horizontal width as Y, but decimated by 2 vertically. 422R differs from 422P by decimating horizontally and replicating vertically)
  - YCbCr420P (3 surfaces)
  - YUV422P – like YCbCr422P but with “True” YUV
  - YUV422R – like YCbCr422R but with “True” YUV
  - YUV420P – like YCbCr420P but with “True” YUV

True YUV formats are supported in display along with YCrCb. YUV differs from YCbCr in that UV is signed -127 to 128 where CbCr is offset 128 and ranges 0 to 255.

25.3.3 Horizontal Filter

Memfetch and scalar provide 6 adjacent pixels per clock, along with DDA fraction indicating filter kernel phase. Fraction selects among 16 sets of coefficients for filter kernel.

25.3.4 Vertical Filter

When enabled, memfetch provides 2 adjacent lines in parallel, which are independently horizontally filtered before being sent to vertical filter. The fractional DDA from vertical scalar (indicating filter phase) selects among 16 filter kernel coefficients. For coefficient entry N, the weights are N and 1-N.

25.3.5 Color Space Converter

Most of the display datapath is RGB. The color space conversion unit can convert YCbCr and YUV to RGB. It can also do some RGB to RGB conversions.

25.3.6 Color Palette/LUT

To support gamma and palletized formats, the LUT has three 256x8-bit tables, one each for red, green, blue. The three tables are independent and can represent arbitrary functions. For 4-bit palette modes, only the bottom 16 entries are used.

25.3.7 Digital Vibrance

Using the same algorithm as NVIDIA® GeForce GPUs, Digital Vibrance can increase the saturation of colors.

25.3.8 Cursor

Cursor supports two pixel formats:

- Legacy 2-bit-per-pixel, where the four values are background color, foreground color, transparent, and invert. Foreground and background color are programmable via registers with 24-bit RGB values. Transparent means cursor is invisible and desktop shows through. Invert means desktop RGB is inverted (red' = 255 – red, etc.). Pixels are packed 4 per byte, and each line is 16 bytes pitch, regardless of whether it is 32 or 64 pixels wide.
  - Cursor size of 32x32 or 64x64
- 32-bpp RGBA pitch linear
  - Full color with alpha
  - Cursor size of:

    32x32

    64x64

    128x128

    256x256

The blending required for alpha cursor will occur after the blending stage and use the following blend equation:

Final_image = cursor_alpha * cursor_color + (1-cursor_alpha) * blending_stage_output_color

Note: Legacy cursor does not support per-pixel or global alpha.

Cursor can be clipped to either the display, or window A, B, or C. Thus the cursor active region for blending must be computed according to that mode. In regions where cursor is clipped, or outside the cursor entirely, blending behaves as if cursor is disabled (i.e., previous blend stage passes through.)

Note: The Tegra 4 display cursor supports partial clipping but does not support trivial reject of the cursor when the cursor is completely outside of the window region. It is the responsibility of software to ensure that the cursor is at least partially visible.

25.3.8.1 Legacy Support for Blending

The Tegra 4 display supports cursor modes used in previous generations of the Tegra display. Legacy cursor blending uses 2 bits per pixel and programming for this mode will remain unchanged.

25.3.8.2 32-bpp RGBA Cursor Mode

In 32-bpp RGBA cursor mode, legacy adaption is disabled. Cursor RGBA is blended with the last stage of the window blending unit. Cursor alpha value controls this blending.

25.3.9 Blending

The Tegra 4 display uses weighted blending between windows. Legacy cursor blending must be disabled when full-color alpha-blended cursor is in use.

The Tegra 4 device uses "parallel" blending.

Each Tegra 4 display controller has three windows (called A, B, and C) and a cursor. The three windows and cursor are combined to form the final output image; this operation is called "blending" or "compositing".

Each window and cursor has an independent position and size on the output raster. Areas with no window are filled with a background (“border”) color, which is programmable. The border color, however, does not participate in blending, except for cursor. In other words, the background under windows is effectively opaque black.

The cursor is always on top of the three windows and is logically a separate blending stage. The three windows do not have separate sequential stages or order; they are essentially peers and all contribute color in parallel to the final result.

In the example image below, three windows plus cursor are shown. The cursor is the upper-right square. The red area is “border” color. As you can see, the border color does not show within a window, but may show within the cursor. There are three areas where two windows overlap, and an area where all three overlap.

Figure 93: Window Blending Example

At each pixel of the output raster, the three windows can overlap in eight different ways:

- A only
- B only
- C only
- A and B
- A and C
- B and C
- A and B and C
- No window

The “no window” case is just filled with border color, as mentioned above. The seven other overlap cases each have separate blending equations. For example, Window A has four overlap conditions:

- A only
- A and B
- A and C
- A and B and C

These can be generalized for any window as:

- One window: self only
- Two windows: self + “other window 1”
- Two windows: self + “other window 2”
- Three windows: self plus other two windows

The blending control registers are organized per-window as the four cases above. Thus there are 12 sets of blending registers: three windows times four overlap cases each. There are additional cases to cover color-key match and non-match, but this document does not address color key.

The fundamental blending equation is

$$Color_{OUT} = Weight_A * Color_A + Weight_B * Color_B + Weight_C * Color_C$$

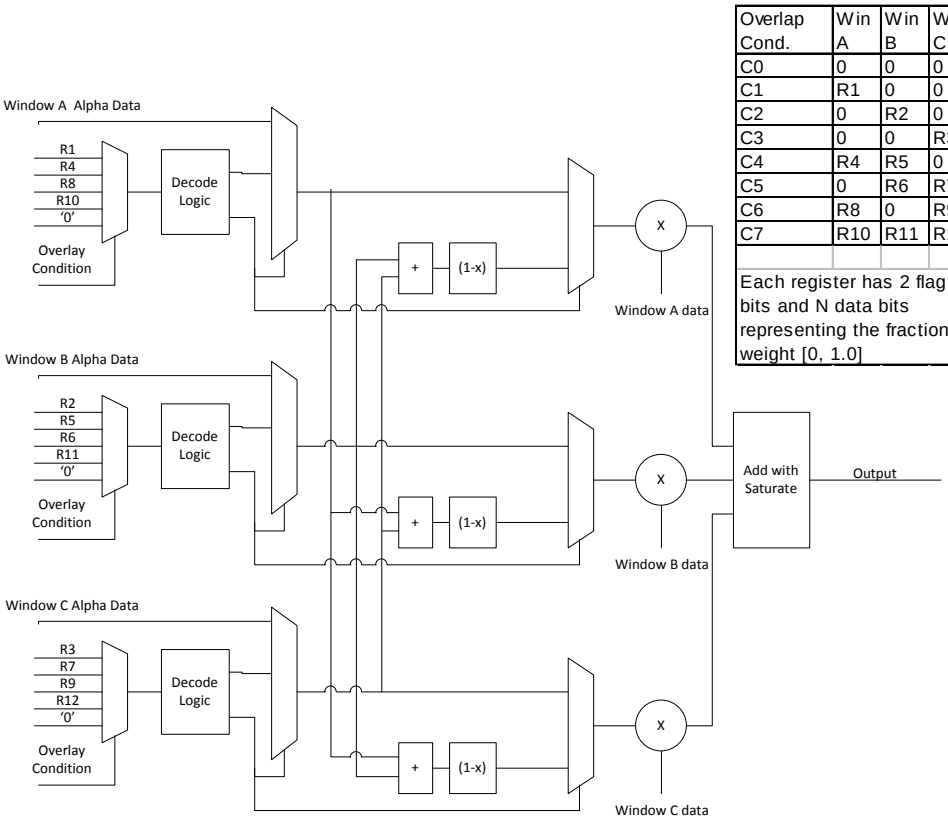
Where:

- Weight for each window is specified by blending control registers.
- Color is the result of each windows’ processing pipeline.

If a window does not participate in an overlap case, its weight is 0.

This architecture is shown schematically in the figure below.

Figure 94: Blending Schematic



Overlap Cond.	Win A	Win B	Win C
C0	0	0	0
C1	R1	0	0
C2	0	R2	0
C3	0	0	R3
C4	R4	R5	0
C5	0	R6	R7
C6	R8	0	R9
C7	R10	R11	R12

Each register has 2 flag bits and N data bits representing the fractional weight [0, 1.0]

For each of the four cases, each involved window has the following blending parameters:

- BLEND_CONTROL: FIX_WEIGHT, ALPHA_WEIGHT, DEPENDENT_WEIGHT, or PREMULT_WEIGHT
- BLEND_WEIGHT. 8-bit weight used for FIX_WEIGHT case

BLEND_CONTROL specifies the windows' weight for the blending equation:

- FIX_WEIGHT: the weight is from BLEND_WEIGHT register. This allows a window without per-pixel alpha to have a constant alpha.
- ALPHA_WEIGHT: The window surfaces' per-pixel alpha is used. The pixel RGB has not been pre-multiplied by alpha.
- DEPENDENT_WEIGHT: The window weight is the inverse of the *other* window(s)' weight(s). For example, in a two-window overlap case, if the other window has per-pixel alpha, then this window's weight is 255 – other_window_alpha. In a three-window overlap case, the weight is 255 – other_window1_weight – other_window2_weight.
- PREMULT_WEIGHT: Like ALPHA_WEIGHT except the pixel RGB has been pre-multiplied by its alpha.

25.3.9.1 Color Key

When color key is enabled on a window, there is an additional blending mode. When the key color is not matched, the window is forced to the foreground (i.e., the other two windows' blending weights are forced to 0.) When the color key is matched, blending proceeds normally. The window with color key would be programmed with FIX_WEIGHT and BLEND_WEIGHT=0 for all overlap cases, so that in the color key match case, the key color is not visible.

25.3.9.2 Two-Window Blending

A over B, where B is an opaque bottom window, can be achieved with:

- A BLEND_CONTROL = PREMULT_WEIGHT
- B BLEND_CONTROL = DEPENDENT_WEIGHT

Giving $Color_{OUT} = Color_A + (1 - Alpha_A) * Color_B$.

25.3.9.3 Three-Window Blending

The parallel blending described above is different than Porter-Duff style blending. Two-window Porter-Duff style "A over B" blending can be done. Three-window Porter-Duff-style blending – A over (B over C) – can be done in some but not all cases.

The three window case -- A over (B over C) – uses the general equation:

$$Color_{OUT} = Color_A + (1 - Alpha_A) * Color_B + (1 - Alpha_A)(1 - Alpha_B) * Color_C$$

In cases where two windows (for example, B and C) are opaque, this simplifies to:

$$Color_{OUT} = Color_A + (1 - Alpha_A) * Color_B + 0 * Color_C$$

which can be supported.

There are some limitations in the case where two of three windows are not opaque and all overlap. In Tegra 4 devices, a BLEND_CONTROL can be set to PREMULT_WEIGHT for the $Color_A$ term but the proper $Color_B$ or $Color_C$ terms cannot be achieved. Both B and C require inverse of window A weight but the blender only allows one window to be DEPENDENT_WEIGHT. Also, it cannot supply $(1 - Alpha_A)(1 - Alpha_B)$.

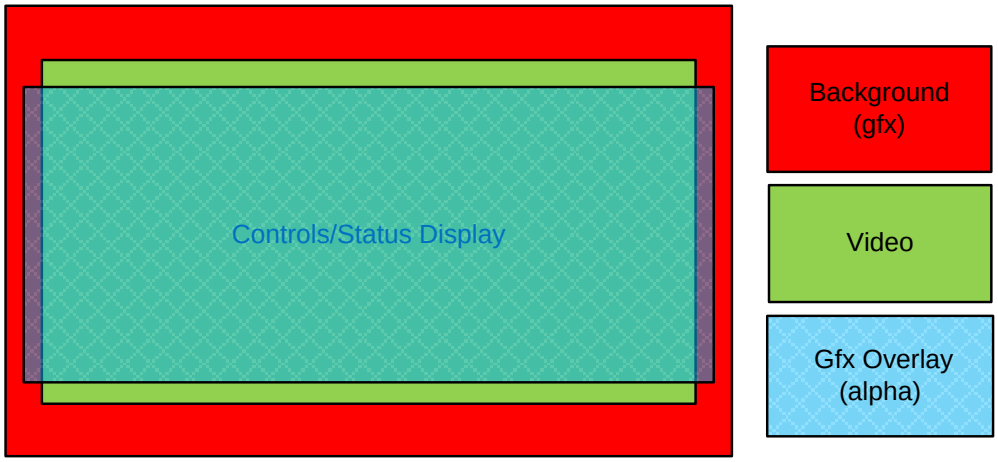
25.3.9.4 Example Use Cases

General Porter-Duff-style blending is not needed in many cases, such as when only one of three windows have per-pixel alpha.

Example 1

In Example 1, window A is a graphics background, window B is a video window, and window C is a graphics overlay on top of video and background. Windows A and B are fully opaque, and window C has per-pixel alpha.

Figure 95: Example 1



Window A weights:

- A and B. Video has precedence so use FIX_WEIGHT with BLEND_WEIGHT=0
- A and C. Graphics overlay has alpha so use DEPENDENT_WEIGHT
- A and B and C. Video has precedence so use FIX_WEIGHT with BLEND_WEIGHT=0

Window B (video) weights:

- A and B: Video has precedence so use FIX_WEIGHT with BLEND_WEIGHT=255
- B and C: Graphics overlay has alpha so use DEPENDENT_WEIGHT
- A and B and C: Graphics overlay has alpha so use DEPENDENT_WEIGHT (since A has BLEND_WEIGHT=0, video has weight 255 – window_C_alpha.)

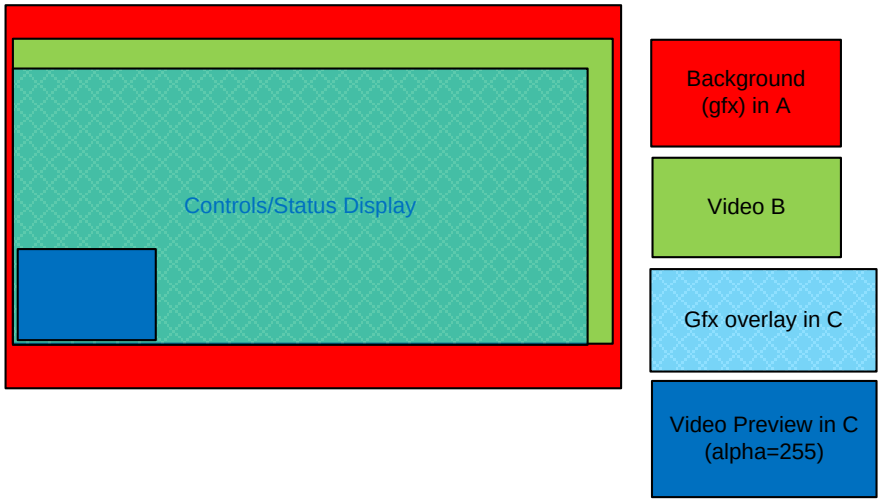
Window C (graphics overlay) weights:

- A and C: There is alpha so use ALPHA_WEIGHT or PREMULT_WEIGHT
- B and C: There is alpha so use ALPHA_WEIGHT or PREMULT_WEIGHT
- A and B and C: There is alpha so use ALPHA_WEIGHT or PREMULT_WEIGHT

Example 2

Example 2 has a similar scenario to Example 1 in which the graphics overlay (with alpha) can be composited by 2D or GPU to have opaque areas (for example, video preview, thumbnails) and transparent areas.

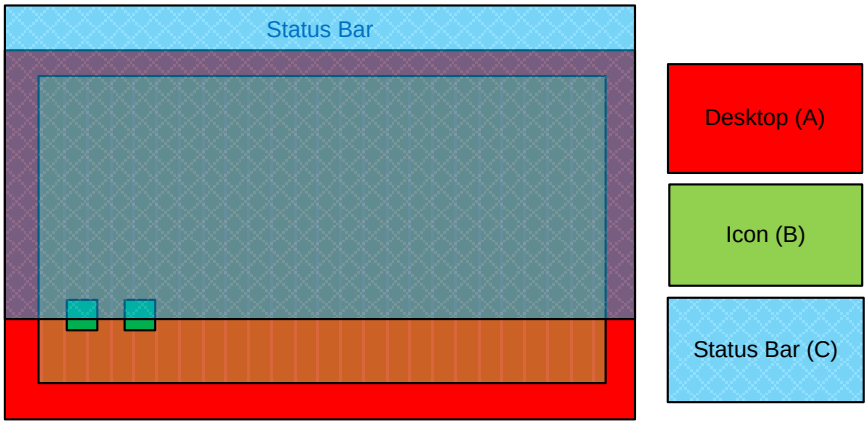
Figure 96: Example 2



Example 3

Example 3 is a phone/tablet use case. The Background (for example, active wallpaper) is opaque graphics. The next layer is icons, perhaps animated. The top layer is the status bar, which can be dragged down to be larger. Both icon and status layers are partially transparent.

Figure 97: Example 3



The two-window overlap cases work fine. The three-window case can use

$$Color_{OUT} = (1 - Alpha_B - Alpha_C) * Color_A + Alpha_B * Color_B + Alpha_C * Color_C$$

Which yields:

- In opaque icon areas, no desktop is shown, as desired. But the resulting color is $Color_B + Alpha_C * Color_C$ rather than the ideal $(1 - Alpha_C) * Color_B + Alpha_C * Color_C$. In other words, the icon color is not dimmed but is diluted by status bar color.
- In transparent icon areas, the desktop will show to the extent allowed by status bar alpha: color is $(1 - Alpha_C) * Color_A + Alpha_C * Color_C$. This is desired.

Window weights for the overlap conditions:

- Window A (desktop) weights:
  - A and B. Icon layer has alpha so use DEPENDENT_WEIGHT
  - A and C. Status bar is transparent so DEPENDENT_WEIGHT
  - A and B and C. DEPENDENT_WEIGHT. Alpha = (255 – icon_alpha – status_bar_alpha).
- Window B (Icon) weights:
  - A and B: There is alpha so use ALPHA_WEIGHT or PREMULT_WEIGHT
  - B and C: Does not happen since the desktop fully overlaps icon
  - A and B and C: ALPHA_WEIGHT
- Window C (status bar) weights.
  - A and C: There is alpha so use ALPHA_WEIGHT or PREMULT_WEIGHT
  - B and C: Does not happen
  - A and B and C: ALPHA_WEIGHT

25.3.9.5 Blending Alternatives

Composition in the 2D unit or with the GPU may be necessary to achieve blending modes not supported by the display controller for three surfaces. Also consider having per-pixel alpha in only one of the windows.

25.3.10 PRISM

This section describes the enhancements to PRISM. PRISM was formerly known as Smart Dimmer, and so the abbreviation SD is commonly used in register names for PRISM.

Features added:

- Programmable statistics window
- Separate crush/adaptation
- Programmable soft clipping
- Increase pixel count limits
- Programmable smooth transitions
- Run histogram on VPULSE2, rather than VSYNC
- LUT/CSC after enhancement

25.3.10.1 Programmable Statistics Window

This feature allows statistics to be gathered over a subset of the active display. It is useful when part of the display is not interesting for PRISM statistics purposes, such as letterbox or border around a video. Without this feature, the border would influence the histogram and therefore the brightness, giving suboptimal results for the video.

The programming interface is a control bit SD_WINDOW_ENABLE in SD_CONTROL register to enable the feature, and two registers containing position and size of the window. When SD_CONTROL == DISABLE (the default), the position/size registers are ignored, and the entire active display region is used, like in Tegra 3.

The coordinate system is relative to display active area – (0,0) is upper left corner of display active. The active region will have upper left corner (H_POSITION, V_POSITION), and lower right corner (H_POSITION + SD_WIN_H_SIZE – 1, V_POSITION + V_SIZE – 1) inclusive. Note this display coordinate system does not take into account surface rotation or device rotation. It is the same coordinate system use by window position (e.g., B_H_POSITION, B_V_POSITION).

The limitation on minimum pixel count of 2^16 must be obeyed.

The programmable window has no direct effect on enhancement – every pixel of display active area is enhanced.

25.3.10.2 Separate Crush/Adaptation

As in Tegra 3 devices, the AGGRESSIVENESS register controlled both the maximum crushed pixel percentage, and the lowest K (maximum gain). This feature separates them and allows software to separately control lowest K (maximum gain). AGRESSIVENESS continues to control the maximum crushed pixel percentage.

The programming interface is a control bit K_LIMIT_ENABLE, and a register SD_K_LIMIT.

As in Tegra 3 devices, the initial K (as determined by accumulating histogram bins until maximum crush pixel percentage is reached). When K_LIMIT_ENABLE=ENABLE, the initial K is clamped to SD_K_LIMIT rather than default “lowest_K”. When K_LIMIT_ENABLE = DISABLE (the default), SD_K_LIMIT register is ignored and the default “lowest_L” are used based on AGRESSIVENESS, as in Tegra 3.

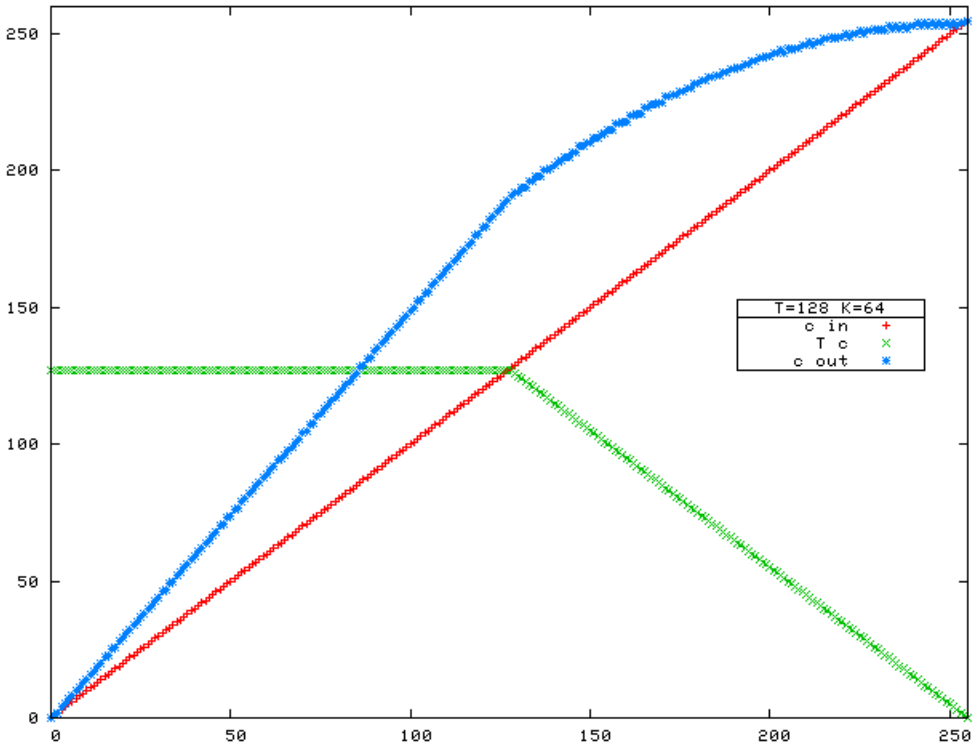
25.3.10.3 Programmable Soft Clipping

In PRISM enhancement, soft clipping is employed to avoid harsh clipping of amplified high-value pixels, and resulting loss of detail in bright areas. The gain applied to high-valued pixels is reduced gradually from 1/K to 1.0, for pixels above a threshold of 128. In Tegra 4 devices, the threshold is fixed at 128, and soft clipping is always enabled. This feature gives more software control.

Since soft clipping is performed after statistics, and it affects the brightness of the image, the statistics and therefore the backlight brightness will be incorrect. This can somewhat compensated for in the backlight transfer-function and/or enhancement value lookup tables.

The Tegra 4 transfer function is shown here, for K=1.5. The T_c plot is the weight applied to fractional portion of K, and goes from 127 to 0, representing 1 to 0.

Figure 98: Default Threshold=128 at K=1.5



With programmable thresholds, other curves are possible. For example, Figure 99 and Figure 100 show more gradual curves using threshold=64 and 0 respectively.

Figure 99: Threshold=64 at K=1.5

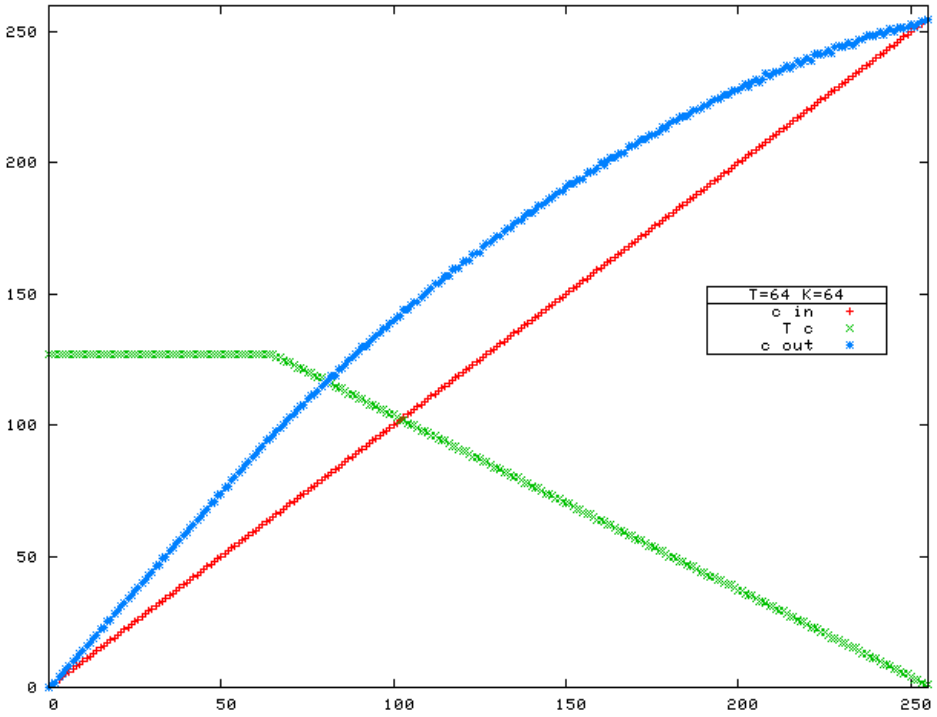


Figure 100: Threshold 0 at K=1.5

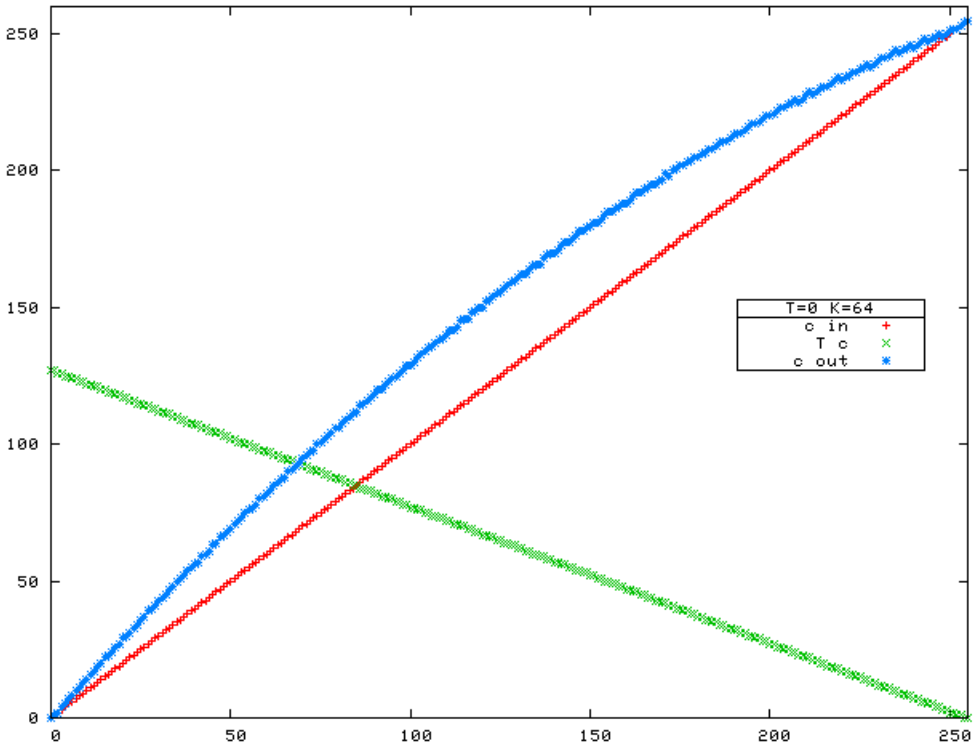

Thresholds too high are not usable, because the soft clipping does not kick in early enough to prevent clipping as K grows; note in Figure 101 (threshold 170 at K=1.5) the value of c_out rises about 255. The curve is also not monotonically increasing. Software would need to reduce maximum K to 1.25 or so for such a threshold. Figure 102 shows threshold of 170 with K = 1.25.

Figure 101: Overflowing at Threshold=170 at K=1.5

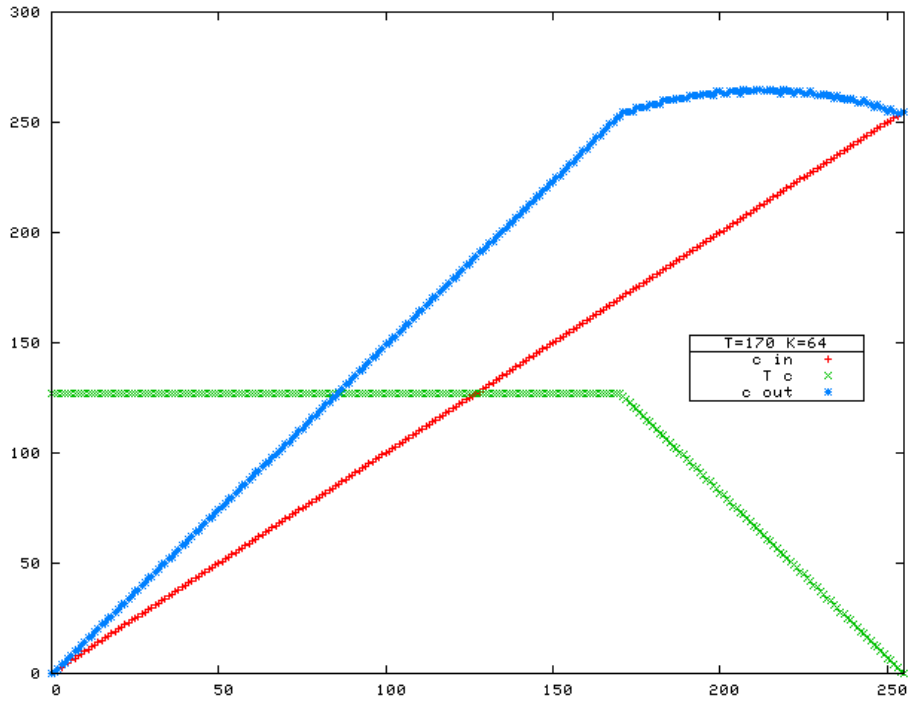

Figure 102: Threshold 170 at K=1.25

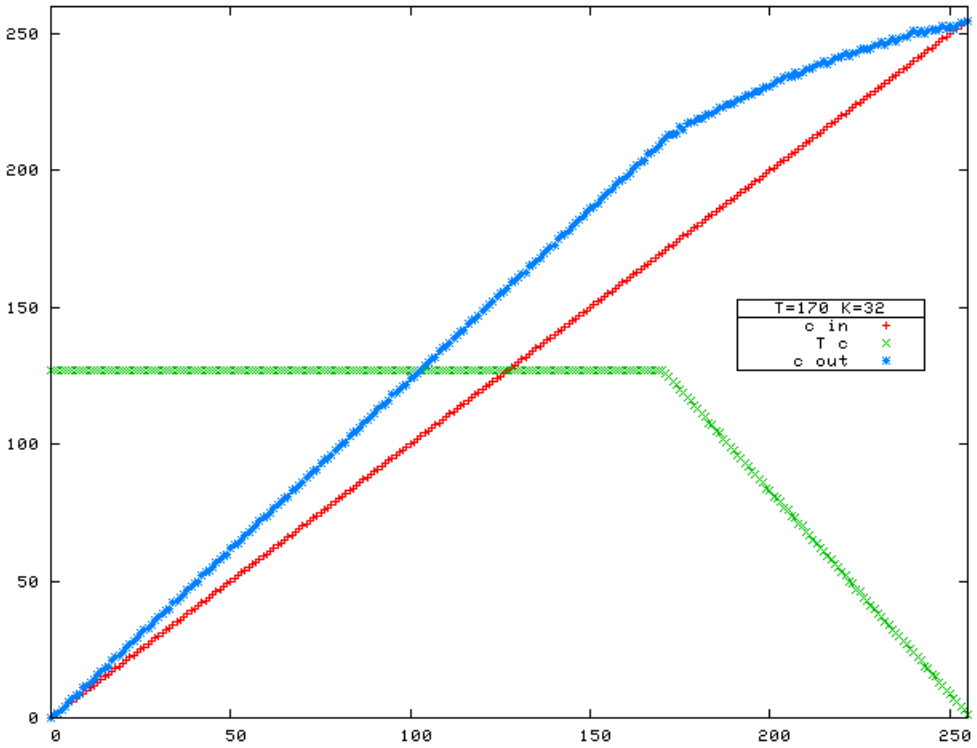


The programming interface consists of a control bit SOFT_CLIPPING_ENABLE and one register SD_SOFT_CLIPPING. The latter contains both the threshold and a software-computed reciprocal of inverse threshold. The software-computed reciprocal

avoids the need to perform division in hardware. RECIP is computed as 64*1024 * 1.0 / (256 – threshold), truncated to 16-bit unsigned integer. Internally, the hardware may use fewer than 16 bits as described below.

When SOFT_CLIPPING_ENABLE=DISABLE, then SD_SOFT_CLIPPING is ignored and no clipping is done.

When SOFT_CLIPPING_ENABLE=ENABLE, SD_SOFT_CLIPPING is used. At the default values of SD_SOFT_CLIPPING, it behaves like Tegra 3.

The soft clipping equation performed in hardware, per component, is

```
If SD_CONTROL.SOFT_CLIPPING_ENABLE==ENABLE and c_in >= threshold:
        T_c = 0x7f - (((c_in - threshold) * (recip >> 2)) >> 7);
Else
        T_c = 0x7f
```

Where recip is the programmed SOFT_CLIPPING_RECIP; it is shifted right 2 bits to yield a 14-bit value. T_c is a 7-bit weight. The shift by 7 represents discarding 6 bits from recip plus one to give a 7-bit rather than 8-bit result. As before, T_c is used to scale the fractional portion of K:

```
c_k_limited = (K_c * T_c) >> 7;
```

and then apply the fractional gain to the component:

```
c_mul = (c_in * c_k_limited) >> 7;
```

and finally add the integer portion of gain (which is always 1, i.e., 1 * c_in = c_in):

```
c_out = c_in + c_mul
```

25.3.10.4 Increase Pixel Count Limits

Displays are trending to 2560x1600 and larger panels. Tegra 3 smart dimmer supported a maximum of 2^{21} pixels. As 2560x1600 exceeds that, PRISM now needs to support at least 2^{23}. For simplification, the minimum screen size of 2^{16} is retained. Therefore the pixel count dynamic range increases from 32:1 to 128:1. The total_pixels and histogram accumulator counters must support that range. Also, the histogram normalization must support an expanded range of exponents and shifting (0-7 rather than 0-5).

The SD_HISTOGRAM bins need not expand because they contain normalized pixel percentages, not raw counts.

The programming model does not change. SD_PIXEL_COUNT already accommodates this range.

25.3.10.5 Run Histogram on VPULSE2, rather than VSYNC

In the past, Smart Dimmer histogram processing is done on vsync, which is at the beginning of the frame. This means that a new BRIGHTNESS, based on previous frame's histogram, is not available until the beginning of the next frame. In non-continuous (display self-refresh) mode, there can be a long delay. In Tegra 4 devices, Smart Dimmer can be configured to run on V_PULSE2 instead. This can be programmed to occur at the end of a frame, so that software can get the results in a timely manner, and decide whether to change brightness, retransmit frame with new enhancement value, or neither.

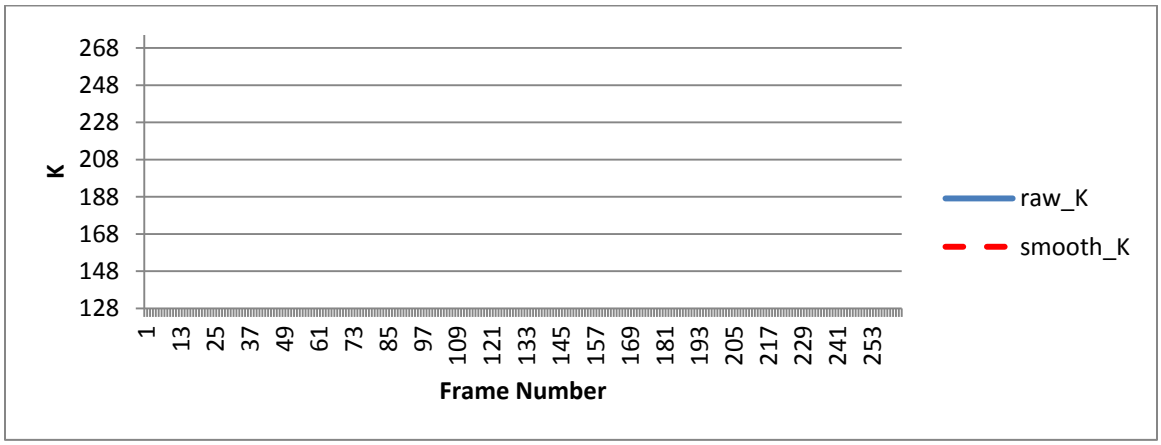
25.3.10.6 Programmable Smooth Transitions

Sudden changes in Smart Dimmer enhancement K and backlight can be noticeable and objectionable. While the soft-clipping compensation algorithm in section on "Programmable Soft Clipping" can help, it may not be enough. To improve user experience, this feature allows changes to be automatically phased in (smoothed) over time.

When enabled, the hardware-generated raw K is the target value. It is not used directly for enhancement or backlight brightness. Rather, a "smooth_K" is used. Each frame, the current smooth_K is incremented or decremented if different than the target raw K. The smooth_K and increment value have four additional fraction bits. The minimum SMOOTH_K_INCR value of 0x1 changes smooth_K by 1/16 per frame. For a maximum raw_K change of 128, the maximum phase-in time is 128*16 = 2048 frames, or about 34 seconds.

Figure 103 illustrates the smooth_k function; SMOOTH_K_INCR = 64 which changes smooth_K by at most 1.0 per frame.

Figure 103: Smooth K



Software can compute SMOOTH_K_INCR as follows. Assume a maximum desired brightness change rate of R L* / second = SMOOTH_K_INCR K/frame. Assume L* is roughly linear with respect to K (L* = K/2). R L* / second = SMOOTH_K_INCR K/frame, and we solve for SMOOTH_K_INCR . R L* / second = R L* / (60 frames) = R K / (2*60 frames) = R/120 K/frame. So SMOOTH_K_INCR = R/120. Because the register is encoded as 8.6 fixed-point, encode as round(R/120 * 64).

25.3.11 Display Color Management Unit (LUT/CSC)

This unit, new to Tegra 4 devices, adds an additional LUT -> CSC -> LUT after the PRISM unit to enable gamma and color gamut change. While this feature is independent from PRISM, and more generally useful, it helps PRISM accommodate non-standard (non-sRGB) panels. It also helps convert from the display's native gamma and gamut (de facto of sRGB) into panels.

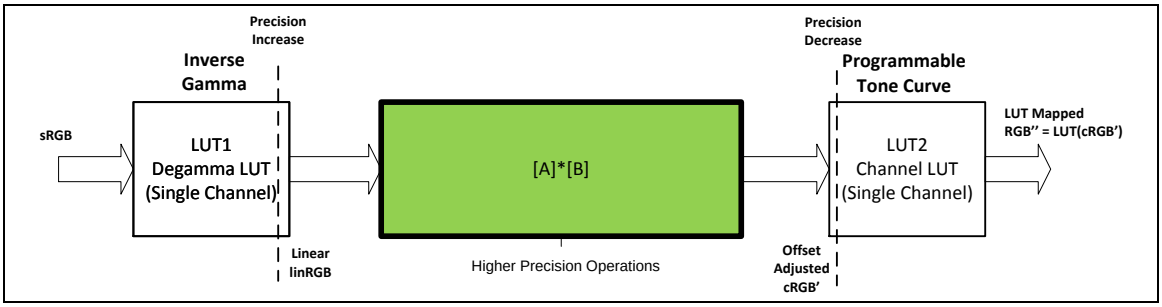
First stage – LUT1 – is an 8-bit to 12-bit RAM-based look-up table (LUT) to convert gamma from sRGB 2.2 to linear (1.0). The output is 8.4 unsigned fixed-point format. A single LUT may be used for all 3 channels.

Second stage – CSC – is 3x3 matrix multiply, to convert color gamut / whitepoint. 12 bits unsigned in, and 12 bits unsigned out. Its nine coefficients are 10-bit (S1.8 signed).

Third stage – LUT2 – is a 12-bit to 8-bit LUT to convert from linear gamma to sRGB or similar gamma (for example, 1 / 2.2). A single LUT may be used for all 3 channels.

> **Note:** The window datapaths have subunits called LUT (CP) and CSC already, but they are for different purposes. The CP is for converting linear framebuffer data into sRGB, or for color index modes, or for applying aesthetic changes like contrast. CSC is for converting YCbCr into RGB. They are for normalizing all surfaces into a common format, nominally sRGB, for blending.

Figure 104: Color Management Unit



25.3.11.1 CMU LUT1

LUT1 maps 8-bit gamma-corrected input to 12-bit linear output. A single LUT may be used for all 3 RGB channels – per-channel control is not required.

```
R′ = LUT1[R]
G′ = LUT1[G]
B′ = LUT1[B]
```

25.3.11.2 CSC Matrix

CSC equation is

$$\begin{bmatrix} KRR & KGR & KBR \\ KRG & KGG & KBG \\ KRB & KGB & KBB \end{bmatrix} * \begin{bmatrix} R \\ G \\ B \end{bmatrix} = \begin{bmatrix} R' \\ G' \\ B' \end{bmatrix}$$

25.3.11.3 CMU LUT2

LUT2 maps 12-bit linear input to 8-bit gamma corrected output. A single LUT may be used for all 3 RGB channels – per-channel control is not required. LUT2 is only 960 rows deep, and divided unevenly so that precision is variable; greater precision (more entries) are allocated to darker values. The first 512 entries 0..511, representing range [0.0, 32.0), are darker values, and are mapped with full 9-bit precision (5.4). The top 448 entries are for lower-precision brighter range [32, 256); they are reduced from 8.4 to 8.1 and offset so that values [32,256) map to 512..959 rather than 576..1023

```
R′ = LUT2[zone_select(R)]
G′ = LUT2[zone_select(G)]
B′ = LUT2[zone_select(B)]
```

The zone_select function maps 12 bit component value to 10-bit RAM index, with variable precision:

If C >= THRESHOLD:

C’ = (C >> PRECISION_DIFF) + THRESHOLD – OVERLAP

Else:

C’ = C[9:0]

Where THRESHOLD=2^9 = 512, PRECISION_DIFF = 12 – 9 = 3, and OVERLAP = THRESHOLD >> PRECISION_DIFF = 512 >> 3 = 64.

Software would use an inverse_zone_select to initialize the LUT2:

If C >= THRESHOLD:

C’ = (C - THRESHOLD + OVERLAP) << PRECISION_DIFF

Else:

C’ = C

25.3.11.4 Programming Interface

The CMU LUTs and CSC registers are single-buffered; shadow update and activation have no effect. However, the CMU_ENABLE bit is double-buffered, so it can be enabled/disabled at frame boundaries.

Host interface writes and reads take precedence over the datapath and may result in visible glitches. Software is responsible for ensuring the datapath is idle before writing or reading. An interrupt will be raised upon a conflict. The LUTs are guaranteed to be idle during blanking and when CMU_ENABLE=DISABLE. Software must explicitly enable reading, and reading is only performed for debugging reasons.

Note:	**When reading LUTs:** due to internal RAM latency, after changing read-enable or read address, data is not available until two clocks later. Best way to ensure this is issue two back-to-back writes of same read address, as shown in read sequence.

Software initialization sequence:

```
Insure CMU_ENABLE=DISABLE or display idle
For C = 0 .. 255:
        C’ = ungamma_function(C/255) * 4095
        CMU_LUT1.LUT1_ADDR = C
        CMU_LUT1.LUT1_DATA = C’
        Write CMU_LUT1
For C = 0 .. 959:
        C’ = gamma_function(inverse_zone_select(C)/4095) * 255
        CMU_LUT2.LUT2_ADDR = C
        CMU_LUT2.LUT2_DATA = C’
        Write CMU_LUT2
Write DISP_COLOR_CONTROL.CMU_ENABLE = ENABLE
Use GENERAL_ACT_REQ
```

Where typically functions are: ungamma_function(x) = $x^{2.2}$, and gamma_function(x) = $x^{1/2.2}$.

LUT read sequence:

```
Insure CMU_ENABLE=DISABLE or display idle
For C = 0 .. 255:
        CMU_LUT1_READ.LUT1_READ_EN = 1
        CMU_LUT1_READ.LUT1_READ_ADDR = C
        Write CMU_LUT1_READ
        Write CMU_LUT1_READ # ensure one cycle delay
        Read CMU_LUT1.LUT1_DATA
Write CMU_LUT1_READ.LUT1_READ_EN = 0
```

25.3.11.5 LUT Conflict Interrupt

To help debug conflicts caused by accessing LUTs while datapath is using them, CMU_LUT_CONFLICT interrupt is raised if:

- host write during scanout (pixel read when cmu_enable=1)
- host read during scanout
- host write during host read (i.e; LUT1_READ_EN=1)

25.3.12 Dither

Increases the line buffer from 1280 to 2560 pixels.

The Tegra 4 display uses the following dither methods:

- Error Diffusion
- Dynamic and Static Ordered Dither

25.4 Programming Model

25.4.1 Software Alignment Requirements

For Tegra 4 devices, the pixel data alignment restriction has increased to 64B boundaries. The table below describes what registers are affected.

Parameter	Register name	Pitch (Packed) 1/2/4 Bpp	Pitch (Planar) 1 Bpp per Surface	Tiled (Packed) 1/2/4 Bpp	Tiled (Planar) 1 Bpp per Surface
line_stride	B_LINE_STRIDE	64	64	64	64
h_prescale_size	B_H_PRESCALED_SIZE	Bpp	Even	Bpp	Even
v_prescale_size	B_V_PRESCALED_SIZE	NA	Even for 420	NA	Even for 420
h_offset	B_ADDR_H_OFFSET	Bpp	Even	Bpp	Even
v_offset	B_ADDR_V_OFFSET	NA	Even for 420	NA	Even for 420
Startaddr	B_START_ADDR	64	64	256	256

25.5 Display Controller Registers

Refer to “Reading Register Tables” in the Introduction section for the register table protocol as well as recommendations for accessing registers.

The display memory map is shown below.

25.5.1 Address Map

Space Name	Offset	Notes
DC_CMD	0x0	Non-shadowed command/sync registers
DC_COM	0x300	Non-shadowed non-window registers
DC_DISP	0x400	Shadowed non-window registers
DC_WINC	0x500	Non-shadowed indirect window registers; All windows; use DISPLAY_WINDOW_HEADER
DC_WIN	0x700	Shadowed indirect window registers; All windows; use DISPLAY_WINDOW_HEADER
DC_WINBUF	0x800	Triple-buffered indirect window registers; All windows; use DISPLAY_WINDOW_HEADER
DC_A_WINC	0xa00	Window A direct alias for DC_WINC
DC_A_WIN	0xb80	Window A direct alias for DC_WIN
DC_A_WINBUF	0xbc0	Window A direct alias for DC_WINBUF
DC_B_WINC	0xc00	Window B direct alias for DC_WINC
DC_B_WIN	0xd80	Window B direct alias for DC_WIN
DC_B_WINBUF	0xdc0	Window B direct alias for DC_WINBUF
DC_C_WINC	0xc00	Window C direct alias for DC_WINC
DC_C_WIN	0xd80	Window C direct alias for DC_WIN
DC_C_WINBUF	0xbc0	Window C direct alias for DC_WINBUF

25.5.2 New Registers for Tegra 4 Devices

The following registers are new or changed for Tegra 4 devices.

Register	Field	Description
B_SURFACE_WEIGHT	B_SURFACE_WEIGHT_OVERRIDE	Override the default weights of the arbiter in display. 0 – disable, 1 - enable

Register	Field	Description
	B_SURFACE_WEIGHT_Y	Surface weight of Y surface
	B_SURFACE_WEIGHT_U	Surface weight of U surface
	B_SURFACE_WEIGHT_V	Surface weight of V surface
B_UFLOW_STATUS	UFLOW_COUNT	Underflow count. This field indicates the number of contiguous groups of output pixels for which there was no data in the FIFO. For example, if the valid from the FIFO is low for 10 consecutive cycles and then goes high, the counter will increment by one. Reset to zero on write.
	COUNT_OFLOW	Flag bit that indicates that the underflow event counter has overflowed. There were too many events. If COUNT_OFLOW is set, UFLOW_COUNT is meaningless. Cleared on write.
B_UFLOW_CTRL	B_UFLOW_CTRL_DBG_MODE	When the underflow debug mode is enabled. Instead of sending out the last valid pixel, DBG_PIXEL is sent out. 0 – disable, 1 - enable
B_UFLOW_DBG_PIXEL	B_UFLOW_DBG_PIXEL	32-bit debug pixel color.
B_UFLOW_THRESHOLD	B_UFLOW_THRESHOLD	Number of lines to skip when underflow continues to the point where display (XY) is greater than display memfetch request (XY)
B_WIN_OPTIONS	B_SCAN_COLUMN	Load memory columns into display line buffer. 0=disable, 1=enable
B_SCALEFACTOR_ THRESHOLD	B_SF_HWM_THRESHOLD	16-bit high water mark (HWM) value used to compare window line buffer depth against Default – 0xffff
	B_SF_LWM_THRESHOLD	16-bit low water mark (LWM) value used to compare window line buffer depth against Default – 0xffff
B_LATENCY_THRESHOLD	B_RDY4LATENCY_THRESHOLD	Used for DVFS buffering.16-bit HWM value used to compare window line buffer depth against Default – 0xffff
CURSOR_PREFETCH_ LATENCY	SCANLINE_COUNT	5 bits. Number of scan lines prior to cursor first active scan-line when cursor DVFS readiness is disabled. Default: 3
CURSOR_START_ADDR	CURSOR_SIZE	Extend enums to: • 32x32 • 64x64 • 128x128 • 256x256
CURSOR_START_ADDR_ NS	CURSOR_SIZE	Extend enums to: • 32x32 • 64x64 • 128x128 • 256x256
BLEND_CURSOR_ CONTROL	CURSOR_MODE_SELECT	Enums: • Legacy • Normal
SD_K_LIMIT	All	New PRISM feature: Separate Crush/Adaptation; see 25.3.10.2
SD_WINDOW_POSITION	All	New PRISM feature: Programmable Statistics Window; see 25.3.10.1
SD_WINDOW_SIZE	All	As above
SD_SOFT_CLIPPING	All	New PRISM feature: Programmable Soft Clipping; see 25.3.10.3

Register	Field	Description
SD_SMOOTH_K	All	New PRISM feature: Programmable Smooth Transitions; see 25.3.10.6

25.5.2.1 PRISM CMU Registers

For new CMU registers, see the section on Display Color Management Unit (LUT/CSC).

25.5.3 Display Controller Register Definition

Each display supports three windows: Window A, Window B, Window C

The windows may have different features, as described above; however, the register interfaces are the same.

The Display Controller register consists of two template files:

- ardisplay_TEMPLATE.spec: these registers are applicable to all display windows
- ardisplay_b_TEMPLATE.spec: these registers are applicable to windows, A, B, or C. There are three copies of these registers in DISPLAY. Window A, B, and C registers are copies of each other, except for differences in window features. Additionally, the registers can be accessed either indirectly or directly. In indirect mode, the copies of a register in window A, B, and C share the same address; register field DISPLAY_WINDOW_HEADER is used to control whether the subsequent programming goes to window A, B, or C registers, or any combination of them. Before reading these registers, DISPLAY_WINDOW_HEADER must be programmed to enable only one window, so that DISPLAY knows which register copy is being read. In direct mode, the copies in window A, B, and C have separate addresses; DISPLAY_WINDOW_HEADER is ignored.

Color Palette

These appear as three instances of 256 32-bit registers with each register consisting of one RGB pixel so not all 32 bits in the registers are used. One instance is used for window A, another instance is used for window B, and the third instance is used for window C. In reality, each instance is implemented as triple 256-word dual-port register files (2P RF) with one read port and one write port (1R1W) and with each word consisting of 1 red/green/blue component. Read port of the color palettes are used for the corresponding window A, window B, or window C and write port of the color palettes are used for host write.

Note that the host cannot read these color palettes, so it must cache this color palette somewhere else to be able to read them. This is done to reduce area.

25.5.4 Display Shadow Registers

Display registers have three shadow types:

1. Not Shadowed

   Writes to these registers take effect immediately.
2. Double Buffered

   Each register has two copies: ASSEMBLY and ACTIVE. ACTIVE is the working copy.

   These two copies share the same address/offset.

   WRITE_MUX can be programmed to choose which copy the subsequent register writes goes to:
   - When set to ACTIVE, both ACTIVE and ASSEMBLY copies will be written
   - When set to ASSEMBLY, only ASSEMBLY copy will be written

   READ_MUX can be programmed to choose which copy the subsequent register reads comes from.

   If display is in STOP mode, ASSEMBLY copy is latched into ACTIVE copy immediately after

(GENERAL/WIN_A/WIN_B/WIN_C)_ACT_REQ is programmed. In other modes the latching happens on the next frame boundary after (GENERAL/WIN_A/WIN_B/WIN_C)_ACT_REQ is programmed.

3. Triple Buffered

   Each register has three copies: ASSEMBLY, ARM, and ACTIVE. ACTIVE is the working copy.

   ASSEMBLY and ACTIVE copies share the same address/offset, the ARM copy is located at the address/offset one bigger than the ASSEMBLY/ACTIVE copy.

   WRITE_MUX can be programmed to choose which copy the subsequent register writes goes to:

   - When set to ACTIVE, all three copies will be written
   - When set to ASSEMBLY, only ASSEMBLY copy will be written

   READ_MUX can be programmed to choose which copy the subsequent register reads comes from.

   - To read back ASSEMBLY or ACTIVE copy, set READ_MUX correctly before register reads.

   These two copies share the same address.

   - To read back ARM copy, do not set READ_MUX, but read back the register/register-field with "_NS" in their names, the offset of which is 1 bigger than its ASSEMBLY/ACTIVE counterpart.

   ASSEMBLY copy is latched into ARM copy immediately after GENERAL/WIN_A/WIN_B/WIN_C)_UPDATE is programmed.

   If display is in STOP mode, ARM copy is latched into ACTIVE copy immediately after (GENERAL/WIN_A/WIN_B/WIN_C)_ACT_REQ is programmed. In other modes the latching happens on the next frame boundary after (GENERAL/WIN_A/WIN_B/WIN_C)_ACT_REQ is programmed.

25.5.5 Display Control Modes

The DISPLAY_COMMAND is used to set display control mode (**CONTINUOUS**, **ONE-SHOT**, or **STOP**).

Display switches mode when CONTROL_MODE is programmed to shadow register and then activated.

Display enters a mode when the register activation happens, either on frame boundary when entering **STOP** mode, or immediately when exiting **STOP** mode.

In **STOP** mode, display is in idle. Pixel clock is not running.

In **CONTINUOUS** mode, display keeps refreshing the output frame by frame. This mode is mostly used for the panels without internal frame buffer.

In **ONE-SHOT** mode, also known as non-continuous mode, display waits for a trigger before refreshing each frame. Between those frames, display is in idle. This mode is usually for the panels with internal frame buffer.

In ONE-SHOT mode, there are different types of triggers as follows:

- Input triggers

  Input trigger is to notify DISPLAY that a new memory surface is ready to be displayed.

  - Host Trigger

    Host trigger is requested when NC_HOST_TRIG_ENABLE is programmed. This register field is in the same register as shadow registers UPDATE/ACT_REQ so that the trigger can happen atomically with register updates for the new frame. When host trigger is requested within a frame, the requested frame will start immediately after the end of the current frame.

- Output Triggers

  Output trigger is to notify DISPLAY that a panel is ready to receive data from DISPLAY.

  - Tear Effect Signal Triggers

When MSF/SSF register field is set to ENABLE, DISPLAY holds off a frame requested by input triggers until DISPLAY receives a "ready" from the pins that connect to the tearing effect signals from the panel, then sends a new frame to panel. However, if no input trigger has been requested, DISPLAY does not send a new frame.

In CONTINUOUS mode, the meaning of the triggers is different.

- Input Triggers

  Since in CONTINUOUS mode trigger happen automatically and repeatedly, trigger here only affects the buffer address change on a window.

  - Host Trigger

    Host can change the buffer address and then write WIN_A/B/C_ACT_REQ to request the buffer address change. Note that for syncpt logic, it cannot tell if a WIN_A/B/C register activation indicates the change of address, so it always behaves like a change of address happens on any register activation requested by WIN_A/B/C_ACT_REQ. As the result, RD_DONE/OP_DONE is returned.

- Output triggers

  These triggers are not applicable in CONTINUOUS mode. MSF/SSF_ENABLE should never be set in CONTINUOUS mode.

25.5.6 Sync Points

DISPLAY has 4 syncpt clients:

- GENERAL

  Conditions

  - 0: IMMEDIATE return INDX immediately
  - 1: OP_DONE not meaningful, same as IMMEDIATE
  - 2: RD_DONE not meaningful, same as IMMEDIATE
  - 3: REG_WR_SAFE returns INDX whenever it is safe to program GENERAL shadow registers (when all previous GENERAL activation has happened)
  - 4: HSPI returns INDX whenever it is safe to send HSPI data (when all HSPI_*** registers are safe to be programmed)
  - 5: FRAME_DONE returns INDX on the next frame end
  - 6: VPULSE3 returns INDX on the next vpulse3 leading edge (for timing sensitive operations if needed)
  - 7: FRAME_START returns INDX on the next frame start (currently for hardware testing, but can be used if needed)

- WIN_A

  Conditions

  - 0: IMMEDIATE return INDX immediately
  - 1: OP_DONE same as RD_DONE
  - 2: RD_DONE returns INDX when all WIN_A reads for frames activated before the INCR_SYNCPT are complete. In ONE-SHOT mode with TVO disabled, this happens after the last row of window A display. In CONTINUOUS mode, or in ONE-SHOT mode with TVO enabled, this happens on the last row of window A or on frame end (depending if the INCR_SYNCPT is issued before or after the window A last row).
  - 3: REG_WR_SAFE returns INDX whenever it is safe to program WIN_A shadow registers (when all previous WIN_A activation has happened)

- WIN_B

  Similar to WIN_A

- WIN_C

  Similar to WIN_A
- DISPLAY Continuous syncpt

  VSYNC: When enabled, return syncpt whenever a vblank start happens.

25.5.7 Raise Actions (Legacy)

The Raise action is used to check the state of the display's command execution. The Raise action can be enabled by itself or with other actions.

The raise value is returned to the host controller if the current and all previous commands have completed execution. If the command is executed with the delayed mode, the raise is not returned till that command is executed at the end of the frame.

If there is no pending command when the Raise is issued, the raise value is returned immediately. The raise value is a 4-bit number included in the command.

Context switch acknowledge, register reads, and raises are returned to the host through a read FIFO. However, because there may be more than one raise, read, or acknowledge available for writing to the FIFO in a certain cycle, there must be a priority encoder. Here is the priority:

1. Context switch
2. Register read
3. SIGNAL_RAISE
4. SIGNAL_RAISE1
5. SIGNAL_RAISE2
6. SIGNAL_RAISE3
7. DISP_COMMAND_RAISE
8. HSPI_RAISE
9. Refcount

These packets are for verification; they have no relevance to software. The RAISE packet should include the intended return channel. This channel should be passed back to the host so the RAISE will be reflected in the correct channel.

25.6 Display CMD Registers

25.6.1 DC_CMD_GENERAL_INCR_SYNCPT_0

Offset: 0x0 | Byte Offset: 0x0 | Read/Write: R/W | Reset: 0x00000000 (0bxxxxxxxxxxxxxxxx0000000000000000)

Bit	Reset	Description

Bit	Reset	Description
15:8	0x0	GENERAL_COND: Condition mapped from raise/wait 0 = IMMEDIATE 1 = OP_DONE 2 = RD_DONE 3 = REG_WR_SAFE 4 = HSPI 5 = FRAME_DONE 6 = VPULSE3 7 = FRAME_START 8 = COND_8 9 = COND_9 10 = COND_10 11 = COND_11 12 = COND_12 13 = COND_13 14 = COND_14 15 = COND_15
7:0	0x0	GENERAL_INDX: syncpt index value

25.6.2 DC_CMD_GENERAL_INCR_SYNCPT_CNTRL_0

Offset: 0x1 | Byte Offset: 0x4 | Read/Write: R/W | Reset: 0x00000000 (0bxxxxxxxxxxxxxxxxxxxxxxxx0xxxxxxx0)

Bit	Reset	Description
8	0x0	GENERAL_INCR_SYNCPT_NO_STALL: If NO_STALL is 1, then when FIFOs are full, INCR_SYNCPT methods will be dropped and the INCR_SYNCPT_ERROR[COND] bit will be set. If NO_STALL is 0, then when FIFOs are full, the client host interface will be stalled.
0	0x0	GENERAL_INCR_SYNCPT_SOFT_RESET: If SOFT_RESET is set, then all internal state of the client syncpt block will be reset. To do a soft reset, first set SOFT_RESET of all Host1x clients affected, then clear all SOFT_RESETs.

25.6.3 DC_CMD_GENERAL_INCR_SYNCPT_ERROR_0

Offset: 0x2 | Byte Offset: 0x8 | Read/Write: R/W | Reset: 0x00000000 (0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx)

Bit	Reset	Description
31:0	X	GENERAL_COND_STATUS: COND_STATUS[COND] is set if the FIFO for COND overflows. This bit is sticky and will remain set until cleared. Cleared by writing 1.

25.6.4 DC_CMD_WIN_A_INCR_SYNCPT_0

Offset: 0x8 | Byte Offset: 0x20 | Read/Write: R/W | Reset: 0x00000000 (0bxxxxxxxxxxxxxxxx0000000000000000)

Bit	Reset	Description

Bit	Reset	Description
15:8	0x0	WIN_A_COND: Condition mapped from raise/wait 0 = IMMEDIATE 1 = OP_DONE 2 = RD_DONE 3 = REG_WR_SAFE 4 = COND_4 5 = COND_5 6 = COND_6 7 = COND_7 8 = COND_8 9 = COND_9 10 = COND_10 11 = COND_11 12 = COND_12 13 = COND_13 14 = COND_14 15 = COND_15
7:0	0x0	WIN_A_INDX: syncpt index value

25.6.5 DC_CMD_WIN_A_INCR_SYNCPT_CNTRL_0

Offset: 0x9 | Byte Offset: 0x24 | Read/Write: R/W | Reset: 0x00000000 (0bxxxxxxxxxxxxxxxxxxxxxxxx0xxxxxxx0)

Bit	Reset	Description
8	0x0	WIN_A_INCR_SYNCPT_NO_STALL: If NO_STALL is 1, then when FIFOs are full, INCR_SYNCPT methods will be dropped and the INCR_SYNCPT_ERROR[COND] bit will be set. If NO_STALL is 0, then when FIFOs are full, the client host interface will be stalled.
0	0x0	WIN_A_INCR_SYNCPT_SOFT_RESET: If SOFT_RESET is set, then all internal states of the client syncpt block will be reset. To do a soft reset, first set SOFT_RESET of all Host1x clients affected, then clear all SOFT_RESETs.

25.6.6 DC_CMD_WIN_A_INCR_SYNCPT_ERROR_0

Offset: 0xa | Byte Offset: 0x28 | Read/Write: R/W | Reset: 0x00000000 (0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx)

Bit	Reset	Description
31:0	X	WIN_A_COND_STATUS: COND_STATUS[COND] is set if the FIFO for COND overflows. This bit is sticky and will remain set until cleared. Cleared by writing 1.

25.6.7 DC_CMD_WIN_B_INCR_SYNCPT_0

Offset: 0x10 | Byte Offset: 0x40 | Read/Write: R/W | Reset: 0x00000000 (0bxxxxxxxxxxxxxxxx0000000000000000)

Bit	Reset	Description

Bit	Reset	Description
15:8	0x0	WIN_B_COND: Condition mapped from raise/wait 0 = IMMEDIATE 1 = OP_DONE 2 = RD_DONE 3 = REG_WR_SAFE 4 = COND_4 5 = COND_5 6 = COND_6 7 = COND_7 8 = COND_8 9 = COND_9 10 = COND_10 11 = COND_11 12 = COND_12 13 = COND_13 14 = COND_14 15 = COND_15
7:0	0x0	WIN_B_INDX: syncpt index value

25.6.8 DC_CMD_WIN_B_INCR_SYNCPT_CNTRL_0

Offset: 0x11 | Byte Offset: 0x44 | Read/Write: R/W | Reset: 0x00000000 (0bxxxxxxxxxxxxxxxxxxxxxxxx0xxxxxxx0)

Bit	Reset	Description
8	0x0	WIN_B_INCR_SYNCPT_NO_STALL: If NO_STALL is 1, then when FIFOs are full, INCR_SYNCPT methods will be dropped and the INCR_SYNCPT_ERROR[COND] bit will be set. If NO_STALL is 0, then when FIFOs are full, the client host interface will be stalled.
0	0x0	WIN_B_INCR_SYNCPT_SOFT_RESET: If SOFT_RESET is set, then all internal states of the client syncpt block will be reset. To do a soft reset, first set SOFT_RESET of all Host1x clients affected, then clear all SOFT_RESETs.

25.6.9 DC_CMD_WIN_B_INCR_SYNCPT_ERROR_0

Offset: 0x12 | Byte Offset: 0x48 | Read/Write: R/W | Reset: 0x00000000 (0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx)

Bit	Reset	Description
31:0	X	WIN_B_COND_STATUS: COND_STATUS[COND] is set if the FIFO for COND overflows. This bit is sticky and will remain set until cleared. Cleared by writing 1.

25.6.10 DC_CMD_WIN_C_INCR_SYNCPT_0

Offset: 0x18 | Byte Offset: 0x60 | Read/Write: R/W | Reset: 0x00000000 (0bxxxxxxxxxxxxxxxx0000000000000000)

Bit	Reset	Description

Bit	Reset	Description
15:8	0x0	WIN_C_COND: Condition mapped from raise/wait 0 = IMMEDIATE 1 = OP_DONE 2 = RD_DONE 3 = REG_WR_SAFE 4 = COND_4 5 = COND_5 6 = COND_6 7 = COND_7 8 = COND_8 9 = COND_9 10 = COND_10 11 = COND_11 12 = COND_12 13 = COND_13 14 = COND_14 15 = COND_15
7:0	0x0	WIN_C_INDX: syncpt index value

25.6.11 DC_CMD_WIN_C_INCR_SYNCPT_CNTRL_0

Offset: 0x19 | Byte Offset: 0x64 | Read/Write: R/W | Reset: 0x00000000 (0bxxxxxxxxxxxxxxxxxxxxxxxx0xxxxxxx0)

Bit	Reset	Description
8	0x0	WIN_C_INCR_SYNCPT_NO_STALL: If NO_STALL is 1, then when FIFOs are full, INCR_SYNCPT methods will be dropped and the INCR_SYNCPT_ERROR[COND] bit will be set. If NO_STALL is 0, then when FIFOs are full, the client host interface will be stalled.
0	0x0	WIN_C_INCR_SYNCPT_SOFT_RESET: If SOFT_RESET is set, then all internal states of the client syncpt block will be reset. To do a soft reset, first set SOFT_RESET of all Host1x clients affected, then clear all SOFT_RESETs.

25.6.12 DC_CMD_WIN_C_INCR_SYNCPT_ERROR_0

Offset: 0x1a | Byte Offset: 0x68 | Read/Write: R/W | Reset: 0x00000000 (0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx)

Bit	Reset	Description
31:0	X	WIN_C_COND_STATUS: COND_STATUS[COND] is set if the FIFO for COND overflows. This bit is sticky and will remain set until cleared. Cleared by writing 1.

25.6.13 DC_CMD_CONT_SYNCPT_VSYNC_0

Offset: 0x28 | Byte Offset: 0xa0 | Read/Write: R/W | Reset: 0x00000000 (0bxxxxxxxxxxxxxxxxxxxxxxxx0xxxxxxx)

Bit	Reset	Description
8	0x0	VSYNC_EN: On host read bus every time VSYNC (V-blank leading edge) happens and VSYNC_EN is set 0 = DISABLE 1 = ENABLE
7:0	X	VSYNC_INDX: Return INDX (set HOST_CLRD packet TYPE field to SYNCPT)

25.6.14 DC_CMD_CTXSW_0

Context switch registers for class and channel

Should be common to all modules. Includes the current channel/class (writable by software) and the next channel/class (which the hardware sets when it receives a context switch).

Context switch works like this:

Any context switch request triggers an interrupt to the host and causes the new channel/class to be stored in NEXT_CHANNEL/NEXT_CLASS (see vmod/chexample). Software sees that there is a context switch interrupt and does the necessary operations to make the module ready to receive traffic from the new context. It clears the context switch interrupt and writes CURR_CHANNEL/CLASS to the same value as NEXT_CHANNEL/CLASS, which causes a context switch acknowledge packet to be sent to the host. This completes the context switch and allows the host to continue sending data to the module.

Context switches can also be pre-loaded. If CURR_CLASS/CHANNEL are written and updated to the next CLASS/CHANNEL before the context switch request occurs, an acknowledge will be generated by the module and no interrupt will be triggered. This is one way for software to avoid dealing with context switch interrupts.

Another way to avoid context switch interrupts is to set the AUTO_ACK bit.

This bit tells the module to automatically acknowledge any incoming context switch requests without triggering an interrupt. CURR_* and NEXT_* will be updated by the module so they will always be current.

Offset: 0x30 | Byte Offset: 0xc0 | Read/Write: R/W | Reset: 0xf000f800 (0bxxxxxxxxxxxxxxxxx11111x0000000000)

Bit	R/W	Reset	Description
31:28	RO	X	NEXT_CHANNEL: Next requested channel
25:16	RO	X	NEXT_CLASS: Next requested class
15:12	RW	0xf	CURR_CHANNEL: Current working channel, reset to 'invalid'
11	RW	0x1	AUTO_ACK: Automatically acknowledge any incoming context switch requests 0 = MANUAL 1 = AUTOACK
9:0	RW	0x0	CURR_CLASS: Current working class

25.6.15 DC_CMD_DISPLAY_COMMAND_OPTION0_0

Display Controller Option 0. This register is not effective until DISPLAY_COMMAND is written.

Class: Display Command

Offset: 0x31 | Byte Offset: 0xc4 | Read/Write: R/W | Reset: 0x00000000 (0bxxxxxxxxxxxxxx000xxxxxxx00000000)

Bit	Reset	Description
18	0x0	WINDOW_C_NC_DISPLAY: Window C Non-Continuous Display. This is effective only in Non-Continuous Display mode when window B buffer switching is not controlled by host. If this bit is enabled, a frame is sent whenever Window B buffer is switched. 0 = DISABLE 1 = ENABLE
17	0x0	WINDOW_B_NC_DISPLAY: Window B Non-Continuous Display. This is effective only in Non-Continuous Display mode when window B buffer switching is not controlled by host. If this bit is enabled, a frame is sent whenever Window B buffer is switched. 0 = DISABLE 1 = ENABLE
16	0x0	WINDOW_A_NC_DISPLAY: Window A Non-Continuous Display. This is effective only in Non-Continuous Display mode when window A buffer switching is not controlled by host. If this bit is enabled, a frame is sent whenever Window A buffer is switched. 0 = DISABLE 1 = ENABLE
7:6	0x0	SSF_SOURCE: Source pin for the SSF input. Controls which pin will be used as the source for the trigger input when MSF mode is enabled. Note that although the same pins are available for both MSF and SSF, the order in the enum and hence the values differ between the pins. This is to maintain backwards compatibility with previous chips, which had a fixed mapping. The init value and the first value in the enum reflect this historical mapping. 0= LCD_DC pin (legacy default) 1= LCD_SPI pin 2= LCD_SDI pin 3= RESERVED for future use. 0 = SSF_LDC 1 = SSF_LSPI 2 = SSF_LSDI
5	0x0	SSF_ENABLE: Sub-Display Stop Frame (SSF) input. This is effective only in Non-Continuous Display mode. When enabled, SSF signal can be input through LDC pin. When SSF is enabled a trigger to send a frame in Non-Continuous Display mode will be delayed until SSF is active. 0 = DISABLE 1 = ENABLE
4	0x0	SSF_POLARITY: Sub-Display Stop Frame (SSF) Polarity 0= Active high 1= Active low
3:2	0x0	MSF_SOURCE: Source pin for the MSF input. Controls which pin will be used as the source for the trigger input when MSF mode is enabled. Note that although the same pins are available for both MSF and SSF, the order in the enum and hence the values differ between the pins. This is to maintain backwards compatibility with previous chips, which had a fixed mapping. The init value and the first value in the enum reflects this historical mapping. 0= LCD_SPI pin (legacy default) 1= LCD_DC pin 2= LCD_SDI pin 3= RESERVED for future use. 0 = MSF_LSPI 1 = MSF_LDC 2 = MSF_LSDI
1	0x0	MSF_ENABLE: Main-Display Stop Frame (MSF) input This is effective only in Non-Continuous Display mode. When enabled, the MSF signal can be input through the LSPI pin. When MSF is enabled, a trigger to send a frame in Non-Continuous Display mode will be delayed until MSF is active. 0 = DISABLE 1 = ENABLE

Bit	Reset	Description
0	0x0	MSF_POLARITY: Main-Display Stop Frame (MSF) Polarity 0= Active high 1= Active low

25.6.16 DC_CMD_DISPLAY_COMMAND_0

Display Command

Offset: 0x32 | Byte Offset: 0xc8 | Read/Write: R/W | Reset: 0x00000000 (0bxxxxxxxxxxxxxxxxxxxxxxxxxx00xxxx0)

Bit	Reset	Description
30:27	X	DISP_COMMAND_RAISE_CHANNEL_ID: Display Command Channel ID
26:22	X	DISP_COMMAND_RAISE_VECTOR: Display Command Raise Vector. This raise vector is at the next line or frame boundary, depending on GENERAL_ACT_CNTR_SEL
6:5	0x0	DISPLAY_CTRL_MODE: Display Controller Mode 0= Stop Display, this can be used to stop sending frame at the next frame boundary. This is automatically generated in Non-Continuous Display after sending one frame. If this is issued when display controller is already stopped then there is no frame sent. Raise vector (if raise is enabled) is also returned immediately. This command can also be used in non-continuous display mode to stop accepting non-host trigger conditions from other clients. 1= Continuous Display, the display controller will continuously send frame. Continuous display mode can be stopped by switching to Non-Continuous Display or by issuing Stop Display. 2= Non-Continuous Display, the display controller is forced to send one frame of each active display and then wait for the next time this command is issued or for other (non-host) trigger conditions to send frame. The sending of frames may be delayed by MSF or SSF input signals from the display device. If a Stop Display is issued while in non-continuous display mode then non-host trigger conditions will no longer be accepted until the next time Non-Continuous Display is issued 0 = STOP 1 = C_DISPLAY 2 = NC_DISPLAY
0	0x0	DISP_COMMAND_RAISE: Display Command Raise. Raise vector will be returned at the end of command completion 0 = DISABLE 1 = ENABLE

25.6.17 DC_CMD_SIGNAL_RAISE_0

When written, the next occurrence of the selected SIGNAL will cause a RAISE to be sent to the host. Software must not write this register if a previous request (from previous write) is still outstanding. Added SIGNAL_RAISE_TYPE option so that multiple raises can be returned without software intervention. SIGNAL_RAISE1, SIGNAL_RAISE2, or SIGNAL_RAISE3 can be used if more than one source signal is needed.

Offset: 0x33 | Byte Offset: 0xcc | Read/Write: R/W | Reset: 0x00000000 (0bxxxxxxxxxxxxxxxxxxx0xxxxxxxxxxx)

Bit	Reset	Description
19:16	X	SIGNAL_RAISE_CHANNEL_ID: Signal Raise Channel ID
12	0x0	SIGNAL_RAISE_TYPE: 0= One-shot, single raise returned. 1= Continuous, raise is returned persistently whenever raise event is true until this register is reprogrammed such that SIGNAL_RAISE_SELECT=NONE or SIGNAL_RAISE_TYPE=ONESHOT 0 = ONESHOT 1 = CONT

Bit	Reset	Description
10:8	X	SIGNAL_RAISE_SELECT: which signal to raise on 0= none, no raise sent back 1= Frame End signal 2= V Blank signal 3= V Pulse 3 signal 4= Rising edge of V Blank signal 5= Falling edge of V Blank signal 6= Rising edge of V Pulse 3 signal 7= Falling edge of V Pulse 3 signal 0 = NONE 1 = FRAME_END 2 = VBLANK 3 = VPULSE3 4 = VBLANK_START 5 = VBLANK_END 6 = VPULSE3_START 7 = VPULSE3_END
4:0	X	SIGNAL_RAISE_VECTOR: bit number to raise

25.6.18 DC_CMD_DISPLAY_POWER_CONTROL_0

Display Power Control

Offset: 0x36 | Byte Offset: 0xd8 | Read/Write: R/W | Reset: 0x00000000 (0bxxxxxx00xxxxx0x0xxxxxxx0x0x0x0x0)

Bit	Reset	Description
25	0x0	HSPI_ENABLE: Host SPI write cycle enable. SPI_ENABLE must be enabled also for this bit to be effective. 0 = DISABLE 1 = ENABLE
24	0x0	SPI_ENABLE: SPI interface enable. This enables clock to SPI interface logic for Host SPI, IS SPI, and LCD SPI. 0 = DISABLE 1 = ENABLE
18	0x0	PM1_ENABLE: PM1 signal enable 0 = DISABLE 1 = ENABLE
16	0x0	PM0_ENABLE: PM0 signal enable 0 = DISABLE 1 = ENABLE
8	0x0	PW4_ENABLE: PW4 signal enable. This signal can be output at the pad for display power sequencing. 0 = DISABLE 1 = ENABLE
6	0x0	PW3_ENABLE: PW3 signal enable. This signal can be output at the pad for display power sequencing. 0 = DISABLE 1 = ENABLE
4	0x0	PW2_ENABLE: PW2 signal enable. This signal controls pixel data processing. It should be enabled during V blank time. This signal also controls the time when pin polarity takes effect at the pad. This signal can be output at the pad for display power sequencing. 0 = DISABLE 1 = ENABLE

Bit	Reset	Description
2	0x0	PW1_ENABLE: PW1 signal enable. This signal can be output at the pad for display power sequencing. 0 = DISABLE 1 = ENABLE
0	0x0	PW0_ENABLE: PW0 signal enable. This signal controls the display H and V counters. It must be enabled first and disabled last during display power sequencing. This signal can be output at the pad for display power sequencing. 0 = DISABLE 1 = ENABLE

25.6.19 DC_CMD_INT_STATUS_0

This reflects status of all pending interrupts which is valid as long as the interrupt is not cleared even if the interrupt is masked. A pending interrupt can be cleared by writing a '1' to this the corresponding interrupt status bit in this register.

Display Interrupt and Status

Offset: 0x37 | Byte Offset: 0xdc | Read/Write: R/W | Reset: 0x00000000 (0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx)

Bit	Reset	Description
23	X	HC_UF_INT: Cursor Underflow Interrupt Status 0= interrupt not pending 1= interrupt pending
22	X	CMU_LUT_CONFLICT_INT: CMU LUT read/write conflict; write 1 to clear
16	X	WIN_C_OF_INT: Window C Overflow Interrupt Status 0= interrupt not pending 1= interrupt pending
15	X	WIN_B_OF_INT: Window B Overflow Interrupt Status 0= interrupt not pending 1= interrupt pending
14	X	WIN_A_OF_INT: Window A Overflow Interrupt Status 0= interrupt not pending 1= interrupt pending
13	X	SSF_INT: Sub-Display Stop Frame Interrupt Status 0= interrupt not pending 1= interrupt pending
12	X	MSF_INT: Main-Display Stop Frame Interrupt Status 0= interrupt not pending 1= interrupt pending
10	X	WIN_C_UF_INT: Window C Underflow Interrupt Status 0= interrupt not pending 1= interrupt pending
9	X	WIN_B_UF_INT: Window B Underflow Interrupt Status 0= interrupt not pending 1= interrupt pending

Bit	Reset	Description
8	X	WIN_A_UF_INT: Window A Underflow Interrupt Status 0= interrupt not pending 1= interrupt pending
7	X	SPI_BUSY_INT: SPI Busy Interrupt Status 0= interrupt not pending 1= interrupt pending
5	X	V_PULSE2_INT: Vertical Pulse 2 Interrupt 0= interrupt not pending 1= interrupt pending
4	X	V_PULSE3_INT: Vertical Pulse 3 Interrupt 0= interrupt not pending 1= interrupt pending
3	X	H_BLANK_INT: Horizontal Blank Interrupt 0= interrupt not pending 1= interrupt pending
2	X	V_BLANK_INT: Vertical Blank Interrupt 0= interrupt not pending 1= interrupt pending
1	X	FRAME_END_INT: Frame End Interrupt 0= interrupt not pending 1= interrupt pending
0	X	CTXSW_INT: Context Switch Interrupt Status (this is cleared on write) 0= interrupt not pending 1= interrupt pending

25.6.20 DC_CMD_INT_MASK_0

Setting bits in this register masks the corresponding interrupt but neither clears a pending interrupt nor prevents a pending interrupt from being generated. Masking an interrupt also does not clear a pending interrupt status and does not prevent a pending interrupt status from being generated.

Interrupt Mask

Offset: 0x38 | Byte Offset: 0xe0 | Read/Write: R/W | Reset: 0x00000000 (0bxxxxxxxx00xxxxx00000x0000x000000)

Bit	Reset	Description
23	0x0	HC_UF_INT_MASK: Cursor Underflow Interrupt Mask. 0 = MASKED 1 = NOTMASKED
22	0x0	CMU_LUT_CONFLICT_INT_MASK: CMU LUT read/write conflict. 0 = MASKED 1 = NOTMASKED
16	0x0	WIN_C_OF_INT_MASK: Window C Overflow Interrupt Mask 0 = MASKED 1 = NOTMASKED
15	0x0	WIN_B_OF_INT_MASK: Window B Overflow Interrupt Mask 0 = MASKED 1 = NOTMASKED

Bit	Reset	Description
14	0x0	WIN_A_OF_INT_MASK: Window A Overflow Interrupt Mask 0 = MASKED 1 = NOTMASKED
13	0x0	SSF_INT_MASK: Sub-Display Stop Frame Interrupt Mask 0 = MASKED 1 = NOTMASKED

0	0x0	CTXSW_INT_MASK: Context Switch Interrupt Mask 0 = MASKED 1 = NOTMASKED

25.6.21 DC_CMD_INT_ENABLE_0

Setting bits in this register enable the corresponding interrupt event to generate a pending interrupt. Interrupt output signal will be activated only if the corresponding interrupt is not masked.

Disabling an interrupt will not clear a corresponding pending interrupt - it only prevents a new interrupt event to generate a pending interrupt.

Interrupt Enable

Offset: 0x39 | Byte Offset: 0xe4 | Read/Write: R/W | Reset: 0x00000001 (0bxxxxxxxx00xxxx00000x0000x000001)

Bit	Reset	Description
23	0x0	HC_UF_INT_ENABLE: Cursor Underflow Interrupt Enable 0 = DISABLE 1 = ENABLE
22	0x0	CMU_LUT_CONFLICT_INT_ENABLE: CMU LUT read/write conflict 0 = DISABLE 1 = ENABLE
16	0x0	WIN_C_OF_INT_ENABLE: Window C Overflow Interrupt Enable 0 = DISABLE 1 = ENABLE
15	0x0	WIN_B_OF_INT_ENABLE: Window B Overflow Interrupt Enable 0 = DISABLE 1 = ENABLE
14	0x0	WIN_A_OF_INT_ENABLE: Window A Overflow Interrupt Enable 0 = DISABLE 1 = ENABLE
13	0x0	SSF_INT_ENABLE: Sub-Display Stop Frame Interrupt Enable 0 = DISABLE 1 = ENABLE
12	0x0	MSF_INT_ENABLE: Main-Display Stop Frame Interrupt Enable 0 = DISABLE 1 = ENABLE
10	0x0	WIN_C_UF_INT_ENABLE: Window C Underflow Interrupt Enable 0 = DISABLE 1 = ENABLE
9	0x0	WIN_B_UF_INT_ENABLE: Window B Underflow Interrupt Enable 0 = DISABLE 1 = ENABLE

0	0x0	GENERAL_ACT_CNTR_SEL: Select which counter to use for general activation 0 = VCOUNTER 1 = HCOUNTER

25.7 Display COM Registers

25.7.1 DC_COM_CRC_CONTROL_0

CRC Control

CRC is provided for at speed testing and diagnostic. When CRC is enabled, the CRC logic waits for the next VSync pulse or the one after that (depending on CRC_WAIT) and then it captures one frame of data at the end of display pipeline and computes the CRC value.

After one frame of data is captured, the CRC logic will stop capturing data.

When CRC_INPUT_DATA = FULL_FRAME, DISPLAY_COMMAND.DISPLAY_CTRL_MODE should be programmed to C_DISPLAY so that CRC works properly.

When CRC_INPUT_DATA = ACTIVE_DATA, it can work on both NC_DISPLAY and C_DISPLAY modes, and can work for multiple frames if CRC is checked, disabled, and re-enabled after the end of frame v-active area and before next VSYNC.

CRC logic takes 8 bits of control signals and 24-bit RGB pixel after dither and after display color (R and B) swap option.

Input [31:0] into CRC depends on CRC_INPUT_DATA. If programmed as FULL_FRAME, input data is { LVP1, LPV0, LHP2, LHP1, LHP0, VSYNC, HSYNC, ACTIVE, R[7:0], G[7:0], B[7:0]} and CRC runs over the entire frame (including blank). If programmed as ACTIVE_DATA, input data is {R[7:0], G[7:0], B[7:0]} and CRC runs only during active display area.

Offset: 0x300 | Byte Offset: 0xc00 | Read/Write: R/W | Reset: 0x00000000 (0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx0000)

Bit	Reset	Description
3	0x0	CRC_ALWAYS: CRC always: calculates CRC for every following frame. Must use with CRC_INPUT_DATA = ACTIVE_DATA. If enabled, CRC_WAIT field is ignored. 0 = DISABLE 1 = ENABLE
2	0x0	CRC_INPUT_DATA: CRC input data 0= Full frame (RGB data and control) 1= Active display (Only RGB data) 0 = FULL_FRAME 1 = ACTIVE_DATA
1	0x0	CRC_WAIT: CRC Wait 0= 1 Vsync 1= 2 Vsyncs
0	0x0	CRC_ENABLE: CRC Enable 0 = DISABLE 1 = ENABLE

25.7.2 DC_COM_CRC_CHECKSUM_0

CRC Checksum

This register can be read by host after CRC logic stops capturing data.

Offset: 0x301 | Byte Offset: 0xc04 | Read/Write: RO | Reset: 0x00000000 (0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx)

Bit	Reset	Description
31:0	0x0	CRC_CHECKSUM: CRC Checksum

25.7.3 DC_COM_PIN_MISC_CONTROL_0

Pin Miscellaneous Control

Pin Miscellaneous Control

Offset: 0x31b | Byte Offset: 0xc6c | Read/Write: R/W | Reset: 0x00000000 (0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx0xx)

Bit	Reset	Description
2	0x0	DISP_CLOCK_OUTPUT: Display Clock (DCLK) Enable. 0= disable. 1= enable display clock to be output on LCD_DE pin (LCD_DE output select must be appropriately programmed for this to be effective) 0 = DISABLE 1 = ENABLE

25.7.4 DC_COM_PM0_CONTROL_0

PM0 Signal Control

Class: Pulse Width Modulation

PM0 signal is programmable pulse width modulation signal that can be output on several pins. The control register should be initialized once before PM0 is enabled.

> **Note:** The period is expressed as multiples of 4 times the divider value.
> The actual period - in clock cycles - is given by:
> period = (1 + PM0_CLOCK_DIVIDER) * ((PM0_PERIOD + 1) * 4)

Offset: 0x31c | Byte Offset: 0xc70 | Read/Write: R/W | Reset: 0x00000000 (0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx)

Bit	Reset	Description
23:18	X	PM0_PERIOD: PM0 Period (4, 8, ... , 256 clock cycles)
17:4	X	PM0_CLOCK_DIVIDER: PM0 Clock Divider (1 to 16384)
1:0	X	PM0_CLOCK_SELECT: PM0 Clock Select. 0= output of shift clock divider 1= pixel clock 2= line clock 3= frame clock Notes: 1) Pixel clock, line clock, and frame clock are running only when the PW0 signal is enabled. 2) In non-continuous mode, shift clock and pixel clock run continuously, but line clock and frame clock only run while a frame is being sent.

25.7.5 DC_COM_PM0_DUTY_CYCLE_0

PM0 Duty Cycle

A counter repeatedly counts up from 0 to ((PM0_PERIOD << 2) + 3) pre-scaled cycles.

The period always starts with the output value == 1. After DUTY_CYCLE number of pre-scaled cycles, the output value is cleared for the remainder of the period. In order to output constant 0, simply set the DUTY_CYCLE to 0. To output a constant 1, set DUTY_CYCLE to be any value greater than ((PM0_PERIOD << 2) + 3).

Offset: 0x31d | Byte Offset: 0xc74 | Read/Write: R/W | Reset: 0x00000000 (0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx)

Bit	Reset	Description
8:0	X	PM0_DUTY_CYCLE: PM0 Duty Cycle (or D) From 1/P to D/P pulse high time where P is the period.

25.7.6 DC_COM_SCRATCH_REGISTER_A_0

Scratch Register A

Class: Software Scratch Registers

Offset: 0x325 | Byte Offset: 0xc94 | Read/Write: R/W | Reset: 0x00000000 (0b00000000000000000000000000000000)

Bit	Reset	Description
31:0	0x0	SCRATCH_REGISTER_A: Scratch Register A

25.7.7 DC_COM_SCRATCH_REGISTER_B_0

Scratch Register B

Offset: 0x326 | Byte Offset: 0xc98 | Read/Write: R/W | Reset: 0x00000000 (0b00000000000000000000000000000000)

Bit	Reset	Description
31:0	0x0	SCRATCH_REGISTER_B: Scratch Register B

25.7.8 DC_COM_CRC_CHECKSUM_LATCHED_0

CRC Checksum latched

This register is a latched version of CRC_CHECKSUM. Latching happens at frame end.

> **Note:** CRC_INPUT_DATA needs to be set to ACTIVE_DATA if this register is used. In full frame mode, CRC is frozen two cycles after frame end due to pipelining, so only in active area mode, CRC is consistent and independent of display control mode, and can be checked continuously frame by frame.

Offset: 0x329 | Byte Offset: 0xca4 | Read/Write: RO | Reset: 0x00000000 (0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx)

Bit	Reset	Description
31:0	0x0	CRC_CHECKSUM_LATCHED: CRC Checksum latched

25.7.9 DC_COM_CMU_CSC_KRR_0

CMU Color Space Conversion Matrix

R' = sat(KRR * R + KGR * G + KBR * B)

G' = sat(KRG * R + KGG * G + KBG * B)

B' = sat(KRB * R + KGB * G + KBB * B)

Coefficients are signed 1.8 fixed point, for a range of approximately [-2.0, +1.996]

Offset: 0x32a | Byte Offset: 0xca8 | Read/Write: R/W | Reset: 0x00000000 (0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx)

16	0x0	CURSOR_ENABLE: Cursor Enable 0 = DISABLE 1 = ENABLE

25.8.3 DC_DISP_DISP_TIMING_OPTIONS_0

Display Timing Options

Class: Display Standard Timings

Programming of display timing registers must meet these restrictions:

Constraint 1: H_REF_TO_SYNC + H_SYNC_WIDTH + H_BACK_PORCH > 20.

Constraint 2: V_REF_TO_SYNC + V_SYNC_WIDTH + V_BACK_PORCH > 1.

Constraint 3: V_FRONT_PORCH + V_SYNC_WIDTH + V_BACK_PORCH > 1 (vertical blank).

Constraint 4: V_SYNC_WIDTH >= 1

H_SYNC_WIDTH >= 1

Constraint 5: V_REF_TO_SYNC >= 1

H_REF_TO_SYNC >= 0

Constraint 6: V_FRONT_PORCH >= (V_REF_TO_SYNC + 1)

H_FRONT_PORCH >= (H_REF_TO_SYNC + 1)

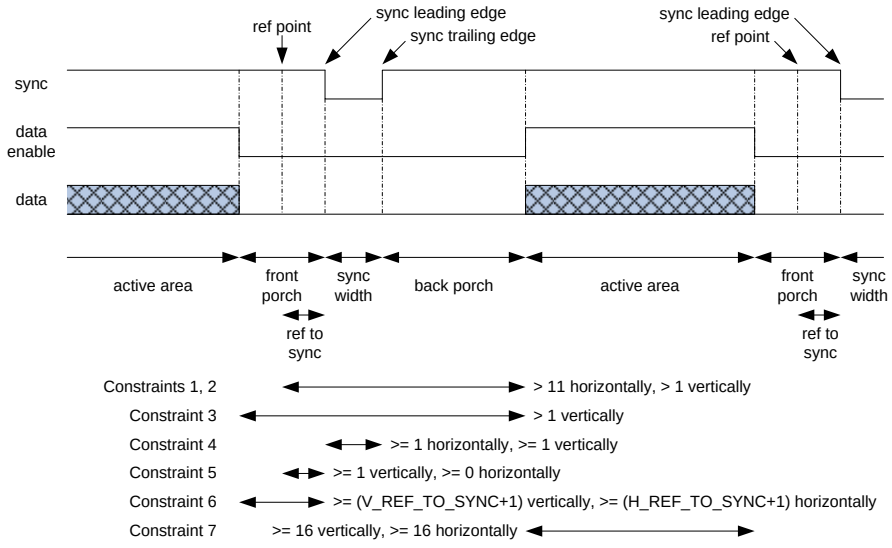
Constraint 7: H_DISP_ACTIVE >= 16

V_DISP_ACTIVE >= 16

Timing Diagram

- This diagram applies to both vertical and horizontal timing
- The back porch is the only parameter that can be negative

Figure 105: Display Timing Options Timing Diagram



This register specifies display timing options for HSYNC and VSYNC.

Offset: 0x405 │ Byte Offset: 0x1014 │ Read/Write: R/W │ Reset: 0x00000000 (0bxxxxxxxxxxxxxxxxxxxx0000000000000)

Bit	Reset	Description
12:0	0x0	VSYNC_H_POSITION: VSYNC Horizontal Position. This parameter specifies the position where VSYNC can toggle with respect to H reference point.

25.8.4 DC_DISP_REF_TO_SYNC_0

H/V Reference to Sync

This register specifies the start position of HSYNC and VSYNC with respect to H and V reference point (line and frame start) correspondingly. The H and V reference points correspond to the time when H and V display timing counter is re-initialized to zero correspondingly.

The H reference point also determines the point where V display timing counter is incremented so this points the horizontal relationship between HSYNC and VSYNC.

Note: VSYNC's rising/falling edge is fixed at H reference point zero.

Offset: 0x406 | Byte Offset: 0x1018 | Read/Write: R/W | Reset: 0x00000000 (0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx)

Bit	Reset	Description
28:16	X	V_REF_TO_SYNC: V reference to VSYNC (minimum 1 line clock)
12:0	X	H_REF_TO_SYNC: H reference to HSYNC (minimum 0 pixel clock)

25.8.5 DC_DISP_SYNC_WIDTH_0

H/V SYNC Pulse Width

This register specifies the width of HSYNC and VSYNC pulses. Check the Display Timing Options section for programming restrictions for REF_TO_SYNC.

Offset: 0x407 | Byte Offset: 0x101c | Read/Write: R/W | Reset: 0x00000000 (0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx)

Bit	Reset	Description
28:16	X	V_SYNC_WIDTH: VSYNC pulse width (minimum 1 line clock)
12:0	X	H_SYNC_WIDTH: HSYNC pulse width (minimum 1 pixel clock)

25.8.6 DC_DISP_BACK_PORCH_0

H/V Back Porch

This register specifies the distance between H/V SYNC trailing edge to beginning of display active area. This is a 2's complement value, and a negative value indicates that H/V SYNC overlaps with the corresponding display active area. Check the Display Timing Options section for programming restrictions for REF_TO_SYNC.

Offset: 0x408 | Byte Offset: 0x1020 | Read/Write: R/W | Reset: 0x00000000 (0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx)

Bit	Reset	Description
28:16	X	V_BACK_PORCH: V back porch
12:0	X	H_BACK_PORCH: H back porch

25.8.7 DC_DISP_DISP_ACTIVE_0

H/V Display Active Width

This register specifies the width of the H/V display active area. Check the Display Timing Options section for programming restrictions for REF_TO_SYNC.

Offset: 0x409 | Byte Offset: 0x1024 | Read/Write: R/W | Reset: 0x00000000 (0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx)

Bit	Reset	Description
28:16	X	V_DISP_ACTIVE: V display active width (minimum 16 lines)
12:0	X	H_DISP_ACTIVE: H display active width (minimum 16 pixels)

25.8.8 DC_DISP_FRONT_PORCH_0

H/V Front Porch

This register specifies the distance between end of H/V display active area to the leading edge of the corresponding H/V SYNC.

H/V active end plus the H/V front porch value minus the H/V reference to H/VSYNC determines the H/V total (final H/V count value for the H/V display counter). Check the Display Timing Options section for programming restrictions for REF_TO_SYNC.

Offset: 0x40a │ Byte Offset: 0x1028 │ Read/Write: R/W │ Reset: 0x00000000 (0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx)

Bit	Reset	Description
28:16	X	V_FRONT_PORCH: VSYNC front porch (minimum -=PS_=-V_REF_TO_SYNC + 1)
12:0	X	H_FRONT_PORCH: HSYNC front porch (minimum -=PS_=-H_REF_TO_SYNC + 1)

25.8.9 DC_DISP_H_PULSE0_CONTROL_0

H Pulse 0 Control

Class: Display Extended Timings

Horizontal pulse 0 is programmable pulse that repeats every line.

In NORMAL mode, this signal can have several pulses (A to D) per line with programmable width as defined by the pairs of start and end positions. The pulses must not overlap and must occur in sequence: pulse A, then pulse B, etc. In this case, the Enable field must be set to one of the End position. If the Enable field is set to one of the Start position then the pulse generator will stop as if the Enable field is set to the previous End position. If the Enable field is set to the Start A position, then no pulse is generated.

In ONE_CLOCK mode, this signal can have up to twice the number of pulses per line with each pulse having a width of 1 pixel clock. In this mode, the position of the one-clock pulses corresponds to the enabled Start and End positions.

Regardless of the mode, the pulse generator processes the pairs of start and end position sequentially in the order of: Start A, End A, Start B, End B, etc.

So these start/end positions should be programmed in increasing order. If any of the positions are programmed in non-increasing order (has invalid value) then the pulse generator will stop at the last valid position.

Polarity adjustment is made prior to V display qualification. This register specifies options for Horizontal pulse 0.

Offset: 0x40b │ Byte Offset: 0x102c │ Read/Write: R/W │ Reset: 0x00000000 (0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx)

25.8.19 DC_DISP_H_PULSE2_CONTROL_0

H Pulse 2 Control

Horizontal pulse 2 is a programmable pulse that repeats every line.

In NORMAL mode, this signal can have several pulses (A to D) per line with programmable width as defined by the pairs of start and end positions. The pulses must not overlap and must occur in sequence: pulse A, then pulse B, etc. In this case, the Enable field must be set to one of the End position. If the Enable field is set to one of the Start position then the pulse generator will stop as if the Enable field is set to the previous End position. If the Enable field is set to the Start A position, then no pulse is generated.

In ONE_CLOCK mode this signal can have up to twice the number of pulses per line with each pulse having a width of 1 pixel clock. In this mode, the position of the one-clock pulses corresponds to the enabled Start and End positions.

Regardless of the mode, the pulse generator processes the pairs of start and end position sequentially in the order of: Start A, End A, Start B, End B, etc. So these start/end positions should be programmed in increasing order. If any of the positions are programmed in non-increasing order (has invalid value), then the pulse generator will stop at the last valid position. Polarity adjustment is made prior to V display qualification. This register specifies options for Horizontal pulse 2.

25.8.36 DC_DISP_DISP_CLOCK_CONTROL_0

Display Clock Control

The shift clock divider is used to divide root clock for display controller module to generate internal shift clock for shifting data to the display. Output of this divider is typically used to generate the external shift clock which is sent to the display (SC0 and/or SC1) except for 1-pixel/1-clock parallel display.

The output of this divider is also used to generate Programmable Pulse (PP) signal. For 1-pixel/1-clock parallel display, SC0 and SC1 are generated using the output of pixel clock divider which can be set to 1, 2, or 4 for 1-pixel/1-clock parallel display.

The reason pixel clock divider 2 and 4 are allowed for 1-pixel/1-clock parallel display interface is so that the clock that generates PP can be generated with 2x or 4x higher frequency than pixel clock and therefore can produce higher resolution PP pulse positions. For all cases of parallel display, SC0 and SC1 can be further divided by 1, 2, or 4.

Class: Display Interface Settings

This register controls generation of shift clock to the display and internal pixel clock. Internal display pipeline runs with pixel clock and processes 1 pixel per clock.

Offset: 0x42e │ Byte Offset: 0x10b8 │ Read/Write: R/W │ Reset: 0x00000006 (0bxxxxxxxxxxxxxxxxxxxx000000000110)

Bit	Reset	Description

Bit	Reset	Description
7:0	0x6	SHIFT_CLK_DIVIDER: Shift Clock Divider. 0 = divide by 1 1 = divide by 1.5 2 = divide by 2 3 = divide by 2.5 4 = divide by 3 : : : : 254 = divide by 128 255 = divide by 128.5 Pixel clock divider is used to divide output of internal shift clock divider to generate internal pixel clock which is used to clock the internal horizontal and vertical counters. This divider also determines the output format for parallel interface, serial interface, and LCD SPI interface in conjunction with Display Data Format parameter. For 1-pixel/1-clock parallel display interface, valid settings are PCD1, PCD2, and PCD4. Note that the main reason to use PCD2 and PCD4 is to get higher frequency PP clock because the PP clock is always generated from the output of shift clock divider. For non 1-pixel/1-clock parallel display interface, valid settings are, PCD1H (2-pixel/3-clock), PCD2 (1-pixel/2-clock), and PCD3 (1-pixel/3-clock). For 1-channel serial display interface, valid settings are PCD3 (3-bpp 1-ch), PCD4 (3-bpp 1-ch), PCD6 (6-bpp 1-ch), PCD9 (9-bpp 1-ch), PCD12 (12-bpp 1-ch), PCD16 (16-bpp 1-ch), PCD18 (18-bpp 1-ch). For 2-channel serial display interface, valid settings are PCD2 (3-bpp 2-ch), PCD3 (6-bpp 2-ch), PCD6 (12-bpp 2-ch), PCD8 (16-bpp 2-ch), PCD9 (18-bpp 2-ch). For 3-channel serial display interface, valid settings are PCD1 (3-bpp 3-ch), PCD2 (6-bpp 3-ch), PCD3 (9-bpp 3-ch), PCD4 (12-bpp 3-ch), PCD6 (18-bpp 3-ch). For LCD SPI interface, valid settings are PCD12 (B4G4R4), PCD16 (B5G6R5), PCD18 (B6G6R6), PCD24 (B8G8R8), PCD8 (B5G6R5 with data/command bit), PCD6 (B5G6R5 with data/command start byte - depending on data/command bit), PCD4 (P8 for spi8), PCD9 (B5G6R5 with chip select deassertion at 8-bit boundary, spi16x2), PCD3 (P8 for spidc), PCD2 (B5G6R5 with data/command bit and chip select de-assertion at 9-bit boundary, spi16x2dc), and PCD13 (spi12p2, no chip select de-assertion between pairs of pixels).

25	0x0	LCD_MD1: LCD Mode 1 signal 0 = LOW 1 = HIGH
24	0x0	LCD_MD0: LCD Mode 0 signal 0 = LOW 1 = HIGH
20	DISABLE	CMU_ENABLE: MD0-3 signals are general purpose mode signals that can be output in various pins (see Pin Output Select) to configure the display device. These bits are effective at start of frame. Typically these can be programmed in shadow register which takes effect on the next frame. 0 = DISABLE 1 = ENABLE
18	0x0	NON_BASE_COLOR: Non Base Color 0= zeros 1= ones
17	X	BLANK_COLOR: Blank Color 0= zeros 1= ones Non Base Color applies to least significant color bits which are not part of base color and it has higher priority over Border Color but lower priority over Blank color.
16	0x0	DISP_COLOR_SWAP: Display Color Swap 0= RGB (normal) 1= BGR (red-blue reverse) 0 = RGB 1 = BGR
13:12	0x0	ORD_DITHER_ROTATION: Ordered Dither Frame Rotation. This parameter specifies the rotation frequency of the dither matrix in terms of number of frames. If programmed to 0, there is no dither matrix rotation. If programmed to N, where N is larger than 0, the dither matrix is rotated clockwise every N frame.
9:8	X	DITHER_CONTROL: Dither Control 00= dither disabled 01= reserved 10= ordered dither 11= error-diffusion dither (maximum line width is 1280) Design Note: initial dither matrix (where d is 2 dither bits) d=00 d=01 d=10 d=11 --------- ---------- --------- --------- 0 0 1 0 0 1 0 1 --------- --------- --------- --------- 0 0 0 0 1 0 1 1 --------- ---- Note: 0 in the matrix specifies no addition to base color 1 in the matrix specifies incrementation of base color (with saturation) 0 = DISABLE 2 = ORDERED 3 = ERRDIFF

Bit	Reset	Description
3:0	0x0	BASE_COLOR_SIZE: Display Base Color Size. This parameter determines the number of bits per color after dither. 0= 6 bits 1= 1 bit 2= 2 bits 3= 3 bits 4= 4 bits 5= 5 bits 6= 5 bits for R,B and 6 bits for G 7= 3 bits for R,G and 2 bits for B 8= 8 bits, this also forces dither to be disabled. This setting can be used to output 24-bit data in 1-pixel/clock parallel display data format. 0 = BASE666 1 = BASE111 2 = BASE222 3 = BASE333 4 = BASE444 5 = BASE555 6 = BASE565 7 = BASE332 8 = BASE888

25.8.39 DC_DISP_BORDER_COLOR_0

Border Color

Border Color defines the color of areas within the active display area which are outside the defined active windows. This is 24-bit color which is applied after blending.

Offset: 0x435 │ Byte Offset: 0x10d4 │ Read/Write: R/W │ Reset: 0x00000000 (0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx)

Bit	Reset	Description
23:16	X	BORDER_COLOR_B: Blue Border Color
15:8	X	BORDER_COLOR_G: Green Border Color
7:0	X	BORDER_COLOR_R: Red Border Color

25.8.40 DC_DISP_COLOR_KEY0_LOWER_0

Color Key 0 Lower Value

Color Key 0 and Color Key 1

Two ranges of color key are defined and they are common for all windows because it is expected that typically only one window will have the color key enabled. Because there are two sets of color key, it is possible to have 2 windows each using one color key set.

Usage of this color key is described in the Display Color Key and Blending class.

25.8.44 DC_DISP_CURSOR_FOREGROUND_0

Cursor Foreground Color

Class: Hardware Cursor

Hardware cursor is supported for 32x32 or for 64x64 2-bpp cursor.

Cursor start address is aligned to 1 KB boundary. All cursor registers except for cursor foreground and background colors are triple buffered.

GENERAL_UPDATE controls ASSEMBLY->ARM latching, GENERAL_ACT_REQ controls ARM->ACTIVE latching.

Cursor scaling and flipping are not implemented so this must be done by software if needed. Cursor H/V positions are signed number with respect to one of the display windows or with respect to upper left position of display active area as specified by cursor clipping parameter which also determines cursor clipping boundary. If cursor position is with respect to one of the display window and the corresponding display window is disabled then cursor will also be disabled.

0	0x0	PHASE_SHIFT_2P1C18B: Enable phase shift for 2P1C format phase shift SC0/SC1 will be delayed for one pixel clock cycle. In 2P1C format, data will hold for 2 pixel clocks, so either choice should work 0 = DISABLE 1 = ENABLE

25.8.55 DC_DISP_SD_CONTROL_0

The Smart Dimmer function takes advantage of the fact that a perceived pixel brightness in an LCD depends on both the pixel brightness value and the backlight intensity to reduce the backlight intensity to save power. Statistics are gathered on the current video frame and an "enhancement" is applied to subsequent frames that increases the pixel brightness value and reduces the backlight brightness to give an overall image intensity that is mostly the same as before.

Smart Dimmer Control

Offset: 0x4c2 | Byte Offset: 0x1308 | Read/Write: R/W | Reset: 0x00004000 (0bxxx0xxxxxxxxxxxx0100000000000000)

Bit	Reset	Description
28	VSYNC	SD_FRAME_PROC_CONTROL: when to run per-frame processing. VSYNC is legacy behavior. 0 = VSYNC 1 = VPULSE2
15	DISABLE	SMOOTH_K_ENABLE: When enable, maximum raw K change per frame is limited to SMOOTH_K_INCR 0 = DISABLE 1 = ENABLE
14	ENABLE	SOFT_CLIPPING_ENABLE: When enabled, enhancement gain (K) is reduced for pixels above SOFT_CLIPPING_THRESHOLD level to avoid saturation (clipping). 0 = DISABLE 1 = ENABLE
13	DISABLE	SD_WINDOW_ENABLE: When enabled, constrain histogram (and therefore backlight) to a rectangular subset of display. The rectangle has upper/left corner described by SD_WINDOW_POSITION, and width/height by SD_WINDOW_SIZE. Useful for when display has regions that should not influence SD, such as letterbox borders, etc. Enhancement is always performed on whole display, regardless. DISABLE: SD histogram done over whole display ENABLE: SD histogram done over rectangular subset given by SD_WINDOW* registers 0 = DISABLE 1 = ENABLE
12	DISABLE	K_LIMIT_ENABLE: When enabled, Max. K is taken from K_LIMIT register rather than computed from AGGRESSIVENESS. DISABLE: K is limited by AGGRESSIVENESS ENABLE: K is limited by K_LIMIT register. 0 = DISABLE 1 = ENABLE

Bit	Reset	Description
11	0x0	SD_CORRECTION_MODE: Determines which K values are used to modify the pixel values. MANUAL : The K values in the SD_MAN_K_VALUES register are used to modify pixel values. 0 = AUTO_CORRECT : AUTO_CORRECT : SD Hardware computed K values are used to 1 = MANUAL
10	0x0	SD_ONE_SHOT: Enables the Smart Dimmer function for one frame only. on which the SD statistics are gathered. NOTE: The SD_ENABLE field (see above) must be set to ONE_SHOT in order to use this function. 0 = DISABLE : Automatically cleared to DISABLE at the end of the frame 1 = ENABLE
9:8	0x0	HW_UPDATE_DLY: Determines the delay - in video frames - of the update of the hardware enhancement value that is applied to the pixels. This is useful for allowing the software some time to update the backlight control, when the control must be sent via side-band control packets or by some other means of control that incurs a sizeable delay. Being able to delay the hardware update ensures that the modification of the pixels occurs as nearly simultaneously with the update of the backlight as possible. Value Description 0 No delay - pixels modified immediately 1 New enhancement value delayed by 1 frame. 2 New enhancement value delayed by 2 frames. 3 New enhancement value delayed by 3 frames.
7:5	0x0	AGGRESSIVENESS: The "aggressiveness" level of the Smart Dimmer algorithm. Higher aggressiveness levels result in higher power savings at the potential expense of image quality. The number programmed determines how many highlight pixels will be allowed to exceed the maximum representable brightness value and be clipped to that value. It also determines the maximum allowed enhancement value (k) applied to the pixel brightness. AGGRESSIVENESS Description % pixels Max. k value crushed value 0 Essentially off 0% 1.00 1 Highest quality < 5% 1.10 2 Higher quality < 10% 1.15 3 Balanced < 15% 1.20 4 Higher battery life < 20% 1.25 5 Highest battery life < 25% 1.50
4:3	0x0	BIN_WIDTH: Width of the Histogram bins, in quantization levels. EIGHT = 8 levels per bin. Bins span range from 0 to 255 0 = ONE : ONE = 1 level per bin. Bins span range from 224 to 255 1 = TWO : TWO = 2 levels per bin. Bins span range from 192 to 255 2 = FOUR : FOUR = 4 levels per bin. Bins span range from 128 to 255 3 = EIGHT
2	0x0	USE_VID_LUMA: Use Video Luminance control of luminance: Luminance = MAX(R, G, B) ENABLE = use "video" luminance, which is determined by the coefficients in the SD_CSC_COEFFS register See the SD_CSC_COEFFS register for details. 0 = DISABLE : DISABLE = use Hue Saturation Value (HSV) version 1 = ENABLE
1:0	0x0	SD_ENABLE: Enables the Smart Dimmer Function ONE_SHOT = SD function enabled, but statistics gathering limited to the next frame only. 0 = DISABLE : DISABLE = SD function disabled. 1 = ENABLE : ENABLE = SD function enabled and operational. 2 = ONE_SHOT

25.8.56 DC_DISP_SD_CSC_COEFF_0

Luminance calculation coefficients used to convert the red, green, and blue color components into a luminance value. The conversion is performed according to the following equation: Luminance = (R * R_COEFF + G * G_COEFF + B * B_COEFF) >> 4 It is suggested that the values of the coefficients be programmed as shown below, though user-defined color spaces are also accommodated. Color Space R_COEFF G_COEFF B_COEFF ITU-R Bt601 5 9 2 ITU-R Bt709 3 12 1. The coefficients

do not have to be particularly accurate, hence their low precision, and the coefficients used are open to experimentation to obtain the best results.

Offset: 0x4c3 | Byte Offset: 0x130c | Read/Write: R/W | Reset: 0x00000000 (0bxxxxxxxx0000xxxx0000xxxx0000xxxx)

Bit	Reset	Description
23:20	0x0	B_COEFF: Blue coefficient for luminance calculation
15:12	0x0	G_COEFF: Green coefficient for luminance calculation
7:4	0x0	R_COEFF: Red coefficient for luminance calculation

25.8.57 DC_DISP_SD_LUT_0

Enhancement value (k) Look Up Table. Each LUT entry contains the value of k for each of the three color components. Since the value of k for the color components must be the reciprocal of the hardware-computed value of k, and the hardware value is guaranteed to be less than or equal to 1, the values in the LUT represent the fractional part of k, with an implied 1 to the left of the decimal place. For example, if the programmed value of R_LUT was 64 (01000000 in binary), then the actual value of k generated would be 1.01000000 in binary or 1.25 in decimal. To program a default, linear response into the LUT, use the following code as a guide: for (i = 0; i < 9; i++) { t = (4096 / (8 + i)) - 256; if (t > 255) t = 255; R_LUT[i] = t; G_LUT[i] = t; B_LUT[i] = t; } For other non-linear response curves (for example, to take display gamma into consideration), this code will have to be modified.

This is an array of 9 identical register entries; the register fields below apply to each entry.

Offset: 0x4c4..0x4cc | Byte Offset: 0x1310..0x1330 | Read/Write: R/W | Reset: 0x00000000 (0bxxxxxxxx00000000000000000000000)

Bit	Reset	Description
23:16	0x0	B_LUT: Blue Enhancement value (k) Look Up Table

7:0	0x0	R_LUT: Red Enhancement value (k) Look Up Table

25.8.58 DC_DISP_SD_FLICKER_CONTROL_0

Flicker Reduction Control Register

The flicker control prevents rapid and frequent changes in the enhancement value.

Offset: 0x4cd | Byte Offset: 0x1334 | Read/Write: R/W | Reset: 0x00000000 (0bxxxxxxxxxxxxxxxxx0000000000000000)

Bit	Reset	Description
15:8	0x0	THRESHOLD: The amount by which the currently calculated enhancement value must deviate from the currently active enhancement value for it to increment the TIME_LIMIT counter.
7:0	0x0	TIME_LIMIT: Length of time - in frames - that the enhancement value must deviate from the current value by more than THRESHOLD, before the enhancement value changes.

25.8.59 DC_DISP_SD_PIXEL_COUNT_0

Status / debug register showing the total number of active pixels

Offset: 0x4ce │ Byte Offset: 0x1338 │ Read/Write: RO │ Reset: 0x00000000 (0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx)

Bit	Reset	Description
15:0	X	NUM_PIXELS: in the preceding output frame. Expressed as a quantity of 256 pixels. In other words, a 640 x 480 image has 307200 pixels. The value in this register would be 307200 / 256 = 1200

25.8.60 DC_DISP_SD_HISTOGRAM_0

Status/debug registers showing the gathered histogram data. Each register contains 4 histogram bins, for a total of 8 x 4 = 32 bins. Each bin has been approximately scaled to the number of pixels in the image so that a single quantization step in a bin represents a fraction of between 1/256 and 1/128 of the total number of pixels in the image.

This is an array of 8 identical register entries; the register fields below apply to each entry.

Offset: 0x4cf..0x4d6 │ Byte Offset: 0x133c..0x1358 │ Read/Write: RO │ Reset: 0x00000000 (0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx)

25.8.61 DC_DISP_SD_BL_PARAMETERS_0

Backlight response parameters. Defines the parameters for the backlight temporal response model.

Offset: 0x4d7 │ Byte Offset: 0x135c │ Read/Write: R/W │ Reset: 0x00000400 (0bxxxxxxxx00000000xxxxx10000000000)

Bit	Reset	Description
23:16	0x0	STEP: Determines the instantaneous portion of the target value of enhancement that is applied. 0 = 0% : response is entirely exponential and determined by TIME_CONSTANT 128 = 50% : response will instantly step up by 50% and will then be exponential. 255 = 100% : response is entirely instantaneous. TIME_CONSTANT has no effect.
10:0	0x400	TIME_CONSTANT: The time constant for the response curve. This value represents the fraction by which the value of enhancement value approaches the target value each frame. Example values are shown below: 0 : The value will never reach the target (infinite TC) 512 : The next value will be halfway between the current value and the target value. 1024 : The next value will be 100% of the target value. In other words - an instantaneous response.

25.8.62 DC_DISP_SD_BL_TF_0

Backlight Transfer Function

Each register contains 4 points on the Transfer Function curve that defines how the backlight output changes with respect to the control input. Each point defines a value at the vertex of a 16 segment line. The 17th point is defined to be the maximum value (it is assumed 100% control == 100% light output).

This is an array of 4 identical register entries; the register fields below apply to each entry.

Offset: 0x4d8..0x4db │ Byte Offset: 0x1360..0x136c │ Read/Write: R/W │Reset: 0x00000000 (0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx)

Bit	Reset	Description

25.8.63 DC_DISP_SD_BL_CONTROL_0

Backlight Control Register

Offset: 0x4dc │ Byte Offset: 0x1370 │ Read/Write: R/W │ Reset: 0x00000000 (0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx00)

Bit	R/W	Reset	Description
15:8	RO	X	BRIGHTNESS: Backlight brightness modification value. This value is determined by the hardware according to all the other control registers and the image content. The amount by which the backlight should be modified is given as a fraction with 0 representing that the backlight should be off and 255 representing no change in the backlight intensity. Other values vary linearly between these two extremes. New BL control = (Old BL control * BRIGHTNESS) / 255
1:0	RW	0x0	BL_MODE: Control Mode: and adjust the backlight brightness itself. PWM_AUTO : Hardware will adjust the backlight PWM control signal directly using the value in BRIGHTNESS. * OTHER VALUES ARE RESERVED FOR FUTURE USE * 0 = MANUAL : MANUAL : Hardware makes no BL corrections. Software must read the BRIGHTNESS field 1 = PWM_AUTO

25.8.64 DC_DISP_SD_HW_K_VALUES_0

Hardware-computed values of K for each color component. These values are used to modify the pixel values when CORRECTION_MODE in the SD_CONTROL register is set to AUTO_CORRECT. The numerical format is a fractional 10-bit number. Since we only ever want to make the pixel values bigger, there is an implied integer "1" not present in the register value. Only the fractional part is returned. Also in Tegra 4 devices, only the top 7 bits of the 10-bit K word have any meaning. The bottom 3 bits are always 0 and are reserved for future expansion. This register is read only.

Offset: 0x4dd │ Byte Offset: 0x1374 │ Read/Write: RO │ Reset: 0x00000000 (0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx)

Bit	Reset	Description
29:20	X	HW_K_BLUE: Value of K for blue pixels.
19:10	X	HW_K_GREEN: Value of K for green pixels.
9:0	X	HW_K_RED: Value of K for red pixels.

25.8.65 DC_DISP_SD_MAN_K_VALUES_0

Manual values of K for each color component. These values are used to modify the pixel values when CORRECTION_MODE in the SD_CONTROL register is set to MANUAL. The numerical format is a fractional 10-bit number. Since we only ever want to make the pixel values bigger, there is an implied integer "1" not present in the register value. Only the fractional part can be programmed. Therefore, K values can only be programmed from 1.0 to slightly less than 2.0 .Also note that only the top 7 bits of the 10-bit K word have any effect in the hardware. The bottom 3 bits are reserved for future expansion.

Offset: 0x4de | Byte Offset: 0x1378 | Read/Write: R/W | Reset: 0x00000000 (0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx)

Bit	Reset	Description
29:20	X	MAN_K_BLUE: Value of K for blue pixels.
19:10	X	MAN_K_GREEN: Value of K for green pixels.
9:0	X	MAN_K_RED: Value of K for red pixels.

25.8.66 DC_DISP_SD_K_LIMIT_0

Offset: 0x4df | Byte Offset: 0x137c | Read/Write: R/W | Reset: 0x00000000 (0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx)

Bit	Reset	Description
9:0	X	K_LIMIT: When K_LIMIT_ENABLE=ENABLE, limits raw K independently of AGGRESSIVENESS. Currently, only the top 8 bits are effective. The bottom 2 are reserved for future expansion.

25.8.67 DC_DISP_SD_WINDOW_POSITION_0

SD Window Position

Offset: 0x4e0 | Byte Offset: 0x1380 | Read/Write: R/W | Reset: 0x00000000 (0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx)

Bit	Reset	Description
28:16	X	SD_WIN_V_POSITION: SD window vertical position. This is specified with respect to the top edge of active display area.
12:0	X	SD_WIN_H_POSITION: SD window horizontal position (pixels). This is specified with respect to the left edge of active display area.

25.8.68 DC_DISP_SD_WINDOW_SIZE_0

SD Window Size

Offset: 0x4e1 | Byte Offset: 0x1384 | Read/Write: R/W | Reset: 0x00000000 (0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx)

Bit	Reset	Description
28:16	X	SD_WIN_V_SIZE: SD window vertical height (lines).
12:0	X	SD_WIN_H_SIZE: SD window horizontal width (pixels).

25.8.69 DC_DISP_SD_SOFT_CLIPPING_0

SD soft clipping parameters. Software programs both threshold and a reciprocal thereof.

Offset: 0x4e2 | Byte Offset: 0x1388 | Read/Write: R/W | Reset: 0x02000080 (0b00000010000000000xxxxxxx10000000)

Bit	Reset	Description
31:16	0x200	SOFT_CLIPPING_RECIP: Reciprocal of inverse threshold. Compute as RECIP = int(64*1024 * 1.0 / (256 - THRESHOLD)). For example, for THRESHOLD=128, RECIP = int(64*1024 * 1.0 / (256 - 128)) = 512.
7:0	0x80	SOFT_CLIPPING_THRESHOLD: Threshold at which pixel enhancement gain is reduced.

25.8.70 DC_DISP_SD_SMOOTH_K_0

Offset: 0x4e3 | Byte Offset: 0x138c | Read/Write: R/W | Reset: 0x00000000 (0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx)

Bit	Reset	Description
13:0	X	SMOOTH_K_INCR: When SMOOTH_K_ENABLE=1, the raw K is changed at most by SMOOTH_K_INCR per frame. 8.6 fixed-point fraction, with resolution 1/64. Currently, only the top 12 bits are effective. The bottom 2 are reserved for future expansion, so the effective resolution is 1/16.

25.8.71 DC_DISP_CURSOR_UNDERFLOW_CTRL_0

Offset: 0x4eb | Byte Offset: 0x13ac | Read/Write: R/W | Reset: 0x00000000 (0bxxxxxxxxxxxxxxxxxxxxxxxx1xxxxxx0)

Bit	Reset	Description
7	0x0	CURSOR_UFLOW_CYA: 0 = DISABLE 1 = ENABLE
0	0x0	CURSOR_UFLOW_CTRL_DBG_MODE: 0 = DISABLE 1 = ENABLE

25.8.72 DC_DISP_BLEND_CURSOR_CONTROL_0

Offset: 0x4f1 | Byte Offset: 0x13c4 | Read/Write: R/W | Reset: 0x00000000 (0bxxxxxxx0xxxxxxxxxxxxxxxxxxxxxxx)

Bit	Reset	Description
24	0x0	CURSOR_MODE_SELECT: 0 = LEGACY 1 = NORMAL

25.8.73 DC_DISP_DVFS_CURSOR_CONTROL_0

Programmable threshold to deassert for cursor. Default value is 3 lines ahead of cursor active.

Offset: 0x4f2 | Byte Offset: 0x13c8 | Read/Write: R/W | Reset: 0x00000003 (0bxxxxxxxxxxxxxxxxxxxxxxxx00000011)

Bit	Reset	Description
7:0	0x3	CURSOR_DVFS_THRESHOLD

25.8.74 DC_DISP_CURSOR_UFLOW_DBG_PIXEL_0

Offset: 0x4f3 | Byte Offset: 0x13cc | Read/Write: R/W | Reset: 0x00000000 (0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx)

Bit	Reset	Description
31:0	X	CURSOR_UFLOW_DBG_PIXEL

25.8.75 DC_DISP_CURSOR_SPOOLUP_CONTROL_0

Programmable spool up for cursor. If spoolup count > hc_vactive_start, it will be clamped to zero.

Offset: 0x4f4 | Byte Offset: 0x13d0 | Read/Write: R/W | Reset: 0x00000001 (0bxxxxxxxxxxxxxxxxxxxxxxxx00000001)

Bit	Reset	Description
7:0	0x1	CURSOR_SPOOLUP_START

25.8.76 DC_DISP_DISPLAY_CLK_GATE_OVERRIDE_0

Offset: 0x4f5 | Byte Offset: 0x13d4 | Read/Write: R/W | Reset: 0x00000000 (0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx00)

Bit	Reset	Description
1	0x0	CMU_CLK_GATE_OVERRIDE: Disable clock-gating of the CMU module. 0 = DISABLE 1 = ENABLE
0	0x0	CURSOR_CLK_GATE_OVERRIDE: Disable clock-gating of cursor memfetch/control modules 0 = DISABLE 1 = ENABLE

25.8.77 DC_DISP_DISPLAY_DBG_TIMING_0

Offset: 0x4f6 | Byte Offset: 0x13d8 | Read/Write: RO | Reset: 0x00000000 (0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx)

Bit	Reset	Description
31	X	H_BLANK
28:16	X	H_COUNT
15	X	V_BLANK
12:0	X	V_COUNT

25.8.78 DC_DISP_DISPLAY_SPARE0_0

Offset: 0x4f7 | Byte Offset: 0x13dc | Read/Write: R/W | Reset: 0x00000000 (0b00000000000000000000000000000000)

Bit	Reset	Description
31:0	0x0	SCRATCH_0

25.8.79 DC_DISP_DISPLAY_SPARE1_0

Offset: 0x4f8 | Byte Offset: 0x13e0 | Read/Write: R/W | Reset: 0x00000000 (0b00000000000000000000000000000000)

Bit	Reset	Description
31:0	0x0	SCRATCH_1

25.9 Window A (WINC_A) Registers

These registers control window A parameters.

> **Note:** There are three copies of these registers for windows A, B, and C. Windows A, B, and C support different features

Window A: color palette, digital vibrance

Window B: color palette, digital vibrance, color space conversion, horizontal/vertical filtering

Window C: color palette, digital vibrance, color space conversion, horizontal filtering. The registers under DC_WINC are usually not shadowed.

25.9.1 DC_WINC_A_COLOR_PALETTE_0

This is used for palletized data format (color depth of 8 bpp or less) or for gamma correction for non-palletized data formats (color depth of more than 8 bpp).

Each window has its own color palette which consists of three 256x8 register files which can be written by the host and indexed (read) by the window.

For palletized data formats less than 8 bpp, the pixel data is aligned to least significant bits of the palette index (address), and the remaining upper bits are filled with the corresponding bits of the Palette Color Extension. For example, for 4-bpp mode, the pixel data occupies bits 3:0 of the palette index, and bits 7:4 of the palette index are set to bits 7:4 of the Palette Color Extension.

Note that a host read is assumed to be not needed - software can cache the color palette in system memory.

This is an array of 256 identical register entries; the register fields below apply to each entry.

Window A Color Palette

Offset: 0x500..0x5ff │ Byte Offset: 0x1400..0x17fc │ Read/Write: WO │ Reset: 0x00000000 (0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx)

Bit	Reset	Description
23:16	X	A_COLOR_PALETTE_B: Blue Color Palette
15:8	X	A_COLOR_PALETTE_G: Green Color Palette
7:0	X	A_COLOR_PALETTE_R: Red Color Palette

25.9.2 DC_WINC_A_PALETTE_COLOR_EXT_0

Palette extension for 1-bpp, 2-bpp, and 4-bpp. These bits provide the upper most significant bits for indexing the color palette.

Window A Palette Color Extension

Offset: 0x600 │ Byte Offset: 0x1800 │ Read/Write: R/W │ Reset: 0x00000000 (0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx)

Bit	Reset	Description
7:1	X	A_PALETTE_COLOR_EXT: Window A Palette Color Extension. Bits 7:1 are used for 1-bpp mode, bits 7:2 are used for 2-bpp mode, and bits 7:4 are used for 4-bpp mode

25.9.3 DC_WINC_A_H_FILTER_P00_0

Horizontal Scaling Filter Coefficients

Horizontal scaling filter is a 6-tap filter with 4-bit positional phase.

- Coefficients 0 and 5 are 3-bit signed values ranging from -4 to 3.
- Coefficients 1 and 4 are 5-bit signed values ranging from -16 to 15.
- Coefficients 2 and 3 are 8-bit unsigned values ranging from 0 to 128.
- Coefficient 0 is the multiplier for the earliest pixel (P0) in the group of 6 pixels and
- Coefficient 5 is the multiplier for the latest pixel (P5) in the group. The output pixel positional phase is defined as centered in P2 if the positional phase is 0 or proportionally in between P2 and P3 if the positional phase is larger than 0.

The sum of all coefficients for each phase should be 128 typically, and software should never program the sum of all coefficients for a phase to be more than 128.

For each horizontal positional phase, the 6 filter coefficients require 32 register bits.

Note that color value ranges from 0 to 255 for Y, R, G, B, and -128 to 127 for U and V.

Window A Horizontal Filter phase 00

Offset: 0x601 | Byte Offset: 0x1804 | Read/Write: R/W | Reset: 0x00000000 (0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx)

Bit	Reset	Description
31:29	X	A_H_FILTER_P00C5: Phase 00 coefficient 5 (typically 0)
28:24	X	A_H_FILTER_P00C4: Phase 00 coefficient 4 (typically 0)
23:16	X	A_H_FILTER_P00C3: Phase 00 coefficient 3 (typically 0)
15:8	X	A_H_FILTER_P00C2: Phase 00 coefficient 2 (typically 128)
7:3	X	A_H_FILTER_P00C1: Phase 00 coefficient 1 (typically 0)
2:0	X	A_H_FILTER_P00C0: Phase 00 coefficient 0 (typically 0)

25.9.4 DC_WINC_A_H_FILTER_P01_0

Window A Horizontal Filter phase 01

Offset: 0x602 | Byte Offset: 0x1808 | Read/Write: R/W | Reset: 0x00000000 (0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx)

Bit	Reset	Description
31:29	X	A_H_FILTER_P01C5: Phase 01 coefficient 5 (typically 1)
28:24	X	A_H_FILTER_P01C4: Phase 01 coefficient 4 (typically -2)
23:16	X	A_H_FILTER_P01C3: Phase 01 coefficient 3 (typically 8)
15:8	X	A_H_FILTER_P01C2: Phase 01 coefficient 2 (typically 124)
7:3	X	A_H_FILTER_P01C1: Phase 01 coefficient 1 (typically -4)
2:0	X	A_H_FILTER_P01C0: Phase 01 coefficient 0 (typically 1)

25.9.5 DC_WINC_A_H_FILTER_P02_0

Window A Horizontal Filter phase 02

25.9.19 DC_WINC_A_CSC_YOF_0

Color Space Conversion Coefficients

The CSC can be used for YUV to RGB conversion with brightness and hue/saturation control. The CSC can only be enabled for window A controlled by CSC_ENABLE register bits.

For Y color, the Y offset is applied first and saturation (clipping) is performed immediately after the Y offset is applied.

R = sat(KYRGB * sat(Y + YOF) + KUR * U + KVR * V)

G = sat(KYRGB * sat(Y + YOF) + KUG * U + KVG * V)

B = sat(KYRGB * sat(Y + YOF) + KUB * U + KVB * V)

Saturation and rounding is performed in the range of 0 to 255 for the above equations.

Typical values are:

YOF = -16.000, KYRGB = 1.1644

KUR = 0.0000, KVR = 1.5960

KUG = -0.3918, KVG = -0.8130

KUB = 2.0172, KVB = 0.0000

KUR and KVB are typically 0.0000 but they may be programmed non-zero for hue rotation.

The CSC can also take RGB input, in which case YOF, KVB, KUG, and KUR should be programmed to 0, and KYRGB will be forced to 0 by the hardware for generating R and B. KYRGB will not be forced to 0 for generating G. KVR, KYRGB, and KUB can be programmed to 1.0 or used as gain control for R, G, B, correspondingly.

Note that color value ranges from 0 to 255 for Y, R, G, B, and -128 to 127 for U and V.

25.9.27 DC_WINC_A_V_FILTER_P00_0

Vertical Scaling Filter Coefficients

The vertical scaling filter is a 2-tap filter with 4-bit positional phase. Coefficients 0 and 1 are 8-bit unsigned values ranging from 0 to 128.

Coefficient 0 is the multiplier for the earlier pixel (P0) in the group of 2 pixels, and coefficient 1 is the multiplier for the later pixel (P1) in the group. The output pixel positional phase is defined as centered in P0 if the positional phase is 0 or proportionally in between P0 and P1 if the positional phase is larger than 0.

The sum of all coefficients for each phase should be 128 typically. Therefore coefficient 1 can be calculated from (1 - coefficient 0) and only coefficient 0 is programmed. For each vertical positional phase, the filter coefficient requires 8 register bits. Note that color value ranges from 0 to 255 for Y, R, G, B, and -128 to 127 for U and V.

25.9.45 DC_WIN_A_COLOR_DEPTH_0

Window A Color Depth For YCbCr data format, Cb and Cr are 8-bit unsigned values. For YUV data format, U and V are 8-bit signed values.

YCbCr422R is similar to YCbCr422P but the Cb and Cr are shared vertically.

YUV422R is similar to YUV422P but the U and V are shared vertically.

YCbCr422RA is the same as YCbCr422R in memory, and YUV422RA is the same as YUV422R in memory. However, while reading from memory, for YCbCr422RA and YUV422RA, chroma averaging is applied for each pixel pair so that they can be processed as YUV422 by the display pipeline.

For YCbCr422R and YUV422R, every other chroma pixels are not used (discarded) by the display pipeline. B6x2G6x2R6x2A8 is similar to B8G8R6A8 but with the 2 LSBs zeroed out.

R6x2G6x2B6x2A8 is similar to R8G8B6A8 but with the 2 LSBs zeroed out. Some formats have NVCF_ or T_ prefix aliases for NVidia surface format naming convention, wherein left-to-right component names correspond to MSB to LSB bits within a word. In old names without NVCF_ or T_, left-to-right component names generally map LSB to MSB within a word.

25.9.46 DC_WIN_A_POSITION_0

Window A Position

This register defines the H position and size of Window A after scaling (if there is any)

Offset: 0x704 │ Byte Offset: 0x1c10 │ Read/Write: R/W │ Reset: 0x00000000 (0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx)

Bit	Reset	Description
28:16	X	A_V_POSITION: Window A V Position. This is specified with respect to the top edge of active display area.
12:0	X	A_H_POSITION: Window A H Position. This is specified with respect to the left edge of active display area.

25.9.47 DC_WIN_A_SIZE_0

Window A Size

This register defines the V position and size of Window A after scaling (if there is any)

Note: programming on window size should guarantee the whole window is inside the active area, otherwise extra rows/columns will be fetched and discarded which affects performance.

Offset: 0x705 │ Byte Offset: 0x1c14 │ Read/Write: R/W │ Reset: 0x00000000 (0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx)

Bit	Reset	Description
28:16	X	A_V_SIZE: Window A V Size (lines). This is the vertical size after scaling.
12:0	X	A_H_SIZE: Window A H Size (pixels). This is the horizontal size after scaling.

25.9.48 DC_WIN_A_PRESCALED_SIZE_0

Window A Pre-scaled Size

This register defines Window A pre-scaled size.

The H pre-scaled size is needed to determine how many bytes to fetch from memory per line and this parameter must be programmed exactly as needed taking into account the scaling factor. For planar YUV or YCbCr data formats, this parameter refer to the H pre-scaled of the Y plane.

The total number of lines to be fetched from memory is determined by post-scale V size but V pre-scaled size is needed to 'clamp' the last valid line if the vertical DDA is exactly or slightly beyond the specified V pre-scaled size.

H pre-scaled size ideally should be in terms of pixels but then hardware needs to convert this precisely to bytes to determine the amount of data to request from memory.

Offset: 0x706 │ Byte Offset: 0x1c18 │ Read/Write: R/W │ Reset: 0x00000000 (0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx)

Bit	Reset	Description
28:16	X	A_V_PRESCALED_SIZE: Window A V Pre-scaled Size (lines). In 420P/422R/422RA formats, it must be even.
14:0	X	A_H_PRESCALED_SIZE: Window A H Pre-scaled Size (bytes). In 420P and 422P formats, it must be even.

25.9.49 DC_WIN_A_H_INITIAL_DDA_0

Window A H Initial DDA

Design Note: the first pixel of pre-scaled image is always used to output the first pixel so essentially this is the same as forcing the H Initial DDA integer portion to 1 initially even though the user typically programs this to 0. If it makes the implementation easier, it is possible to force software to program the Initial DDA integer portion to 1. Similarly, with the V Initial DDA.

Offset: 0x707 │ Byte Offset: 0x1c1c │ Read/Write: R/W │ Reset: 0x00000000 (0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx)

Bit	Reset	Description
15:0	X	A_H_INITIAL_DDA: Window A H Initial DDA (4.12). This is typically programmed to 0.0

25.9.50 DC_WIN_A_V_INITIAL_DDA_0

Window A V Initial DDA

Offset: 0x708 │ Byte Offset: 0x1c20 │ Read/Write: R/W │ Reset: 0x00000000 (0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx)

Bit	Reset	Description
15:0	X	A_V_INITIAL_DDA: Window A V Initial DDA (4.12). This is typically programmed to 0.0 for both non-interlaced and interlaced sources.

25.9.51 DC_WIN_A_DDA_INCREMENT_0

Window A DDA Increment

DDA increment is typically calculated by dividing (pre-scaled size in pixels - 1) by (post-scaled size in pixels - 1). The result should be rounded up and expressed as 4.12 format (4-bit integer and 12-bit fraction). For non-filtered image this value can be slightly larger so that it is not missing the last row/column. Reference programming values (H and V should be calculated separately depending on filter on/off and sizes):

- Filter on: min(round((prescaled_size_in_pixels - 1) * 0x1000 / (post_scaled_size_in_pixels - 1)), MAX)
- Filter off: min(round(prescaled_size_in_pixels * 0x1000 / (post_scaled_size_in_pixels - 1) - 0.5), MAX)

Where the value of MAX is as follows:

For V_DDA_INCREMENT: 15.0 (0xF000)

For H_DDA_INCREMETN: 4.0 (0x4000) for 4 Bytes/pix formats.

8.0 (0x8000) for 2 Bytes/pix formats.

They are theoretically the biggest values that guarantee not displaying beyond an image boundary. If the DDA increment is less than 1.0, then the image is upscaled. If the DDA increment is more than 1.0, then the image is downscaled.

Offset: 0x709 │ Byte Offset: 0x1c24 │ Read/Write: R/W │ Reset: 0x00000000 (0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx)

Bit	Reset	Description
31:16	X	A_V_DDA_INCREMENT: Window A Vertical DDA Increment (4.12). This should be set to 1.0 if there is no scaling. Maximum value is 15.0 regardless of the number of bytes per pixel.

Bit	Reset	Description
15:0	X	A_H_DDA_INCREMENT: Window A Horizontal DDA Increment (4.12). This should be set to 1.0 if there is no scaling. The maximum value for downscaling depends on the number of bytes per pixel. For 4-byte/pixel modes (32-bpp) the maximum value is 4.0 and for all other modes the maximum value is 8.0.

25.9.52 DC_WIN_A_LINE_STRIDE_0

Window A Line Stride

Offset: 0x70a │ Byte Offset: 0x1c28 │ Read/Write: R/W │ Reset: 0x00000000 (0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx)

Bit	Reset	Description
31:16	X	A_UV_LINE_STRIDE: Window A Line Stride for Chroma. This is stride (in bytes) for planar YUV or YCbCr data formats for the chroma plane, with the restriction that it must be programmed to be multiples of 4 (16 if tiled or in horizontal flipping) This is not used (ignored) for other non-planar data formats.
15:0	X	A_LINE_STRIDE: Window A Line Stride. This is stride (in bytes) for all non-planar data formats. If the memory surface is tiled, the stride needs to be a multiple of 16. If H_DIRECTION of window A is set to DECREMENT, the stride also needs to be a multiple of 16. For planar YUV or YCbCr data formats, this is stride (in bytes) for the luma plane with the restriction that it must be multiples of 8 (16 if tiled or in horizontal flipping) For tiled surface this value may affect starting address of a window. Refer to the comment of START_ADDR for detail.

25.9.53 DC_WIN_A_BUFFER_ADDR_MODE_0

Memory Controller Tiling definitions

Offset: 0x70d │ Byte Offset: 0x1c34 │ Read/Write: R/W │ Reset: 0x00000000 (0bxxxxxxxxxxxxxxxx0xxxxxxxxxxxxxxx0)

Bit	Reset	Description
16	0x0	A_UV_TILE_MODE: Window A Memory surface tiling mode. For YUV planar pixel format, this specifies tiling mode for the U/V plane. 0 = LINEAR 1 = TILED
0	0x0	A_TILE_MODE: Window A Memory surface tiling mode. For YUV planar pixel format, this specifies tiling mode for the Y plane. 0 = LINEAR 1 = TILED

25.9.54 DC_WIN_A_DV_CONTROL_0

Window A Digital Vibrance Control

If enabled, Digital Vibrance is applied after H and V scaling and after color palette or color space conversion logic but before color keying multiplexer and before cursor multiplexer.

- After DV, new R = R + (2R - G - B) * FR, where FR is fraction from 0 to 7/8
- After DV, new G = G + (2G - R - B) * FG, where FG is fraction from 0 to 7/8
- After DV, new B = B + (2B - R - G) * FB, where FB is fraction from 0 to 7/8

Offset: 0x70e │ Byte Offset: 0x1c38 │ Read/Write: R/W │ Reset: 0x00000000 (0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx)

Bit	Reset	Description
18:16	X	A_DV_CONTROL_B: Digital Vibrance control for B
10:8	X	A_DV_CONTROL_G: Digital Vibrance control for G
2:0	X	A_DV_CONTROL_R: Digital Vibrance control for R

25.9.55 DC_WIN_A_BLEND_NOKEY_0

Blend Control for this window area where color key is enabled but the pixel color is not within the color key range (color key not match). This is valid for all overlapping condition but only if there is no overlap with other window with higher priority color key enabled and color key not match.

Class: Display Color Keying and Blending

Color keying and blending of the display windows are done prior to cursor blending.

Cursor always goes on top of the blended windows. Blending is controlled independently on each possible overlap area of the display windows. If 3 windows are enabled there are 7 possible overlap area combinations. For every window in each overlap area combination, color key can be disabled or enabled. Also, for every window in each overlap area combination, there is a corresponding window blend control parameter and a window blend weight parameter. The window blend control parameter is always effective but the window blend weight is not always used. The window blend weight can also be derived from pixel alpha value or from the reverse of other overlapping windows weight.

Color keying has the highest priority for display window blending. Color key consists of a range of color which is searched independently for each window. If more than 1 windows color key is enabled, then Window A color key has the highest priority, followed by Window B color key, and then followed by Window C color key. Two sets of color key ranges (Color Key 0 and Color Key 1) can be defined; they are shared for all windows. It is possible to use both color key sets for the same window or for two separate windows.

The two sets of color key ranges should not overlap. If they do, the overlapped colors are treated as if they are part of Color Key 0 and not part of Color Key 1.

Assuming that there is no overlap with other higher priority window with color key not matched, if a window color key is enabled for any overlap condition and the window pixel is not within the color key range (key not match), then the window pixel will not be blended with other overlapping window pixels but it will be weighted. The weight is not dependent on the overlap condition it is controlled by the same set of parameters for all overlapping condition.

Assuming that there is no overlap with other higher priority window with color key not matched, if a window color key is enabled for a particular overlap condition and the window pixel is within the color key range (key match), then the window pixel will be weighted and blended with other overlapping pixels and this is controlled separately for each overlap condition.

Assuming that there is no overlap with other higher priority window with color key not matched, if a window color key is disabled then the window pixel will be blended with other overlapping pixels and this is controlled separately for each overlap condition.

Display Color Key parameters

For B4G4R4A4, B5G6R5A, or B5G6R5 mode, the color key should be compared prior to color conversion to 24-bpp and unused least significant bits of the pixel are filled with zeros.

For palletized mode, the color key is compared prior to the color palette, and the palletized color is compared against the green color key values/mask.

For YUV mode, U and V are offset by +128 before performing the color key comparison. In all cases, the color key is compared prior to the horizontal/vertical scaling filter and prior to digital vibrance control.

Both upper and lower values are inclusive.

Offset: 0x70f │ Byte Offset: 0x1c3c │ Read/Write: R/W │ Reset: 0x00000000 (0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx)

Bit	Reset	Description
23:16	X	A_BLEND_WEIGHT1_NOKEY: Window blend weight 1 for color key not match areas. This is used only for alpha weight with 1-bit alpha and alpha value of 1.
15:8	X	A_BLEND_WEIGHT0_NOKEY: Window blend weight 0 for color key not match areas. For alpha weight, this is used for 1-bit alpha with value of 0.
0	X	A_BLEND_CONTROL_NOKEY: Window blend control for color key not match areas. 0 = Fix weight using window blend weight 0 for color key not matched. 1 = Alpha weight using the alpha value. This is only valid if the window color format includes an alpha value. For 1-bit alpha value, if the alpha is 0 window blend weight 0 is used and if alpha is 1, window blend weight 1 is used. 0 = FIX_WEIGHT 1 = ALPHA_WEIGHT

25.9.56 DC_WIN_A_BLEND_1WIN_0

Blend Control for this window area where it does not overlap with other windows.

Offset: 0x710 │ Byte Offset: 0x1c40 │ Read/Write: R/W │ Reset: 0x00000000 (0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx)

Bit	Reset	Description
23:16	X	A_BLEND_WEIGHT1_1WIN: Window blend weight 1 for color key disabled or color key enabled with key matched areas. This is used only for alpha weight with 1-bit alpha and alpha value of 1.
15:8	X	A_BLEND_WEIGHT0_1WIN: Window blend weight 0 for color key disabled or color key enabled with key matched areas. For alpha weight, this is used for 1-bit alpha with value of 0.
2	X	A_BLEND_CONTROL_1WIN: Window blend control in area where it does not overlap with other windows and either color key disabled or color key enabled with key matched. 0 = Fix weight using the window blend weight 0 if color key disabled or color key 0 enabled with key matched, or using the window blend weight 1 if color key 1 enabled with key matched. 1 = Alpha weight using the alpha value. This is only valid if the window color format includes an alpha value. For 1-bit alpha value, if the alpha is 0 window blend weight 0 is used and if alpha is 1, window blend weight 1 is used. 0 = FIX_WEIGHT 1 = ALPHA_WEIGHT
1:0	X	A_CKEY_ENABLE_1WIN: Window color key enable 0 = Color Key 0 and 1 Disable 1 = Color Key 0 Enable 2 = Color Key 1 Enable 3 = Color Key 0 and 1 Enable 0 = NOKEY 1 = CKEY0 2 = CKEY1 3 = CKEY01

25.9.57 DC_WIN_A_BLEND_2WIN_B_0

Blend Control for this window area that overlaps with window B only.

Offset: 0x711 | Byte Offset: 0x1c44 | Read/Write: R/W | Reset: 0x00000000 (0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx)

Bit	Reset	Description
23:16	X	A_BLEND_WEIGHT1_2WIN_B: Window blend weight 1 for color key disabled or color key enabled with key matched areas. This is used only for alpha weight with 1-bit alpha and alpha value of 1.
15:8	X	A_BLEND_WEIGHT0_2WIN_B: Window blend weight 0 for color key disabled or color key enabled with key matched areas. For alpha weight, this is used for 1-bit alpha with value of 0.
3:2	X	A_BLEND_CONTROL_2WIN_B: Window blend control in area where either color key disabled or color key enabled with key matched. 0 = Fix weight using the window blend weight 0 if color key disabled or color key 0 enabled with key matched, or using the window blend weight 1 if color key 1 enabled with key matched. 1 = Alpha weight using the alpha value. This is only valid if the window color format includes an alpha value. For 1-bit alpha value, if the alpha is 0 window blend weight 0 is used and if alpha is 1, window blend weight 1 is used. 2 = Dependent weight, in this case, the window blend weight is 1 - the weights of the other window that overlaps with this window. Only 1 of the overlapping windows may have this setting. 3 = Premultipled weight; in this case, the window blend weight is 1. But other windows that use DEPENDENT_WEIGHT get (1 - alpha value), like ALPHA_WEIGHT. This is only valid if the window color format includes an alpha value. This allows a blending equation like: result = win_a * 1 + (1 - win_a_alpha) * win_c. 0 = FIX_WEIGHT 1 = ALPHA_WEIGHT 2 = DEPENDENT_WEIGHT 3 = PREMULT_WEIGHT
1:0	X	A_CKEY_ENABLE_2WIN_B: Window color key enable 0 = Color Key 0 and 1 Disable 1 = Color Key 0 Enable 2 = Color Key 1 Enable 3 = Color Key 0 and 1 Enable 0 = NOKEY 1 = CKEY0 2 = CKEY1 3 = CKEY01

25.9.58 DC_WIN_A_BLEND_2WIN_C_0

Blend Control for this window area that overlaps with window C only.

Offset: 0x712 | Byte Offset: 0x1c48 | Read/Write: R/W | Reset: 0x00000000 (0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx)

Bit	Reset	Description

25.9.60 DC_WIN_A_GLOBAL_ALPHA_0

Window A Global Alpha

When enabled, per pixel alpha values are scaled by GLOBAL_ALPHA before blending: a' = a * GLOBAL_ALPHA/255. When per pixel alpha is not used in blending, global alpha has no affect.

Note: 1- and 4-bits per pixel alpha are quantized back to 1 and 4 bits, respectively, after scaling. For the 1-bit alpha case, finer scaling can be achieved by changing BLEND_WEIGHT* instead.

Offset: 0x715 │ Byte Offset: 0x1c54 │ Read/Write: R/W │ Reset: 0x00000000 (0bxxxxxxxxxxxxxxxx0xxxxxxxxxxxxxxx)

Bit	Reset	Description
16	DISABLE	A_GLOBAL_ALPHA_ENABLE: When enabled, color palette *must* also be enabled and programmed. 0 = DISABLE 1 = ENABLE
7:0	X	A_GLOBAL_ALPHA: Global alpha: 0..255 map to 0.0 – 1.0. i.e., 255 yields no-operation. For power, better to set GLOBAL_ALPHA_ENABLE=DISABLE when GLOBAL_ALPHA=255.

25.10 WINBUF_A Registers

The registers under DC_WINBUF are triple-buffered.

25.10.1 DC_WINBUF_A_START_ADDR_0

Window A Start Address

Overview

START_ADDR, BUF_STRIDE, LINE_STRIDE, ADDR_H_OFFSET, ADDR_V_OFFSET combined, specify the starting address of a window buffer in the memory surface. Generally, START_ADDR is programmed with the starting address of the memory surface. H/V_OFFSET specifies the address offsets of the pixel at the beginning of the window with respect to the starting address of the memory surface. (There is an exception to that when memory surface is not well aligned, see ”For linear address mode” in Programming Restrictions below.)

Note that "beginning of the window" here means the top-left corner of a window in normal mode, top-right corner in horizontal flipping, bottom-left corner in vertical flipping, and bottom-right in horizontal+vertical flipping.

Starting Address Calculation

These formulae are same for both tiled and linear modes. However, for linear mode, the addresses calculated are real physical addresses. For tiled mode, these addresses will be translated to the real physical addresses by the memory controller client before being used.

- When a window is host triggered, starting address of a window is calculated as follows by hardware:
  - non-YUV-planar modes:

    starting-address = START_ADDR + ADDR_V_OFFSET * LINE_STRIDE + ADDR_H_OFFSET
  - YUV-planar modes:

    Y-starting-address = START_ADDR + ADDR_V_OFFSET * LINE_STRIDE + ADDR_H_OFFSET

    U-starting-address = START_ADDR_U + ADDR_V_OFFSET * UV_LINE_STRIDE / denom1 + ADDR_H_OFFSET / denom2

    V-starting-address = START_ADDR_V + ADDR_V_OFFSET * UV_LINE_STRIDE / denom1 + ADDR_H_OFFSET / denom2 where denom1/denom2 equal to 1 or 2 depending on the actual planar format, derived natively by hardware.
- When a window is non-host triggered, starting address of a window buffer is calculated as below.
  - non-YUV-planar mode:

    starting-address = START_ADDR + BUF_STRIDE * buf_index + ADDR_V_OFFSET * LINE_STRIDE + ADDR_H_OFFSET
  - YUV-planar mode:

    Y-starting-address = START_ADDR + BUF_STRIDE * buf_index + ADDR_V_OFFSET * LINE_STRIDE + ADDR_H_OFFSET

    U-starting-address = START_ADDR_U + UV_BUF_STRIDE * buf_index + ADDR_V_OFFSET * UV_LINE_STRIDE / denom1 + ADDR_H_OFFSET / denom2

    V-starting-address = START_ADDR_V + UV_BUF_STRIDE * buf_index + ADDR_V_OFFSET * UV_LINE_STRIDE / denom1 + ADDR_H_OFFSET / denom2 where denom1/denom2 equal to 1 or 2 depending on the actual planar format, derived natively by hardware.

    buf_index is the index transmitted by the triggering module pointing to the first buffer of a frame.

Programming Restrictions

i. For tiled address mode:

Image surface can only aligned to multiples of 256, thus the following restrictions.

- START_ADDR, START_ADDR_U, START_ADDR_V need to be multiples of 256.
- BUF_STRIDE, UV_BUF_STRIDE need to be multiples of 256
- LINE_STRIDE, UV_LINE_STRIDE need to be multiples of 16
- ADDR_H_OFFSET needs to be even in YUV planar format, or a multiple of bytes per pixel in other formats. If H_DIRECTION=DECREMENT, however, it should point to last valid byte, which is an odd offset.
- ADDR_V_OFFSET needs to be a multiple of 2 in YUV planar format, unless H_DIRECTION=DECREMENT, but with no restrictions on other color formats.

ii. For linear address mode:

Image surface can be aligned 2, 4 or 8 bytes, depending on the color formats.

As an additional restriction for display, START_ADDR, START_ADDR_U and START_ADDR_V need to be multiples of 16.

When a surface is not aligned to 16 bytes, program START_ADDR with the memory surface address with its least 4 significant bits zeroed out and add these 4 address bits to the original H_OFFSET. (So the formulae in Starting Address Calculation above still hold)

- For all formats:
  - START_ADDR, START_ADDR_U and START_ADDR_V need to be multiples of 16.
- For 16-bpp formats,
  - (START_ADDR+H_OFFSET) need to be a multiple of 2.
- For 32-bpp formats,
  - (START_ADDR+H_OFFSTE) needs to be a multiple of 4.
- For YUV planar formats:
  - BUF_STRIDE, UV_BUF_STRIDE:

    BUF_STRIDE[2:1]=UV_BUF_STRIDE[1:0]

    or as a stricter constraint: BUF_STRIDE is a multiple of 8, UV_BUF_STRIDE is a multiple of 4.
  - LINE_STRIDE, UV_LINE_STRIDE:

    LINE_STRIDE and UV_LINE_STRIDE need to be at least 16.

    LINE_STRIDE needs to be a multiple of 8, UV_LINE_STRIDE needs to be a multiple of 4.
  - ADDR_H_OFFSET: Needs to be even unless H_DIRECTION=DECREMENT, in which case should point to the last byte pixel, which is at an odd offset. .
  - ADDR_V_OFFSET: Needs to be even unless V_DIRECTION=DECREMENT, in which case should point to the last valid line, which is at an odd offset. .

iii. Memory allocation for non-host triggered case:

When a window buffer is not controlled by host (software) then a frame may be stored in multiple buffers. In this case, the buffers must be contiguous in the memory because display will use the same luma or chroma line strides for all lines in the frame. Also buffer wraparound must not occur in the middle of the displayed part of the frame.

The controlling module will send frame start and frame end indicators (flags) to display module to indicate the beginning and end of frame. Buffer start address is latched when frame start flag is active but the actual buffer start address is not

switched until frame end flag is active. In the case where one buffer corresponds to one frame then frame start and frame end flag are active every time a buffer index is sent.

Offset: 0x800 | Byte Offset: 0x2000 | Read/Write: R/W | Reset: 0x00000000 (0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx)

Bit	Reset	Description
31:0	X	A_START_ADDR: Window A Start Address. This is a byte address. The LSB is not used for 16-bpp non-planar pixel format and the last 2 LSBs are not used for 32-bpp non-planar pixel format. For YUV planar pixel format, this specifies start address for the Y plane.

25.10.2 DC_WINBUF_A_START_ADDR_NS_0

Window A Shadowed Start Address

25.10.9 DC_WINBUF_A_ADDR_V_OFFSET_0

Window A Vertical Address Offset

Offset: 0x808 | Byte Offset: 0x2020 | Read/Write: R/W | Reset: 0x00000000 (0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx)

Bit	Reset	Description
31:0	X	A_ADDR_V_OFFSET: Window A Vertical address offset. This is a line number. The LSB is not used for 16-bpp non-planar pixel format and the last 2 LSBs are not used for 32-bpp non-planar pixel format. For YUV planar pixel format, this specifies vertical offset of Y plane. The vertical offsets of U/V plane is derived by hardware.

25.10.10 DC_WINBUF_A_ADDR_V_OFFSET_NS_0

Window A Shadowed Vertical Address Offset

Offset: 0x809 | Byte Offset: 0x2024 | Read/Write: R/W | Reset: 0x00000000 (0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx)

Bit	Reset	Description
31:0	X	A_ADDR_V_OFFSET_NS: Window A Shadowed Vertical address offset. This is the ARM set shadow of ADDR_V_OFFSET.

25.10.11 DC_WINBUF_A_UFLOW_STATUS_0

Window A FIFO Underflow Status Register

Offset: 0x80a │ Byte Offset: 0x2028 │ Read/Write: R/W │ Reset: 0x00000000 (0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx)

Bit	Reset	Description
30	X	COUNT_OFLOW: Flag bit that indicates that the underflow event counter has overflowed. There were too many events. If COUNT_OFLOW is set, UFLOW_COUNT is meaningless. Cleared on write.
23:0	X	UFLOW_COUNT: Underflow count. This field indicates the number of contiguous groups of output pixels for which there was no data in the FIFO. For example, if the valid from the FIFO is low for 10 consecutive cycles and then goes high, the counter will increment by one. Reset to zero on write.

25.10.12 DC_WINBUF_A_SURFACE_WEIGHT_0

Window A Surface Weights

Offset: 0x80c │ Byte Offset: 0x2030 │ Read/Write: R/W │ Reset: 0x00000000 (0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx0)

Bit	Reset	Description
6:5	X	A_SURFACE_WEIGHT_V: Window A V Surface Weights. 00 - Weight is 2 01 - Weight is 4 10 - Weight is 8 11 - Weight is 16 0 = WEIGHT_2 1 = WEIGHT_4 2 = WEIGHT_8 3 = WEIGHT_16
4:3	X	A_SURFACE_WEIGHT_U: Window A U or UV Surface Weights. 00 - Weight is 2 01 - Weight is 4 10 - Weight is 8 11 - Weight is 16 0 = WEIGHT_2 1 = WEIGHT_4 2 = WEIGHT_8 3 = WEIGHT_16
2:1	X	A_SURFACE_WEIGHT_Y: Window A Y or packed Surface Weights. 00 - Weight is 2 01 - Weight is 4 10 - Weight is 8 11 - Weight is 16 0 = WEIGHT_2 1 = WEIGHT_4 2 = WEIGHT_8 3 = WEIGHT_16
0	0x0	A_SURFACE_WEIGHT_OVERRIDE: Weight Override 0 = DISABLE 1 = ENABLE

25.10.13 DC_WINBUF_A_START_ADDR_HI_0

Window A Higher 32 bits of Start Address

Makes the start address 64 bits by adding the higher 32 bits below.

Offset: 0x80d │ Byte Offset: 0x2034 │ Read/Write: R/W │ Reset: 0x00000000 (0b00000000000000000000000000000000)

Bit	Reset	Description
31:0	0x0	A_START_ADDR_HI: Window A Start Address. This is a byte address. The LSB is not used for 16-bpp non-planar pixel format and the last 2 LSBs are not used for 32-bpp non-planar pixel format. For YUV planar pixel format, this specifies start address for the Y plane.

25.10.14 DC_WINBUF_A_START_ADDR_HI_NS_0

Window A Shadowed Higher 32 bits of Start Address

Offset: 0x80e │ Byte Offset: 0x2038 │ Read/Write: R/W │ Reset: 0x00000000 (0b00000000000000000000000000000000)

Bit	Reset	Description
31:0	0x0	A_START_ADDR_HI_NS: Window A Shadowed Start Address. This is ARM set shadow of Start Address.

25.10.15 DC_WINBUF_A_START_ADDR_HI_U_0

Window A Higher 32 bits of Start Address for U Plane

Offset: 0x80f │ Byte Offset: 0x203c │ Read/Write: R/W │ Reset: 0x00000000 (0b00000000000000000000000000000000)

Bit	Reset	Description
31:0	0x0	A_START_ADDR_HI_U: Window A Start Address for U plane. This is a byte address.

25.10.16 DC_WINBUF_A_START_ADDR_HI_U_NS_0

Window A Shadowed Higher 32 bits of Start Address for U Plane

Offset: 0x810 │ Byte Offset: 0x2040 │ Read/Write: R/W │ Reset: 0x00000000 (0b00000000000000000000000000000000)

Bit	Reset	Description
31:0	0x0	A_START_ADDR_HI_U_NS: Window A Shadowed Higher 32 bits of Start Address for U plane. This is ARM set shadow register of U start address

25.10.17 DC_WINBUF_A_START_ADDR_HI_V_0

Window A Higher 32 bits of Start Address for V Plane

Offset: 0x811 │ Byte Offset: 0x2044 │ Read/Write: R/W │ Reset: 0x00000000 (0b00000000000000000000000000000000)

Bit	Reset	Description
31:0	0x0	A_START_ADDR_HI_V: Window A Higher 32 bits of Start Address for V plane. This is a byte address.

25.10.18 DC_WINBUF_A_START_ADDR_HI_V_NS_0

Window A Shadowed Higher 32 bits of Start Address for V Plane

Offset: 0x812 | Byte Offset: 0x2048 | Read/Write: R/W | Reset: 0x00000000 (0b00000000000000000000000000000000)

Bit	Reset	Description
31:0	0x0	A_START_ADDR_HI_V_NS: Window A Shadowed Higher 32 bits of Start Address for V plane. This is ARM set shadow register of U start address

25.10.19 DC_WINBUF_A_UFLOW_CTRL_0

When the underflow debug mode is enabled. Instead of sending out the last valid pixel, DBG_PIXEL is sent out.

Offset: 0x824 | Byte Offset: 0x2090 | Read/Write: R/W | Reset: 0x00000000 (0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx0)

Bit	Reset	Description
0	0x0	A_UFLOW_CTRL_DBG_MODE: 0 = DISABLE 1 = ENABLE

25.10.20 DC_WINBUF_A_UFLOW_DBG_PIXEL_0

Offset: 0x825 | Byte Offset: 0x2094 | Read/Write: R/W | Reset: 0x00000000 (0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx)

Bit	Reset	Description
31:0	X	A_UFLOW_DBG_PIXEL

25.10.21 DC_WINBUF_A_UFLOW_THRESHOLD_0

Offset: 0x826 | Byte Offset: 0x2098 | Read/Write: R/W | Reset: 0x00000000 (0bxxxxxxxxxxxxxxxxxxx0000000000000)

Bit	Reset	Description
12:0	0x0	A_UFLOW_THRESHOLD

25.10.22 DC_WINBUF_A_SPOOL_UP_0

Spool up time configuration for different windows related logic.

SPOOL_UP_CTRL = MAX - This is the current Tegra 4 behavior. This allows for memfetch to start fetching for a window (irrespective of its relative position on the screen), at the very beginning of the vblank of the next frame. Since the spool up time is maximum, this should have the least probability of underflow of the display pipe. However, on the down side, since all three windows would start fetching at the same time, and since display is a high priority client for MC, it has a high potential to starve out other clients.

SPOOL_UP_CTRL = PROGRAMMABLE, SPOOL_UP_DURATION = 1 - This corresponds to the Tegra 3 behavior. Since the fetch starts only 1 line prior to the active scan line of a window, this has high probability of causing underflow, but has a lesser impact on the other MC clients.

So, this register programmability programs a method to modulate the spool up time between the best and worst, if required, when other MC clients are present. For example when GPU/VIC is active, we may not want a very aggressive spool up and program some definite spool up duration. So, spool up time is a general knob, which would be a function of the resolution, bpp, active clients, memory speed, etc.

SPOOL_UP_EDGE :- By default the memfetch start signal generated by the hvtgen logic is one line clock wide.

For SPOOL_UP_CTRL = MAX:

- In this case if SPOOL_UP_EDGE is programmed to NEGEDGE. This ensures that if any act_req is sent during the time vcounter = 0(at the beginning of the frame). The activate value is loaded into the active state and the memfetch would see the latest updated value. The downside of programming it to NEGDGE is that 1 line clock worth of spool up is lost. This is required based upon Tegra compatibility and the way tests are written.
- In this case if SPOOL_UP_EDGE is programmed to POSEDGE. Then the memfetch would start fetching at the very beginning of the frame start pulse (1 line clock wide) and would give maximum spool up time. However, this may give test failure and potential Tegra compatibility issues as described above.

FOR SPOOL_UP_CTRL = PROGRAMMABLE :

- Special care must be taken here. If SPOOL_UP_DURATION is set to 1. SPOOL_UP_EDGE must be set to POSEDGE to allow for at least 1 line worth of spool up.
- If SPOOL_UP_DURATION is > 1. Then SPOOL_UP_EDGE can be either POSEDGE or NEGEDGE. If it is NEGEDGE, then the effective spool up duration would be 1 line clock less than the SPOOL_UP_DURATION.

Offset: 0x827 │ Byte Offset: 0x209c │ Read/Write: R/W │ Reset: 0x00000000 (0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx00)

Bit	Reset	Description
28:16	X	A_SPOOL_UP_DURATION
1	0x0	A_SPOOL_UP_EDGE: 0 = NEGEDGE 1 = POSEDGE
0	0x0	A_SPOOL_UP_CTRL: 0 = MAX 1 = PROGRAMMABLE

25.10.23 DC_WINBUF_A_SCALEFACTOR_THRESHOLD_0

Registers for latency allowance scaling. Threshold is in terms of 64 byte atoms. Display memfetch compares its buffer occupancy with the threshold and generates indication to MC if its buffer occupancy is above HWM or below LWM.

Offset: 0x828 │ Byte Offset: 0x20a0 │ Read/Write: R/W │ Reset: 0xffffffff (0b11111111111111111111111111111111)

Bit	Reset	Description
31:16	0xffff	A_SF_LWM_THRESHOLD
15:0	0xffff	A_SF_HWM_THRESHOLD

25.10.24 DC_WINBUF_A_LATENCY_THRESHOLD_0

Register for ready for latency event like DVFS. Threshold is in terms of 64 byte atoms. Display memfetch compares its buffer occupancy with the threshold and generates indication to MC if its buffer occupancy is above the threshold.

Offset: 0x829 │ Byte Offset: 0x20a4 │ Read/Write: R/W │ Reset: 0x0000ffff (0bxxxxxxxxxxxxxxxx1111111111111111)

Bit	Reset	Description
15:0	0xffff	A_RDY4LATENCY_THRESHOLD

25.10.25 DC_WINBUF_A_MEMFETCH_DEBUG_STATUS_0

Memfetch Debug Status

Offset: 0x82a │ Byte Offset: 0x20a8 │ Read/Write: R/W │ Reset: 0x00000000 (0bxxxxxxxxxxxxxxxx0000000000000000)

Bit	Reset	Description
15	0x0	B_ALIGN_FIFO_NON_IDLE: align FIFO idle at end of frame. 0= align FIFO is idle at end of frame. 1= align FIFO is not idle at end of frame

Bit	Reset	Description
31:0	0x0	A_SCRATCH_REGISTER_1:Scratch register 1

25.11 Window B (WINC_B) Registers

These registers control window B parameters

25.11.1 DC_WINC_B_COLOR_PALETTE_0

Window B Color Palette

This is used for palletized data format (color depth of 8-bpp or less) or for gamma correction for non-palletized data formats (color depth of more than 8-bpp).

Each window has its own color palette which consists of three 256x8 register file which can be written by host and indexed (read) by the window.

For palletized data format less than 8 bpp, the pixel data is aligned to least significant bits of the palette index (address) and the remaining upper bits are filled with the corresponding bits of the Palette Color Extension. For example, for 4-bpp mode, the pixel data occupies bits 3-0 of the palette index, and bits 7-4 of the palette index are set to bits 7-4 of the Palette Color Extension.

Note that host read is assumed to be not needed - software can cache the color palette in system memory.

This is an array of 256 identical register entries; the register fields below apply to each entry.

Offset: 0x500..0x5ff │ Byte Offset: 0x1400..0x17fc │ Read/Write: WO │ Reset: 0x00000000 (0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx)

Bit	Reset	Description

15:8	X	B_COLOR_PALETTE_G: Green Color Palette
7:0	X	B_COLOR_PALETTE_R: Red Color Palette

25.11.2 DC_WINC_B_PALETTE_COLOR_EXT_0

Window B Palette Color Extension

Palette extension for 1-bpp, 2-bpp, and 4-bpp. These bits provide the upper most significant bits for indexing the color palette.

Offset: 0x600 │ Byte Offset: 0x1800 │ Read/Write: R/W │ Reset: 0x00000000 (0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx)

Bit	Reset	Description
7:1	X	B_PALETTE_COLOR_EXT: Window B Palette Color Extension bits 7-1 are used for 1-bpp mode bits 7-2 are used for 2-bpp mode bits 7-4 are used for 4-bpp mode

25.11.3 DC_WINC_B_H_FILTER_P00_0

Window B Horizontal Filter phase 00

Horizontal Scaling Filter Coefficients

Horizontal scaling filter is a 6-tap filter with 4-bit positional phase.

- Coefficients 0 and 5 are 3-bit signed values ranging from -4 to 3.
- Coefficients 1 and 4 are 5-bit signed values ranging from -16 to 15.
- Coefficients 2 and 3 are 8-bit unsigned values ranging from 0 to 128.

- Coefficient 0 is the multiplier for the earliest pixel (P0) in the group of 6 pixels and coefficient 5 is the multiplier for the latest pixel (P5) in the group. The output pixel positional phase is defined as centered in P2 if the positional phase is 0 or proportionally in between P2 and P3 if the positional phase is larger than 0.

Sum of all coefficients for each phase should be 128 typically, and software should never program the sum of all coefficients for a phase to be more than 128. For each horizontal positional phase, the 6 filter coefficients requires 32 register bits. Note that color value ranges from 0 to 255 for Y, R, G, B, and -128 to 127 for U and V.

25.11.19 DC_WINC_B_CSC_YOF_0

Window B CSC Y Offset

Color Space Conversion coefficients.

The CSC can be used for YUV to RGB conversion with brightness and hue/saturation control.

The CSC can only be enabled for window B controlled by CSC_ENABLE register bits.

For Y color, the Y offset is applied first and saturation (clipping) is performed immediately after the Y offset is applied.

R = sat(KYRGB * sat(Y + YOF) + KUR * U + KVR * V)

G = sat(KYRGB * sat(Y + YOF) + KUG * U + KVG * V)

B = sat(KYRGB * sat(Y + YOF) + KUB * U + KVB * V)

Saturation and rounding is performed in the range of 0 to 255 for the above equations.

Typical values are:

YOF = -16.000, KYRGB = 1.1644

KUR = 0.0000, KVR = 1.5960

KUG = -0.3918, KVG = -0.8130

KUB = 2.0172, KVB = 0.0000

KUR and KVB are typically 0.0000 but they may be programmed non-zero for hue rotation.

The CSC can also take RGB input, in which case YOF, KVB, KUG, KUR should be programmed to 0, and KYRGB will be forced to 0 by the hardware for generating R and B. KYRGB will not be forced to 0 for generating G. KVR, KYRGB, and KUB can be programmed to 1.0 or used as gain control for R, G, B, correspondingly.

Note that color value ranges from 0 to 255 for Y, R, G, B and -128 to 127 for U and V.

25.11.27 DC_WINC_B_V_FILTER_P00_0

Window B Vertical Filter phase 00

Vertical scaling filter coefficients

Vertical scaling filter is a 2-tap filter with 4-bit positional phase.

Coefficients 0 and 1 are 8-bit unsigned values ranging from 0 to 128.

Coefficient 0 is the multiplier for the earlier pixel (P0) in the group of 2 pixels and coefficient 1 is the multiplier for the later pixel (P1) in the group. The output pixel positional phase is defined as centered in P0 if the positional phase is 0 or proportionally in between P0 and P1 if the positional phase is larger than 0.

Sum of all coefficients for each phase should be 128 typically therefore coefficient 1 can be calculated from (1 - coefficient 0) and therefore only coefficient 0 is programmed.

For each vertical positional phase, the filter coefficient requires 8 register bits. Note that color value ranges from 0 to 255 for Y, R, G, B, and -128 to 127 for U and V.

30	0x0	B_WIN_ENABLE: Window B Window enable 0 = DISABLE 1 = ENABLE
22	X	B_YUV_RANGE_EXPAND: Window B Enable range expansion in the cases where RANGEREDFRM is 1 from mpd. Formula: Y = clip((Y-128)*2 + 128); Cb = clip((Cb-128)*2 + 128); Cr = clip((Cr-128)*2 + 128); where clip() function clips between 0 and 255. 0 = DISABLE 1 = ENABLE
20	X	B_DV_ENABLE: Window B Digital Vibrance Enable 0 = DISABLE 1 = ENABLE
18	X	B_CSC_ENABLE: Window B Color Space Conversion Enable. This controls the color space conversion and should be enabled for YCbCr/YUV color modes for conversion to B8G8R8 and for hue and saturation control. This can also be used for gain control for RGB color modes 0 = DISABLE 1 = ENABLE
16	0x0	B_CP_ENABLE: Window B Color Palette Enable. This controls the color palette and should be enabled for palletized color modes. For non-palletized color modes, the color palette can be enabled for gamma correction. 0 = DISABLE 1 = ENABLE
14	0x0	B_V_FILTER_UV_ALIGN: Window B V Filter UV Alignment. This is effective only when vertical scaling filter is enabled and only on these formats YCbCr420P, YUV420P, YCbCr422R, YUV422R, YCbCr422RA YUV422RA. When UV alignment is enabled, the chroma components are aligned to the even number of luma component lines. When disabled the chroma components are aligned to half a pixel below the corresponding even number of luma component lines. It is usually disabled unless the incoming video stream specifically indicates otherwise. 0 = DISABLE 1 = ENABLE

Bit	Reset	Description
12	X	B_V_FILTER_OPTIMIZE: Window B V Filter Optimization. This is effective only when vertical scaling filter is enabled. This can be used (enabled) to temporarily disable the vertical scaling filter when the vertical scaling DDA fraction is zero. In this case the next line is not fetched from memory to save bandwidth and power. This feature cannot be used in 420P/422R/422RA formats. 0 = DISABLE 1 = ENABLE
10	X	B_V_FILTER_ENABLE: Window B V Filter Enable. This controls V scaling filter and is effective only for non-palletized color modes. If V filter is disabled, only one line is read from memory for each output line. NOTE: This feature is not supported. This bit is ignored and is a don't care. 0 = DISABLE 1 = ENABLE
8	X	B_H_FILTER_ENABLE: Window B H Filter Enable. This controls H scaling filter and is effective only for non-palletized color modes. 0 = DISABLE 1 = ENABLE
6	X	B_COLOR_EXPAND: Window B 12/15/16/18-to-24 bpp color expansion. This bit should be enabled only for 12-bpp B4G4R4A4, 15-bpp B5G5R5A, 16-bpp B5G6R5, 18-bpp B6G6R6 color modes. If enabled the color conversion is performed prior to horizontal scaling. 0 = DISABLE 1 = ENABLE
4	0x0	B_SCAN_COLUMN: Window B Scanning direction. 0= Scan in horizontal direction (for 0 or 180 degrees) 1= Scan in vertical direction (for 90 or 270 degrees) 0 = DISABLE 1 = ENABLE
2	X	B_V_DIRECTION: Window B Vertical (Y) drawing Direction 0 = INCREMENT 1 = DECREMENT
0	X	B_H_DIRECTION: Window B Horizontal (X) drawing Direction 0 = INCREMENT 1 = DECREMENT

25.11.44 DC_WIN_B_BYTE_SWAP_0

Window B Byte Swap

Offset: 0x701 │ Byte Offset: 0x1c04 │ Read/Write: R/W │ Reset: 0x00000000 (0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx)

Bit	Reset	Description
2:0	X	B_BYTE_SWAP: Window B Byte Swap. This controls byte swap of frame data read from memory prior to any data processing in the display module. 000= no byte swap (3 2 1 0) 001= byte swap for each 2-byte word (2 3 0 1) 010= byte swap for each 4-byte word (0 1 2 3) 011= word swap for each 4-byte word (1 0 3 2) 100= byte0 swapped with byte2 (3 0 1 2) 101= left shift every byte (2 1 0 3) 0 = NOSWAP 1 = SWAP2 2 = SWAP4 3 = SWAP4HW 4 = SWAP02 5 = SWAPLEFT

25.11.45 DC_WIN_B_COLOR_DEPTH_0

Window B Color Depth for YCbCr data format. Cb and Cr are 8-bit unsigned values. For YUV data format, U and V are 8-bit signed values. YCbCr422R is similar to YCbCr422P, but the Cb and Cr are shared vertically.

YUV422R is similar to YUV422P, but the U and V are shared vertically. YCbCr422RA is the same as YCbCr422R in memory, and YUV422RA is the same as YUV422R in memory but while reading from memory, for YCbCr422RA and YUV422RA, chroma averaging is applied for each pixel pair so that they can be processed as YUV422 by the display pipeline.

For YCbCr422R and YUV422R, every other chroma pixel is not used (discarded) by the display pipeline. B6x2G6x2R6x2A8 is similar to B8G8R6A8 but with the 2 LSBs zeroed out. R6x2G6x2B6x2A8 is similar to R8G8B6A8 but with the 2 LSBs zeroed out.

Some formats have NVCF_ or T_ prefix aliases for NVIDIA surface format naming convention, wherein left-to-right component names correspond to MSB to LSB bits within a word. In old names without NVCF_ or T_, left-to-right component names generally map LSB to MSB within a word.

25.11.46 DC_WIN_B_POSITION_0

Window B Position

This register defines H position and size of Window B after scaling (if there is any)

Offset: 0x704 │ Byte Offset: 0x1c10 │ Read/Write: R/W │ Reset: 0x00000000 (0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx)

Bit	Reset	Description
28:16	X	B_V_POSITION: Window B V Position. This is specified with respect to the top edge of active display area.
12:0	X	B_H_POSITION: Window B H Position. This is specified with respect to the left edge of active display area.

25.11.47 DC_WIN_B_SIZE_0

Window B Size

This register defines V position and size of Window B after scaling (if there is any)

Note: programming on window size should guarantee the whole window is inside the active area; otherwise extra rows/columns will be fetched and discarded, affecting performance.

Offset: 0x705 │ Byte Offset: 0x1c14 │ Read/Write: R/W │ Reset: 0x00000000 (0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx)

Bit	Reset	Description
28:16	X	B_V_SIZE: Window B V Size (lines). This is the vertical size after scaling.
12:0	X	B_H_SIZE: Window B H Size (pixels). This is the horizontal size after scaling.

25.11.48 DC_WIN_B_PRESCALED_SIZE_0

Window B Pre-scaled Size

This register defines Window B pre-scaled size.

The H pre-scaled size is needed to determine how many bytes to fetch from memory per line and this parameter must be programmed exactly as needed taking into account the scaling factor. For planar YUV or YCbCr data formats, this parameter refer to the H pre-scaled of the Y plane.

The total number of lines to be fetched from memory is determined by post-scale V size but V pre-scaled size is needed to 'clamp' the last valid line if the vertical DDA is exactly or slightly beyond the specified V pre-scaled size.

H pre-scaled size ideally should be in terms of pixels but then hardware needs to convert this precisely to bytes to determine the amount of data to request from memory.

Offset: 0x706 │ Byte Offset: 0x1c18 │ Read/Write: R/W │ Reset: 0x00000000 (0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx)

Bit	Reset	Description
28:16	X	B_V_PRESCALED_SIZE: Window B V Pre-scaled Size (lines). In 420P/422R/422RA formats, it must be even.
14:0	X	B_H_PRESCALED_SIZE: Window B H Pre-scaled Size (bytes). In 420P and 422P formats, it must be even.

25.11.49 DC_WIN_B_H_INITIAL_DDA_0

Window B H Initial DDA

Design Note: the first pixel of pre-scaled image is always used to output the first pixel so essentially this is the same as forcing the H Initial DDA integer portion to 1 initially even though user typically programs this to 0. If it makes the implementation easier, it is possible to force software to program the Initial DDA integer portion to 1. Similarly with the V Initial DDA.

Offset: 0x707 │ Byte Offset: 0x1c1c │ Read/Write: R/W │ Reset: 0x00000000 (0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx)

Bit	Reset	Description
15:0	X	B_H_INITIAL_DDA: Window B H Initial DDA (4.12). This is typically programmed to 0.0

25.11.50 DC_WIN_B_V_INITIAL_DDA_0

Window B V Initial DDA

Offset: 0x708 │ Byte Offset: 0x1c20 │ Read/Write: R/W │ Reset: 0x00000000 (0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx)

Bit	Reset	Description
15:0	X	B_V_INITIAL_DDA: Window B V Initial DDA (4.12). This is typically programmed to 0.0 for both non-interlaced and interlaced sources.

25.11.51 DC_WIN_B_DDA_INCREMENT_0

Window B DDA Increment

The DDA increment is typically calculated by dividing (Pre-scaled size in pixels - 1) by (Post-scaled size in pixels - 1). The result should be rounded up and expressed as 4.12 format (4-bit integer and 12-bit fraction). For non-filtered images, this

value can be slightly larger so that it is not missing the last row/column. Reference programming values (H and V should be calculated separately depending on filter on/off and sizes):

- Filter on: min(round((prescaled_size_in_pixels - 1) * 0x1000 / (post_scaled_size_in_pixels - 1)), MAX)
- Filter off: min(round(prescaled_size_in_pixels * 0x1000 / (post_scaled_size_in_pixels - 1) - 0.5), MAX)

Where the value of MAX is as follows:

For V_DDA_INCREMENT: 15.0 (0xF000)

For H_DDA_INCREMETN: 4.0 (0x4000) for 4 Bytes/pix formats.

8.0 (0x8000) for 2 Bytes/pix formats.

They are theoretically the biggest values that guarantee not displaying beyond an image boundary.

If the DDA increment is less than 1.0 then the image will be upscaled.If the DDA increment is more than 1.0 then the image will be downscaled.

Offset: 0x709 │ Byte Offset: 0x1c24 │ Read/Write: R/W │ Reset: 0x00000000 (0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx)

Bit	Reset	Description
31:16	X	B_V_DDA_INCREMENT: Window B Vertical DDA Increment (4.12) This should be set to 1.0 if there is no scaling. Maximum value is 15.0 regardless of the number of bytes per pixel.
15:0	X	B_H_DDA_INCREMENT: Window B Horizontal DDA Increment (4.12) This should be set to 1.0 if there is no scaling. The maximum value for downscaling depends on the number of bytes per pixel. For 4-byte/pixel modes (32-bpp) the maximum value is 4.0 and for all other modes the maximum value is 8.0.

25.11.52 DC_WIN_B_LINE_STRIDE_0

Window B Line Stride

Offset: 0x70a │ Byte Offset: 0x1c28 │ Read/Write: R/W │ Reset: 0x00000000 (0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx)

Bit	Reset	Description
31:16	X	B_UV_LINE_STRIDE: Window B Line Stride for Chroma This is stride (in bytes) for planar YUV or YCbCr data formats for the chroma plane, with the restriction that it must be programmed to be multiples of 4 (16 if tiled or in horizontal flipping) This is not used (ignored) for other non-planar data formats.
15:0	X	B_LINE_STRIDE: Window B Line Stride This is stride (in bytes) for all non-planar data formats. If the memory surface is tiled, the stride needs to be a multiple of 16. If H_DIRECTION of window B is set to DECREMENT, the stride also needs to be a multiple of 16. For planar YUV or YCbCr data formats, this is stride (in bytes) for the luma plane with the restriction that it must be multiples of 8 (16 if tiled or in horizontal flipping). For tiled surface, this value may affect starting address of a window. Refer to the comment of START_ADDR for detail.

25.11.53 DC_WIN_B_BUFFER_ADDR_MODE_0

Memory Controller Tiling definitions

Offset: 0x70d │ Byte Offset: 0x1c34 │ Read/Write: R/W │ Reset: 0x00000000 (0bxxxxxxxxxxxxxxxx0xxxxxxxxxxxxxxx0)

Bit	Reset	Description
16	0x0	B_UV_TILE_MODE: Window B Memory surface tiling mode. For YUV planar pixel format, this specifies tiling mode for the U/V plane.

Bit	Reset	Description
		0 = LINEAR 1 = TILED
0	0x0	B_TILE_MODE: Window B Memory surface tiling mode. For YUV planar pixel format, this specifies tiling mode for the Y plane. 0 = LINEAR 1 = TILED

25.11.54 DC_WIN_B_DV_CONTROL_0

Window B Digital Vibrance Control

If enabled, Digital Vibrance is applied after H and V scaling and after color palette or color space conversion logic but before color keying multiplexer and before cursor multiplexer.

- After DV, new R = R + (2R - G - B) * FR, where FR is fraction from 0 to 7/8
- After DV, new G = G + (2G - R - B) * FG, where FG is fraction from 0 to 7/8
- After DV, new B = B + (2B - R - G) * FB, where FB is fraction from 0 to 7/8

Offset: 0x70e │ Byte Offset: 0x1c38 │ Read/Write: R/W │ Reset: 0x00000000 (0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx)

Bit	Reset	Description
18:16	X	B_DV_CONTROL_B: Digital Vibrance control for B
10:8	X	B_DV_CONTROL_G: Digital Vibrance control for G
2:0	X	B_DV_CONTROL_R: Digital Vibrance control for R

25.11.55 DC_WIN_B_BLEND_NOKEY_0

Blend Control for this window area where color key is enabled but the pixel color is not within the color key range (color key not match). This is valid for all overlapping condition but only if there is no overlap with other window with higher priority color key enabled and color key not match.

Class: Display Color Keying and Blending

Color keying and blending of the display windows are done prior to cursor blending.

Cursor always goes on top of the blended windows. Blending is controlled independently on each possible overlap area of the display windows. If 3 windows are enabled there are 7 possible overlap area combinations. For every window in each overlap area combination, color key can be disabled or enabled. Also, for every window in each overlap area combination, there is a corresponding window blend control parameter and a window blend weight parameter. The window blend control parameter is always effective but the window blend weight is not always used. The window blend weight can also be derived from pixel alpha value or from the reverse of other overlapping windows weight.

Color keying has the highest priority for display window blending. Color key consists of a range of color which is searched independently for each windows. If more than 1 windows color key is enabled, then Window A color key has the highest priority, followed by Window B color key, and then followed by Window C color key. Two sets of color key ranges (Color Key 0 and Color Key 1) can be defined; they are shared for all windows. It is possible to use both color key sets for the same window or for two separate windows.

The two sets of color key ranges should not overlap. If they do, the overlapped colors are treated as if they are part of Color Key 0 and not part of Color Key 1.

Assuming that there is no overlap with other higher priority window with color key not matched, if a window color key is enabled for any overlap condition and the window pixel is not within the color key range (key not match), then the window pixel will not be blended with other overlapping window pixels but it will be weighted. The weight is not dependent on the overlap condition it is controlled by the same set of parameters for all overlapping condition.

Assuming that there is no overlap with other higher priority window with color key not matched, if a window color key is enabled for a particular overlap condition and the window pixel is within the color key range (key match), then the window pixel will be weighted and blended with other overlapping pixels and this is controlled separately for each overlap condition.

Assuming that there is no overlap with other higher priority window with color key not matched, if a window color key is disabled then the window pixel will be blended with other overlapping pixels and this is controlled separately for each overlap condition.

Display Color Key Parameters

For B4G4R4A4, B5G6R5A, B5G6R5 modes, the color key should be compared prior to color conversion to 24-bpp and unused least significant bits of the pixel are filled with zeros.

For palletized mode, the color key is compared prior to the color palette, and the palletized color is compared against the green color key values/mask.

For YUV mode, U and V are offset by +128 before performing the color key comparison.

In all cases, the color key is compared prior to the horizontal/vertical scaling filter and prior to digital vibrance control. Both upper and lower values are inclusive.

Offset: 0x70f │ Byte Offset: 0x1c3c │ Read/Write: R/W │ Reset: 0x00000000 (0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx)

Bit	Reset	Description
23:16	X	B_BLEND_WEIGHT1_NOKEY: Window blend weight 1 for color key not match areas. This is used only for alpha weight with 1-bit alpha and alpha value of 1.
15:8	X	B_BLEND_WEIGHT0_NOKEY: Window blend weight 0 for color key not match areas. For alpha weight, this is used for 1-bit alpha with value of 0.
0	X	B_BLEND_CONTROL_NOKEY: Window blend control for color key not match areas. 0 = Fix weight using window blend weight 0 for color key not matched. 1 = Alpha weight using the alpha value. This is only valid if the window color format includes an alpha value. For 1-bit alpha value, if the alpha is 0 window blend weight 0 is used and if alpha is 1, window blend weight 1 is used. 0 = FIX_WEIGHT 1 = ALPHA_WEIGHT

25.11.56 DC_WIN_B_BLEND_1WIN_0

Blend Control for this window area where it does not overlap with other windows.

Offset: 0x710 │ Byte Offset: 0x1c40 │ Read/Write: R/W │ Reset: 0x00000000 (0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx)

Bit	Reset	Description
23:16	X	B_BLEND_WEIGHT1_1WIN: Window blend weight 1 for color key disabled or color key enabled with key matched areas. This is used only for alpha weight with 1-bit alpha and alpha value of 1.
15:8	X	B_BLEND_WEIGHT0_1WIN: Window blend weight 0 for color key disabled or color key enabled with key matched areas. For alpha weight, this is used for 1-bit alpha with value of 0.
2	X	B_BLEND_CONTROL_1WIN: Window blend control in area where it does not overlap with other windows and either color key disabled or color key enabled with key matched.

Bit	Reset	Description
		0 = Fix weight using the window blend weight 0 if color key disabled or color key 0 enabled with key matched, or using the window blend weight 1 if color key 1 enabled with key matched. 1 = Alpha weight using the alpha value. This is only valid if the window color format includes an alpha value. For 1-bit alpha value, if the alpha is 0, window blend weight 0 is used; if alpha is 1, window blend weight 1 is used. 0 = FIX_WEIGHT 1 = ALPHA_WEIGHT
1:0	X	B_CKEY_ENABLE_1WIN: Window color key enable. 0 = Color Key 0 and 1 Disable 1 = Color Key 0 Enable 2 = Color Key 1 Enable 3 = Color Key 0 and 1 Enable 0 = NOKEY 1 = CKEY0 2 = CKEY1 3 = CKEY01

25.11.57 DC_WIN_B_BLEND_2WIN_A_0

Blend Control for this window area that overlaps with window A only.

Offset: 0x711 │ Byte Offset: 0x1c44 │ Read/Write: R/W │ Reset: 0x00000000 (0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx)

Bit	Reset	Description
23:16	X	B_BLEND_WEIGHT1_2WIN_A: Window blend weight 1 for color key disabled or color key enabled with key matched areas. This is used only for alpha weight with 1-bit alpha and alpha value of 1.
15:8	X	B_BLEND_WEIGHT0_2WIN_A: Window blend weight 0 for color key disabled or color key enabled with key matched areas. For alpha weight, this is used for 1-bit alpha with value of 0.
3:2	X	B_BLEND_CONTROL_2WIN_A: Window blend control in area where either color key disabled or color key enabled with key matched. 0 = Fix weight using the window blend weight 0 if color key disabled or color key 0 enabled with key matched, or using the window blend weight 1 if color key 1 enabled with key matched. 1 = Alpha weight using the alpha value. This is only valid if the window color format includes an alpha value. For 1-bit alpha value, if the alpha is 0 window blend weight 0 is used and if alpha is 1, window blend weight 1 is used. 2 = Dependent weight, in this case, the window blend weight is 1 - the weights of the other window that overlaps with this window. Only 1 of the overlapping windows may have this setting. 3 = Premultipled weight; in this case, the window blend weight is 1. But other windows that use DEPENDENT_WEIGHT get (1 - alpha value),like ALPHA_WEIGHT. This is only valid if the window color format includes an alpha value. This allows a blending equation like: result = win_b * 1 + (1 - win_b_alpha) * win_c 0 = FIX_WEIGHT 1 = ALPHA_WEIGHT 2 = DEPENDENT_WEIGHT 3 = PREMULT_WEIGHT

25.11.60 DC_WIN_B_GLOBAL_ALPHA_0

Window B Global Alpha

When enabled, per pixel alpha values are scaled by GLOBAL_ALPHA before blending: a' = a * GLOBAL_ALPHA/255. When per pixel alpha is not used in blending, global alpha has no affect.

Note: 1- and 4-bits per pixel alpha are quantized back to 1 and 4 bits, respectively, after scaling. For the 1-bit alpha case, finer scaling can be achieved by changing BLEND_WEIGHT* instead.

Offset: 0x715 │ Byte Offset: 0x1c54 │ Read/Write: R/W │ Reset: 0x00000000 (0bxxxxxxxxxxxxxxxx0xxxxxxxxxxxxxxx)

Bit	Reset	Description
16	DISABLE	B_GLOBAL_ALPHA_ENABLE: When enabled, color palette *must* also be enabled and programmed. 0 = DISABLE 1 = ENABLE
7:0	X	B_GLOBAL_ALPHA: Global alpha: 0..255 map to 0.0 – 1.0. i.e., 255 yields no-operation. For power, better to set GLOBAL_ALPHA_ENABLE=DISABLE when GLOBAL_ALPHA=255.

25.12 WINBUF_B Registers

The registers under DC_WINBUF are triple-buffered.

25.12.1 DC_WINBUF_B_START_ADDR_0

Window B Start Address

Overview

START_ADDR, BUF_STRIDE, LINE_STRIDE, ADDR_H_OFFSET, ADDR_V_OFFSET combined, specify the starting address of a window buffer in the memory surface. Generally START_ADDR is programmed with the starting address of the memory surface. H/V_OFFSET specifies the address offsets of the pixel at the beginning of the window, with respect to the starting address of the memory surface. (There is an exception to that when memory surface is not well aligned, see ”For linear address mode” in Programming Restrictions below.)

Note that "beginning of the window" here means the top-left corner of a window in normal mode, top-right corner in horizontal flipping, bottom-left corner in vertical flipping, and bottom-right in horizontal+vertical flipping.

Starting Address Calculation

These formulae are the same for both tiled and linear modes. However, for linear mode, the addresses calculated are real physical addresses, but for tiled mode, these addresses will be translated to the real physical addresses by the memory controller client before used.

- When a window is host triggered, the starting address of a window is calculated as follows by hardware:
  - non-YUV-planar modes:

    starting-address = START_ADDR + ADDR_V_OFFSET * LINE_STRIDE + ADDR_H_OFFSET
  - YUV-planar modes:

    Y-starting-address = START_ADDR + ADDR_V_OFFSET * LINE_STRIDE + ADDR_H_OFFSET

    U-starting-address = START_ADDR_U + ADDR_V_OFFSET * UV_LINE_STRIDE / denom1 + ADDR_H_OFFSET / denom2

    V-starting-address = START_ADDR_V + ADDR_V_OFFSET * UV_LINE_STRIDE / denom1 + ADDR_H_OFFSET / denom2 where denom1/denom2 equal to 1 or 2 depending on the actual planar format, derived natively by hardware.
- When a window is non-host triggered, starting address of a window buffer is calculated as below:
  - non-YUV-planar mode:

    starting-address = START_ADDR + BUF_STRIDE * buf_index + ADDR_V_OFFSET * LINE_STRIDE + ADDR_H_OFFSET
  - YUV-planar mode:

    Y-starting-address = START_ADDR + BUF_STRIDE * buf_index + ADDR_V_OFFSET * LINE_STRIDE + ADDR_H_OFFSET

    U-starting-address = START_ADDR_U + UV_BUF_STRIDE * buf_index + ADDR_V_OFFSET * UV_LINE_STRIDE / denom1 + ADDR_H_OFFSET / denom2

    V-starting-address = START_ADDR_V + UV_BUF_STRIDE * buf_index + ADDR_V_OFFSET * UV_LINE_STRIDE / denom1 + ADDR_H_OFFSET / denom2 where denom1/denom2 equal to 1 or 2 depending on the actual planar format, derived natively by hardware.

    buf_index is the index transmitted by the triggering module pointing to the first buffer of a frame.

Programming Restrictions

- For tiled address mode:

  Image surface can only aligned to multiples of 256, thus the following restrictions.

  - START_ADDR, START_ADDR_U, START_ADDR_V need to be multiples of 256.
  - BUF_STRIDE, UV_BUF_STRIDE need to be multiples of 256
  - LINE_STRIDE, UV_LINE_STRIDE need to be multiples of 16
  - ADDR_H_OFFSET needs to be even in YUV planar format, or a multiple of bytes per pixel in other formats. If H_DIRECTION=DECREMENT, however, it should point to last valid byte, which is an odd offset.
  - ADDR_V_OFFSET needs to be multiple of 2 in YUV planar format, unless H_DIRECTION=DECREMENT, but with no restrictions on other color formats.

- For linear address mode:

  Image surface can be aligned 2, 4 or 8 bytes, depending on the color formats.

  As an additional restriction for display, START_ADDR, START_ADDR_U and START_ADDR_V need to be multiples of 16.

  When a surface is not aligned to 16 bytes, program START_ADDR with the memory surface address with its least 4 significant bits zeroed out and add these 4 address bits to the original H_OFFSET. (So the formulae in Starting Address Calculation above still hold)

  - For all formats:

    START_ADDR, START_ADDR_U and START_ADDR_V need to be multiples of 16.
  - For 16-bpp formats,

    (START_ADDR+H_OFFSET) needs to be a multiple of 2.
  - For 32-bpp formats,

    (START_ADDR+H_OFFSTE) needs to be a multiple of 4.
  - For YUV planar formats:

    BUF_STRIDE, UV_BUF_STRIDE:

    BUF_STRIDE[2:1]=UV_BUF_STRIDE[1:0]

    or as a stricter constraint: BUF_STRIDE be multiple of 8, UV_BUF_STRIDE be a multiple of 4.

    LINE_STRIDE, UV_LINE_STRIDE:

    LINE_STRIDE and UV_LINE_STRIDE need to be at least 16.

    LINE_STRIDE needs to be multiple of 8, UV_LINE_STRIDE needs to be a multiple of 4.

    ADDR_H_OFFSET: Needs to be even unless H_DIRECTION=DECREMENT, in which case should point to the last byte pixel, which is at an odd offset.

    ADDR_V_OFFSET: Needs to be even unless V_DIRECTION=DECREMENT, in which case should point to the last valid line, which is at an odd offset.

- Memory allocation for non-host triggered case

  When a window buffer is not controlled by host (software) then a frame may be stored in multiple buffers. In this case, the buffers must be contiguous in the memory because the display will use the same luma or chroma line strides for all lines in the frame.

  Also buffer wraparound must not occur in the middle of the displayed part of the frame. The controlling module will send frame start and frame end indicators (flags) to display module to indicate the beginning and end of frame. Buffer start address is latched when frame start flag is active but the actual buffer start address is not switched until frame end flag is active. In the case where one buffer corresponds to one frame then frame start and frame end flag are active every time a buffer index is sent.

Offset: 0x800 | Byte Offset: 0x2000 | Read/Write: R/W | Reset: 0x00000000 (0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx)

Bit	Reset	Description
31:0	X	B_START_ADDR: Window B Start Address. This is a byte address. The LSB is not used for 16-bpp non-planar pixel format and the last 2 LSBs are not used for 32-bpp non-planar pixel format. For YUV planar pixel format, this specifies start address for the Y plane.

25.12.2 DC_WINBUF_B_START_ADDR_NS_0

Window B Shadowed Start Address

Offset: 0x801 | Byte Offset: 0x2004 | Read/Write: R/W | Reset: 0x00000000 (0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx)

Bit	Reset	Description
31:0	X	B_START_ADDR_NS: Window B Shadowed Start Address. This is ARM set shadow of Start Address.

25.12.3 DC_WINBUF_B_START_ADDR_U_0

Window B Start Address for U plane

Offset: 0x802 | Byte Offset: 0x2008 | Read/Write: R/W | Reset: 0x00000000 (0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx)

Bit	Reset	Description
31:0	X	B_START_ADDR_U: Window B Start Address for U plane. This is a byte address.

25.12.4 DC_WINBUF_B_START_ADDR_U_NS_0

Window B Shadowed Start Address for U plane

Offset: 0x803 | Byte Offset: 0x200c | Read/Write: R/W | Reset: 0x00000000 (0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx)

Bit	Reset	Description
31:0	X	B_START_ADDR_U_NS: Window B Shadowed Start Address for U plane. This is ARM set shadow register of U start address

25.12.5 DC_WINBUF_B_START_ADDR_V_0

Window B Start Address for V plane

Offset: 0x804 | Byte Offset: 0x2010 | Read/Write: R/W | Reset: 0x00000000 (0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx)

Bit	Reset	Description
31:0	X	B_START_ADDR_V: Window B Start Address for V plane. This is a byte address.

25.12.6 DC_WINBUF_B_START_ADDR_V_NS_0

Window B Shadowed Start Address for V plane

Offset: 0x805 | Byte Offset: 0x2014 | Read/Write: R/W | Reset: 0x00000000 (0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx)

Bit	Reset	Description

31:0	X	B_START_ADDR_V_NS: Window B Shadowed Start Address for V plane. This is ARM set shadow register of U start address

25.12.7 DC_WINBUF_B_ADDR_H_OFFSET_0

Window B Horizontal address offset

Offset: 0x806 | Byte Offset: 0x2018 | Read/Write: R/W | Reset: 0x00000000 (0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx)

Bit	Reset	Description
31:0	X	B_ADDR_H_OFFSET: Window B Horizontal address offset. This is a byte address. The LSB is not used for 16-bpp non-planar pixel format and the last 2 LSBs are not used for 32-bpp non-planar pixel format. For YUV planar pixel format, this specifies horizontal offset of Y plane. The horizontal offsets of U/V plane is derived by hardware.

25.12.8 DC_WINBUF_B_ADDR_H_OFFSET_NS_0

Window B Shadowed Horizontal address offset

Offset: 0x807 | Byte Offset: 0x201c | Read/Write: R/W | Reset: 0x00000000 (0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx)

Bit	Reset	Description
31:0	X	B_ADDR_H_OFFSET_NS: Window B Shadowed Horizontal address offset. This is ARM set shadow of ADDR_H_OFFSET

25.12.9 DC_WINBUF_B_ADDR_V_OFFSET_0

Window B Vertical address offset

Offset: 0x808 | Byte Offset: 0x2020 | Read/Write: R/W | Reset: 0x00000000 (0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx)

Bit	Reset	Description
31:0	X	B_ADDR_V_OFFSET: Window B Vertical address offset. This is the vertical coordinate. For YUV planar pixel format, this specifies the vertical coordinate of Y plane. The vertical coordinate of U/V plane is derived by hardware.

25.12.10 DC_WINBUF_B_ADDR_V_OFFSET_NS_0

Window B Shadowed Vertical address offset

Offset: 0x809 | Byte Offset: 0x2024 | Read/Write: R/W | Reset: 0x00000000 (0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx)

Bit	Reset	Description
31:0	X	B_ADDR_V_OFFSET_NS: Window B Shadowed Vertical address offset. This is ARM set shadow of ADDR_V_OFFSET.

25.12.11 DC_WINBUF_B_UFLOW_STATUS_0

Window B FIFO Underflow Status Register

Offset: 0x80a | Byte Offset: 0x2028 | Read/Write: R/W | Reset: 0x00000000 (0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx)

Bit	Reset	Description
30	X	COUNT_OFLOW: Flag bit that indicates that the underflow event counter has overflowed. There were too many events. If COUNT_OFLOW is set, UFLOW_COUNT is meaningless. Cleared on write.
23:0	X	UFLOW_COUNT: Underflow count. This field indicates the number of contiguous groups of output pixels for which there was no data in the FIFO. For example, if the valid from the FIFO is low for 10 consecutive cycles and then goes high, the counter will increment by one. Reset to zero on write.

25.12.12 DC_WINBUF_B_SURFACE_WEIGHT_0

Window B Surface Weights

Offset: 0x80c │ Byte Offset: 0x2030 │ Read/Write: R/W │ Reset: 0x00000000 (0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx0)

Bit	Reset	Description
6:5	X	B_SURFACE_WEIGHT_V: Window B V Surface Weights 00 - Weight is 2 01 - Weight is 4 10 - Weight is 8 11 - Weight is 16 0 = WEIGHT_2 1 = WEIGHT_4 2 = WEIGHT_8 3 = WEIGHT_16
4:3	X	B_SURFACE_WEIGHT_U: Window B U or UV Surface Weights 00 - Weight is 2 01 - Weight is 4 10 - Weight is 8 11 - Weight is 16 0 = WEIGHT_2 1 = WEIGHT_4 2 = WEIGHT_8 3 = WEIGHT_16
2:1	X	B_SURFACE_WEIGHT_Y: Window B Y or packed Surface Weights 00 - Weight is 2 01 - Weight is 4 10 - Weight is 8 11 - Weight is 16 0 = WEIGHT_2 1 = WEIGHT_4 2 = WEIGHT_8 3 = WEIGHT_16
0	0x0	B_SURFACE_WEIGHT_OVERRIDE: weight override 0 = DISABLE 1 = ENABLE

25.12.13 DC_WINBUF_B_START_ADDR_HI_0

Window B Higher 32 bits of Start Address

Make the start address 64 bits by adding the higher 32 bits below.

Offset: 0x80d │ Byte Offset: 0x2034 │ Read/Write: R/W │ Reset: 0x00000000 (0b00000000000000000000000000000000)

Bit	Reset	Description
31:0	0x0	B_START_ADDR_HI: Window B Start Address. This is a byte address. The LSB is not used for 16-bpp non-planar pixel format and the last 2 LSBs are not used for 32-bpp non-planar pixel format. For YUV planar pixel format, this specifies start address for the Y plane.

25.12.14 DC_WINBUF_B_START_ADDR_HI_NS_0

Window B Shadowed Higher 32 bits of Start Address

Offset: 0x80e │ Byte Offset: 0x2038 │ Read/Write: R/W │ Reset: 0x00000000 (0b00000000000000000000000000000000)

Bit	Reset	Description
31:0	0x0	B_START_ADDR_HI_NS: Window B Shadowed Start Address. This is ARM set shadow of Start Address.

25.12.15 DC_WINBUF_B_START_ADDR_HI_U_0

Window B Higher 32 bits of Start Address for U plane

Offset: 0x80f │ Byte Offset: 0x203c │ Read/Write: R/W │ Reset: 0x00000000 (0b00000000000000000000000000000000)

Bit	Reset	Description
31:0	0x0	B_START_ADDR_HI_U: Window B Start Address for U plane. This is a byte address.

25.12.16 DC_WINBUF_B_START_ADDR_HI_U_NS_0

Window B Shadowed Higher 32 bits of Start Address for U plane

Offset: 0x810 │ Byte Offset: 0x2040 │ Read/Write: R/W │ Reset: 0x00000000 (0b00000000000000000000000000000000)

Bit	Reset	Description
31:0	0x0	B_START_ADDR_HI_U_NS: Window B Shadowed Higher 32 bits of Start Address for U plane. This is ARM set shadow register of U start address

25.12.17 DC_WINBUF_B_START_ADDR_HI_V_0

Window B Higher 32 bits of Start Address for V plane

Offset: 0x811 │ Byte Offset: 0x2044 │ Read/Write: R/W │ Reset: 0x00000000 (0b00000000000000000000000000000000)

Bit	Reset	Description
31:0	0x0	B_START_ADDR_HI_V: Window B Higher 32 bits of Start Address for V plane. This is a byte address.

25.12.18 DC_WINBUF_B_START_ADDR_HI_V_NS_0

Window B Shadowed Higher 32 bits of Start Address for V plane

Offset: 0x812 │ Byte Offset: 0x2048 │ Read/Write: R/W │ Reset: 0x00000000 (0b00000000000000000000000000000000)

Bit	Reset	Description
31:0	0x0	B_START_ADDR_HI_V_NS: Window B Shadowed Higher 32 bits of Start Address for V plane. This is ARM set shadow register of U start address

25.12.19 DC_WINBUF_B_UFLOW_CTRL_0

When the underflow debug mode is enabled. Instead of sending out the last valid pixel, DBG_PIXEL is sent out.

Offset: 0x824 | Byte Offset: 0x2090 | Read/Write: R/W | Reset: 0x00000000 (0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx0)

Bit	Reset	Description
0	0x0	B_UFLOW_CTRL_DBG_MODE: 0 = DISABLE 1 = ENABLE

25.12.20 DC_WINBUF_B_UFLOW_DBG_PIXEL_0

Offset: 0x825 | Byte Offset: 0x2094 | Read/Write: R/W | Reset: 0x00000000 (0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx)

Bit	Reset	Description
31:0	X	B_UFLOW_DBG_PIXEL

25.12.21 DC_WINBUF_B_UFLOW_THRESHOLD_0

Offset: 0x826 | Byte Offset: 0x2098 | Read/Write: R/W | Reset: 0x00000000 (0bxxxxxxxxxxxxxxxxxxx0000000000000)

Bit	Reset	Description
12:0	0x0	B_UFLOW_THRESHOLD

25.12.22 DC_WINBUF_B_SPOOL_UP_0

Spool up time configuration for different windows related logic.

SPOOL_UP_CTRL = MAX - This is the current Tegra 4 behavior. This allows for memfetch to start fetching for a window (irrespective of its relative position on the screen), at the very beginning of the vblank of the next frame. Since the spool up time is maximum, this should have the least probability of underflow of the display pipe. However, on the down side, since all three windows would start fetching at the same time, and since display is a high priority client for MC, it has a high potential to starve out other clients.

SPOOL_UP_CTRL = PROGRAMMABLE, SPOOL_UP_DURATION = 1 - This corresponds to Tegra 3 behavior. Since the fetch starts only 1 line prior to the active scan line of a window, this has high probability of causing underflow, but has a lesser impact on the other MC clients.

So, this register programmability programs us a method to modulate the spool up time between the best and worst, if required, when other MC clients are present. For example when GPU/VIC is active, we may not want a very aggressive spool up and program some definite spool up duration. So, spool up time is a general knob, which would be a function of the resolution, bpp, active clients, memory speed, etc.

SPOOL_UP_EDGE:- By default the memfetch start signal generated by the hvtgen logic is one line clock wide.

For SPOOL_UP_CTRL = MAX:

- In this case if SPOOL_UP_EDGE is programmed to NEGEDGE. This ensures that if any act_req is sent during the time vcounter = 0(at the beginning of the frame). The activate value is loaded into the active state and the memfetch would see the latest updated value. The downside of programming it to NEGDGE is that 1 line clock worth of spool up is lost. This is required based upon Tegra 3 compatibility and the way tests are written.
- In this case if SPOOL_UP_EDGE is programmed to POSEDGE. Then the memfetch would start fetching at the very beginning of the frame start pulse (1 line clock wide) and would give maximum spool up time. However, this may give test failure and potential Tegra 3 compatibility issues as described above

FOR SPOOL_UP_CTRL = PROGRAMMABLE:

- Special care must be taken here. If SPOOL_UP_DURATION is set to 1. SPOOL_UP_EDGE must be set to POSEDGE to allow for at least 1 line worth of spool up.
- If SPOOL_UP_DURATION is > 1. Then SPOOL_UP_EDGE can be either POSEDGE or NEGEDGE. If its NEGEDGE, then the effective spool up duration would be 1 line clock less than the SPOOL_UP_DURATION.

Offset: 0x827 | Byte Offset: 0x209c | Read/Write: R/W | Reset: 0x00000000 (0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx00)

Bit	Reset	Description
28:16	X	B_SPOOL_UP_DURATION
1	0x0	B_SPOOL_UP_EDGE: 0 = NEGEDGE 1 = POSEDGE
0	0x0	B_SPOOL_UP_CTRL: 0 = MAX 1 = PROGRAMMABLE

25.12.23 DC_WINBUF_B_SCALEFACTOR_THRESHOLD_0

Registers for latency allowance scaling. Threshold is in terms of 64 byte atoms. Display memfetch compares its buffer occupancy with the threshold and generates indication to MC if its buffer occupancy is above HWM or below LWM.

Offset: 0x828 | Byte Offset: 0x20a0 | Read/Write: R/W | Reset: 0xffffffff (0b11111111111111111111111111111111)

Bit	Reset	Description
31:16	0xffff	B_SF_LWM_THRESHOLD
15:0	0xffff	B_SF_HWM_THRESHOLD

25.12.24 DC_WINBUF_B_LATENCY_THRESHOLD_0

Register for ready for latency event like DVFS. Threshold is in terms of 64 byte atoms. Display memfetch compares its buffer occupancy with the threshold and generates indication to MC if its buffer occupancy is above the threshold.

Offset: 0x829 | Byte Offset: 0x20a4 | Read/Write: R/W | Reset: 0x0000ffff (0bxxxxxxxxxxxxxxxx1111111111111111)

Bit	Reset	Description
15:0	0xffff	B_RDY4LATENCY_THRESHOLD

25.12.25 DC_WINBUF_B_MEMFETCH_DEBUG_STATUS_0

Memfetch Debug Status

Offset: 0x82a | Byte Offset: 0x20a8 | Read/Write: R/W | Reset: 0x00000000 (0bxxxxxxxxxxxxxxxx0000000000000000)

Bit	Reset	Description
15	0x0	B_ALIGN_FIFO_NON_IDLE: align FIFO idle at end of frame. 0= align FIFO is idle at end of frame. 1= align FIFO is not idle at end of frame

25.12.29 DC_WINBUF_B_SCRATCH_REGISTER_1_0

Offset: 0x82e | Byte Offset: 0x20b8 | Read/Write: R/W | Reset: 0x00000000 (0b00000000000000000000000000000000)

Bit	Reset	Description
31:0	0x0	B_SCRATCH_REGISTER_1:Scratch register 1

25.13 Window C (WIN_C) Registers

These registers control window C parameters

25.13.1 DC_WINC_C_COLOR_PALETTE_0

Window C Color Palette

This is used for palletized data format (color depth of 8-bpp or less) or for gamma correction for non-palletized data formats (color depth of more than 8 bpp). Each window has its own color palette which consists of three 256x8 register file which can be written by host and indexed (read) by the window.

For palletized data format less than 8 bpp, the pixel data is aligned to least significant bits of the palette index (address) and the remaining upper bits are filled with the corresponding bits of the Palette Color Extension. For example, for 4-bpp mode, the pixel data occupies bits 3:0 of the palette index and bits 7:4 of the palette index are set to bits 7:4 of the Palette Color Extension. Host read is assumed to be not needed - software can cache the color palette in system memory. This is an array of 256 identical register entries; the register fields below apply to each entry.

Color Palette

Offset: 0x500..0x5ff | Byte Offset: 0x1400..0x17fc | Read/Write: WO | Reset: 0x00000000 (0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx)

Bit	Reset	Description
23:16	X	C_COLOR_PALETTE_B: Blue Color Palette
15:8	X	C_COLOR_PALETTE_G: Green Color Palette
7:0	X	C_COLOR_PALETTE_R: Red Color Palette

25.13.2 DC_WINC_C_PALETTE_COLOR_EXT_0

Window C Palette Color Extension

Palette extension for 1-bpp, 2-bpp, and 4-bpp. These bits provide the upper most significant bits for indexing the color palette.

Offset: 0x600 │ Byte Offset: 0x1800 │ Read/Write: R/W │ Reset: 0x00000000 (0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx)

Bit	Reset	Description
7:1	X	C_PALETTE_COLOR_EXT: Window C Palette Color Extension. Bits 7:1 are used for 1-bpp mode, bits 7:2 are used for 2-bpp mode, and bits 7:4 are used for 4-bpp mode

25.13.3 DC_WINC_C_H_FILTER_P00_0

Window C Horizontal Filter phase 00

Horizontal scaling filter coefficients.

Horizontal scaling filter is a 6-tap filter with 4-bit positional phase.

- Coefficients 0 and 5 are 3-bit signed values ranging from -4 to 3.
- Coefficients 1 and 4 are 5-bit signed values ranging from -16 to 15.
- Coefficients 2 and 3 are 8-bit unsigned values ranging from 0 to 128.
- Coefficient 0 is the multiplier for the earliest pixel (P0) in the group of 6 pixels and coefficient 5 is the multiplier for the latest pixel (P5) in the group. The output pixel positional phase is defined as centered in P2 if the positional phase is 0 or proportionally in between P2 and P3 if the positional phase is larger than 0.

Sum of all coefficients for each phase should be 128 typically, and software should never program the sum of all coefficients for a phase to be more than 128.

For each horizontal positional phase, the 6 filter coefficients require 32 register bits. Note that color value ranges from 0 to 255 for Y, R, G, B and -128 to 127 for U and V.

25.13.19 DC_WINC_C_CSC_YOF_0

Window C CSC Y Offset

Color Space Conversion coefficients

The CSC can be used for YUV to RGB conversion with brightness and hue/saturation control. The CSC can only be enabled for window C controlled by CSC_ENABLE register bits.

For Y color, the Y offset is applied first and saturation (clipping) is performed immediately after the Y offset is applied.

- R = sat(KYRGB * sat(Y + YOF) + KUR * U + KVR * V)
- G = sat(KYRGB * sat(Y + YOF) + KUG * U + KVG * V)
- B = sat(KYRGB * sat(Y + YOF) + KUB * U + KVB * V)

Saturation and rounding is performed in the range of 0 to 255 for the above equations.

Typical values are:

- YOF = -16.000, KYRGB = 1.1644
- KUR = 0.0000, KVR = 1.5960
- KUG = -0.3918, KVG = -0.8130
- KUB = 2.0172, KVB = 0.0000

KUR and KVB are typically 0.0000 but they may be programmed non-zero for hue rotation.

The CSC can also take RGB input, in which case YOF, KVB, KUG, and KUR should be programmed to 0, and KYRGB will be forced to 0 by the hardware for generating R and B. KYRGB will not be forced to 0 for generating G. KVR, KYRGB, and KUB can be programmed to 1.0 or used as gain control for R, G, B, correspondingly. Note that color value ranges from 0 to 255 for Y, R, G, B, and -128 to 127 for U and V.

25.13.27 DC_WINC_C_V_FILTER_P00_0

Window C Vertical Filter phase 00

Vertical scaling filter coefficients

Vertical scaling filter is a 2-tap filter with 4-bit positional phase. Coefficients 0 and 1 are 8-bit unsigned values ranging from 0 to 128.

Coefficient 0 is the multiplier for the earlier pixel (P0) in the group of 2-pixels and coefficient 1 is the multiplier for the later pixel (P1) in the group. The output pixel positional phase is defined as centered in P0 if the positional phase is 0 or proportionally in between P0 and P1 if the positional phase is larger than 0.

Sum of all coefficients for each phase should be 128 typically; therefore coefficient 1 can be calculated from (1 - coefficient 0) and only coefficient 0 is programmed.

For each vertical positional phase, the filter coefficient requires 8 register bits. Note that color value ranges from 0 to 255 for Y, R, G, B and -128 to 127 for U and V.

Offset: 0x624 | Byte Offset: 0x1890 | Read/Write: R/W | Reset: 0x00000000 (0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx)

Bit	Reset	Description
7:0	X	C_V_FILTER_P0BC0: Phase 0B coefficient 0 (typically 40)

25.13.39 DC_WINC_C_V_FILTER_P0C_0

Window C Vertical Filter phase 0C

Offset: 0x625 | Byte Offset: 0x1894 | Read/Write: R/W | Reset: 0x00000000 (0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx)

Bit	Reset	Description
7:0	X	C_V_FILTER_P0CC0: Phase 0C coefficient 0 (typically 32)

25.13.40 DC_WINC_C_V_FILTER_P0D_0

Window C Vertical Filter phase 0D

Offset: 0x626 | Byte Offset: 0x1898 | Read/Write: R/W | Reset: 0x00000000 (0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx)

Bit	Reset	Description
7:0	X	C_V_FILTER_P0DC0: Phase 0D coefficient 0 (typically 24)

25.13.41 DC_WINC_C_V_FILTER_P0E_0

Window C Vertical Filter phase 0E

Offset: 0x627 | Byte Offset: 0x189c | Read/Write: R/W | Reset: 0x00000000 (0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx)

Bit	Reset	Description
7:0	X	C_V_FILTER_P0EC0: Phase 0E coefficient 0 (typically 16)

25.13.42 DC_WINC_C_V_FILTER_P0F_0

Window C Vertical Filter phase 0F

Offset: 0x628 │ Byte Offset: 0x18a0 │ Read/Write: R/W │ Reset: 0x00000000 (0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx)

Bit	Reset	Description
7:0	X	C_V_FILTER_P0FC0: Phase 0F coefficient 0 (typically 8)

The registers under DC_WIN are double buffered.

25.13.43 DC_WIN_C_WIN_OPTIONS_0

Window C Options

Class: Display Window Settings

Display Window C parameters

Offset: 0x700 │ Byte Offset: 0x1c00 │ Read/Write: R/W │ Reset: 0x00000000 (0bx0xxxxxxxxxxxx0x0xxxxxxxx0xxxx)

Bit	Reset	Description
30	0x0	C_WIN_ENABLE: Window C Window enable 0 = DISABLE 1 = ENABLE
22	X	C_YUV_RANGE_EXPAND: Window C Enable range expansion in the cases where RANGEREDFRM is 1 from mpd. Formula: Y = clip((Y-128)*2 + 128); Cb = clip((Cb-128)*2 + 128); Cr = clip((Cr-128)*2 + 128); where clip() function clips between 0 and 255. 0 = DISABLE 1 = ENABLE
20	X	C_DV_ENABLE: Window C Digital Vibrance Enable 0 = DISABLE 1 = ENABLE
18	X	C_CSC_ENABLE: Window C Color Space Conversion Enable. This controls the color space conversion and should be enabled for YCbCr/YUV color modes for conversion to B8G8R8 and for hue and saturation control. This can also be used for gain control for RGB color modes. 0 = DISABLE 1 = ENABLE
16	0x0	C_CP_ENABLE: Window C Color Palette Enable. This controls the color palette and should be enabled for palletized color modes. For non-palletized color modes, the color palette can be enabled for gamma correction. 0 = DISABLE 1 = ENABLE
14	0x0	C_V_FILTER_UV_ALIGN: Window C V Filter UV Alignment. This is effective only when vertical scaling filter is enabled and only on these formats YCbCr420P, YUV420P, YCbCr422R, YUV422R, YCbCr422RA YUV422RA. When UV alignment is enabled, the chroma components are aligned to the even number of luma component lines. When disabled the chroma components are aligned to half a pixel below the corresponding even number of luma component lines. It is usually disabled unless the incoming video stream specifically indicates otherwise. 0 = DISABLE 1 = ENABLE

Bit	Reset	Description
12	X	C_V_FILTER_OPTIMIZE: Window C V Filter Optimization. This is effective only when vertical scaling filter is enabled. This can be used (enabled) to temporarily disable the vertical scaling filter when the vertical scaling DDA fraction is zero. In this case the next line is not fetched from memory to save bandwidth and power. This feature cannot be used in 420P/422R/422RA formats. 0 = DISABLE 1 = ENABLE
10	X	C_V_FILTER_ENABLE: Window C V Filter Enable. This controls the V scaling filter and is effective only for non-palletized color modes. If V filter is disabled, only one line is read from memory for each output line. NOTE: This feature is not supported. This bit is ignored and is a don't care. 0 = DISABLE 1 = ENABLE
8	X	C_H_FILTER_ENABLE: Window C H Filter Enable. This controls H scaling filter and is effective only for non-palletized color modes. 0 = DISABLE 1 = ENABLE
6	X	C_COLOR_EXPAND: Window C 12/15/16/18-to-24 bpp color expansion. This bit should be enabled only for 12-bpp B4G4R4A4, 15-bpp B5G5R5A, 16-bpp B5G6R5, 18-bpp B6G6R6 color modes. If enabled, the color conversion is performed prior to horizontal scaling. 0 = DISABLE 1 = ENABLE
4	0x0	C_SCAN_COLUMN: Window C Scanning direction. 0= Scan in horizontal direction (for 0 or 180 degrees). 1= Scan in vertical direction (for 90 or 270 degrees) 0 = DISABLE 1 = ENABLE
2	X	C_V_DIRECTION: Window C Vertical (Y) drawing Direction 0 = INCREMENT 1 = DECREMENT
0	X	C_H_DIRECTION: Window C Horizontal (X) drawing Direction 0 = INCREMENT 1 = DECREMENT

25.13.44 DC_WIN_C_BYTE_SWAP_0

Window C Byte Swap

Offset: 0x701 │ Byte Offset: 0x1c04 │ Read/Write: R/W │ Reset: 0x00000000 (0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx)

Bit	Reset	Description
2:0	X	C_BYTE_SWAP: Window C Byte Swap. This controls byte swap of frame data read from memory prior to any data processing in the display module. 000= no byte swap (3 2 1 0) 001= byte swap for each 2-byte word (2 3 0 1) 010= byte swap for each 4-byte word (0 1 2 3) 011= word swap for each 4-byte word (1 0 3 2) 100= byte0 swapped with byte2 (3 0 1 2) 101= left shift every byte (2 1 0 3) 0 = NOSWAP 1 = SWAP2 2 = SWAP4 3 = SWAP4HW 4 = SWAP02 5 = SWAPLEFT

25.13.45 DC_WIN_C_COLOR_DEPTH_0

Window C Color Depth. For YCbCr data format, Cb and Cr are 8-bit unsigned values. For YUV data format, U and V are 8-bit signed values. YCbCr422R is similar to YCbCr422P but the Cb and Cr are shared vertically.

YUV422R is similar to YUV422P, but the U and V are shared vertically. YCbCr422RA is the same as YCbCr422R in memory and YUV422RA is the same as YUV422R in memory but while reading from memory, for YCbCr422RA and YUV422RA, chroma averaging is applied for each pixel pair so that they can be processed as YUV422 by the display pipeline.

For YCbCr422R and YUV422R, every other chroma pixels are not used (discarded) by the display pipeline. B6x2G6x2R6x2A8 is similar to B8G8R6A8 but with the 2 LSBs zeroed out. R6x2G6x2B6x2A8 is similar to R8G8B6A8 but with the 2 LSBs zeroed out.

Some formats have NVCF_ or T_ prefix aliases for NVidia surface format naming convention, wherein left-to-right component names correspond to MSB to LSB bits within a word. In old names without NVCF_ or T_, left-to-right component names generally map LSB to MSB within a word.

Offset: 0x703 │ Byte Offset: 0x1c0c │ Read/Write: R/W │ Reset: 0x0000000c (0bxxxxxxxxxxxxxxxxxxxxxxxxxxxx001100)

25.13.46 DC_WIN_C_POSITION_0

Window C Position

This register defines H position and size of Window C after scaling (if there is any)

Offset: 0x704 │ Byte Offset: 0x1c10 │ Read/Write: R/W │ Reset: 0x00000000 (0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx)

Bit	Reset	Description
28:16	X	C_V_POSITION: Window C V Position. This is specified with respect to the top edge of active display area.
12:0	X	C_H_POSITION: Window C H Position. This is specified with respect to the left edge of active display area.

25.13.47 DC_WIN_C_SIZE_0

Window C Size

This register defines V position and size of Window C after scaling (if there is any)

> **Note:** Programming on window size should guarantee the whole window is inside the active area, otherwise extra rows/columns will be fetched and discarded which affects performance.

Offset: 0x705 │ Byte Offset: 0x1c14 │ Read/Write: R/W │ Reset: 0x00000000 (0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx)

Bit	Reset	Description
28:16	X	C_V_SIZE: Window C V Size (lines). This is the vertical size after scaling.
12:0	X	C_H_SIZE: Window C H Size (pixels). This is the horizontal size after scaling.

25.13.48 DC_WIN_C_PRESCALED_SIZE_0

Window C Pre-scaled Size

This register defines Window C pre-scaled size.

The H pre-scaled size is needed to determine how many bytes to fetch from memory per line and this parameter must be programmed exactly as needed taking into account the scaling factor. For planar YUV or YCbCr data formats, this parameter refer to the H pre-scaled of the Y plane.

The total number of lines to be fetched from memory is determined by post-scale V size but V pre-scaled size is needed to 'clamp' the last valid line if the vertical DDA is exactly or slightly beyond the specified V pre-scaled size.

H pre-scaled size ideally should be in terms of pixel but then hardware needs to convert this precisely to bytes to determine the amount of data to request from memory.

Offset: 0x706 │ Byte Offset: 0x1c18 │ Read/Write: R/W │ Reset: 0x00000000 (0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx)

Bit	Reset	Description
28:16	X	C_V_PRESCALED_SIZE: Window C V Pre-scaled Size (lines). In 420P/422R/422RA formats, it must be even.
14:0	X	C_H_PRESCALED_SIZE: Window C H Pre-scaled Size (bytes). In 420P and 422P formats, it must be even.

25.13.49 DC_WIN_C_H_INITIAL_DDA_0

Window C H Initial DDA

The first pixel of the pre-scaled image is always used to output the first pixel, so essentially this is the same as forcing the H Initial DDA integer portion to 1 initially even though user typically programs this to 0. If it makes the implementation easier, it is possible to force software to program the Initial DDA integer portion to 1. Similarly with the V Initial DDA.

Offset: 0x707 │ Byte Offset: 0x1c1c │ Read/Write: R/W │ Reset: 0x00000000 (0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx)

Bit	Reset	Description
15:0	X	C_H_INITIAL_DDA: Window C H Initial DDA (4.12). This is typically programmed to 0.0

25.13.50 DC_WIN_C_V_INITIAL_DDA_0

Window C V Initial DDA

Offset: 0x708 │ Byte Offset: 0x1c20 │ Read/Write: R/W │ Reset: 0x00000000 (0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx)

Bit	Reset	Description
15:0	X	C_V_INITIAL_DDA: Window C V Initial DDA (4.12). This is typically programmed to 0.0 for both non-interlaced and interlaced sources.

25.13.51 DC_WIN_C_DDA_INCREMENT_0

Window C DDA Increment

DDA increment is typically calculated by dividing (Pre-scaled size in pixels - 1) by (Post-scaled size in pixels - 1). The result should be rounded up and expressed as 4.12 format (4-bit integer and 12-bit fraction). For non-filtered image this value can be

slightly larger so that it is not missing the last row/column. Reference programming values (H and V should be calculated separately depending on filter on/off and sizes):

- Filter on: min(round((prescaled_size_in_pixels - 1) * 0x1000 /(post_scaled_size_in_pixels - 1)), MAX)
- Filter off: min(round(prescaled_size_in_pixels * 0x1000 / post_scaled_size_in_pixels - 1) - 0.5), MAX)

Where the value of MAX is as follows:

- For V_DDA_INCREMENT: 15.0 (0xF000)
- For H_DDA_INCREMENT: 4.0 (0x4000) for 4 Bytes/pix formats.
  8.0 (0x8000) for 2 Bytes/pix formats.

They are theoretically the biggest values that guarantee not displaying beyond an image boundary. If the DDA increment is less than 1.0 then image will be upscaled and if DDA increment is more than 1.0, then the image will be downscaled.

Offset: 0x709 │ Byte Offset: 0x1c24 │ Read/Write: R/W │ Reset: 0x00000000 (0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx)

Bit	Reset	Description
31:16	X	C_V_DDA_INCREMENT: Window C Vertical DDA Increment (4.12). This should be set to 1.0 if there is no scaling. Maximum value is 15.0 regardless of the number of bytes per pixel.
15:0	X	C_H_DDA_INCREMENT: Window C Horizontal DDA Increment (4.12). This should be set to 1.0 if there is no scaling. The maximum value for downscaling depends on the number of bytes per pixel. For 4-byte/pixel modes (32-bpp) the maximum value is 4.0 and for all other modes the maximum value is 8.0.

25.13.52 DC_WIN_C_LINE_STRIDE_0

Window C Line Stride

Offset: 0x70a │ Byte Offset: 0x1c28 │ Read/Write: R/W │ Reset: 0x00000000 (0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx)

Bit	Reset	Description
31:16	X	C_UV_LINE_STRIDE: Window C Line Stride for Chroma. This is stride (in bytes) for planar YUV or YCbCr data formats for the chroma plane, with the restriction that it must be programmed to be multiples of 4 (16 if tiled or in horizontal flipping) This is not used (ignored) for other non-planar data formats.
15:0	X	C_LINE_STRIDE: Window C Line Stride. This is stride (in bytes) for all non-planar data formats. If the memory surface is tiled, the stride needs to be a multiple of 16. If H_DIRECTION of window C is set to DECREMENT, the stride also needs to be a multiple of 16. For planar YUV or YCbCr data formats, this is stride (in bytes) for the luma plane with the restriction that it must be multiples of 8 (16 if tiled or in horizontal flipping) For tiled surface this value may affect starting address of a window. Refer to the comment of START_ADDR for detail.

25.13.53 DC_WIN_C_BUFFER_ADDR_MODE_0

Memory Controller Tiling definitions

Offset: 0x70d │ Byte Offset: 0x1c34 │ Read/Write: R/W │ Reset: 0x00000000 (0bxxxxxxxxxxxxxxxx0xxxxxxxxxxxxxxx0)

Bit	Reset	Description
16	0x0	C_UV_TILE_MODE: Window C Memory surface tiling mode. For YUV planar pixel format, this specifies tiling mode for the U/V plane. 0 = LINEAR 1 = TILED

Bit	Reset	Description
0	0x0	C_TILE_MODE: Window C Memory surface tiling mode. For YUV planar pixel format, this specifies tiling mode for the Y plane. 0 = LINEAR 1 = TILED

25.13.54 DC_WIN_C_DV_CONTROL_0

Window C Digital Vibrance Control

If enabled, Digital Vibrance is applied after H and V scaling and after color palette or color space conversion logic but before color keying multiplexer and before cursor multiplexer.

- After DV, new R = R + (2R - G - B) * FR, where FR is fraction from 0 to 7/8
- After DV, new G = G + (2G - R - B) * FG, where FG is fraction from 0 to 7/8
- After DV, new B = B + (2B - R - G) * FB, where FB is fraction from 0 to 7/8

Offset: 0x70e │ Byte Offset: 0x1c38 │ Read/Write: R/W │ Reset: 0x00000000 (0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx)

Bit	Reset	Description
18:16	X	C_DV_CONTROL_B: Digital Vibrance control for B
10:8	X	C_DV_CONTROL_G: Digital Vibrance control for G
2:0	X	C_DV_CONTROL_R: Digital Vibrance control for R

25.13.55 DC_WIN_C_BLEND_NOKEY_0

Blend Control for this window area where color key is enabled but the pixel color is not within the color key range (color key not match). This is valid for all overlapping condition but only if there is no overlap with other window with higher priority color key enabled and color key not match.

Class: Display Color Keying and Blending

Color keying and blending of the display windows are done prior to cursor blending. Cursor always goes on top of the blended windows. Blending is controlled independently on each possible overlap area of the display windows. If 3 windows are enabled there are 7 possible overlap area combinations. For every window in each overlap area combination, color key can be disabled or enabled. Also, for every window in each overlap area combination, there is a corresponding window blend control parameter and a window blend weight parameter. The window blend control parameter is always effective but the window blend weight is not always used. The window blend weight can also be derived from pixel alpha value or from the reverse of other overlapping windows weight.

Color keying has the highest priority for display window blending. Color key consists of a range of color which is searched independently for each window. If more than 1 window color key is enabled, then Window A color key has the highest priority, followed by Window B color key, and then followed by Window C color key. Two sets of color key ranges (Color Key 0 and Color Key 1) can be defined; they are shared for all windows. It is possible to use both color key sets for the same window or for two separate windows.

The two sets of color key ranges should not overlap. If they do, the overlapped colors are treated as if they are part of Color Key 0 and not part of Color Key 1.

Assuming that there is no overlap with other higher priority window with color key not matched, if a window color key is enabled for any overlap condition and the window pixel is not within the color key range (key not match), then the window pixel

will not be blended with other overlapping window pixels but it will be weighted. The weight is not dependent on the overlap condition it is controlled by the same set of parameters for all overlapping condition.

Assuming that there is no overlap with other higher priority window with color key not matched, if a window color key is enabled for a particular overlap condition and the window pixel is within the color key range (key match), then the window pixel will be weighted and blended with other overlapping pixels and this is controlled separately for each overlap condition.

Assuming that there is no overlap with other higher priority window with color key not matched, if a window color key is disabled then the window pixel will be blended with other overlapping pixels and this is controlled separately for each overlap condition.

Display Color Key Parameters

For B4G4R4A4, B5G6R5A, and B5G6R5 modes, the color key should be compared prior to the color conversion to 24-bpp and the unused least significant bits of the pixel are filled with zeros.

For palletized mode, the color key is compared prior to the color palette, and the palletized color is compared against the green color key values/mask.

For YUV mode, U and V are offset by +128 before performing the color key comparison.

In all cases, the color key is compared prior to the horizontal/vertical scaling filter and prior to digital vibrance control.

Both upper and lower values are inclusive.

Offset: 0x70f │ Byte Offset: 0x1c3c │ Read/Write: R/W │ Reset: 0x00000000 (0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx)

Bit	Reset	Description
23:16	X	C_BLEND_WEIGHT1_NOKEY: Window blend weight 1 for color key not match areas. This is used only for alpha weight with 1-bit alpha and alpha value of 1.
15:8	X	C_BLEND_WEIGHT0_NOKEY: Window blend weight 0 for color key not match areas. For alpha weight, this is used for 1-bit alpha with value of 0.
0	X	C_BLEND_CONTROL_NOKEY: Window blend control for color key not match areas. 0 = Fix weight using window blend weight 0 for color key not matched. 1 = Alpha weight using the alpha value. This is only valid if the window color format includes an alpha value. For 1-bit alpha value, if the alpha is 0 window blend weight 0 is used and if alpha is 1, window blend weight 1 is used. 0 = FIX_WEIGHT 1 = ALPHA_WEIGHT

25.13.56 DC_WIN_C_BLEND_1WIN_0

Blend Control for this window area where it does not overlap with other windows.

Offset: 0x710 │ Byte Offset: 0x1c40 │ Read/Write: R/W │ Reset: 0x00000000 (0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx)

Bit	Reset	Description
23:16	X	C_BLEND_WEIGHT1_1WIN: Window blend weight 1 for color key disabled or color key enabled with key matched areas. This is used only for alpha weight with 1-bit alpha and alpha value of 1.
15:8	X	C_BLEND_WEIGHT0_1WIN: Window blend weight 0 for color key disabled or color key enabled with key matched areas. For alpha weight, this is used for 1-bit alpha with value of 0.
2	X	C_BLEND_CONTROL_1WIN: Window blend control in area where it does not overlap with other windows and either color key disabled or color key enabled with key matched. 0 = Fix weight using the window blend weight 0 if color key disabled or color key 0 enabled with key matched, or using the window blend weight 1 if color key 1 enabled with key matched.

Bit	Reset	Description
		1 = Alpha weight using the alpha value. This is only valid if the window color format includes an alpha value. For 1-bit alpha value, if the alpha is 0 window blend weight 0 is used and if alpha is 1, window blend weight 1 is used. 0 = FIX_WEIGHT 1 = ALPHA_WEIGHT
1:0	X	C_CKEY_ENABLE_1WIN: Window color key enable. 0 = Color Key 0 and 1 Disable 1 = Color Key 0 Enable 2 = Color Key 1 Enable 3 = Color Key 0 and 1 Enable 0 = NOKEY 1 = CKEY0 2 = CKEY1 3 = CKEY01

25.13.57 DC_WIN_C_BLEND_2WIN_A_0

Blend Control for this window area that overlaps with window A only.

Offset: 0x711 │ Byte Offset: 0x1c44 │ Read/Write: R/W │ Reset: 0x00000000 (0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx)

Bit	Reset	Description
23:16	X	C_BLEND_WEIGHT1_2WIN_A: Window blend weight 1 for color key disabled or color key enabled with key matched areas. This is used only for alpha weight with 1-bit alpha and alpha value of 1.
15:8	X	C_BLEND_WEIGHT0_2WIN_A: Window blend weight 0 for color key disabled or color key enabled with key matched areas. For alpha weight, this is used for 1-bit alpha with value of 0.
3:2	X	C_BLEND_CONTROL_2WIN_A: Window blend control in area where either color key disabled or color key enabled with key matched. 0 = Fix weight using the window blend weight 0 if color key disabled or color key 0 enabled with key matched, or using the window blend weight 1 if color key 1 enabled with key matched. 1 = Alpha weight using the alpha value. This is only valid if the window color format includes an alpha value. For 1-bit alpha value, if the alpha is 0 window blend weight 0 is used and if alpha is 1, window blend weight 1 is used. 2 = Dependent weight, in this case, the window blend weight is 1 - the weights of the other window that overlaps with this window. Only 1 of the overlapping windows may have this setting. 3 = Premultipled weight; in this case, the window blend weight is 1. But other windows that use DEPENDENT_WEIGHT get (1 - alpha value),like ALPHA_WEIGHT. This is only valid if the window color format includes an alpha value. This allows a blending equation like: result = win_b * 1 + (1 - win_b_alpha) * win_c 0 = FIX_WEIGHT 1 = ALPHA_WEIGHT 2 = DEPENDENT_WEIGHT 3 = PREMULT_WEIGHT
1:0	X	C_CKEY_ENABLE_2WIN_A: Window color key enable. 0 = Color Key 0 and 1 Disable 1 = Color Key 0 Enable 2 = Color Key 1 Enable 3 = Color Key 0 and 1 Enable 0 = NOKEY 1 = CKEY0 2 = CKEY1 3 = CKEY01

25.13.58 DC_WIN_C_BLEND_2WIN_B_0

Blend Control for this window area that overlaps with window B only.

Offset: 0x712 │ Byte Offset: 0x1c48 │ Read/Write: R/W │ Reset: 0x00000000 (0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx)

Bit	Reset	Description
23:16	X	C_BLEND_WEIGHT1_2WIN_B: Window blend weight 1 for color key disabled or color key enabled with key matched areas. This is used only for alpha weight with 1-bit alpha and alpha value of 1.
15:8	X	C_BLEND_WEIGHT0_2WIN_B: Window blend weight 0 for color key disabled or color key enabled with key matched areas. For alpha weight, this is used for 1-bit alpha with value of 0.
3:2	X	C_BLEND_CONTROL_2WIN_B: Window blend control in area where either color key disabled or color key enabled with key matched. 0 = Fix weight using the window blend weight 0 if color key disabled or color key 0 enabled with key matched, or using the window blend weight 1 if color key 1 enabled with key matched. 1 = Alpha weight using the alpha value. This is only valid if the window color format includes an alpha value. For 1-bit alpha value, if the alpha is 0 window blend weight 0 is used and if alpha is 1, window blend weight 1 is used. 2 = Dependent weight, in this case, the window blend weight is 1 - the weights of the other window that overlaps with this window. Only 1 of the overlapping windows may have this setting. 3 = Premultipled weight; in this case, the window blend weight is 1. But other windows that use DEPENDENT_WEIGHT get (1 - alpha value), like ALPHA_WEIGHT. This is only valid if the window color format includes an alpha value. This allows a blending equation like: result = win_a * 1 + (1 - win_a_alpha) * win_c. 0 = FIX_WEIGHT 1 = ALPHA_WEIGHT 2 = DEPENDENT_WEIGHT 3 = PREMULT_WEIGHT

25.13.60 DC_WIN_C_GLOBAL_ALPHA_0

Window C Global Alpha

When enabled, per pixel alpha values are scaled by GLOBAL_ALPHA before blending: a' = a * GLOBAL_ALPHA/255. When per pixel alpha is not used in blending, global alpha has no affect.

Note: 1 and 4 bits per pixel alpha are quantized back to 1 and 4 bits, respectively, after scaling. For the 1-bit alpha case, finer scaling can be achieved by changing BLEND_WEIGHT* instead.

Offset: 0x715 │ Byte Offset: 0x1c54 │ Read/Write: R/W │ Reset: 0x00000000 (0bxxxxxxxxxxxxxxxx0xxxxxxxxxxxxxxx)

Bit	Reset	Description
16	DISABLE	C_GLOBAL_ALPHA_ENABLE: When enabled, color palette *must* also be enabled and programmed. 0 = DISABLE 1 = ENABLE
7:0	X	C_GLOBAL_ALPHA: Global alpha: 0..255 map to 0.0 – 1.0. i.e., 255 yields no-operation. For power, better to set GLOBAL_ALPHA_ENABLE=DISABLE when GLOBAL_ALPHA=255.

25.14 WINBUF_C Registers

The registers under DC_WINBUF are triple-buffered.

25.14.1 DC_WINBUF_C_START_ADDR_0

Window C Start Address

Overview

START_ADDR, BUF_STRIDE, LINE_STRIDE, ADDR_H_OFFSET, ADDR_V_OFFSET combined, specify the starting address of a window buffer in the memory surface. Generally START_ADDR is programmed with the starting address of the memory surface. H/V_OFFSET specifies the address offsets of the pixel at the beginning of the window, with respect to the starting address of the memory surface. (There is an exception to that when memory surface is not well aligned, see “For linear address mode” under Programming Restrictions below.)

Note that "beginning of the window" here means the top-left corner of a window in normal mode, top-right corner in horizontal flipping, bottom-left corner in vertical flipping, and bottom-right in horizontal+vertical flipping.

Starting Address Calculation

These formulae are same for both tiled and linear modes. However, for linear mode, the addresses calculated are real physical addresses. For tiled mode, these addresses will be translated to the real physical addresses by the memory controller client before being used.

- When a window is host triggered, the starting address of a window is calculated as follows by hardware.
  - non-YUV-planar modes

    starting-address = START_ADDR + ADDR_V_OFFSET * LINE_STRIDE + ADDR_H_OFFSET
  - YUV-planar modes

    Y-starting-address = START_ADDR + ADDR_V_OFFSET * LINE_STRIDE + ADDR_H_OFFSET

    U-starting-address = START_ADDR_U + ADDR_V_OFFSET * UV_LINE_STRIDE / denom1 + ADDR_H_OFFSET / denom2

    V-starting-address = START_ADDR_V + ADDR_V_OFFSET * UV_LINE_STRIDE / denom1 + ADDR_H_OFFSET / denom2 where denom1/denom2 equal to 1 or 2 depending on the actual planar format, derived natively by hardware.
- When a window is non-host triggered, starting address of a window buffer is calculated as below.
  - non-YUV-planar mode

    starting-address = START_ADDR + BUF_STRIDE * buf_index + ADDR_V_OFFSET * LINE_STRIDE + ADDR_H_OFFSET
  - YUV-planar mode:

    Y-starting-address = START_ADDR + BUF_STRIDE * buf_index + ADDR_V_OFFSET * LINE_STRIDE + ADDR_H_OFFSET

    U-starting-address = START_ADDR_U + UV_BUF_STRIDE * buf_index + ADDR_V_OFFSET * UV_LINE_STRIDE / denom1 + ADDR_H_OFFSET / denom2

    V-starting-address = START_ADDR_V + UV_BUF_STRIDE * buf_index + ADDR_V_OFFSET * UV_LINE_STRIDE / denom1 + ADDR_H_OFFSET / denom2

    where denom1/denom2 are equal to 1 or 2 depending on the actual planar format, derived natively by hardware.

    buf_index is the index transmitted by the triggering module pointing to the first buffer of a frame.

Programming Restrictions

- For tiled address mode:

  Image surface can only aligned to multiples of 256, thus the following restrictions:

- START_ADDR, START_ADDR_U, START_ADDR_V need to be multiples of 256.
- BUF_STRIDE, UV_BUF_STRIDE need to be multiples of 256
- LINE_STRIDE, UV_LINE_STRIDE need to be multiples of 16
- ADDR_H_OFFSET needs to be even in yuv planar format, or a multiple of bytes per pixel in other formats. If H_DIRECTION=DECREMENT, however, it should point to last valid byte, which is an odd offset..
- ADDR_V_OFFSET needs to be multiple of 2 in YUV planar format, unless H_DIRECTION=DECREMENT, but with no restrictions on other color formats

- For linear address mode:

  Image surface can be aligned 2, 4, or 8 bytes, depending on the color formats.

  As an additional restriction for display, START_ADDR, START_ADDR_U and START_ADDR_V need to be multiples of 16. When a surface is not aligned to 16 bytes, program START_ADDR with the memory surface address with its least 4 significant bits zeroed out and add these 4 address bits to the original H_OFFSET. (So the formulae in Starting Address Calculation above still hold)

  - For all formats:

    START_ADDR, START_ADDR_U and START_ADDR_V need to be multiples of 16.

    For 16-bpp formats,

    (START_ADDR+H_OFFSET) need to be a multiple of 2.

    For 32-bpp formats,

    (START_ADDR+H_OFFSTE) needs to be a multiple of 4.

  - For YUV planar formats:

    BUF_STRIDE, UV_BUF_STRIDE:

    BUF_STRIDE[2:1]=UV_BUF_STRIDE[1:0]

    or as a stricter constraint: BUF_STRIDE be a multiple of 8, UV_BUF_STRIDE be a multiple of 4.

    LINE_STRIDE, UV_LINE_STRIDE:

    LINE_STRIDE and UV_LINE_STRIDE need to be at least 16.

    LINE_STRIDE needs to be a multiple of 8, UV_LINE_STRIDE needs to be a multiple of 4.

    ADDR_H_OFFSET: Needs to be even unless H_DIRECTION=DECREMENT, in which case should point to the last byte pixel, which is at an odd offset.

    ADDR_V_OFFSET: Needs to be even unless V_DIRECTION=DECREMENT, in which case should point to the last valid line, which is at an odd offset

- Memory allocation for non-host triggered case:

  When a window buffer is not controlled by host (software) then a frame may be stored in multiple buffers. In this case, the buffers must be contiguous in the memory because display will use the same luma or chroma line strides for all lines in the frame.

  Also buffer wraparound must not occur in the middle of the displayed part of the frame. The controlling module will send frame start and frame end indicators (flags) to display module to indicate the beginning and end of frame. Buffer start address is latched when frame start flag is active but the actual buffer start address is not switched until frame end flag is active. In the case where one buffer corresponds to one frame then frame start and frame end flag are active every time a buffer index is sent.

Bit	Reset	Description
12:0	0x0	C_UFLOW_THRESHOLD

25.14.22 DC_WINBUF_C_SPOOL_UP_0

Spool up time configuration for different windows related logic.

SPOOL_UP_CTRL = MAX - This is the current Tegra 4 behavior. This allows for memfetch to start fetching for a window (irrespective of its relative position on the screen), at the very beginning of the VBlank of the next frame. Since the spool up time is maximum, this should have the least probability of underflow of the display pipe. However, on the down side, since all three windows would start fetching at the same time, and since display is a high priority client for the MC, it has a high potential to starve out other clients.

SPOOL_UP_EDGE :- By default the memfetch start signal generated by the hvtgen logic is one line clock wide.

For SPOOL_UP_CTRL = MAX:

- If SPOOL_UP_EDGE is programmed to NEGEDGE, it ensures that if any act_req is sent during the time vcounter = 0 (at the beginning of the frame). The activate value is loaded into the active state and the memfetch would see the latest updated value.

  The downside of programming SPOOL_UP_EDGE to NEGDGE is 1 line clock worth of spool up is lost. This is required based upon Tegra compatibility.
- If SPOOL_UP_EDGE is programmed to POSEDGE, the memfetch starts fetching at the very beginning of the frame start pulse (1 line clock wide) and gives maximum spool up time. However, this may give test failure and potential Tegra compatibility issues as described above.

Offset: 0x827 | Byte Offset: 0x209c | Read/Write: R/W | Reset: 0x00000000 (0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx00)

Bit	Reset	Description
28:16	X	C_SPOOL_UP_DURATION

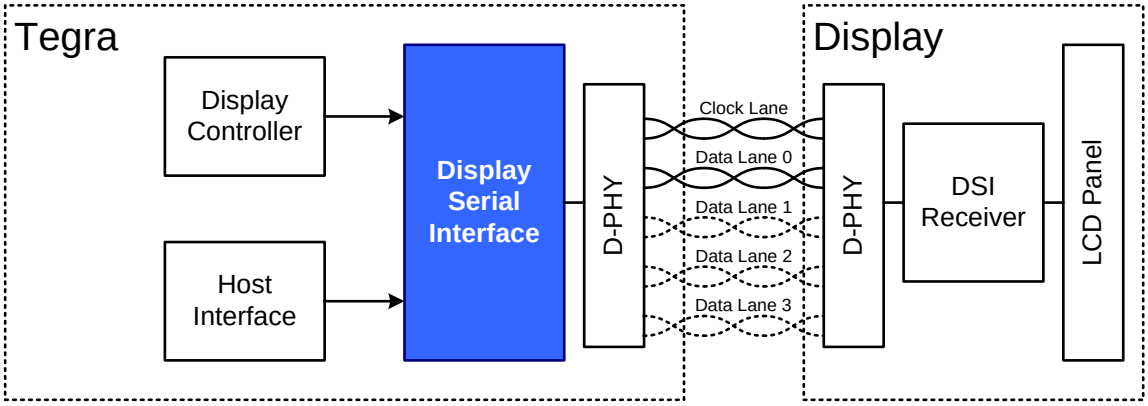
26.0 MIPI-DSI (DISPLAY SERIAL INTERFACE)

PRELIMINARY: Pending Review

The Display Serial Interface (DSI) is a MIPI standard serial bitstream that provides a low pin-count interface to a display panel. DSI reduces both package pin-count and I/O power consumption compared with parallel solutions. It transfers pixel data from either one of the display controllers (internal to the Tegra® 4 device) to an external third-party LCD module. The physical positioning of the DSI module in relation to other units / devices in the system is shown in Figure 106.

Figure 106: System Block Diagram



DSI is a replacement for the MIPI DPI and DBI standards and follows the use cases of these interfaces. From a data transport point of view, MIPI DPI is an interface similar to a traditional raster-based isochronous display interface, and DBI is an asynchronous packet based transfer mechanism. DSI behaves like MIPI DPI when in Video Mode, and implements a Command Mode to handle the DBI interface. Any implementation must implement both these modes of operation.

26.1 Functionality

26.1.1 Display Controller Interface

The interface between the display controller and the DSI unit consists of pixel data, Sync data, and a Line-Type code.

DSI captures the state of the line type code every line. This information is then used to look up a pre-programmed packet sequence that corresponds to that line type. There are several different line types to select from.

26.1.2 Packet Poster

The packet poster determines which packets will be sent on what video line when the DSI is in any of the 3 video modes and is being controlled by the display controller. The functions that this sub-unit performs are:

- Line type look-up
- Packet sequence generation
- Pixel data / packet stream integration

There are currently 6 valid line types that can be encoded on the 3 bits from the display controller. The other 2 line types are reserved for future use. The line type coding is shown in the following table.

Table 74: Line Type Descriptions

Line Type	Description
0	Blank line starting with VS
1	Blank line starting with VE
2	Blank line starting with HS
3	Active line
4	First blank line after active
5	First active line
6, 7	Reserved

The packet sequences corresponding to each line type are held in a pair of 32-bit registers. Each register holds three packet descriptors, and each packet descriptor has the following information:

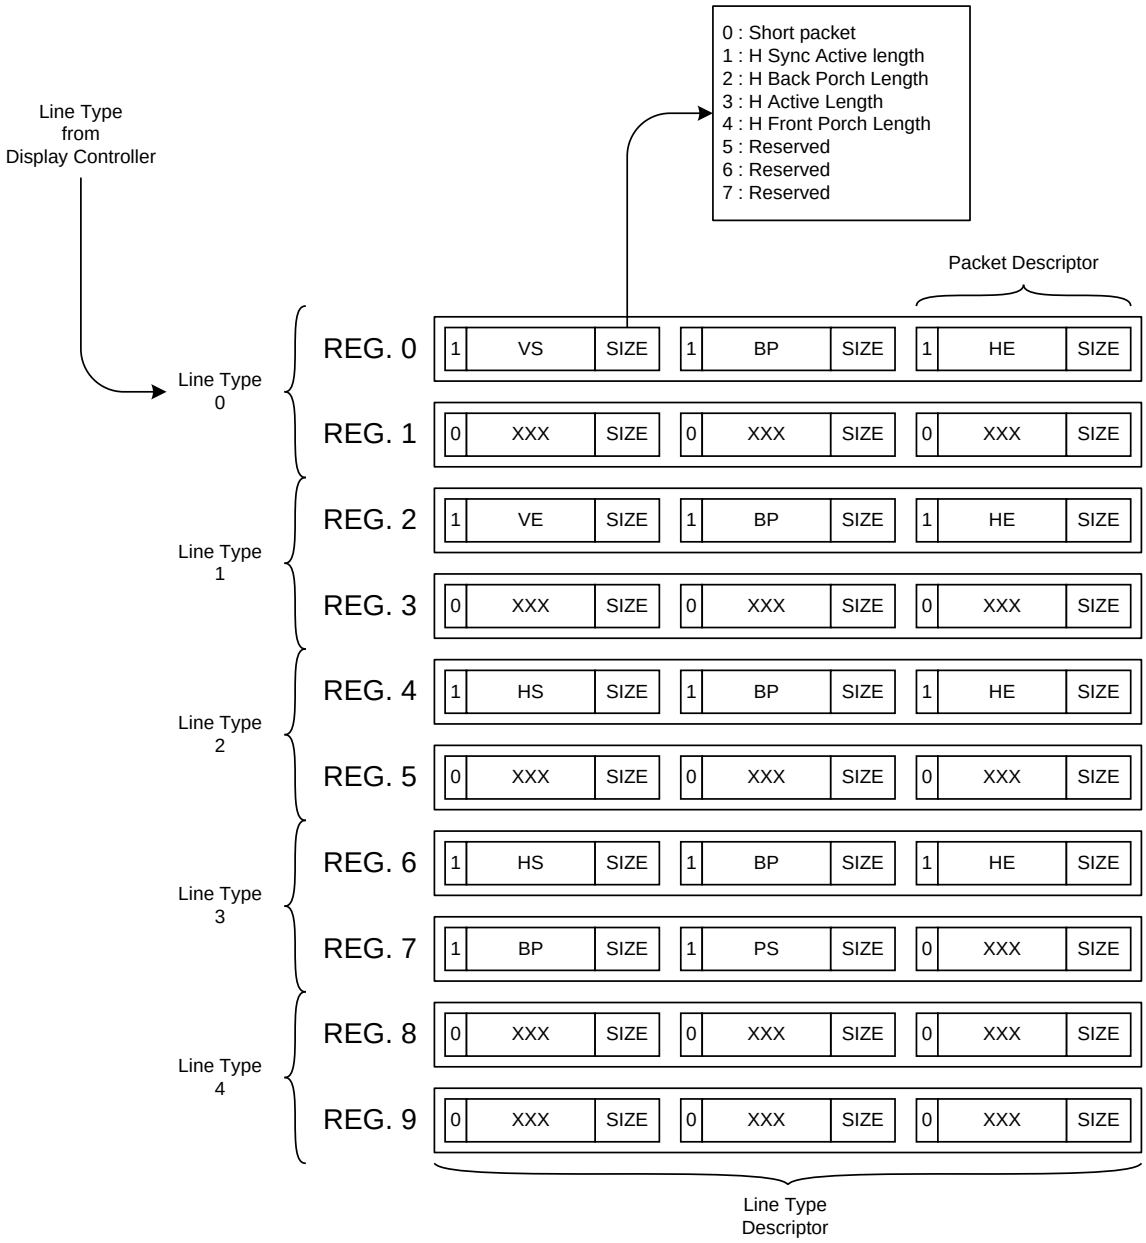
- Valid bit
- 6-bit packet ID
- 3-bit length index

The valid bit simply states whether or not a packet should be generated from that descriptor. A zero valid bit implies that no more packets in this packet sequence should be generated. Thus, the valid bit acts like a null terminator for the list of packet descriptors.

The packet ID is simply the MIPI DSI packet ID value. Software can therefore program any sequence of packets required for that line type.

Rather than have a 16-bit packet length field for every packet descriptor, the length is replaced by a 3-bit index which addresses the full 16-bit length for that packet type. This length is held elsewhere in separate length registers. A complete picture of the packet description data structures is shown in the following figure. This diagram shows typical packet mnemonics for the packets to be generated for video mode with sync pulses. By changing the programming of the packet sequences, any of the video modes, including burst mode, can be realized.

Figure 107: Line Type Look-up and Packet Sequence Descriptors



26.1.3 Host Interface

While many displays use a raster-based packet stream, in some applications it is more efficient to have a frame store in the display device itself and to only update the contents of the frame store when the required pixels have changed. For these types of displays, there is a software-accessible interface for sending command packets using the DSI command mode operation. This mode should also be used to access control and status registers within the display device.

The Host interface consists of a small FIFO for holding packet information and a special register for writing data into the FIFO. In this way, several packets may be queued up by software and sent in one HS burst. This is more efficient that sending the packets one at a time.

When very long sequences of packets are required to be sent – for example, when the host interface is emulating video mode, or where a large amount of data needs to be sent to the display device in one packet – it is possible for the host to use the large video line-store FIFO.

26.1.4 Clocking

The clocks in the DSI include:

- Host Clock = 275 MHz {Maximum frequency}
- Pixel Clock = 2.49 to 300 MHz for all modes.
- Application/Lane Management Byte Clock = function of lanes, pixel clock, pixel depth. 10 to 125 Mbps
- Fixed LP receive clock = 20 to 216 MHz
- Lane Bit clock = 40 to 500 MHz differential clock, DDR data (80 to 1000 bps).

More details on pixel clock/byte_clock selection are explained in the next section.

Pixel Clock / DSI Byte Clock Ratios

When running the DSI interface in one of the two non-burst video modes, the relationship between the DSI D-PHY bit-rate clock, the DSI byte-rate lane clock, and the display controller pixel clock must be exact. This will ensure that precise raster timing information is conveyed to the display peripheral.

There is always a fixed ratio of 8:1 between the D-PHY bit clock and the lane management layer byte clock since there are 8 bits in each byte that are serialized. Therefore, only relationships between pixel clock and byte clock and between pixel clock and bit clock will be discussed.

The relationship between pixel clock and byte clock is shown in Table 75. As can be seen, for some modes, these ratios are not simple powers of 2.

Table 75: Pixel Clock: Byte Clock for Various Modes

Lanes	Pixel Data Format			
	16 bpp	18 bpp (packed)	18 bpp	24 bpp
1	1:2	4:9	1:3	1:3
2	1:1	8:9	2:3	2:3
3	3:2	12:9	1:1	1:1
4	2:1	16:9	4:3	4:3
5	5:2	20:9	5:3	5:3
6	3:1	8:3	2:1	2:1
7	7:2	28:9	7:3	7:3
8	4:1	32:9	8:3	8:3

Because the pixel clock is effectively derived from the D-PHY bit clock, it can be more instructive to look at the number by which you must divide the bit clock to get the correct pixel clock. This information is shown in Table 76. Here, the numbers look reasonable except for the problematic cases of 16bpp over a 3-lane link and 18 bpp (packed) over a 4 lane link. For these two situations, you cannot simply divide the bit rate clock by some integer to arrive at the pixel clock. Moreover, if you need a 50:50 duty cycle for the pixel clock, then you will need to toggle the pixel clock every N/2 bit clock cycles, where N is the number in Table 76. However, if you do this, 18 bpp (packed) over 2 lanes also becomes a problem.

Table 76: Value to Divide Bit Clock by to Get Pixel Clock

Lanes	Pixel Data Format			
	16 bpp	18 bpp (packed)	18 bpp	24 bpp
1	16	18	24	24
2	8	9	12	12

Lanes	Pixel Data Format			
	16 bpp	18 bpp (packed)	18 bpp	24 bpp
3	16 / 3	6	8	8
4	4	9 / 2	6	6
5	16/5	18/5	24/5	24/5
6	8/3	3	4	4
7	16/7	18/7	24/7	24/7
8	2	9/4	3	3

Table 77: Value of Shift Clock Divider to Get Pixel Clock (Non-Burst Mode)

Lanes	Data Format (16 bpp)	Data Format (18 bpp)	Data Format (24 bpp)
1	14	16	22
2	6	7	10
3	3.333334	4	6
4	2	2.5	4
5	1.6	1.8	2.4
6	0.666667	1	2
7	1.14285714	1.285714286	1.714285714
8	0	0.25	1

Note: The fractional values in the above table cannot be supported through configuration fields because of a possible limitation in programming the shift divider for deriving the pixel clock from the byte clock in non-burst mode, that is, the SHIFT_CLK_DIVIDER field of the DC_DISP_DISP_CLOCK_CONTROL_0 field. This limitation occurs only in non-burst video mode.

To resolve these issues, derive the display controller pixel clock from a separate PLL and then lock that PLL to the DSI D-PHY PLL using a phase comparator and the appropriate divide ratios obtained from the tables.

DSI PLL – Clock Mux

In the Tegra 4 device, the DSI implements a clock mux for the clock selection of the write clock domain to the line buffer and its upstream path in the DSI.

A single DSI instance receives a pixel data stream from either of the display controller heads. The single bit register field dsi_vid_src in the dsi_clk domain selects the active display head. The selected display pixel clock provides the necessary clocking to the front end of the DSI.

In cases where the Host transmission uses the line buffer, dsi_clk can provide the necessary clocking using the single bit register field pkt_wr_fifo_sel.

26.2 Modes of Operation

The DSI operates in two transmission modes: Video and Host/Command

26.2.1 Video Mode

Communication with the peripheral is by isochronous data transfer similar to a typical video interface. There is no Bus Turn Around permitted in Video Mode, though there is a mandatory period of LP operation at least once per frame. There are three different sub-modes of Video Mode. These are outlined below:

Non-Burst Mode with Start and End

In this mode, the DSI must match the timing of a traditional video raster as closely as possible. This means all information about the start and end of parameters like vertical and horizontal sync, front and back porches must be conveyed to the receiving peripherals via the timing of the transmission of the High-Speed sync packets.

Non-Burst Mode without Start and End

This is like Non-Burst Mode with Start and End, except that the Sync-Active and Sync-End packets are not sent. Pixels must still be delivered at the correct rate.

Burst Mode

Only the timing of Sync-Start packets is required to be accurately conveyed in this mode. The data rate of the pixel data is arbitrary and is typically higher than the pixel rate of the peripheral. This allows time to transmit other information during the periods where no more pixels are needed.

26.2.2 Host/Command Mode

Communication with the peripheral is by asynchronously timed and variable length packets. The packets may contain video data (Display Controller/Host) or control data. In Command Mode, return (read) data can be requested from the peripheral. The DSI will issue a Bus Turn Around (BTA) request and relinquish control of the bus to the peripheral.

26.3 FIFO Buffers

26.3.1 Video Mode Operation

26.3.1.1 Writing Data

The following packets are written into the large data FIFO based on the various triggering events described.

Table 78: FIFO Trigger Events

Trigger Event	Packet
Leading edge of Vertical Sync.	VSync Start
Trailing edge of Vertical Sync	VSync End
Leading edge of Horizontal Sync, *unless* simultaneous with leading or trailing edge of vertical sync	HSync Start
Trailing edge of Horizontal Sync	HSync End
Immediately following VS, HS, VE or HE packets. Packet Word Count determined by display controller timing parameters.	Blanking packet
Immediately following blanking packet	Pixel Stream packet (16, 18, or 24 bits/pixel)

26.3.1.2 Reading Data

The initiation of the reading of the FIFO is triggered by a delayed version of the horizontal sync pulse from the display controller. The delay should be sufficient that the FIFO will not completely drain as reading of the FIFO continues. However, the delay should not be so long as to cause the FIFO to overflow with data.

26.3.2 Command Mode Operation

26.3.2.1 Writing Data from the Display Controller

Upon receipt of the leading edge of Vertical Sync, the display controller sends whatever DCS command packets are required to initialize the display to receive pixels. Then, as pixels start to arrive from the display controller, a DCS Long Write packet is sent – one per line – which contains the pixel data for that line. No synchronization or blanking packets should be sent. Data packets continue to be sent until the end of the active period. Like video mode packets, there is no need to calculate ECC or CRC words, as this is performed by the hardware on the other side of the data FIFO.

The Packet Sequence registers behave in the same manner as they do for Video Mode packet generation with the following exceptions:

- For Long packets, a DCS command ID byte must be inserted as the first byte of the data payload of the packet, ahead of the pixel data. The packet header Word Count must be 1 more than the number of bytes in the pixel data to take into account this extra byte. It is the responsibility of software to make sure the packet length is programmed correctly.
- For Line Type 4, any data contained in the Host Data FIFO should be appended to the end of any packets defined in the Packet Sequence for Line Type 4. In this way, the Host may send DCS commands to the Display Peripheral while the Display Controller is sending pixel information to the Display Peripheral.

26.3.2.2 Writing Data from the Host

The host should choose which data FIFO – small or large – to use prior to sending packet information. The large data FIFO is only available if the display controller is not currently using it. The software is responsible for constructing whatever packets are required for the desired operation and should be written into the FIFO via the host. There is no need for the software to compute ECC or CRC words, because this is performed by the hardware on the other side of the data FIFO.

26.3.2.3 Reading Data

The initiation of the reading of data from the FIFO is triggered by a FIFO threshold. Once the threshold is reached, the D-PHY starts to drain the FIFO, and the packets are sent to the display. The threshold should be set such that there is no danger of either FIFO overflow from excessive data from the host or display controller, or FIFO underflow caused by a lack of sufficient data in the FIFO.

26.3.3 FIFO Sizing

This subsection provides the threshold calculations for video non-burst and non-burst with sync ends modes.

- InRate = pixClk (pixel clock)
- OutRate = (PhyClk x LaneNum) / BytePerPix
- Length = Input frame width (length in pixels)
- Threshold = Minimum FIFO depth to start transfer of data to CIL
- Length/OutRate > (Length – Threshold) / InRate
- Threshold > Length * (1 – InRate / OutRate)

Table 79: Output Rates and Thresholds for Width = 800, PhyClk = 128 MHz

Data Format		Number of Lanes			
Bytes per Pixel		**1**	**2**	**4**	**8**
16	Out Rate	62.5	250	10000	4000
	Threshold	199.68	343.2	385.8	396.45
18 (Packed)	Out Rate	55.55	222.22	888.88	3555.55
	Threshold	207.72	378.1	432	445.5
24/18 (Loose)	Out Rate	41.66	166.66	666.66	2666.66
	Threshold	209.28	472.2	568	592

26.4 Programming Guidelines

The packet timing diagrams in this section use the following key:

Figure 108: Video Mode Timing Diagram Key

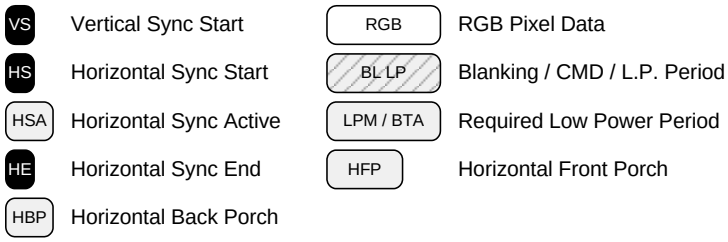


Table 80: Timing Diagram Parameter List

Parameter	Description
tHBP	Horizontal Back Porch period
tHACT	Horizontal Active period
tVBP	Vertical Back Porch period
tVACT	Vertical Active period
tVFP	Vertical Front Porch period
tL	Total line period

26.4.1 Initialization

The start-up and shut-down procedures vary depending on what mode of operation is required. Examples of programming sequences for the main modes are given below.

26.4.1.1 PLLD Programming

The DSI PLL is called PLLD in the Tegra 4 devices. Just like the other PLLs in the system, the PLLD has M, N, and P registers for programming the various divide ratios for the clock. When used to drive the Display pixel clock and DSI byte clock, the P divider is not used. Instead, there is a second divider that is used specifically for obtaining the Display pixel clock. The division ratio is labeled as D in the code below, but the correct name of the register should be used when programming the PLL.

```
//**** Environment ... ****

const float Fomin = 80.0;   // Min. oscillator frequency (MHz)
const float Fomax = 1000.0; // Max. oscillator frequency (MHz)
const float Fcmin = 1.0;    // Min. PLL phase comparison frequency (MHz)
```

```
const float Fcmax = 6.5;    // Max. PLL phase comparison frequency (MHz)

// MIPI Pixel formats ...
typedef enum { BIT16P, BIT18P, BIT18NP, BIT24P } pixel fmt;

//**** PLL Programming Information ... ****

int   M;         // Value by which the Reference clock is divided
                 // to get the comparison frequency
int   N;         // Value by which the Oscillator clock is divided
                 // to get the comparison frequency
int   D;         // Ratio between D-PHY bit clock and pixel clock

float Fosc;      // PLL oscillator frequency, in MHz   (information only)
float Fcomp;     // Phase comparator frequency, in MHz (information only)

//**** Function that computes the values of M, N and D ... ****

bool calc M N D(float Fref, float Fpixel, float tolerance,
                pixel fmt fmt, int lanes)

/******************
  Fref      : Input Reference frequency - in MHz
  Fpixel    : Desired output pixel clock frequency
  tolerance : Fractional error allowed in the output frequency
  fmt       : Pixel format. One of BIT16P, BIT18P, BIT18NP and BIT24P
  lanes     : Number of DSI lanes in use
  Function returns "true" on success and "false" otherwise
*******************/

{
  float Nfrac;
  bool  done = false;

  // Compute the value of D ...

  switch (fmt) {
    case BIT16P  : D = 16; break;
    case BIT18P  : D = 18; break;
    case BIT18NP :
    case BIT24P  : D = 24; break;
    }

  D = D / lanes;
  Fosc = Fpixel * clk ratio; // Calculate the Oscillator Frequency

  // Compute the values of M and N ...

  if ((Fosc > Fomin) && (Fosc < Fomax)) {
   // If the oscillator frequency is "legal" ...
    M = (int)(0.99 + Fref / Fcmax);
    do {
      // For each value of M, compute the comparison frequency
```

```
      Fcomp = Fref / (float)(M);
      // Now compute the exact value of N ...
      Nfrac = Fosc / Fcomp;
      // Strip off the integer and fractional parts ...
      N     = (int)(Nfrac);
      Nfrac = Nfrac - (float)(N);
      if (N > 0) {
        if ((Nfrac / N) < tolerance)
          // If the error is less than the tolerance, then we're done
          done = true;
        else
          // Too much error, so try dividing the reference some more ...
          M++;
        }
      else // N too small, so divide the reference by some more ...
        M++;
      } while (!done && (M < 32) && (Fcomp > Fcmin));
    }

  return (done);
}
```

26.4.1.2 Video Mode Start-up

All 3 video modes – Burst, Non-Burst and Non-Burst with Sync Ends –have the same start-up sequence with a slight variation between Burst and Non-Burst modes:

- Set up the clocks. This involves configuring and enabling the DSI PLL (PLLD). For Non-Burst and Non-Burst with Sync End modes, the Display Controller must also be programmed to take its pixel clock from the DSI PLL. For Burst Mode, the Display Controller can take its pixel clock either from the DSI PLL or from another clock source. Program the PLLD registers with the correct OSC_FREQ and program the PLLD_BASE register. In addition, the PLLP must be running in order to provide the LP receive clock. Program the PLLP registers with the correct OSC_FREQ and program the PLLP_BASE register.
- Depending on the sub-mode, the various Packet Sequence registers and Packet Length registers must be programmed.
- Set the `VID_TX_TRIG_SRC` field in the `DSI_CONTROL` register to `SOL` to select which display controller will source the video data.
- Enable the DSI
- Program the display controller to produce the raster size required
- Enable the display controller

When the display controller starts sending SOL and data, the DSI automatically starts creating and transmitting packets to the display device.

26.4.1.3 Command Mode Start-up

- Set up the clocks. Program and enable the DSI PLL (PLLD). In addition, the PLLP must be running in order to provide the LP receive clock. Program the PLLP registers with the correct OSC_FREQ and program the PLLP_BASE register. Unlike the Video modes, the selection of the PLLD output clock frequency is essentially arbitrary. The clock frequency should be based on the expected data throughput and the requirements of the particular display device. Program the PLLD registers with the correct OSC_FREQ and program the PLLD_BASE register. In addition, the

PLLP must be running in order to provide the LP receive clock. Program the PLLP registers with the correct OSC_FREQ and program the PLLP_BASE register.

- Set the HOST_TX_TRIG_SRC field in the HOST_DSI_CONTROL registers to `IMMEDIATE`. Set any other state required.
- Enable DSI.

The DSI should now be ready to accept command packets written to the DSI_WR_DATA register.

26.4.2 Video Mode Programming

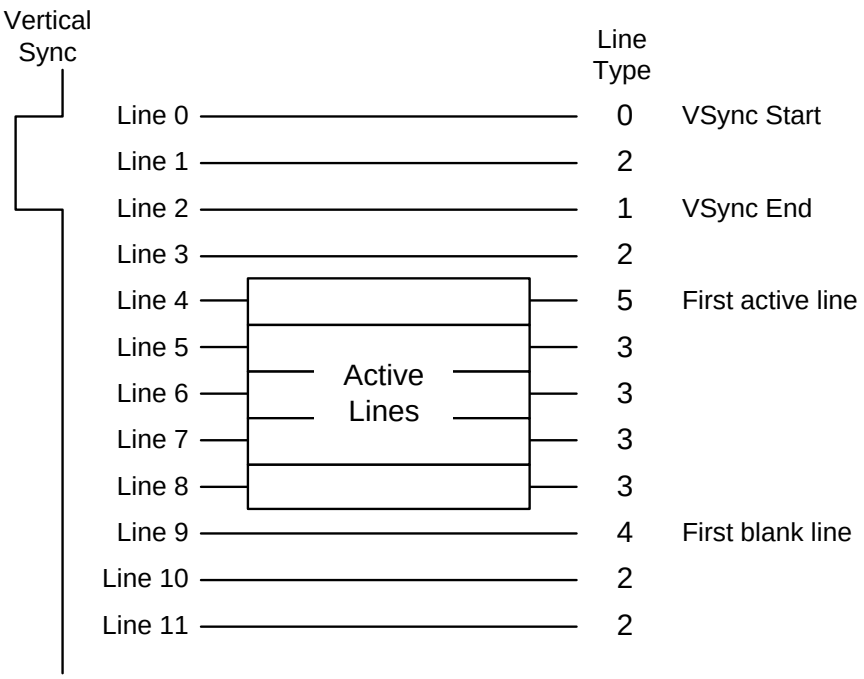
The programming model has been designed to accommodate current video mode sequences and potentially future variation. Each line of video output is associated with a “line type”. This line type is automatically generated by the display controller hardware according to the following table.

Table 81: Line Type Descriptions

Line Type	Description	Typical raster position
0	Blank line starting with VS	First line of the raster
1	Blank line starting with VE	Line corresponding to Vsync end.
2	Blank line starting with HS	Vertical blanking line
3	Active line starting with HS	Active line
4	First blank line after active	First blank line after active
5	First active line	First active line
6, 7	Reserved	

Figure 109 illustrates a typical raster showing the relationship between various events in the raster and the line types.

Figure 109: Example Video Raster Showing Line Types



The line type acts like a pointer to a data structure containing the information about the “*packet sequence*” for that line type. The packet sequence information is actually held within a pair of registers. For example, the packet sequence for line type 0 is

held in the pair of registers DSI_PKT_SEQ_0_LO and DSI_PKT_SEQ_0_HI. Each pair of packet sequence registers contains all the information required to generate up to 6 packets. This is sufficient to generate any packet sequence for any DSI video line. The information stored for each packet is shown in the following table:

Table 82: Packet Sequence Description Fields

Field	No. bits	Description
PKT_*_SIZE	3	Pointer to packet size register
PKT_*_ID	6	Packet ID as defined in the MIPI DSI spec.
PKT_*_EN	1	Enable. Determines which packets are active.

Using the same pair of registers as an example, Table 83 shows how all six packet descriptors fit into the pair of 32-bit packet sequence registers.

Table 83: Packet Sequence 0 Registers

Register	Field	Bits	Description
DSI_PKT_SEQ_0_LO	PKT_00_SIZE	2:0	Packet 0 Size
	PKT_00_ID	8:3	Packet 0 ID
	PKT_00_EN	9	Packet 0 Enable
	PKT_01_SIZE	12:10	Packet 1 Size
	PKT_01_ID	18:13	Packet 1 ID
	PKT_01_EN	19	Packet 1 Enable
	PKT_02_SIZE	22:20	Packet 2 Size
	PKT_02_ID	28:23	Packet 2 ID
	PKT_02_EN	29	Packet 2 Enable
	SEQ_0_FORCE_LP	30	End in LP state
DSI_PKT_SEQ_0_HI	PKT_03_SIZE	2:0	Packet 3 Size
	PKT_03_ID	8:3	Packet 3 ID
	PKT_03_EN	9	Packet 3 Enable
	PKT_04_SIZE	12:10	Packet 4 Size
	PKT_04_ID	18:13	Packet 4 ID
	PKT_04_EN	19	Packet 4 Enable
	PKT_05_SIZE	22:20	Packet 5 Size
	PKT_05_ID	28:23	Packet 5 ID
	PKT_05_EN	29	Packet 5 Enable

Finally, the SIZE field in the packet descriptor is used as a pointer to a 16-bit "*packet length*" field in the packet length registers. An indirect pointer is used rather than storing the packet length directly in the packet descriptor because the packet lengths are physically large – 16 bits – but there is a lot of re-use. There are only a few different lengths used in a typical raster layout. Thus, it is more efficient to hold the lengths in separate length registers and then to simply refer to them with a short pointer. This allows the storing of 36 packet descriptors in only 6 pairs of packet sequence registers.

Note that one of the packet length registers is reserved for short packets. If a `SIZE` field in the packet descriptor is programmed to 0, this packet is likely a short packet. Short packets are fixed in length to 4 bytes including the packet header byte and ECC byte. In the context of video mode, they are essentially reserved for timing packets. All other packet length registers can be used to determine the length of any associated long packet.

The `SEQ_0_FORCE_LP` bit is used to determine if the link should be placed in the LP state at the end of the packet transmission. In Burst Mode operation, the link always drops back into LP state at the end of the HS packet transmission on a line. However, for Non-Burst Modes, the HS transmission may continue to the next line. It is important the that the hardware

state machine that generates packets not attempt to go to the LP state, but should instead prepare for the next sequence of packets associated with the next video line and keep the line in the HS transmission state.

The packet length registers are shown in Table 84. The packet size pointer in the packet descriptor can point to any of the available length registers – with the one exception of short packets, whose SIZE field must point to length register 0. It is recommended that the suggested packet length assignment for various length registers is followed to reduce confusion when debugging packet descriptors and packet sequences.

Table 84: Packet Length Registers and Assignments

Register	Field	Suggested Assignment
DSI_PKT_LEN_0_1	LENGTH_0	Must be used for short packets
	LENGTH_1	Horizontal sync active length (HSA)
DSI_PKT_LEN_2_3	LENGTH_2	Horizontal back porch length (HBP)
	LENGTH_3	Horizontal active length (ACTIVE)
DSI_PKT_LEN_4_5	LENGTH_4	Horizontal front porch length (HFP)
	LENGTH_5	- reserved -
DSI_PKT_LEN_6_7	LENGTH_6	- reserved -
	LENGTH_7	- reserved -

When programming the length registers, remember that these contain byte counts, not pixel counts. Therefore, the DSI pixel format, number of DSI lanes in use and the finite (non-zero) size of the packet header and CRC words should be taken into account when programming these values – especially for blanking packets since all of these parameters affect the number of bytes that should be used to emulate a specific blanking time. The equations required to determine the byte count in the packets are given in the examples that follow. The identification of the length given in the tables and equations has been included in three video mode examples so that the values in the examples can be easily tied to the registers.

26.4.3 SOL Delay Programming

In order to ensure that the pixel FIFO from display to DSI does not underflow when in video mode, it is necessary to delay the start of packet generation by the DSI by a fixed amount from the arrival of the SOL signal from the display. This is especially true of Burst-Mode, because the DSI byte clock can be very much faster than display pixel clock. If no delay is applied, the DSI will very quickly consume all the pixels in the FIFO and the FIFO will underflow. The SOL_DELAY registers are used to set this delay.

26.4.3.1 Non-Burst Mode

In non-burst mode, the rate at which the DSI consumes pixels is the same as the rate at which the display module produces them, so it is merely sufficient to ensure that enough pixels have been fed into the FIFO to overcome the internal latency. This internal latency is approximately 8 pixel clock cycles. However, SOL_DELAY is programmed in DSI byte clocks, so the pixel format and the number of lanes being used should be taken into account when programming this value. Contact your NVIDIA FAE for details on the relationship between display pixel clock and byte clock. These ratios are then used to determine the value of SOL_DELAY as follows:

SOL_DELAY = (((Sol2VldDly) + 12) * F_{DSI} / Fpixel) + FifoLatency

FifoLatency = Ceil (2 * (F_{DSI} / Fpixel)) + 6

Sol2VldDly = Hsync start to Pixel valid delay

Where F_{DSI} and F_{pixel} are the DSI byte and pixel clocks, respectively.

Alternatively, a fixed value of SOL_DELAY that will work for all pixel formats and numbers of lanes can be programming by taking the worst-case ratio of 1:3 (pixel:byte) clock and multiplying by 8 to give SOL_DELAY = 24.

26.4.3.2 Burst Mode

In Burst mode, not only must the pixel format, number of lanes, and the DSI / pixel clock ratio be taken into account, but also the horizontal back porch time (including Hsync) and the Horizontal active time. So, for Burst mode:

- When EOTp packets are enabled:

  SOL_DELAY = (((Sol2VldDly + 4 + Tactive + 1) * FDSI / Fpixel) –

  ((Tactive + 1) * FDSI_NB / Fpixel_NB))) + FifoLatency

- When EOTp packets are not enabled:

  SOL_DELAY = (((Sol2VldDly + 4 + Tactive) * FDSI / Fpixel) –

  ((Tactive) * FDSI_NB / Fpixel_NB))) + FifoLatency

That is,

FifoLatency = Ceil (2 * (FDSI / Fpixel)) + 6

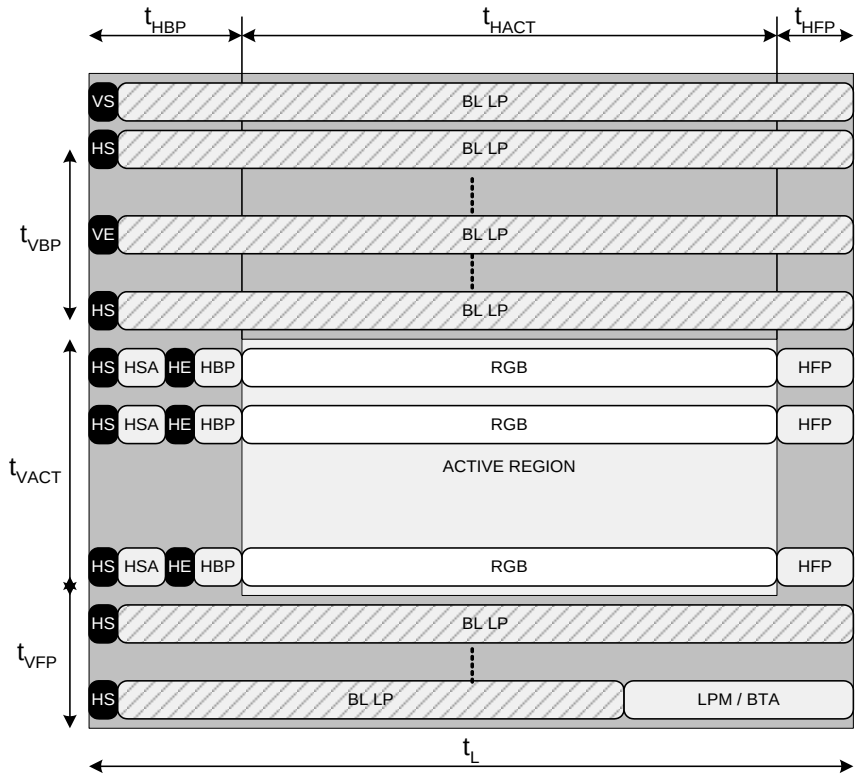
Sol2VldDly = Hsync start to Pixel valid delay

Where the ratio F_{DSI_NB} / F_{pixel_NB} is determined by the clock ratio tables for Non-Burst mode, according to the pixel format used and the number of active lanes.

26.4.4 Non-Burst Mode with Start and End

This mode conveys traditional raster synchronization information across the link to the peripheral by sending both start and end sync packets.

Figure 110: Timing Diagram for Video Non-Burst Mode with Start and End



During the Vertical Active period, all packets should be concatenated into a single HS transmission for the duration of the Vertical Active period.

The figure below shows how a single line is constructed from multiple packets.

Figure 111: Non-Burst Mode with Start and End Packet Timing Detail

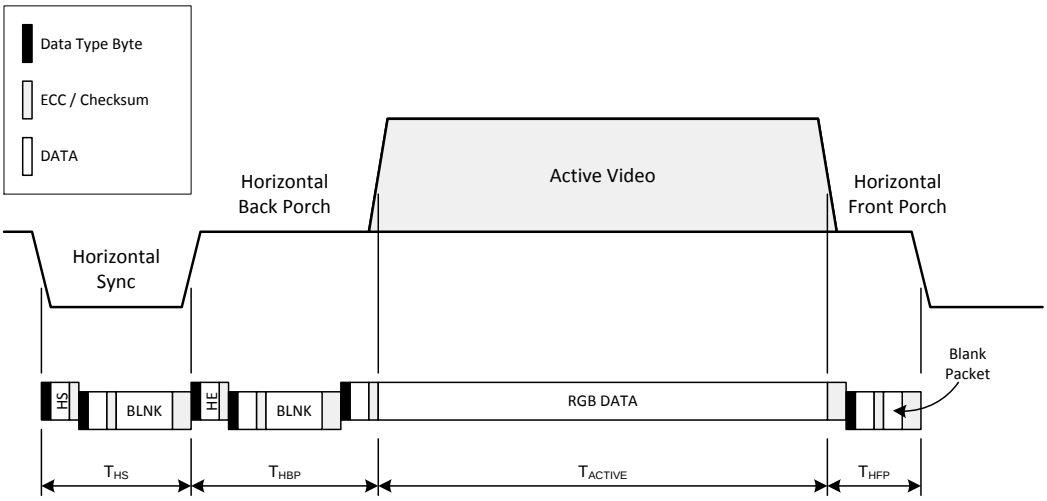


Table 85: Payload Size Table - Non-Burst Mode with Start and End

Packet	Payload Size (Bytes)
HSA	(T_{HS} * B) – 10
HBP	(T_{HBP} * B) – 14
ACTIVE	(T_{ACTIVE} * B)
HFP	(T_{HFP} * B) – 8

B = 2, 2.25 or 3, depending on pixel format.

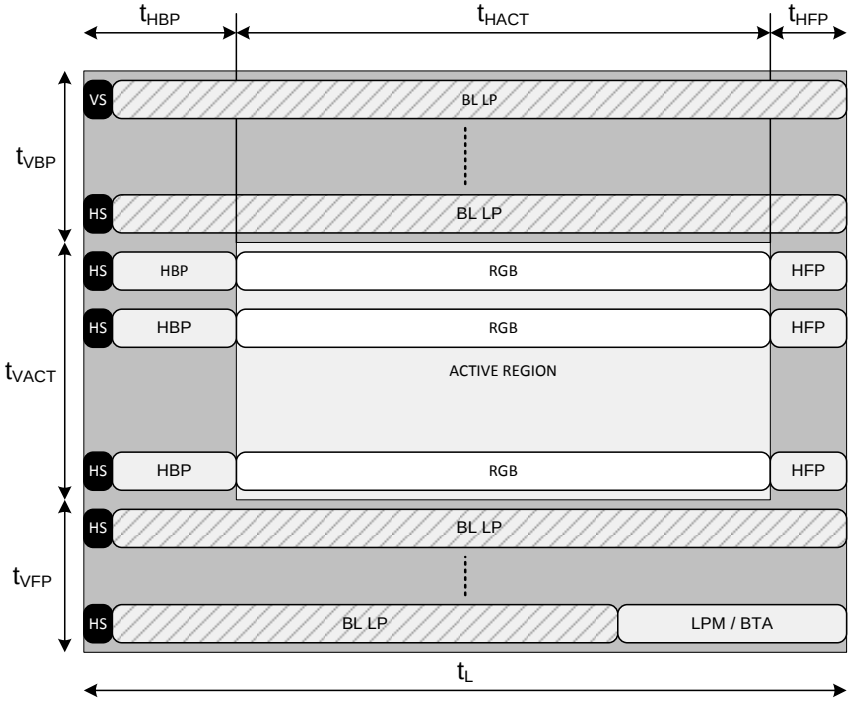
Table 86: Line Type Packet Sequences - Non-Burst with Sync Ends

LT	ID	Len	ID	Len	ID	Len	ID	Len	ID	Len	ID	Len
0	VS	0	EOT	7								
1	VE	0	EOT	7								
2	HS	0	EOT	7								
3	HS	0	BLNK	1	HE	0	BLNK	2	RGB	3	BLNK	4
4	HS	0	EOT	7								
5	HS	0	BLNK	1	HE	0	BLNK	2	RGB	3	BLNK	4

26.4.5 Non-Burst Mode (without Ends)

This mode relaxes the requirement to mimic the generation of sync pulses and merely mandates that the start of the line is indicated and that the pixels appear at the same rate and in the same area of the raster as a tradition raster structure.

Figure 112: Timing Diagram for Video Non-Burst Mode



During the Vertical Active period, all packets should be concatenated into a single HS transmission for the duration of the Vertical Active period.

The figure below shows how a single line is constructed from multiple packets.

Figure 113: Non-Burst Mode Packet Timing Detail

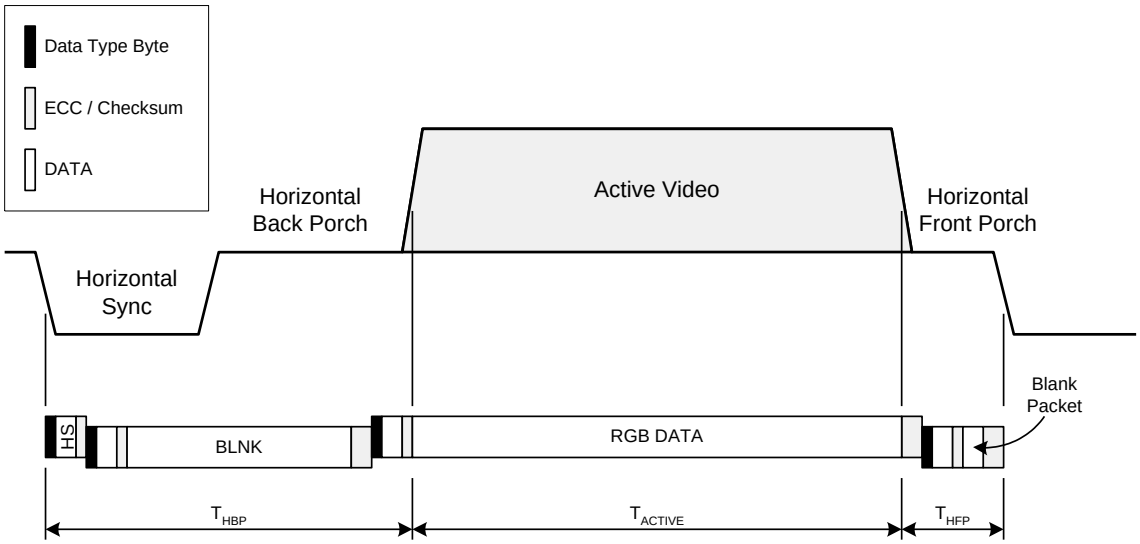


Table 87: Payload Size Table - Non-Burst Mode

Packet	Payload Size (Bytes)
HBP	(T_{HBP} * B) – 14
ACTIVE	(T_{ACTIVE} * B)
HFP	(T_{HFP} * B) – 8

B = 2, 2.25, or 3, depending on pixel format.

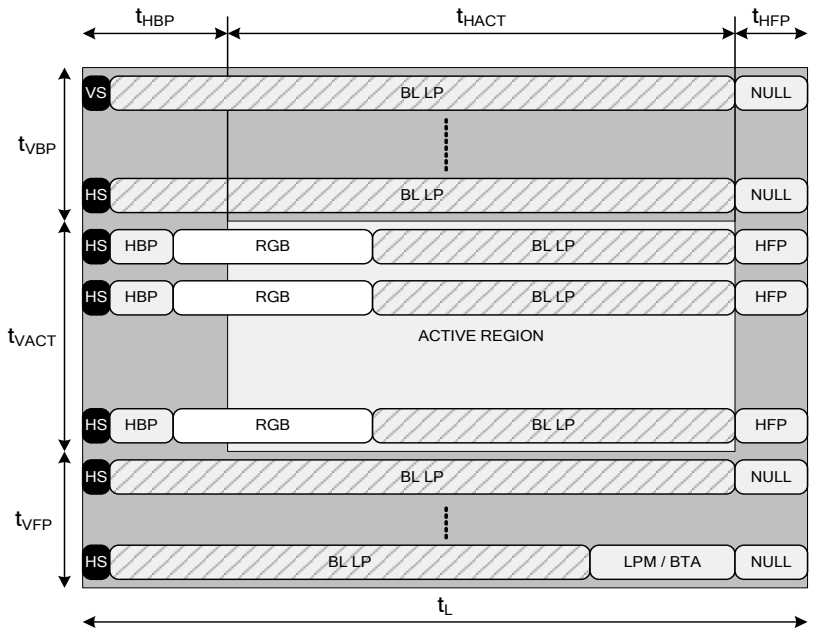
Table 88: Line Type Packet Sequences – Non Burst

LT	ID	Len	ID	Len	ID	Len	ID	Len	ID	Len	ID	Len
0	VS	0	EOT	7								
1	HS	0	EOT	7								
2	HS	0	EOT	7								
3	HS	0	BLNK	2	RGB	3	BLNK	4				
4	HS	0	EOT	7								
5	HS	0	BLNK	2	RGB	3	BLNK	4				

26.4.6 Burst Mode

In Burst Mode, the only attempt to match the raster structure is with the timing of the sync start events. The actual RGB pixel data is transmitted at whatever rate is convenient. This means that the HS, HBP, and RGB packets become compressed with respect to the timing of the underlying raster. This allows some period of idle time for each line that can be used for the transmission of other packets.

Figure 114: Timing Diagram for Video Burst Mode



During the Vertical Active period, packets on an individual line should be concatenated into a single HS transmission. However, unlike Non-Burst Mode, the bus should go idle – if possible – at the end of this transmission. This will allow additional non-video packets to be sent simultaneously with the video stream. The NULL and HFP packets may be optional. Check the latest MIPI DSI specification for clarification.

Table 89: Line Type Packet Sequences - Burst Mode

LT	ID	Len	ID	Len	ID	Len	ID	Len	ID	Len
0	VS	0	EOT	7						
1	HS	0	EOT	7						
2	HS	0	EOT	7						
3	HS	0	BLNK	2	RGB	3	EOT	7		
4	HS	0	EOT	7						
5	HS	0	BLNK	2	RGB	3	EOT	7		

Notes:

- Burst mode always forces the LP packet field to LP mode. DSI_DSI_PKT_SEQ_0_LO/HI_0/1/2/3/4/5[SEQ_0_FORCE_LP] = 1'b1
- The register programming updates in video mode that impact the raster timing (DSI_DSI_PKT_SEQ_*_LO/HI_*, video mode control fields DSI_DSI_CONTROL_0) are assumed to be static with respect to the display controller. On-the-fly updates are not supported.

This programming sequence must be followed when switching the modes/updates to raster timing:

26. Disable the DSI (DSI_LEG_EN disable)
27. Disable the DC2DSI interface path (DC_DISP_DISP_WIN_OPTIONS [DSI_ENABLE] = 1'b0)
28. Update the DSI configuration registers.
29. Enable the DSI (DSI_LEG_EN enable)
30. Enable the DC2DSI interface path (DC_DISP_DISP_WIN_OPTIONS [DSI_ENABLE] = 1'b1).

26.4.7 Sequence while Switching the Modes/Updates to Raster Timing

The following programming sequence need to be followed while switching the modes/ updates to raster timing.

1. Disable DC2DSI interface path (DC_DISP_DISP_WIN_OPTIONS [DSI_ENABLE] = 1'b0).
2. Disable DSI (DSI_LEG_EN disable).
3. Update the DSI configuration registers.
4. Enable the DC2DSI interface path (DC_DISP_DISP_WIN_OPTIONS [DSI_ENABLE] = 1'b1).
5. Enable DSI (DSI_LEG_EN enable).

26.4.8 Command Mode Programming

There are two sources of command mode packet sequences:

- Display Controller
- Host Interface

Only one of these sources will be active at any particular time.

26.4.8.1 Command Mode from Host

In this mode of operation, all packets sent over the DSI interface are determined by software. There may be hardware assistance in the generation of error correction codes (ECCs) and cyclic redundancy checks (CRCs), but all other data is passed unaltered to the DSI physical layer.

Host Packet Writes

Packets are written to the hardware by writing to the DSI_WR_DATA register. The data written is passed into the DSI Host transmit FIFO. If the data is a packet header and the ECC_ENABLE field in the HOST_DSI_CONTROL register is set to

ENABLE, then the MSBs of the 32-bit packet header word are replaced with a hardware-computed ECC byte prior to being written into the FIFO. If this field is set to DISABLE, then no action is taken by the hardware and the packet header is written unchanged.

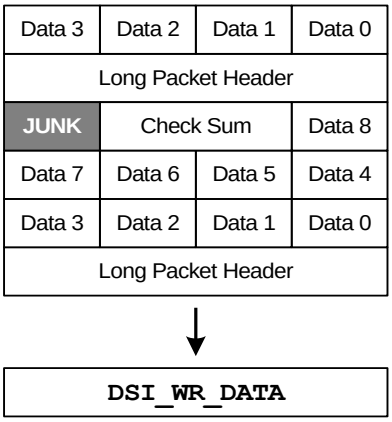
If the packet is a long packet, then the packet payload should be written to the register after the packet header is written. If the ECC_ENABLE field of the HOST_DSI_CONTROL register is set to ENABLE, then the hardware computes the check-sum and appends it to the packet information. If this field is set to DISABLE, then software must append the correctly computed check-sum to the packet data.

Rules:

1. Software should make sure packets are transmitted in their entirety and that once transmission starts, the FIFO contains enough data to finish a transition on a packet boundary. This can be achieved by only initiating a transmission – either explicitly or indirectly – once all data required for a transmission has been written to the transmit FIFO.
2. In Type-1 Display modules (i.e., the display device includes the full frame buffer to hold image data), the complete image data can be written to the frame buffer via the Host command mode. Software configures the register field to enable the Frame buffer selection for transfer of high-resolution image data.
   DSI_HOST_DSI_CONTROL[PKT_WR_FIFO_SEL]

   Note: The maximum length of the long packet supported is 1920 words including header, payload, and CRC.
3. Packets should be written such that the packet header is always written in one 32-bit word and is never split across writes. In other words, if the end of a packet does not fall on a 32-bit word boundary (if the payload has an odd length, for example), then the header for the next packet should not border the last packet, but should realign with the register. See Figure 115 for an example.

Figure 115: Packet Alignment for Writes to DSI_WR_DATA



Note: For unaligned word transfers, the host transactions are split into multiple host transfers at the unaligned boundary.

Host Packet Transmission

When the Host write FIFO starts to drain (flush) is programmable via an explicit FLUSH bit in a control register

Immediate (HOST_TX_TRIG_SRC == IMMEDIATE**)**

As the name implies – if a '1' is written to the `DSI_HOST_TRIGGER` field of the `DSI_TRIGGER` register, then transmission of the data in the Host write FIFO will start immediately. It is recommended that all data required for transmission is written to the DSI_WR_DATA register prior to setting this bit.

26.4.8.2 Command Mode from Display Controller

This mode of operation allows the display controller to write pixel data packets to a DBI-like device that does not require data to be sent in an isochronous raster structure like a DPI device. The data coming from the display controller is sent in an isochronous manner, but the commands sent will be DCS control commands, rather than Video Mode timing and blanking packets.

Setup

There are six steps to operating in this mode:

1. Program the Peripheral display device using DCS commands via the Host Command interface. It is important to send the set_column_address, set_page_address, and set_pixel_format commands. These effectively define the area to which you will be writing pixels.
2. Program the DSI_INIT_SEQ_CONTROL and DSI_INIT_SEQ_DATA_* registers in the DSI interface with the appropriate values. Any commands required to be sent once per frame and *every* frame by way of setup prior to the pixel data being sent should be put in here.
3. Program the `DSI_DATA_FORMAT` field of the DSI_CONTROL register to the required pixel format. Note that `BIT18NP` should not be programmed – see the section below on pixel format restrictions.
4. Program the DSI_PKT_SEQ_* registers. Program the registers in the following way:
   - Packet Sequence registers for Line Types 0, 1, 2, and 4 should all be programmed with 0 in all the Packet Enable fields. In other words, there should not be any packets generated for these line types.
   - Packet Sequence registers for Line Types 3 and 5 should be programmed with a DCS Long Write packet.
5. Program the DCS command ID register to have a write_start command associated with Line Type 5 (First line of active) and a write_continue command associated with Line Type 3 (all other active lines).
6. Enable the display. When Vertical syncs arrive from the display, the initialization sequence should be sent, and for every active line, the pixel data will be sent in a DCS Long Write packet.

Pixel Format Restrictions

The MIPI DCS specification allows for up to 6 different pixel data formats to be transmitted in a write_start or write_continue command. These pixel formats are listed in Table 90. The DSI supports 3 of these pixel formats.

The formats supported are also shown in the “supported” column of Table 90. Do not set `BIT18NP` as a pixel format. There is no DCS equivalent of this format, so undefined behavior may result.

Table 90: DCS Pixel Format Support

DCS ID	DCS Format	Supported	Name
0	reserved	N/A	-
1	3bpp	N	-
2	8bpp	N	-
3	12bpp	N	-
4	reserved	N/A	-
5	16bpp	Y	BIT16P
6	18bpp	Y	BIT18P
7	24bpp	Y	BIT24P

Simultaneous Host Command Packets

It is necessary, from time to time, to send a DCS command to the display peripheral in a “side-band” fashion while the display controller is continuing to send DCS write commands with pixel information. Line Type 4 (first blank line) is reserved to indicate to the hardware when it should attempt to send any DCS command packets requested by software.

If it is desired to send a DCS command in this way, the DCS command packet should be written in its entirety (header, ECC, DCS command, payload, CSC) into the Host Command FIFO. The HOST_TX_TRIG_SRC field should then be set to IMMEDIATE.

The DSI hardware will then send the entire contents of the FIFO out on the DSI interface on the first line of blanking. Sending the data on this line guarantees the Host packet transmission will have enough time to complete before the next packet generated by the Display Controller is generated.

> **Note:** There is no BTA permitted in this mode, so no ACK, ACK with error report, or read return data will be generated.

If the host transfer is enabled during the frame video blanking interval, the following sequence needs to be performed at the end of the frame:

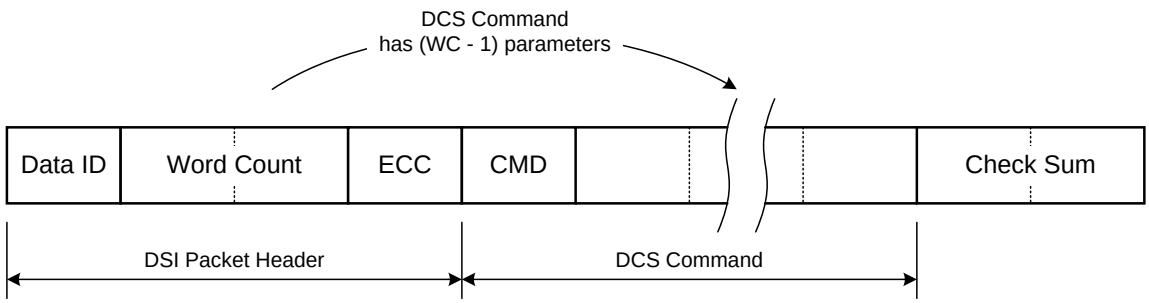
1. Wait for an end of frame event from the display controller.
2. Set the increment syncpt soft reset; that is, program the INCR_SYNCPT_SOFT_RESET field in the DSI_INCR_SYNCPT_CNTRL_0 register to 1’b1.
3. Clear the increment syncpt soft reset; that is, program the INCR_SYNCPT_SOFT_RESET field in the DSI_INCR_SYNCPT_CNTRL_0 register to 1’b0.
4. Continue with the subsequent configuration.

26.4.9 Display Command Set (DCS) Packets

DCS is a legacy control command set that is used to program various control registers present in typical LCD panels used in cell phones. Historically, the commands would be sent to the display over a MIPI DBI interface. Since MIPI DSI is meant to replace both DPI and DBI, it must also transport these control commands.

There are several DCS-specific commands in the MIPI DSI specification that can be used to send DCS commands to the Peripheral Display Device. However, the most useful is probably the DCS Long Write packet since it can be used to send commands with more than one parameter. The DCS command is embedded with an MIPI DSI Long Packet as follows: The DCS Command Byte and all the DCS Command Parameters (payload) are concatenated and sent in the Payload of the MIPI DSI Long Packet. The Word Count of the DSI packet conveys the total size of the DSC packet. As usual, a 2-byte CS footer is appended to the DSI Long Packet. The figure below shows how a DCS Long Write packet is constructed.

Figure 116: DCS Command Placement in DSI Long Packet



16 bpp Byte Ordering in 16 bpp Format for Video/Command Mode

The DSI specification suggests a different byte order in the 16 bpp video and command mode data bit order, i.e., data packing in:

Video mode [16:0] -> {B[4-0],G[5-3]},{G[2-0],R[4-0]} (Default)

Command mode [16:0] -> {G[2-0],B [4-0]},{R[4-0],G[5-3]} (SwapEn)

The byte order can be configured through the DSI_DSI_CONTROL_0 register, DFMT_16BPP_SWAP_EN field. By default, the video mode order is selected and the command mode can be selected by the programing DFMT_16BPP_SWAP_EN to 1.

Frame Synchronization Between Identical Command Mode Displays

When stretching a single surface across multiple identical displays, frame synchronization can be achieved to avoid visual artifacts due to timing drifts across both the displays.

DCS command “adjust_vsync_timing” provides a mechanism for adjusting the command mode display vsync/frame sync timing with respect to another identical display. Vsync can be shifted, i.e., delayed/advanced by the specified number of scan lines.

Host Command Mode Byte Transmission

Command mode operation primarily involves sending the commands and data to the peripheral (the display device). The host processor indirectly controls activity at the peripheral by sending commands, parameters, and data to the display controller. Command Mode operation requires a bidirectional interface capabilities.

Command mode transfers are classified into,

- HS/LP mode

  Host command mode transmission can be enabled in High Speed and Low Power modes. Follow this programming sequence to configure the DSI to enable command mode transactions.

  - Configure DSI_DSI_CONTROL_0 [DSI_HOST_ENABLE]
  - Enable checksum/Ecc mode via DSI_HOST_DSI_CONTROL_0[CS_ENABLE], …, DSI_HOST_DSI_CONTROL_0[ECC_ENABLE].
  - Write the host data to the register DSI_DSI_WR_DATA_0. Once all the command packets are pushed into the FIFO, trigger the start of the transaction via the HOST_TX_TRIG_SRC field in the DSI_HOST_DSI_CONTROL_0 register.
  - LP/HS mode of transmission is selected by configuring the DSI_HIGH_SPEED_TRANS in the DSI_HOST_DSI_CONTROL_0 register.

- Raw Mode

  Host command mode transmission also supports RAW data bytes to be transferred to the display device. In Raw mode, the data written to the host is transferred with no concept of packets and the DSI hardware does not decode the packet headers and ECC/CS computation is not performed.

  In order to send the RAW data bytes (debug / diagnostic workaround mode):

  - Program the number of bytes to be transferred to the DSI_RAW_DATA_BYTE_COUNT register. The byte count programmed is equal to the total number of raw bytes (not to be interpreted as the byte count of a packet).
  - Write raw data bytes to the DSI Host.
  - Enable RAW_DATA in the DSI_HOST_DSI_CONTROL_0 register.

26.4.10 High-Speed Clock Configurations

In High Speed mode, the Host provides a low-swing, differential DDR clock signal for high-speed data transfers. The high-speed clock lane is configurable via the DSI_HS_CLK_CTRL] field in the DSI_DSI_CONTROL register.

- Free Running Mode /Continuous

  The D-Phy clock lane operates in HS free running or continuous mode; i.e., used in systems where the D-Phy clock lane acts as a clock source to the display devices eliminating the need for an alternate oscillator clock source.

- TX Mode/Discontinuous Mode

  The D-Phy clock lane operates in burst mode or discontinuous mode; i.e., the D-Phy clock lane remains active only during the HS transmission and stops the clock lane when there are no high-speed transmissions active in any of the data lanes.

Notes:

1. The Host programs the total horizontal blank period to meet the following criteria to provide enough time for HS <-> LP transitions.

   (HBLANK) >= (number_of_lanes * (HS_Trail + HS-Exit + CLK_POST + CLK_TRAIL + HS_EXIT + TLPX + TLPX + TCLK_PREPARE + TCLK_ZERO + TCLK_PRE + 1 + TLPX + THS_PREPARE + TDAT_ZERO + 1))

   The parameters in this equation are defined in the DSI_DSI_PHY_TIMING registers.

2. The DSI_HS_CLK_CTRL field in the DSI_DSI_CONTROL_0 register control field for the HS clock lane is programmed when the DSI_HIGH_SPEED_TRANS control field in the DSI_DSI_CONTROL_0 register is programmed for HS packet transmission of packets.
3. The HS clock lane state transitions from continuous to discontinuous with soft reset assertion.

26.4.11 Ultra-Low Power Sequence

In this procedure, starting from the Stop state, the transmit side drives the TX-ULPS-Rqst state (LP-10) and then drives the TX-ULPS State (LP-00). After this, the clock lane enters the Ultra-Low Power state. If an error occurs, and an LP-01 or LP-11 is detected immediately after the TX-ULPS-Rqst state, the Ultra-Low Power state entry procedure is aborted, and the receive side waits for or returns to the Stop state, respectively.

The Clock lane and Data lanes can be configured to enter and exit ULPS independently/simultaneously:

- Independent control of the ULPS

  The Clock needs to be in the HS state, sending the active clock when data lanes are entering ULPS, When entering ULPS, the data lanes enter the ULPS first, followed by the clock lanes. Similarly, when exiting ULPS, the Data lanes exit the ULPS first, followed by the clock lanes.

  DSI_ULTRA_LOW_POWER_CONTROL register configures the control to enter the ULPS on particular clock/Data lane.

  ULPS Entry

  - Program the data lane to enter ULP sequence, wait for syncpt.
  - Program the clock lane to enter ULP sequence and, wait for syncpt

  ULPS Exit

  - Program the data lanes to exit the sequence, wait for syncpt
  - Program the clock lanes to exit the sequence, wait for syncpt

- Simultaneous control of the ULPS

  The DSI_ULTRA_LOW_POWER field in the HOST_DSI_CONTROL register controls the ULPS for all lanes (clock and data lanes 0-3) simultaneously.

Notes:

- The DSI_TWAKEUP field in the DSI_PHY_TIMING_2 register defines the length of the exit interval in multiples of 512 byte clocks common for all lanes (Clock/Data).
- The ULPM entry sequence always starts from the NORMAL state. Software should place the control fields in the NORMAL state after the exit sequence after the last operation is done. That is, in case of a ULPM sequence on clock, data lanes, you are recommended to program the register to the NORMAL state after the data lane exit sequence.

26.4.12 End of Transmission Packet (EOTp)

The DSI specification defines a dedicated End of Transmission packet (EoTp) at the protocol layer to indicate the end of HS transmission. For backwards compatibility with earlier DSI systems, this EoTp can be enabled or disabled.

For host transactions during the video mode, EOTp is programmed in the Packet Sequence register, and host data is sent on the interface followed by the last video packet byte, including the EOTp packet as the last word. That is, software programs the EOTP packet as part of the host data during host transactions during video mode.

26.4.13 Host Command Packet During Video Mode Transmission

DSI supports transmission of host command packets during vertical blanking in Video mode.

Host packet transmission during vertical blank time is possible and programmable through the DSI_VID_MODE_CONTROL register to enable and select the line type to trigger the host command packets during video mode. The 0/1/2/4 line types with single short packet transmission as part of video raster can enable simultaneous host transfer in Video mode.

Video blank line types are:

- Line Type = 0 - Blank line starting with VS
- Line Type = 1 - Blank line starting with VE
- Line Type = 2 - Blank line starting with HS
- Line Type = 4 - First Blank line after active starting with HS.

The programming sequence to enable host transactions during Video mode is:

1. Choose the line type 0/1/2/4 (Video Blanking) for simultaneous host transfers during Video mode. Program the DSI_LINE_TYPE field in the DSI_DSI_VID_MODE_CONTROL_0 register to FOUR.
2. Simultaneous host transfers are enabled during Video mode via the Video mode control field. Program the DSI_CMD_PKT_VID_ENABLE field in the DSI_DSI_VID_MODE_CONTROL_0 to 1’b1.
3. Write host data transactions to the host data buffer via the DSI_DSI_WR_DATA_0 register.

HS Packet	Host Data Packets (<= 64 Words)

4. Trigger host transmission when the complete host data for transmission is pushed into the buffer. Program the DSI_HOST_TRIGGER field in the DSI_DSI_TRIGGER_0 to 1’b1.
5. Wait for FRAME_DONE syncpt from the display controller.
6. Set the increment syncpt soft reset; that is, program the INCR_SYNCPT_SOFT_RESET field in the DSI_INCR_SYNCPT_CNTRL_0 register to 1’b1.
7. Clear the increment syncpt soft reset; that is, program the INCR_SYNCPT_SOFT_RESET field in the DSI_INCR_SYNCPT_CNTRL_0 register to 1’b0.

Notes:

- The host packet data transmission cannot be enabled in Video burst mode, where NULL_PACKETs are included with the HSYNC packet.
- Checksum/ECC computation for the host packets can be performed by either the hardware or software by programming the CS/ECC_Enable fields in the DSI_HOST_DSI_CONTROL_0 register.
- After a single VSYNC/VSYNCEND/HSYNC short packet is transmitted, if the Host transmission is enabled, software-constructed Host data packets are transmitted.
- The length of the Host FIFO data is limited to 64 words deep.
- Host data should be pushed into the Host FIFO before the frame is triggered.
- Host packets must be aligned to a word boundary. For host packets ending on an unaligned word boundary, there is support for a maximum of 4 such consecutive packets transferring in a worst-case configuration scenario and relaxed for other configurations. In the worst-case configuration scenario, the number of lanes is 4, and the Host packets end on Byte 0 (that is, a single byte is written in the last word).

  For an unaligned word boundary, if the end of a packet does not fall on a 32-bit word boundary, then the header for the next packet should not border the last packet (see the figure showing packet alignment for writes to DSI_WR_DATA).

26.4.14 Ganged Mode (Odd-Even/Left-Right) Programming

The reader is expected to be familiar with the DSI specification and normal video mode programming guidelines before reading this section on Ganged Mode.

Odd-Even

For Odd-Even Ganged mode, the programming guidelines are based on these assumptions/limitations:

1. Both partitions have a single PLLD and clock source (DSI instances)
2. For VNB, all data lanes end in the same clock cycle aligned to the number of configured lanes.
3. The number of pixels in the 18 bpp packed case is always a multiple of four.
4. The number of active pixels from the display controller is not greater than 4096 pixels.

Programming guidelines/sequence and equations for Odd-Even Ganged mode are listed below:

1. Required inputs are: image resolution data format, and optional number of lanes
2. Compute the pixel clock frequency from the given resolution and specification
   pixel frequency = (TotalHorizontalPeriod * TotalVerticalPeriod * FrameRate) / 10^6
3. Determine the possible shift clock divider value and ganged mode image split information from the number of pixels, data format, and pixel frequency

   (pixel frequency = byte frequency * 4/clock divider)
4. Symmetrical split is possible for all resolutions. Determine the possibility of an asymmetrical split.

   Let n1 = number of lanes for the first partition and n2 = number of lanes for the second partition from step 3.

   totalNumLanesInGangedMode = n1 + n2
5. Determine the correction pixels needed to align the totalNumPixels and totalNumBytes with totalNumLanesInGangedMode.
   - The pixelsNeededToInitiallyAlign should be such that the updated totalNumPixels is a multiple of LCM (total Num Lane sInGangedMode,X).
   - totalNumBytes = totalNumPixels*bytesPerPixel is a multiple of totalNumLanesInGangedMode

Notes:

- LCM – least common multiple (X=4 for 18bpp packed else X=1)
- In 18bpp packed case, else X=1. If remainder is non-zero/ganged alignment was not successful (from STEP 9), add 'n' number of additional active pixels (zeros/random data) so that the updated image active width is divisible by the LCM above. This is needed to support image split as determined in step 4.
- Add the additional correction/dummy pixels to HFP, determine new pixel frequency and compute the byte frequency using the clock divider. Use this information to program the PLLD and shift clock divider. It is okay to add dummy active pixels since panels provide an option using a register field that can be configured to drop/discard the padded pixels.
- Update total number of pixels now with the newly added active pixels, ensure the total number of active pixels does not exceed 4096 pixels. In case the total number of pixels exceed 4096 pixels then and the frame is considered not to support asymmetrically split for the given configuration, i.e.,,frame rate and split configurations.
- In the 18 bpp packed format case, you cannot complete more than a definite set of iterations for a given frame rate. If the alignment is not achieved in within 50-60 pixels, we assume the pixel alignment is not possible for the frame for asymmetric split for that frame rate.

6. Determine if the (first partition width) : (second partition width) ratio = n1/n2. If successful, proceed to the next step. If not, ganged width alignment is not successful. Repeat from step 5 by adding more active pixels that still meet the requirement mentioned there.

splitFactor (for first partition)= n1/ totalNumLanesInGangedMode;
First Partition Width (active pixels)= CEIL(spliFactor*image width)
Pixels per line of first Partition = CEIL(splitFactor*totalNumPixels)
second partition active width = imagewidth – first partition width
pixels per line of second partition = totalNumPixels - Pixels per line of first Partition

Note:

- In consideration of constraint #4, software will ensure that the total number of pixels does not exceed 4096 pixels. If the total number of pixels exceeds 4096 pixels, then the frame does not support asymmetrically split for the given configuration, i.e., frame rate and split configurations.
- The number of active pixels added is limited to no more than 60 pixels. If this value exceeds 60 in these iterations, the input image cannot be split as per the split ratio (cannot deviate much from the selected frame rate).

7. Determine the new pixel frequency (new active pixels and HFP correction) and compute the byte frequency using the clock divider. Use this information to program the PLLD and shift clock divider.
8. Determine the factors of the first partition width and second partition width.

   Select 'x' from the factors of the first partition and 'y' from the factors of the second partition such that x:y = n1/n2. The minimum of 1:1 (symmetrical) is possible for any image.

   To send the first group of pixels, ganged start pointer = 0, valid width = x, and low width = y. For the second group, ganged start pointer = x, valid width = y, and low width = x.
9. In Odd-Even Ganged mode, program the HSYNC, HACT, and HFP packets.

   HACT payload size = Total Actual Image Bytes on Data lanes

   Initial HFP payload size = totalNumBytesForTheSelectedPartition - numActBytesToBeSent - 16 (16 is because of 4 Bytes - HSYNC, (4+2) Bytes - HACT, (4+2) Bytes - HFP)

10. Compute the correction bytes (per line of partition) again to align with the line width and number of lanes (per partition), limitation #2

    correctionBytesPerLane = CEIL(totalNoOfPixelsPer HorzLine*(FDSI/ Fpixel) – (BPP/ Gangedmode_lanes))

    totalNumBytesForTheSelectedPartition = (correctionBytesPerLane * numOfLanesForSelectedPartition)

    total Horizontal Blank(Bytes) = (totalNumBytesForTheSelectedPartition -16+ correctionBytesForAlignment)

11. Ganged mode register programming
    - Even Partition

      DSI_DSI_GANGED_MODE_CONTROL_0[DSI_GANGED_MODE_EN] = 1;

      DSI_DSI_GANGED_MODE_START_0[DSI_GANGED_START_POINTER] = 0

      DSI_DSI_GANGED_MODE_SIZE_0[DSI_GANGED_VALID_HIGH_WIDTH] = Even partition active width

      DSI_DSI_GANGED_MODE_SIZE_0[DSI_GANGED_VALID_LOW_WIDTH] = Even partition inactive/low width.
    - Odd Partition

      DSI_DSI_GANGED_MODE_CONTROL_0[DSI_GANGED_MODE_EN] = 1;

      DSI_DSI_GANGED_MODE_START_0[DSI_GANGED_START_POINTER] = High width of Even partition

      DSI_DSI_GANGED_MODE_SIZE_0[DSI_GANGED_VALID_HIGH_WIDTH] = odd partition active width.

      DSI_DSI_GANGED_MODE_SIZE_0[DSI_GANGED_VALID_LOW_WIDTH] = odd partition inactive/low width.

12. SOL delay calculation:

    solFactor = ((Sol2VldDly + 6) * (FDSI / Fpixe)) + 6;

    sol_delay =

    Ceil (TotalHorzPixelWidth * (FDSI / Fpixel)) -
    Ceil (((SplitFactor * TotalHorzPixelWidth) * BPP) /
      Gangedmode_lanes) + SolFactor;

    Final_sol_delay = (dcs_mode) ? (sol_delay + 20) : (sol_delay)

    DSI_DSI_SOL_DELAY_0 = Final_sol_delay

    Notes:
    - Sol2VldDly = Hsync start to Pixel valid delay
    - totalNoOfPixelsPerHorzLine = Total Number of horizontal pixel count.
    - SplitFactor = DSI_partition_lanes / Gangedmode_lanes.
    - Gangedmode_lanes = Total number of lanes required in Ganged mode transfer
    - DSI_partition_lanes = Total lanes in current partition/channel.
    - BPP = Bytes per pixel

Left-Right:

For Left-Right Ganged mode, the programming guidelines are based on these assumptions/limitations:

1. Both partitions have a single PLLD and clock source (DSI instances)

2. For VNB, all data lanes end in the same clock cycle aligned to the number of configured lanes (per the DSI specification).
3. The number of pixels in the 18 bpp packed case is always aligned to 4 pixels (per DSI specification).
4. The number of active pixels from the display controller is not greater than 4096 pixels.

Programming guidelines/sequence and equations for Left-Right Ganged mode are listed below:

1. Required inputs are Image resolution and data format, and optional number of lanes
2. Compute the pixel clock frequency from the given resolution and specification
   pixel frequency = (TotalHorizontalPeriod * TotalVerticalPeriod * FrameRate) / 10^6
3. Determine the shift clock divider value and ganged mode image split information from the number of pixels, pixel frequency, and data format.

   (pixel frequency = DSI clock (byte frequency) * 4/clock divider)
4. Symmetrical split is possible for all resolutions. Determine the possibility of the asymmetrical split.
5. Let n1=number of lanes for first partition and n2 = number of lanes for second partition from step 3

   totalNumLanesInGangedMode = n1 + n2
6. Determine the correction/additional pixels needed to align the totalNumPixels and totalNumBytes with totalNumLanesInGangedMode.
   From Limitation #3:

   The pixelsNeededToInitiallyAlign should be such that updated totalNumPixels is a multiple of LCM (total Num Lane sInGangedMode,X)

   totalNumBytes = totalNumPixels*bytesPerPixel

   Ensure the total Number of Bytes to be a multiple of totalNumLanesInGangedMode.

   Note: For the least common multiple (LCM), X = 4 for 18 bpp packed; otherwise X = 1

   In the 18 bpp packed format case, you may not complete over a definite set of iterations for a given frame rate. Hence check if the total additional pixels added to Align doesn't exceed 50-60 pixels. If it exceeds which means pixel alignment not possible and the frame considered not to support asymmetrically split for the 18BPP packed case (for that frame rate)..

   Add the additional correction pixels to the HFP, determine a new pixel frequency, and compute the byte frequency using the clock divider. Use this information to program the PLLD and shift clock divider.
7. Determine the number of pixels per split on the computed Pixel count from step 6:
   - Determine the first partition width, and then the remaining pixels will be in the second partition.

   splitFactor (for first partition)= n1/ totalNumLanesInGangedMode

   First Partition Width (active pixels)= CEIL(splitFactor*image width)

   Pixels per line of the first partition = CEIL(splitFactor*totalNumPixels)

   second partition active width = imagewidth – first partition width

   pixels per line of the second partition = totalNumPixels - Pixels per line of the first partition.

For 18 bpp packed, software should recheck if each of the widths determined above is multiple of 4. Otherwise, adjust the active pixels of the partition (increase) to align to 4 pixels and correspondingly decrease the pixels in the HFP (to still meet the line time) accordingly. Adjust pixels in the second partition, too.

numActBytesToBeSent = partition active width * bytesPerPixel

totalNumBytesForTheSelectedPartition = pixels per line of selected partition * bytesPerPixel

8. In Left-Right Ganged mode, program the HSYNC, HACT, and HFP packets.

   HACT payload size = Total Actual Image Bytes on Data lanes

   Initial HFP payload size = totalNumBytesForTheSelectedPartition - numActBytesToBeSent - 16

   (16 is because of 4 bytes - HSYNC, (4+2) Bytes - HACT, (4+2) Bytes - HFP)

9. Compute the correction bytes (per line of partition) again to align with line width and number of lanes (per partition) (limitation #2)

   correctionBytesPerLane = CEIL(totalNoOfPixelsPerHorzLine *(FDSI/ Fpixel) – (BPP/ Gangedmode_lanes))

   totalNumBytesForTheSelectedPartition = (correctionBytesPerLane * numOfLanesForSelectedPartition)

   total Horizontal Blank(Bytes) = (totalNumBytesForTheSelectedPartition -16+ correctionBytesForAlignment)

10. Ganged mode register programming
    a. Left Partition

       DSI_DSI_GANGED_MODE_CONTROL_0[DSI_GANGED_MODE_EN] = 1;

       DSI_DSI_GANGED_MODE_START_0[DSI_GANGED_START_POINTER] = 0;

       DSI_DSI_GANGED_MODE_SIZE_0[DSI_GANGED_VALID_HIGH_WIDTH] = Total horizontal active width

       DSI_DSI_GANGED_MODE_SIZE_0[DSI_GANGED_VALID_LOW_WIDTH] = Total horizontal width – Total horizontal active width.

    b. Right Partition

       DSI_DSI_GANGED_MODE_CONTROL_0[DSI_GANGED_MODE_EN] = 1;

       DSI_DSI_GANGED_MODE_START_0[DSI_GANGED_START_POINTER] = leftPartitionWidth (for right partition)

       DSI_DSI_GANGED_MODE_SIZE_0[DSI_GANGED_VALID_HIGH_WIDTH] = Total horizontal active width

       DSI_DSI_GANGED_MODE_SIZE_0[DSI_GANGED_VALID_LOW_WIDTH] = Total horizontal width – Total horizontal active width.

11. SOL delay calculation:

    solFactor = ((Sol2VldDly + 6) * (FDSI / Fpixel)) + 6

    sol_delay =

    Ceil (TotalHorzPixelWidth * (FDSI / Fpixel)) -
    Ceil (((SplitFactor * TotalHorzPixelWidth) * BPP) /
    Gangedmode_lanes) + SolFactor;

    Final_sol_delay = (dcs_mode) ? (sol_delay + 20) : sol_delay

    Notes:

    - Sol2VldDly = Hsync start to Pixel valid delay
    - totalNoOfPixelsPerHorzLine = Total Number of horizontal pixel count.
    - SplitFactor = DSI_partition_lanes / Gangedmode_lanes.
    - Gangedmode_lanes = Total number of lanes required in Ganged mode transfer
    - DSI_partition_lanes = Total lanes in current partition/channel.
    - BPP = Bytes per pixel

Recommended Packet Sequence

Packet	Payload Size (Bytes)
ACTIVE	(T_{ACTIVE} * B)
HFP	(T_{HFP} * B) – 8

- B = 2, 2.25 or 3, depending on pixel format.
- N = Number of Lanes used.

Table 91: Recommended Payload Size Table - Ganged Mode

LT	ID	Len	ID	Len	ID	Len	ID	Len	ID	Len
0	VS	0								
1	HS	0								
2	HS	0								
3	HS	0	RGB	3	BLNK	4				
4	HS	0

5	HS	0	BLNK	2	RGB	3	BLNK	4		

26.4.15 Soft Reset Programming

Soft reset is asserted in the DSI through the LEG_DSI_ENABLE control field of the DSI_DSI_POWER_CONTROL_0 register. When soft reset is asserted, the DSI controller transitions the internal states to default mode. When it is asserted between

valid transactions, the current transaction is halted, the internal states are moved to default mode, and a new transaction starts by programming the desired values following the programming sequence explained in the other sections.

Note:	For Host transmissions enabled through the DSI_HOST_TRIGGER field of the DSI_DSI_TRIGGER_0 register, soft reset cannot be issued between a transaction, and software will write 1'b0 to the register to clear the trigger bit.

26.4.16 Function Programming

26.4.16.1 ECC Generation

For precise details on the calculation of the ECC field of the packet header, reference should be made to the MIPI Alliance Standard for Display Serial Interface. This subsection presents an overview of how the ECC can be created quite simply.

Each bit of the ECC byte is the result of XORing a number of bits from the packet header together. Which header bits contribute to which ECC bit is contained in a special table which can be used to calculate the ECC as follows:

```
const UCHAR ecc parity[24] = { 0x07, 0x0b, 0x0d, 0x0e, 0x13, 0x15, 0x16, 0x19,
                               0x1a, 0x1c, 0x23, 0x25, 0x26, 0x29, 0x2a, 0x2c,
                               0x31, 0x32, 0x34, 0x38, 0x1f, 0x2f, 0x37, 0x3b
                             };
ULONG packet header;
UCHAR ecc byte;
UINT  i;

// Assume bottom 24 bits of packet header
// contains header ID and byte count, then ...

ecc_byte = 0;
for (i = 0; i < 24; i++) {
  ecc_byte ^= ((packet_header >> i) & 1) ? ecc_parity[i] : 0x00;
}
packet_header |= (ULONG)(ecc_byte) << 24;
```

Note that the table in the DSI specification contains 64 entries. Since short packets have been fixed in length to be the same as a long packet header since the original specification was written, there will now always be just 24 data bits in the packet header, so only 24 entries are needed.

26.4.16.2 CRC Insertion

The DSI checksum used for long packets is derived using the generator polynomial $x^{16}+x^{12}+x^5+x^0$. Details of this can be found in section 9.6 of the MIPI DSI specification. To understand how the CRC is generated, think of the packet data as consisting of a continuous serialized stream of bits, rather than a sequence of 8-bit bytes. When thought of in this way, it is relatively straight forward to generate the CRC. Reproduced below is an abridged version of the example C code contained in Appendix B of the MIPI DSI specification.

```
// Polynomial, bit reversed form (since DSI transmits LSB first) …
const unsigned short CRC16GenerationCode = 0x8408;

unsigned short CalculateCRC16( unsigned char *DataStream ptr, unsigned short NumberOfDataBytes)

{
  unsigned short ByteCounter;
```

```
  unsigned char  BitCounter;
  unsigned char  CurrentData;
  unsigned short CRC16Result = 0xFFFF;

  if (NumberOfDataBytes > 0) {
    for (ByteCounter = 0; ByteCounter < NumberOfDataBytes; ByteCounteer++) {
      CurrentData = DataStream ptr[ByteCounter];
      for (BitCounter = 0; BitCounter < 8; BitCounter++) {
        if ((CRC16Result & 0x0001) ^ (CurrentData ^ 0x0001))
          CRC16Result = ((CRC16Result >> 1) & 0x7FFF) ^ CRCGenerationCode;
        else
          CRC16Result =  (CRC16Result >> 1) & 0x7FFF;
        CurrentData = (CurrentData >> 1) & 0x7F;
      }
    }
  }
  return CRC16Result;
}
```

This code may not be very high-performance due to the inner for loop which iterates over bits, rather than bytes. While it is instructive and could form the basis of a reference piece of code, it is not recommended where performance is important. There are many documented methods of performing this calculation in parallel in order to speed up the computations. These methods are beyond the scope of this document.

26.4.17 Read Data Return

DSI is a bidirectional interface. Data is returned from the peripheral display device only after the display controller has requested information by issuing a Bus Turn Around (BTA). All returned data is written into a FIFO that can be read using Host reads of a DSI register.

26.4.17.1 Reading Peripheral Registers

A typical application of a BTA is in the reading of a register from the display peripheral. This is achieved in the following way:

1. Set up the DSI interface to be in Host-driven command mode.
2. Set the DSI_MAX_THRESHOLD to 3.
3. Set the HOST_TX_TRIG_SRC field of the HOST_DSI_CONTROL register to FIFO_LEVEL.
4. Set the PKT_BTA field of the HOST_DSI_CONTROL register to ENABLE.
5. Write a DCS READ command packet (see section 8.8.8.2 of the MIPI DSI specification) into the Command FIFO by writing to the DSI_WR_DATA register.

This will result in the transmission of a DCS READ packet to the peripheral, the initiation of a BTA and – assuming the peripheral received the packet without error – the return of the requested data to the Host Read Return FIFO. The data can then be read from the FIFO by reading the DSI_RD_DATA register.

26.4.17.2 Bus Turn Around

- BTA is only supported for Host driven Command Mode interface. There will be no BTA during video mode transmission.
- Whether or not a BTA is initiated is controlled by the `PKT_BTA` field of the HOST_DSI_CONTROL register.
- The DSI Read Return FIFO is 4 bytes wide and 8 entries deep, so 32 bytes in total. This is enough to hold 8 short packets, or a mixture of short and long packets. The length of long packets must be severely restricted.

- Hardware does not perform ECC or CS checks on the read return data. Entire packets are simply made available to software to perform whatever checks they desire.
- There is the ability to increment a sync point counter on the arrival of the returned data or on the receipt of an error report in the event there was a problem with the read packet transaction.
- Software will ensure to program the byte clock frequency dsi_clk greater than 52 MHz, when performing BTA transactions.

26.4.17.3 BTA – Response Time Parameter

When a peripheral receives a READ Request, it is expected that a Bus Turn Around will immediately follow to extend support for the display device that cannot handle the request immediately after the Read request is issued.

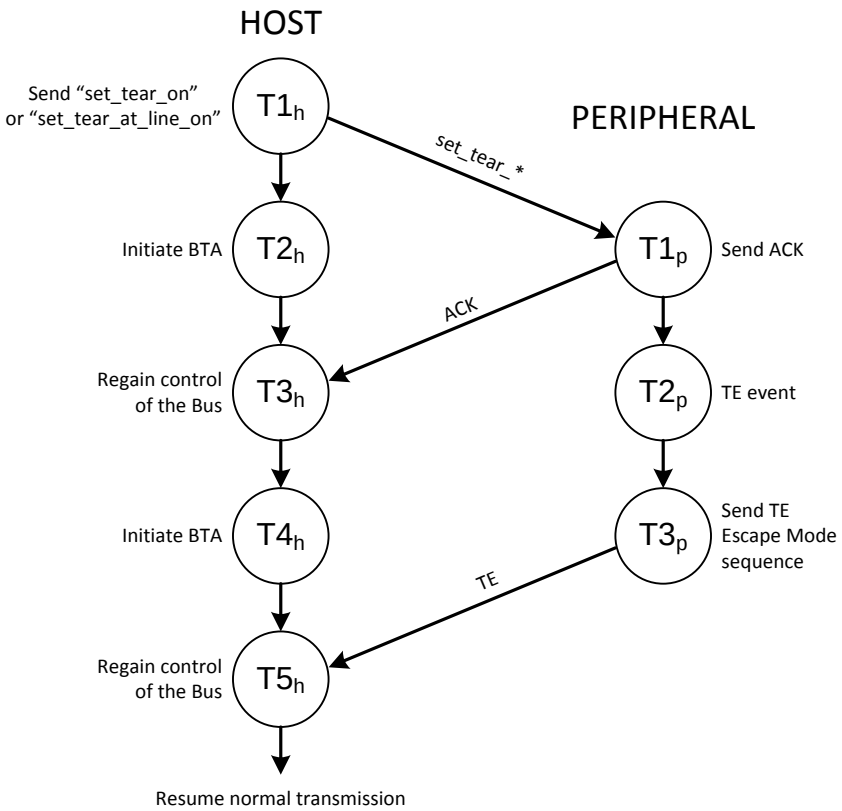
The DSI_DSI_BTA_TIMING_0 register defines DSI_TPKTBTA to allow a programmable delay between the end of host transmission and generation of BTA request for extending support for the display devices with slow response.

Note:	Valid programmable values for all the DSI_DSI_BTA_TIMING_0 register fields (DSI_TTAGO/DSI_TTASURE/DSI_TTAGET/DSI_TPKTBTA) are 0 to 254. Invalid value is 255.

26.4.18 Tearing Effect

In order to synchronize the update of a Command Mode display with data from the Host, a signal from the display can be sent to indicate when it is safe to proceed with the transmission of new data. This is the Tearing Effect reporting signal. Refer to section 8.12, “TE Signaling in DSI” of the DSI specification for more details.

Figure 117: Tearing Effect State Transition Diagram



Programmatically, this is achieved in the following way:

1. Send SET_TEAR_ON or SET_TEAR_AT_LINE_ON command with the PKT_BTA field in the HOST_DSI_CONTROL register set to ENABLE. This is state T1h.
2. Wait for ACK to come back from the peripheral. This is states T2h and T3h.
3. Set the IMM_BTA field in the HOST_DSI_CONTROL register set to ENABLE. This will cause the D-PHY to go into BTA without having to send a command first. This is state T4h.
4. Wait for TE return byte from the peripheral. This is state T5h.

Note: a trigger from panel/device to the Display Controller issued when a panel is ready to receive data from the Display Controller. The tear effect signal triggers when MSF/SSF register field in the “DC_CMD_DISPLAY_COMMAND_OPTION0_0” register is set to ENABLE. The Display Controller holds off a frame requested by input triggers until it receives a "ready" from the GPIO pins that connect to the tearing effect signals from the panel. It then sends a new frame to panel. In case no in-out trigger has been requested, the Display Controller shall not send a new frame.

26.4.19 Pad Calibration Programming

- Configure the mipi calibration clock to operate at 72 MHz via programming the CLK_RST_CONTROLLER_PLLP_BASE_0 register.
- Enable the MIPI calibration clock via Set CLK_ENB_MIPI_CAL to 1.
- Release reset to mipi_cal logic via deasserting SWR_MIPI_CAL_RST to 0
- Configure the DSI pad/bias pads to the appropriate values
  - DSI_PAD_CONTROL_3_0= 0x0
  - DSI_PAD_CONTROL_4_0 = 0x0
  - MIPI_CAL_MIPI_BIAS_PAD_CFG0_0 = 0x0
  - MIPI_CAL_MIPI_BIAS_PAD_CFG1_0 = 0x00020000
  - MIPI_CAL_MIPI_BIAS_PAD_CFG2_0 = 0x00000000
- Configure MIPI calibration settings for DSI pads for setup MIPI_CAL_DSI* _MIPI_CAL_CONFIG [*SELDSI*/ *OVERIDEDSI*/ *HSPDOSDSI*/ *HSPUOSDSI*/ *TERMOSDSI*]. MIPI_CAL_DSI*_MIPI_CAL_CONFIG_0
- Enable all the DSI lanes that require calibration driving LP_11 state.
- MIPI calibration start via - MIPI_CAL_MIPI_CAL_CTRL_0[MIPI_CAL_STARTCAL]
- Monitor the status via MIPI_CAL_CIL_MIPI_CAL_STATUS_0[*].

26.4.20 CRC Computation (Debug)

A CRC is computed on the byte data transmitted over the DSI lanes for debug purposes. Follow these steps for CRC generation:

1. Enable the DSI_DBG_ENABLE field in the DSI_DSI_CONTROL_0 register to turn on CRC computation.
2. When Video mode is enabled, CRC is generated from all bytes transmitted during a frame of video. Hardware will capture the CRC into a DSI_DSI_TX_CRC_0 register so that it can continue to calculate the CRC for the next frame without having to wait for software to read the current result.
3. In Host command mode, the CRC is generated from all bytes transmitted during the transaction. Software will latch the final CRC from the DSI_DSI_TX_CRC_0 register at the end of current host data transaction.

26.4.21 Error Reporting

There is no actual error recovery circuitry in the hardware, only error reporting. Any error that is reported via a protocol-level packet will be processed like all other return data and will be written to the data return FIFO for processing by the Host / Software.

Low level hardware errors such as bus contention will not be flagged, but will increment counters that can be queried by software so as to determine the reliability of the link.

26.4.21.1 Acknowledge with Error Report

The peripheral device (display) can be instructed to return an error report along with an acknowledge at the end of a transmission sequence. This is achieved by setting the PKT_BTA field in the HOST_DSI_CONTROL register to ENABLE. When this is done, there are several outcomes as shown in Table 93.

Table 93: Peripheral Response to Various Conditions

Condition	Non-Read Packet	Read Packet
No error	ACK	Read Data
Corrected single bit error	ACK with ERR	Read Data + ACK with ERR
Non-corrected multi-bit error	ACK with ERR	ACK with ERR
SOT, EOT, VI ID or other D-PHY error	ACK with ERR	ACK with ERR

ACK Return

If a BTA request is enabled and there is no error, then the peripheral will return an ACK trigger to the DSI hardware. This single byte trigger has the value 0x84. Since the return FIFO is 32 bits wide, the 0x84 value will be placed in the bottom 8 bits of the FIFO.

Read Data

If a read command packet is sent, then BTA request should be enabled to allow the peripheral to return the read data. If no error occurs in the transmission of the read packet, or a corrected single bit error occurs, then the read data will be returned to the host DSI hardware in the form of a read packet. The precise form will depend on the type of read packet transmitted. Refer to the MIPI DSI specification, section 8.10 for details.

If a corrected error occurs during the transmission of the read command, the requested read data will be returned in the normal way, but an ACK with Error report packet will be appended to the read return data packet.

ACK with Error Report

The error report is contained in the 16 payload bits of a special short packet returned by the peripheral. The bits allocations of the packet data are detailed in section 8.9.5 of the MIPI DSI specification but are repeated here for convenience.

Table 94: Error Report Bit Assignments

Bit	Description
0	SOT error
1	SOT sync error
2	EOT sync error
3	Escape Mode Entry Command error
4	Low-Power Transmit Sync Error
5	HS Receive Timeout error
6	False Control Error

Bit	Description
7	RESERVED
8	ECC Error, single bit (corrected)
9	ECC Error, multi-bit (not corrected)
10	CS Error (long packet only)
11	DSI data type not recognized
12	DSI Virtual Channel ID invalid
13	RESERVED
14	RESERVED
15	RESERVED

26.4.22 Time Outs

There are three compulsory and one optional time out counters required by the MIPI DSI specification for Processors (display controller). Each timer will consist of a simple counter which will count DSI byte clocks. The counters will reset to 0 on an event and will then simply increment their count every DSI byte clock cycle. If the event that the time out is protecting occurs before the time out reaches its terminal count, the counter will simply stop counting and hold its value. If the counter reaches software programmed maximum count before the expected event occurs, the counter will stop counting and hold its count value. Any action that is required by the MIPI DSI specification upon reaching the time out will also be performed by the hardware.

Table 95: Time-out Counter Summary

Time Out Name	Abbreviation	Start Condition	Length Greater Than	Action
HS Transmit TO	HTX_TO	SOT	Longest HS sequence	EOT + LP-11
LP Receive TO	LRXH_TO	LP Rx start	LTXP_TO (on periph.)	LP-11
Turn Around TO	TA_TO	BTA start	BTA response time	LP-11
Peripheral Reset	PR_TO	Reset Entry CMD	Peripheral resp. time	None.

In the table, the Peripheral Reset time out is the only timer that is optional. All the other timers are required by the MIPI DSI specification. Note that under “Action”, the listed operations are forced on the interface by the D-PHY under the instruction of the protocol layer (hardware). In the case of the optional Peripheral Reset time out, there is no action since this time out simply exists to issue a reset to the peripheral. Once the reset command is issued, the only further action required is to wait for an appropriate length of time to allow the peripheral to go through its reset sequence.

In the case of the HTX_TO, LRXH_TO and TA_TO time outs, the reaching of a terminal count will not only cause the action as listed in Table 95, but will also cause a tally counter to increment so that software can read the register and determine if any of the time outs have occurred. Software will be able to reset these tally counters to 0 by writing to the tally register. The value written will be irrelevant. The PR_TO will report its operation in a different manner. When the PR_TO counter is actually counting, there will be a status bit that reads as ‘0’. When the PR_TO terminal count is reached and time out ends, the status bit will become ‘1’. This will allow software to determine when the peripheral has been reset.

Table 96: Time Out and Tally Registers

Register	Field	Description
DSI_TIMEOUT_0	HTX_TO	High Speed Transmit time out duration
	LRXH_TO	Low Power Receive time out duration
DSI_TIMEOUT_1	TA_TO	Turn Around time out duration
	PR_TO	Peripheral Reset duration

Register	Field	Description
DSI_TO_TALLY	HTX_TALLY	High Speed Transmit time out Tally
	LRXH_TALLY	Low Power Receive time out Tally
	TA_TALLY	Turn Around time out Tally
	P_RESET_STATUS	Peripheral Reset Status: 0= Reset, 1 = Ready

26.5 MIPI-DSI Registers

Refer to “Reading Register Tables” in the Introduction section for the register table protocol as well as recommendations for accessing registers.

26.5.1 DSI_INCR_SYNCPT_0

Offset: 0x0 │ Byte Offset: 0x0 │ Read/Write: R/W │ Reset: 0x00000000 (0bxxxxxxxxxxxxxxxx0000000000000000)

Bit	Reset	Description
15:8	0x0	COND: Condition mapped from raise/wait 0 = IMMEDIATE 1 = OP_DONE 2 = RD_DONE 3 = REG_WR_SAFE 4 = COND_4 5 = COND_5 6 = COND_6 7 = COND_7 8 = COND_8 9 = COND_9 10 = COND_10 11 = COND_11 12 = COND_12 13 = COND_13 14 = COND_14 15 = COND_15
7:0	0x0	INDX: syncpt index value

26.5.2 DSI_INCR_SYNCPT_CNTRL_0

Offset: 0x1 │ Byte Offset: 0x4 │ Read/Write: R/W │ Reset: 0x00000000 (0bxxxxxxxxxxxxxxxxxxxxxxxx0xxxxxx0)

Bit	Reset	Description
8	0x0	INCR_SYNCPT_NO_STALL: If NO_STALL is 1, then when FIFOs are full, INCR_SYNCPT methods will be dropped and the INCR_SYNCPT_ERROR[COND] bit will be set. If NO_STALL is 0, then when FIFOs are full, the client host interface will be stalled.
0	0x0	INCR_SYNCPT_SOFT_RESET: If SOFT_RESET is set, then all internal states of the client syncpt block will be reset. To do a soft reset, first set SOFT_RESET of all affected Host1x clients, then clear all SOFT_RESETs.

26.5.3 DSI_INCR_SYNCPT_ERROR_0

Offset: 0x2 │ Byte Offset: 0x8 │ Read/Write: R/W │ Reset: 0x00000000 (0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx)

Bit	Reset	Description
31:0	X	COND_STATUS: COND_STATUS[COND] is set if the FIFO for COND overflows. This bit is sticky and will remain set until cleared. Cleared by writing 1.

26.5.4 DSI_CTXSW_0

Context Switch Register

Should be common to all modules. Includes the current channel/class (which is writable by software) and the next channel/class (which the hardware sets when it receives a context switch).

Any context switch request triggers an interrupt to the host and causes the new channel/class to be stored in NEXT_CHANNEL/NEXT_CLASS (see vmod/chexample). Software sees that there is a context switch interrupt and does the necessary operations to make the module ready to receive traffic from the new context. It clears the context switch interrupt and writes CURR_CHANNEL/CLASS to the same value as NEXT_CHANNEL/CLASS, which causes a context switch acknowledge packet to be sent to the host. This completes the context switch and allows the host to continue sending data to the module.

Context switches can also be pre-loaded. If CURR_CLASS/CHANNEL are written and updated to the next CLASS/CHANNEL before the context switch request occurs, an acknowledge will be generated by the module, and no interrupt will be triggered. This is one way for software to avoid dealing with context switch interrupts.

Another way to avoid context switch interrupts is to set the AUTO_ACK bit. This bit tells the module to automatically acknowledge any incoming context switch requests without triggering an interrupt. CURR_* and NEXT_* will be updated by the module so they will always be current.

Offset: 0x8 │ Byte Offset: 0x20 │Read/Write: R/W │ Reset: 0xf000f800 (0bxxxxxxxxxxxxxxxx11111x0000000000)

Bit	R/W	Reset	Description
31:28	RO	X	NEXT_CHANNEL: Next requested channel
25:16	RO	X	NEXT_CLASS: Next requested class
15:12	RW	0xf	CURR_CHANNEL: Current working channel, reset to 'invalid'
11	RW	0x1	AUTO_ACK: Automatically acknowledge any incoming context switch requests 0 = MANUAL 1 = AUTOACK
9:0	RW	0x0	CURR_CLASS: Current working class

Note: **PACKET DEFINITIONS**

Packet for Display Controller -> DSI communication:

Line Type is used to convey the type of video line from the display controller to the DSI block. The line type implies the generation of one of the associated packet sequences as defined in the DSI packet sequence registers (see below). Used to construct packet headers. All packet headers are now 32-bits wide regardless of whether they are short or long packets. Used for validation infrastructure only.

26.5.5 DSI_DSI_RD_DATA_0

DSI Read Return Data

Offset: 0x9 | Byte Offset: 0x24 | Read/Write: RO | Reset: 0xXXXXXXXX (0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx)

Bit	Reset	Description
31:0	X	DSI_RD_DATA: Each read to this register will pop 32 bits from the 32-bit wide read return data FIFO. The FIFO has NV_DSI_HOST_DATA_RETURN_FIFO_DEPTH entries.

26.5.6 DSI_DSI_WR_DATA_0

Host FIFO Write Input

Offset: 0xa | Byte Offset: 0x28 | Read/Write: R/W | Reset: 0xXXXXXXXX (0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx)

Bit	Reset	Description
31:0	X	DSI_WR_DATA: Each write to this register will push 32 bits into the 32-bit wide Host data FIFO. FIFO has NV_DSI_HOST_DATA_FIFO_DEPTH entries

26.5.7 DSI_DSI_POWER_CONTROL_0

Display Power Control

DSI Enable

Offset: 0xb | Byte Offset: 0x2c | Read/Write: R/W | Reset: 0x00000000 (0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx0)

Bit	Reset	Description
0	0x0	LEG_DSI_ENABLE: DSI interface Enable 0 = DISABLE : Disable DSI 1 = ENABLE : Enable DSI

26.5.8 DSI_INT_ENABLE_0

Interrupt Enable Register

Offset: 0xc | Byte Offset: 0x30 | Read/Write: R/W | Reset: 0x00000001 (0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx1)

Bit	Reset	Description
0	0x1	CTXSW_INT_ENABLE: Context Switch Interrupt Enable 0 = DISABLE : interrupt disabled 1 = ENABLE : interrupt enabled

26.5.9 DSI_INT_STATUS_0

Interrupt Status Register

Offset: 0xd | Byte Offset: 0x34 | Read/Write: R/W | Reset: 0x00000000 (0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx0)

Bit	Reset	Description
0	0x0	CTXSW_INT: Context switch interrupt status (clear on write)

26.5.10 DSI_INT_MASK_0

Interrupt Mask

Setting bits in this register mask the corresponding interrupt but does not clear a pending interrupt and does not prevent a pending interrupt to be generated. Masking an interrupt also does not clear a pending interrupt status and does not prevent a pending interrupt status to be generated.

Offset: 0xe │ Byte Offset: 0x38 │ Read/Write: R/W │ Reset: 0x00000000 (0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx0)

Bit	Reset	Description
0	0x0	CTXSW_INT_MASK: Context Switch Interrupt Mask 0 = MASKED : interrupt masked 1 = NOTMASKED : interrupt not masked

26.5.11 DSI_HOST_DSI_CONTROL_0

DSI Control Register When Input is from HOST

Offset: 0xf │ Byte Offset: 0x3c │ Read/Write: R/W │ Reset: 0x00000043 (0bxxxxxxxxxx00x000xx00xx0001000011)

Bit	Reset	Description
21	0x0	FIFO_STAT_RESET: write only bit to clear FIFO underflow/overflow flags. If a new underflow/overflow event occurs during the same time, current access cannot clear the status bits
20	0x0	CRC_RESET: Write only bit. When written with a 1, causes the Verification CRC generator to reset to 0xFFFF_FFFF. If written with 0, it has no effect.
18:16	0x0	DSI_PHY_CLK_DIV: Phy clock divider value for byte clock 0 = DIV1 1 = DIV2
13:12	0x0	HOST_TX_TRIG_SRC: Controls the source of the trigger to start sending packets. 0 = SOL : Start of Line signal from the Display Controller. 1 = FIFO_LEVEL : How full the FIFO is. Level determined elsewhere. 2 = IMMEDIATE : Determined by a write to the DSI_HOST_TRIGGER field of the DSI_TRIGGER register
9:8	0x0	DSI_ULTRA_LOW_POWER: Ultra Low Power 0 = NORMAL 1 = ENTER_ULPM 2 = EXIT_ULPM
7	0x0	PERIPH_RESET: Initiate an Escape Mode Peripheral Reset. 0 = DISABLE : Causes an Escape Mode Command to be sent to reset the 1 = ENABLE : External display device. Also starts the PR_TO counter. PR_TO state can be checked with the P_RESET_STATUS field in the DSI_TO_TALLY register. Hardware clears this bit upon completion of issuing "Trigger Reset" OR called "Reset Entry" command is sent out.
6	0x1	RAW_DATA: Host raw data mode. In this mode. All data is sent exactly as written. No attempt to decode packet headers is made. This bit will also override the function of the ECC and CS ENABLE fields. No ECC or CS will be generated. This mode is intended as a debug / diagnostic workaround mode only. 0 = DISABLE : Normal mode. 1 = ENABLE : Enable raw data transmission.
5	0x0	DSI_HIGH_SPEED_TRANS: DSI high speed transmission of packets 0 = LOW : Low speed - Note: Unlikely ever to be used. 1 = HIGH : High speed

Bit	Reset	Description
4	0x0	PKT_WR_FIFO_SEL: Host Write FIFO Select. In video mode, software shall not program PKT_WR_FIFO_SEL=VIDEO. 0 = HOST : Write data to the small host data FIFO only. 1 = VIDEO : Write data to both the host and video line store FIFO, in series. Note: Software shall only program PKT_WR_FIFO_SEL field in Host mode.
3	0x0	IMM_BTA: Generate BTA immediately, e.g., for Tearing Effect reporting. Note: This will generate a BTA and pass control of the D-PHY to the remote peripheral without the need to send any packet. Once the BTA is initiated on interface this bit gets cleared. Later on Host syncpt opdone is returned when the remote peripheral has responded and relinquished control of the bus. 0 = DISABLE : Do not generate BTA 1 = ENABLE : Generate BTA immediately, without waiting for a packet.
2	0x0	PKT_BTA: Generate BTA at the end of Host packets 0 = DISABLE : Do not generate BTA 1 = ENABLE : Generate BTA after the next packet is sent.
1	0x1	CS_ENABLE: enable Hardware Check Sum (CS) for Host packets Note: when CS is disabled, Host is responsible for generating proper CRC and adding the 2-byte CRC to the end of the packet after the payload. 0 = DISABLE : Disable hardware generation of CS (Host must calculate CS). 1 = ENABLE : Enable hardware generation of CS.
0	0x1	ECC_ENABLE: Enable hardware Error Correction Code (ECC) for Host packets Note: when ECC is disabled, Host is responsible for generating proper ECC byte for header 0 = DISABLE : Disable hardware generation of ECC (Host must calculate ECC). 1 = ENABLE : Enable hardware generation of ECC.

26.5.12 DSI_DSI_CONTROL_0

General DSI Control Register

Offset: 0x10 │ Byte Offset: 0x40 │ Read/Write: R/W │ Reset: 0x00000000 (0b00xxxxxxxxx0xx00xx00xx00xx000000)

Bit	Reset	Description
31	0x0	DSI_DBG_ENABLE: Control signal to turn off clock monitoring when enabled for debug, on every DSI byte clock debug signal toggle. Also TX CRC computation aid will turn on.
30	0x0	DFMT_16BPP_SWAP_EN: DSI specification supports different bit ordering (only 16 BPP) in command mode. Command Mode (Default) : 16BPP[15:0] -> B[4-0]G[5-0]R[4-0]; Command Mode (SWAP_EN) : 16BPP[15:0] -> G[2-0]B[4-0]R[4-0]G[5-3]
20	0x0	DSI_HS_CLK_CTRL: Control for the HS clock lane 0 = CONTINUOUS : HS clock is on all the time. 1 = TX_ONLY : HS clock is only active during HS transmissions.
17:16	0x0	DSI_VIRTUAL_CHANNEL: Virtual channel ID. The virtual channel is sent as part of the packet header and used to distinguish multiple displays.
13:12	0x0	DSI_DATA_FORMAT: Pixel Data format transmitted. Note that although the pixel format is specified in the packet header ID for RGB data packets, this information is ignored by the hardware. Only the information used in this register is used in the construction of RGB data packets. 0 = BIT16P : 16 bpp RGB Packed. 2 bytes used per pixel 1 = BIT18NP : 18 bpp RGB Not-packed. 3 bytes used per pixel 2 = BIT18P : 18 bpp RGB Packed. 2.25 bytes used per pixel 3 = BIT24P : 24 bpp RGB Packed. 3 bytes used per pixel
9:8	0x0	VID_TX_TRIG_SRC: Controls the source of the trigger to start sending packets. 0 = SOL : Start of Line signal from the Display Controller. 1 = FIFO_LEVEL : How full the FIFO is. Level determined elsewhere. 2 = IMMEDIATE : Determined by a write to the DSI_VID_TRIGGER field of the DSI_TRIGGER register

Bit	Reset	Description
5:4	0x0	DSI_NUM_DATA_LANES: Number of D-PHY data lanes used by Display for HS transmission. 0 = ONE : 1 data lane. 1 = TWO : 2 data lanes. 2 = THREE : 3 data lanes. 3 = FOUR : 4 data lanes.
3	0x0	VID_DCS_ENABLE: Enable for insertion of DCS commands during Display Controller generated packets. When enabled, the DCS commands defined in the LT3_DCS_CMD and LT5_DCS_CMD fields of the DSI_DCS_CMDS register will be inserted in long packets defined in packet sequence 3 and 5. 0 = DISABLE : No DCS commands will be inserted. 1 = ENABLE : DCS command IDs will be inserted as described above.
2	0x0	DSI_VID_SOURCE: Source of video pixels 0 = DISPLAY_0 : Pixels come from "display" 1 = DISPLAY_1 : Pixels come from "displayb"
1	0x0	DSI_VID_ENABLE: Video DSI Interface Enable 0 = DISABLE : Disable 1 = ENABLE : Enable
0	0x0	DSI_HOST_ENABLE: Host DSI Interface Enable 0 = DISABLE : Disable 1 = ENABLE : Enable

26.5.13 DSI_DSI_SOL_DELAY_0

Number of Byte-Clock Counts to Wait after Reception

Offset: 0x11 | Byte Offset: 0x44 | Read/Write: R/W | Reset: 0x0000XXXX (0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx)

Bit	Reset	Description
15:0	X	SOL_DELAY: Start Of Line before generating output packets.

26.5.14 DSI_DSI_MAX_THRESHOLD_0

Maximum Threshold Registers for DSI Related Packets

Offset: 0x12 | Byte Offset: 0x48 | Read/Write: R/W | Reset: 0x0000XXXX (0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx)

Bit	Reset	Description
15:0	X	MAX_THRESHOLD: Start draining FIFO once this threshold is met. This register can be used for DBI mode when line packet data exceeds the size of the data FIFO.

26.5.15 DSI_DSI_TRIGGER_0

Manual Transmission Trigger Register

Offset: 0x13 | Byte Offset: 0x4c | Read/Write: R/W | Reset: 0x0000000X (0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx)

Bit	Reset	Description
1	X	DSI_HOST_TRIGGER: A 1 written to this bit will start host transmission when HOST_DSI_CONTROL.HOST_TX_TRIG_SRC is set to IMMEDIATE. Hardware auto clears on operation completion
0	X	DSI_VID_TRIGGER: A 1 written to this bit will start video transmission when DSI_CONTROL.VID_TX_TRIG_SRC is set to IMMEDIATE. Hardware auto clears on operation completion

26.5.16 DSI_DSI_TX_CRC_0

Transmission CRC

Offset: 0x14 | Byte Offset: 0x50 | Read/Write: RO | Reset: 0xXXXXXXXX (0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx)

Bit	Reset	Description
31:0	X	TX_CRC: Long Packet CRC appended to the end of long packets. This CRC is that result of generating a CRC from all transmitted bytes. If DSI_HOST_ENABLE == ENABLE, then a CRC is generated from all bytes transmitted from the Host interface in Command Mode. If DSI_VID_ENABLE == ENABLE, then a CRC is generated from all bytes transmitted during a frame of video when in Video Mode. Note that the hardware will capture the CRC into a separate internal register so that it can continue to calculate the CRC for the next frame without having to wait for software to read the current result.

26.5.17 DSI_DSI_STATUS_0

DSI Status Register

Offset: 0x15 | Byte Offset: 0x54 | Read/Write: RO | Reset: 0x00000XXX (0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx)

Bit	Reset	Description
10	X	DSI_IDLE: Indicated that the DSI is IDLE.
9	X	LB_UNDERFLOW: Indicates that a Line buffer underflow event happened
8	X	LB_OVERFLOW: Indicates that a Line buffer overflow event happened
4:0	X	RD_FIFO_COUNT: Count of how many data words are left in the Host Read Data Return FIFO. Typically, software knows how much data to read from the DSI_RD_DATA register after a Read packet / BTA has been sent / requested, since these transactions are initiated by software. However, under error conditions, insufficient data may have been read from the FIFO. Software should therefore check this field to make sure it is 0 after reading all the information it expected to get.

26.6 Initialization Sequence Registers

26.6.1 DSI_DSI_INIT_SEQ_CONTROL_0

DSI Initialization Sequence Control

Offset: 0x1a | Byte Offset: 0x68 | Read/Write: R/W | Reset: 0x0000XX00 (0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx0)

Bit	Reset	Description
14:8	X	DSI_FRAME_INIT_BYTE_COUNT: Frame Initialization Sequence Byte Count. This parameter specifies the number of frame initialization sequence cycles to send. If programmed to 0, there is no frame initialization cycle generated. Valid programmable values: 0 to 64. Invalid programmable values: 65 to 127.
0	0x0	DSI_SEND_INIT_SEQUENCE: Send Initialization Sequence (IS) 0 = DISABLE 1 = ENABLE

26.6.2 DSI_DSI_INIT_SEQ_DATA_0_0

DSI Init Sequence Write Data 0

Offset: 0x1b | Byte Offset: 0x6c | Read/Write: R/W | Reset: 0xXXXXXXXX (0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx)

Bit	Reset	Description
31:0	X	DSI_INIT_SEQ_DATA_0: DSI Init Sequence Write Data bits 31:0

26.6.3 DSI_DSI_INIT_SEQ_DATA_1_0

DSI Init Sequence Write Data 1

Offset: 0x1c | Byte Offset: 0x70 | Read/Write: R/W | Reset: 0xXXXXXXXX (0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx)

Bit	Reset	Description
31:0	X	DSI_INIT_SEQ_DATA_1: DSI Init Sequence Write Data bits 31:0

26.6.4 DSI_DSI_INIT_SEQ_DATA_2_0

DSI Init Sequence Write Data 2

Offset: 0x1d | Byte Offset: 0x74 | Read/Write: R/W | Reset: 0xXXXXXXXX (0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx)

Bit	Reset	Description
31:0	X	DSI_INIT_SEQ_DATA_2: DSI Init Sequence Write Data bits 31:0

26.6.5 DSI_DSI_INIT_SEQ_DATA_3_0

DSI Init Sequence Write Data 3

Offset: 0x1e | Byte Offset: 0x78 | Read/Write: R/W | Reset: 0xXXXXXXXX (0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx)

Bit	Reset	Description
31:0	X	DSI_INIT_SEQ_DATA_3: DSI Init Sequence Write Data bits 31:0

26.6.6 DSI_DSI_INIT_SEQ_DATA_4_0

DSI Init Sequence Write Data 4

Offset: 0x1f | Byte Offset: 0x7c | Read/Write: R/W | Reset: 0xXXXXXXXX (0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx)

Bit	Reset	Description
31:0	X	DSI_INIT_SEQ_DATA_4: DSI Init Sequence Write Data bits 31:0

26.6.7 DSI_DSI_INIT_SEQ_DATA_5_0

DSI Init Sequence Write Data 5

Offset: 0x20 | Byte Offset: 0x80 | Read/Write: R/W | Reset: 0xXXXXXXXX (0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx)

Bit	Reset	Description
31:0	X	DSI_INIT_SEQ_DATA_5: DSI Init Sequence Write Data bits 31:0

26.6.8 DSI_DSI_INIT_SEQ_DATA_6_0

DSI Init Sequence Write Data 6

Offset: 0x21 | Byte Offset: 0x84 | Read/Write: R/W | Reset: 0xXXXXXXXX (0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx)

Bit	Reset	Description
31:0	X	DSI_INIT_SEQ_DATA_6: DSI Init Sequence Write Data bits 31-0

26.6.9 DSI_DSI_INIT_SEQ_DATA_7_0

DSI Init Sequence Write Data 7

Offset: 0x22 | Byte Offset: 0x88 | Read/Write: R/W | Reset: 0xXXXXXXXX (0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx)

Bit	Reset	Description
31:0	X	DSI_INIT_SEQ_DATA_7: DSI Init Sequence Write Data bits 31-0

26.7 Packet Sequence Registers

These registers allow the construction of arbitrary packet sequences associated with various video line types as sent from the Display Controller to the DSI block.

The first digit of the pair of digits in each field below is the sequence number, and the second digit denotes the packet number within each sequence. For example, field PKT_23_ID, defines the ID for packet 3 in sequence 2.

26.7.1 DSI_DSI_PKT_SEQ_0_LO_0

DSI Packet Sequence 0 LO Half

Offset: 0x23 | Byte Offset: 0x8c | Read/Write: R/W | Reset: 0xXXXXXXXX (0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx0)

Bit	Reset	Description
30	X	SEQ_0_FORCE_LP: For packet sequence 0, forces the D-PHY to go to LP mode after the last packet of the sequence has been transmitted. 0 = DISABLE 1 = ENABLE
29	X	PKT_02_EN: Packet 2 enable 0 = DISABLE 1 = ENABLE
28:23	X	PKT_02_ID: Packet 2 Packet ID
22:20	X	PKT_02_SIZE: Packet 2 size pointer
19	X	PKT_01_EN: Packet 1 enable 0 = DISABLE 1 = ENABLE
18:13	X	PKT_01_ID: Packet 1 Packet ID
12:10	X	PKT_01_SIZE: Packet 1 size pointer
9	X	PKT_00_EN: Packet 0 enable 0 = DISABLE 1 = ENABLE
8:3	X	PKT_00_ID: Packet 0 Packet ID
2:0	X	PKT_00_SIZE: Packet 0 size pointer

26.7.2 DSI_DSI_PKT_SEQ_0_HI_0

DSI Packet Sequence 0 HI Half

Line Type 0 is associated with the first line in the frame and should contain a packet sequence that starts with a VS packet.

Offset: 0x24 │ Byte Offset: 0x90 │ Read/Write: R/W │ Reset: 0xXXXXXXXX (0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx0)

Bit	Reset	Description
29	X	PKT_05_EN: Packet 5 enable 0 = DISABLE 1 = ENABLE
28:23	X	PKT_05_ID: Packet 5 Packet ID
22:20	X	PKT_05_SIZE: Packet 5 size pointer
19	X	PKT_04_EN: Packet 4 enable 0 = DISABLE 1 = ENABLE
18:13	X	PKT_04_ID: Packet 4 Packet ID
12:10	X	PKT_04_SIZE: Packet 4 size pointer
9	X	PKT_03_EN: Packet 3 enable 0 = DISABLE 1 = ENABLE
8:3	X	PKT_03_ID: Packet 3 Packet ID
2:0	X	PKT_03_SIZE: Packet 3 size pointer

26.7.3 DSI_DSI_PKT_SEQ_1_LO_0

DSI Packet Sequence 1 LO Half

Line Type 1 is associated with the last line of Vertical Sync and should contain a packet sequence that starts with a VE packet.

Offset: 0x25 │ Byte Offset: 0x94 │ Read/Write: R/W │ Reset: 0xXXXXXXXX (0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx0)

Bit	Reset	Description
30	X	SEQ_1_FORCE_LP: For packet sequence 1, forces the D-PHY to go to LP mode after the last packet of the sequence has been transmitted. 0 = DISABLE 1 = ENABLE
29	X	PKT_12_EN: Packet 2 enable 0 = DISABLE 1 = ENABLE
28:23	X	PKT_12_ID: Packet 2 Packet ID
22:20	X	PKT_12_SIZE: Packet 2 size pointer
19	X	PKT_11_EN: Packet 1 enable 0 = DISABLE 1 = ENABLE
18:13	X	PKT_11_ID: Packet 1 Packet ID
12:10	X	PKT_11_SIZE: Packet 1 size pointer
9	X	PKT_10_EN: Packet 0 enable 0 = DISABLE 1 = ENABLE
8:3	X	PKT_10_ID: Packet 0 Packet ID

Bit	Reset	Description
2:0	X	PKT_10_SIZE: Packet 0 size pointer

26.7.4 DSI_DSI_PKT_SEQ_1_HI_0

DSI Packet Sequence 1 HI Half

Offset: 0x26 | Byte Offset: 0x98 | Read/Write: R/W | Reset: 0xXXXXXXXX (0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx0)

Bit	Reset	Description
29	X	PKT_15_EN: Packet 5 enable 0 = DISABLE 1 = ENABLE
28:23	X	PKT_15_ID: Packet 5 Packet ID
22:20	X	PKT_15_SIZE: Packet 5 size pointer
19	X	PKT_14_EN: Packet 4 enable 0 = DISABLE 1 = ENABLE
18:13	X	PKT_14_ID: Packet 4 Packet ID
12:10	X	PKT_14_SIZE: Packet 4 size pointer
9	X	PKT_13_EN: Packet 3 enable 0 = DISABLE 1 = ENABLE
8:3	X	PKT_13_ID: Packet 3 Packet ID
2:0	X	PKT_13_SIZE: Packet 3 size pointer

26.7.5 DSI_DSI_PKT_SEQ_2_LO_0

DSI Packet Sequence 2 LO Half

Line Type 2 is associated with any vertical blank line except the first one after active and should contain a packet sequence that starts with an HS packet.

Offset: 0x27 | Byte Offset: 0x9c | Read/Write: R/W | Reset: 0xXXXXXXXX (0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx0)

Bit	Reset	Description
30	X	SEQ_2_FORCE_LP: For packet sequence 2, forces the D-PHY to go to LP mode after the last packet of the sequence has been transmitted. 0 = DISABLE 1 = ENABLE
29	X	PKT_22_EN: Packet 2 enable 0 = DISABLE 1 = ENABLE
28:23	X	PKT_22_ID: Packet 2 Packet ID
22:20	X	PKT_22_SIZE: Packet 2 size pointer

2:0	X	PKT_53_SIZE: Packet 3 size pointer

26.8 DCS Command and Packet Length Registers

26.8.1 DSI_DSI_DCS_CMDS_0

DCS command IDs used for Line Types 3 and 5. These command IDs are inserted at the start of the data payload of DCS long packets when the Display Controller is being used to transmit DCS commands.

Offset: 0x33 │ Byte Offset: 0xcc │ Read/Write: R/W │ Reset: 0xXXXXXXXX (0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx0)

Bit	Reset	Description
15:8	X	LT5_DCS_CMD: DCS command for Line Type 5.
7:0	X	LT3_DCS_CMD: DCS command for Line Type 3.

26.8.2 DSI_DSI_PKT_LEN_0_1_0

DSI Packet Lengths 0 and 1

Offset: 0x34 | Byte Offset: 0xd0 | Read/Write: R/W | Reset: 0xXXXXXXXX (0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx)

Bit	Reset	Description
31:16	X	LENGTH_1: Packet length 1 (in bytes)
15:0	X	LENGTH_0: Packet length 0 (in bytes)

26.8.3 DSI_DSI_PKT_LEN_2_3_0

DSI Packet Lengths 2 and 3

Offset: 0x35 | Byte Offset: 0xd4 | Read/Write: R/W | Reset: 0xXXXXXXXX (0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx)

Bit	Reset	Description
31:16	X	LENGTH_3: Packet length 3 (in bytes)
15:0	X	LENGTH_2: Packet length 2 (in bytes)

26.8.4 DSI_DSI_PKT_LEN_4_5_0

DSI Packet Lengths 4 and 5

Offset: 0x36 | Byte Offset: 0xd8 | Read/Write: R/W | Reset: 0xXXXXXXXX (0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx)

Bit	Reset	Description
31:16	X	LENGTH_5: Packet length 5 (in bytes)
15:0	X	LENGTH_4: Packet length 4 (in bytes)

26.8.5 DSI_DSI_PKT_LEN_6_7_0

DSI Packet Lengths 6 and 7

Offset: 0x37 | Byte Offset: 0xdc | Read/Write: R/W | Reset: 0xXXXXXXXX (0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx)

Bit	Reset	Description
31:16	X	LENGTH_7: Packet length 7 (in bytes)
15:0	X	LENGTH_6: Packet length 6 (in bytes)

26.9 Physical Interface Timing Registers

The DSI PHY timing registers must be initialized before the interface is enabled. Based on the equations provided in the table below, all PHY timing parameters should be programmed in the timing registers. T_{byte} refers to just the DSI controller clock.

Table 97 D-PHY Timing Values

Parameter	MIPI D-PHY Spec Value	Programmed Value
THS-PREPARE	(40 ns + 4*UI , 85 ns + 6*UI)	Min - (40 + (4 T_{bit}))) / T_{byte} Max - ((85 + 6 T_{bit})) / T_{byte}

Parameter	MIPI D-PHY Spec Value	Programmed Value
THS-ZERO	105 ns + 6*UI min.	(105 + (6 T_{bit})) / T_{byte} -2
THS-TRAIL	max(8*UI, 60 ns + 4*UI)	3 + max(8 T_{bit}, 60 + 4 T_{bit}) / T_{byte}
THS-EXIT	100 ns min.	100 / T_{byte}
TLPX	50 ns min.	50 / T_{byte}
TCLK-ZERO	300 ns along with TCLK-PREPARE	260/ T_{byte}
TCLK-PREPARE	(38 ns, 95 ns)	THS-PREPARE timing should guarantee to meet both these timing requirements
TCLK-POST	60 ns + 52*UI min.	(60 + (52 T_{bit})) / T_{byte} - 2
TCLK-TRAIL	60 ns min.	60 / T_{byte}
TCLK-PRE	8 UI	8 T_{bit}
TTA-GO	4 * TLPX	3 * TLPX
TTA-SURE	(TLPX, 2 * TLPX)	TLPX - 1
TTA-GET	5 * TLPX	4 * TLPX
TWAKEUP	1 ms	1 ms/10 ns x 512 {in terms of 512 byte clocks}

Notes:

- T_{byte} = Period of one byte clock in nanoseconds.
- T_{bit} = Period of one bit time in nanoseconds. (T_{bit} = T_{byte} / 8)
- All figures and time periods are in nanoseconds.
- All timing register values are multiples of byte clock period, T_{byte}.
- All fractional results are truncated. No rounding.

26.9.1 DSI_DSI_PHY_TIMING_0_0

DSI D-PHY Timing Register 0

Offset: 0x3c │ Byte Offset: 0xf0 │ Read/Write: R/W │ Reset: 0xXXXXXXXX (0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx)

Bit	Reset	Description
31:24	X	DSI_THSDEXIT: Time to drive LP11 after HS **Note:** Valid programmable values for all the fields in this register (i.e., DSI_THSPREPR/DSI_TDATZERO/DSI_THSTRAIL/DSI_THSDEXIT) are 0 to 254. Invalid value is 255.
23:16	X	DSI_THSTRAIL: Time to drive HS flipped bit at EOT
15:8	X	DSI_TDATZERO: Time to drive HS0 before SOT
7:0	X	DSI_THSPREPR: Time to drive LP00 before HS data

26.9.2 DSI_DSI_PHY_TIMING_1_0

DSI D-PHY Timing Register 1

Offset: 0x3d │ Byte Offset: 0xf4 │ Read/Write: R/W │ Reset: 0xXXXXXXXX (0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx)

Bit	Reset	Description
31:24	X	DSI_TCLKTRAIL: Time to drive HS0 before the clock goes to LP1 **Note:** Valid programmable values for all the fields in this register (i.e., DSI_TTLPX/DSI_TCLKZERO/DSI_TCLKPOST/ DSI_TCLKTRAIL) are 0 to 254 Invalid value is 255.
23:16	X	DSI_TCLKPOST: Time to drive clock after the last HS data
15:8	X	DSI_TCLKZERO: Time to drive LP00 before HS clock
7:0	X	DSI_TTLPX: LP period

26.9.3 DSI_DSI_PHY_TIMING_2_0

DSI D-PHY Timing Register 2

Offset: 0x3e │ Byte Offset: 0xf8 │ Read/Write: R/W │ Reset: 0xXXXXXXXX (0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx0)

Bit	Reset	Description
23:16	X	DSI_TCLKPREPARE: Time to drive LP0 before CLK_ZERO starts off on the clock lane. **Note:** Valid programmable values for the following register fields (i.e., DSI_TCLKPRE/DSI_TCLKPREPARE) are 0 to 254. Invalid value is 255
15:8	X	DSI_TCLKPRE: Time to run clock before enabling data lane
7:0	X	DSI_TWAKEUP: LP period when exiting ULPM, in units of 512 byte clocks.

26.9.4 DSI_DSI_BTA_TIMING_0

DSI D-PHY Bus-Turn-Around Timing

Offset: 0x3f │ Byte Offset: 0xfc │ Read/Write: R/W │ Reset: 0xXXXXXXXX (0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx)

Bit	Reset	Description
31:24	X	DSI_TPKTBTA: Programmable Time delay between end of Host packet transmission and generation of Pkt BTA in PKT_BTA mode (i.e., HOST_DSI_CONTROL[2]) - Generate BTA at the end of Host packets **Note**: Valid programmable values for all the fields in this register (i.e., DSI_TTAGO/DSI_TTASURE/DSI_TTAGET/ DSI_TPKTBTA) are 0 to 254. Invalid value is 255.
23:16	X	DSI_TTAGET: Time to Drive LP00 at end of BTA (5 * TTLPX)
15:8	X	DSI_TTASURE: Time to Receive LP00 at end of BTA (2 * TTLPX)
7:0	X	DSI_TTAGO: Time to drive LP00 at start of BTA (4 * TTLPX)

26.10 Contention Recovery Timers

These registers control the length of time - in units of 512 DSI byte clocks – that can elapse before the hardware will decide that a bus contention error has occurred.

There are several counters to deal with various forms of error that may occur. For details, refer to the MIPI DSI Specification, section 7.2.2.

26.10.1 DSI_DSI_TIMEOUT_0_0

DSI Time Out Terminal Count Register 0

Offset: 0x44 | Byte Offset: 0x110 | Read/Write: R/W | Reset: 0xXXXXXXXX (0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx)

Bit	Reset	Description
31:16	X	LRXH_TO: Low Power Receive (Host) Time Out terminal count
15:0	X	HTX_TO: High Speed Transmit Time Out terminal count

26.10.2 DSI_DSI_TIMEOUT_1_0

DSI Time Out Terminal Count Register 1

Offset: 0x45 | Byte Offset: 0x114 | Read/Write: R/W | Reset: 0xXXXXXXXX (0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx)

Bit	Reset	Description
31:16	X	PR_TO: Peripheral Reset duration.
15:0	X	TA_TO: Turn Around Time Out terminal count

26.10.3 DSI_DSI_TO_TALLY_0

DSI Time Out Tally Register

Each time one of the time-out counters reaches its terminal count, it will increment the associated tally register.

Offset: 0x46 | Byte Offset: 0x118 | Read/Write: R/W | Reset: 0xXXXXXXXX (0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx0)

Bit	R/W	Reset	Description
24	RO	X	P_RESET_STATUS: Peripheral Reset time out status 0 = IN_RESET 1 = READY
23:16	RW	X	TA_TALLY: Turn Around time out tally
15:8	RW	X	LRXH_TALLY: LP Rx time out tally
7:0	RW	X	HTX_TALLY: HS Tx time out tally

26.11 Physical Pad Control Registers

26.11.1 DSI_PAD_CONTROL_0

DSI PHY Configuration Register

Software can program this register to work with different panels.

Offset: 0x4b │ Byte Offset: 0x12c │ Read/Write: R/W │ Reset: 0x010f010f (0bxxxxxxx1xxxx1111xxxxxxx1xxxx1111)

Bit	Reset	Description
24	0x1	DSI_PAD_PULLDN_CLK_ENAB:1= Enable pad pulldown for clock bit at power on
19:16	0xf	DSI_PAD_PULLDN_ENAB:1= Enable pad pulldown for data bits at power on
8	0x1	DSI_PAD_PDIO_CLK: Power down for clock bit, drivers, receivers, and contention detectors
3:0	0xf	DSI_PAD_PDIO: Power down for data bit, drivers, receivers, and contention detectors

26.11.2 DSI_PAD_CONTROL_CD_0

Contention Detection Logic Enable Signals

Offset: 0x4c │ Byte Offset: 0x130 │ Read/Write: R/W │ Reset: 0x00000000 (0bxxxxxxxxxxxxxx000xxxxxxx0xxxx0000)

Bit	Reset	Description
18:16	0x0	DSI_PAD_CDDNADJ: Level adjust on low limit of detection. Tie to 0 (DSI emu, miniTMC control). 000 = 0.3V 001 = 0.375V 010 = 0.45V 011 = 0.525V 100 = 0.3V 101 = 0.225V 110 = 0.15V 111 = 0.075V
8	0x0	DSI_PAD_CD_EN_CLK: Clock bit contention detector enable. 1 = Enable
3:0	0x0	DSI_PAD_CD_EN: Data bits contention detector enable. 1 = EnableCD_EN_[1] = 0 in DSI.

26.11.3 DSI_PAD_CD_STATUS_0

Contention Detection Status from MIPI PAD

Offset: 0x4d │ Byte Offset: 0x134 │ Read/Write: RO │ Reset: 0x000X0X0X (0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx)

Bit	Reset	Description
18	X	DSI_PAD_CDN_CLK
16	X	DSI_PAD_CDP_CLK
11:8	X	DSI_PAD_CDN
3:0	X	DSI_PAD_CDP

26.11.4 DSI_DSI_VID_MODE_CONTROL_0

Host Command Packet During Video Mode

Offset: 0x4e │ Byte Offset: 0x138 │ Read/Write: R/W │ Reset: 0x00000000 (0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx0000)

Bit	Reset	Description
3:1	0x0	DSI_LINE_TYPE: Vertical blank. LINE TYPE on which the host command packet is to be transmitted, i.e., valid values are 0/1/2/4 0 = ZERO : Line type 0 1 = ONE : Line type 1 2 = TWO : Line type 2 3 = THREE : NA: Host command packets on line type 3 are invalid 4 = FOUR : Line type 4 5 = FIVE : NA: Host command packets on line type 5 are invalid 6 = SIX : NA: Host command packets on line type 6 are invalid 7 = SEVEN : NA: Host command packets on line type 7 are invalid
0	0x0	DSI_CMD_PKT_VID_ENABLE: 0 = DISABLE : Disable host command packet during video mode 1 = ENABLE : Enable host command packet during video mode

26.11.5 DSI_PAD_CONTROL_1_0

DSI PHY Configuration Register

Software can program this register to work with different panels.

Offset: 0x4f │ Byte Offset: 0x13c │ Read/Write: R/W │ Reset: 0x00000000 (0bxxxxxxxxxxxxxxxxxx000x000x000x000)

Bit	Reset	Description
14:12	0x0	DSI_PAD_OUTADJ3: Input delay trimmer for data bit 3. Each tap delays 40 ps
10:8	0x0	DSI_PAD_OUTADJ2: Input delay trimmer for data bit 2. Each tap delays 40 ps
6:4	0x0	DSI_PAD_OUTADJ1: Input delay trimmer for data bit 1. Each tap delays 40 ps
2:0	0x0	DSI_PAD_OUTADJ0: Input delay trimmer for data bit 0.Each tap delays 40 ps

26.11.6 DSI_PAD_CONTROL_2_0

DSI PHY Configuration Register

Software can program this register to work with different panels.

Offset: 0x50 │ Byte Offset: 0x140 │ Read/Write: R/W │ Reset: 0x00000000 (0bxxxxxxxxxxxxx000x000x000x000x000)

Bit	Reset	Description
18:16	0x0	DSI_PAD_SLEWUPADJ: Pull-up slew rate adjust. 000 = 011: slew rate increases 100 = 000, 100 =111: skew rate decreases
14:12	0x0	DSI_PAD_SLEWDNADJ: Pull-down slew rate adjust. 000 = 011, slew rate increases 100 = 000, 100 = 111: skew rate decreases.
10:8	0x0	DSI_PAD_LPUPADJ: Driver pull-up impedance control. 00 = 130 ohms, default, 01 = 110 ohms 10 = 130 ohms 11 = 150 ohms

Bit	Reset	Description
6:4	0x0	DSI_PAD_LPDNADJ: Driver pull-down impedance control. 00 = 130 ohms, default 01 = 110 ohms 10 = 130 ohms, same as 0 011 = 150 ohms
2:0	0x0	DSI_PAD_OUTADJCLK: Output trimmer delay for clock bit. Each tap delays 40 ps

26.11.7 DSI_PAD_CONTROL_3_0

DSI PHY Configuration Register

Software can program this register to work with different panels.

Offset: 0x51 │ Byte Offset: 0x144 │ Read/Write: R/W │ Reset: 0x10000000 (0bxxx1xxxxxxxxxxx0xx00xx00xx00xx00)

Bit	Reset	Description
28	0x1	DSI_PAD_PDVCLAMP: Power down regulator which supplies current to serializer/deserializer logic. Active high, 1=power down
16	0x0	DSI_PAD_BANDWD_IN: Increase bandwidth of differential receiver
13:12	0x0	DSI_PAD_PREEMP_PD_CLK: Clock bit HS driver pull down pre-emphasis. 00 = no_preemphasis 11= max
9:8	0x0	DSI_PAD_PREEMP_PU_CLK: Clock bit HS driver pull up pre-emphasis. 00 = no_preemphasis 11= max
5:4	0x0	DSI_PAD_PREEMP_PD: Data bit HS driver pull down pre-emphasis. 00 = no_preemphasis 11= max
1:0	0x0	DSI_PAD_PREEMP_PU: Data bit HS driver pull up pre-emphasis. 00 = no_preemphasis 11= max

26.11.8 DSI_PAD_CONTROL_4_0

DSI PHY Configuration Register

Software can program this register to work with different panels.

Offset: 0x52 │ Byte Offset: 0x148 │ Read/Write: R/W │ Reset: 0x00000000 (0bxxx0xxxx0000xxx0xxxx0000xxx0xxx0)

Bit	Reset	Description
28	0x0	DSI_PAD_HS_BSO_CLK:1= Enables BIAS and power regulators on for HS mode
23:20	0x0	DSI_PAD_HS_BSO:1= Enables BIAS and power regulators on for HS mode
16	0x0	DSI_PAD_LP_BSO_CLK:1= Enables BIAS and power regulators on for LP mode
11:8	0x0	DSI_PAD_LP_BSO:1= Enables BIAS and power regulators on for LP mode
4	0x0	DSI_PAD_TXBW_EN:1= Increase bandwidth of output driver, default=0
0	0x0	DSI_PAD_REV_CLK:1= Reverse clock polarity

26.11.9 DSI_DSI_GANGED_MODE_CONTROL_0

Offset: 0x53 | Byte Offset: 0x14c | Read/Write: R/W | Reset: 0x00000000 (0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx0)

Bit	Reset	Description
0	0x0	DSI_GANGED_MODE_EN: 0 = DISABLE : Ganged mode transaction disabled 1 = ENABLE : Ganged mode transaction enabled

26.11.10 DSI_DSI_GANGED_MODE_START_0

Offset: 0x54 | Byte Offset: 0x150 | Read/Write: R/W | Reset: 0x00000000 (0bxxxxxxxxxxxxxxxxxxx0000000000000)

Bit	Reset	Description
12:0	0x0	DSI_GANGED_START_POINTER: Start pointer for indicating the start of partial active valid pixel data to be latched from the valid pixels of the display controller in Left-Right/Even-Odd ganged mode. Note: Program to the default value/zero when DSI_GANGED_MODE_EN = DISABLE (non ganged mode).

26.11.11 DSI_DSI_GANGED_MODE_SIZE_0

Offset: 0x55 | Byte Offset: 0x154 | Read/Write: R/W | Reset: 0x00000000 (0bxxx0000000000000xxx0000000000000)

Bit	Reset	Description
28:16	0x0	DSI_GANGED_VALID_LOW_WIDTH: Width of Partial Inactive/Ignored pixel data from the valid pixels of the display controller in Left-Right/Even-Odd ganged mode. Note: Program to the default value/zero when DSI_GANGED_MODE_EN = DISABLE (non-ganged mode).
12:0	0x0	DSI_GANGED_VALID_HIGH_WIDTH: Width of Partial Active valid pixel data latched from the valid pixels of display controller in Left-Right/Even-Odd ganged mode. Note: Program to the default value/zero when DSI_GANGED_MODE_EN = DISABLE (non-ganged mode).

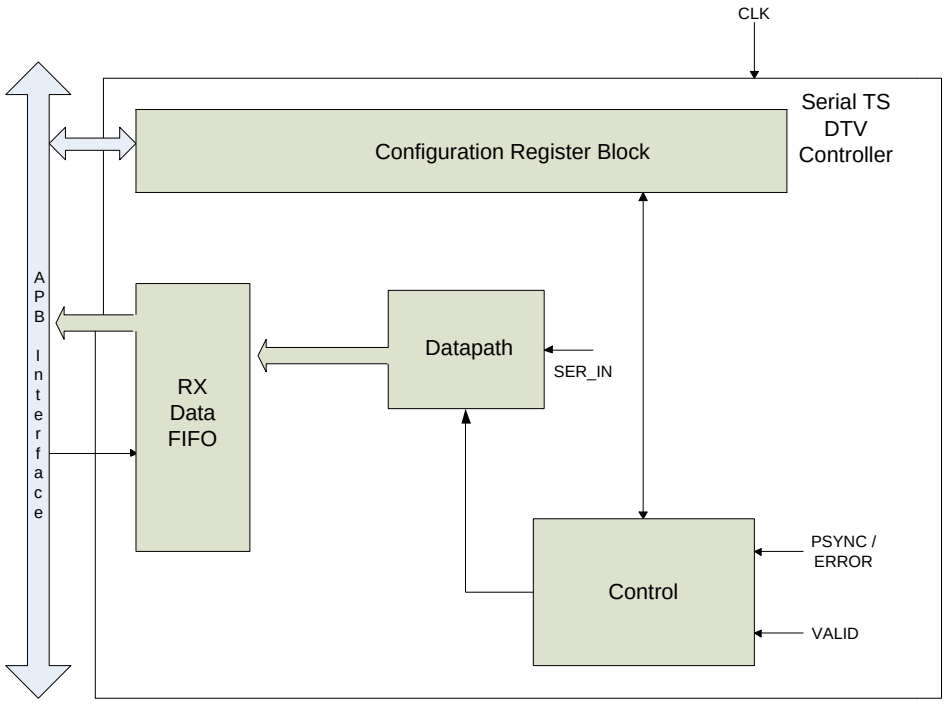
27.0 SERIAL TRANSPORT STREAM DTV CONTROLLER

The Tegra® 4 device supports a Serial Transport Stream (Serial TS) used to carry digital television data in some applications. The protocol is similar to the Motorola SPI protocol, but is not directly compatible. This section describes the Serial TS DTV controller.

27.1 Functional Description

The Serial TS DTV controller connects to the APB bus and works as a slave. It has a Receive FIFO size of 32 x 32 bits. Software programs the controller to generate transactions of a required packet length, where a transaction is a sequence of packets in the receive direction. The controller uses APB DMA to read from the FIFOs as required. Software reads the Data and FEC from the FIFO and does the necessary operation. The figure below shows the Serial TS DTV controller's internal blocks.

Figure 118: Transport Stream with Internal Blocks



Features

- Slave support for the serial TS interface for different mobile TV protocols
- Programmable polarity for valid / packet sync and error signals
- Minimum packet size is 4 bytes
- Capture of Reed-Solomon data
- 0-20 MHz frequency of operation
- Statistics counters
- DMA mastering capability

Hardware/Software Partitioning

- **Hardware** – Converts the serially incoming Data and FEC to parallel and stores them to make them visible to software. Updates the status registers (for different error conditions).
- **Software** – Reads the Data and FEC to perform necessary tasks, programs the control registers, and handles the status registers for different error conditions.

27.1.1 Signal Sanitization

The following internal signals provide flexibility to variations on the protocol:

Polarity normalized inputs:

- PSYNC = (TS_PSYNC ^ PSYNC_POL)
- VALID = (TS_VALID ^ VALID_ POL)
- ERROR = (TS_ERROR ^ ERROR_POL)

START: defined as one of the following (programming choice START_SELECT):

- Rising edge of VALID
- Rising edge of PSYNC
- Rising edge of (VALID & PSYNC)

START signal is internally used to delimit the beginning of the packet.

BODY_VALID: defined as one of the following (programming choice BODY_VALID_SELECT):

- byte_cnt = 0 on reset and gets incremented by 1 for each byte received. BODY_SIZE can be programmed to be in the inclusive range of 1-255 bytes (default is 188).
- The interval between START and the falling edge of VALID.

FEC_VALID: asserted from the deassertion of BODY_VALID and held high during FEC_SIZE bytes.

- FEC_SIZE can be programmed to be in the inclusive range of 0-127 bytes (default is 16).
- If FEC_SIZE = 0, this internal signal is not asserted.

PROTOCOL_SELECT: defined as one of the following (programming choice PROTOCOL_SELECT):

- 00b: ERROR and PSYNC are tied to zero
- 01b: ERROR is tied to the error/PSYNC input port. PSYNC is tied to zero
- 10b: ERROR is tied to zero. PSYNC is tied to the error/PSYNC input port.
- 11b: Reserved

CLK_MODE: defines one of the following with the programmable option of DTV_MODE_0.clk_mode:

- 0: a discontinuous clock source.
- 1: a continuous clock source.

A discontinuous clock source is one where the clock toggles exactly 8*N times for a given packet size of N bytes. Any number of clocks greater than 8*N is regarded as a continuous clock.

27.1.2 Protocol Handling

A serial interface packet consists of a BODY section and an FEC section.

BODY: TS packet. BODY is validated by BODY_VALID. The first byte of the packet is expected to be a sync byte.

FEC: FEC_SIZE bytes, FEC data (typically Reed-Solomon parity bytes). FEC is validated by FEC_VALID.

Packet capture stops after BODY and (if FEC_SIZE > 0) FEC are captured.

If START is reasserted prior to completing a full packet, the packet will be considered a PACKET_UNDERRUN_ERROR. The sections below describe error conditions.

27.1.3 Error Conditions

Error Packet

A packet is considered an error packet in any of the following cases:

1. **UPSTREAM_ERROR:** TS_ERROR is asserted during the first clock cycle of the packet and remains high during the capture of the whole packet.
2. **BODY_UNDERRUN_ERROR:** If the number of bytes captured in BODY (BODY SIZE) is less than EXPECTED BODY_SIZE. Occurs only when DTV_CONTROL_0.body_valid_select is set to 1.
3. **BODY_OVERRUN_ERROR:** If the number of bytes captured in BODY (BODY SIZE) is greater than EXPECTED BODY_SIZE. Occurs only when DTV_CONTROL_0.body_valid_select is set to 1.
4. **PACKET_UNDERRUN_ERROR:** None of the above (1 through 3) occur and If the total number of bytes captured (whole of the packet) is less than EXPECTED (BODY_SIZE + FEC_SIZE)

The error conditions described above are checked in the order specified. The first one encountered is reported. A packet will produce at most one error condition.

Statistics Counters

There are two statistics counters: ERROR_COUNTER and PACKET_COUNTER:

- Error packets are counted in ERROR_COUNTER.
- Total packets are counted in PACKET_COUNTER (regardless of whether they contain errors or not).
- Both statistics counters are sticky on 0xFFFF and are not free-running. Both are cleared on writes and cannot be preloaded with user-defined values.
- The byte stream stored in memory contains no explicit indication of the error.
- All packets are stored in memory regardless of their size and type.
- There is no specific hardware mechanism to signal software where the errors are located. Software is expected to perform the required checks to make sure the packet is correct.

Writing Error Packets into Memory

Error packets (including the case where they are signaled up front, i.e., UPSTREAM ERROR) are stored in memory with the captured length.

27.1.4 SERIAL TS Memory Format

Captured data is stored in memory according to the following format:

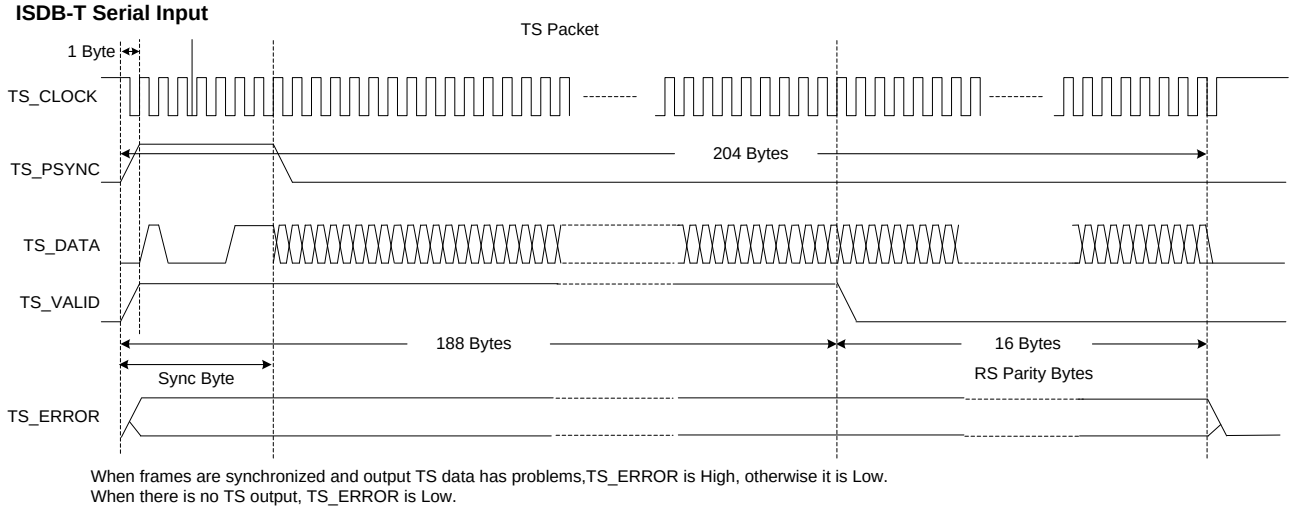
- BODY: BODY_SIZE bytes out of which the first byte is considered a sync byte and
- FEC: FEC_SIZE bytes, if FEC is present.

Functional Description

- The Start signal is generated as explained above with the programmable option START_SELECT.
- VALID is asserted for Body and deasserted for FEC, if at all it is taken into consideration with BODY_VALID_SELECT.
- VALID_POLARITY determines the polarity of the VALID signal.
- Sync byte is the first byte in body to indicate the start of a new packet. The value of the sync byte is fixed at 0x47 to indicate the new packet is properly aligned.
- Either Error/Sync or both are tied to zero based on the programmed value in PROTOCOL_SELECT. Error/Sync polarity depends on ERROR_POLARITY and PSYNC_POLARITY, respectively.
- Serially captured information on DATA is deserialized (shift register) and stored in a FIFO.

The timing diagram for a serial communication of a packet with DATA, PSYNC, and VALID is shown below:

Figure 119: Serial Communication Timing Diagram



When frames are synchronized and output TS data has problems,TS_ERROR is High, otherwise it is Low.
When there is no TS output, TS_ERROR is Low.

27.1.5 Control

The control logic includes:

- Generation of start signal and the polarity for PSYNC / ERROR and VALID
- Byte counter to count the number of bytes received in DATA and FEC
- Assert the error bits on respective error conditions
- End of packet generation based on the byte counter

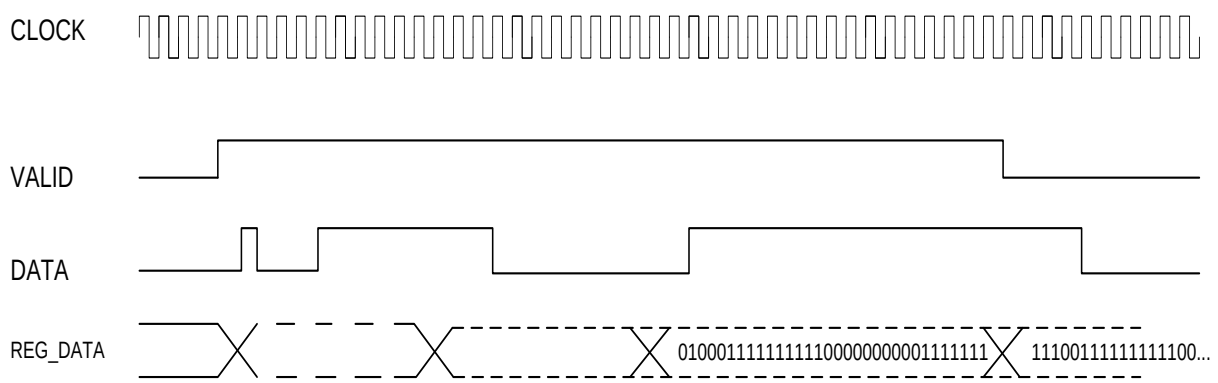
27.1.6 Datapath

Datapath logic performs these functions:

- Writes 32-bit data from the DTV clock domain into the sync FIFO
- Clears the status on writes to the respective error status bits
- Counts the number of packets (non-error and error)

The deserialization is shown in the following figure:

Figure 120: Deserializing of Incoming Serial Data



27.1.7 Status Information

There are certain bits of status information in the registers that the software can use to determine the status of the currently ongoing transfer.

RXF_OVF bit: This bit indicates an overflow in RX FIFO and is set to 1 whenever an error is detected during a receive operation.

RXF_FULL: This bit indicates whether the RX FIFO is full or not and is set to 1 when RX FIFO is full. If this bit is set to 1 during a reception, it indicates that the controller has received data in the RX FIFO and is waiting for the firmware to read these data before receiving any more data.

RXF_EMPTY: This bit indicates whether the RX FIFO is empty or not and is set to 1 when RX FIFO is empty.

INTERRUPT_STATUS: The respective bit is asserted high when one of the following occurs:

- Upstream error or
- Body Underrun error or
- Body Overrun error or
- Packet Underrun error.

The bit remains asserted until acted upon by the CPU to make it deasserted.

PACKET_COUNTER.VALUE: This field contains the number of packets that have been transferred during current transfer irrespective of whether they are error or not.

ERROR_COUNTER.VALUE: This field contains the number of error packets. Increments when there is an upstream error or when one of the error conditions is asserted.

27.2 Programming Guidelines

Follow these steps to program the Serial TS DTV controller:

1. Enable DTV in the DTV_SPI_CONTROL register
2. Program the DTV_MODE register for bit/byte swizzle, clock edge, etc.
3. Program the FEC size, body size, polarities, etc. in the DTV_CONTROL register
4. Enable DTV by writing a 1 to bit 0 of the DTV_MODE register

27.3 DTV Registers

Refer to “Reading Register Tables” in the Introduction section for the register table protocol as well as recommendations for accessing registers.

27.3.1 DTV_SPI_CONTROL_0

Offset: 0x40 │ Read/Write: R/W │ Reset: 0x00000001 (0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx1)

Bit	Reset	Description
0	0x1	SELECT: Kept to maintain compatibility. 1 = DTV enabled, 0 = SPI CTLR enabled 0 = DISABLED 1 = ENABLED

27.3.2 DTV_MODE_0

Mode Selection Register

DTV MODE Register por=0x00000002

Offset: 0x44 │ Read/Write: R/W │ Reset: 0x00000000 (0bxxxxxxxxxxxxxxxxxxxxxxxx0000000)

Bit	Reset	Description
6	0x0	BYTE_SWIZZLE: This determines byte order during deserialization. 0 = DISABLED 1 = ENABLED
5	0x0	BIT_SWIZZLE: This determines bit order during deserialization. 0 = DISABLED 1 = ENABLED
4	0x0	CLK_EDGE_SELECT: This determines the clock edge to be used to sample DTV input signals. 0 = POSEDGE 1 = NEGEDGE
3:2	0x0	PROTOCOL_SELECT: For selecting the pin configuration for VD[1]. NONE: ERROR is tied to 0. PSYNC is tied to 0. ERROR: ERROR is tied to VD[1]. PSYNC is tied to 0. PSYNC: ERROR is tied to 0. PSYNC is tied to VD[1]. 0 = NONE 1 = ERROR 2 = PSYNC 3 = RESERVED
1	0x0	CLK_MODE: Determines if the input clock is continuous or discontinuous. 0 = DISCONTINUOUS 1 = CONTINUOUS
0	0x0	ENABLE: DTV protocol handling global enable. 0 = DISABLED 1 = ENABLED

27.3.3 DTV_CONTROL_0

Mode Control Register

DTV CONTROL Register por=0x00000000

Offset: 0x48 | Read/Write: R/W | Reset: 0x10bc0300 (0bx0010000101111100xx000011x000x000)

Bit	Reset	Description
30:24	0x10	FEC_SIZE: Stores the number of FEC bytes to capture, after the BODY has been captured.
23:16	0xbc	BODY_SIZE: Stores the number of BODY bytes to capture including PSYNC.
13:8	0x3	RX_FIFO_ATTN_LEVEL: Receive FIFO trigger level. 0x0 = 1 word DMA trigger is asserted when at least one word full in the FIFO. 0x1 = 2 word DMA trigger is asserted when at least 2 words are full in the FIFO
6	0x0	BODY_VALID_SELECT: Determines if VALID is used during BODY packet capture. IGNORE: VALID signal is ignored during the BODY capture. GATE: VALID gates the capture of BODY data. 0 = IGNORE 1 = GATE
5:4	0x0	START_SELECT: Determines the START of the packet condition. PSYNC: PSYNC assertion rising edge. VALID: VALID assertion rising edge. BOTH: PSYNC && VALID asserted rising edge. 0 = RESERVED 1 = PSYNC 2 = VALID 3 = BOTH
2	0x0	ERROR_POLARITY: Indicates the polarity of ERROR, has effect only when MODE.ENABLE == ENABLED. LOW: Indicates the polarity of ERROR is active low. HIGH: Indicates the polarity of ERROR is active high. 0 = HIGH 1 = LOW
1	0x0	PSYNC_POLARITY: Indicates the polarity of PSYNC, has effect only when MODE.ENABLE == ENABLED. LOW: Indicates the polarity of PSYNC is active low. HIGH: Indicates the polarity of PSYNC is active high. 0 = HIGH 1 = LOW
0	0x0	VALID_POLARITY: Indicates the polarity of VALID, has effect only when MODE.ENABLE == ENABLED. LOW: Indicates the polarity of VALID is active low. HIGH: Indicates the polarity of VALID is active high. 0 = HIGH 1 = LOW

27.3.4 DTV_PACKET_COUNT_0

Packet Count Register

DTV PACKET COUNT Register por=0x00000000

Offset: 0x4c │ Read/Write: RO │ Reset: 0x00000000 (0bxxxxxxxxxxxxxxxx0000000000000000)

Bit	Reset	Description
15:0	0x0	PACKET_COUNT_VALUE: Holds the current value of the received packet counter. This counter increments in the presence of a new packet, regardless of whether it is a flagged error or not. The counter is cleared on writes, and it cannot be loaded with a preloaded value.

27.3.5 DTV_ERROR_COUNT_0

Error Count Register

DTV ERROR COUNT Register por=0x00000000

Offset: 0x50 │ Read/Write: RO │ Reset: 0x00000000 (0bxxxxxxxxxxxxxxxx0000000000000000)

Bit	Reset	Description
15:0	0x0	ERROR_COUNT_VALUE: Holds the current value of the error packet counter. This counter increments in the scenario when a packet is flagged as an error or when a protocol violation has occurred. The counter is cleared on writes, and it cannot be loaded with a preloaded value This register returns interrupt status when read. When this register is written, the interrupt status corresponding to the bits written with 1 will be reset. The interrupt status corresponding to the bits written with 0 will be left unchanged.

27.3.6 DTV_INTERRUPT_STATUS_0

Interrupt Enable

DTV INTERRUPT STATUS Register por=0x00000000

Offset: 0x54 │ Read/Write: RO │ Reset: 0x00000000 (0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx0000)

Bit	Reset	Description
3	0x0	PACKET_UNDERRUN_ERROR_INT_STATUS: Start condition detected prior to receiving a full packet. 0 = Interrupt not detected. 1 = Interrupt detected 0 = NOINTR 1 = INTR
2	0x0	BODY_OVERRUN_ERROR_INT_STATUS: This bit shows the status of the condition when the DTV input gets a body overrun error, i.e., more bytes in body than specified. 0 = Interrupt not detected. 1 = Interrupt detected 0 = NOINTR 1 = INTR
1	0x0	BODY_UNDERRUN_ERROR_INT_STATUS: This bit shows the status of the condition when the DTV input gets a body underrun error. 0 = Interrupt not detected. 1 = Interrupt detected 0 = NOINTR 1 = INTR
0	0x0	UPSTREAM_ERROR_INT_STATUS: This bit shows the status of the condition when the DTV input gets an upstream error. 0 = Interrupt not detected. 1 = Interrupt detected 0 = NOINTR 1 = INTR

27.3.7 DTV_STATUS_0

DTV Status Register por=0b0xx

Offset: 0x58 │ Read/Write: R/W │ Reset: 0x0000000X (0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx0xx)

Bit	R/W	Reset	Description
2	RW	0x0	RXF_UNR: RX FIFO Underrun: This bit is set to 1 whenever software tries to read from an empty RX FIFO. An interrupt is generated if the interrupt enable is set for receive operations. Software writes a 1 to clear this bit. Clearing this bit also clears the interrupt.
1	RO	X	RXF_EMPTY: RX FIFO empty status. Hardware sets this bit to 1 if the RX FIFO is empty. Otherwise this bit is set to 0. 0 = NOT_EMPTY 1 = EMPTY
0	RO	X	RXF_FULL: RX FIFO full status. Hardware sets this bit to 1 if the RX FIFO is full. Otherwise, this bit is set to 0. 0 = NOT_FULL 1 = FULL

27.3.8 DTV_RX_FIFO_0

DTV RX FIFO Register por=0x00000000

Offset: 0x5c │ Read/Write: RO │ Reset: 0xXXXXXXXX (0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx)

Bit	Reset	Description
31:0	X	RD_DATA: RX FIFO

[THIS PAGE INTENTIONALLY LEFT BLANK]

28.0 HIGH-DEFINITION MULTIMEDIA INTERFACE

The High-Definition Multimedia Interface (HDMI) receives pixels from the Display Controller and audio from the HDA. It combines and transmits them together.

28.1 Features

- 300 MHz pixel clock supported to enable 1080p @ 60 3D and 4k x 2k @ 30 resolutions
- HARDWARE_N feature enabled
- New TMDS I/O macro with new controls
- S/PDIF audio is not supported
- HDMI in power-gated partition DISB (with displayB)
- Display CMU added, allowing color management
- HDMI and display have more limited clocking options. HDMI always uses PLLD2.
- Audio features for HD audio include:
    - 2, 6, or 8 channels of LPCM (i.e., uncompressed linear PCM)
    - 16, 20, or 24 bits per sample
    - 32, 44.1, 48, 88.2, 96, 176.4, 192 K samples/second

28.2 Programming Guidelines

The overall sequence to start up HDMI is:

- Program power, pin mux, clocks, resets, etc.
- Copy HDCP keys from KFUSE to HDMI
- Program display timing registers, etc.
- Program HDMI registers and Serial Output Resource (SOR) sequencer
- Start HDMI SOR
- Start display

Since audio is entirely asynchronous to HDMI or the display, the HDA module can be started any time.

28.2.1 Power

Turn on the necessary power supplies.

- MIPI_PLL
- HDMI_PLL_HVDD
- HDMI_AVDD: 3.3V
- +5V for DDC, HDMI_INT, CEC, etc.

These need to be enabled in the PMIC via I^2C.

28.2.2 DDC / I2C

DDC I^2C is used for E-EDID reading, HDCP, and other communication with downstream HDMI device. I^2C has no connection to HDMI block; the platform defines which I^2C engine is connected to the DDC.

28.2.3 Hot Plug

HDMI_INT is a pad that feeds the GPIO block and the PMC. It has no connection to the HDMI block. It operates as a general-purpose I/O pin.

28.2.4 Clocks

HDMI uses two main clocks:

- hdmi_clk: variable from 25.2 MHz to 300 MHz based on video pixel rate. Must be identical frequency and source as display's pixel clock. (i.e., display and HDMI clocks are isochronous).
- hda2codec_2x_clk: fixed 48 MHz HD Audio bit clock. Same source as HDA Controller's bitclk. The HDA Controller clock enable should not affect it.

And three others:

- display2hdmi_pclk and displayb2hdmi_pclk: Copy of display pixel clocks for display2hdmi and displayb2hdmi pixel buses. Only used to write display data into FIFOs.
- host1x2hdmi_clk: Copy of host1x clock for host interface; only used to write host1x transactions into the FIFO.

All three main clocks have common first-level gate: the CAR CLK_ENB_HDMI register. hdmi_audio_clk has a second level gate controlled by hardware – it is gated when S/PDIF is not used.

The display controllers and HDMI have separate clock source registers. However, they must be programmed to the same source and the same frequency. Typical settings for a 13 MHz oscillator using PLLD2 are listed in the following table:

Pixel Clk MHz	PLLD2 Frequency	PLL M	PLL N	HDMI_ CLK_ DIVISOR	Display SHIFT_ CLK_ DIVIDER	HDMI_ CLK_ SRC	DISP1_ CLK_ SRC
27	216/2	13	216	0x6 (/4)	0x6 (/4)	PLLD2_OUT0	PLLD2_OUT0
74.25	594/2	13	594	0x6 (/4)	0x6 (/4)	PLLD2_OUT0	PLLD2_OUT0
148.5	594/2	13	594	0x2 (/2)	0x2 (/2)	PLLD2_OUT0	PLLD2_OUT0
297	594/2	13	594	0x0 (/1)	0x0 (/1)	PLLD2_OUT0	PLLD2_OUT0

In addition, the HDA modules must use the same oscillator as display and HDMI, since audio and video clock frequencies must be a fixed ratio. For HDA Audio, HDA2CODEC_2X clock must be enabled and configured for 48 MHz.

28.2.5 Display Timing

Frame timing is controlled by the display. HDMI has certain requirements, however, imposed by both the module itself and the HDMI standards.

HDMI gets the following signals from the display:

- h_blank – derived in hardware from h_ref_to_sync, h_sync_width, h_back_porch, h_disp_active, h_front_porch
- v_blank – derived in hardware from v_ref_to_sync, v_sync_width, v_back_porch, v_disp_active, v_front_porch
- h_sync – derived from h_ref_to_sync, h_sync_width
- v_sync – derived from v_ref_to_sync, v_sync_width
- video_preamble – derived from h_pulse2_control, h_pulse2_position.

EIA (CEA-861-B) Formats	ref_to_sync	sync_width	back_porch	disp_active	front_porch
480P_60 (2,3)					
horizontal	1	62	60	720	16
vertical	1	6	30	480	9
720P_60 (4)					
horizontal	1	40	220	1280	110
vertical	1	5	20	720	5
720P_50 (19)					
horizontal	1	40	220	1280	440
vertical	1	5	20	720	5
640x480_60 (1)					
horizontal	1	96	48	640	16
vertical	1	2	33	480	10
576p_50 (17/18)					
horizontal	1	64	68	720	12
vertical	1	5	39	576	5
1080p_60 (16)					
horizontal	1	44	148	1920	88
vertical	1	5	36	1080	4
4kx2k_30					
horizontal	1	88	296	3840	176
vertical	1	10	72	2160	8

The video_preamble uses h_pulse2, with the following settings:

disp_signal_options0.h_pulse2_enable	ENABLE
h_pulse2_control.h_pulse2_mode	NORMAL
h_pulse2_control.h_pulse2_polarity	HIGH
h_pulse2_control.h_pulse2_v_qual	VACTIVE
h_pulse2_control.h_pulse2_last_end	END_A
h_pulse2_position.h_pulse2_start_a	h_ref_to_sync + h_sync_width + h_back_porch - 10
h_pulse2_position.h_pulse2_end_a	h_pulse2_start_a + 8

Miscellaneous registers required:

DISP_TIMING_OPTIONS.VSYNC_H_POSITION	1
DISP_CLOCK_CONTROL.PIXEL_CLK_DIVIDER	PCD1
DISP_COLOR_CONTROL.DITHER_CONTROL	DISABLE
DISP_WIN_OPTIONS.HDMI_ENABLE	ENABLE

28.2.6 Display Datapath

28.2.6.1 Dither

Dithering should be disabled, since HDMI uses a full 8 bits per component.

28.2.6.2 Component Range

For most HDMI resolutions (i.e., everything except VGA 640x480), R/G/B should be scaled to lie in the [16, 235] nominal range; See the HDMI specification, section 6.6. The range scaling can be done in either of two places in Tegra® 4 series processors; CMU is recommended:

- Front of pipe (per-window), using color palette. Palette can contain function int(i/255 * 219 + 0.5) + 16 where ‘i’ is palette index 0..255.
- After compositing, in the CMU block (recommended).

```
proc cmu_lut1_flt2fix {flt} {
    set fx [expr floor($flt * 4095.0 + 0.5)]
    if {$fx > 4095} {
        error "cmu_lut1_flt2fix out of range input $flt"
    }
    return $fx
}
proc cmu_lut2_flt2fix {flt} {
    set fx [expr floor($flt * 255.0 + 0.5)]
    if {$fx > 255} {
        error "cmu_lut1_flt2fix out of range input $flt"
    }
    return $fx
}
proc srgb_ungamma {x args} {
    if {$x <= 0.03928} {
        set y [expr $x/12.92]
    } else {
        set y [expr pow(($x + 0.055)/1.055, 2.4)]
    }
    return [cmu_lut1_flt2fix $y]
}
proc rec709_gamma_offset16 {x args} {
    if {$x <= 0.018} {
        set y [expr $x * 4.5]
    } else {
        set y [expr 1.099 * pow($x, 0.45) - 0.099]
    }
    set lut2 [expr 16 + [cmu_lut2_flt2fix $y]]
    return [expr min(255, max($lut2, 0))]
}

#
# program CMU to convert to limited-range RGB with Rec. 709 gamma.
# Display pipe should be using full-range RGB.
# [0..255] is mapped to [16,235].
# NOTE: sRGB primaries and whitebpoint are same as 709, so matrix is just scale.
# We could do everything in LUT as well.
#
proc cmu_to_rec709_rgb219 {} {
```

```
    set scale [expr 219.0 / 255.0]
    set mat "
        $scale 0.0    0.0    \
        0.0    $scale 0.0    \
        0.0    0.0    $scale \
    "
    cmu lut1 srgb ungamma
    cmu csc $mat
    cmu lut2 rec709 gamma offset16
    DISP COLOR CONTROL.CMU ENABLE ENABLE
}
```

For most HDMI modes, codes 0 and 255 must be removed; HDMI'S NV_PDISP_INPUT_CONTROL.ARM_VIDEO_RANGE = LIMITED enables this.

28.2.6.3 Gamma

Most content uses sRGB gamma which is not quite the same as Rec. 709 gamma used by HDMI for most modes. Post-composite gamma can be changed in the CMU. The above code illustrates these.HDMI basics.

28.2.7 HDMI Basics

- Select display a/b source with NV_PDISP_HDMI_SRC_SELECT
- If appropriate to the platform, program HDCP timing dividers, based on the HDMI pixel clock. For Tegra 4 platforms, ROM I^2C clock frequency should be 200 KHz.
- Program SOR reference clock, based on the HDMI pixel clock – see the NV_PDISP_SOR_REFCLK register description in this section. For example,

```
dispclk div 8 2 = int(dispclk freq / 1000000.0 * 4)
NV_PDISP_SOR_REFCLK.DIV_INT = dispclk_div_8_2 >> 2
NV_PDISP_SOR_REFCLK.DIV_FRAC = dispclk_div_8_2 & 0x3
```

- Program SOR sequences for power up and power down.

28.2.8 TMDS Macro Configuration

The default TMDS macro settings for Tegra 4 devices are listed in the table below:

HDMI Register	HDMI Register init	Default	Clamp Value (HDMI)
BG_TEMP_COEF	3	3	3
BG_VREF_LEVEL	4	4	4
DIV_RATIO_OVERRIDE	0		0
n/a (PMC)			
FUSE_OVERRIDE	0	n/a	n/a
NV_PDISP_SOR_IO_PEAK_CURRENT	0	0	0
NV_PDISP_SOR_LANE_DRIVE_CURRENT	0x20	0x18	0x20
KICKSTART	0	0	0
KVCO_2NDVCO	0	0	0
NV_PDISP_SOR_PLL1.LOADADJ	3	3	3
LOADADJ_BYPN	0	0	0
LOADADJ_SYNC_EN	0	0	0
NV_PDISP_SOR_PLL0.PDBG	1		1
SOR_PLL0.PWR	1		1
PDPORT	1		1

HDMI Register	HDMI Register init	Default	Clamp Value (HDMI)
SOR_CSTM.PD_TX*/etc.	0xf		0xf
NV_PDISP_PE_CURRENT	8	8	8
NV_PDISP_SOR_PLL1.PE_EN	0		0
PLL_BYPASS	0	0	0
PLL_NDIV_RATIO	0	NO USE	0
PLL_PDIV_RATIO	0	1	0
ICHPMP	2	2	2
FILTER	0	0	0
VCOCAP	3		3
PULLDOWN	1	NO USE	1
AVDD10_LEVEL	2	2	2
AVDD10_LOAD	3	3	3
AVDD23_LEVEL	2	2	2
AVDD23_LOAD	3	3	3
REG_BYPASS	0	0	0
RESISTORSEL	1	1	1
SOR_PLL2.AUX	0	0	0
TMDS_TERMADJ	9	6	9
TMDS_TERM	0		0
TESTMUX	0	0	0
TX_REG_LOAD	0	NOT USED	0
VCOCALIB_ENB	0	0	0
VCOCALIB_OVRWRB	0	0	0
VCOCALIB_TS0	0	0	0
VCOLIMIT_DISABLE	0	0	0
VCOLIMIT_SEL	0	0	0

Note: NV_PDISP_SOR_LANE_DRIVE_CURRENT. LANE0..3 are only used if NV_PDISP_SOR_LANE_DRIVE_CURRENT.FUSE_OVERRIDE is TRUE. HDMI TMDS calibration can be performed and burned into fuses, but are not currently .

28.2.9 HDA Controller Initialization

Basic operations:

- HDA IPFS initialization, FPCI and HDA configuration, and memory spaces allocated
- Deassert soft reset, bring up link. AZA.GCTL.CRST = DEASSERT, and wait for reset completion by spinning until CRST = DEASSERT. Wait 4 frame times (poll AZA.WALCLK for 2000 ticks to elapse)
- Verify internal codec (and external if desired) have been detected by reading AZA.WAKEEN.SDIWAKE3 for internal codec, and SDIWAKE1 for external.

28.2.10 HDA Audio Codec Initialization

When HDA is the audio source, the codec must be initialized before audio can flow. The internal codec uses industry-standard verbs, so in theory, the out-of-box driver should correctly discover and configure the codec. See the HD Audio specification. Below is a summary of the necessary verbs:

1. AOC widget: SET_CONV_STREAM_CHAN with desired output stream ID
2. AOC widget: SET_CONV_FMT to desired audio format (sampling frequency, sample depth, number of channels)
3. AOC widget: SET_DIGITAL_CONV_CONTROL1
   - Bit 0: 1 (DigEn=1)
   - Bit 3..6: channel status pre/copy/audio/pro bits
   - Bit 7: channel status CC bit 7 (called GEN_LEVEL)
4. AOC widget: SET_DIGITAL_CONV_CONTROL2:
   - Bit 6:0: channel status CC bits 6:0
5. Pin widget: SET_CONVERTER_CHANNEL_TO_DIGITAL_SLOT_MAPPING= 0x22 and SET_CONVERTER_CHANNEL_TO_DIGITAL_SLOT_MAPPING= 0x33 to undo default swap of channels 2 and 3
6. AOC widget: SET_STRIPE_CONTROL to select number of lanes. Recommend programming to 2 lanes all the time.
7. Pin widget: SET_PIN_WIDGET_CTRL = 0x40, to enable output and use PCM packets.
8. If desired to use HDA for info packets, program them with SET_DIP_INDEX/SET_DIP_DATA and enable with SET_DIP_XMIT_CTRL.

28.2.11 Audio

Two methods of generating the CTS portion of ACR packets are supported:

- In “Force SW CTS”, software computes CTS for the current audio and pixel clocks and writes it to registers.
- In “Hardware CTS”, hardware computes CTS automatically.

Likewise, two methods for generating N portion are supported.

- In “SW N”, software programs current desired N into 0441_SUBPACK_HIGH register and AUDIO_N.VALUE.
- In “HW N”, software programs all the ACR_*_SUBPACK_HIGH per-frequency N, then hardware chooses the one to use.

1. Set NV_PDISP_HDMI_ACR_CTRL (all fields) to 0
2. Reset N counter: HDMI.NV_PDISP_AUDIO_N.RESETF = ASSERT, GENERATE=ALTERNATE, LOOKUP per table
3. Based on pixel clock and audio sample clock frequencies, program the appropriate ACR N value into NV_PDISP_HDMI_ACR_0441_SUBPACK_ HIGH (see HDMI 1.2a specification, section 7.2.3). LSB of N goes in SB6, and MSB into SB4.
4. Likewise, program the appropriate ACR CTS value into NV_PDISP_HDMI_ACR_0441_SUBPACK_LOW. The LSB of CTS goes in SB3, and the MSB into SB1.
5. Program the computed AVAL into the appropriate SOR_AUDIO_AVAL_ register
6. Set NV_PDISP_AUDIO_N.VALUE = N – 1 (from above)
7. Set NV_PDISP_HDMI_ACR_*_SUBPACK_HIGH.ENABLE = YES.
8. Set NV_PDISP_HDMI_SPARE = 0x10000 OR’d with bits 0 and 1
9. Bring the N counter of reset: set HDMI.NV_PDISP_AUDIO_N.RESETF = DEASSERT
10. For S/PDIF, for each supported audio sample frequency, program NV_PDISP_AUDIO_FS*.HIGH and LOW:
    - eight_half = int(8 * 216000000 / (audio_sample_freq * 128)). For example, for 48 kHz audio: eight_half = 8 * 216000000 / (48000 * 128) = 281.25

- HIGH = eight_half + 9
- LOW = eight_half - 9

11. Program the audio source with SOR_AUDIO_CNTRL0.SOURCE_SELECT = SPDIF for S/PDIF, HDAL for HDA, or AUTO. AUTO automatically selects HDA if HDMI's internal HDA codec has been enumerated by HDA controller, else SPDIF is selected.
12. Enable HDMI audio: Set HDMI_CTRL.ENABLE = EN, HDMI_GENERIC_CTRL.AUDIO = EN, AUDIO_ENGINE.PWRDWN=0

Note:	CTS and N values depend on the ratio of the actual pixel clock and audio clock rates. The chip's clock generators cannot create every frequency exactly. For example 25.2 MHz (for 640x480p@60) cannot be exactly generated – 25.25 is the result. Thus CTS and N must be adjusted accordingly.

28.2.12 Other HDMI Configurations

1. Set HDMI_CTRL.MAX_AC_PACKET based on horizontal blanking width. Using display timing registers, MAX_AC_PACKET = floor((H_SYNC_WIDTH + H_BACK_PORCH + H_FRONT_PORCH – HDMI_CTRL.REKEY – 18) / 32)
2. Program and enable Audio InfoFrames. When using HDA audio, its contents come from verbs sent to internal codec, so this step can be skipped. When using SPDIF audio, Audio InfoFrame contents come from HDMI registers:
   - Set HDMI_AUDIO_INFOFRAME_HEADER = 0x000A0184
   - Set PB4-7 = 0, typically, in HDMI_AUDIO_INFOFRAME_SUBPACK0_HIGH
   - Set PB1-3 and CRC in HDMI_AUDIO_INFOFRAME_SUBPACK0_LOW. Typically PB1 = 1, and PB2 and PB3 are 0. CRC = (256 – (0x0a + 0x01 + 0x84 + PB1 + PB2 …) & 0xff) & 0xff
   - Set HDMI_AUDIO_INFOFRAME_CTRL.ENABLE = EN
3. Program and enable AVI InfoFrames. When using HDA Audio, this *may* come from the HDA Codec if desired, using one of its Generic packets. If so, do not enable the HDMI one:
   - Set HDMI_AVI_INFOFRAME_HEADER = 0x000D0282
   - Program checksum, PB1, PB2, PB3 in HDMI_AVI_INFOFRAME_SUBPACK0_LOW. PB4 contains the video format code from the CEA-861-D specification. See HDMI and EIA/CEA-861-D for all the fields. CRC is computed over header and PB1…PB13 as above.
   - Program PB4…PB6 in HDMI_AVI_INFOFRAME_SUBPACK0_HIGH, and PB7..PB13 in HDMI_AVI_INFOFRAME_SUBPACK1_LOW / HIGH.
   - Set HDMI_AVI_INFOFRAME_CTRL.ENABLE = EN
4. For HDMI 1.4 3D, program and enable the GENERIC InfoFrame to send an HDMI Vendor-Specific InfoFrame. When using HDA Audio, this *might* come from the HDA Codec, if desired, using one of its Generic packets. If so, do not enable the HDMI one.
   - Set HDMI_GENERIC_HEADER = 0x00LL0181 where LL is length of packet – 0x05 for the basic version described here.
   - HDMI_GENERIC_SUBPACK0_LOW.PB1/PB2/PB3 = 0x03/0c/00 (IEEE registration ID)
   - PB4 = 0x40 (Hdmi_video_format = 3d_structure present)
   - PB5 = 0x00 (3D_Structure = Frame packing)
   - PB6...PB27 = 0 (no 3D_Ext_Data for Frame packing)
   - Compute checksum over header and PB1..PB27 and put in PB0, as above.
   - HDMI_GENERIC_CTRL.ENABLE=EN. OTHER, SINGLE, HBLANK= DIS.
   - Be sure to keep HDMI_GENERIC_CTRL.AUDIO = EN

28.2.13 Start HDMI SOR

1. Enable TMDS macro with SOR_PLL0.PWR=0, VCOPD=0, PULLDOWN=0. Observe the power sequencing requirement. After PWR is cleared, you must wait 10 microseconds before setting PDBG=0.
2. Write SOR_PWR with NORMAL_STATE = PU, SAFE_STATE = PD, SETTING_NEW = TRIGGER.
3. Write SOR_PWR with the same settings but with SETTING_NEW = DONE.
4. Poll SOR_PWR for SETTING_NEW = DONE.
5. Write SOR_STATE2 with ASY_OWNER=HEAD0, SUBOWNER=3, ASY_PROTOCOL=SINGLE_TMDS_A, ASY_HSYNCPOL=POSITIVE_TRUE, ASY_VSYNCPOL=POSITIVE_TRUE, ASY_DEPOL=POSITIVE_TRUE.
6. Write SOR_STATE1 with ASY_HEAD_OPMODE=AWAKE, ASY_ORMODE=NORMAL, ATTACHED=0, ARM_SHOW_VGA=0.
7. Write SOR_STATE0 with UPDATE=0.
8. Write SOR_STATE0 with UPDATE=1.
9. Write SOR_STATE1 with ATTACHED=1.
10. Write SOR_STATE0 with UPDATE=0.

28.2.14 Start Display

- Set DISP_WIN_OPTIONS.HDMI_ENABLE = ENABLE.
- Start the display with DISPLAY_COMMAND.DISPLAY_CTRL_MODE and DISPLAY_POWER_CONTROL.

28.3 HDCP

HDCP requires the presence of a correctly programmed KFUSE. Two main sequences are downstream authentication and upstream authentication. Downstream authentication permits encryption of the HDMI output, and involves a handshake between the HDMI module and the display device. Upstream authentication is more of a software convention between the application and HDMI driver, although the HDMI module does perform KFUSE operations to assist.

Communication with the downstream receiver uses DDC, which requires I^2C.

28.3.1 HDCP KFUSE Key Copying

HDCP keys are stored encrypted in the KFUSE module. Before starting HDCP, software must copy the keys (576 bytes) from the KFUSE to the HDMI registers.

1. To enable use of KFUSE keys, set NV_PDISP_KEY_CTRL.LOCAL_KEYS = ENABLED.
2. Bring the KFUSE module out of reset and enable the clock, if not already enabled. This can be before or after HDMI is out of reset.
3. Wait for the KFUSE to read the keys from the fuse to its SRAM and perform error correction and CRC checking:
   a. Poll for KFUSE.STATE.DONE == 1
   b. Check KFUSE.STATE.CRCPASS == 1
   c. Check that NV_PDISP_KEY_CTRL.PKEY_LOADED == TRUE
4. Prepare to copy:
   a. KFUSE.KEYADDR.ADDR = 0
   b. KFUSE.KEYADDR.AUTOINC = 1
5. For each line in 0 .. 35 # 576 bytes = 144 words / 4 words-per-line = 36 lines
   a. For each word in 0..3:

      data[word] = KFUSE.KEYS # auto-increments read address

b. HDMI.NV_PDISP_KEY_HDCP_KEY_0 = data[0]
c. HDMI.NV_PDISP_KEY_HDCP_KEY_1 = data[1]
d. HDMI.NV_PDISP_KEY_HDCP_KEY_2 = data[2]
e. HDMI.NV_PDISP_KEY_HDCP_KEY_3 = data[3]
f. HDMI.NV_PDISP_KEY_HDCP_KEY_TRIG.LOAD_HDCP_KEY = TRIGGER # trigger decryption of 16 bytes
g. If line == 0: HDMI.NV_PDISP_KEY_CTRL.AUTOINC = DISABLED. Else: HDMI.NV_PDISP_KEY_CTRL.AUTOINC = ENABLED
h. HDMI. NV_PDISP_KEY_CTRL.WRITE16 = TRIGGER # wait for decrypt, and copy decrypted 16 bytes to the local key store.
i. Poll for HDMI. NV_PDISP_KEY_CTRL.WRITE16 == DONE

6. Write NV_PDISP_KEY_SKEY_INDEX.IDX_VALUE with the AES key selector that was used to encrypt the keyglob data. This is currently fixed at 0.

28.3.2 Downstream Authentication

This can be done before enabling transmission.

1. Set RG_HDCP_CTRL.ONEONE = ENABLE. RG_HDCP_CTRL.RUN = YES. Causes the RTL to access HDCP keys and compute An and other parameters.
2. Poll for RG_HDCP_CTRL.AN = VALID
3. Read Aksv from RG_HDCP_AKSV_LSB/MSB and check validity (exactly 20 of 40 bits = 1). If invalid, the KFUSE might be blank.
4. Read Bksv from the receiver (via I2C), check validity (20 high bits), and write it into RG_HDCP_BKSV_LSB/MSB.
5. Read An from RG_HDCP_AN_LSB/MSB, and write to the receiver via I^2C.
6. Read Aksv from RG_HDCP_AKSV_LSB/MSB, check validity (20 high bits), and write to receiver via I^2C.
7. Poll for RG_HDC_CTRL.R0 = VALID
8. Read RG_HDCP_RI and compare with the receiver's RI. They should match.

If the above procedure is successful, then RG_HDCP_CTRL.CRYPT can be set to ENABLE.

To verify that encryption is enabled, check that RG_HDCP_CTRL.RUN == YES.

28.3.3 Upstream Authentication

The HDMI module does not do the protocol itself. Rather, it provides primitives that software can use. These primitives access HDCP keys and status, and compute values.

Typically, downstream authentication has been completed before doing the upstream.

The "Upstream Setup" sequence is:

1. Set RG_HDCP_CMODE.MODE = READ_S
2. Poll for RG_HDCP_CTRL.SPRIME = INVALID
3. Program RG_HDCP_CN_LSB/MSB and RG_HDCP_CKSV_LSB/MSB with Cn and Cksv. NOTE: CKSV_MSB must be last since it is a trigger.
4. Poll for HDCP_CTRL.SPRIME = VALID
5. Read Dksv from RG_HDCP_DKSV_LSB/MSB and verify validity
6. Read Cs from RG_HDCP_CS_LSB/MSB
7. Read S' from RG_HDCP_SPRIME_LSB1/LSB2/MSB

Software uses these read values to perform the authentication handshake with application software.

The “Upstream M” sequence is:

1. Set RG_HDCP_CMODE.MODE = READ_M
2. Poll for RG_HDCP_CTRL.MPRIME = INVALID
3. Program RG_HDCP_CN_LSB/MSB and RG_HDCP_CKSV_LSB/MSB with Cn and Cksv. NOTE: CKSV_MSB must be last since it is a trigger.
4. Poll for HDCP_CTRL.MPRIME = VALID
5. Read Dksv from RG_HDCP_DKSV_LSB/MSB and verify validity
6. Read M' from RG_HDCP_MPRIME_LSB/MSB

28.4 Audio / Display Driver Communication

HDMI combines video and audio and so the display and audio drivers need to coordinate. The HDA Codec and HDMI implement the methods defined in the audio specifications.

28.4.1 Hot-Plug and ELD (EDID-like data)

When the HDMI driver receives notification of a hot-plug interrupt, it reads the downstream TV’s E-EDID ROM. The EDID contains audio-related data, so the audio driver needs it, too. The HDMI can send the hot-plug event and EDID buffer to the Audio driver via the HDA Codec.

Note:	See register comments in SOR_AUDIO_HDA_PRESENSE and SOR_AUDIO_HDA_ELD_BUFWR later in this section.

28.4.2 Copy-Protection

The audio driver can query copy-protection state (i.e., HDCP enabled), and request that HDCP be enabled by the HDMI driver.

Note:	See SOR_AUDIO_HDA_CP register and CP_REQUEST interrupt in INT_STATUS later in this section.

28.4.3 InfoPacket

In HDA mode, the Audio InfoFrame data is provided by the internal HDA Codec, not by the HDMI_AUDIO_INFOFRAME* registers. The SET_DIP_INDEX/SET_DIP_DATA verbs write this data.

Three generic infopackets are provided by the HDA Codec, in addition to the exiting generic packet.

28.4.4 Miscellaneous

For Audio to HDMI signaling, the HDA Codec has SCRATCH verbs that are reflected in the HDMI SOR_AUDIO_HDA_CODEC_SCRATCH* registers and CODEC_SCRATCH* interrupts.

For HDMI to Audio signaling, HDMI SOR_AUDIO_HDA_SCRATCH* registers, when written, are reflected to the HDA Codec GET_NV_SCRATCH_REGN_FROM_DISP verb and cause an Unsolicited Response (interrupt in the HDA Controller).

28.5 Clock Use Cases

Tegra 4 HDMI has the following clock sources. All five are required for HDMI operation.

DISP1 or DISP2	Display controller (pixel clock)
HDMI	HDMI controller (pixel clock)
HDA2CODEC_2X	HDA interface clock (48 MHz)
HDA2HDMICODEC	HDMI audio clock
HDA	HDA controller

28.6 CTS/N/AVAL Algorithm

```
void get_hda_cts_n(
// inputs:
NvU32 audio_freq_hz /* Fs */,
NvU32 pixclk_freq_hz /* Fpix */,
// outputs:
NvU32 &best_cts, NvU32 &best_n, NvU32 &best_a)
{
    // Ideal ACR interval is 1000 hz (1 ms);
    // acceptable is 300 hz .. 1500 hz
    const int min_n = 128 * audio_freq_hz / 1500;
    const int max_n = 128 * audio_freq_hz / 300;
    const int ideal_n = 128 * audio_freq_hz / 1000;

    float min_err = 100.0;

    best_n = 0;
    best_cts = 0;
    best_a = 0;

    for (int n = min_n; n <= max_n; n ++)
    {
        float cts_f = pixclk_freq_hz * (float)n / (128.0 * (float)audio_freq_hz);
        int cts = (int)(cts_f + 0.5); // round to nearest integer
        float err = fabs(cts_f - (float)cts);
        float aval_f = 24000000.0 * (float)n / (128.0 * (float)audio_freq_hz);
        int aval = (int)aval_f; // truncate (round toward zero)
        if ((float)aval == aval_f &&
(err < min_err ||
            ((err == min_err) && (abs(n - ideal_n) < abs((int)best_n - ideal_n)))))
        {
            min_err = err;
            best_n = (NvU32)n;
            best_cts = (NvU32)cts;
            best_a = (NvU32)aval;
        }
    }
```

```
    assert(best_n != 0 && best_cts != 0);
    assert((double)best_cts ==
     ((double)pixclk_freq_hz * best_n) / (128.0 * audio_freq_hz));

}
```

28.7 HDMI Registers

Refer to “Reading Register Tables” in the Introduction section for the register table protocol as well as recommendations for accessing registers.

28.7.1 HDMI_CTXSW_0

Channel IDs

Context switch register. Should be common to all modules. Includes the current channel/class (which is writable by software) and the next channel/class (which the hardware sets when it receives a context switch).

Context switch works like this: Any context switch request triggers an interrupt to the host and causes the new channel/class to be stored in NEXT_CHANNEL/NEXT_CLASS (see vmod/chexample). Software sees that there is a context switch interrupt and does the necessary operations to make the module ready to receive traffic from the new context. It clears the context switch interrupt and writes CURR_CHANNEL/CLASS to the same value as NEXT_CHANNEL/CLASS, which causes a context switch acknowledge packet to be sent to the host. This completes the context switch and allows the host to continue sending data to the module.

Context switches can also be pre-loaded. If CURR_CLASS/CHANNEL are written and updated to the next CLASS/CHANNEL before the context switch request occurs, an acknowledge will be generated by the module and no interrupt will be triggered. This is one way for software to avoid dealing with context switch interrupts. Another way to avoid context switch interrupts is to set the AUTO_ACK bit.

This bit tells the module to automatically acknowledge any incoming context switch requests without triggering an interrupt. CURR_* and NEXT_* will be updated by the module so they will always be current.

Offset: 0x0 │ Byte Offset: 0x0 │ Read/Write: R/W │ Reset: 0xXXXXf800 (0bxxxxxxxxxxxxxxxx11111x0000000000)

Bit	R/W	Reset	Description
31:28	RO	X	NEXT_CHANNEL: Next requested channel
25:16	RO	X	NEXT_CLASS: Next requested class
15:12	RW	0xf	CURR_CHANNEL: Current working channel, reset to 'invalid'
11	RW	0x1	AUTO_ACK: Automatically acknowledge any incoming context switch requests 0 = MANUAL 1 = AUTOACK
9:0	RW	0x0	CURR_CLASS: Current working class

28.7.2 HDMI_NV_PDISP_SOR_STATE0_0

Writing a 1 to this field causes a 1-cycle pulse, which is used to activate the fields in registers NV_PDISP_SOR_STATE[1,2]. These fields are assembly registers; the active state is located in disp_sor_aa_core.v and disp_or_aaa_super.v

The ATTACHED field in SOR_STATE1 is flopped to create the read-only field "ATTACHED" in the NV_PDISP_SOR_TEST register.

Offset: 0x1 | Byte Offset: 0x4 | Read/Write: R/W | Reset: 0x00000000 (0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx0)

Bit	Reset	Description
0	0x0	UPDATE

28.7.3 HDMI_NV_PDISP_SOR_STATE1_0

Offset: 0x2 | Byte Offset: 0x8 | Read/Write: R/W | Reset: 0x00000000 (0bxxxxxxxxxxxxxxxxxxxxxxxxxxx00000)

Bit	Reset	Description
4	0x0	ARM_SHOW_VGA
3	0x0	ATTACHED
2	SAFE	ASY_ORMODE: 0 = SAFE 1 = NORMAL
1:0	0x0	ASY_HEAD_OPMODE: 0 = SLEEP 1 = SNOOZE 2 = AWAKE

28.7.5 HDMI_NV_PDISP_RG_HDCP_AN_MSB_0

HDCP control registers in the pipeline.

HDCP AN MSB REGISTER

The AN_MSB register holds the 32 most significant bits of the link encryption session random number. See the HDCP specification and the Upstream Link for HDCP specification for more information.

Usage: Normal Operation

Offset: 0x4 │ Byte Offset: 0x10 │ Read/Write: RO │ Reset: 0xXXXXXXXX (0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx)

Bit	Reset	Description
31:0	X	VALUE: 0 = ZERO

28.7.6 HDMI_NV_PDISP_RG_HDCP_AN_LSB_0

HDCP AN LSB REGISTER

The AN_LSB register holds the 32 least significant bits of the link encryption session random number. See the HDCP specification and the Upstream Link for HDCP specification for more information.

Usage: Normal Operation

Offset: 0x5 │ Byte Offset: 0x14 │ Read/Write: RO │ Reset: 0xXXXXXXXX (0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx)

Bit	Reset	Description
31:0	X	VALUE: 0 = ZERO

28.7.7 HDMI_NV_PDISP_RG_HDCP_CN_MSB_0

HDCP CN MSB REGISTER

The CN_MSB register holds the 32 most significant bits of the upstream exchange random number. See the HDCP specification and the Upstream Link for HDCP specification for more information.

Usage: Normal Operation

Offset: 0x6 │ Byte Offset: 0x18 │ Read/Write: R/W │ Reset: 0x00000000 (0b00000000000000000000000000000000)

Bit	Reset	Description
31:0	0x0	VALUE: 0 = ZERO

28.7.8 HDMI_NV_PDISP_RG_HDCP_CN_LSB_0

HDCP CN LSB REGISTER

The CN_LSB register holds the 32 least significant bits of the upstream exchange random number. See the HDCP specification and the Upstream Link for HDCP specification for more information.

Usage: Normal Operation

Offset: 0x7 │ Byte Offset: 0x1c │ Read/Write: R/W │ Reset: 0x00000000 (0b00000000000000000000000000000000)

Bit	Reset	Description
31:0	0x0	VALUE: 0 = ZERO

28.7.9 HDMI_NV_PDISP_RG_HDCP_AKSV_MSB_0

HDCP AKSV MSB REGISTER

The AKSV_MSB register holds the 8 most significant bits of the transmitter's downstream key selection vector (KSV). See the HDCP specification and the Upstream Link for HDCP specification for more information.

Usage: Normal Operation

Offset: 0x8 │ Byte Offset: 0x20 │ Read/Write: RO │ Reset: 0x000000XX (0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx)

Bit	Reset	Description
7:0	X	VALUE: 0 = ZERO

28.7.10 HDMI_NV_PDISP_RG_HDCP_AKSV_LSB_0

HDCP AKSV LSB REGISTER

The AKSV_LSB register holds the 32 least significant bits of the transmitter's downstream key selection vector (KSV). See the HDCP specification and the Upstream Link for HDCP specification for more information.

Usage: Normal Operation

Offset: 0x9 │ Byte Offset: 0x24 │ Read/Write: RO │ Reset: 0xXXXXXXXX (0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx)

Bit	Reset	Description
31:0	X	VALUE: 0 = ZERO

28.7.11 HDMI_NV_PDISP_RG_HDCP_BKSV_MSB_0

HDCP BKSV MSB REGISTER

The BKSV_MSB register holds the 8 most significant bits of the receiver's key selection vector (KSV), as well as the receiver's REPEATER bit. See the HDCP specification and the Upstream Link for HDCP specification for more information.

Usage: Normal Operation

Offset: 0xa │ Byte Offset: 0x28 │ Read/Write: R/W │ Reset: 0x00000000 (0b0xxxxxxxxxxxxxxxxxxxxxxx00000000)

Bit	Reset	Description
31	0x0	REPEATER: 0 = VALUE
7:0	0x0	VALUE: 0 = ZERO

28.7.12 HDMI_NV_PDISP_RG_HDCP_BKSV_LSB_0

HDCP BKSV LSB REGISTER

The BKSV_LSB register holds the 32 least significant bits of the receiver's key selection vector (KSV). See the HDCP specification and the Upstream Link for HDCP specification for more information.

Usage: Normal Operation

Offset: 0xb │ Byte Offset: 0x2c │ Read/Write: R/W │ Reset: 0x00000000 (0b00000000000000000000000000000000)

Bit	Reset	Description
31:0	0x0	VALUE: 0 = ZERO

28.7.13 HDMI_NV_PDISP_RG_HDCP_CKSV_MSB_0

HDCP CKSV MSB REGISTER

The CKSV_MSB register holds the 8 most significant bits of the software's key selection vector (KSV). See the HDCP specification and the Upstream Link for HDCP specification for more information.

Note: Writing CKSV_MSB is the trigger for computing MPRIME and DKSV. It must be written last, after HDCP_CMODE, CN_MSB/LSB, and CKSV_LSB.

Usage: Normal Operation

Offset: 0xc │ Byte Offset: 0x30 │ Read/Write: R/W │ Reset: 0x00000000 (0bxxxxxxxxxxxxxxxxxxxxxxxx00000000)

Bit	Reset	Description
7:0	0x0	VALUE: 0 = ZERO

28.7.14 HDMI_NV_PDISP_RG_HDCP_CKSV_LSB_0

HDCP CKSV LSB REGISTER

The CKSV_LSB register holds the 32 least significant bits of the software's key selection vector (KSV). See the HDCP specification and the Upstream Link for HDCP specification for more information.

Usage: Normal Operation

Offset: 0xd │ Byte Offset: 0x34 │ Read/Write: R/W │ Reset: 0x00000000 (0b00000000000000000000000000000000)

Bit	Reset	Description
31:0	0x0	VALUE: 0 = ZERO

28.7.15 HDMI_NV_PDISP_RG_HDCP_DKSV_MSB_0

HDCP DKSV MSB REGISTER

The DKSV_MSB register holds the 8 most significant bits of the transmitter's upstream key selection vector (KSV). See the HDCP specification and the Upstream Link for HDCP specification for more information.

Usage: Normal Operation

Offset: 0xe │ Byte Offset: 0x38 │ Read/Write: RO │ Reset: 0x000000XX (0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx)

Bit	Reset	Description
7:0	X	VALUE: 0 = ZERO

28.7.16 HDMI_NV_PDISP_RG_HDCP_DKSV_LSB_0

HDCP DKSV LSB REGISTER

The DKSV_LSB register holds the 32 least significant bits of the transmitter's upstream key selection vector (KSV). See the HDCP specification and the Upstream Link for HDCP specification for more information.

Usage: Normal Operation

Offset: 0xf │ Byte Offset: 0x3c │ Read/Write: RO │ Reset: 0xXXXXXXXX (0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx)

Bit	Reset	Description
31:0	X	VALUE: 0 = ZERO

28.7.17 HDMI_NV_PDISP_RG_HDCP_CTRL_0

HDCP CTRL REGISTER

The CTRL register is used to facilitate synchronization between the display driver and hardware.

- RUN: Set by the driver to start or stop the downstream protocol
- CRYPT: Set by the driver to turn encryption on.
- Write ENABLED to enable, but only after RUN == YES. Once enabled, it is disabled by writing RUN=NO.
- DUAL_LINK_EN: Set by the driver to turn dual-link mode on or off
- ONEONE: ONEONE_EN enables the HDCP 1.1 features. This enables HDCP EESS signaling and Advance_Cipher.

- Write ENABLED to enable, but only after RUN == YES. Once enabled, it is disabled by writing RUN=NO. This should be enabled if your receiver supports HDCP 1.1

See Chapter 2.7 in the HDCP 1.1 specification for EESS signaling. See Chapter 2.2 in the HDCP 1.1 specification for ADVANCE_CIPHER.

- AN: Set by hardware when a valid An value has been generated
- R0: Set by hardware when Km, Ks, M0, and R0 have been calculated
- SPRIME: Set by hardware when S' has been calculated
- MPRIME: Set by hardware when M' has been calculated
- SROM_EN: Set by hardware while the HDCP SROM is in use, cleared when not in use
- SROM_ERR: Set by hardware when an error occurs while using the HDCP SROM

Usage: Normal operation

Offset: 0x10 │ Byte Offset: 0x40 │ Read/Write: R/W │ Reset: 0x0000XX00 (0bxxxxxxxxxxxxxxxxxxxxxxxxxxxx0000)

Bit	R/W	Reset	Description
13	RO	X	SROM_ERR: 0 = NOERROR 1 = ERROR
12	RO	X	SROM_EN: 0 = DISABLED 1 = ENABLED
11	RO	X	MPRIME: 0 = INVALID 1 = VALID
10	RO	X	SPRIME: 0 = INVALID 1 = VALID
9	RO	X	R0: 0 = INVALID 1 = VALID
8	RO	X	AN: 0 = INVALID 1 = VALID
3	RW	0x0	ONEONE: 0 = DISABLED 1 = ENABLED
2	RW	0x0	DUAL_LINK_EN: 0 = DISABLED 1 = ENABLED
1	RW	0x0	CRYPT: 0 = DISABLED 1 = ENABLED
0	RW	0x0	RUN: 0 = NO 1 = YES

28.7.18 HDMI_NV_PDISP_RG_HDCP_CMODE_0

HDCP CMODE REGISTER

The CMODE register indicates to hardware which upstream protocol calculation to perform. See the HDCP specification and the Upstream Link for HDCP specification for more information.

Writing to the CMODE register kicks off a "Read Status" or a "Read M" operation. When performing a "Read Status" operation, use the CMODE_INDEX field to identify the port for which you wish to obtain status.

Usage: Normal Operation

Offset: 0x11 │ Byte Offset: 0x44 │ Read/Write: R/W │ Reset: 0x00000001 (0bxxxxxxxxxxxxxxxxxxxxxxxxx00000001)

Bit	Reset	Description
7:4	0x0	INDEX: 0 = TMDS0_LINK1 1 = TMDS0_LINK0 2 = TMDS1_LINK1 3 = TMDS1_LINK0 4 = DVOA 5 = DVOB 6 = DAC1 7 = DAC2 8 = DAC3 9 = TMDS2_LINK1 10 = TMDS2_LINK0 11 = DP2_LINK1 12 = DP2_LINK0 13 = DP1_LINK1 14 = DP1_LINK0
3:0	0x1	MODE: 1 = READ_S 2 = READ_M

28.7.19 HDMI_NV_PDISP_RG_HDCP_MPRIME_MSB_0

HDCP MPRIME MSB REGISTER

The MPRIME_MSB register holds the 32 most significant bits of the encrypted M0 value. See the HDCP specification and the Upstream Link for HDCP specification for more information.

Usage: Normal Operation

Offset: 0x12 │ Byte Offset: 0x48 │ Read/Write: RO │ Reset: 0xXXXXXXXX (0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx)

Bit	Reset	Description
31:0	X	VALUE: 0 = ZERO

28.7.20 HDMI_NV_PDISP_RG_HDCP_MPRIME_LSB_0

HDCP MPRIME LSB REGISTER

The MPRIME_LSB register holds the 32 least significant bits of the encrypted M0 value. See the HDCP specification and the Upstream Link for HDCP specification document for more information.

Usage: Normal Operation

Offset: 0x13 │ Byte Offset: 0x4c │ Read/Write: RO │ Reset: 0xXXXXXXXX (0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx)

Bit	Reset	Description
31:0	X	VALUE: 0 = ZERO

28.7.21 HDMI_NV_PDISP_RG_HDCP_SPRIME_MSB_0

HDCP SPRIME MSB REGISTER

The SPRIME_MSB register holds the 8 most significant bits of the S' value. See the HDCP specification and the Upstream Link for HDCP specification for more information.

STATUS_READZ indicates whether or not this chip implements the HDCP Upstream Spec's "Read Z" operation. Currently, "Read Z" is not implemented.

STATUS_CS indicates whether or not this chip implements the connection state (CS) register. If this field is set to STATUS_CS_NOT_IMPL, it means this chip will always follow the standard "Read Status" protocol when reporting status. If this field is set to STATUS_CS_IMPLMNTD, it means this chip will always follow the "Read Status With Connection State" protocol when reporting status. STATUS_SCOPE indicates how the chip will report the status for the STATUS_UNPROTECTED field. See the STATUS_UNPROTECTED description below for more information.

STATUS_INTPNL indicates if the port you are querying (identified by the CMode index) is transmitting to an internal panel on this head. If the port you are querying is not transmitting on this head (see the ** note below), or if it is transmitting on this head but to a device other than an internal panel, then STATUS_INTPNL_INACTV will be returned.

STATUS_MAX_CMODE_IDX identifies the maximum CMode index allowed for requesting status.

> ****Note:** Unlike the STATUS_UNPROTECTED field, the other STATUS fields always use the _HA_ registers to report status for ports on head A and the _HB_ registers to report status on head B. If you use the _HA_ versions of the CMODE and SPRIME registers to query the status of a port that is actually being driven by head B, the status will indicate that the port isn't transmitting at all (everything will come back as INACTV).

Usage: Normal operation

Offset: 0x14 │ Byte Offset: 0x50 │ Read/Write: RO │ Reset: 0x000000XX (0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx)

Bit	Reset	Description
7	X	STATUS_READZ: 0 = NOT_IMPL 1 = IMPLMNTD
6	X	STATUS_CS: 0 = NOT_IMPL 1 = IMPLMNTD
5	X	STATUS_SCOPE: 0 = SCOPE_TWO_HEADS 1 = SCOPE_1_HEAD

Bit	Reset	Description
4	X	STATUS_INTPNL: 0 = INACTV 1 = ACTV
3:0	X	STATUS_MAX_CMODE_IDX

28.7.22 HDMI_NV_PDISP_RG_HDCP_SPRIME_LSB2_0

HDCP SPRIME LSB2 REGISTER

The SPRIME_LSB2 register holds the 32 next-most significant bits of the S' value. See the HDCP specification and the Upstream Link for HDCP specification for more information.

STATUS_CMODE_IDX identifies the index of the port to which the status request was actually routed. STATUS_UNPROTECTED indicates whether the port you queried (identified by the CMode index) is transmitting unprotected data. If STATUS_SCOPE is set to STATUS_SCOPE_1_HEAD, then make sure to use the _HA_ registers to see if any ports on head A are unprotected, and use the _HB_ registers to see if any ports on head B are unprotected. If STATUS_SCOPE is set to STATUS_SCOPE_2_HEADS, then STATUS_UNPROTECTED combines the status of both heads. In this case, both the _HA_ registers and the _HB_ registers will report the same value for the STATUS_UNPROTECTED field.

Value of STATUS_SCOPE	Meaning of STATUS_UNPROTECTED
_1_HEAD	UNPROTECTED_Y means that at least one port driven by this head is transmitting "unprotected" data. UNPROTECTED_N means that none of the ports driven by this head are transmitting "unprotected" data.
_2_HEADS	UNPROTECTED_Y means that at least one port driven by either head is transmitting "unprotected" data. UNPROTECTED_N means that none of the ports driven by either head are transmitting "unprotected" data.

"Unprotected" data does not necessarily mean data that is not being encrypted. Data being transmitted out of a DAC is *always* considered unprotected. Data being transmitted out of a DVO is considered unprotected if it is not being encrypted. Data being transmitted by a TMDS link is also considered unprotected if it is not being encrypted,*except* for the case where the link feeds the internal panel of a laptop. The HDCP specification dictates that since the bus feeding an internal panel is essentially inaccessible to users, it can be considered "protected" even when sending clear data.

STATUS_EXTPNL is set to STATUS_EXTPNL_ACTV if the port identified by the CMode index is a digital interface (i.e., a DVO or TMDS interface), and it is transmitting on this head to something *other* than an internal panel. The STATUS_INTPNL field and the STATUS EXTPNL field will never be both set to ACTV for the same port. If a digital port is transmitting on this head, and it is physically connected to an internal panel, then the STATUS_INTPNL bit is set to ACTV and the STATUS_EXTPNL is set to INACTV; if it is transmitting on this head but it is *not* connected to an internal panel (even if it is not connected to anything at all), then STATUS_INTPNL is set to INACTV and STATUS_EXTPNL is set to ACTV.

STATUS_RPTR is set to STATUS_RPTR_ACTV if 1) the STATUS_EXTPNL field is set to ACTV, and 2) the REPEATER bit of the BKSV_MSB register is set to 0x1. This scenario should only occur after we are transmitting to an external HDCP-compliant device whose "repeater" bit is set.

STATUS_ENCRYPTING will be set to STATUS_ENCRYPTING_Y if the HDCP unit in this head is actually encrypting the data it receives. Note that if this bit is set, it means that *all* ports driven by this head whose data streams flow through the HDCP unit will be transmitting encrypted data, but any ports driven by this head whose data streams *bypass* the HDCP unit will be transmitting *clear* data. The DACs always use a data path that bypasses the HDCP unit and therefore must always be considered "unprotected".

Usage: Normal Operation

Offset: 0x15 | Byte Offset: 0x54 | Read/Write: RO | Reset: 0xXXXXXXXX (0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx)

28.7.23 HDMI_NV_PDISP_RG_HDCP_SPRIME_LSB1_0

HDCP SPRIME LSB1 REGISTER

The SPRIME_LSB1 register holds the 32 least significant bits of the S' value. See the HDCP specification and the Upstream Link for HDCP specification for more information.

Usage: Normal Operation

Offset: 0x16 | Byte Offset: 0x58 | Read/Write: RO | Reset: 0xXXXXXXXX (0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx)

Bit	Reset	Description
31:0	X	VALUE: 0 = ZERO

28.7.24 HDMI_NV_PDISP_RG_HDCP_RI_0

HDCP RI REGISTER

The RI register holds the 16-bit link integrity check value. See the HDCP specification and the Upstream Link for HDCP specification for more information.

Usage: Normal Operation

Offset: 0x17 | Byte Offset: 0x5c | Read/Write: RO | Reset: 0x0000XXXX (0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx)

Bit	Reset	Description
15:0	X	VALUE: 0 = ZERO

28.7.25 HDMI_NV_PDISP_RG_HDCP_CS_MSB_0

HDCP CS MSB REGISTER

The CS_MSB register holds the 8 most significant bits of the connection state. See the HDCP specification and the Upstream Link for HDCP specification for more information.

Usage: Normal Operation

Offset: 0x18 │ Byte Offset: 0x60 │ Read/Write: RO │ Reset: 0x000000XX (0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx)

Bit	Reset	Description
7:0	X	Reserved

28.7.26 HDMI_NV_PDISP_RG_HDCP_CS_LSB_0

HDCP CS LSB REGISTER

The CS_LSB register holds the 32 least significant bits of the connection state. See the HDCP specification, and the Upstream Link for HDCP specification for more information.

Usage: Normal Operation

Offset: 0x19 │ Byte Offset: 0x64 │ Read/Write: RO │ Reset: 0xXXXXXXXX (0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx)

Bit	Reset	Description
31:0	X	RESERVED

28.7.27 HDMI_NV_PDISP_HDMI_AUDIO_EMU0_0

HDMI_AUDIO_EMU

HDMI_AUDIO_EMU0 and HDMI_AUDIO_EMU1 are used to program the S/PDIF transmitter during RTL simulation and emulation. This is strictly for verification. This register is write-only.

Offset: 0x1a │ Byte Offset: 0x68 │ Read/Write: WO │ Reset: 0x00000000 (0b00000000000000000000000000000000)

Bit	Reset	Description
31:0	0x0	REGX

28.7.28 HDMI_NV_PDISP_HDMI_AUDIO_EMU_RDATA0_0

HDMI_AUDIO_EMU_RDATA0 is read-only.

Offset: 0x1b │ Byte Offset: 0x6c │ Read/Write: RO │ Reset: 0xXXXXXXXX (0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx)

Bit	Reset	Description
31:0	X	RDATA

28.7.29 HDMI_NV_PDISP_HDMI_AUDIO_EMU1_0

HDMI_AUDIO_EMU1 and EMU2 allow control over S/PDIF transmitter clock ratios (which are fixed in the GPU). They do indirect addressing.

EMU1 has the address, and EMU2 has the data.

To write:

1. Write data register with data

2. Write address register with bit 31=1, and address in 15:0

3. Write address register with bit 31=0

To read:

1. Write address register with bit 31=0 and address in 15:0

2. Read back address register to introduce delay allowing read data to propagate

3. Read data register

Offset: 0x1c │ Byte Offset: 0x70 │ Read/Write: R/W │ Reset: 0x00000000 (0b0xxxxxxxxxxxxxxxxxxxxxxx00000000)

28.7.31 HDMI_NV_PDISP_HDMI_AUDIO_INFOFRAME_CTRL_0

This is the register space for the HDMI block. Refer to HDMI Version 1.1. Refer to IEC60958-1 for general information and IEC60958-3 for consumer specifications for related audio information.

Additional notes regarding the ACR packet:

There are several methods that can be used to generate the N and CTS values in the Audio Clock Regeneration packet. The details of these methods are described here.

Full Software control: Software controls the contents of the possible ACR packets. Software writes the contents of the ACR_XXXX_SUBPACK_HIGH and ACR_XXXX_SUBPACK_LOW for all seven audio frequencies.

Software selects a method in ACR_CTRL to determine the audio sampling frequency

1. Measured in the audio block (MEASURE)
2. Read from the channel status information encoded in the audio stream (PACKET)
3. Defined by software (FREQS)

Software writes _YES to the ENABLE field of the SUBPACK_HIGH registers to allow that pair of registers to be used as the ACR packet. The audio sampling frequency specified in ACR_CTRL will select one of the seven pairs of SUBPACK registers to use as the ACR packet. This packet is sent on every Frame 27 of the audio block if that pair's ENABLE field is _YES.

Hardware controlled CTS: Software provides the N value and the hardware measures the CTS value. This is described in the HDMI_SPARE comments and mentioned in all other affected registers.

Software writes _ENABLE to HDMI_SPARE_HW_CTS to enable this feature.

Software writes 1 to HDMI_SPARE_CTS_RESET_VAL. This controls what the internal CTS counter resets to when it starts the next round of measurement. Resetting to zero was not correct, and adding a few bits of control helped to fine tune the measurement.

Software sets all ENABLEs in ACR_CTRL to _NO. (The easy way to do this is just to write zero to the whole register.)

Software writes the value of N in two places:

1. ACR_0441_SUBPACK_HIGH_SB[4/5/6]: It is written here so that the ACR packet contains the correct information for N.

2. AUDIO_N_VALUE: It is written here so that the audio block knows what N to use while it is measuring CTS. (Software does not need to write N to these places if Hardware Selected N is used.)

Software enables the sending of ACR_0441_SUBPACK* by setting ACR_0441_SUBPACK_ENABLE to _YES. (This pair of registers is used for all audio frequencies when Hardware controlled CTS is enabled.)

Software writes _USE_HW_CTS_VAL to ACR_0441_SUBPACK_LOW_SB1.

Hardware selected N: Software provides the possible N values whenever the pixel clock frequency changes. Hardware looks up the correct N value from a table stored in priv registers.

Software writes the 7 possible N values into the 7 AUDIO_NVAL registers. This is based on pixel clock frequency.

Software enables this feature by setting AUDIO_N_LOOKUP to _ENABLE. Hardware will use the audio sampling frequency detected by the audio block to select the correct N value.

NOTE: This is not the audio sampling frequency reported by the channel status information in the audio stream. Hardware will ignore whatever if written in the SUBPACK_HIGH registers when this feature is enabled and send the value of N it selected in these bytes of the ACR packet. CTS can come from the SUBPACK_LOW registers or the Hardware controlled CTS.

Audio frequency notes: There are several places in the HDMI and Audio registers where the audio sampling frequency is reported or set. Here is a breakdown of all such fields.

In SPDIF audio encoding, one bit of each audio sample is part of the "channel status" information. The bits from all 192 audio samples combine to form the 192 bit channel status packet. For consumer applications, only the first 40 bits have defined values. These bits are included in the encoded HDMI audio packet. Four of these bits contain the audio sampling frequency as reported by the audio source. See the IEC60958-3 specification for more information.

SPDIF_CHN_STATUS1 and SPDIF_CHN_STATUS2 are read-only registers that contain the 40 bits of channel status data read from the last audio block. The audio frequency the audio stream reports can be read from SPDIF_CHN_STATUS1_SFREQ. This is the sampling frequency that ACR_CTRL refers to with _PACKET.

SPDIF_CHN_STATUS1_ORIGINAL is the original sampling frequency of the audio. If the source of the audio stream changed the sampling frequency from its original frequency for any reason, the original sampling frequency is reported here.

AUDIO_CNTRL0_SAMPLING_FREQ is the sampling frequency measured by the audio block. It counts the number of dispclks periods that occur between to specific points in the audio stream. It compares this count to the thresholds in the AUDIO_FS registers to determine what the audio sampling frequency is. This is the sampling frequency that ACR_CTRL refers to as _MEASURE. This is the sampling frequency used to determine the correct value of N when Hardware selected N is enabled (see AUDIO_N).

The CHANNEL_STATUS1 and CHANNEL_STATUS2 registers are for debug. They can be used to replace the channel status bits that were in the original SPDIF stream with user-defined bits. CHANNEL_STATUS1_SFREQ can be used to report a different sampling frequency to downstream devices.

ACR_CTRL_FREQS can be written to select a specific pair of SUBPACK registers to send as your ACR packet. ACR_CTRL_FREQS_ENABLE must be set to _YES for this to have any effect.

The HDMI Audio InfoFrame, AVI InfoFrame, and Generic InfoFrame have nearly identical priv register interfaces. The next five registers control the Audio InfoFrame as described in section 8.2.2 of the HDMI specification.

HDMI_AUDIO_INFOFRAME_CTRL

This register controls the frequency and generation of audio InfoFrame packets. The contents of the packet should be written into the header (HDMI_AUDIO_INFOFRAME_HEADER) and subpacket (HDMI_AUDIO_INFOFRAME_SUBPACK0_LOW, HDMI_AUDIO_INFOFRAME_SUBPACK0_HIGH) registers.

ENABLE: Setting this field to _YES will initiate InfoFrame generation. Setting this bit to _NO will disable InfoFrame generation at the beginning of the next frame. The frequency of InfoFrame generation is controlled by OTHER and SINGLE fields.

OTHER: Setting this field to _EN while SINGLE is set to _DIS will cause InfoFrame to be transmitted to every other frame.

SINGLE: Setting this field to _EN while OTHER is set to _DIS will cause InfoFrame to be transmitted exactly once.

If OTHER and SINGLE fields are both set to _DIS, an InfoFrame will be generated every frame. Software should never set OTHER and SINGLE both to _EN.

See chapter 8.2.2 - Audio InfoFrame, in the HDMI specification for more information

CHKSUM_HW: Hardware provides a way to calculate the checksum for the InfoFrames.

_ENABLE will enable the hardware calculation to be passed to the packet

_DISABLE:

- Uses the register value defined in NV_PDISP_SOR_HDMI_AUDIO_INFOFRAME_SUBPACK0_LOW_PB0 for the S/PDIF
- Uses the checksum provided by the Azalia codec for the Azalia audio formats.

Usage: Normal Operation

Offset: 0x1e │ Byte Offset: 0x78 │ Read/Write: R/W │ Reset: 0x00000200 (0bxxxxxxxxxxxxxxxxxxxxxxxx10xxx0xxx0)

Bit	Reset	Description
9	ENABLE	CHKSUM_HW: CHKSUM_HW is an optional feature for software to use. Not required to be enabled. 0 = DISABLE 1 = ENABLE
8	0x0	SINGLE: 0 = DIS 1 = EN
4	0x0	OTHER: 0 = DIS 1 = EN
0	0x0	ENABLE: 0 = NO 1 = YES 0 = DIS 1 = EN

28.7.32 HDMI_NV_PDISP_HDMI_AUDIO_INFOFRAME_STATUS_0

HDMI_AUDIO_INFOFRAME_STATUS

The SENT bit will be set to _DONE, after the first packet is sent. After the ENABLE bit in INFOFRAME_CTRL is set to _NO, the SENT bit will be set to _WAITING after the start of the next frame to indicate that it is safe to change the contents of the packet header and subpacket registers.

Usage: Normal Operation

Offset: 0x1f │ Byte Offset: 0x7c │ Read/Write: RO │ Reset: 0x0000000X (0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx)

Bit	Reset	Description
0	X	SENT: 1 = DONE 0 = WAITING

28.7.33 HDMI_NV_PDISP_HDMI_AUDIO_INFOFRAME_HEADER_0

HDMI_AUDIO_INFOFRAME_HEADER

This register should be written with the value of the HDMI Audio InfoFrame header. This header is described in table 8-4 of chapter 8.2.2 of the HDMI specification. HB0, HB1, and HB2 are defined fields of the header from the specification.

Offset: 0x20 │ Byte Offset: 0x80 │ Read/Write: R/W │ Reset: 0x00000000 (0bxxxxxxxx00000000000000000000000)

Bit	Reset	Description
23:16	0x0	HB2
15:8	0x0	HB1
7:0	0x0	HB0

28.7.34 HDMI_NV_PDISP_HDMI_AUDIO_INFOFRAME_SUBPACK0_LOW_0

HDMI_AUDIO_INFOFRAME_SUBPACK0_LOW

This register should be written with the lower 4 bytes of the HDMI Audio InfoFrame. PB0, PB1, PB2, and PB3 are defined fields from the specification. See chapter 8.2.2 - Audio InfoFrame, Table 8-5, in the HDMI specification for more information

Offset: 0x21 │ Byte Offset: 0x84 │ Read/Write: R/W │ Reset: 0x00000000 (0b00000000000000000000000000000000)

Bit	Reset	Description

23:16	0x0	PB2
15:8	0x0	PB1
7:0	0x0	PB0

28.7.35 HDMI_NV_PDISP_HDMI_AUDIO_INFOFRAME_SUBPACK0_HIGH_0

HDMI_AUDIO_INFOFRAME_SUBPACK0_HIGH

This register should be written with the upper 2 bytes of the HDMI Audio InfoFrame. PB4 and PB5 are defined fields from the specification. See chapter 8.2.2 - Audio InfoFrame, Table 8-5, in the HDMI specification for more information

Offset: 0x22 │ Byte Offset: 0x88 │ Read/Write: R/W │ Reset: 0x00000000 (0bxxxxxxxxxxxxxxxx0000000000000000)

Bit	Reset	Description
15:8	0x0	PB5
7:0	0x0	PB4

28.7.36 HDMI_NV_PDISP_HDMI_AVI_INFOFRAME_CTRL_0

The following registers are used to send a 14-byte packet intended for sending AVI InfoFrame packet as described in section 8.2.1 of the HDMI specification.

HDMI_AVI_INFOFRAME_CTRL

This register controls the frequency and generation of AVI InfoFrame packets. The fields of this register are identical to HDMI_AUDIO_INFOFRAME_CTRL. See chapter 8.2.1 - Auxiliary Video information (AVI) InfoFrame, in the HDMI specification for more information

Offset: 0x23 | Byte Offset: 0x8c | Read/Write: R/W | Reset: 0x00000200 (0bxxxxxxxxxxxxxxxxxxxxxxxx10xxx0xxx0)

Bit	Reset	Description
9	ENABLE	CHKSUM_HW: CHKSUM_HW is an optional feature for software to use. Not required to be enabled 0 = DISABLE 1 = ENABLE
8	DIS	SINGLE: 0 = DIS 1 = EN
4	DIS	OTHER: 0 = DIS 1 = EN
0	NO	ENABLE: 0 = NO 1 = YES 0 = DIS 1 = EN

28.7.37 HDMI_NV_PDISP_HDMI_AVI_INFOFRAME_STATUS_0

HDMI_AVI_INFOFRAME_STATUS

The SENT bit will be set to _DONE, after the first packet is sent. After the ENABLE bit in INFOFRAME_CTRL is set to _NO, the SENT bit will be set to _WAITING after the start of the next frame to indicate that it is safe to change the contents of the packet header and subpacket registers.

Offset: 0x24 | Byte Offset: 0x90 | Read/Write: RO | Reset: 0x0000000X (0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx)

Bit	Reset	Description
0	X	SENT: 1 = DONE 0 = WAITING

28.7.38 HDMI_NV_PDISP_HDMI_AVI_INFOFRAME_HEADER_0

HDMI_AVI_INFOFRAME_HEADER

This register should be written with the value of the HDMI AVI InfoFrame header. This header is described in table 8-1 of chapter 8.2.1 of the HDMI specification. HB0, HB1, and HB2 are defined fields of the header from the specification.

Offset: 0x25 | Byte Offset: 0x94 | Read/Write: R/W | Reset: 0x00000000 (0bxxxxxxxx00000000000000000000000)

Bit	Reset	Description
23:16	0x0	HB2
15:8	0x0	HB1
7:0	0x0	HB0

28.7.39 HDMI_NV_PDISP_HDMI_AVI_INFOFRAME_SUBPACK0_LOW_0

HDMI_AVI_INFOFRAME_SUBPACK0_LOW

This register should be written with the lower 4 bytes of the HDMI AVI InfoFrame. PB0, PB1, PB2, and PB3 are defined fields from the specification. See chapter 8.2.1 - Auxiliary Video information (AVI) InfoFrame, Table 8-2, in the HDMI specification for more information.

Offset: 0x26 | Byte Offset: 0x98 | Read/Write: R/W | Reset: 0x00000000 (0b00000000000000000000000000000000)

Bit	Reset	Description
31:24	0x0	PB3
23:16	0x0	PB2
15:8	0x0	PB1
7:0	0x0	PB0

28.7.40 HDMI_NV_PDISP_HDMI_AVI_INFOFRAME_SUBPACK0_HIGH_0

HDMI_AVI_INFOFRAME_SUBPACK0_HIGH

This register should be written with bytes 4-6 of the HDMI AVI InfoFrame. PB3, PB5, and PB6 are defined fields from the specification. See chapter 8.2.1 - Auxiliary Video information (AVI) InfoFrame, Table 8-2, in the HDMI specification for more information.

Offset: 0x27 | Byte Offset: 0x9c | Read/Write: R/W | Reset: 0x00000000 (0bxxxxxxxx000000000000000000000000)

Bit	Reset	Description
23:16	0x0	PB6
15:8	0x0	PB5
7:0	0x0	PB4

28.7.41 HDMI_NV_PDISP_HDMI_AVI_INFOFRAME_SUBPACK1_LOW_0

HDMI_AVI_INFOFRAME_SUBPACK1_LOW

This register should be written with bytes 7-10 of the HDMI AVI InfoFrame. PB7, PB8, PB9, and PB10 are defined fields from the specification. See chapter 8.2.1 - Auxiliary Video information (AVI) InfoFrame, Table 8-2, in the HDMI specification for more information.

Offset: 0x28 | Byte Offset: 0xa0 | Read/Write: R/W | Reset: 0x00000000 (0b00000000000000000000000000000000)

Bit	Reset	Description
31:24	0x0	PB10
23:16	0x0	PB9
15:8	0x0	PB8
7:0	0x0	PB7

28.7.42 HDMI_NV_PDISP_HDMI_AVI_INFOFRAME_SUBPACK1_HIGH_0

HDMI_AVI_INFOFRAME_SUBPACK1_HIGH

This register should be written with bytes 11-13 of the HDMI AVI InfoFrame. PB11, PB12, and PB13 are defined fields from the specification. See chapter 8.2.1 - Auxiliary Video information (AVI) InfoFrame, Table 8-2, in the HDMI specification for more information.

Offset: 0x29 │ Byte Offset: 0xa4 │ Read/Write: R/W │ Reset: 0x00000000 (0bxxxxxxxx00000000000000000000000)

Bit	Reset	Description
23:16	0x0	PB13
15:8	0x0	PB12
7:0	0x0	PB11

28.7.43 HDMI_NV_PDISP_HDMI_GENERIC_CTRL_0

The following registers are used to send a 28-byte packet intended for sending any packet type. These registers will most likely be used for debug purposes.

HDMI_GENERIC_CTRL

This register controls the frequency and generation of generic InfoFrame packets. The fields of this register are identical to HDMI_AUDIO_INFOFRAME_CTRL except where noted below.

HBLANK: If HBLANK is set to _EN, then this packet will be sent (once) during the next horizontal blanking interval. The packet will still be sent at most once per frame. Software can poll GENERIC_STATUS_SENT to determine when the packet has been sent.

Using HBLANK is intended to mimic Audio Sample Packets and ACR Packets and therefore sending of the actual audio packets should be disabled by setting AUDIO to _DIS. This feature is used for debug purposes only.

To mimic an audio packet:

- begin
- wait for GENERIC_STATUS_SENT=_WAITING
- write next 4 audio samples to GENERIC_HEADER/GENERIC_SUBPACK registers
- set HBLANK = _EN
- wait for GENERIC_STATUS_SENT=_SENT
- set HBLANK = _DIS
- end

AUDIO: Audio packet transmission will be stopped when set to _DIS. Normal audio packet transmission will be allowed when set to _EN. This is used during debug to disable normal audio when using HBLANK.

Offset: 0x2a │ Byte Offset: 0xa8 │ Read/Write: R/W │ Reset: 0x00010000 (0bxxxxxxxxxxxxxxxx1xxx0xxx0xxx0xxx0)

Bit	Reset	Description
16	EN	AUDIO: Set to 1 in audio mode and 0 in DVI mode. 0 = DIS 1 = EN
12	DIS	HBLANK: 0 = DIS 1 = EN
8	DIS	SINGLE: 0 = DIS 1 = EN
4	DIS	OTHER: 0 = DIS 1 = EN

Bit	Reset	Description
0	NO	ENABLE: 0 = NO 1 = YES 0 = DIS 1 = EN

28.7.44 HDMI_NV_PDISP_HDMI_GENERIC_STATUS_0

HDMI_GENERIC_STATUS

The SENT bit will be set to _DONE, after the first packet is sent. After the ENABLE bit in INFOFRAME_CTRL is set to _NO, the SENT bit will be set to _WAITING after the start of the next frame to indicate that it is safe to change the contents of the packet header and subpacket registers.

Offset: 0x2b │ Byte Offset: 0xac │ Read/Write: RO │ Reset: 0x0000000X (0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx)

Bit	Reset	Description
0	X	SENT: 1 = DONE 0 = WAITING

28.7.45 HDMI_NV_PDISP_HDMI_GENERIC_HEADER_0

HDMI_GENERIC_HEADER

This register should be written with the contents of the packet header.

Offset: 0x2c │ Byte Offset: 0xb0 │ Read/Write: R/W │ Reset: 0x00000000 (0bxxxxxxxx000000000000000000000000)

7:0	0x0	PB25

28.7.54 HDMI_NV_PDISP_HDMI_ACR_CTRL_0

HDMI_ACR_CTRL

The Audio Clock Regeneration (ACR) packet contains the N and CTS values that the HDMI sink requires to recreate the audio clock. This mechanism is described in chapter 7.2 of the HDMI specification.

If software needs to specify N and CTS directly, this register is used to select the audio sampling frequency detection mechanism. The sampling rate is used to index one of the seven ACR_XXXX_SUBPACK_LOW/HIGH registers which must be

written with the correct value of N and CTS. N and CTS are determined by the current audio sampling frequency and the pixel clock frequency:

CTS = (PixelClock*N) / (128*AudioSamplingFrequency)

The selected sampling rate must point to a valid entry (i.e., one of the 7 listed below) and the selected ACR_XXXX_SUBPACK_HIGH_ENABLE must be set to enable sending the packet.

When software is controlling N and CTS directly, the ACR packet is sent every 27th audio frame (of 0 to 191) of the audio block. The sampling frequency read from the channel status bits is not available until the 27th audio frame.

PACKET_ENABLE: Set this to _YES to use the channel status information read from the incoming SPDIF audio stream to determine the sampling frequency.

MEASURE_ENABLE: Set this to _YES to use the sampling frequency measured in the in the audio block to determine the sampling frequency. This is the sampling frequency that is read from AUDIO_CNTRL0_SAMPLING_FREQ.

FREQS_ENABLE: Set this to _YES to use the sampling frequency written into the _FREQS field of this register.

FREQS: This is the audio sampling frequency that will be used when FREQS_ENABLE is _YES.

When Hardware is used to measure CTS, all ENABLE fields of this register should be set to _NO.

All four subpackets contain the same ACR packet.

Offset: 0x35 │ Byte Offset: 0xd4 │ Read/Write: R/W │ Reset: 0x02010000 (0bxxxx0010xxxxxxx1xxxxxxx0xxxxxxx0)

Bit	Reset	Description

28.7.57 HDMI_NV_PDISP_HDMI_ACR_0441_SUBPACK_LOW_0

HDMI_ACR_0441_SUBPACK_LOW

Contains bytes 1-3 of the 44.1 kHz ACR packet. This is the CTS value. If Hardware measured CTS is enabled, SB1 should be set to zero. See table 5-11 in chapter 5.3.3 in the HDMI specification for more information.

Offset: 0x38 │ Byte Offset: 0xe0 │ Read/Write: R/W │ Reset: 0x00000000 (0b00000000000000000000000xxxxxxxx)

Bit	Reset	Description
31:24	0x0	SB1: 0 = USE_HW_CTS_VAL
23:16	0x0	SB2
15:8	0x0	SB3

28.7.58 HDMI_NV_PDISP_HDMI_ACR_0441_SUBPACK_HIGH_0

HDMI_ACR_0441_SUBPACK_HIGH

Contains bytes 4-6 of the 44.1 kHz ACR packet. This is the N value. See table 5-11 in chapter 5.3.3 in the HDMI specification for more information.

If Hardware measured CTS is enabled, ACR_0441_SUBPACK_HIGH_N should be written with the N value for the current audio sampling frequency.

If the hardware N value selection is enabled, the N value does not need to be written to this register.

ENABLE: _YES allows this packet to be sent. This should be set to _YES when hardware measured CTS is being used. When set to _NO, this ACR packet will not be sent even if the sampling frequency defined in ACR_CTRL points to this register set.

Offset: 0x39 │ Byte Offset: 0xe4 │ Read/Write: R/W │ Reset: 0x00000000 (0b0xxxxxxx00000000000000000000000)

28.7.69 HDMI_NV_PDISP_HDMI_CTRL_0

HDMI_CTRL

REKEY: REKEY is the number of clocks required for HDCP rekey, starting from when DE is deasserted. No HDMI packets can be sent during this time. Due to a two cycle delay in hardware, REKEY should be set to two less than the desired value.

AUDIO_LAYOUT: AUDIO_LAYOUT controls layout (HB1[4]) of the Audio Sample Packet Header. Two different layouts are supported in the HDMI specification. The hardware only supports layout _2CH (2 channel audio). This should not need to be programmed beyond its init value of _2CH.

See Section 5.3.4 of the HDMI specification.

AUDIO_LAYOUT_SELECT: For projects with integrated audio codec, the AUDIO_LAYOUT information is automatically detected by hardware (default). We can override this capability and fall back on AUDIO_LAYOUT based selection by setting AUDIO_LAYOUT_SELECT to _SW_BASED.

If NV_CHIP_DISP_EXTENDED_AUD_FMT is not defined in the project specification, this field has no meaning, and only AUDIO_LAYOUT field will take effect.

SAMPLE_FLAT: SAMPLE_FLAT controls the values of (HB2[3:0]) of the Audio Sample Packet Header and should be _CLR. See Section 5.3.4 of the HDMI specification.

MAX_AC_PACKET: Set MAX_AC_PACKET to the maximum number of 32-pixel packets that will fit in the horizontal blanking interval. This controls the maximum number of audio packets, ACR packets, GCP packets, InfoFrames, etc. that will be sent during the horizontal blanking period.

MAX_AC_PACKET <= Floor[((HBLANK-REKEY-18)/32)]

CT_SELECT: Diagnostic workaround bit to decide whether the value of "coding type" will be hardware based or software based. The CT field is required in the construction of Audio InfoFrame packet (HDMI Specification, section 8.2.2). By default, the CT field is constructed by software. However, by setting this bit, the CT field in the construction of the Audio InfoFrame packet comes as a sideband signal from the HDA codec. If NV_CHIP_DISP_EXTENDED_AUD_FMT is not defined in projects.spec, this field is reserved.

CC_SELECT: Diagnostic workaround bit to decide whether the value of "channel count" will be hardware based or software based. The CC field is required in the construction of Audio InfoFrame packet (HDMI Specification, section 8.2.2). By default, the CC field is constructed by software. However,by setting this bit, the CC field in the construction of the Audio InfoFrame packet comes as a sideband signal from the HDA codec. If NV_CHIP_DISP_EXTENDED_AUD_FMT is not defined in projects.spec, this field is reserved.

SF_SELECT: Diagnostic workaround bit to decide whether the value of "sampling frequency" will be hardware based or software based. The SF field is required in the construction of Audio InfoFrame packet (HDMI Specification, section 8.2.2). By default, the SF field is constructed by software. However, by setting this bit, the SF field in the construction of the Audio InfoFrame packet comes as a sideband signal from the HDA codec. If NV_CHIP_DISP_EXTENDED_AUD_FMT is not defined in projects.spec, this field is reserved.

SS_SELECT: Diagnostic workaround bit to decide whether the value of "sample size" will be hardware based or software based. The SS field is required in the construction of Audio InfoFrame packet (HDMI Specification, section 8.2.2). By default, the SS field is constructed by software. However, by setting this bit, the SS field in the construction of the Audio InfoFrame

packet comes as a sideband signal from the HDA codec. If NV_CHIP_DISP_EXTENDED_AUD_FMT is not defined in projects.spec, this field is reserved.

CA_SELECT: Diagnostic workaround bit to decide whether the value of "channel allocation" will be hardware based or software based. The CA field is required in the construction of Audio InfoFrame packet (HDMI Specification, section 8.2.2). By default, the CA field is constructed by software. However, by setting this bit, the CA field in the construction of the Audio InfoFrame packet comes as a sideband signal from the HDA codec. If NV_CHIP_DISP_EXTENDED_AUD_FMT is not defined in projects.spec, this field is reserved.

ENABLE: Set to _YES to enable HDMI for this head. Set to _NO to disable HDMI for this head.

Offset: 0x44 │ Byte Offset: 0x110 │ Read/Write: R/W │ Reset: 0x00020038 (0bx0x00000xxx00010xxx0x0x0x0111000)

28.7.70 HDMI_NV_PDISP_HDMI_VSYNC_KEEPOUT_0

HDMI_VSYNC_KEEPOUT

Defines the start and end of the VSYNC keepout period where HDMI packets should not be sent. This is defined in chapter 2.7 the HDCP 1.1 specification.

END: Defines the end of the keepout period. This is measured in pixels after the active edge of VSYNC. This is defined in the specification and should not need to be written beyond its initialized value.

START: Defines the start of the keepout period. This is measured in pixels after the active edge of VSYNC. This is defined in the specification and should not need to be written beyond its initialized value.

ENABLE: When set to _YES, the keepout window is respected and no HDMI packets are sent in the period of time between START and END. This bit should be set to _YES. When set to _NO, the keepout window is ignored and HDMI packets may be sent regardless of the keepout window.

Offset: 0x45 │ Byte Offset: 0x114 │ Read/Write: R/W │ Reset: 0x819a028a (0b1xxxxx0110011010xxxxxx1010001010)

Bit	Reset	Description
31	YES	ENABLE: 0 = NO 1 = YES 0 = DIS 1 = EN
25:16	0x19a	START
9:0	0x28a	END

28.7.71 HDMI_NV_PDISP_HDMI_VSYNC_WINDOW_0

HDMI_VSYNC_WINDOW

Defines the start and end of the window of opportunity where the HDCP EESS signaling occurs. This is defined in chapter 2.7 of the HDCP 1.1 specification.

END: Defines the end of the window of opportunity. This is measured in pixels after the active edge of VSYNC. This is defined in the specification and should not need to be written beyond its initialized value.

START: Defines the start of the window of opportunity. This is measured in pixels after the active edge of VSYNC. This is defined in the specification and should not need to be written beyond its initialized value.

ENABLE: _YES will allow EESS signaling during the window of opportunity. _NO will prevent EESS signaling.

Offset: 0x46 │ Byte Offset: 0x118 │ Read/Write: R/W │ Reset: 0x82000210 (0b1xxxxx1000000000xxxxxx1000010000)

25:16	0x200	START
9:0	0x210	END

28.7.72 HDMI_NV_PDISP_HDMI_GCP_CTRL_0

The following registers are used to send a single-byte packet intended for sending the general control packet as described in section 5.3.6 of the HDMI specification. This control packet is used to control the AVMUTE flag.

HDMI_GCP_CTRL

This register controls the frequency and generation of GCP packets. The fields of this register are identical to HDMI_AUDIO_INFOFRAME_CTRL.

All four subpackets contain the same GCP packet.

Offset: 0x47 │ Byte Offset: 0x11c │ Read/Write: R/W │ Reset: 0x00000000 (0bxxxxxxxxxxxxxxxxxxxxxxxx0xxx0xxx0)

Bit	Reset	Description
8	DIS	SINGLE: 0 = DIS 1 = EN
4	DIS	OTHER: 0 = DIS 1 = EN
0	NO	ENABLE: 0 = NO 1 = YES 0 = DIS 1 = EN

28.7.73 HDMI_NV_PDISP_HDMI_GCP_STATUS_0

HDMI_GCP_STATUS

The SENT bit will be set to _DONE, after the first packet is sent. After the ENABLE bit in INFOFRAME_CTRL is set to _NO, the SENT bit will be set to _WAITING after the start of the next frame to indicate that it is safe to change the contents of the packet header and subpacket registers.

Offset: 0x48 │ Byte Offset: 0x120 │ Read/Write: RO │ Reset: 0x0000000X (0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx)

Bit	Reset	Description
0	X	SENT: 1 = DONE 0 = WAITING

28.7.74 HDMI_NV_PDISP_HDMI_GCP_SUBPACK_0

HDMI_GCP_SUBPACK

This register should be written with the contents of the general control packet.

See chapter 5.3.6 of the HDMI specification for more information.

Offset: 0x49 │ Byte Offset: 0x124 │ Read/Write: R/W │ Reset: 0x00000001 (0bxxxxxxxx00000000000000000000001)

Bit	Reset	Description
23:16	0x0	SB2
15:8	0x0	SB1
7:0	0x1	SB0: 1 = SET_AVMUTE 16 = CLR_AVMUTE

28.7.75 HDMI_NV_PDISP_HDMI_CHANNEL_STATUS1_0

HDMI_CHANNEL_STATUS1

This register is used for debug purposes only. Normally, the channel status bits encoded in the SPDIF sample stream are passed directly into the HDMI audio packet. HDMI_CHANNEL_STATUS1/2 can be used to override these bits with user defined values.

If STATUS2_ENABLE is set to _YES, then the 40-bit contents of CHANNEL_STATUS2/1 is inserted into the Cl and Cr bits of the audio sample packets for audio frames 0-39. Cl and Cr contain the channel status bits. See chapter 5.3.4 of the HDMI specification for information on Cr and Cl.

The fields in SPDIF_CHN_STATUS1/2 correspond to the fields in CHANNEL_STATUS1/2 for all values except for the ABCDM field. The values read from SPDIF_CHN_STATUS1/2 can be passed directly into the fields for CHANNEL_STATUS1/2 without any manipulation. This could be used if the user only needs to force one of the fields to a specific value and leave the rest untouched. Information on the channel status bits can be found in Chapter 5 of the IEC60958-3 specification.

ABCDM: This is the first byte of the channel status information. These bits have several meanings. See chapter 5.2.1 of IEC60958-3 for more information.

CODE: This byte defines the Category Code of the input device. This code indicates what type of equipment is generating the input. See 5.3.1 of the IEC60958-3 specification for the values of codes.

SOURCE: Source number of the audio.

CHANNEL: Channel number of the audio. The channel number inserted into channel 2 will be STATUS1_CHANNEL + 1

SFREQ: The reported sampling frequency of the audio stream.

ACCURACY: Transmitter Clock accuracy.

- LVL1 High accuracy mode: Transmitted sampling frequency is within a tolerance of +/-50*10^-6
- LVL2 Normal accuracy mode: Transmitted sampling frequency is within a tolerance of +/-1000*10^-6
- LVL3 Variable pitch shifted clock mode: Only specially designed receivers can receive the signal in this mode.
- OTHER: Interface frame rate not matched to sampling frequency: This is for all other modes that do not have an embedded sampling frequency clock.

Offset: 0x4a │ Byte Offset: 0x128 │ Read/Write: R/W │ Reset: 0xf2ffffff (0b11110010111111111111111111111111)

19:16	0xf	SOURCE
15:8	0xff	CODE
7:0	0xff	ABCDM

28.7.76 HDMI_NV_PDISP_HDMI_CHANNEL_STATUS2_0

HDMI_CHANNEL_STATUS2

MAX_LENGTH: Reports if the maximum audio sample word length is 20 bits or 24 bits.

LENGTH: Reports the audio sample word length of this block. The value of these bits is dependent on the value of MAX_LENGTH

If MAX_LENGTH = _20 then refer to the MAX20_* defines.

If MAX_LENGTH = _24 then refer to the MAX24_* defines.

All other bit combinations are reserved.

ORIGINAL: Defines the original sampling frequency of the audio stream.

ENABLE: _YES: override the channel status data with the value of these registers. _NO: Send the original channel status data

Offset: 0x4b │ Byte Offset: 0x12c │ Read/Write: R/W │ Reset: 0x000000f1 (0b0xxxxxxxxxxxxxxxxxxxxxxxx11110001)

28.7.77 HDMI_NV_PDISP_HDMI_EMU0_0

HDMI_EMU0 and 1 do indirect addressing. EMU0 has the address, and EMU1 has the data.

To write:

1. Write the data register with data.

2. Write the address register with bit 31=1, and the address in bits 15:0.

3. Write the address register with bit 31=0.

To read:

1. Write the address register with bit 31=0 and the address in bits 15:0.

2. Read back the address register to introduce delay allowing the read data to propagate.

3. Read the data register.

Offset: 0x4c │ Byte Offset: 0x130 │ Read/Write: R/W │ Reset: 0x00000000 (0b00000000000000000000000000000000)

28.7.80 HDMI_NV_PDISP_HDMI_SPARE_0

HDMI_SPARE

HW_CTS - If this is set to _ENABLE, Hardware measured CTS will be enabled. This method is more accurate than using software controlled CTS. The HDMI block will count the number of TMDS clocks that occur during the interval 1/(128 * audio sample rate) and use the value as CTS and issue the ACR Packet at each interval. When hardware measured CTS is enabled, all ENABLE fields of ACR_CTRL must be set to _NO. Also, ACR_0441_SUBPACK_HIGH_ENABLE must be set to _YES.

ACR_0441_SUBPACK_HIGH_N should be written with the value of N for the current sampling frequency.

The N value must also be written into AUDIO_N_VALUE (See the AUDIO register section for more details).

The value of N can be determined from the current audio sampling frequency, the current pixel clock rate, and tables 7-1. 7-2, and 7-3 in the HDMI specification. In most cases the value in the "Other" row can be used.

FORCE_SW_CTS: When HW_CTS = ENABLE, it uses measured CTS. However, when the audio clock / video clock ratio is known, this is undesirable. Currently, HW_CTS cannot be disabled.

When FORCE_SW_CTS=ENABLE along with HW_CTS=ENABLE, the HW_CTS is used to control transmission of ACR packets, but the CTS is programmed by software in the ACR_0441_SUBPACK_LOW registers.

SUPRESS_SP_B: Default SUPRESS_SP_B=0 is to disable B bits in audio sample packets, for non-present samples. Setting SUPRESS_SP_B=1 restores the old behavior.

CTS_RESET_VAL: When an ACR packet is sent, the CTS counter is reset to the value in this field. This should be set to the INIT value of 1

ACR_PRIORITY: This controls the priority of the ACR packet with respect to Audio Sample packets. This should be set to _HIGH.

LOW: ACR packets will have lower priority than Audio Sample packets

HIGH: ACR packets will have higher priority than Audio Sample packets

Software needs to make sure these registers are set when audio is active:

- HDMI_SPARE_HW_CTS = _HW_CTS_ENABLE
- HDMI_SPARE_CTS_RESET_VAL = 1
- HDMI_SPARE_ACR_PRIORITY = _HIGH
- ACR_CTRL_*_ENABLE = _NO
- ACR_0441_SUBPACK_HIGH_ENABLE = _YES

- ACR_0441_SUBPACK_HIGH_N = N
- AUDIO_N_VALUE = N
- ACR_0441_SUBPACK_LOW_SB1 = _USE_HW_CTS_VAL

HDMI_SPARE: 0:0 rw HW_CTS init=DISABLE

enum (DISABLE,ENABLE)

1:1 rw FORCE_SW_CTS init=DISABLE

enum (DISABLE,ENABLE)

2:2 rw SUPRESS_SP_B init=SUPRESS

enum (SUPRESS, KEEP)

18:16 rw CTS_RESET_VAL init=1

31:31 rw ACR_PRIORITY init=HIGH

enum (HIGH, LOW)

Offset: 0x4f │ Byte Offset: 0x13c │ Read/Write: R/W │ Reset: 0x00010000 (0b00000000000000010000000000000000)

Bit	Reset	Description
31:0	0x10000	Reserved.

28.7.81 HDMI_NV_PDISP_HDMI_SPDIF_CHN_STATUS1_0

HDMI_SPDIF_CHN_STATUS1

HDMI_SPDIF_CHN_STATUS1/2 contains the value of the channel status bits extracted from the incoming S/PDIF audio data stream. See IEC60958-3 chapter 5 for more information on these fields.

USE Specifies consumer use (CONSUMER) or professional (PRO) use of the channel status block. SPDIF_CHN_STATUS1/2 assumes consumer use.

TYPE: Specifies the type of data the audio word represents.

- PCM: Audio sample word represents linear PCM samples
- OTHER: Audio sample word is something other than liner PCM (i.e., compressed audio)

COPYRIGHT: Copyright status of the audio.

- YES: Copyright is asserted
- NO: Copyright is not asserted

D: The values of these bits have different meanings based on the value of _TYPE.

If _TYPE==_PCM, then:

- NO_PREEMPHASIS: 2 audio channels without pre-emphasis
- PREEMPHASIS: 2 audio channels with 50 microseconds/15 microseconds pre-emphasis

All other states are reserved for future use.

MODE Defines one of four possible channel status formats for bytes 1-23 of channel status. Currently only the value "0" is defined. This format is assumed for the SPDIF_CHN_STATUS1/2.

CODE: This byte defines the Category Code of the input device. This code indicates what type of equipment is generating the input. See 5.3.1 of the IEC60958-3 specification for the values of codes.

SOURCE: Source number of the audio. If this value is zero then no source number was reported.

CHANNEL: Channel number of the audio. This reports the channel number reported for the first subframe of audio. If this value is zero then the channel number was not reported.

SFREQ: This is the reported sampling frequency of the input audio stream. The value UNDEFINED means that the sampling frequency was not indicated by the audio stream.

ACCURACY: Transmitter Clock accuracy.

- LVL1 High accuracy mode: Transmitted sampling frequency is within a tolerance of +/-50*10^-6
- LVL2 Normal accuracy mode: Transmitted sampling frequency is within a tolerance of +/-1000*10^-6
- LVL3 Variable pitch shifted clock mode: Only specially designed receivers can receive the signal in this mode
- OTHER: Interface frame rate not matched to sampling frequency: This is for all other modes that do not have an embedded sampling frequency clock.

28.7.83 HDMI_NV_PDISP_CRC_CONTROL_0

CRC_CONTROL

The main CRC enable bit flows along the pipeline. This register controls the injection of this bit at the top of the pipeline. This register is double-buffered. The active value is updated at start of each frame from this 'ARM' register.

Other registers such as SOR_STATE2.ASY_CRCMODE and SOR_*CRC* control the actual CRC logic, once enabled.

ARM_CRC_CONTROL enables or disables computation of CRC, effective at the start of next frame.

Offset: 0x96 │ Byte Offset: 0x258 │ Read/Write: R/W │ Reset: 0x00000000 (0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx0)

Bit	Reset	Description
0	NO	ARM_CRC_ENABLE: 0 = NO 1 = YES 0 = DIS 1 = EN

28.7.84 HDMI_NV_PDISP_INPUT_CONTROL_0

INPUT_CONTROL

HDMI_SRC_SELECT selects from which of the two display units to take input. This register should be changed only when HDMI is idle.

ARM_RGB_RANGE controls whether R/G/B values of 0 and 255 are permitted (FULL), or removed by clamping to [1,254] (LIMITED).

According to the EIA/CEA-861-B and HDMI specifications, the 640x480 VGA mode uses FULL, and all others use LIMITED.

Note that this does not scale the video or change the black and white points (VGA is [0,255], others are [16,235]). That must be done, if necessary, in display or at the source.

See the HDMI 1.2a specification, section 6.6.

This register is double-buffered and will take effect on next frame boundary.

Offset: 0x97 │ Byte Offset: 0x25c │ Read/Write: R/W │ Reset: 0x00000000 (0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx00) | Default: 0x00000001

28.7.87 HDMI_NV_PDISP_KEY_CTRL_0

HDCP KEY SRAM Register Control

This is the register space for the HDCP ROM interface control register. This register controls writing the contents of the hdcp_key_data bus (56 bits) into the local key store. The keys are decoded in the Crypto block, and then the key data is presented on the bus.

LOCAL: If this bit is ENABLED the on-chip HDCP key store will be used by the HDCP encryption block. If DISABLED, external Crypto-ROM will be used.

AUTOINC: If this bit is ENABLED, the address written to by the WRITE16 function will auto-increment after the operation is complete. This is the normal operating mode.

WRITE16: If this bit is set to TRIGGER, the HDCP keys module will write all 16 bytes of data from the hdcp_key_data bus (sourced by the CD module) into the local key store. The bytes are written into the store at contiguous bytes pointed to by the ADDRESS field in auto-increment mode, or contiguous bytes pointed to by the LOAD_ADDRESS field otherwise. Poll this bit until it reports DONE to ensure the write is complete.

PKEY_REQUEST_RELOAD: Requests that the private key be requested again from KFUSE. Will autoclear to zero as soon as the requested transfer of the key begins. ,Only PKEY_LOADED will indicate when the key is ready for use.

PKEY_LOADED: Indicates that the private key value has been received from KFUSE and is ready for use.

LOAD_ADDRESS: For the WRITE16 function, this field selects the start byte address of the contiguous locations in the local key store to be written with the hdcp_key_data. This field is ignored if the AUTOINC bit is ENABLED. Addresses start at 0.

ADDRESS: This read-only field reports the next byte address in the local key store to be written to once the TRIGGER bits are DONE. For the WRITE16 operation, the address will increment by 16. Addresses start at 0.

Typical operation is as follows:

1. Write to the register with LOCAL_ENABLED, AUTOINC_DISABLED, WRITE5_INIT, WRITE7_INIT, LOAD_ADDRESS_ZERO.
2. Write the downstream KSV key data into the CD module and decrypt the key (see dev_cd.ref - HDCP_KEY_REG(i) and NV_PCIPHER_CTL1).
3. Write to the register with LOCAL_ENABLED, AUTOINC_ENABLED, WRITE5_TRIGGER, WRITE7_INIT, LOAD_ADDRESS_ZERO. Poll for WRITE5_DONE.
4. Write the first downstream key data into the CD module and decrypt the key (see dev_cd.ref - HDCP_KEY_REG(i) and NV_PCIPHER_CTL1).

5. Write to the register with LOCAL_ENABLED, AUTOINC_ENABLED, WRITE7_TRIGGER, WRITE7_INIT, LOAD_ADDRESS_ZERO. Poll for WRITE7_DONE.
6. Repeat steps 4 and 5 39 more times. There are always 40 keys and one KSV value.

If upstream key authentication is required do the following:

7. Write the upstream KSV key data into the CD module and decrypt the key.
8. Write to the register with LOCAL_ENABLED, AUTOINC_ENABLED, WRITE5_TRIGGER, WRITE7_INIT, LOAD_ADDRESS_ZERO. Poll for WRITE5_DONE.
9. Write the first upstream key data into the CD module and decrypt the key (see dev_cd.ref - HDCP_KEY_REG(i) and NV_PCIPHER_CTL1).
10. Write to the register with LOCAL_ENABLED, AUTOINC_ENABLED, WRITE7_TRIGGER, WRITE7_INIT, LOAD_ADDRESS_ZERO. Poll for WRITE7_DONE.
11. Repeat steps 9 and 10 39 more times. There are always 40 keys and one KSV value.

This will leave the store as follows (the required format):

- Byte 0 to Byte 4: downstream KSV
- Byte 5 to Byte 11: 1st downstream key
- Byte 12 to Byte 18: 2nd downstream key

  ...
- Byte 278 to Byte 284: 40th downstream key
- Byte 285 to Byte 289: upstream KSV
- Byte 290 to Byte 296: 1st upstream key

  ...
- Byte 563 to Byte 569: 40'th upstream key

28.8 Serial Output Resource Registers

Refer to “Reading Register Tables” in the Introduction section for the register table protocol as well as recommendations for accessing registers.

28.8.1 HDMI_NV_PDISP_SOR_PWR_0

This register contains bits that control the power state of the SOR. For simplicity, the sequencer will be used to perform all power control operations in the SOR (even in TMDS where the sequencing is relatively simple). This unifies the approach and makes it easier for the hardware and software to deal with the SOR's. At boot, the software must load and configure the SOR sequencer via the SOR_SEQ_CTL and SOR_SEQ_INST registers below. The sequencer must be properly programmed for power control to work.

NORMAL_STATE: Sets the normal operating state. There are two choices: powered up and powered down. To change this register, software should load in the new value and write SETTING_NEW=TRIGGER. Once the change has been successfully completed, SETTING_NEW will indicate DONE. This is the state that software will want to control in order to power up and down the interface.

NORMAL_START: The execution of the power up and power down sequence can be modified somewhat by choosing to use either the NORM or ALT program entry point.

SAFE_STATE: Sets the safe operating state. There are only two choices: powered up and powered down. To change this register, software should load in the new value and write SETTING_NEW=TRIGGER. Once the change has been successfully completed, the SETTING_NEW will indicate DONE. The execution of the power up and power down sequence can be modified somewhat by choosing to use either the standard or the alternate program entry point. This is the state that the hardware will use whenever it initiates the mode switch/shutdown procedure for HDMI. In general, this should be set to STATE_PD and left there always.

SAFE_START: The execution of the power up and power down sequence can be modified somewhat by choosing to use either the NORM or ALT program entry point.

HALT_DELAY: Once the sequencer gets to the instruction with the HALT=1, the program is essentially complete; that is, the attached unit is powered up or down as was requested. Some panels, however, have a minimum time before their state can be changed again. If the halt instruction has a non-zero delay, this bit will be set while that time expires.

MODE: The currently active state, normal or safe. After reset, the MODE is always SAFE.

SETTING_NEW: This bit is used to trigger a new setting of power mode to take effect. The typical procedure might be something like:

1. Make sure SETTING_NEW==DONE, i.e., not already an outstanding change request. If there is an outstanding change request, software must wait for it to complete.

2. Update the NORMAL and SAFE power mode fields.

3. Write SETTING_NEW=TRIGGER.

4. Poll for SETTING_NEW=DONE. If it does not happen within one frame time, then software may opt to accelerate the change by writing SOR_SEQ_CTL SWITCH=FORCE (be careful not to disturb other settings in that register!).

Usage: boot / initialization / mode switch / normal operation / shutdown

Offset: 0x55 │ Byte Offset: 0x154 │ Read/Write: R/W │ Reset: 0xXX000000 (0b0xxxxxxxxxxxxx00xxxxxxxxxxxxxx00)

Bit	R/W	Reset	Description
31	RW	0x0	SETTING_NEW: 0 = DONE 1 = PENDING 1 = TRIGGER

Bit	R/W	Reset	Description
28	RO	X	MODE: 0 = NORMAL 1 = SAFE
24	RO	X	HALT_DELAY: 0 = DONE 1 = ACTIVE
17	RW	0x0	SAFE_START: 0 = NORMAL 1 = ALT
16	RW	0x0	SAFE_STATE: 0 = PD 1 = PU
1	RW	0x0	NORMAL_START: 0 = NORMAL 1 = ALT
0	RW	0x0	NORMAL_STATE: The normal state depends on the power sequencing state. NORMAL_STATE=1 is correct for powered-up HDMI. 0 is for the powered-down / reset state. 0 = PD 1 = PU

28.8.2 HDMI_NV_PDISP_SOR_TEST_0

This register contains control bits that configure certain aspects of testing mode of the SOR.

TEST_ENABLE: To enable testing:

- 0 = normal operation
- 1 = test mode

In test mode test_fastclkint and test_loadpulse signals from the core are used in place of the internally generated signals.

INVD: Invert the data. Note that combining INVD with the choice of DSRC and TPAT below permits ramp up, ramp down, walking ones, walking zeros, all ones, all zeros.

ACT_HEAD_OPMODE: Report the current OR operating mode.

ATTACHED: Report whether the OR is currently attached to a head.

DSRC: When DSRC=NORMAL, the serializers behave normally and use the encoded RGB data. When DSRC=DEBUG, the serializers load from DEBUGA0, DEBUGA1, DEBUGB0, and DEBUGB1 bits instead of the normal data coming down the pipe. When DSRC=TGEN, the data is taken from the built in test generator.

TPAT: Selects the test generator pattern. When test generator is running, H will be high for 1 in 4 repetitions (of duration 1024 clocks), V will be high for 4 in 16 repetitions coincident with H. Only operates when test mode is enabled.

LO: force all 0s

TDAT: use hardware fixed value

RAMP: test generator output ramps

WALK: test generator output is a walking one

MAXSTEP: 0, 1023, ...

MINSTEP: 511, 512, ...

CRC: The source of the data for CRC computation (for verification) can be either before the high-speed serializer logic, or after the high-speed serializer/deserializer logic.

TESTMUX[7:0]: Test MUX select - output seen on PROBE

Usage: Debug

Offset: 0x56 │ Byte Offset: 0x158 │ Read/Write: R/W │ Reset: 0x00800X00 (0b000000001000xx00xxxxxxxxx0xxxx0x)

6	RW	0x0	INVD: 0 = DISABLE 1 = ENABLE
1	RW	0x0	TEST_ENABLE: 0 = DISABLE 1 = ENABLE

28.8.3 HDMI_NV_PDISP_SOR_PLL0_0

These registers configure the main SOR PLL and other frequency-dependent controls. The value loaded is a function of the pixel clock frequency, and whenever the pixel clock changes, these registers must be updated. In general, these registers will be updated during the second interrupt of a mode switch.

PWR: 1 = power down the TMDS PLL

PDBG: 1 = power down the bandgap

VCOPD: 1 = power down the VCO

PDPORT: 1 = power down the output drivers

RESISTORSEL: Selects the internal resistor (0) or external resistor (1).

PULLDOWN: Weak pull-down enable

- 1 = 2Kohm pulldown on all outputs.
- 0 = Weak pulldown disabled.

Note: pulldown is also controlled by the sequencer. the pulldown is derived from an OR of:

NV_PDISP_SOR_PLL0_PULLDOWN and the sequencer control of pulldown. This priv register field does not read the final pull-down value. In other words if software writes NV_PDISP_SOR_PLL0_PULLDOWN to DISABLED and sequencer pulldown is enabled, then an NV_PDISP_SOR_PLL0_PULLDOWN read will return DISABLED (while pulldown might be ENABLED due to sequencer control).

VCOCAP[3:0]: Selects the VCO capacitor and adjusts ring oscillator inter-stage load.

FILTER[3:0]: Selects the loop filter and adjusts the filter resistor value.

ICHPMP[3:0]: Specifies additions to the charge pump current in steps of 0.375 µA.

TMDS_TERM: This bit is used to enable termination. Termination is only used in TMDS mode of operation, and may not be needed at lower operating frequencies (in which case, disabling it saves power).

TERMADJ[3:0]: Termination resistance control.

LOADADJ[3:0]: Load pulse position adjust.

AUX0-AUX7: Most of these bits currently have no assigned function, but are provided to permit control of possible future features of the macro.

- AUX0: No function
- AUX1: No function
- AUX2: No function
- AUX3: Rotate green channel by 1 bit to reduce TMDS EMI
- AUX4: No function
- AUX5: No function
- AUX6: No function
- AUX7: No function

TMDS_ANALOG_X4_HP_B revision:

BG_V17_S[3:0]: Bandgap 1.7V output voltage control

TX_REG_LOAD[1:0]: TX regulator default loading

- 00: 0.5mA (default)
- 01: 1.0mA
- 10: 1.5mA
- 11: 2.0mA

PE_EN: Pre-emphasis enable. PE_EN active only at 1080p, but turn off at 720p

- 0: Disable
- 1: Enable

HALF_FULL_PE: Pre-emphasis half bit time or full bit time (Note 2)

- 0: Half bit time (default)
- 1: Full bit time (for long trace)

S_D_PIN_PE: Pre-emphasis on one single pin or on differential pins (D+ and D-) (Note 2)

- 0: Single pin (default)
- 1: Differential pins

See also the NV_PDISP_PE_CURRENT register below.

28.8.6 HDMI_NV_PDISP_SOR_CSTM_0

The class permits the driver to select a number of operating modes for the SOR. Some of these modes (TMDS modes) are well defined and stable. Some modes may require customization by software before they will work. These registers are used for that customization. The fields available for customization are:

- PD_TXDA[3:0]: Bitwise control to power down the data pins of link A. Set to DISABLE to power down the pin.
- PD_TXDB[3:0]: Bitwise control to power down the data pins of link B. Set to DISABLE to power down the pin.
- PD_TXCA: Power down the clock pin of link A. Set to DISABLE to power down the pin.
- PD_TXCB: Power down the clock pin of link B. Set to DISABLE to power down the pin.

UPPER: Designates whether LVDS bank A is the upper, odd, or first pixel. Bank B is always set to !UPPER. The serial output from UPPER=1 will be Clock and A0-A3. The serial output from UPPER=0 (and DUALMODE) will be Clock and A4-A7. The default is bank A has UPPER=1, bank B has UPPER=0.

MODE[1:0]: Controls the digital output encoding applied to the data stream in custom mode and is only used for data muxing at the input of the SOR. This field does not control the TMDS macro.

- 0 = LVDS
- 1 = TMDS
- 2 = Reserved
- 3 = Reserved

LINKACTA, LINKACTB: Enables (1) or disables (0) the digital logic of links A and B

LVDS_EN: Output driver configuration for controlling the encoding of the data and the output common mode control. This does not control the internal clock dividers of the TMDS macro.

- 0 = TMDS
- 1 = LVDS

DUP_SYNC: This field only has an effect when in LVDS mode. When asserted in LVDS mode, it forces the link to use DE, HSYNC, and VSYNC for the encoding and to never use RES, CNTLE, and CNTLF. RES becomes DE. CNTLE becomes HSYNC. CNTLF becomes VSYNC.

NEW_MODE: For backwards compatibility, set register to 0 so the old mode is used. In old mode, for the second link in dual link mode, all the control bits are zeroed out except for VSYNC. When a new mode is used, none of the control bits of the second link for dual-link mode are zeroed out.

BALANCED: For MODE = LVDS, this enables balanced encoding. Balanced mode will selectively invert sets of bits in the serial stream in an attempt to keep the average DC value near zero. Default is unbalanced. Has no effect in other modes.

PLLDIV: Controls the internal clock dividers of the TMDS_MACRO by setting the feedback divider for the high-speed PLL.

- 0 = divide by 7 (LVDS)
- 1 = divide by 10 (TMDS)

ROTCLK[3:0]: Skews the TXC clock to come out earlier. By changing this register value, you can configure the skew between output data (TX data) and output clock (TXC). This field specifies the number of sclk cycles which the output clock should come out earlier than its normal phase. For TMDS, sclk is a 10x pixel clock, so ROTVAL should be between 0-9. For LVDS, sclk is a 7x pixel clock, so ROTVAL should be between 0-7.

ROTDAT[2:0]: Before encoding the 8 bits of each color channel, the 8 bits within each color channel can be right rotated. All color channels are rotated by the same amount. For example, if ROTDAT = 6, then input channel data (r7,r6,r5,r4,r3,r2,r1,r0} would become {r5,r4,r3,r2,r1,r1,r7,r6}.

ROTDAT should be between 0 and 7.

TMDS modes of operation are standard and stable. The table below summarizes the fixed values the hardware uses for the above fields for TMDS operating modes.

	SINGLE TMDS_A	SINGLE TMDS_B	SINGLE TMDS_AB	SINGLE TMDS	Dual TMDS
PD_TXDA[2:0]	0	7	0	0	0
PD_TXDA[3]	1	1	1	1	1
PD_TXDB[2:0]	7	0	0	0	0
PD_TXDB[3]	1	1	1	1	1
PD_TXCA	0	1	0	0	0
PD_TXCB	1	0	0	0	1
UPPER	1	1	1	1	1
MODE[1:0]	1	1	1	1	1
LINKACTA	1	0	1	1	1
LINKACTB	0	1	1	1	1
LVDS_EN	0	0	0	0	0

	SINGLE TMDS_A	SINGLE TMDS_B	SINGLE TMDS_AB	SINGLE TMDS	Dual TMDS
DUP_SYNC	0	0	0	0	0
NEW_MODE	0?	1	1	1	0?
BALANCED	0	0	0	0	0
PLLDIV	1	1	1	1	1
ROTCLK[3:0]	0	0	0	0	0
ROTDAT[2:0]	0	0	0	0	0

The first register defines the total custom mode. This is useful for defining possible new modes of operation as well as for test and characterization in the lab. Which is to say, this is a debug register set. Software should really never need to use it. Also, note that if LVDS_ONLY=TRUE, then this register cannot be used as the hardware will only permit Protocol=LVDS to be enabled. This register is intended to have the same format as the second register.

Usage: boot / initialization / mode switch

28.8.8 HDMI_NV_PDISP_SOR_CRCA_0

The following three registers are used to fetch CRC's when running VGA mode tests. One contains the valid bit, one contains the actual computed CRC, and the third contains the error (overrun bit). Proper use of these registers is as follows:

1) Poll SOR_CRCA for VALID == TRUE.

2) Reset SOR_CRCA by writing RESET to it.

3) Read SOR_CRCB to get the CRC

Usage: verification

Offset: 0x5c │ Byte Offset: 0x170 │ Read/Write: R/W │ Reset: 0x00000000 (0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx0)

Bit	Reset	Description
0	0x0	VALID: 0 = FALSE

		1 = TRUE 1 = RESETV

28.8.9 HDMI_NV_PDISP_SOR_CRCB_0

Usage: verification

Offset: 0x5d │ Byte Offset: 0x174 │ Read/Write: RO │ Reset: 0xXXXXXXXX (0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx)

Bit	Reset	Description
31:0	X	CRC

28.8.10 HDMI_NV_PDISP_SOR_BLANK_0

This register can be used to override the SOR output resource pixels with blank data.

OVERRIDE: Setting this field to true will override the pixel bus from the RG and output black pixels instead.

TRANSITION: This field controls the timing of the output resource blank override. The choices are IMMEDIATE. The output resource will be blanked or restored to its previous output data immediately.

NEXT_VSYNC The output resource will be blanked or restored to its previous output data at the next vsync.

STATUS This read-only field returns BLANKED when the output resource is sending blank pixels forced by the OVERRIDE bit, otherwise it returns NOT_BLANKED.

Usage: boot / initialization / mode switch / normal operation

Offset: 0x5e │ Byte Offset: 0x178 │ Read/Write: R/W │ Reset: 0x0000000X (0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx00)

Bit	R/W	Reset	Description
2	RO	X	STATUS: 0 = NOT_BLANKED 1 = BLANKED
1	RW	0x0	TRANSITION: 0 = IMMEDIATE 1 = NEXT_VSYNC
0	RW	0x0	OVERRIDE: 0 = FALSE 1 = TRUE

28.8.11 HDMI_NV_PDISP_SOR_SEQ_CTL_0

Sequencer control registers for SOR. Up to three pins can be assigned to an SOR for use in controlling the power to an attached LVDS flat panel. The meaning of any particular pin and whether it is actually available to this SOR is controlled in either the host or PCB manager. In addition, the sequencer can override the individual link clock and data power control pins, thereby forcing them all into disabled or tristate mode and it can override the DE signal from the RG (for TMDS mode) to force the link to become inactive.

PU_PC: The program counter for the start of the power up program sequence. Always 0.

PU_PC_ALT: The alternate entry point into the power up program sequence. Defaults to the same value as PU_PC.

PD_PC: The program counter for the start of the power down program sequence. Defaults to 8, evenly dividing the available program space.

PD_PC_ALT: The alternate entry point into the power down program sequence. Defaults to the same default value as PD_PC.

PC: The current value of the program counter (useful for status and debug).

STATUS: Indicates if the sequencer is STOPPED or RUNNING.

SWITCH: If a particular sequencer instruction is waiting for vsync to arrive, writing this bit to FORCE will cause the wait condition to be satisfied immediately.

> **Note:** The sequencer can begin with arbitrary phase relative to the 1 µs timer that is used to advance the internal counters. Thus the actual time delay for the first event can be almost one microsecond less than what is requested. Subsequent instructions in a chain of events do transition on 1 µs boundaries, however. If a minimum specification of "x" µs is required, then it is best to program "x+1" µs of delay.

Usage: boot / initialization / mode switch

Offset: 0x5f │ Byte Offset: 0x17c │ Read/Write: R/W │ Reset: 0xX00X880X (0bx0xxxxxxxxxxxxxx100010000000xxxx)

28.8.29 HDMI_NV_PDISP_SOR_REFCLK_0

SOR_REFCLK

The HDMI clock is programmable and varies, depending on screen resolution. The NV_PDISP_SOR_SEQ_INSTn instructions (above) can wait for certain time intervals to elapse. Whenever hdmi_clk frequency is changed, this register must be reprogrammed to divide hdmi_clk to produce a 1 µs time reference, otherwise the time intervals requested by NV_PDISP_SOR_SEQ_INSTn will not be accurate.

The format of DIVISOR is an unsigned 8.2 divider. Because this is a simple digital divider, not a PLL, fractional values result in a jitter of one hdmi_clk between successive "1 µs" intervals, but the long-term average works out to the requested divisor. This

jitter is OK because the NV_PDISP_SOR_SEQ_INST wait intervals do not need to be exact. If the integer part is written as 0, it will be interpreted the same as "1".

Offset: 0x95 │ Byte Offset: 0x254 │ Read/Write: R/W │ Reset: 0x00001900 (0bxxxxxxxxxxxxxxxx0001100100xxxxxx)

28.9 Test and Debug Registers

Refer to “Reading Register Tables” in the Introduction section for the register table protocol as well as recommendations for accessing registers.

28.9.1 HDMI_NV_PDISP_SOR_VCRCA0_0

To quickly determine if the TMDS is working properly, a running CRC stamp is kept, which is reset at each VSYNC. For each sub-link, there are up to 40 bits of encoded data that have been re-parallelized from the serial data going out.

These encoded bits of data are broken up into three 16-bit pieces depending on either LVDS or TMDS encoding:

For TMDS, the encoded data is as follows:

- CRCH: {8'b00000000,TMDS_CLK_ENC[9:2]}
- CRCM: {TMDS_CLK_ENC[1:0],TMDS_TX2_ENC[9:0],TMDS_TX1_ENC[9:6]}
- CRCL: {TMDS_TX1_ENC[5:0],TMDS_TX0_ENC[9:0]}

For LVDS, the encoded data is as follows:

- CRCH: {8'b00000000,LVDS_CLK_ENC[6:4]}
- CRCM: {LVDS_CLK_ENC[3:0],,LVDS_A3_ENC[6:0],LVDS_A2_ENC[6:2]}
- CRCL: {LVDS_A2_ENC[1:0],LVDS_A1_ENC[6:0],LVDS_A0_ENC[6:0]}

For each of these pieces, a CRC16 is computed, CRCH for the upper 16-bit piece, CRCM forms the middle 16-bit piece, and CRCL for the lower 16-bit piece. The CRC16 takes in the 16 bits of encoded data plus the CRC16 value of the previous cycle to generate the new CRC16. The CRC equation which is used is:

x^16 + x^11 + x^4 + 1.

At each VSync, the previously running CRC16 values are captured into the VCRC registers and a previous CRC value of all zeroes is fed into the CRC16 units. This means the running CRC16 is reset at each VSync.

Note: For power saving, the VCRC is only computed when NV_PDISP_SOR_TRIG != 0. Also, it seems these are not latched at VSync but are free-running.

The VCRC registers for sub-link A

Usage: debug

Offset: 0x72 | Byte Offset: 0x1c8 | Read/Write: RO | Reset: 0x00000000 (0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx)

Bit	Reset	Description
31:16	X	CRCM

Bit	Reset	Description
15:0	X	CRCH

28.9.5 HDMI_NV_PDISP_SOR_EDATAA0_0

EDATA has the encoded data for the serial channels TXC, TX3, TX2, TX1, and TX0. For each link, there are up to 40 bits of encoded data. The encoded bits making up the data are as follows:

For TMDS, the encoded data is as follows:

```
EDATA[39:0] =
{TMDS_CLK_ENC[9:0],
TMDS_TX2_ENC[9:0],
TMDS_TX1_ENC[9:0],
TMDS_TX0_ENC[9:0]}
```

For LVDS, the encoded data is as follows:

```
EDATA[39:0] =
{5'b00000,
LVDS_CLK_ENC[6:0],
LVDS_A3_ENC[6:0],
LVDS_A2_ENC[6:0],
LVDS A1 ENC[6:0],
LVDS_A0_ENC[6:0]}
```

The EDATA registers can be written to when any of the trigger bits for capture are set high.

The EDATA registers for sub-link A

Usage: debug

Offset: 0x76 | Byte Offset: 0x1d8 | Read/Write: RO | Reset: 0x00000000 (0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx)

Bit	Reset	Description
31:0	X	VAL

28.9.6 HDMI_NV_PDISP_SOR_EDATAA1_0

Usage: debug

Offset: 0x77 | Byte Offset: 0x1dc | Read/Write: RO | Reset: 0x00000000 (0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx)

Bit	Reset	Description
7:0	X	VAL

28.9.7 HDMI_NV_PDISP_SOR_COUNTA0_0

There are three 16-bit counts for each sub-link (TX0, TX1, TX2). The count registers for sub-link A.

Usage: debug

Offset: 0x78 | Byte Offset: 0x1e0 | Read/Write: RO | Reset: 0x00000000 (0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx)

Bit	Reset	Description
31:16	X	TX1
15:0	X	TX0

28.9.8 HDMI_NV_PDISP_SOR_COUNTA1_0

Usage: debug

Offset: 0x79 | Byte Offset: 0x1e4 | Read/Write: RO | Reset: 0x00000000 (0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx)

Bit	Reset	Description
15:0	X	TX2

28.9.9 HDMI_NV_PDISP_SOR_DEBUGA0_0

The debug registers for sub-link A

The following registers control the debug data input to the serializer. These bits are only relevant when TEST_ENABLE is set.

DEBUGA0 has the data for the serial channels TXC, TX3, TX2, TX1, and TX0. For each link, there are up to 40 bits of data to be encoded. The bits to be encoded which make up the data are as follows:

For TMDS, the data to be encoded are loaded as follows:

```
{TMDS_CLK_ENC[9:0], TMDS_TX2_ENC[9:0], TMDS_TX1_ENC[9:0], TMDS_TX0_ENC[9:0]}
 =
 {DEBUGA1, DEBUGA0}
```

For LVDS, the encoded data is as follows:

```
 {5'b00000, LVDS_CLK_ENC[6:0], LVDS_A3_ENC[6:0], LVDS_A2_ENC[6:0],
LVDS_A1_ENC[6:0], LVDS_A0_ENC[6:0]}
 =
 {DEBUGA1[2:0], DEBUGA0}
```

Usage: debug

Offset: 0x7a | Byte Offset: 0x1e8 | Read/Write: R/W | Reset: 0x00000000 (0b00000000000000000000000000000000)

Bit	Reset	Description
31:0	0x0	VAL: 0 = RESETV

28.9.10 HDMI_NV_PDISP_SOR_DEBUGA1_0

Usage: debug

Offset: 0x7b │ Byte Offset: 0x1ec │ Read/Write: R/W │ Reset: 0x00000000 (0bxxxxxxxxxxxxxxxxxxxxxxxxx00000000)

Bit	Reset	Description
7:0	0x0	VAL: 0 = RESETV

28.9.11 HDMI_NV_PDISP_SOR_TRIG_0

TRIG specifies the number of pixel clock cycles after the previous VSYNC was detected to capture state data into IDATA, EDATA, CNT, and CCRC. After the trigger has captured data, the trigger gets reset with the next VSYNC and waits TRIG pixel cycles to capture data again. If the TRIG value is greater than the number of cycles between consecutive VSYNCs, then the trigger is not reset while it is still pending to capture data. Once the data has been captured, the trigger is reset with the following VSYNC to capture data again. If TRIG is all zeros, then the trigger is disabled and no capturing occurs.

Usage: debug

Offset: 0x7c │ Byte Offset: 0x1f0 │ Read/Write: R/W │ Reset: 0x00000000 (0bxxxxxxxx000000000000000000000000)

Bit	Reset	Description
23:0	0x0	VAL: 0 = RESETV

28.9.12 HDMI_NV_PDISP_SOR_MSCHECK_0

The mode switch monitor is used for hardware debug only. To use, the test should set the CTL bit to CLEAR and then to RUN. At the end of the test, the register can be read. The various fields indicate the number of times the following conditions occurred:

- CRC enable went from false to true
- CRC enable went from true to false
- Data enable went from false to true
- Data enable went from true to false

All counts have 4 bits, so the count will clamp at 15.

Usage: debug

Offset: 0x7d │ Byte Offset: 0x1f4 │ Read/Write: R/W │ Reset: 0x80000000 (0b1xxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx)

Bit	R/W	Reset	Description
31	RW	0x1	CTL: 0 = CLEAR 1 = RUN
15:12	RO	X	DATA_ENABLE_T2F
11:8	RO	X	DATA_ENABLE_F2T
7:4	RO	X	CRC_ENABLE_T2F
3:0	RO	X	CRC_ENABLE_F2T

28.10 Audio Registers

Refer to “Reading Register Tables” in the Introduction section for the register table protocol as well as recommendations for accessing registers.

28.10.1 HDMI_NV_PDISP_AUDIO_DEBUG0_0

This is the register space for the S/PDIF audio decoding block. Please refer to IEC60958-1 for general and IEC60958-3 for consumer specifications.

AUDIO_DEBUG0

This register is meant for debugging. It indicates various possible errors in the incoming S/PDIF stream or FIFO overflows. _NO indicates that no error of this type has occurred. _YES indicates that an error of the given type occurred at least once.

This is a write-1-to-clear register. To clear the _ERROR bits, just write _RESET to the bit you want to clear.

THRESHOLD_ERROR: When THRESHOLD_LOW is bigger than THRESHOLD_HIGH, this bit will be set. This indicates the internal state machine has reached an invalid state likely due to glitches in the input or the input being disconnected/reconnected.

HA/HB_FIFO_ERROR: The data is passed from the audio to the HDMI block via an async FIFO. This bit indicates that the FIFO is full. There is one bit for each head. This is an indication that the HDMI unit does not drain the audio sample data fast enough. We should only be looking at the bit for the head currently running HDMI. The bit for the other head will always be set since that FIFO will never be drained.

FRAME_ERROR: A block should have 192 frames. When a non-192 frames' block is detected, this bit will be set. Again, this indicates a problem with the incoming S/PDIF stream.

BITS_ERROR: A frame should have a 56-bit audio sample + an 8-bit preamble. If a non 56-bit audio sample is detected in a frame, this bit will be set.

OVERFLOW_ERROR: If the S/PDIF input stream is floating, the 10-bit pulse width counter will be overflowed, and this bit will be set. See OVERFLOW_TH for detail.

PREAMBLE_ERROR: A frame should have a 56-bit audio sample + an 8-bit preamble. If there is no valid preamble for a given sample, this bit will be set.

Offset: 0x7f │ Byte Offset: 0x1fc │ Read/Write: R/W │ Reset: 0x00000000 (0bxxxxxxx0xxx0xxx0xxx0xxx0xxx0xxx0)

Bit	Reset	Description
24	0x0	PREAMBLE_ERROR: 0 = NO 1 = YES 1 = RESETV
20	0x0	OVERFLOW_ERROR: S/PDIF input stream is floating for Tegra 4 devices, so ignore the related overflow error. 0 = NO 1 = YES 1 = RESETV
16	0x0	BITS_ERROR: 0 = NO 1 = YES 1 = RESETV
12	0x0	FRAME_ERROR: 0 = NO 1 = YES 1 = RESETV

Bit	Reset	Description
8	0x0	HB_FIFO_ERROR: 0 = NO 1 = YES 1 = RESETV
4	0x0	HA_FIFO_ERROR: 0 = NO 1 = YES 1 = RESETV
0	0x0	THRESHOLD_ERROR: 0 = NO 1 = YES 1 = RESETV

28.10.2 HDMI_NV_PDISP_AUDIO_DEBUG1_0

AUDIO_DEBUG1

OVERFLOW_TH (bit 9:0): There is a 10-bit counter running on dispclk_audio_fs and counting S/PDIF's input pulse length. The maximum pulse length count is 305, when dispclk=416 MHz and fs=32 kHz. If someone unplugged the S/PDIF input connector, this counter will count above 305 (0x131) and then overflow eventually. OVERFLOW_TH is the threshold that being used to conclude when the S/PDIF input is being unplugged or floating. If the 10-bit counter is greater than or equal to OVERFLOW_TH, then OVERFLOW_ERROR bit will be set.

Software should not need to program this register to anything but its initialized value. The initialized value is the maximum value that the 10-bit counter can reach before overflowing.

PACKET_NOISE_FILTER_ENABLE: A register delays packets long enough to determine if the packet was of a legitimate length. If a packet contains more than 56 bits, the packet is dropped and an error condition is flagged (NV_PDISP_AUDIO_DEBUG0_PREAMBLE_ERROR = _YES). This register is included as a debug to allow disabling of the packet delay and dropping functionality.

When ENABLE is _YES, bad audio packets will be dropped and preamble errors flagged

When ENABLE is _NO, bad audio frames will be sent through as is.

PREAMBLE_RECOVER_DEBUG: When YES, audio recover circuit accepts a new preamble and audio sample even when it arrives unexpectedly (i.e., before previous sample has completed). NO restores legacy behavior, which is to drop the new sample. Software should not need to change this bit.

Offset: 0x80 │ Byte Offset: 0x200 │ Read/Write: R/W │ Reset: 0x800103ff (0b1xxxxxxxxxxxxxx1xxxxxx1111111111)

Bit	Reset	Description
31	YES	PREAMBLE_RECOVER_DEBUG: 0 = NO 1 = YES
16	0x1	PACKET_NOISE_FILTER_ENABLE: 0 = NO 1 = YES
9:0	0x3ff	OVERFLOW_TH

28.10.3 HDMI_NV_PDISP_AUDIO_DEBUG2_0

AUDIO_DEBUG2

There is an LFSR (linear feedback shift register) that can generate pseudo- random data to feed the output FIFO rather than use the incoming SPDIF stream. This is useful for testing in emulation or bring-up; a feature that software should not worry about.

LFSR_COUNT: LFSR_COUNT is the rate of filling LFSR data into the FIFO. The rate needs to be close to actual S/PDIF data input rate, which is depended on fs (audio sampling frequency). Set LFSR_COUNT according to the following table:

For dispclk_audio_fs = 416 MHz:

- fs = 32.0KHz, LFSR_COUNT = 0x32DC
- fs = 44.1KHz, LFSR_COUNT = 0x24E8
- fs = 48.0KHz, LFSR_COUNT = 0x21E8
- fs = 88.2KHz, LFSR_COUNT = 0x1274
- fs = 96.0KHz, LFSR_COUNT = 0x10F4
- fs = 176.4KHz, LFSR_COUNT = 0x093A
- fs = 192.0KHz, LFSR_COUNT = 0x087A

For dispclk_audio_fs = 277 MHz:

- fs = 32.0KHz, LFSR_COUNT = 0x21EB
- fs = 44.1KHz, LFSR_COUNT = 0x189A
- fs = 48.0KHz, LFSR_COUNT = 0x169B
- fs = 88.2KHz, LFSR_COUNT = 0x0C4D
- fs = 96.0KHz, LFSR_COUNT = 0x0B4D
- fs = 176.4KHz, LFSR_COUNT = 0x0626
- fs = 192.0KHz, LFSR_COUNT = 0x05A6

CHANNEL_STATUS: This bit does not do anything right now, since the channel status bit is generated on HDMI side.

USER: This is the user bit that is going into the FIFO when LFSR_DATA_EN is set.

VALIDITY: This is the validity bit that is going into the FIFO when LFSR_DATA_EN is set.

LFSR_DATA_EN: When this bit is set, the FIFO will be filled with LFSR (Linear Feedback Shift Register) data and ignore incoming S/PDIF input stream. LFSR will generate pseudo-random data in following pattern:

F->E->C->8->1->2->4->9->3->6->D->A->5->B->7->F->E.....

Offset: 0x81 │ Byte Offset: 0x204 │ Read/Write: R/W │ Reset: 0x000021e8 (0b0xxxxxx0xxx0xxx00010000111101000)

Bit	Reset	Description
31	0x0	LFSR_DATA_EN: 0 = NO 1 = YES
24	0x0	VALIDITY
20	0x0	USER
16	0x0	CHANNEL_STATUS
15:0	0x21e8	LFSR_COUNT

28.10.4 HDMI_NV_PDISP_AUDIO_FS1_0

When a B preamble (a B preamble is an indicator of the start of a frame in S/PDIF) is detected, a counter that is running on dispclk_audio_fs will count the number of clocks needed for the 8 HALFs (or 4 bits) B preamble length and compare against each of FSx_LOW and FSx_HIGH. (where x goes from 1 to 7, one entry per audio frequency).

For one of the 7 cases, we will have the case that:

FSx_LOW <= 8 HALF count <= FSx_HIGH

and the hardware will report that the incoming stream is running at frequency 'x' in the AUDIO_CNTRL0_SAMPLING_FREQ register field.

- FS1 is for fs = 32.0 KHz.
- FS2 is for fs = 44.1 KHz.
- FS3 is for fs = 48.0 KHz.
- FS4 is for fs = 88.2 KHz.
- FS5 is for fs = 96.0 KHz.
- FS6 is for fs = 176.4 KHz.
- FS7 is for fs = 192.0 KHz.

The formula to compute 8 HALFs is:

8 HALFs = 8 * hdmi_audio_clk / (fs * 128)

The value programmed in FSx_HIGH should be 8 HALF count + 10

The value programmed in FSx_LOW should be 8 HALF count - 10

For example: if the audio sample frequency is 32 kHz and dispclk_audio_fs is 216 MHz, then the 8 HALFs (or 4 bits) preamble length is:

8 HALFs = 8 * 216.0 MHz / (32.0 kHz * 128)

= 421 (or 422)

So, when FS1_LOW = 412 (0x19c) and FS1_HIGH = 430 (0x1ae), the 412 <= 8 HALFs <= 430 condition will be true. And AUDIO_CNTRL0_SAMPLING_FREQ will be equal to _32_0KHZ, which means 32 kHz of audio sampling frequency is detected.

The init values of the registers below are based on an hdmi_audio_clk of 216 MHz, and software should reprogram these every time that changes (which should not happen).

AUDIO_FS1

LOW: Low threshold (in dispclk periods) for 32 kHz audio detection.

HIGH: High threshold (in dispclk periods) for 32 kHz audio detection.

Offset: 0x82 │ Byte Offset: 0x208 │ Read/Write: R/W │ Reset: 0x01ae019c (0bxxxx000110101110xxxx000110011100)

Bit	Reset	Description
27:16	0x48	HIGH
11:0	0x44	LOW

28.10.11 HDMI_NV_PDISP_AUDIO_PULSE_WIDTH_0

AUDIO_PULSE_WIDTH

This is a status only register used for debugging.

HALF: Because the S/PDIF input stream is in biphase coding, a 32 bit sub-frame is broken down to 64 states. HALF (half bit or 1 state) is the number of dispclk_audio_fs periods for a minimum pulse length that can be measured on the S/PDIF input stream at any given audio fs.

For example, HALF = dispclk_audio_fs / (fs * 128)

THREE_HALF: THREE_HALF is the number of dispclk_audio_fs periods for the maximum pulse length in the S/PDIF input stream. THREE_HALF should be approximately 3 times of HALF; this only happens in the B, M, or W preamble.

COUNT2LOCK: If LOCK is set, COUNT2LOCK is number of frames to skip before locking down the HALF and THREE_HALF values. This field has no effect if LOCK is not set.

LOCK: If LOCK is set, it locks down the HALF and THREE_HALF values. If LOCK is clear, then HALF and THREE_HALF are updated every frame (B or M preamble) Setting LOCK means that the hardware will not detect changes in speeds of the incoming audio stream.

This mode should not be used by software. It is meant as a debugging tool.

Offset: 0x89 │ Byte Offset: 0x224 │ Read/Write: R/W │ Reset: 0x01XXXXXX (0bxxx0xx01xxxxxxxxxxxxxxxxxxxxxxxx)

Bit	R/W	Reset	Description
28	RW	0x0	LOCK: 0 = NO 1 = YES

21:12	RO	X	THREE_HALF
9:0	RO	X	HALF

28.10.12 HDMI_NV_PDISP_AUDIO_THRESHOLD_0

AUDIO_THRESHOLD

This status-only register is useful for debugging. It provides information about some characteristics of the S/PDIF stream.

THRESHOLD_LOW: THRESHOLD_LOW is 1.5 times of HALF. If a S/PDIF pulse is less than or equal to THRESHOLD_LOW, then a bit '1' is detected.

THRESHOLD_HIGH: THRESHOLD_HIGH is 2.5 times of HALF. If a S/PDIF pulse is less than or equal to THRESHOLD_HIGH and bigger than THRESHOLD_LOW, then a bit '0' is detected.

Offset: 0x8a │ Byte Offset: 0x228 │ Read/Write: RO │ Reset: 0x00XXXXX (0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx)

Bit	Reset	Description
21:12	X	HIGH
9:0	X	LOW

28.10.13 HDMI_NV_PDISP_AUDIO_CNTRL0_0

AUDIO_CNTRL0

ERROR_TOLERANCE: Because the (dispclk_audio_fs / audio sampling frequency) is a non-integer in general and due to the S/PDIF input stream's jitter, THREE_HALF is not exactly equal to 3 times of HALF. ERROR_TOLERANCE is the error count in dispclk periods allowed for 3 x HALF vs THREE_HALF. Based on simulation, the value of 4 to 7 is a good value when dispclk_audio_fs = 416 MHz. It is anticipated that software does not need to change this field from its init value.

SOFT_RESET: Reset the frame_counter and wait for the next B preamble to resume the audio data transfer. This is intended to clear registers in case the hardware ends up in a bad state, and should only be used for debug.

SOFT_RESET_ALL: Reset all register in audio block. This is currently a placeholder and is not implemented.

SAMPLING_FREQ: This will report the incoming S/PDIF audio stream sampling frequency. The HDMI specification only supports 7 audio sample frequency (fs), anything other than those 7 fs, will be reported as UNKNOWN.

SOURCE_SELECT: Determines whether to use the S/PDIF or Azalia (HDAL) audio input. This field has no effect on chips without the HDAL input. The default is AUTO: selects S/PDIF audio until the HDAL audio input is initialized by the external controller.

FRAMES_PER_BLOCK: FRAMES_PER_BLOCK is number of frames per block. By specification, each block has 192 (0xC0) frames.

Offset: 0x8b │ Byte Offset: 0x22c │ Read/Write: R/W │ Reset: 0xc00X0006 (0b11000000xxxxxxxxxxx0xxx000000110)

7:0	RW	0x6	ERROR_TOLERANCE

28.10.14 HDMI_NV_PDISP_AUDIO_N_0

AUDIO_N

N_VALUE: N_VALUE is the N parameter in HDMI Audio Clock Regeneration Packet. This value should be written when hardware measured CTS is enabled. The correct N value can be read from tables 7-1, 7-2, and 7-3 in the HDMI specification.

N_RESET: N_RESET is the reset for the N counter. If software is controlling the value of N, every time the audio stream changes sampling frequency (fs), software (driver) need to reset the N counter by writing _ASSERT to N_RESET followed by writing a _DEASSERT to N_RESET.

If the hardware selected N feature is enabled (N_LOOKUP = _ENABLE), software only needs to reset the N counter when writing to the AUDIO_NVAL registers and when enabling/disabling N_LOOKUP.

1) Set N_RESET = _ASSERT

2) Modify N value registers

3) Set N_RESET = _DEASSERT

Modifying N_VALUE can be done in step 1.

N_GENERATE: N_GENERATE controls how the audio block generates the 128*fs/N pulse, which is related to CTS. The detail of CTS can be found in HDMI 1.1 specification, Chapter 7. This bit is strictly for debugging purposes only.

_NORMAL: This method increments the CTS counter a variable number of times based on the length of the S/PDIF pulse.

_ALTERNATE: This method attempts to recreate the 128*fs clock and increments the CTS counter at regular intervals based on HALF.

N_LOOKUP: When set to _ENABLE, the hardware will select the appropriate value of N to use from one of the AUDIO_NVAL registers. This selection is based on the audio sampling frequency detected by the audio block. This is not the sampling frequency reported in the channel status bits. N_RESET should be toggled when this feature is enabled. When set to _DISABLE, software must program the correct N value into AUDIO_N.

Offset: 0x8c │ Byte Offset: 0x230 │ Read/Write: R/W │ Reset: 0x01000000 (0bxxx0xxx1xxx00000000000000000000)

20	0x0	RESETF: 1 = ASSERT 0 = DEASSERT
19:0	0x0	VALUE

28.10.15 HDMI_NV_PDISP_AUDIO_NVAL_0320_0

The following seven registers are used when Hardware N lookup is enabled (AUDIO_N_LOOKUP). These registers should be written with the correct N values for the current pixel clock frequency. These values can be found in tables 7-1, 7-2, and 7-3 of the HDMI specification. These registers are initialized to the value in the "other" row of these tables.

These registers may need to be reprogrammed when the pixel clock frequency changes. When changing the value of these registers, the N counter should be reset by toggling _RESET in AUDIO_N.

VALUE: The correct N value for 32 kHz audio at the current pixel clock frequency should be written here.

Offset: 0x8d │ Byte Offset: 0x234 │ Read/Write: R/W │ Reset: 0x00001000 (0bxxxxxxxxxxxxx0000001000000000000)

19:0	0x6000	VAL_1920_VALUE

28.10.22 HDMI_NV_PDISP_SOR_AUDIO_CNTRL0_0

HD Audio (also known as Azalia)

PORT_CONNECTIVITY: This controls the behavior of the Port Connectivity field of the Azalia Configuration Defaults Verb. This can be used to disable a codec that is associated with an SOR that does not connect to a physical port.

- ENABLE: Report 00 in the Port Connectivity field by default. This corresponds to "The Port Complex is connected to a jack"
- DISABLE: Report 01 in the Port Connectivity field by default. This corresponds to "No physical connection for Port" See table 100 and table 101 of the High Definition Audio Specification (Revision 1.0) for more information.

AFIFO_FLUSH: When the DP and HDMI logic are not in the middle of sending an audio packet, they will flush out any entries at the head of the AFIFO that is not tagged as the beginning of a sample. This ensures that the next new audio packet sent will begin on the correct channel. This is a diagnostic workaround bit to disable the flushing.

- ENABLE: Automatically fix the AFIFO if it gets out of alignment
- DISABLE: Do not throw out any AFIFO entries.

SAMPLING_FREQ: This will report the incoming audio stream sampling frequency in the Azalia codec. The HDMI specification only supports 7 audio sample frequencies (fs). Anything other than those 7 fs will be reported as UNKNOWN. See the HDMI 1.1 specification, Table 7-4 (page 77).

SOURCE_SELECT: Determines whether to use the S/PDIF or Azalia (HDAL) audio input. This field has no effect on chips without the HDAL input. The default is AUTO: selects S/PDIF audio until the HDAL audio input is initialized by the external controller

INJECT_NULLSMPL: When the bit is enabled, if the audio format is stereo LPCM as indicated by the stream format in the corresponding output converter widget, the codec inserts null samples into the audio FIFO for each Azalia frame in which it did

not receive any samples. This is done only for stereo LPCM and not for any other audio format. This bit should be disabled by default for backwards compatibility.

INPUT_MODE: This bit indicates what the audio data source is. HDA is Azalia data, S/PDIF is S/PDIF data.

SOR_AUDIO_CNTRL0

Offset: 0xac │ Byte Offset: 0x2b0 │ Read/Write: R/W │ Reset: 0xX01X1000 (0bxx0xxxxxxx01xxxxxxx1xxxxxxxxxxx0)

28.10.23 HDMI_NV_PDISP_SOR_AUDIO_DEBUG_0

SOR_AUDIO_DEBUG

This register is used for debug purposes only.

FIFO_ERROR: The data is passed from the audio (Azalia or S/PDIF) to the SOR via an async FIFO. This bit indicates that the FIFO is full. There is one bit for each head. This is an indication that the SOR units do not drain away the audio sample data fast enough.

Offset: 0xad │ Byte Offset: 0x2b4 │ Read/Write: R/W │ Reset: 0x00000000 (0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx0)

28.10.25 HDMI_NV_PDISP_SOR_AUDIO_NVAL_0320_0

SOR_AUDIO_NVAL

The following seven registers are used for HDMI N values for Azalia. These registers should be written with the correct N values for the current pixel clock frequency. These values can be found in tables 7-1, 7-2, and 7-3 of the HDMI specification. These registers are initialized to the value in the "other" row of these tables.

For DisplayPort audio, a value of 2^15 (0x8000) is always used.

VALUE: The correct N value for 32 kHz audio at the current pixel clock frequency should be written here.

28.10.38 HDMI_NV_PDISP_SOR_AUDIO_HDA_ELD_BUFWR_0

Software Programming Model

In an integrated graphics chip, which includes an NVIDIA® Audio Controller, with support for an NVIDIA audio codec driver, the following is the background and the suggested programming model.

The audio software for the HDMI codec will need information about the audio capabilities of an attached HDMI sink device. This information is stored in the HDMI sink device's EDID. Typically, the EDID flows through a graphics adapter to graphics software, so the graphics adapter hardware will not have knowledge of the EDID contents.

To that end, a new mechanism is defined for passing the HDMI sink device's audio EDID information from the graphics software to the audio software. The data payload containing the audio information will be known as EDID-Like Data (or ELD) and will contain a subset of the HDMI sink devices EDID information.

The ELD information will be valid if the HDMI sink is attached and powered on and the ELD Valid bit is set. The Pin Widget that is associated with this HDMI widget will report if the device is attached and that the ELD memory is populated and valid by reporting Presence Detect of 1 and ELD Valid of 1 to a Pin Sense control command. As with the Presence Detect bit, the changes to the ELD Valid bit can also result in the generation of unsolicited responses.

Each codec implements a 96-byte ELD buffer that is written by the resource manager and read by the audio driver. Once the ELD buffer is written by the resource manager, the valid bit, NV_PDISP_SOR_AUDIO_HDA_PRESENSE_ELDV is set to _VALID to indicate that ELD contents have been initialized by the resource manager. On hot unplug events, NV_PDISP_SOR_AUDIO_HDA_PRESENSE_ELDV is set to _INVALID to erase ELD programming in the audio driver.

Offset: 0xbc │ Byte Offset: 0x2f0 │ Read/Write: R/W │ Reset: 0x00000000 (0bxxxxxxxxxxxxxxxx0000000000000000)

Bit	Reset	Description
15:8	0x0	INDEX
7:0	0x0	DATABYTE

28.10.39 HDMI_NV_PDISP_SOR_AUDIO_HDA_PRESENSE_0

Reports the Hot Plug state and ELD state to the audio driver. Changes to this state can cause an unsolicited response.

ELDV: Indicates whether the data in the ELD buffer is valid and ready to read.

PD: Presence Detect. This should be set to _PRESENT by software upon hot plug and _NOT_PRESENT on unplug.

Offset: 0xbd │ Byte Offset: 0x2f4 │ Read/Write: R/W │ Reset: 0x00000000 (0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx00)

Bit	Reset	Description
1	INVALID	ELDV: 0 = INVALID 1 = VALID
0	NOT_PRESENT	PD: 0 = NOT_PRESENT 1 = PRESENT

28.10.40 HDMI_NV_PDISP_SOR_AUDIO_HDA_CP_0

Reports the Content Protection state requested by the Audio driver. It is at the discretion of the video driver to enable or disable content protection. This is a read-only register set by the Content Protection Control (CP_CONTROL) verb.

REQUEST_STATE

_DONT_CARE: No state change requested

_RESERVED: Unused

_PROTECTION_OFF: Audio driver requests content protection to be disabled.

_PROTECTION_ON: Audio driver requests content protection to be enabled.

Offset: 0xbe │ Byte Offset: 0x2f8 │ Read/Write: RO │ Reset: 0x0000000X (0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx)

Bit	Reset	Description
2	X	REQUEST_STATE_VALID
1:0	X	REQUEST_STATE: 0 = DONT_CARE 2 = PROTECTION_OFF 3 = PROTECTION_ON

28.10.41 HDMI_NV_PDISP_SOR_AUDIO_AVAL_0320_0

When using the Azalia codec, it is difficult to recover the 128*fs clock frequency from the incoming audio stream. Therefore, when using the Azalia codec, these registers must be programmed to emulate the N counter.

When using S/PDIF, the N counter will run at 128*fs (audio sampling frequency) and count to a value determined by the HDMI specification. The Azalia counter will run at 24 MHz at all times, and it needs to count for the same period of time as the N counter would have.

Refer to section 7.2 of the HDMI specification, 1.2.

AVAL values do not need to be programmed by software. Their default values are OK. If the NVAL changes, it will change the N counter frequency. AVAL will need to be changed to match with this new NVAL. Certain resolutions may require different NVALs.

For Mobile chips, the clock is 24 MHz, not 54 MHz. For 44.1, the default N of 6272 gives non-integer AVAL. Choosing N of 4704 instead (nominal CTS 61875) gives an N frequency of 1200 Hz.

48k: 1ms 24000 azaclk cycles (0x5DC0)

44.1k: 1ms/1.2 20000 azaclk cycles (0x4E20)

But this is academic because CTS/N is hardcoded since the pixel clock / audio clock ratios are known and fixed.

At 27 MHz Pixel Clock			
	CTS	**N**	**AVAL**
44.1	22500	4704	20000
88.2	22500	9408	20000
176.4	22500	18816	20000
At 74.25 MHz Pixel Clock			
44.1	61875	4704	20000
88.2	61875	9408	20000
176.4	61875	18816	20000
At 148.5 MHz Pixel Clock:			
44.1	123750	4704	20000
88.2	123750	9408	20000
176.4	123750	18816	20000

VALUE: The correct A value for 32 kHz audio at the current pixel clock frequency should be written here.

29.0 HDMI CEC

The HDMI Consumer Electronics Control (CEC) block supports CEC standard communication over an HDMI connection. It support both remote control of HDMI devices attached to the Tegra® 4 device, and also allows other HDMI devices to control Tegra functions. Refer to the CEC appendix of the HDMI specification for details of this link.

29.1 Functional Description

The CEC module is an APB slave. It is located at address NV_ADDRESS_MAP_APB_CEC_BASE (0x70015000).

The CEC consists of hardware state machines that send and receive bytes over the CEC wire. Its simple host interface allows one byte to be sent and received at a time.

The CEC has interrupts for interrupt-driven input and output, and also permits polling I/O.

29.2 Programming Guidelines

29.2.1 Initialization

29.2.1.1 Clock and Reset

The CEC uses a fixed clock source – the APB bus clock. It also has a clock enable and reset in the CAR block.

- CAR.RST_DEVICES_W.SWR_CEC_RST = DISABLE
- CAR.CLK_OUT_ENB_W.CLK_ENB_CEC = ENABLE

29.2.1.2 Interrupt

The CEC is on PRI interrupt controller bit 3.

CEC INT_MASK should be enabled for TX_* and RX_* interrupts. TX_REGISTER_EMPTY and RX_REGISTER_FULL are the key interrupts; most others are errors.

Refer to the Interrupt Controller section for more information.

29.2.1.3 Pin Mux

The CEC is available on the HDMI_CEC pin. HDMI_CEC pin mux should be configured for:

- PM=0 (primary CEC function)
- PUPD=NORMAL
- TRISTATE=NORMAL
- E_INPUT=ENABLE
- OD=ENABLE

29.2.2 CEC Timing

Timing parameters are in units of 32 microseconds. See the HDMI specification for CEC timing requirements. In Tegra 4 devices, the registers have default (reset) values as indicated in the following table.

Register	Field	Value	Comment
RX_TIMING_0	RX_START_BIT_MAX_LO_TIME	0x7a	
	RX_START_BIT_MIN_LO_TIME	0x6d	
	RX_START_BIT_MAX_DURATION	0x93	
	RX_START_BIT_MIN_DURATION	0x86	
RX_TIMING_1	RX_DATA_BIT_MAX_LO_TIME	0x35	
	RX_DATA_BIT_SAMPLE_TIME	0x21	
	RX_DATA_BIT_MAX_DURATION	0x56	
	RX_DATA_BIT_MIN_DURATION	0x40	
RX_TIMING_2	RX_END_OF_BLOCK_TIME	0x50	
TX_TIMING_0	TX_START_BIT_LO_TIME	0x74	
	TX_START_BIT_DURATION	0x8d	
	TX_BUS_XITION_TIME	0x8	
	TX_BUS_ERROR_LO_TIME	0x71	
TX_TIMING_1	TX_LO_DATA_BIT_LO_TIME	0x2f	
	TX_HI_DATA_BIT_LO_TIME	0x13	
	TX_DATA_BIT_DURATION	0x4b	
	TX_ACK_NAK_BIT_SAMPLE_TIME	0x21	
TX_TIMING_2	BUS_IDLE_TIME_ADDITIONAL_FRAME	0x7	
	BUS_IDLE_TIME_NEW_FRAME	0x5	
	BUS_IDLE_TIME_RETRY_FRAME	0x3	

29.2.3 CEC Control

The CEC has several modes but only some are simulated or supported. TX_RX_MODE=ENABLE should be set last.

Register	Field	Value	Comment
SW_CONTROL	MODE	DISABLE	Use HW mode
INPUT_FILTER	FIFO_LENGTH	0	
	MODE	DISABLE	
HW_CONTROL	RX_LOGICAL_ADDRS	*Slave addresses (bitmap)*	If slave, holds addresses
	RX_SNOOP	DISABLE	
	RX_NAK_MODE	BLOCK	
	TX_NAK_MODE	BLOCK	
	FAST_SIM_MODE	DISABLE	SW should use DISABLE

Register	Field	Value	Comment
	TX_RX_MODE	ENABLE	Enable last
INT_MASK	TX_*, RX_*	DISABLE/ENABLE	ENABLE to enable interrupt

29.2.4 Transmission

Each message is a series of bytes, and each byte has several flags associated with it.

Register	Field	Value	Comment
TX_REGISTER	DATA	*byte*	8-bit byte
	EOM	1 on last byte	End of message flag
	ADDRESS_MODE	DIRECT/BROADCAST	
	GENERATE_START_BIT	1	
	RETRY_FRAME	0/1	

In general, the first byte contains source and destination addresses, per the CEC specification. The source address is chosen by software as the Tegra address. The destination address is either 15 for broadcast, or less than 15 for a particular slave. The last byte contains EOM=1. When sending to address 15 (broadcast), ADDRESS_MODE must be BROADCAST so that ACK and NAK have correct polarity. If this transmission is a retry of a previous one, RETRY_FRAME should be 1 so that correct retry timing is used.

The TX register interface is unusual in that the interrupt (TX_REGISTER_EMPTY) controls transmission – it's not merely a status signal. To transmit a byte, TX_REGISTER is first written with data, then the INT_STAT.TX_REGISTER_EMPTY interrupt must be cleared. If interrupt service routines are used, they must be careful when clearing an interrupt, because doing so incorrectly could cause a spurious or lost byte.

Transmission pseudo-code:

```
Transmit(unsigned char data, bool eom?, bool broadcast?):
        // enqueue byte
        Write TX_REGISTER: DATA = data,
                EOM = eom?,
                ADDRESS_MODE = broadcast?,
                GENERATE_START_BIT = 1
        // clear interrupt to enable transmission
        Write INT_STAT: TX_REGISTER_EMPTY = 1
        // wait for transmission
        Either Poll INT_STAT.TX_* to go high, or wait for TX_* interrupt.
        If TX_REGISTER_EMPTY=1, transfer is complete.
        If other TX_* interrupts set, then error.
```

Transmission of multi-block frames requires the blocks (bytes) to be sent back-to-back with no idle space between. If software does not provide the bytes in time, hardware will signal a TX_REGISTER_UNDERRUN interrupt and halt transmission (see Error Recovery below).

29.2.5 Reception

The RX_REGISTER_FULL interrupt indicates that a byte has been received and blocks further reception until cleared. If a subsequent byte is received while RX_REGISTER_FULL is high, an RX_REGISTER_OVERRUN error results.

When a byte is received, two additional EOM and ACK flags are provided as well.

Register	Field	Value	Comment
RX_REGISTER	DATA	*byte*	8-bit byte
	EOM	1 on last byte	End of message flag
	ACK	*bit from bus*	Expected value depends on whether broadcast or direct

Once INT_STAT indicates a byte has been received, first read the byte (and flags), and then clear the interrupt.

Reception pseudo-code:

```
Receive( unsigned char &data, bool &eom, bool &ack):
        // wait for data
        Either Poll INT_STAT.RX_REGISTER_FULL, or
               wait for CEC RX_REGISTER_FULL interrupt
        If INT_STAT.RX_* error interrupts set, then error
        data, eom, ack = Read RX_REGISTER.DATA/EOM/ACK
        // clear interrupt to allow further reception
        Write INT_STAT.RX_REGISTER_FULL = 1
```

29.2.6 Error Recovery

In case of transmission error such as UNDERRUN or NAKD, the transmission will stop. Alternatively, the soft reset sequence should be used:

```
tmp = CEC_HW_CONTROL
CEC_HW_CONTROL = 0
CEC_INT_STATUS = 0xffffffff
CEC_HW_CONTROL = tmp
```

29.3 CEC Registers

Refer to “Reading Register Tables” in the Introduction section for the register table protocol as well as recommendations for accessing registers.

29.3.1 CEC_SW_CONTROL_0

SW controlled mode is not supported. Leave disabled.

Offset: 0x0 | Read/Write: R/W | Reset: 0x000000XX (0b0xxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx)

Bit	R/W	Reset	Description
31	RW	DISABLE	MODE: 0 = DISABLE 1 = ENABLE
4	RO	X	FILTERED_RX_DATA_PIN
0	RO	X	RAW_INPUT_DATA_PIN

29.3.2 CEC_HW_CONTROL_0

The following steps are the best way to reset the CEC engine:

1. Set the CEC_HW_CONTROL_TX_RX_MODE to DISABLE
2. Set all the interrupt enable bits in CEC_HW_INTR_EN to DISABLE

3. Wait 1 second (1 second is the maximum CEC bus timeout period from the HDMI specification)
4. Set the CEC_HW_CONTROL_TX_RX_MODE to ENABLE and restart.

Other devices on the bus might have been communicating just fine. When the restart has completed, there might be a few spurious false start bits and other receive bus anomalies before normal operation is resumed.

The CEC_HW_CONTROL register contains the control bits and fields for operating and configuring the HW CEC engine.

Note:	Once the block is enabled, software should not attempt to change these configuration parameters without first disabling the block, except for the RX_LOGICL_ADDRS and RX_SNOOP fields.

RX_LOGICAL_ADDRS

The HDMI specification permits a single physical entity to claim logical addresses reserved for different functions (e.g., "Tuner x" and "Playback device y"). For a PC, it is entirely possible to be a multi-function device, so hardware might need to respond to 2 (or more) logical addresses (as many combinations as make sense). The next fields are used to configure the logical addresses that hardware will respond to. As per the specification, hardware will always respond to the broadcast address. This is a 15-bit field, where each bit position is associated with one of the logical addresses. A '1' in any bit position causes the hardware to respond to the associated logical address (i.e., capture data blocks/frames addressed to the address and properly ack/nak said blocks). To keep things simple, the mapping of bit position to logical address is direct, i.e., bit N maps to logical address N.

RX_SNOOP

When enabled, the hardware will intercept and forward to software all traffic on the CEC bus. It will continue to ack/nak only those addresses that are assigned to it.

RX_NAK_MODE

The HDMI specification is a bit unclear about what the initiator is supposed to do if an intermediate block of a frame is NAK’d, i.e., should the initiator cease transmitting immediately or complete the rest of the frame. The HDMI specification says that a follower may NAK a frame at any time, but the concern is that some initiator might not recover from such an early NAK’d frame. This bit will permit the receive state machine to operate in either mode. The choices are:

- BLOCK which means that a frame will be NAK’d as soon as a RX_REGISTER_OVERRUN is detected
- FRAME which means that the hardware will keep track of any RX_REGISTER_OVERRUNs that occur during frame reception, and NAK only during the last block.

TX_NAK_MODE

The HDMI specification is a bit unclear about what the initiator is supposed to do if an intermediate block of a frame is NAK’d, i.e., should the initiator cease transmitting immediately or complete the rest of the frame. This bit will permit the transmit state machine to operate in either mode. The choices are:

- BLOCK which means transmission will cease at the first NAK'd block
- FRAME which means that transmission will always continue to the end of the frame.

TX_RX_INTERRUPT_ROUTING

The engine generates a single composite interrupt output signal which can then be routed to either PMU or HOST. This bit controls that routing.

TX_RX_MODE

This bit enables or disables the operation of the HW CEC engine. If the TX_RX_MODE is changed to DISABLE, then the HW engine returns to the IDLE state irrespective of what it is doing and drives a 1 onto the CEC bus. If CEC_SW_CONTROL_MODE is ENABLED, the HW CEC engine operation is automatically disabled.

Offset: 0x4 | Read/Write: R/W | Reset: 0x0000XXXX (0b00xxxxx0xxxxxxx00xxxxxxxxxxxxxx)

Bit	Reset	Description
31	DISABLE	TX_RX_MODE: 0 = DISABLE 1 = ENABLE
30	DISABLE	FAST_SIM_MODE: 0 = DISABLE 1 = ENABLE
24	BLOCK	TX_NAK_MODE: 0 = BLOCK 1 = FRAME
16	BLOCK	RX_NAK_MODE: 0 = BLOCK 1 = FRAME
15	DISABLE	RX_SNOOP: 0 = DISABLE 1 = ENABLE
14:0	X	RX_LOGICAL_ADDRS: All logical addresses that should be matched. One bit per address.

29.3.3 CEC_INPUT_FILTER_0

The CEC_INPUT_FILTER register is used to configure the HW filtering that is required to deglitch the incoming receive data line. As data arrives into the chip, it is pushed into a 1 bit wide FIFO with a maximum of 64 entries deep. The actual used depth of the FIFO is set using the CEC_INPUT_FILTER_FIFO_LENGTH field. The used length is equal to CEC_INPUT_FILTER_FIFO_LENGTH+1. A datum is pushed into the FIFO once per microsecond tick. The FIFO bits should reset to '1' (the idle condition of the CEC bus).

The filtered output of the FIFO is computed roughly as follows:

```
filterMsk[63:0] = (1 << CEC_INPUT_FILTER_FIFO_LENGTH + 1) - 1;

if (reset || (CEC_INPUT_FILTER_MODE == CEC_INPUT_FILTER_MODE_DISABLE))
    fifo[63:0] = 0xffffffffffffffff;
else if (clock tick time)
    fifo[63:0] = (fifo[63:0] << 1) | rawInputDataPin;

if (reset || (CEC_INPUT_FILTER_MODE == CEC_INPUT_FILTER_MODE_DISABLE))
    filteredRxDataPin = 1;
else if ((clock tick time) && ((fifo & filterMsk) == filterMsk))
    filteredRxDataPin = 1;
else if ((clock tick time) && ((~fifo & filterMsk) == filterMsk))
    filteredRxDataPin = 0;
else
    filteredRxDataPin = filteredRxDataPin;
```

This logic should make sure that the filteredRxDataPin output only transitions to 0 or 1 when all the examined bits in the FIFO are also 0 or 1. Thus the filtered data line will not transition as long as there are glitches in the FIFO. The length of 64 provides a maximum operational length of 64 µs.

Every state transition on the filtered receive data line is reportable to software via the interrupt register described later.

Offset: 0x8 | Read/Write: R/W | Reset: 0x000000XX (0b0xxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx)

Bit	Reset	Description
31	DISABLE	MODE: 0 = DISABLE 1 = ENABLE
5:0	X	FIFO_LENGTH

29.3.4 CEC_SPARE_0

Spare register for future use.

Offset: 0xc | Read/Write: R/W | Reset: 0x0000XXXX (0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx)

Bit	Reset	Description
15:0	X	SPARES

29.3.5 CEC_TX_REGISTER_0

CEC_HW_TX_REGISTER register

This register is used by software to provide the hardware with the actual data to be transmitted on the bus. Note that hardware will 'blindly' transmit what it is given. For example, it will not check to be sure that a proper legal initiator address has been provided, it will not check to be sure that the maximum frame length of 16 is not violated, etc. These higher level protocol checks are the domain of the SW. In order to facilitate easier software programming and smoother operation, hardware will make its own working copy of the fields in this register, thus quickly freeing up the register for software to write the next block. (Basically, it is a one-deep FIFO with fullness reported via the TX_REGISTER_EMPTY bit).

DATA

The actual 8 bits of address/data to be transmitted on the bus. The data is always transmitted MSB (bit 7) first.

EOM

This is the "end of message" bit for this block of data. This bit is set at the last block of the frame.

ADDRESS_MODE

This bit indicates to the hardware whether this particular block is directly addressed or broadcast addressed (which in turn dictates how hardware is to interpret the ACK/NAK for the block).

GENERATE_START_BIT

Indicates to the hardware that it should precede the transmission of this block of data with a start bit.

RETRY_FRAME

Indicates if the current frame is a retry frame or not. Based on this value, hardware chooses an appropriate bus idle time programmed in TX_TIMING2 register and waits for the bus to be idle before it can attempt to send a start bit. This bit is only meaningful when TX_GENERATE_START_BIT is set.

RETRY FRAME	LAST_FRAM_ SENT_BY_US	WAIT TIME
1	YES	TIMING2_BUS_IDLE_TIME_RETRY_FRAME
1	NO	TIMING2_BUS_IDLE_TIME_RETRY_FRAME
0	NO	TIMING2_BUS_IDLE_TIME_NEW_FRAME
0	YES	TIMING2_BUS_IDLE_TIME_ADDITIONAL_FRAME

If a frame is being sent immediately following the previous frame, hardware waits for "TIMING2_BUS_IDLE_TIME_ADDITIONAL_FRAME". However, if someone else uses the bus before that time elapses, the hardware resets its wait time counter and waits for "TIMING2_BUS_IDLE_TIME_NEW_FRAME".

Offset: 0x10 | Read/Write: R/W | Reset: 0x00010000 (0bxxxxxxxxxxxxxxx01xxx0xxx000000000)

Bit	Reset	Description
17	DISABLE	RETRY_FRAME: 0 = DISABLE 1 = ENABLE
16	ENABLE	GENERATE_START_BIT: 0 = DISABLE 1 = ENABLE
12	DIRECT	ADDRESS_MODE: 0 = DIRECT 1 = BROADCAST
8	0x0	EOM
7:0	0x0	DATA

29.3.6 CEC_RX_REGISTER_0

CEC_HW_RX_REGISTER register

This register is used by hardware to buffer data to the software. When a block of data has been received from the bus, it is stored here for software (and the RX_REGISTER_FULL bit is set). The hardware also has a 'working copy' of the receive register to give software as much time as possible to empty it. When a full block is assembled, hardware places it into RX_REGISTER, so the register is like a 1 deep FIFO.

DATA

The 8 bits of data that were read from the bus.

EOM

The EOM bit read from the bus.

ACK_NAK

The ACK/NAK bit as read from the bus. In some cases (broadcast block) even though the device may have ACK'd the frame, some other device on the bus may NAK the frame, and software would need to know this.

Offset: 0x14 | Read/Write: RO | Reset: 0x00000XXX (0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx)

Bit	Reset	Description
9	X	ACK
8	X	EOM
7:0	X	DATA

29.3.7 CEC_RX_TIMING_0_0

CEC_HW_RX_TIMING0 register

Note: All timing registers must be configured before the HW CEC engine is enabled.

RX_START_BIT_MAX_LO_TIME

nominal 3.9 ms, (3900/32 = 122 intervals) = 3.904 ms

The maximum time the received bus can remain low, and still be considered the beginning of a proper start bit. If the start bit low time overruns this time, the start bit is considered invalid and is ignored.

RX_START_BIT_MIN_LO_TIME

nominal 3.5 ms, (3500/32 = 109 intervals) = 3.488 ms

The minimum time the received bus can remain low and still be considered the beginning of a proper start bit. If the start bit low time underruns this time, the start bit is considered invalid and is ignored.

RX_START_BIT_MAX_DURATION

nominal 4.7 ms, (4700/32 = 147 intervals) = 4.704 ms

The maximum total duration of the start bit from the first detected high-to-low transition to the high-to-low transition that begins the first address bit. If the start bit duration overruns this time, the start bit is considered invalid and is ignored.

RX_START_BIT_MIN_DURATION

nominal 4.3 ms (4300/32 = 134 intervals) = 4.288 ms

The minimum total duration of the start bit from the first detected high-to-low transition to the high-to-low transition that begins the first address bit. If the start bit duration underruns this time, the start bit is considered invalid and is ignored.

Offset: 0x18 | Read/Write: R/W | Reset: 0xXXXXXXXX (0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx)

Bit	Reset	Description
31:24	X	RX_START_BIT_MIN_DURATION
23:16	X	RX_START_BIT_MAX_DURATION
15:8	X	RX_START_BIT_MIN_LO_TIME
7:0	X	RX_START_BIT_MAX_LO_TIME

29.3.8 CEC_RX_TIMING_1_0

CEC_HW_RX_TIMING1 register

Note: All timing registers must be configured before the HW CEC engine is enabled.

RX_DATA_BIT_MAX_LO_TIME

nominal 1.7 ms, (1700/32 = 53 intervals) = 1.696 ms

The maximum time the received bus can remain low and still be considered the beginning of a proper start bit. If the start bit low time overruns this time, the start bit is considered invalid and is ignored.

RX_DATA_BIT_SAMPLE_TIME

nominal 1.05 ms, (1050/32 = 33 intervals) = 1.056 ms

The time to sample that data bit.

RX_DATA_BIT_MAX_DURATION

nominal 2.75 ms, (2750/32 = 86 intervals) = 2.752 ms

The maximum total duration of the start bit from the first detected high-to-low transition to the high-to-low transition that begins the first address bit. If the start bit duration overruns this time, the start bit is considered invalid and is ignored.

RX_DATA_BIT_MIN_DURATION

nominal 2.05 ms (2050/32 = 64 intervals) = 2.048 ms

The minimum total duration of the start bit from the first detected high-to-low transition to the high-to-low transition that begins the first address bit. If the start bit duration underruns this time, the start bit is considered invalid and is ignored.

Offset: 0x1c | Read/Write: R/W | Reset: 0xXXXXXXXX (0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx)

29.3.9 CEC_RX_TIMING_2_0

CEC_HW_RX_TIMING2 register

Note: All timing registers must be configured before the HW CEC engine is enabled.

RX_END_OF_BLOCK_TIME

nominal 1.9 ms, (1900/32 = 80 intervals) = 1.9 ms

The time to wait after the start of the final ACK/NAK phase of frame transmission before returning to the idle state. (Needed since the last ACK/NAK bit will not be followed by another high-to-low transition.)

Offset: 0x20 | Read/Write: R/W | Reset: 0x000000XX (0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx)

Bit	Reset	Description
7:0	X	RX_END_OF_BLOCK_TIME

29.3.10 CEC_TX_TIMING_0_0

The next set of timing registers configures the CEC logic for HW assisted operation. To permit flexible configuration (to support possible semi-compliant devices), the bit timing control and check values are programmable (rather than just directly using the specification values).

While the block itself works on a 1 µs tick, in order to save register space, these timing numbers are specified in units of 32 µs.

First, the registers for the various timing intervals (there are quite a few of them).

CEC_HW_TX_TIMING0 register

Note: All timing registers must be configured before the HW CEC engine is enabled.

For details of exact values and tolerances, refer to the CEC appendix of the HDMI specification.

TX_START_BIT_LO_TIME

nominal 3.7 ms, (3700/32 = 116 intervals) = 3.712 ms

How long to hold the bus low during the start bit.

TX_START_BIT_DURATION

nominal 4.5 ms, (4500/32 = 141 intervals) = 4.512 ms

The total duration of the start bit

TX_BUS_XITION_TIME

nominal 250 µs, (250/32 = 8 intervals) = 256 µs

Time to wait for bus to settle after transitioning output.

TX_BUS_ERROR_LO_TIME

nominal 3.6 ms (3600/32 = 113 intervals) = 3.616 ms

Time to drive bus low when bus error must be signaled on the bus

Offset: 0x24 | Read/Write: R/W | Reset: 0xXX0XXXXX (0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx)

Bit	Reset	Description

29.3.11 CEC_TX_TIMING_1_0

CEC_HW_TX_TIMING1 register

Note: All timing registers must be configured before the HW CEC engine is enabled.

TX_LO_DATA_BIT_LO_TIME

nominal 1.5 ms, (1500/32 = 47 intervals) = 1.504 ms

How long to hold the bus low when transmitting a '0'.

TX_HI_DATA_BIT_LO_TIME

nominal 0.6 ms, (600/32 = 19 intervals) = 6.08 ms

How long to hold the bus low when transmitting a '1'.

TX_DATA_BIT_DURATION

nominal 2.4 ms, (2400/32 = 75 intervals) = 2.4 ms

The total duration of a data or ACK/NAK bit.

TX_ACK_NAK_BIT_SAMPLE_TIME

nominal 1.05 ms, (1050/32 = 33 intervals) = 1.056 ms

The time to sample that ACK/NAK bit.

Offset: 0x28 | Read/Write: R/W | Reset: 0xXXXXXXXX (0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx)

29.3.12 CEC_TX_TIMING_2_0

CEC_HW_TX_TIMING2 register

This register contains the bus idle time values for the various scenarios indicated in the HDMI specification (section 9.1). Software indicates to the hardware the amount of delay in units of data bit periods, as defined by the CEC_HW_TX_TIMING1_TX_DATA_BIT_DURATION field.

ADDITIONAL_FRAME:

The amount of time the bus needs to be idle before a new frame can be sent immediately after sending a frame. The suggested value is >= 7.

NEW_FRAME:

The amount of time the bus needs to be idle before a new frame can be sent if we were not the initiator for the previous frame. The suggested value is >= 5.

RETRY_FRAME:

The amount of time the bus needs to be idle before the same frame can be resent. The suggested value is >= 3.

Offset: 0x2c | Read/Write: R/W | Reset: 0x00000XXX (0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx)

Bit	Reset	Description
11:8	X	BUS_IDLE_TIME_RETRY_FRAME
7:4	X	BUS_IDLE_TIME_NEW_FRAME
3:0	X	BUS_IDLE_TIME_ADDITIONAL_FRAME

29.3.13 CEC_INT_STAT_0

CEC_HW_INTR register

This register contains the individual interrupt and status bits for the CEC HW unit. The CEC_HW_INTR_EN register contains the corresponding enable bit for each interrupt/status bit in the interrupt register. The interrupt enable determines whether the interrupt propagates to the PMIC as an interrupt, but the interrupt status bit itself is always set if the described condition occurs. Software writes a '1' to any interrupt/status bit in order to clear it.

Because the HW state machine also looks at the state of the interrupt bits when determining what action(s) to take, it is important for software to operate in roughly the following order when processing interrupts from this source:

1. Read the interrupt register to determine what caused the interrupt and what needs to be done.
2. Perform the operations required, e.g., reload TX register, read RX register.
3. Finally, clear the corresponding interrupt bits.

TX_REGISTER_EMPTY

The transmit register is empty, so software is free to write the next block of the frame into the register. For multi-block frames, software must in fact provide the next block before the current block is sent, otherwise a TX_REGISTER_UNDERRUN error will occur. When the TX engines reads from the TX_REGISTER register and stores a local copy, this interrupt is asserted.

TX_REGISTER_UNDERRUN

The transmit register was empty at the time the transmit hardware needed to have the next block ready to send. This is an error condition. The transmitter will have stopped transmitting, and recovery will require resending the entire frame from scratch.

TX_FRAME_OR_BLOCK_NAKD

Hardware sets this bit if any block/frame is NAK'd. If software sees this bit set, it knows it will have to resend the frame later.

TX_ARBITRATION_FAILED

Hardware sets this bit during the address block phase of transmitting a frame, if failed to win arbitration. In this case, transmission will cease, and the HW will flush any pending data in the TX_REGISTER. Software will need to retry the frame from scratch (after the appropriate signal free time, i.e., hardware will not automatically retry).

TX_BUS_ANOMALY_DETECTED

Sometime during block transmission, hardware detected anomalous behavior on the bus (e.g., the bus remained low after transmitter had signaled high). When such an anomaly is detected, the transmitter ceases operation, releases the bus high, and flushes any pending data in the TX_TRANSMIT register.

TX_FRAME_TRANSMITTED

This will be asserted at the end of last data bit, i.e., the ACK bit of the last block is sent. This is just an indication that the last block is sent but does not necessarily mean the transmission was successful. Software should still look for other interrupts to check for any errors.

RX_REGISTER_FULL

The hardware has assembled a complete block from the bus and placed it into the RX_REGISTER. Software should read the block immediately to ensure the RX_REGISTER is empty before hardware has the next block ready to load. When the HW RX engine writes RX data to the RX_REGISTER this bit is set.

RX_REGISTER_OVERRUN

Software failed to read the RX_REGISTER before hardware had another block of data ready to transfer. Hardware will NAK the block/frame, and the initiator will need to retry later. Software will need to flush the partially accumulated frame.

RX_START_BIT_DETECTED

Whenever the receive engine detects a start bit, it will set this bit. This bit is used for debug.

RX_BUS_ANOMALY_DETECTED

The receiver detected some anomaly (including bus errors) on the bus. A bus error has a specific definition in the HDMI specification, but there are other kinds of anomalies that can occur. All anomalies and bus errors are reported here.

RX_BUS_ERROR_DETECTED

The receiver has detected the specific anomaly called a bus error and then signaled a bus error on the bus per the HDMI specification.

FILTERED_RX_DATA_PIN_TRANSITION_H2L

In direct SW bus drive mode, software needs to be interrupted whenever the state of the received data line transitions. This interrupt is asserted on a 1 to 0 transition.

FILTERED_RX_DATA_PIN_TRANSITION_L2H

In direct SW bus drive mode, software needs to be interrupted whenever the state of the received data line transitions. This interrupt is asserted on a 0 to 1 transition

30.0 MIPI-CSI (CAMERA SERIAL INTERFACE)

This section describes the Camera Serial Interface (CSI), which is based on the MIPI CSI 2.0 standard specification. The MIPI CSI 2.0 standard is available from MIPI to its members at http://www.mipi.org/.

30.1 Functional Description

The CSI implements a MIPI compliant CSI receiver that may receive data from an external camera module with a CSI transmitter. The CSI is designed to provide for direct connection to 3 camera modules and allow any two of the modules to be active simultaneously:

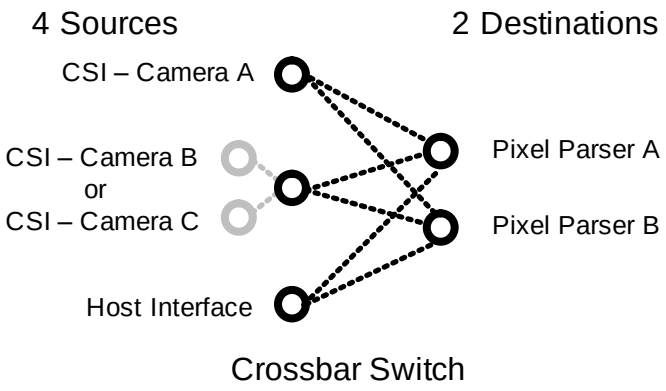
- CSI-A interface supports 1 clock lane and up to 4 data lanes for Camera A.
- CSI-B interface supports 1 clock lane and up to 4 data lanes for Camera B OR a single data lane for Camera C.

The CSI-B interface is shared between Camera A and Camera B, allowing only one or the other to be active at a time. The CSI offers both single and multi-camera configuration options. These options include a single camera configuration with a 1 to 4 lane sensor connected to CSI-A or CSI-B, a dual camera configuration with a 1 to 4 lane sensor connected to CSI-A and a 1 lane sensor to CSI-B, or a stereo camera configuration with a 1 to 4 lane sensor connected to CSI-A and another 1 to 4 lanes sensor to CSI-B.

In addition to direct connection to camera modules, the CSI interface can also receive a digital CSI compatible byte stream or payload data only from the host interface. The CSI stream coming from the host is provided to take advantage of the rich CSI data formats.

A maximum of two data/pixel streams can be processed simultaneously at any given time. The two streams can come from any one or two of the four possible sources, as shown in Figure 121. If the two streams come from a single source, then the streams are separated using a filter indexed on different virtual channel numbers or data types. In case of separation using data types, the normal data type is separated from the embedded data type. Because there are only two pixel parsers (PPA and PPB), the virtual channel and embedded data capability cannot be used at the same time.

Figure 121: Data Source/Destination Options



The CSI may receive data from camera modules through the MIPI serial or the host interfaces. A test pattern generator has been implemented to assist validation.

The CSI supports both single-shot mode and continuous mode.

The CSI is designed with error resilience.

30.2 Use Cases

The use cases supported by the CSI include basic single camera, multiple cameras, embedded data, virtual channel, and host. The still and video capture sequences involve different single camera and multi-camera configuration options. Table 98 summarizes the use case categories.

Table 98: Summary of CSI Camera Use Cases

Case	Description	Sources	Destinations
Single Camera Video Capture	Standard CSI Basic preview or video capture using single camera	Camera A,B, or C	PPA or PPB
Stereo Camera Video Capture	Stereo pair video capture	Camera A and B	PPA and PPB
Single Camera Still Capture	Basic high resolution still capture supporting single shot and burst capture	Camera A, B, or C	PPA or PPB
Stereo Camera Still Capture	Stereo camera high resolution still capture	Camera A and B	PPA and PPB
Dual Camera Video Capture*	Video feed of front facing camera and user facing camera for video annotation, video preview during Video Conference	Camera A or B, and C	PPA and PPB
Video Conference Mono Still Capture & Preview*	Video feed of user facing camera for video conference and mono still capture from front facing camera.	Camera A or B, and C	PPA and PPB
Virtual Channel	One stream goes to two parsers. Packet filtering based on VC number in header	Camera A,B,C, or Host	PPA and PPB
Embedded Data	One stream goes to one parser. Packet filtering based on data type in header	Camera A,B,C, or Host	PPA or PPB
Embedded Data	One stream goes to one parser. Has normal and embedded data	Camera A,B,C, or Host	PPA or PPB
Host	Payload-only or Packet from Host interface	Host I/F	PPA or PPB

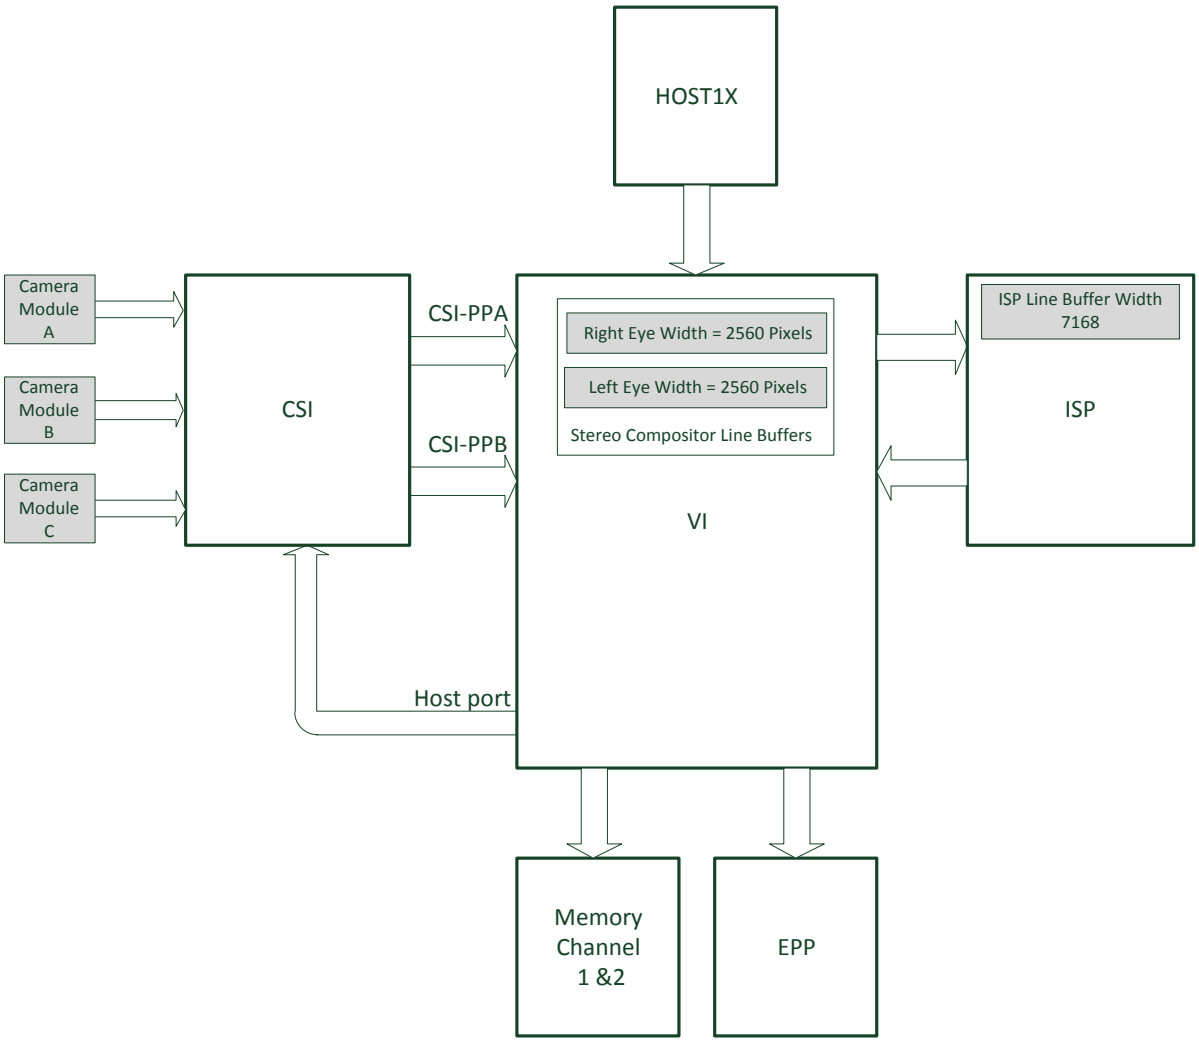
* Non-stereo dual camera models assume mixed data formats: Camera A – RAW10, Camera B - YCbCr 4:2:2.

The dual camera use cases require two capture streams from two different sensors, each imaging a separate scene. Within the Tegra® 4 camera system, it is necessary to process two different images with different algorithm sequences/ISP setup or to receive a preprocessed YCbCr image and deliver the stream to system memory and the other to the ISP.

30.2.1 Primary Mono and Stereo Camera Use Cases

The primary mono and stereo camera user models involve the capture of either pre-processed image data from a camera module in YCbCr 4:2:2 format or as a Raw Bayer stream with 10-bit precision. Additional pixel formats for image data may be accepted, but Raw 10-bit and YCbCr 4:2:2 are used primarily. Figure 122 illustrates the datapaths associated with the Tegra 4 camera subsystem.

Figure 122: Illustration of Datapath Through the Tegra 4 Camera Subsystem



Depending on the mode of operation, image resolution, and resulting pixel rate, one of several paths through the VI may be used. Table 25 summarizes the primary video and still captures use cases and the path through the VI.

Table 99: Data Through VI for Primary Camera Use Case

Use Cases	Data Received from Camera	Destination through VI
Mono Video Capture and Preview	Raw Bayer (10 bpp)	CSI -> VI -> ISP
	YCbCr 4:2:2 (16 bpp)	CSI -> VI -> MEMC or EPP
Stereo Video Capture and Preview	Raw Bayer (10 bpp)	CSI -> VI Stereo Comp -> ISP
	YCbCr 4:2:2 (16 bpp)	CSI -> VI -> MEMC or EPP
Mono Raw Bayer Still Capture	Raw Bayer (10 bpp)	CSI -> VI -> ISP
Stereo Raw Bayer Still Capture	Raw Bayer (10 bpp) Image A	CSI -> VI -> ISP
	Raw Bayer (10 bpp) Image B	CSI -> VI -> MEMC Host1X -> VI -> ISP

The raw Bayer mono and stereo video capture use cases are either processed by the ISP directly or are first buffered using the 2560 pixel stereo compositor prior to being presented to the ISP. Since the YCbCr 4:2:2 data has already been processed, it is likely that it will either be routed to memory channel 1 or 2 or EPP for both mono and stereo use cases.

The ISP can support from 300 to 350 MP/s peak throughput, depending on operating frequency, for raw 10-bit Bayer data and provides line buffering to manage up to 7168 pixel image width. During mono still image capture of raw 10-bit data, the data may be presented directly to the ISP through the VI as long as the frame rate and data rate are managed within the throughput constraint.

The stereo still capture model will require two high-resolution images to be captured simultaneously, resulting in a 2X increase in pixel data rate both into and out of the CSI. One of the stereo pair images may be processed through the ISP with the same limitations as with the mono still capture with the second stereo image being presented to memory through memory channel 1 or 2.

30.2.1.1 Video Capture and Preview Use Case

Table 100 defines the various camera configurations that the CSI can support for the primary HD video capture user models. The table summarizes the data rates for HD video capture when either raw 10-bit Bayer or processed YCbCr 4:2:2 data is being received by the CSI.

Table 100: Summary of Bayer (10-bit) and YCbCr 4:2:2 Video Capture Data Rates @ 60 fps

Input Format	Camera Video Capture Modes	Pixel Data Rate MPixels/s	MIPI Lanes Required @ Bit Rate		
			600 Mbps	800 Mbps	1 Gbps
Bayer 10 bpp	1280x720p	55.296	1	1	1
	1280x720p Stereo	110.592	2 (1+1)	2 (1+1)	2 (1+1)
	1920x1080p	124.416	3	2	2
	1920x1080p Stereo	248.832	6 (3+3)	4 (2+2)	4 (2+2)
YCbCr 4:2:2 16 bpp	1280x720p	55.296	2	2	1
	1280x720p Stereo	110.592	4 (2+2)	4 (2+2)	2 (1+1)
	1920x1080p	124.416	4	3	3
	1920x1080p Stereo	248.832	8 (4+4)	6 (3+3)	6 (3+3)

All raw 10-bit Bayer video capture sequences are presented to the ISP by the VI directly because the pixel data rate required is below 300 MP/s and the number of pixels per row is less than 7168 pixels. The stereo capture sequences will buffer a row of pixels from the left and right cameras within the VI prior to presenting the stereo composite super row to the ISP for processing. The stereo compositor within the VI provides up to 2560 pixels to be buffered for the right and left cameras.

30.2.1.2 Still Image Capture Use Case

The still image capture use case assumes that the ISP is first used to process the preview stream. When a still capture is indicated, the sensor is reconfigured, and a still frame is captured and presented to the ISP. Because the ISP is limited in throughput, higher resolution images may be captured and processed directly by the ISP at lower frame rates. For example, a 24 MP image may be captured at 12 fps instead of 15 fps with a 300 MP/sec throughput limitation at the expense of rolling shutter artifacts in case of scene or user motion. Similarly, with the increased pixel throughput at 350 MP/sec, the 24 MP image may be captured at 14 fps. The number of MIPI lanes required to support the peak data rate for various configurations will vary as a function of both the bit rate and pixel throughput. Table 101 summarizes the mono still capture pixel rate and the corresponding MIPI lanes for 600 Mbps, 800 Mbps, and 1 Gbps for maximum ISP throughput of 300 or 350 MP/s.

Table 101: Summary of 10-bit Bayer Mono Still Image Capture Data Rates

Sensor Size (MP)	HRES x VRES	Peak Data Rate (FPS)/(MP/s)		MIPI Lanes Required @ Peak FPS (FPS)/(Number of Lanes)					
				Max of 300 MP/s			Max of 350 MP/s		
		Max of 300 MP/s	Max of 350 MP/s	0.6	0.8	1.0	0.6	0.8	1.0
5.17	2592x1944	15/75.58	15/75.58	15/2	15/1	15/1	15/2	15/1	15/1
8	3264x2448	15/119.85	15/119.85	15/3	15/2	15/2	15/3	15/2	15/2
9	3488x2616	15/136.87	15/136.87	15/3	15/2	15/2	15/3	15/2	15/2
10	4320x2430	15/157.46	15/157.46	15/3	15/3	15/2	15/3	15/3	15/2
12.6	4224x3000	15/190.08	15/190.08	15/4	15/3	15/2	15/4	15/3	15/2
14.6	4416x3312	15/219.39	15/219.39	15/4	15/3	15/3	15/4	15/3	15/3
16	4928x3280	15/242.46	15/242.46	-	15/4	15/3	-	15/4	15/3
21	5616x3744	14/294.37	15/315.39	-	14/4	14/4	-	-	15/4
24	6048x4032	12/292.63	14/341.40	-	12/4	12/4	-	-	14/4
32	6464x4864	9/282.97	11/345.85	-	9/4	9/4	-	-	11/4

In Table 101, the dashed cells are lane configurations that cannot support the maximum pixel rate and are limited by a 15 fps capture target and peak data rate driven by the ISP throughput. These lane configurations are still possible; however, it is necessary to degrade the frame rate (and data rate) from the sensor so that the maximum bit rate supported by the MIPI configuration is not exceeded.

The stereo still image capture use case assumes the ISP is used to first process the image data for user scene composition. When indicated, the sensor is reconfigured to capture a high-resolution still image pair from the left and right camera modules. Still images 5.17 MP and greater exceed the 2560 line width for the stereo compositor and need to utilize system memory to buffer the raw Bayer data from one of the cameras. Table 102 summarizes the aggregate pixel data rate for the stereo still use case for maximum ISP throughput of 300 and 350 MP/s.

Table 102: Summary of 10-bit Bayer Stereo Still Image Capture Data Rates

Sensor Size (MP)	HRES x VRES	Stereo Peak Data Rate (FPS)/(MP/s)		MIPI Lanes Required @ Peak FPS (FPS)/(Number of Lanes Right + Number of Lanes Left)					
				Max of 300 MP/s			Max of 350 MP/s		
		Max of 300 MP/s	Max of 350 MP/s	0.6	0.8	1.0	0.6	0.8	1.0
5.17	2592x1944	15/151.16	15/151.16	15/2+2	15/1+1	15/1+1	15/2+2	15/1+1	15/1+1
8	3264x2448	15/239.70	15/239.70	15/3+3	15/2+2	15/2+2	15/3+3	15/2+2	15/2+2
9	3488x2616	15/273.74	15/273.74	15/3+3	15/2+2	15/2+2	15/3+3	15/2+2	15/2+2
10	4320x2430	15/314.92	15/314.92	15/3+3	15/3+3	15/2+2	15/3+3	15/3+3	15/2+2
12.6	4224x3000	15/380.16	15/380.16	15/4+4	15/3+3	15/2+2	15/4+4	15/3+3	15/2+2
14.6	4416x3312	15/438.78	15/438.78	15/4+4	15/3+3	15/3+3	15/4+4	15/3+3	15/3+3
16	4928x3280	15/484.92	15/484.92	-	15/4+4	15/3+3	-	15/4+4	15/3+3
21	5616x3744	14/588.74	15/630.79	-	14/4+4	14/4+4	-	-	15/4+4
24	6048x4032	12/585.26	14/682.80	-	12/4+4	12/4+4	-	-	14/4+4
32	6464x4864	9/565.94	11/691.70	-	9/4+4	9/4+4	-	-	11/4+4

The capture of the stereo high-resolution stills may be either first routed to system memory through the VI memory interface and the pair is processed in an offline mode while the preview is disabled or one image in the pair may be processed through the ISP while the other is passed to system memory. The image passed to system memory may be processed through the ISP in an offline mode prior to enabling the preview.

30.3 Input Data Format

The supported data formats are summarized in Table 103.

Table 103: Supported CSI Formats

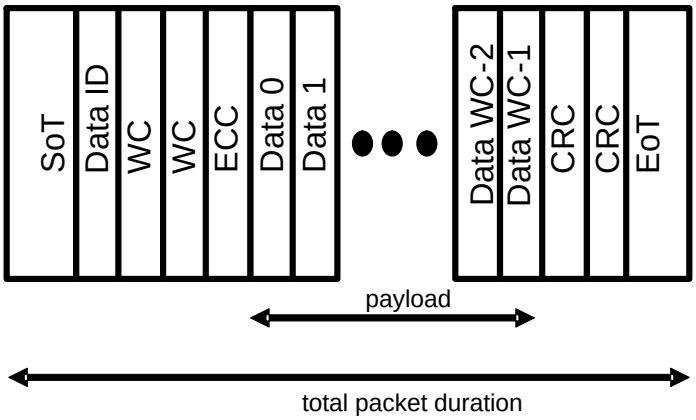
Data Format	
RGB	RGB888, RGB666, RGB565, RGB555, RGB444
YUV	YUV422-8b, YUV422-10b, YUV420-8b (legacy), YUV420-8b, YUV420-10b, YUV444-8b
RAW	RAW6, RAW7, RAW8, RAW10, RAW12, RAW14
User defined	JPEG8
Embedded	Embedded control information

The formats YUV422/420-10b are converted to YUV422/420-8b by taking the most significant bits.

30.4 CSI Packet Structure

The CSI packet structure is illustrated in Figure 123. It has a start-of-transmission sequence (SoT), which contains a 1-byte preamble sequence. The packet is composed of a 4-byte header, a body of word count (WC) bytes, and a 2-byte CRC check. The end-of-transmission (EoT) is indicated by the line state going from high-speed transmission to the LP11 state.

Figure 123: CSI Packet Structure



30.5 CSI Implementation

The CSI interface consists of:

- MIPI D-PHY block
- Control Interface Logic (CIL) for Serial Clock Receiver
- CSI datapath module which is implemented as a sub-module of VI module

In the Tegra 4 implementation, two CSI bricks including csia_pad with 2x data lanes and csib_pad with 2x data lane receive serial data from cameras, deserialize them into 8-bit parallel data, and send them to the CSICIL block. The CSICIL block performs packet boundary detection by searching for the packet preamble. The main CSI module receives an 8-bit packet aligned data from CSICIL, performs parity checking on the header, header decoding, CRC check, and pixel parsing. The output is sent out to the VI through the 28-bit bus, which outputs 1 pixel per VI clock.

30.6 Performance Limitations

The performance of the CSI interface is subject to several factors that must all be met. The performance factors that are directly related to the CSI interface are the serial data rate and the internal pixel rate. Maximum serial data rate is expected to be 1Gbps given the ideal system condition. This data rate may be degraded depending on system design and may also be limited by the CSI transmitter in the camera.

For each CSI data lane, the serial data stream received by the CSI PHY is internally converted to a byte stream by the CSI Control Interface Logic (CIL) before further processed by the CSI module that resides as part of the Video Input (VI) module. The CSI byte clock is used to transfer this data byte stream (1 byte per data lane) between the CIL and the CSI datapaths. This CSI byte clock is derived from the received CSI serial clock by dividing the CSI serial clock by 4. So for 1 Gbps serial CSI data rate, the serial clock frequency is 500 MHz and the byte clock frequency is 125 MHz.

The byte stream received by the CSI CIL logic is converted to a pixel stream at 1 pixel per clock in the CSI module. This pixel stream output is further processed by other modules (ISP or the rest of VI datapath or EPP). Depending on where the CSI pixel stream is processed (ISP, VI, or EPP), the maximum pixel clock frequency is limited by the pixel clock frequency of the modules that process this pixel stream.

> **Note:** VI/ISP/EPP pixel frequency may be lower than CSI output pixel clock frequency and therefore, may limit the actual pixel data rate. Please refer to the ISP, VI and EPP specifications.

Note that with multiple data lanes per CSI interface, the maximum serial data link speed may not be achievable due to pixel clock frequency limitations. Also, if two data streams come from the same CSI interface, since the streams are interleaved in time, the pixel clock frequency limitations may also limit the frame rate of the combined streams.

Table 104: Packet Efficiency

	Best* WC=65536	Typical* WC=1024
Payload	524 µs	8192 ns
Overhead	356 ns	356 ns
Efficiency	99.9%	96%

30.7 Error Resilience

The CSI is required to tolerate and/or recover stream errors at various levels.

According to the MIPI CSI 2.0 specification, the CSI must be able to detect and correct one-bit header error, detect two or more bits header errors, and detect possible payload errors using 16-bit CRC.

Due to the architectural constraints in VI and EPP, the CSI has to always send “valid” stream data to VI, even when the incoming stream contains errors and causes the CSI to drop packets. For stream data with a format other than *embedded*, “valid” stream data means one or more full frames of data that VI exactly expects for certain frame width and frame height.

If the incoming stream data (non-embedded) contains less bytes than the word count (WC), or less number of lines than the expected frame height, CSI must be able to pad pixels to short lines, or pad lines to short frames, so that CSI always sends “valid” frame data to VI.

30.8 Other Architectural Constraints

The following specifies other architectural constraints for this design:

- Because there are only 2 pixel parsers, embedded data and virtual channel cannot be supported simultaneously.
- Embedded data in a frame can be output in the same output port as the pixel data stream; however, in some cases where image processing or data reformatting is performed in VI/ISP/EPP, this embedded data may be accidentally processed in VI/ISP/EPP. Currently, VI/ISP/EPP cannot differentiate between embedded data or pixel data.
- Same stream going to different pixel parsers. This case will work as long as no stall comes from VI side. If a stall comes, then the current frame will be invalid. This is an exception case which should never normally occur. STM_ERR will be generated and software needs to take appropriate action.

30.9 CSI Datapath Module

The CSI datapath consists of three input ports and two output ports. There are two datapaths for pixel stream processing; therefore, at any time, a maximum of two input ports may be active simultaneously.

The components of the CSI datapath include:

- Three input ports from: CSI A interface, CSI B interface, and 32-bit host interface. Each port is capable of carrying a stream with CSI compatible data format.
- Two asynchronous input buffers (FIFOs) to receive streams from the CSI A interface and the CSI B interface.
- Three header parsers for searching packet header and to perform error detection and correction of CSI header.
- Two pixel parsers with corresponding output ports. Each pixel parser can convert a CSI packet data stream to output a pixel stream. Each output port consists of a maximum 24 bits of data per clock. Depending on the output data format options, one or two pixels per clock may be sent.

30.9.1 Header Parser

CSI pixel stream processing mainly consists of header parser and pixel parser. There are 3 header parsers: header parser A, header parser B, and header parser H.

Header parser A is enabled when CSI A interface is selected as input source. Similarly, header parser B is enabled when CSI B interface is selected as input source.

In general the header parser is used for:

- Detecting long and short packet headers and deciding what to do with the packet. This includes performing error detection and correction on the packet header prior to making decision and dealing with uncorrectable packet header.
- Skipping extra data on longer than expected data packets.
- Skipping next packet on imminent input buffer overflow when the pixel parser is busy processing current packet.

When enabled, the header parser will interpret CSI packet header, perform error detection and correction. If the packet header is uncorrectable, then an error is flagged and interrupt generated. If good or correctable CSI packet header is found, then the header parser will check the Data Identifier (DI) byte in the packet header and check the 2-bit Virtual Channel (VC) identifier and the 6-bit Data Type (DT) within this Data Identifier byte and will also check the 2-byte Word Count (WC) value in the packet header. If the virtual channel ID does not match the expected (programmed) value for the corresponding pixel parser then the packet is discarded. If the virtual channel ID matches the expected (programmed) value for the corresponding pixel parser then the header parser must decide what to do with the packet depending on the Data Type and the Word Count value. For long packet, if the Data Type does not match the expected (programmed) value for the corresponding pixel parser then the packet is discarded. If the Data Type of the long packet matches the expected (programmed) value for the corresponding pixel parser, then the corresponding pixel parser is notified to process the remaining packet data and checksum.

When first enabled, header parser must always search for Frame Start packet which is a CSI short packet. However, when input source is the host, there is an option to indicate Frame Start using the incoming vertical sync signal. If the vertical sync signal is used to indicate frame start and the CSI frame start packet is encountered, then the header parser will discard it. When frame start packet/signal is found, the header parser will notify the corresponding pixel parser so that it can prepare to process a new frame and output frame start code.

30.9.1.1 Data Type

There are 64 possible data types based on the 6-bit Data Type value.

Data Type	Description
0x00 – 0x07	Synchronization Short Packet Data Types
0x08 – 0x0F	Generic Short Packet Data Types
0x10 – 0x17	Generic Long Packet Data Types
0x18 – 0x1F	YUV Data
0x20 – 0x27	RGB Data
0x28 – 0x2F	RAW Data
0x30 – 0x37	User Defined Byte-based Data
0x38 – 0x3F	Reserved

30.9.1.2 Short Packets

There are 16 possible short packets based on Data Type value.

Data Type	Description
0x00	Frame Start Code
0x01	Frame End Code
0x02	Line Start Code (Optional)
0x03	Line End Code (Optional)
0x04 – 0x07	Reserved

30.9.1.3 Long Packets

CSI long packets are data packets which always consist of 1 line of data per packet with exception of arbitrary data packets. There are various data types defined. Please refer to the Input Data Format section for a summary of CSI data formats and their corresponding CSI module internal output format.

Generic long packets need special handling. There are 3 generic long packet types defined: null packet (DT=0x10), blanking data packet (DT=0x11), and embedded data packet (DT=0x12). There are also 5 reserved generic long packet types (DT=0x13 to 0x17). The header parser should discard all null packets and all reserved generic long packets.

Blanking data packets may contain blank color or blank image information. The transmission of blanking data packet is optional in the CSI2.0 specification. Null and blanking data are defined in the CSI2.0 specification mainly to accommodate a receiver which is timing sensitive and requires line start/end for every line in the frame. As a CSI receiver, this product does not have such blank timing sensitivity and it typically does not process blank data and does not store it to memory. Blanking data packet can therefore be discarded by the header parser.

However, some module may have a requirement for specific number of “blank” or extra lines at the end of vertical active area, such as the ISP module, which requires input active scan area to be about 6 lines larger than output active area. If a module that takes CSI output stream requires extra lines at the end of active image then blanking packet data can be used to generate these additional lines. In the future, there might be other reasons to process blank data. So, an option should be provided to accept and process blanking data. In the absence of better definition of blanking data format in the CSI specification, if software decides that blanking data cannot be discarded then, the pixel parser should assume that the blanking data format is the same as the programmed expected data type of the pixel stream.

The current CSI2.0 specification specifies that embedded data packets consists of 8-bit arbitrary data. This embedded data is, typically not the same pixel color as the image data. It might be used to send headers/status for JPEG/MPEG compressed data at the beginning or end of image data or in between image data lines. It might also be used to send closed caption text information or other type of information.

The exact use of embedded data is not clear, and therefore in most cases, embedded data is probably not used, or if sent by the transmitter, the embedded data packets can simply be discarded. If for some reason, it is important to receive the embedded data, there are other options that should be supported. Since there are two pixel parsers, if there is only one video source, it is best to direct embedded data to the other pixel parser which does not process the normal image data. In this way, the embedded data can be treated the same way as 8-bit arbitrary/compressed image data and can be output in 8-bit/clock or 16-bit/clock format. If there are two video sources that occupy both the pixel parsers, then embedded data if it has to be stored to memory, needs to be output in the same channel as the image data as 8-bit/16-bit data. But this also means that the module that receives output of CSI module and does image processing must have the ability to differentiate embedded data and not do image processing on this data prior to writing it to memory.

30.9.1.4 Top or Bottom Field Tag

During frame start, a tag is passed from CSI to VI to indicate top or bottom field. The 1-bit tag is at the least significant bit of the CSI output bus. If the bit is “1”, the field is top, but bottom otherwise.

30.10 Test Pattern Generator (TPG)

The test pattern generator is a configurable resource introduced to improve hardware verification capability for the Tegra CSI. Because a provision for inserting pixel data from the Host interface is not available, the hardware verification of the CSI and VI unit is difficult. The only sources of pixel data that can exercise the CSI are image sensors. In general, the sensor data cannot be controlled, making any self-checking test impossible. Test pattern generation modes offered by sensors are also ineffective because they have limited control.

There are two separate test pattern generators that can be configured to provide for the generation of synthetic image data, which is delivered to the PPA and PPB input FIFOs. The image data is multiplexed into the CSI data patch between lane-merging logic and the data FIFOs. Programmable configuration parameters are available to allow variation in pixel data, data-type, and spacing between various packets. In the real system, the LP state transition between any two CSI packets guarantees some idle time between the lines.

A difference engine architecture is employed which can generate almost arbitrary patterns that consist of frequency sweeps or intensity ramps in both the horizontal and vertical directions. In addition, by using selected bits from the difference engine variables as addresses, a color patchwork pattern can be generated. The output from the difference engine is modeled off of a second-order partial differential equation of the form:

$$\varphi_{out} = \varphi + x \cdot \frac{d\varphi}{dx} + x^2 \cdot \frac{d^2\varphi}{dx^2}$$

Where:

$$\varphi = PHASE$$

$$\frac{d\varphi}{dx} = FREQ$$

$$\frac{d^2\varphi}{dx^2} = FREQ\_RATE$$

The PHASE, FREQ, and FREQ_RATE variables may be programmed to create a variety of different test patterns and are either used directly or as an index into a look-up table (LUT). Table 105 summarizes the configuration parameters for the TPG.

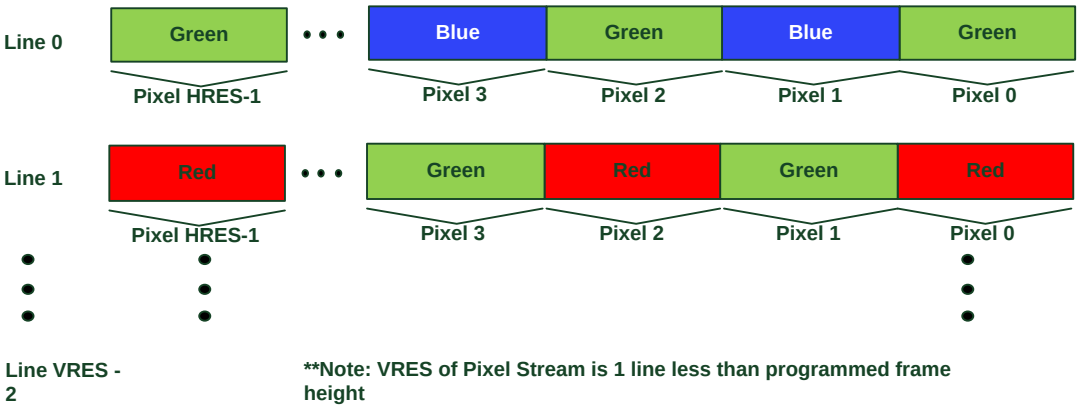
Table 105: Description of TPG Configuration Parameters

Configuration Variables for CSI_0 and CSI_1 Test Pattern Generators	TPG Frame Configuration	Image Height	Lines per frame
		Image Width	Pixels per line
		Vertical Blanking	Blank lines between frames
		Horizontal Blanking	Blank pixels between lines
		Initial Phase	Initial phase
		Mode	Direct or color patch
		Format	RAW8 support
	TPG Channel Configurations (R, G, and B)	Vertical Initial Frequency	Initial frequency
		Horizontal Initial Frequency	Initial frequency
		Vertical Frequency Rate	Rate of change for vertical frequency
		Horizontal Frequency Rate	Rate of change for horizontal frequency

30.10.1 TPG Frame Configuration Parameters

The TPG can be configured to provide the test images in Bayer RAW8 data format only. For the Bayer RAW8 data, the color components of the RGB pixel are sampled in an alternating fashion, depending on whether the current row and pixel within the row is even or odd.

Figure 124: RAW8 TPG Pixel Streams



The data from the test pattern generator has the same format (with the packet header, CRC, ECC, etc.) as received on the output of lane-merging logic during normal operation.

30.10.2 Modes of Operation

The test pattern generator operates in two modes:

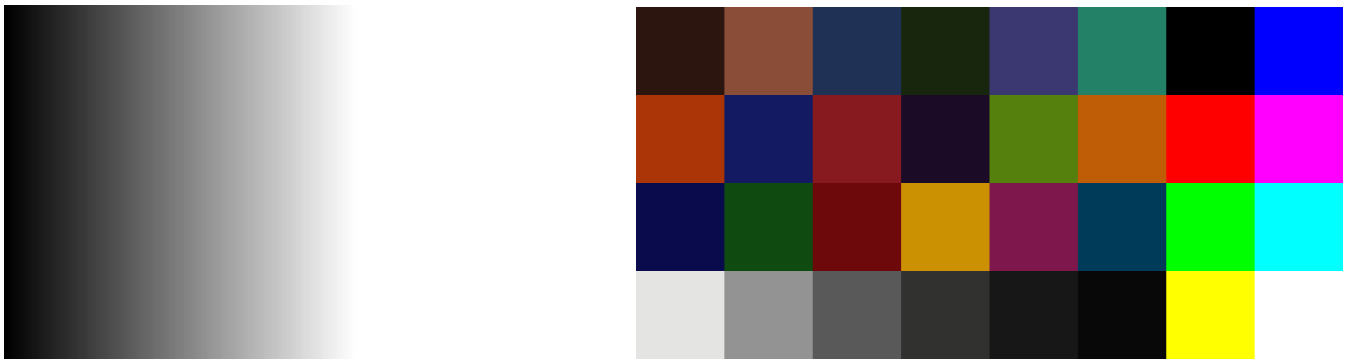
- Direct — The output of the difference engine computation will be viewed directly.
- Color Patch — The difference engine output will be used to generate a patchwork of colors.

In Direct mode, the output comes directly from the value of the phase accumulator in the difference engine. An example of the kind of pattern that can be made is shown in Figure 125(a). In Color Patch mode, the output comes from indexing a 32-element LUT.

The various bits from both the horizontal and vertical phase accumulators are used as address bits into a LUT of standard color values, allowing a patchwork of color test patterns to be generated. The colors in the pattern consist of linear RGB space

representations of the 24 “Macbeth” test chart colors, shown on the left side of Figure 125(b), and the 8 “100% saturation” colors of a TV test pattern, on the right side of Figure 125(a). This gives a total of 32 color patches.

Figure 125: Example of (a) Direct Mode (b) Color Patch Generator Output



(a) (b)

30.11 Software Requirements

30.11.1 Error Counters

To help debug, three 32-bit error counters have been implemented. Software can program each counter to increment at the event of any one of many error conditions or status change. The error conditions are:

- Header errors corrected
- Header uncorrectable errors
- CRC errors
- Packets too short, actual length less than WC
- Overflow errors due to padding packets too short
- FIFO overflow errors
- Illegal word count
- SoT single-bit error
- SoT multi-bit error, packet discarded
- EoT sequence error
- ESC-entry error
- LP-CTRL error
- The statistics that can be monitored include:
- Line packets processed
- Total packets processed
- ESC command processed

30.11.2 Programming Sequence

The following sequence is recommended for capturing a single frame:

1. Set up CSI registers for use case such as number of lanes, virtual channel, etc.
2. Initialize and power up CSI interface

3. Wait for initialization time or done signal from calibration logic
4. Power up camera through the I^2C interface
5. All CSI data and clock lanes are in stop state, LP11
6. Initiate frame capture through the I^2C
7. Frame done, CSI goes back to stop state, LP11

30.11.3 Escape Mode Handling

In the MIPI PHY specification, an escape mode is available for low speed command and data transfer. In our implementation, the escape mode entry is detected inside CSICIL. The command byte will be deposited in a register and interrupt generated from CSI. Software reads the register and decodes. CSI supports only one escape mode command which is Ultra-Low Power Mode (ULPM).

ULPM Command

Upon receiving the ULPM, software will synchronously power down the CSI interface and the camera as follows:

1. Software puts the camera in sleep mode through I^2C
2. The camera sends a ULPM command to CSI
3. CSI receives the ULPM command and raises an interrupt
4. Software powers down CSI, which goes to sleep in sync with the camera's CSI transmitter

30.12 DPHY Modes of Operation

The MIPI DPHY has 3 basic modes of operation. High speed mode employs differential signaling and achieves data rate of 1 Gbps. Both the driver and receiver are matched to 100 ohms differential. The driver is voltage mode for lower power consumption as opposed to current mode.

Low power control mode employs single-ended CMOS signaling for handshaking between camera and host. In this mode, there is no clock and no maximum symbol time defined in the specification. The receiver samples the input using both edges of the internal pixel clock, so the timing resolution is half the clock period of the pixel clock period.

The low power escape mode employs self-clocking using both data P and N pins. The clock is generated by XOR of data P and N. The maximum transfer rate is 20 Mbps for a 50 ns bit time. In our implementation, the receiver samples the input using both edges of the internal pixel clock also. It is the goal to sample at least twice during the bit interval; therefore, the internal pixel clock should have a minimum frequency of 20 MHz.

Table 106: MIPI DPHY Mode of Operations

Modes	Description	Clock
High speed (HS)	High speed differential signaling. Up to 1 Gbps. Burst transmission for low power.	500 MHz differential
Low Power (LP) Control	Single-ended 1.2V CMOS level. Low speed signaling for handshaking. Supports ULPM sleep state.	No Clock
Low Power (LP) Escape	Same as above. Low speed signaling for data, used for escape command entry only. 20Mbps	2 stage synchronizers to VI clock

30.13 MIPI-CSI Registers

Refer to "Reading Register Tables" in the Introduction section for the register table protocol as well as recommendations for accessing registers.

30.13.1 CSI_VI_INPUT_STREAM_CONTROL_0

VI Input Stream Control

Offset: 0x200 | Byte Offset: 0x800 | Read/Write: R/W | Reset: 0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx

Bit	Reset	Description
7	X	VIP_SF_GEN: VIP Start Frame Generation. Do not use vi2csi_vip_vsync to generate start frame (SF) or end frame (EF) markers in the pixel parser output stream. 0 = VSYNC_SF: Pulses on vi2csi_vip_vsync will be used to generate start frame (SF) and end frame (EF) markers in the pixel parser output stream. In Tegra 4 devices, only payload_only mode is supported in the VIP input stream path, and this field may always be programmed to VSYNC_SF. 1 = NO_VSYNC_SF

30.13.2 CSI_HOST_INPUT_STREAM_CONTROL_0

Host Input Stream Control

Offset: 0x202 | Byte Offset: 0x808 | Read/Write: R/W | Reset: 0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx

Bit	R/W	Reset	Description
28:16	RW	X	HOST_FRAME_HEIGHT: Host Frame Height. Specifies the height of the host frame when the host is supplying CSI format payload only data to one of the CSI pixel parsers. Programmed Value = number of lines – 1
8	RO	X	HOST_END_OF_PACKET: Writing this bit with a 1 indicates End of Packet, when CSI Host data is being received in Packet Format. In Packet Format vi2csi_host_hsync is not used to indicate beginning of packet.
7	RW	X	HOST_SF_GEN: Host Start Frame Generation. Do not use CSI Host Line counter to generate start, or End, of Frame control outputs. This setting should only be used if HOST_DATA_FORMAT is set to PACKETS, and the Host data stream has frame sync packets. 0 = LINE_COUNTER: CSI Host Line counter will be used to generate Frame start and end control. To signal the start of the first frame, the pixel parser will send an SF control, and signal start of frame mark, when it is first enabled with Host as its source. This setting should be used when HOST_DATA_FORMAT is set to PAYLOAD_ONLY. 1 = SHORT_PACKETS
3:0	RW	X	HOST_DATA_FORMAT: Host Data Format. Data written to Y_FIFO_WRITE port should be in CSI packet format. To indicate end of packet, a 1 should be written to HOST_END_OF_PACKET. A 1 should also be written to HOST_END_OF_PACKET before writing the first word of packet data to Y_FIFO_WRITE. 0 = PAYLOAD_ONLY: Data written to Y_FIFO_WRITE port should be CSI line payload data only (no header, no footer, and no short packets). A value of 1 should not be written to HOST_END_OF_PACKET (end of packet pulse only gets generated when a 1 is written to this bit). First line will be indicated when one of the pixel parsers is first enabled with its CSI_PPA/B_STREAM_SOURCE set to "HOST". The values in the following PIXEL_STREAM_A/B_CONTROL0 fields, for the pixel parser that is receiving host data, will be ignored; CSI_PPA/B_PACKET_HEADER overridden with "NOT_SENT", CSI_PPA/B_DATA_IDENTIFIER overridden with "DISABLED", CSI_PPA/B_WORD_COUNT_SELECT overridden with "REGISTER". CSI_PPA/B_CRC_CHECK overridden with "DISABLE", CSI_PPA/B_VIRTUAL_CHANNEL_ID, CSI_PPA/B_EMBEDDED_DATA_OPTIONS, and CSI_PPA/B_HEADER_EC_ENABLE. CSI_PPA/B_DATA_TYPE should be programmed with the 6-bit data type that is to be used to interpret the stream. CSI_PPA/B_WORD_COUNT should be programmed with the number of bytes per line. 1 = PACKETS

30.13.3 CSI_INPUT_STREAM_A_CONTROL_0

CSI Input Stream A Control

Offset: 0x204 | Byte Offset: 0x810 | Read/Write: R/W | Reset: 0bxxxxxxxx011111111xxxxxxxxxxx0x101

Bit	Reset	Description
23:16	0xff	CSI_A_SKIP_PACKET_THRESHOLD: CSI-A Skip Packet Threshold. This value is compared against the internal FIFO that buffer the input streams. A packet will be skipped (discarded) if the pixel stream processor is busy (probably due to padding process of a short line) and the number of entries in the internal FIFO exceeds this threshold value. Note that each entry in the internal FIFO buffer is four bytes. To turn off this feature, set the value to its maximum value (all ones).
4	0x0	CSI_A_SKIP_PACKET_THRESHOLD_ENABLE: Enables skip packet threshold feature. Skip packet feature is enabled. 0 = DISABLE: Skip packet feature is disabled. 1 = ENABLE
2	0x1	CSI_A_BYPASS_ALIGN: Bypass aligning CSIA and CSIB lanes if the valids for the lanes are out of sync by one cycle
1:0	0x1	CSI_A_DATA_LANE: CSI-A Data Lane. 0= 1 data lane; 1= 2 data lanes; 2= 3 data lanes; 3= 4 data lanes

30.13.4 CSI_PIXEL_STREAM_A_CONTROL0_0

CSI Pixel Stream A Control 0

Offset: 0x206 | Byte Offset: 0x818 | Read/Write: R/W | Reset: 0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx000

Bit	Reset	Description
29:28	X	CSI_PPA_PAD_FRAME: CSI Pixel Parser A Pad Frame. This specifies how to deal with frames that are shorter (fewer lines) than expected. Short frames are usually caused by line packets being dropped because of packet errors. Expected frame height is specified in PPA_EXP_FRAME_HEIGHT. To do padding the value in CSI_PPA_WORD_COUNT needs to be set to the number of input bytes in each line's payload. Short frames will not be padded out. 0 = PAD0S: Lines of all zeros will be used to pad out frames that are shorter than expected height. PPA_EXP_FRAME_HEIGHT must be programmed to an appropriate value if this field is set to PAD0S. 1 = PAD1S: Lines of all ones will be used to pad out frames that are shorter than expected height. PPA_EXP_FRAME_HEIGHT must be programmed to an appropriate value if this fields is set to PAD1S. 2 = NOPAD
27	X	CSI_PPA_HEADER_EC_ENABLE: CSI Pixel Parser A Packet Header Error Correction Enable. This parameter specifies whether single bit errors in the packet header will be automatically corrected, or not. Single bit errors in the header will not be corrected. Header ECC check will still set header ECC status bits and the packet will be processed by Pixel Parser A. DISABLE should not be used when processing interleaved streams (Same stream going to both PPA and PPB). 0 = ENABLE: Single bit errors in the header will be automatically corrected. 1 = DISABLE

Bit	Reset	Description
25:24	X	CSI_PPA_PAD_SHORT_LINE: CSI Pixel Parser A Pad Short Line. This specifies how to deal with shorter than expected line (the number of bytes received is less than the specified word count). A short line is not padded (will output less pixels than expected). This option is not recommended and may cause other modules that receives CSI output stream to hang up. 0 = PAD0S: short line is padded by pixel of zeros such that the expected number of output pixels is correct. Due to the time required to do the padding, subsequent line packet may be discarded and therefore may cause a short frame (total number of lines per frame is less than expected). 1 = PAD1S: short line is padded by pixel of ones such that the expected number of output pixels is correct. Due to the time required to do the padding, subsequent line packet may be discarded and therefore may cause a short frame (total number of lines per frame is less than expected). 2 = NOPAD
21:20	X	CSI_PPA_EMBEDDED_DATA_OPTIONS: CSI Pixel Parser A Embedded Data Options. This specifies how to deal with embedded data within the specified input stream assuming that the CSI_PPA_DATA_TYPE is not embedded data and assuming that embedded data is not already processed by other CSI pixel stream processor. Output embedded data as 8-bpp arbitrary data stream. 0 = DISCARD: discard (throw away) embedded data 1 = EMBEDDED
19:16	X	CSI_PPA_OUTPUT_FORMAT_OPTIONS: CSI Pixel Parser A Output Format Options. This parameter specifies options for output data format. Output for storing RAW data to memory through ISP. Undefined LS color bits for RGB_666, RGB_565, RGB_555, and RGB_444, will be zeroed. 0 = ARBITRARY: Output as 8-bit arbitrary data stream This may be used for compressed JPEG stream 1 = PIXEL: Output the normal 1 pixel/clock. Undefined LS color bits for RGB_666, RGB_565, RGB_555, and RGB_444, will be zeroed. 2 = PIXEL_REP: Same as PIXEL except MS color bits, for RGB_666, RGB_565, RGB_555, and RGB_444, will be replicated to their undefined LS bits. 3 = STORE
15:14	X	CSI_PPA_VIRTUAL_CHANNEL_ID: CSI Pixel Parser A Virtual Channel Identifier. This is CSI compatible virtual channel identifier as defined in CSI specification. If the source stream contains packet headers and CSI_PPA_DATA_IDENTIFIER is ENABLED this value will be compared to the CSI Virtual Channel Identifier value in the 2 MSBs of the CSI Data Identifier (DI) byte. This value will be ignored if the source stream does not contain packet headers, or CSI_PPA_DATA_IDENTIFIER is DISABLED, then this value will be ignored. 0 = ONE 1 = TWO 2 = THREE 3 = FOUR
13:8	X	CSI_PPA_DATA_TYPE: CSI Pixel Parser A Data Type. This is CSI compatible data type as defined in CSI specification. If the source stream contains packet headers this value can be compared to the CSI Data Type value in the 6 LSBs of the CSI Data Identifier (DI) byte. If the source stream does not contain packet headers, or CSI_PPA_DATA_IDENTIFIER is DISABLED, this value will be used to determine how the stream will be converted to pixels. 24 = YUV420_8 25 = YUV420_10 26 = LEG_YUV420_8 28 = YUV420CSPS_8 29 = YUV420CSPS_10 30 = YUV422_8 31 = YUV422_10 32 = RGB444 33 = RGB555 34 = RGB565 35 = RGB666 36 = RGB888 40 = RAW6 41 = RAW7 42 = RAW8 43 = RAW10 44 = RAW12

Bit	Reset	Description
		45 = RAW14 48 = ARB_DT1 49 = ARB_DT2 50 = ARB_DT3 51 = ARB_DT4
7	X	CSI_PPA_CRC_CHECK: CSI Pixel Parser A Data CRC Check. This parameter specifies whether the last 2 bytes of packet should be treated as CRC checksum and used to perform CRC check on the payload data. Note that in case there are 2 bytes of data CRC at the end of the packet, the packet word count does not include the CRC bytes. Data CRC Check is enabled. 0 = DISABLE: Data CRC Check is disabled regardless of whether there are CRC checksum at the end of the packet. 1 = ENABLE
6	X	CSI_PPA_WORD_COUNT_SELECT: CSI Pixel Parser A Word Count Select. This parameter is effective only if packet header is sent as part of the stream. The number of bytes per line is to be extracted from Word Count field in the packet header. Note that if the serial link is not error free, programming this bit to HEADER may be dangerous because the word count information in the header may be corrupted. 0 = REGISTER: Word Count in packet header is ignored and the number of bytes per line/packet is specified by CSI_PPA_WORD_COUNT. Payload CRC check will not be valid if the word count in CSI_PPA_WORD_COUNT is different than the count in the packet header. It is recommended to always program this bit to REGISTER and always program CSI_PPA_WORD_COUNT. 1 = HEADER
5	X	CSI_PPA_DATA_IDENTIFIER: CSI Pixel Parser A Data Identifier (DI) byte processing. This parameter is effective only if packet header is sent as part of the stream. Enabled - Data Identifier byte in packet header should be compared against the CSI_PPA_DATA_TYPE and the CSI_PPA_VIRTUAL_CHANNEL_ID. 0 = DISABLED: Disabled - Data Identifier byte in packet header should be ignored (not checked against CSI_PPA_DATA_TYPE and against CSI_PPA_VIRTUAL_CHANNEL_ID). In this case, CSI_PPA_DATA_TYPE specifies the stream data format. 1 = ENABLED
4	X	CSI_PPA_PACKET_HEADER: CSI Pixel Parser A Packet Header processing. This specifies whether packet header is sent in the beginning of packet or not. Packet header is sent. This setting should be used if the stream source is CSI Interface A or B. 0 = NOT_SENT: Packet header is not sent. This setting should not be used if the stream source is CSI Interface A or B. Unless CSI-A, or CSI-B, is operating in a stream capture debug mode. In this case, CSI_PPA_DATA_TYPE specifies the stream data format and the number of bytes per line/packet is specified by CSI_PPA_WORD_COUNT. This implies that a packet footer is also not sent. In this case, no packet footer CRC check should be performed. 1 = SENT
2:0	0x0	CSI_PPA_STREAM_SOURCE: CSI Pixel Parser A Stream Source Host 0 = CSI_A: CSI Interface A 1 = CSI_B: CSI Interface B 6 = VI_PORT: VI port 7 = HOST

30.13.5 CSI_PIXEL_STREAM_A_CONTROL1_0

CSI Pixel Stream A Control 1

Offset: 0x207 | Byte Offset: 0x81c | Read/Write: R/W | Reset: 0bxxxxxxxxxxxxxxxxxxxxxxxxx00000000|

Bit	Reset	Description
7:4	0x0	CSI_PPA_TOP_FIELD_FRAME_MASK: CSI Pixel Parser A Top Field Frame Mask
3:0	0x0	CSI_PPA_TOP_FIELD_FRAME: CSI Pixel Parser A Top Field Frame. This parameter specifies the frame number for top field detection for interlaced input video stream. Top Field is indicated when each of the least significant four bits of the frame number that has a one in its mask bit matches the corresponding bit in this parameter. In other words, Top

Bit	Reset	Description
		Field is detected when the bitwise AND of ~(CSI_PPA_TOP_FIELD_FRAME ^ <frame number>) & CSI_PPA_TOP_FIELD_FRAME_MASK is one. Frame Number is taken from the WC field of the Frame Start short packet.

30.13.6 CSI_PIXEL_STREAM_A_WORD_COUNT_0

CSI Pixel Stream A Word Count

Offset: 0x208 | Byte Offset: 0x820 | Read/Write: R/W | Reset: 0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx |

Bit	Reset	Description
15:0	X	CSI_PPA_WORD_COUNT: CSI Pixel Parser A Word Count. This parameter specifies the number of bytes per line/packet in the case where Word Count field in packet header is not used or where packet header is not sent. This count does not include the additional 2 bytes of CRC checksum if data CRC check is enabled. When the input stream comes from a CSI camera port, this parameter must be programmed when CSI_PPA_PAD_SHORT_LINE is set to either PAD0S or PAD1S, no matter whether CSI_PPA_WORD_COUNT_SELECT is set to REGISTER or HEADER. When the input stream comes from the host path or from the VIP path, and the data mode is PAYLOAD_ONLY, this count must be programmed. Given a line width of N pixels, the programming value of this parameters is as follows **Data format** — **Value** YUV420_8 — N bytes YUV420_10 — N/4*5 bytes LEG_YUV420_8 — N/2*3 bytes YUV422_8 — N*2 bytes YUV422_10 — N/2*5 bytes RGB888 — N*3 bytes RGB666 — N/4*9 bytes RGB565 — N*2 bytes RGB555 — N*2 bytes RGB444 — N*2 bytes RAW6 — N/4*3 bytes RAW7 — N/8*7 bytes RAW8 — N bytes RAW10 — N/4*5 bytes RAW12 — N/2*3 bytes RAW14 — N/4*7 bytes

30.13.7 CSI_PIXEL_STREAM_A_GAP_0

CSI Pixel Stream A Gap

Offset: 0x209 | Byte Offset: 0x824 | Read/Write: R/W | Reset: 0b00000000000000000000000000000000

Bit	Reset	Description
31:16	0x0	PPA_FRAME_MIN_GAP: Minimum number of viclk cycles from end of frame (Video_control = EF) to start of next frame (Video_control = SF). This parameter ensures that the minimum V-blank time requirement of VI/ISP is satisfied. This field takes effect only when the frame gap of the input stream is less than the specified value.
15:0	0x0	PPA_LINE_MIN_GAP: Minimum number of viclk cycles from end of previous line (Video_control = EL_DATA) to start of next line (Video_control = SL). This parameter ensures that the minimum H-blank time requirement of VI/ISP is satisfied. This field takes effect only when the line gap of the input stream is less than the specified value.

30.13.8 CSI_PIXEL_STREAM_PPA_COMMAND_0

CSI Pixel Parser A Command

Offset: 0x20a | Byte Offset: 0x828 | Read/Write: R/W | Reset: 0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx00)

Bit	Reset	Description
15:12	X	CSI_PPA_START_MARKER_FRAME_MAX: CSI Pixel Parser A Start Marker Maximum. Start Frame is indicated when the Minimum condition above is met and the least significant four bits of the frame number are less than or equal to this value.
11:8	X	CSI_PPA_START_MARKER_FRAME_MIN: CSI Pixel Parser A Start Marker Minimum. Start Frame is indicated when the Maximum condition below is met and the least significant four bits of the frame number are greater than or equal to this value.
4	X	CSI_PPA_VSYNC_START_MARKER: CSI Pixel Parser A VSYNC Start Marker. The start of frame is indicated when the VSYNC signal is received. When the input stream is from the VIP path and the data mode is PACKET, then this field may be programmed to VSYNC. 0 = FSPKT: Start of frame is indicated when a Frame Start short packet is received with a frame number whose least significant four bits are greater than or equal to CSI_PPA_START_MARKER_FRAME_MIN and less than or equal to CSI_PPA_START_MARKER_FRAME_MAX. When the input stream is from a CSI port, or from the host path, or from the VIP path and the data mode is PAYLOAD_ONLY, then this field may be programmed to FSPKT. 1 = VSYNC
2	X	CSI_PPA_SINGLE_SHOT: CSI Pixel Parser A Single Shot Mode. Software should clear it along with disabling the CSI_PPA_ENABLE, once a frame is captured 0 = DISABLE 1 = ENABLE
1:0	0x0	CSI_PPA_ENABLE: CSI Pixel Parser A Enable. This parameter controls CSI Pixel Parser A to start or stop receiving data. Reset (disable immediately) Enabling the pixel parser does not enable the corresponding input source to receive data. If the pixel parser is enabled later than the corresponding input source, the CSI will keep on rejecting incoming stream, until it encounters a valid SF. 0 = NOP: no operation 1 = ENABLE: enable at the next frame start as specified by the CSI Start Marker 2 = DISABLE: disable after current frame end and before next frame start. 3 = RST

30.13.9 CSI_PIXEL_STREAM_A_EXPECTED_FRAME_0

CSI Pixel Stream A Expected Frame

Offset: 0x232 | Read/Write: R/W | Reset: 0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx

Bit	Reset	Description
28:16	X	PPA_EXP_FRAME_HEIGHT: CSI-PPA Expected Frame Height. Specifies the expected height of the CSI-PPA frame output. Padding out of frames that are shorter than this expected height can be specified using CSI_PPA_PAD_FRAME. If CSI_PPA_PAD_FRAME is set to PAD0S or PAD1S, this parameter must be programmed. If CSI_PPA_PAD_FRAME is set to NOPAD, this parameter may not be programmed. Programmed Value = number of lines
15:4	X	PPA_MAX_CLOCKS: Maximum Number of viclk clock cycles between line start requests. The value in this field is in terms of 256 viclk clock cycles.
0	X	PPA_ENABLE_LINE_TIMEOUT: When set to one, enables checking of the time between start line requests from the Header Parser to CSI-PPA. A fake EF will be output by CSI-PPA if this time between line starts exceeds the value in MAX_CLOCKS_BETWEEN_LINES. Padding lines can be inserted before the fake EF, if the number of lines output, when the fake EF is generated is less than the expected frame height. The type of padding is specified using CSI_PPA_PAD_FRAME.

30.13.10 CSI_INPUT_STREAM_B_CONTROL_0

CSI Input Stream B Control

Offset: 0x20f | Byte Offset: 0x83c | Read/Write: R/W | Reset: 0bxxxxxxx011111111xxxxxxxxxx0x101

Bit	Reset	Description
24:16	0xff	CSI_B_SKIP_PACKET_THRESHOLD: CSI-B Skip Packet Threshold. This value is compared against the internal FIFO that buffers the input streams. A packet will be skipped (discarded) if the pixel stream processor is busy (probably due to padding process of a short line) and the number of entries in the internal FIFO exceeds this threshold value. Note that each entry in the internal FIFO buffer is four bytes. To turn off this feature, set the value to its maximum value (all ones).
4	0x0	CSI_B_SKIP_PACKET_THRESHOLD_ENABLE: Enables skip packet threshold feature. Skip packet feature is enabled. 0 = DISABLE: Skip packet feature is disabled. 1 = ENABLE
2	0x1	CSI_B_BYPASS_ALIGN: Bypass aligning CSIC and CSID lanes if the valids for the lanes are out of sync by one cycle
1:0	0x1	CSI_B_DATA_LANE: CSI-B Data Lane. 0= 1 data lane 1= 2 data lanes 2= 3 data lanes 3= 4 data lanes

30.13.11 CSI_PIXEL_STREAM_B_CONTROL0_0

CSI Pixel Stream A Control 0

Offset: 0x211 | Byte Offset: 0x844 | Read/Write: R/W | Reset: 0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx000

Bit	Reset	Description
29:28	X	CSI_PPB_PAD_FRAME: CSI Pixel Parser B Pad Frame. This specifies how to deal with frames that are shorter (fewer lines) than expected. Short frames are usually caused by line packets being dropped because of packet errors. Expected frame height is specified in PPB_EXP_FRAME_HEIGHT. To do padding the value in CSI_PPB_WORD_COUNT needs to be set to the number of input bytes in each lines payload. Short frames will not be padded out. 0 = PAD0S: Lines of all zeros will be used to pad out frames that are shorter than expected height. PPB_EXP_FRAME_HEIGHT must be programmed to an appropriate value if this field is set to PAD0S. 1 = PAD1S: Lines of all ones will be used to pad out frames that are shorter than expected height. PPB_EXP_FRAME_HEIGHT must be programmed to an appropriate value if this field is set to PAD1S. 2 = NOPAD
27	X	CSI_PPB_HEADER_EC_ENABLE: CSI Pixel Parser B Packet Header Error Correction Enable. This parameter specifies whether single bit errors in the packet header will be automatically corrected or not. Single bit errors in the header will not be corrected. Header ECC check will still set header ECC status bits and the packet will be processed by Pixel Parser B. DISABLE should not be used when processing interleaved streams (Same stream going to both PPA and PPB). 0 = ENABLE: Single bit errors in the header will be automatically corrected. 1 = DISABLE

Bit	Reset	Description
25:24	X	CSI_PPB_PAD_SHORT_LINE: CSI Pixel Parser B Pad Short Line. This specifies how to deal with shorter than expected line (the number of bytes received is less than the specified word count) short line is not padded (will output less pixels than expected). This option is not recommended and may cause other modules that receive CSI output stream to hang up. 0 = PAD0S: short line is padded by pixel of zeros such that the expected number of output pixels is correct. Due to the time required to do the padding, subsequent line packet may be discarded and therefore may cause a short frame (total number of lines per frame is less than expected). 1 = PAD1S: short line is padded by pixel of ones such that the expected number of output pixels is correct. Due to the time required to do the padding, subsequent line packet may be discarded and therefore may cause a short frame (total number of lines per frame is less than expected). 2 = NOPAD
21:20	X	CSI_PPB_EMBEDDED_DATA_OPTIONS: CSI Pixel Parser B Embedded Data Options. This specifies how to deal with embedded data within the specified input stream assuming that the CSI_PPB_DATA_TYPE is not embedded data and that embedded data is not already processed by another CSI pixel stream processor. Output embedded data as 8-bpp arbitrary data stream. 0 = DISCARD: discard (throw away) embedded data 1 = EMBEDDED
19:16	X	CSI_PPB_OUTPUT_FORMAT_OPTIONS: CSI Pixel Parser B Output Format Options. This parameter specifies output data format. Output for storing RAW data to memory through ISP. Undefined LS color bits for RGB_666, RGB_565, RGB_555, and RGB_444, will be zeroed. 0 = ARBITRARY: Output as 8-bit arbitrary data stream This may be used for compressed JPEG stream 1 = PIXEL: Output the normal 1 pixel/clock. Undefined LS. color bits for RGB_666, RGB_565, RGB_555, and RGB_444, will be zeroed. 2 = PIXEL_REP: Same as PIXEL except MS color bits, for RGB_666, RGB_565, RGB_555, and RGB_444, will be replicated to their undefined LS bits. 3 = STORE
15:14	X	CSI_PPB_VIRTUAL_CHANNEL_ID: CSI Pixel Parser B Virtual Channel Identifier. This is CSI compatible virtual channel identifier as defined in the CSI specification. If the source stream contains packet headers and CSI_PPB_DATA_IDENTIFIER is ENABLED this value will be compared to the CSI Virtual Channel Identifier value in the 2 MSBs of the CSI Data Identifier (DI) byte. This value will be ignored if the source stream does not contain packet headers, or CSI_PPB_DATA_IDENTIFIER is DISABLED, then this value will be ignored. 0 = ONE 1 = TWO 2 = THREE 3 = FOUR

Bit	Reset	Description
13:8	X	CSI_PPB_DATA_TYPE: CSI Pixel Parser B Data Type. This is CSI compatible data type as defined in CSI specification. If the source stream contains packet headers this value can be compared to the CSI Data Type value in the 6 LSBs of the CSI Data Identifier (DI) byte. If the source stream does not contain packet headers or CSI_PPB_DATA_IDENTIFIER is DISABLED, this value will be used to determine how the stream will be converted to pixels. 24 = YUV420_8 25 = YUV420_10 26 = LEG_YUV420_8 28 = YUV420CSPS_8 29 = YUV420CSPS_10 30 = YUV422_8 31 = YUV422_10 32 = RGB444 33 = RGB555 34 = RGB565 35 = RGB666 36 = RGB888 40 = RAW6 41 = RAW7 42 = RAW8 43 = RAW10 44 = RAW12 45 = RAW14 48 = ARB_DT1 49 = ARB_DT2 50 = ARB_DT3 51 = ARB_DT4
7	X	CSI_PPB_CRC_CHECK: CSI Pixel Parser B Data CRC Check. This parameter specifies whether the last 2 bytes of packet should be treated as CRC checksum and used to perform CRC check on the payload data. Note that in case there are 2 bytes of data CRC at the end of the packet, the packet word count does not include the CRC bytes. Data CRC Check is enabled. 0 = DISABLE: Data CRC Check is disabled regardless of whether there are CRC checksum at the end of the packet. 1 = ENABLE
6	X	CSI_PPB_WORD_COUNT_SELECT: CSI Pixel Parser B Word Count Select. This parameter is effective only if packet header is sent as part of the stream. The number of bytes per line is to be extracted from Word Count field in the packet header. Note that if the serial link is not error free, programming this bit to HEADER may be dangerous because the word count information in the header may be corrupted. 0 = REGISTER: Word Count in packet header is ignored and the number of bytes per line/packet is specified by CSI_PPB_WORD_COUNT. Payload CRC check will not be valid if the word count in CSI_PPB_WORD_COUNT is different than the count in the packet header. It is recommended to always program this bit to REGISTER and always program CSI_PPB_WORD_COUNT. 1 = HEADER
5	X	CSI_PPB_DATA_IDENTIFIER: CSI Pixel Parser B Data Identifier (DI) byte processing. This parameter is effective only if packet header is sent as part of the stream. Enabled - Data Identifier byte in packet header should be compared against the CSI_PPB_DATA_TYPE and the CSI_PPB_VIRTUAL_CHANNEL_ID. 0 = DISABLED: Disabled - Data Identifier byte in packet header should be ignored (not checked against CSI_PPB_DATA_TYPE and against CSI_PPB_VIRTUAL_CHANNEL_ID). In this case, CSI_PPB_DATA_TYPE specifies the stream data format. 1 = ENABLED

Bit	Reset	Description
4	X	CSI_PPB_PACKET_HEADER: CSI Pixel Parser B Packet Header processing. This specifies whether packet header is sent in the beginning of packet or not. Packet header is sent. This setting should be used if the stream source is CSI Interface A or B. 0 = NOT_SENT: Packet header is not sent. This setting should not be used if the stream source is CSI Interface A or B. Unless CSI-A, or CSI-B, is operating in a stream capture debug mode. In this case, CSI_PPB_DATA_TYPE specifies the stream data format and the number of bytes per line/packet is specified by CSI_PPB_WORD_COUNT. This implies that a packet footer is also not sent. In this case, no packet footer CRC check should be performed. 1 = SENT
2:0	0x0	CSI_PPB_STREAM_SOURCE: CSI Pixel Parser B Stream Source Host 0 = CSI_A: CSI Interface A 1 = CSI_B: CSI Interface B 6 = VI_PORT: VI port 7 = HOST

30.13.12 CSI_PIXEL_STREAM_B_CONTROL1_0

CSI Pixel Stream B Control 1

Offset: 0x212 | Byte Offset: 0x848 | Read/Write: R/W | Reset: 0bxxxxxxxxxxxxxxxxxxxxxxxxx00000000

Bit	Reset	Description
7:4	0x0	CSI_PPB_TOP_FIELD_FRAME_MASK: CSI Pixel Parser B Top Field Frame Mask
3:0	0x0	CSI_PPB_TOP_FIELD_FRAME: CSI Pixel Parser B Top Field Frame. This parameter specifies the frame number for top field detection for interlaced input video stream. Top Field is indicated when each of the least significant four bits of the frame number that has a one in its mask bit matches the corresponding bit in this parameter. In other words, Top Field is detected when the bitwise AND of ~(CSI_PPB_TOP_FIELD_FRAME ^ <frame number>) & CSI_PPB_TOP_FIELD_FRAME_MASK is one. Frame Number is taken from the WC field of the Frame Start short packet.

30.13.13 CSI_PIXEL_STREAM_B_WORD_COUNT_0

CSI Pixel Stream A Word Count

Offset: 0x213 | Byte Offset: 0x84c | Read/Write: R/W | Reset: 0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx

Bit	Reset	Description
15:0	X	CSI_PPB_WORD_COUNT: CSI Pixel Parser B Word Count. This parameter specifies the number of bytes per line/packet in the case where Word Count field in packet header is not used or where packet header is not sent. This count does not include the additional 2 bytes of CRC checksum if data CRC check is enabled. When the input stream comes from a CSI camera port, this parameter must be programmed when CSI_PPB_PAD_SHORT_LINE is set to either PAD0S or PAD1S, no matter whether CSI_PPB_WORD_COUNT_SELECT is set to REGISTER or HEADER. When the input stream comes from the host path or from the VIP path, and the data mode is PAYLOAD_ONLY, this count must be programmed. Given a line width of N pixels, the programming value of this parameters is as follows: **Data Format** — **Value** YUV420_8 — N bytes YUV420_10 — N/4*5 bytes LEG_YUV420_8 — N/2*3 bytes YUV422_8 — N*2 bytes YUV422_10 — N/2*5 bytes RGB888 — N*3 bytes RGB666 — N/4*9 bytes RGB565 — N*2 bytes RGB555 — N*2 bytes

Bit	Reset	Description
		RGB444 N*2 bytes RAW6 N/4*3 bytes RAW7 N/8*7 bytes RAW8 N bytes RAW10 N/4*5 bytes RAW12 N/2*3 bytes RAW14 N/4*7 bytes

30.13.14 CSI_PIXEL_STREAM_B_GAP_0

CSI Pixel Stream B Gap

Offset: 0x214 | Byte Offset: 0x850 | Read/Write: R/W | Reset: 0b00000000000000000000000000000000

Bit	Reset	Description
31:16	0x0	PPB_FRAME_MIN_GAP: Minimum number of viclk cycles from end of frame (Video_control = EF) to start of next frame (Video_control = SF). This parameter ensures that the minimum V-blank time requirement of VI/ISP is satisfied. This field takes effect only when the frame gap of the input stream is less than the specified value.
15:0	0x0	PPB_LINE_MIN_GAP: Minimum number of viclk cycles from end of previous line (Video_control = EL_DATA) to start of next line (Video_control = SL). This parameter ensures that the minimum H-blank time requirement of VI/ISP is satisfied. This field takes effect only when the line gap of the input stream is less than the specified value.

30.13.15 CSI_PIXEL_STREAM_PPB_COMMAND_0

CSI Pixel Parser B Command

Offset: 0x215 | Byte Offset: 0x854 | Read/Write: R/W | Reset: 0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx00

Bit	Reset	Description
15:12	X	CSI_PPB_START_MARKER_FRAME_MAX: CSI Pixel Parser B Start Marker Maximum. Start Frame is indicated when the Minimum condition above is met and the least significant four bits of the frame number are less than, or equal to, this value.
11:8	X	CSI_PPB_START_MARKER_FRAME_MIN: CSI Pixel Parser B Start Marker Minimum. Start Frame is indicated when the Maximum condition below is met and the least significant four bits of the frame number are greater than, or equal to, this value.
4	X	CSI_PPB_VSYNC_START_MARKER: CSI Pixel Parser B VSYNC Start Marker. Start of frame is indicated when VSYNC signal is received. When the input stream is from the VIP path and the data mode is PACKET, then this field may be programmed to VSYNC. 0 = FSPKT: Start of frame is indicated when a Frame Start short packet is received with a frame number whose least significant four bits are greater than, or equal to, CSI_PPB_START_MARKER_FRAME_MIN and less than, or equal to, CSI_PPB_START_MARKER_FRAME_MAX. When the input stream is from a CSI port, or from the host path, or from the VIP path and the data mode is PAYLOAD_ONLY, then this field may be programmed to FSPKT. 1 = VSYNC
2	X	CSI_PPB_SINGLE_SHOT: CSI Pixel Parser B Single Shot Mode. Software should clear it along with disabling CSI_PPB_ENABLE, once a frame is captured 0 = DISABLE 1 = ENABLE

Bit	Reset	Description
1:0	0x0	CSI_PPB_ENABLE: CSI Pixel Parser B Enable. This parameter controls CSI Pixel Parser B to start or stop receiving data. reset (disable immediately). Enabling the pixel parser does not enable the corresponding input source to receive data. If the pixel parser is enabled later than the corresponding input source, the CSI will keep rejecting the incoming stream, until it encounters a valid SF. 0 = NOP: no operation 1 = ENABLE: enable at the next frame start as specified by the CSI Start Marker 2 = DISABLE: disable after current frame end and before next frame start. 3 = RST

30.13.16 CSI_PIXEL_STREAM_B_EXPECTED_FRAME_0

CSI Pixel Stream B Expected Frame

Offset: 0x233 | Read/Write: R/W | Reset: 0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx

Bit	Reset	Description
28:16	X	PPB_EXP_FRAME_HEIGHT: CSI-PPB Expected Frame Height. Specifies the expected height of the CSI-PPB frame output. Padding out of frames that are shorter than this expected height can be specified using CSI_PPB_PAD_FRAME. If CSI_PPB_PAD_FRAME is set to PAD0S or PAD1S, this parameter must be programmed. If CSI_PPB_PAD_FRAME is set to NOPAD, this parameter may not be programmed. Programmed Value = number of lines
15:4	X	PPB_MAX_CLOCKS: Maximum Number of viclk clock cycles between line start requests. The value in this field is in terms of 256 viclk clock cycles.
0	X	PPB_ENABLE_LINE_TIMEOUT: When set to one, enables checking of the time between start line requests from the Header Parser to CSI-PPB. A fake EF will be output by CSI-PPB if this time between line starts exceeds the value in MAX_CLOCKS_BETWEEN_LINES. Padding lines can be inserted before the fake EF, if the number of lines output, when the fake EF is generated is less than the expected frame height. The type of padding is specified using CSI_PPB_PAD_FRAME.

30.13.17 CSI_PHY_CIL_COMMAND_0

CSI PHY and CIL Command

Offset: 0x21a | Byte Offset: 0x868 | Read/Write: R/W | Reset: 0bxx00xx00xx00xx00xxxxxxxxxxxxxx00

Bit	Reset	Description
29:28	0x0	CSI_E_PHY_CIL_ENABLE: CSI E PHY and CIL Enable. This parameter controls CSI E PHY and CIL receiver to start or stop receiving data. 0 = NOP: no operation 1 = ENABLE: enable 2 = DISABLE: reset
25:24	0x0	CSI_D_PHY_CIL_ENABLE: CSI D PHY and CIL Enable. This parameter controls CSI D PHY and CIL receiver to start or stop receiving data. 0 = NOP: no operation 1 = ENABLE: enable 2 = DISABLE: reset
21:20	0x0	CSI_C_PHY_CIL_ENABLE: CSI C PHY and CIL Enable. This parameter controls CSI C PHY and CIL receiver to start or stop receiving data. 0 = NOP: no operation 1 = ENABLE: enable 2 = DISABLE: reset

Bit	Reset	Description
17:16	0x0	CSI_B_PHY_CIL_ENABLE: CSI B PHY and CIL Enable. This parameter controls CSI B PHY and CIL receiver to start or stop receiving data. 0 = NOP: no operation 1 = ENABLE: enable 2 = DISABLE: reset
1:0	0x0	CSI_A_PHY_CIL_ENABLE: CSI A PHY and CIL Enable. This parameter controls CSI A PHY and CIL receiver to start or stop receiving data. 0 = NOP: no operation 1 = ENABLE: enable 2 = DISABLE: reset

30.13.18 CSI_PHY_CILA_CONTROL0_0

CSI-A PHY and CIL Control

Offset: 0x21b | Byte Offset: 0x86c | Read/Write: R/W | Reset: 0bxxxxxxxxxxxxxxxxxxxxx0000xx0x0010

Bit	Reset	Description
11:8	0x0	CILA_CLK_SETTLE: Settle time for clock lane when moving from LP to HS (LP11->LP01->LP00), this setting determines how many CSICIL clock cycles (102 MHz LP clock cycles) to wait after LP00. Hardware uses an internal delay of ~15 csicil cycles for the default value. So the programming value (0 to 15) of this field works like this: 0 = 15 cilclk cycles (default internal delay) 1 = 15 - 7 (8 cilclk cycles) 2 = 15 - 6 (9 cilclk cycles) … 7 = 15 - 1 (14 cilclk cycles) 8 = 15 - 0 (default internal delay) 9 = 15 + 1 (16 cilclk cycles) … 15 = 15 + 7 (22 cilclk cycles)
5	0x0	CILA_BYPASS_LP_SEQ: The LP signals should sequence through LP11->LP01->LP00 state, to indicate to CLOCK CIL about the mode switching to HS Rx mode. In case Camera is enabled earlier than CIL, it is highly likely that camera sends this control sequence sooner than CIL can detect it. Enabling this bit allows the CLOCK CIL to overlook the LP control sequence and step in HS Rx mode directly looking at LP00 only.
3:0	0x2	CILA_THS_SETTLE: Settle time for data lane when moving from LP to HS (LP11->LP01->LP00), this setting determines how many CSICIL clock cycles (102 MHz LP clock cycles) to wait, after LP00, before starting to look at the data. 0xF is an illegal value for this field. 85ns + 6 * UI < (Ths-settle-programmed + 5) * csicil_clk_period < 145ns + 10 * UI

30.13.19 CSI_PHY_CILB_CONTROL0_0

CSI-B PHY and CIL Control

Offset: 0x21c | Byte Offset: 0x870 | Read/Write: R/W | Reset: 0bxxxxxxxxxxxxxxxxxxxxx0000xx0x0010

Bit	Reset	Description
11:8	0x0	CILB_CLK_SETTLE: Settle time for clock lane when moving from LP to HS (LP11->LP01->LP00), this setting determines how many CSICIL clock cycles (102 MHz LP clock cycles) to wait after LP00. Hardware uses an internal delay of ~15 CSICIL cycles for default value. So the programming value (0 to 15) of this field works like this: 0 = 15 cilclk cycles (default internal delay) 1 = 15 - 7 (8 cilclk cycles) 2 = 15 - 6 (9 cilclk cycles) …

Bit	Reset	Description
		7 = 15 - 1 (14 cilclk cycles) 8 = 15 - 0 (default internal delay) 9 = 15 + 1 (16 cilclk cycles) … 15 = 15 + 7 (22 cilclk cycles)
5	0x0	CILB_BYPASS_LP_SEQ: see CILA_BYPASS_LP_SEQ above
3:0	0x2	CILB_THS_SETTLE: Settle time for data lane when moving from LP to HS (LP11->LP01->LP00), this setting determines how many CSICIL clock cycles (102 MHz LP clock cycles) to wait, after LP00, before starting to look at the data. 0xF is an illegal value for this field. 85ns + 6 * UI < (Ths-settle-programmed + 5) * csicil_clk_period < 145ns + 10 * UI

30.13.20 CSI_CSI_PIXEL_PARSER_STATUS_0

Pixel Parser Status

Each status bit is cleared to zero when its bit position is written with one. For example, writing 0x2 to CSI_PIXEL_PARSER_STATUS will clear only PPA_ILL_WD_CNT.

Offset: 0x21e | Byte Offset: 0x878 | Read/Write: RO | Reset: 0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx

Bit	Reset	Description
31	X	HPH_UNC_HDR_ERR: Uncorrectable Header Error. Set when the Host port header parser parses a header with a multi-bit error. This error will be detected by the header's ECC, but cannot be corrected. The packet will be discarded.
30	X	HPV_UNC_HDR_ERR: Uncorrectable Header Error. Set when the VI port header parser parses a header with a multi-bit error. This error will be detected by the header's ECC, but cannot be corrected. The packet will be discarded.
26	X	PPB_SPARE_STATUS_1: PPB Spare Status bit. This bit will get set when Pixel Parser B has a line timeout. Line timeout needs to be enabled by setting PPB_ENABLE_LINE_TIMEOUT and programming PPB_MAX_CLOCKS for the MAX clocks between lines.
25	X	PPB_INTERFRAME_LINE: Set when CSI-PPB receives a request to output a line that is not in the active part of the frame output. That is after EF and before SF, or before start marker is found. The interframe line will not be output by the Pixel Parser.
24	X	PPB_EXTRA_SF: Set when CSI-PPB receives an SF when it is expecting an EF. This happens when the EF of the frame gets corrupted before the arriving CSI. CSI-PPB will insert a fake EF and drop the current frame with Correct SF.
23	X	PPB_SHORT_FRAME: Set when CSI-PPB receives a short frame. This bit gets set even if CSI_PPB_PAD_FRAME specifies that short frames are to be padded to the correct line length.
22	X	PPB_STMERR: Stream Error. Set when the control output of PPB does not follow the correct sequence. The correct sequence for CSI is: SF -> (SL_DATA or EF), SL_DATA -> (DATA or EL_DATA), DATA -> EL_DATA, EL_DATA -> (SL_DATA or EF), EF -> SF. Stream Errors can be caused by receiving a corrupted stream.
21	X	PPB_FIFO_OVRF: FIFO Overflow. Set when the FIFO that is feeding packets to PPB overflows.
20	X	PPB_PL_CRC_ERR: PayLoad CRC Error. Set when a packet that was processed by PPB had a payload CRC error.
19	X	PPB_SL_PKT_DROPPED: Short Line Packet Dropped. Set when an incoming packet gets dropped because the input FIFO level reaches CSI_B_SKIP_PACKET_THRESHOLD when padding a short line.
18	X	PPB_SL_PROCESSED: Short Line Processed. Set when a line with a payload that is shorter than its packet header word count is processed by the PPB.

Bit	Reset	Description
17	X	PPB_ILL_WD_CNT: Illegal Word Count. Set when a line with a word count that does not generate an integer number of pixels (unused bytes at the end of payload) is processed by PPB.
16	X	PPB_HDR_ERR_COR: Header Error Corrected. Set when a packet that was processed by PPB has a single bit header error. This error will be detected by the header's ECC, and corrected by it if header error correction is enabled (CSI_B_HEADER_EC_ENABLE = 0). This flag will be set and the packet will be processed even if the error is not corrected.
15	X	HPB_UNC_HDR_ERR: Uncorrectable Header Error. Set when header parser B parses a header with a multi-bit error. This error will be detected by the header's ECC, but cannot be corrected. The packet will be discarded.
14	X	HPA_UNC_HDR_ERR: Uncorrectable Header Error. Set when header parser A parses a header with a multi bit error. This error will be detected by the headers ECC, but cannot be corrected. The packet will be discarded.
10	X	PPA_SPARE_STATUS_1: PPA Spare Status bit. This bit will get set when Pixel Parser A has a line timeout. Line timeout needs to be enabled by setting PPA_ENABLE_LINE_TIMEOUT and programming PPA_MAX_CLOCKS for the MAX clocks between lines.
9	X	PPA_INTERFRAME_LINE: Set when CSI-PPA receives a request to output a line that is not in the active part of the frame output. That is after EF and before SF, or before start marker is found. The interframe line will not be output by the pixel parser.
8	X	PPA_EXTRA_SF: Set when CSI-PPA receives an SF when it is expecting an EF. This happens when the EF of the frame gets corrupted before the arriving CSI. CSI-PPA will insert a fake EF and drop the current frame with Correct SF.
7	X	PPA_SHORT_FRAME: Set when CSI-PPA receives a short frame. This bit gets set even if CSI_PPA_PAD_FRAME specifies that short frames are to be padded to the correct line length.
6	X	PPA_STMERR: Stream Error. Set when the control output of PPA does not follow the correct sequence. The correct sequence for CSI is: SF -> (SL_DATA or EF), SL_DATA -> (DATA or EL_DATA), DATA -> EL_DATA, EL_DATA -> (SL_DATA or EF), EF -> SF. Stream Errors can be caused by receiving a corrupted stream.
5	X	PPA_FIFO_OVRF: FIFO Overflow. Set when the FIFO that is feeding packets to PPA overflows.
4	X	PPA_PL_CRC_ERR: PayLoad CRC Error. Set when a packet that was processed by PPA had a payload CRC error.
3	X	PPA_SL_PKT_DROPPED: Short Line Packet Dropped. Set when an incoming packet gets dropped because the input FIFO level reaches CSI_A_SKIP_PACKET_THRESHOLD when padding a short line.
2	X	PPA_SL_PROCESSED: Short Line Processed. Set when a line with a payload that is shorter than its packet header word count is processed by PPA.
1	X	PPA_ILL_WD_CNT: Illegal Word Count. Set when a line with a word count that does not generate an integer number of pixels (Unused bytes at the end of payload) is processed by PPA.
0	X	PPA_HDR_ERR_COR: Header Error Corrected. Set when a packet that was processed by PPA has a single bit header error. This error will be detected by the headers ECC, and corrected by it if header error correction is enabled (CSI_A_HEADER_EC_ENABLE = 0). This flag will be set and the packet will be processed even if the error is not corrected.

30.13.21 CSI_CSI_CIL_STATUS_0

CSI Control and Interface Logic Status

Each status bit is cleared to zero when its bit position is written with one. For example, writing 0x2 to CSI_CIL_STATUS will clear only CILA_SOT_MB_ERR.

Offset: 0x21f | Byte Offset: 0x87c | Read/Write: RO | Reset: 0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx

Bit	Reset	Description
22	X	CILB_ESC_DATA_REC: Escape Mode Data Received. Set when CIL-B receives an Escape Mode Data Byte. The Data Byte can be read from bits 23:16 of ESCAPE_MODE_DATA. This status bit will also be cleared when CILB_ESC_CMD_REC is set.
21	X	CILB_ESC_CMD_REC: Escape Mode Command Received. Set when CIL-B receives an Escape Mode Command byte. The Command Byte can be read from bits 23:16 of ESCAPE_MODE_COMMAND.
20	X	CILB_CTRL_ERR: Control Error. Set when CIL-B detects LP state 01 or 10 followed by a stop state (LP11) instead of transitioning into the Escape mode or Turn Around mode (LP00)..
19	X	CILB_ESC_ENTRY_ERR: Escape Mode Entry Error. Set when CIL-B detects an Escape Mode Entry Error. The Escape mode command byte will not be received.
18	X	CILB_SYNC_ESC_ERR: Sync Escape Error. Set when CIL-B detects that the wrong (non-multiple of 8) number of bits have been received for an Escape Command or Data Byte.
17	X	CILB_SOT_MB_ERR: Start of Transmission Multi Bit Error. Set when CIL-B detects a multi-bit start of transmission byte error in one of the packet's SOT bytes. The packet will be discarded.
16	X	CILB_SOT_SB_ERR: Start of Transmission Single Bit Error. Set when CIL-B detects a single bit error in one of the packet's start of transmission bytes. The packet will be sent to CSI-B for processing.
15	X	MIPI_AUTO_CAL_DONE: MIPI Auto Calibrate done. This bit field has been moved to armipi_cal. The definition is maintained here for backward compatibility.
6	X	CILA_ESC_DATA_REC: Escape Mode Data Received. Set when CIL-A receives an Escape Mode Data byte. The Data Byte can be read from bits 7:0 of ESCAPE_MODE_DATA. This status bit will also be cleared when CILA_ESC_CMD_REC is set.
5	X	CILA_ESC_CMD_REC: Escape Mode Command Received. Set when CIL-A receives an Escape Mode Command byte. The Command Byte can be read from bits 7:0 of ESCAPE_MODE_COMMAND.
4	X	CILA_CTRL_ERR: Control Error. Set when CIL-A detects LP state 01 or 10 followed by a stop state (LP11) instead of transitioning into the Escape mode or Turn Around mode (LP00).
3	X	CILA_ESC_ENTRY_ERR: Escape Mode Entry Error. Set when CIL-A detects an escape mode entry error. The Escape mode command byte will not be received.
2	X	CILA_SYNC_ESC_ERR: Sync Escape Error. Set when CIL-A detects that the wrong (non-multiple of 8) number of bits have been received for an Escape Command or Data Byte.
1	X	CILA_SOT_MB_ERR: Start of Transmission Multi Bit Error. Set when CIL-A detects a multi-bit start of transmission byte error in one of the packet's SOT bytes. The packet will be discarded.
0	X	CILA_SOT_SB_ERR: Start of Transmission Single Bit Error. Set when CIL-A detects a single bit error in one of the packet's Start of Transmission bytes. The packet will be sent to the CSI-A for processing.

30.13.22 CSI_CSI_PIXEL_PARSER_INTERRUPT_MASK_0

CSI Pixel Parser Interrupt Mask

Offset: 0x220 | Byte Offset: 0x880 | Read/Write: R/W | Reset: 0b00xx00000000000000xx000000000000

Bit	Reset	Description
31	0x0	HPH_UNC_HDR_ERR_INT_MASK: Interrupt Mask for HPH_UNC_HDR_ERR. Generate an interrupt when HPH_UNC_HDR_ERR is set. 0 = DISABLED: Do not generate an interrupt when HPH_UNC_HDR_ERR is set. 1 = ENABLED
30	0x0	HPV_UNC_HDR_ERR_INT_MASK: Interrupt Mask for HPV_UNC_HDR_ERR. Generate an interrupt when HPV_UNC_HDR_ERR is set. 0 = DISABLED: Do not generate an interrupt when HPV_UNC_HDR_ERR is set. 1 = ENABLED
26	0x0	PPB_SPARE_STATUS_1_INT_MASK: Interrupt Mask for PPB_SPARE_STATUS_1. Generate an interrupt when PPB_SPARE_STATUS_1 is set. 0 = DISABLED: Do not generate an interrupt when PPB_SPARE_STATUS_1 is set. 1 = ENABLED
25	0x0	PPB_INTERFRAME_LINE_INT_MASK: Interrupt Mask for PPB_INTERFRAME_LINE. Generate an interrupt when PPB_INTERFRAME_LINE is set. 0 = DISABLED: Do not generate an interrupt when PPB_INTERFRAME_LINE is set. 1 = ENABLED

30.13.23 CSI_CSI_CIL_INTERRUPT_MASK_0

CSI Control and Interface Logic Interrupt Mask

Offset: 0x221 | Byte Offset: 0x884 | Read/Write: R/W | Reset: 0bxxxxxx0000000000xxxxxx0000000000

Bit	Reset	Description
22	0x0	CILB_ESC_DATA_REC_INT_MASK: Interrupt Mask for CILB_ESC_DATA_REC. Generate an interrupt when CILB_ESC_DATA_REC is set. 0 = DISABLED: Do not generate an interrupt when CILB_ESC_DATA_REC is set. 1 = ENABLED
21	0x0	CILB_ESC_CMD_REC_INT_MASK: Interrupt Mask for CILB_ESC_CMD_REC. Generate an interrupt when CILB_ESC_CMD_REC is set. 0 = DISABLED: Do not generate an interrupt when CILB_ESC_CMD_REC is set. 1 = ENABLED
20	0x0	CILB_CTRL_ERR_INT_MASK: Interrupt Mask for CILB_CTRL_ERR. Generate an interrupt when CILB_CTRL_ERR is set. 0 = DISABLED: Do not generate an interrupt when CILB_CTRL_ERR is set. 1 = ENABLED
19	0x0	CILB_ESC_ENTRY_ERR_INT_MASK: Interrupt Mask for CILB_ESC_ENTRY_ERR. Generate an interrupt when CILB_ESC_ENTRY_ERR is set. 0 = DISABLED: Do not generate an interrupt when CILB_ESC_ENTRY_ERR is set. 1 = ENABLED
18	0x0	CILB_SYNC_ESC_ERR_INT_MASK: Interrupt Mask for CILB_SYNC_ESC_ERR. Generate an interrupt when CILB_SYNC_ESC_ERR is set. 0 = DISABLED: Do not generate an interrupt when CILB_SYNC_ESC_ERR is set. 1 = ENABLED
17	0x0	CILB_SOT_MB_ERR_INT_MASK: Interrupt Mask for CILB_SOT_MB_ERR. Generate an interrupt when CILB_SOT_MB_ERR is set. 0 = DISABLED: Do not generate an interrupt when CILB_SOT_MB_ERR is set. 1 = ENABLED
16	0x0	CILB_SOT_SB_ERR_INT_MASK: Interrupt Mask for CILB_SOT_SB_ERR. Generate an interrupt when CILB_SOT_SB_ERR is set. 0 = DISABLED: Do not generate an interrupt when CILB_SOT_SB_ERR is set. 1 = ENABLED
9	0x0	CILA_CLK_LANE_CTRL_ERR_INT_MASK: Interrupt Mask for CILA_CLK_CTRL_ERR. Generate an interrupt when CILA_CLK_CTRL_ERR is set. 0 = DISABLED: Do not generate an interrupt when CILA_CLK_CTRL_ERR is set. 1 = ENABLED
6	0x0	CILA_ESC_DATA_REC_INT_MASK: Interrupt Mask for CILA_ESC_DATA_REC. Generate an interrupt when CILA_ESC_DATA_REC is set. 0 = DISABLED: Do not generate an interrupt when CILA_ESC_DATA_REC is set. 1 = ENABLED
5	0x0	CILA_ESC_CMD_REC_INT_MASK: Interrupt Mask for CILA_ESC_CMD_REC. Generate an interrupt when CILA_ESC_CMD_REC is set. 0 = DISABLED: Do not generate an interrupt when CILA_ESC_CMD_REC is set. 1 = ENABLED
4	0x0	CILA_CTRL_ERR_INT_MASK: Interrupt Mask for CILA_CTRL_ERR. Generate an interrupt when CILA_CTRL_ERR is set. 0 = DISABLED: Do not generate an interrupt when CILA_CTRL_ERR is set. 1 = ENABLED
3	0x0	CILA_ESC_ENTRY_ERR_INT_MASK: Interrupt Mask for CILA_ESC_ENTRY_ERR. Generate an interrupt when CILA_ESC_ENTRY_ERR is set. 0 = DISABLED: Do not generate an interrupt when CILA_ESC_ENTRY_ERR is set. 1 = ENABLED
2	0x0	CILA_SYNC_ESC_ERR_INT_MASK: Interrupt Mask for CILA_SYNC_ESC_ERR. Generate an interrupt when CILA_SYNC_ESC_ERR is set. 0 = DISABLED: Do not generate an interrupt when CILA_SYNC_ESC_ERR is set. 1 = ENABLED

Bit	Reset	Description
1	0x0	CILA_SOT_MB_ERR_INT_MASK: Interrupt Mask for CILA_SOT_MB_ERR. Generate an interrupt when CILA_SOT_MB_ERR is set. 0 = DISABLED: Do not generate an interrupt when CILA_SOT_MB_ERR is set. 1 = ENABLED
0	0x0	CILA_SOT_SB_ERR_INT_MASK: Interrupt Mask for CILA_SOT_SB_ERR. Generate an interrupt when CILA_SOT_SB_ERR is set. 0 = DISABLED: Do not generate an interrupt when CILA_SOT_SB_ERR is set. 1 = ENABLED

30.13.24 CSI_CSI_READONLY_STATUS_0

CSI Read Only Status

This register is used to return CSI read only status.

Offset: 0x222 | Byte Offset: 0x888 | Read/Write: RO | Reset: 0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx

Bit	Reset	Description
1	X	CSI_PPB_ACTIVE: One only when Pixel Parser B is capturing frame data.
0	X	CSI_PPA_ACTIVE: One only when Pixel Parser A is capturing frame data.

30.13.25 CSI_ESCAPE_MODE_COMMAND_0

Escape Mode Command

This register is used to receive escape mode command bytes from CIL-A and CIL-B.

Offset: 0x223 | Byte Offset: 0x88c | Read/Write: RO | Reset: 0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx

Bit	Reset	Description
31:24	X	CILD_ESC_CMD_BYTE: CIL-D Escape Mode Command Byte. This is the 8-bit entry command that was received by CIL-D, during the last escape mode sequence. This command byte can only be assumed to be valid when the CILD_ESC_CMD_REC status bit is set.
23:16	X	CILB_ESC_CMD_BYTE: CIL-B Escape Mode Command Byte. This is the 8-bit entry command that was received by CIL-C, during the last escape mode sequence. This command byte can only be assumed to be valid when the CILC_ESC_CMD_REC status bit is set.
15:8	X	CILC_ESC_CMD_BYTE: CIL-C Escape Mode Command Byte. This is the 8-bit entry command that was received by CIL-B, during the last escape mode sequence. This command byte can only be assumed to be valid when the CILB_ESC_CMD_REC status bit is set.
7:0	X	CILA_ESC_CMD_BYTE: CIL-A Escape Mode Command Byte. This is the 8-bit entry command that was received by CIL-A, during the last escape mode sequence. CIL-A monitors Byte Lane 0 only for escape mode sequences. This command byte can only be assumed to be valid when the CILA_ESC_CMD_REC status bit is set.

30.13.26 CSI_ESCAPE_MODE_DATA_0

Escape Mode Data

This register is used to receive escape mode data bytes from CIL-A and CIL-B.

Offset: 0x224 | Byte Offset: 0x890 | Read/Write: RO | Reset: 0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx

Bit	Reset	Description
31:24	X	CILD_ESC_DATA_BYTE: CIL-D Escape Mode Data Byte. When read, this field returns the last Escape Mode Data byte that was received by CIL-B. Escape Mode Data bytes are the bytes that are received in Escape Mode after receiving the Escape Mode Command. These bytes can be used to implement MIPI's CSI Specs Low Power Data Transmission. This field is only valid when the status bit, CILD_ESC_DATA_REC, is set, and will be overwritten by the next Escape Mode data byte if not read before the next byte come in.
23:16	X	CILB_ESC_DATA_BYTE: CIL-B Escape Mode Data Byte. When read, this field returns the last Escape Mode Data byte that was received by CIL-B. Escape Mode Data bytes are the bytes that are received in Escape Mode after receiving the Escape Mode Command. These bytes can be used to implement MIPI's CSI Specs Low Power Data Transmission. This field is only valid when the status bit, CILB_ESC_DATA_REC, is set, and will be overwritten by the next Escape Mode data byte if not read before the next byte come in.
15:8	X	CILC_ESC_DATA_BYTE: CIL-C Escape Mode Data Byte. When read, this field returns the last Escape Mode Data byte that was received by CIL-B. Escape Mode Data bytes are the bytes that are received in Escape Mode after receiving the Escape Mode Command. These bytes can be used to implement MIPI's CSI Specs Low Power Data Transmission. This field is only valid when the status bit, CILB_ESC_DATA_REC, is set, and will be overwritten by the next Escape Mode data byte if not read before the next byte come in.
7:0	X	CILA_ESC_DATA_BYTE: CIL-A Escape Mode Data Byte. When read, this field returns the last Escape Mode Data byte that was received by CIL-A. Escape Mode Data bytes are the bytes that are received in Escape Mode after receiving the Escape Mode Command. These bytes can be used to implement MIPI's CSI Specs Low Power Data Transmission. This field is only valid when the status bit, CILA_ESC_DATA_REC, is set, and will be overwritten by the next Escape Mode data byte if not read before the next byte come in.

30.13.27 CSI_CILA_PAD_CONFIG0_0

CIL-A Pad Configuration 0

Offset: 0x225 | Byte Offset: 0x894 | Read/Write: R/W | Reset: 0b0000000000000010x000x0000000x111

Bit	Reset	Description
31	0x0	PAD_CILA_E_TXBW: Increase bandwidth of output driver.
30:28	0x0	PAD_CILA_SLEWDNADJ: Pull-down slew rate adjust. Default = 000. From 000 -> 011, slew rate increases 100 is the same as 000 From 100->111, skew rate decreases.
27:25	0x0	PAD_CILA_SLEWUPADJ: Pull-up slew rate adjust. Default = 000. From 000 -> 011, slew rate increases 100 is the same as 000 From 100->111, skew rate decreases.
24:22	0x0	PAD_CILA_LPDNADJ: Driver pull-down impedance control. 00: 130 ohms, default 01: 110 ohms 10: 130 ohms, same as 00 11: 150 ohms

Bit	Reset	Description
21:19	0x0	PAD_CILA_LPUPADJ: Driver pull-up impedance control. 00: 130 ohms, default 01: 110 ohms 10: 130 ohms, same as 00 11: 150 ohms
18:17	0x1	PAD_AB_BK_MODE: 00: two independent 2x bricks 01: one 4x brick, received clock from partition A is used. Clock from partition B is not used 10: one 4x brick, received clock from partition B is used. Clock from partition A is not used 11: illegal
16	0x0	PAD_CILA_BANDWD_IN: Increase bandwidth of differential receiver
14:12	0x0	PAD_CILA_INADJ1: bit 1 input delay trimmer, each tap delays 20 ps
10:8	0x0	PAD_CILA_INADJ0: bit 0 input delay trimmer, each tap delays 20 ps
7	0x0	PAD_CILA_PDVCLAMP: Power-down regulator which supplies current to the serializer/deserializer logic
6:4	0x0	PAD_CILA_INADJCLK: Clock bit input delay trimmer, each tap delays 20 ps
2	0x1	PAD_CILA_PDIO_CLK: Power down for clock bit, including drivers, receivers, and contention detectors
1:0	0x3	PAD_CILA_PDIO: Power down for each data bit, including drivers, receivers, and contention detectors

30.13.28 CSI_CILA_PAD_CONFIG1_0

CIL-A Pad Configuration 4

Offset: 0x226 | Byte Offset: 0x898 | Read/Write: R/W | Reset: 0bxxxxxxxxxxxxxxxx0000000000000000

Bit	R/W	Reset	Description
31:16	RO	X	PAD_CILA_SPARE_RO: Spare Read only bits for CILA Config
15:8	RW	0x0	PAD_CILA_SPARE: Spare bits for CILA Config. PAD_CILA_SPARE[15] is used to disable the CSI-A RTL code that blocks FIFO pushes that are past the end of the line packet. 0: Disabled 1: Push blocking enabled
7:6	RW	0x0	PAD_CILA_PEMPD_CLK: Enable data bit HS driver pull-down pre-emphasis. 00: no pre-emphasis 11: max
5:4	RW	0x0	PAD_CILA_PEMPU_CLK: Enable data bit HS driver pull up pre-emphasis 00: no pre-emphasis 11: max

30.13.31 CSI_CIL_PAD_CONFIG0_0

CIL Pad Configuration 0

Offset: 0x229 | Byte Offset: 0x8a4 | Read/Write: R/W | Reset: 0bxxxxxxxxxxxxxx00000000000x000xx10

Bit	Reset	Description
18:16	0x0	PAD_CIL_VCLAMP_LEVEL: This field is deprecated VI register space and has been moved to the armipi_cal space.
15:8	0x0	PAD_CIL_SPARE: Spare bit for CIL BIAS Config PAD_CIL_SPARE[7] is used to flush VI's Y-FIFO when it is used as a stream source for one of the Pixel Parsers. Setting PAD_CIL_SPARE[7] to 1 will hold vi2csi_host_stall low, which forces VI's Y-FIFO to be purged. PAD_CIL_SPARE[7] must be low for the pixel parser to receive source data from VI's Y-FIFO.
6:4	0x0	PAD_CIL_VADJ: This field is deprecated VI register space and has been moved to the armipi_cal space.
1	0x1	PAD_CIL_PDVREG: This field is deprecated VI register space and has been moved to the armipi_cal space.
0	0x0	PAD_CIL_VBYPASS: This field is deprecated VI register space and has been moved to the armipi_cal space.

30.13.32 CSI_MIPIBIAS_PAD_CONFIG0_0

All fields of this register are deprecated. Writes are ignored; Reads return zero.

MIPI Bias Pad Configuration Register

Offset: 0x235 | Byte Offset: 0x8d4 | Read/Write: R/W | Reset: 0bxxxxx000xxxxx000xxxxx000xxxxx000

Bit	Reset	Description
26:24	0x0	PAD_TEST_SEL
18:16	0x0	PAD_DRIV_DN_REF
10:8	0x0	PAD_DRIV_UP_REF
2:0	0x0	PAD_TERM_REF

30.13.33 CSI_CSI_CILA_STATUS_0

CSI-CILA Control and Interface Logic Status

Each status bit is cleared to zero when its bit position is written with one. For example, writing 0x20 to CSI_CIL_STATUS will clear only SOT_MB_ERR.

Offset: 0x236 | Byte Offset: 0x8d8 | Read/Write: R/O | Reset: 0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx

Bit	Reset	Description
18	X	CILA_DATA_LANE1_CTRL_ERR: Control Error, set when CIL-A detects LP state 01 or 10 followed by a stop state (LP11) instead of transitioning.
17	X	CILA_DATA_LANE1_SOT_MB_ERR: Start of Transmission Multi Bit Error, set when CIL-A detects a multi-bit start of transmission byte error in one of the packet's SOT bytes on data lane-1. The packet will be discarded.
16	X	CILA_DATA_LANE0_CTRL_ERR: Control Error, set when CIL-A detects LP state 01 or 10 followed by a stop state (LP11) instead of transitioning.
6	X	CILA_DATA_LANE0_CTRL_ERR: Control Error, set when CIL-A detects LP state 01 or 10 followed by a stop state (LP11) instead of transitioning.
5	X	CILA_DATA_LANE0_SOT_MB_ERR: Start of Transmission Multi Bit Error, set when CIL-A detects a multi-bit start of transmission byte error in one of the packet's SOT bytes on data lane-0. The packet will be discarded.
4	X	CILA_DATA_LANE0_SOT_SB_ERR: Start of Transmission Single Bit Error, set when CIL-A detects a single bit error in one of the packet's Start of Transmission bytes on data lane-0. The packet will be sent to the CSI-A for processing.
0	X	CILA_CLK_LANE_CTRL_ERR: Control Error, set when CIL-A detects incorrect line state sequence on the clock lane.

30.13.34 CSI_CSI_CILB_STATUS_0

CSI-CILB Control and Interface Logic Status

Each status bit is cleared to zero when its bit position is written with one. For example, writing 0x20 to CSI_CIL_STATUS will clear only SOT_MB_ERR.

Offset: 0x237 | Byte Offset: 0x8dc | Read/Write: R/O | Reset: 0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx

Bit	Reset	Description
18	X	CILB_DATA_LANE1_CTRL_ERR: Control Error. Set when CIL-B detects LP state 01 or 10 followed by a stop state (LP11) instead of transitioning
17	X	CILB_DATA_LANE1_SOT_MB_ERR: Start of Transmission Multi Bit Error, set when CIL-B detects a multi-bit start of transmission byte error in one of the packet's SOT bytes on data lane 1. The packet will be discarded.
16	X	CILB_DATA_LANE1_SOT_SB_ERR: Start of Transmission Single Bit Error, set when CIL-B detects a single bit error in one of the packet's Start of Transmission bytes on data lane 1. The packet will be sent to the CSI-B for processing.
6	X	CILB_DATA_LANE0_CTRL_ERR: Control Error, set when CIL-B detects LP state 01 or 10 followed by a stop state (LP11) instead of transitioning
5	X	CILB_DATA_LANE0_SOT_MB_ERR: Start of Transmission Multi Bit Error, set when CIL-B detects a multi-bit start of transmission byte error in one of the packet's SOT bytes on data lane 0. The packet will be discarded.
4	X	CILB_DATA_LANE0_SOT_SB_ERR: Start of Transmission Single Bit Error, set when CIL-B detects a single bit error in one of the packet's Start of Transmission bytes on data lane 0. The packet will be sent to the CSI-B for processing.

Bit	Reset	Description
0	X	CILB_CLK_LANE_CTRL_ERR: Control Error, set when CIL-B detects an incorrect line state sequence on the clock lane

30.13.35 CSI_CSI_CILC_STATUS_0

CSI-CILC Control and Interface Logic Status

Each status bit is cleared to zero when its bit position is written with one. For example, writing 0x20 to CSI_CIL_STATUS will clear only SOT_MB_ERR.

Offset: 0x239 | Byte Offset: 0x8e4 | Read/Write: R/O | Reset: 0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx

Bit	Reset	Description
18	X	CILC_DATA_LANE1_CTRL_ERR: Control Error. Set when CIL-C detects LP state 01 or 10 followed by a stop state (LP11) instead of transitioning
17	X	CILC_DATA_LANE1_SOT_MB_ERR: Start of Transmission Multi Bit Error. Set when CIL-C detects a multi-bit start of transmission byte error in one of the packet's SOT bytes on data lane-1. The packet will be discarded.
16	X	CILC_DATA_LANE1_SOT_SB_ERR: Start of Transmission Single Bit Error. Set when CIL-C detects a single bit error in one of the packet's Start of Transmission bytes on data lane-1. The packet will be sent to the CSI-C for processing.
6	X	CILC_DATA_LANE0_CTRL_ERR: Control Error. Set when CIL-C detects LP state 01 or 10 followed by a stop state (LP11) instead of transitioning.
5	X	CILC_DATA_LANE0_SOT_MB_ERR: Start of Transmission Multi Bit Error. Set when CIL-C detects a multi bit start of transmission byte error in one of the packet's SOT bytes on data lane-0. The packet will be discarded.
4	X	CILC_DATA_LANE0_SOT_SB_ERR: Start of Transmission Single Bit Error. Set when CIL-C detects a single bit error in one of the packet's Start of Transmission bytes on data lane-0. The packet will be sent to the CSI-C for processing.
0	X	CILC_CLK_LANE_CTRL_ERR: Control Error. Set when CIL-C detects incorrect line state sequence on the clock lane.

30.13.36 CSI_CSI_CILD_STATUS_0

CSI-CILD Control and Interface Logic Status

Each status bit is cleared to zero when its bit position is written with one. For example, writing 0x20 to CSI_CIL_STATUS will clear only SOT_MB_ERR.

Offset: 0x23a | Byte Offset: 0x8e8 | Read/Write: R/O | Reset: 0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx

Bit	Reset	Description
18	X	CILD_DATA_LANE1_CTRL_ERR: Control Error. Set when CIL-D detects LP state 01 or 10 followed by a stop state (LP11) instead of transitioning.
17	X	CILD_DATA_LANE1_SOT_MB_ERR: Start of Transmission Multi Bit Error. Set when CIL-D detects a multi-bit start of transmission byte error in one of the packet's SOT bytes on data lane-1. The packet will be discarded.
16	X	CILD_DATA_LANE1_SOT_SB_ERR: Start of Transmission Single Bit Error. Set when CIL-D detects a single bit error in one of the packet's Start of Transmission bytes on data lane-1. The packet will be sent to the CSI-D for processing.
6	X	CILD_DATA_LANE0_CTRL_ERR: Control Error. Set when CIL-D detects LP state 01 or 10 followed by a stop state (LP11) instead of transitioning.

Bit	Reset	Description
5	X	CILD_DATA_LANE0_SOT_MB_ERR: Start of Transmission Multi Bit Error. Set when CIL-D detects a multi-bit start of transmission byte error in one of the packet's SOT bytes on data lane-0. The packet will be discarded.
4	X	CILD_DATA_LANE0_SOT_SB_ERR: Start of Transmission Single Bit Error. Set when CIL-D detects a single bit error in one of the packet's Start of Transmission bytes on data lane-0. The packet will be sent to the CSI-D for processing.
0	X	CILD_CLK_LANE_CTRL_ERR: Control Error. Set when CIL-D detects incorrect line state sequence on the clock lane.

30.13.37 CSI_PHY_CILC_CONTROL0_0

CSI-C PHY and CIL Control

Offset: 0x23e | Byte Offset: 0x8f8 | Read/Write: R/W | Reset: 0bxxxxxxxxxxxxxxxxxxxxx0000xx0x0010

Bit	Reset	Description
11:8	0x0	CILC_CLK_SETTLE: Settle time for the clock lane when moving from LP to HS (LP11->LP01->LP00). This setting determines how many CSICIL clock cycles (102 MHz LP clock cycles) to wait after LP00. Hardware uses an internal delay of ~15 CSICIL cycles for default value. So the programming value (0 to 15) of this field works as follows: 0 = 15 cilclk cycles (default internal delay) 1 = 15 - 7 (8 cilclk cycles) 2 = 15 - 6 (9 cilclk cycles) … 7 = 15 - 1 (14 cilclk cycles) 8 = 15 - 0 (default internal delay) 9 = 15 + 1 (16 cilclk cycles) … 15 = 15 + 7 (22 cilclk cycles)
5	0x0	CILC_BYPASS_LP_SEQ: The LP signals should sequence through LP11->LP01->LP00 states to indicate to CLOCK CIL about the mode switching to HS Rx mode. In case the camera is enabled earlier than CIL, it is highly likely that the camera sends this control sequence sooner than CIL can detect it. Enabling this bit allows the CLOCK CIL to overlook the LP control sequence and step in HS Rx mode directly looking at LP00 only.
3:0	0x2	CILC_THS_SETTLE: Settle time for data lane when moving from LP to HS (LP11->LP01->LP00). This setting determines how many csicil clock cycles (102 MHz LP clock cycles) to wait, after LP00, before starting to look at the data. 0xF is an illegal value for this field 85ns + 6 * UI < (Ths-settle-programmed + 5) * csicil_clk_period < 145ns + 10 * UI

30.13.38 CSI_PHY_CILD_CONTROL0_0

CSI-D PHY and CIL Control

31.0 MIPI D-PHY CALIBRATION FOR CSI AND DSI

This section describes the MIPI D-PHY Calibration registers. This information is provided to aid in system debug and diagnostics. It is expected that NVIDIA® supplied drivers will normally be used to program these.

MIPI D-PHY blocks are used for both the DSI display interface and the CSI camera interface. Both interfaces are controlled by these registers.

31.1 MIPI-CAL Registers

Refer to “Reading Register Tables” in the Introduction section for the register table protocol as well as recommendations for accessing registers.

31.1.1 MIPI_CAL_MIPI_CAL_CTRL_0

Calibration Control Register

Offset: 0x0 | Read/Write: R/W | Reset: 0x2a000000 (0bxx101010xxxxxxxxxxxxxxxxxxxx0xx00)

Bit	R/W	Reset	Description
29:26	RW	0xa	MIPI_CAL_NOISE_FLT: The DRIVRY and TERMRY signals coming from MIPI pads are utilized by the Calibration state machine for pad calibration. The drivry/termry comes from a noisy analog source, which might have some glitches. The filter in calibsm is sensitive to these noises. If the calibration done status does not show up, the sensitivity of the filter can be changed through these bits. Ideally, this has to be programmed in a range from 10 to 15. When MIPI_CAL_PRESCALE = 2'b00, this needs to be programmed between 2 to 5.
25:24	RW	0x2	MIPI_CAL_PRESCALE: Auto-Cal calibration step prescale: 00: when calibration step is 0.1 µs 01: when calibration step is 0.5 µs 10: when calibration step is 1.0 µs (default) 11: when calibration step is 1.5 µs This keeps the MIPI bias calibration step between 0.1-1.5 µs.
4	RW	CLK_GATED	MIPI_CAL_CLKEN_OVR: 0 = CLK_GATED 1 = CLK_ALWAYS_ON
1	RW	0x0	MIPI_CAL_AUTOCAL_EN: When set, calibration is triggered periodically. The Period is set using MIPI_CAL_AUTOCAL_CTRL0 register
0	RO	0x0	MIPI_CAL_STARTCAL: Writing a one to this bit starts the Calibration State machine. This bit must be set even if both overrides are set in order to latch in the override value.

31.1.2 MIPI_CAL_MIPI_CAL_AUTOCAL_CTRL0_0

Offset: 0x4 | Read/Write: R/W | Reset: 0xffffffff (0b11111111111111111111111111111111)

Bit	Reset	Description
31:0	-1	MIPI_CAL_AUTOCAL_PERIOD: Auto-calibration period in number of APB sys clk cycles.

31.1.3 MIPI_CAL_CIL_MIPI_CAL_STATUS_0

CIL MIPI Calibrate Status

Offset: 0x8 | Read/Write: RO | Reset: 0xXXXXXXXX (0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx)

Bit	Reset	Description
31	X	MIPI_AUTO_CAL_DONE_DSID: Debug bit. MIPI Auto Calibrate done for DSID. Set when the auto calibrate sequence for DSI pad bricks is done. Write 1-to-clear.
30	X	MIPI_AUTO_CAL_DONE_DSIC: Debug bit. MIPI Auto Calibrate done for DSIC. Set when the auto calibrate sequence for DSI pad bricks is done. Write 1-to-clear.
29	X	MIPI_AUTO_CAL_DONE_DSIB: Debug bit. MIPI Auto Calibrate done for DSIB. Set when the auto calibrate sequence for DSI pad bricks is done. Write 1-to-clear.
28	X	MIPI_AUTO_CAL_DONE_DSIA: Debug bit. MIPI Auto Calibrate done for DSI. Set when the auto calibrate sequence for DSI pad bricks is done. Write 1-to-clear.
24	X	MIPI_AUTO_CAL_DONE_CSIE: Debug bit. MIPI Auto Calibrate done for CSI, set when the auto calibrate sequence for CSI pad bricks is done. Write 1-to-clear.
23	X	MIPI_AUTO_CAL_DONE_CSID: MIPI Auto Calibrate done for CSI. Set when the auto calibrate sequence for CSI pad bricks is done. Write 1-to-clear.
22	X	MIPI_AUTO_CAL_DONE_CSIC: Debug bit. MIPI Auto Calibrate done for CSI. Set when the auto calibrate sequence for CSI pad bricks is done. Write 1-to-clear.
21	X	MIPI_AUTO_CAL_DONE_CSIB: Debug bit. MIPI Auto Calibrate done for CSI. Set when the auto calibrate sequence for CSI pad bricks is done. Write 1-to-clear.
20	X	MIPI_AUTO_CAL_DONE_CSIA: Debug bit. MIPI Auto Calibrate done for CSI. Set when the auto calibrate sequence for CSI pad bricks is done. Write 1-to-clear.
16	X	MIPI_AUTO_CAL_DONE: MIPI Auto Calibrate done. Set when the auto-calibrate sequence for MIPI pad bricks is done. Write 1-to-clear.
15:12	X	MIPI_CAL_DRIV_DN_ADJ: Driver Pull-down calibration code generated by MIPI auto calibrate. Valid only after the auto-calibrate sequence has completed (MIPI_CAL_ACTIVE == 0).
11:8	X	MIPI_CAL_DRIV_UP_ADJ: Driver Pull up calibration code generated by MIPI auto calibrate. Valid only after auto calibrate sequence has completed (MIPI_CAL_ACTIVE == 0).
7:4	X	MIPI_CAL_TERMADJ: Termination code generated by MIPI auto calibrate. Valid only after the auto-calibrate sequence has completed (MIPI_CAL_ACTIVE == 0).
0	X	MIPI_CAL_ACTIVE: One when auto calibrate is active.

31.1.4 MIPI_CAL_CILA_MIPI_CAL_CONFIG_0

Calibration Settings for CIL-A MIPI Pads

Offset: 0x14 | Read/Write: R/W | Reset: 0x00200000 (0bx0xxxxxxx100000xxx00000xxx00000)

Bit	Reset	Description
30	0x0	MIPI_CAL_OVERIDEA: When 0 (normal operation), use TERMOS/HSPUOS/HSPDOS as an offset to the Calibration State machine setting for channel A TERMADJ/HSPUADJ/HSPDADJ values to the MIPI pads. When 1, use the register values above as the actual value going to channel A TERMADJ/HSPUADJ/HSPDADJ on the MIPI pads.
21	0x1	MIPI_CAL_SELA: Select the CSIA pads for auto calibration.
20:16	0x0	MIPI_CAL_HSPDOSA: 2's complement offset for HSPDADJ going to channel A
12:8	0x0	MIPI_CAL_HSPUOSA: 2's complement offset for HSPUADJ going to channel A
4:0	0x0	MIPI_CAL_TERMOSA: 2's complement offset for TERMADJ going to channel A

31.1.5 MIPI_CAL_CILB_MIPI_CAL_CONFIG_0

Calibration Settings for CIL-B MIPI Pads

Offset: 0x18 | Read/Write: R/W | Reset: 0x00200000 (0bx0xxxxxxx100000xxx00000xxx00000)

Bit	Reset	Description
30	0x0	MIPI_CAL_OVERIDEB: When 0 (normal operation), use TERMOS/HSPUOS/HSPDOS as an offset to the Calibration State machine setting for channel B TERMADJ/HSPUADJ/HSPDADJ values to the MIPI pads. When 1, use the register values above as the actual value going to channel B TERMADJ/HSPUADJ/HSPDADJ on the MIPI pads. Writing a one to MIPI_CAL_STARTCAL starts the Calibration State machine.
21	0x1	MIPI_CAL_SELB: Select the CSIB pads for auto calibration.
20:16	0x0	MIPI_CAL_HSPDOSB: 2's complement offset for HSPDADJ going to channel B
12:8	0x0	MIPI_CAL_HSPUOSB: 2's complement offset for HSPUADJ going to channel B
4:0	0x0	MIPI_CAL_TERMOSB: 2's complement offset for TERMADJ going to channel B

31.1.6 MIPI_CAL_CILC_MIPI_CAL_CONFIG_0

Calibration Settings for CIL-C MIPI Pads

Offset: 0x1c | Read/Write: R/W | Reset: 0x00200000 (0bx0xxxxxxx100000xxx00000xxx00000)

Bit	Reset	Description
30	0x0	MIPI_CAL_OVERIDEC: When 0 (normal operation), use TERMOS/HSPUOS/HSPDOS as an offset to the Calibration State machine setting for channel C TERMADJ/HSPUADJ/HSPDADJ values to the MIPI pads. When 1, use the register values above as the actual value going to channel C TERMADJ/HSPUADJ/HSPDADJ on the MIPI pads. Writing a one to MIPI_CAL_STARTCAL starts the Calibration State machine.
21	0x1	MIPI_CAL_SELC: Select the CSIC pads for auto calibration.
20:16	0x0	MIPI_CAL_HSPDOSC: 2's complement offset for HSPDADJ going to channel C
12:8	0x0	MIPI_CAL_HSPUOSC: 2's complement offset for HSPUADJ going to channel C
4:0	0x0	MIPI_CAL_TERMOSC: 2's complement offset for TERMADJ going to channel C

31.1.7 MIPI_CAL_CILD_MIPI_CAL_CONFIG_0

Calibration Settings for CIL-D MIPI Pads

Offset: 0x20 | Read/Write: R/W | Reset: 0x00200000 (0bx0xxxxxxx100000xxx00000xxx00000)

Bit	Reset	Description
30	0x0	MIPI_CAL_OVERIDED: When 0 (normal operation), use TERMOS/HSPUOS/HSPDOS as an offset to the Calibration State machine setting for channel D TERMADJ/HSPUADJ/HSPDADJ values to the MIPI pads. When 1, use the register values above as the actual value going to channel D TERMADJ/HSPUADJ/HSPDADJ on the MIPI pads. Writing a one to MIPI_CAL_STARTCAL starts the Calibration State machine.
21	0x1	MIPI_CAL_SELD: Select the CSID PADS for auto calibration.
20:16	0x0	MIPI_CAL_HSPDOSD: 2's complement offset for HSPDADJ going to channel D
12:8	0x0	MIPI_CAL_HSPUOSD: 2's complement offset for HSPUADJ going to channel D
4:0	0x0	MIPI_CAL_TERMOSD: 2's complement offset for TERMADJ going to channel D

31.1.8 MIPI_CAL_CILE_MIPI_CAL_CONFIG_0

Calibration Settings for CIL-E MIPI Pads

Offset: 0x24 | Read/Write: R/W | Reset: 0x00000000 (0bx0xxxxxxxx000000xxx00000xxx00000)

Bit	Reset	Description
30	0x0	MIPI_CAL_OVERIDEE: When 0 (normal operation), use TERMOS/HSPUOS/HSPDOS as an offset to the Calibration State machine setting for channel E TERMADJ/HSPUADJ/HSPDADJ values to the MIPI pads. When 1, use the register values above as the actual value going to channel E TERMADJ/HSPUADJ/HSPDADJ on the MIPI pads. Writing a one to MIPI_CAL_STARTCAL starts the Calibration State machine.
21	0x0	MIPI_CAL_SELE: Select the CSIE pads for auto calibration.
20:16	0x0	MIPI_CAL_HSPDOSE: 2's complement offset for HSPDADJ going to channel E
12:8	0x0	MIPI_CAL_HSPUOSE: 2's complement offset for HSPUADJ going to channel E
4:0	0x0	MIPI_CAL_TERMOSE: 2's complement offset for TERMADJ going to channel E

31.1.9 MIPI_CAL_DSIA_MIPI_CAL_CONFIG_0

Calibration Settings for DSIA MIPI Pad

Offset: 0x38 | Read/Write: R/W | Reset: 0x00200000 (0bx0xxxxxxxx100000xxx00000xxx00000)

Bit	Reset	Description
30	0x0	MIPI_CAL_OVERIDEDSIA: When 0 (normal operation), use TERMOS/HSPUOS/HSPDOS as an offset to the Calibration State machine setting for TERMADJ/HSPUADJ/HSPDADJ values to the MIPI pads. When 1, use the register values above as the actual value going to TERMADJ/HSPUADJ/HSPDADJ on the MIPI pads. Writing a one to MIPI_CAL_STARTCAL starts the Calibration State machine.
21	0x1	MIPI_CAL_SELDSIA: Select the DSI pads for auto calibration.
20:16	0x0	MIPI_CAL_HSPDOSDSIA: 2's complement offset for HSPDADJ
12:8	0x0	MIPI_CAL_HSPUOSDSIA: 2's complement offset for HSPUADJ
4:0	0x0	MIPI_CAL_TERMOSDSIA: 2's complement offset for TERMADJ

31.1.10 MIPI_CAL_DSIB_MIPI_CAL_CONFIG_0

Calibration Settings for DSIB MIPI Pad

Offset: 0x3c | Read/Write: R/W | Reset: 0x00200000 (0bx0xxxxxxxx100000xxx00000xxx00000)

Bit	Reset	Description
30	0x0	MIPI_CAL_OVERIDEDSIB: When 0 (normal operation), use TERMOS/HSPUOS/HSPDOS as an offset to the Calibration State machine setting for TERMADJ/HSPUADJ/HSPDADJ values to the MIPI pads. When 1, use the register values above as the actual value going to TERMADJ/HSPUADJ/HSPDADJ on the MIPI pads. Writing a one to MIPI_CAL_STARTCAL starts the Calibration State machine.
21	0x1	MIPI_CAL_SELDSIB: Select the DSI PADS for auto calibration.
20:16	0x0	MIPI_CAL_HSPDOSDSIB: 2's complement offset for HSPDADJ
12:8	0x0	MIPI_CAL_HSPUOSDSIB: 2's complement offset for HSPUADJ
4:0	0x0	MIPI_CAL_TERMOSDSIB: 2's complement offset for TERMADJ

31.1.11 MIPI_CAL_DSIC_MIPI_CAL_CONFIG_0

Calibration Settings for DSIC MIPI Pad

Offset: 0x40 | Read/Write: R/W | Reset: 0x00200000 (0bx0xxxxxxx100000xxx00000xxx00000)

Bit	Reset	Description
30	0x0	MIPI_CAL_OVERIDEDSIC: When 0 (normal operation), use TERMOS/HSPUOS/HSPDOS as an offset to the Calibration State machine setting for TERMADJ/HSPUADJ/HSPDADJ values to the MIPI pads. When 1, use the register values above as the actual value going to TERMADJ/HSPUADJ/HSPDADJ on the MIPI pads. Writing a one to MIPI_CAL_STARTCAL starts the Calibration State machine.
21	0x1	MIPI_CAL_SELDSIC: Select the DSI pads for auto calibration.
20:16	0x0	MIPI_CAL_HSPDOSDSIC: 2's complement offset for HSPDADJ
12:8	0x0	MIPI_CAL_HSPUOSDSIC: 2's complement offset for HSPUADJ
4:0	0x0	MIPI_CAL_TERMOSDSIC: 2's complement offset for TERMADJ

31.1.12 MIPI_CAL_DSID_MIPI_CAL_CONFIG_0

Calibration Settings for DSID MIPI Pad

Offset: 0x44 | Read/Write: R/W | Reset: 0x00200000 (0bx0xxxxxxx100000xxx00000xxx00000)

Bit	Reset	Description
30	0x0	MIPI_CAL_OVERIDEDSID: When 0 (normal operation), use TERMOS/HSPUOS/HSPDOS as an offset to the Calibration State machine setting for TERMADJ/HSPUADJ/HSPDADJ values to the MIPI pads. When 1, use the register values above as the actual value going to TERMADJ/HSPUADJ/HSPDADJ on the MIPI pads. Writing a one to MIPI_CAL_STARTCAL starts the Calibration State machine.
21	0x1	MIPI_CAL_SELDSID: Select the DSI pads for auto calibration.
20:16	0x0	MIPI_CAL_HSPDOSDSID: 2's complement offset for HSPDADJ

4:0	0x0	MIPI_CAL_TERMOSDSID: 2's complement offset for TERMADJ

31.1.13 MIPI_CAL_MIPI_BIAS_PAD_CFG0_0

MIPI Bias Pad Configuration Register 0

Offset: 0x58 | Read/Write: R/W | Reset: 0x00000000 (0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx00)

Bit	Reset	Description
1	0x0	MIPI_BIAS_PAD_PDVCLAMP: 1=Power down regulator which supplies current to pre-driver logic.
0	0x0	MIPI_BIAS_PAD_E_VCLAMP_REF: 1=Enable VCLAMP reference voltage

31.1.14 MIPI_CAL_MIPI_BIAS_PAD_CFG1_0

MIPI Bias Pad Configuration Register 1

Offset: 0x5c | Read/Write: R/W | Reset: 0x00000000 (0bxxxxx000xxxxx000xxxxx000xxxxx000)

Bit	Reset	Description
26:24	0x0	PAD_TEST_SEL: Controls which signal to be routed to TEST_OUT 000=VAUXP 001=RUP 010=RDN

Bit	Reset	Description
		011=VREG 1xx=TBD
18:16	0x0	PAD_DRIV_DN_REF: Adjust internal reference level for drive pull-down calibration
10:8	0x0	PAD_DRIV_UP_REF: Adjust internal reference level for drive pull-up calibration
2:0	0x0	PAD_TERM_REF: Adjust internal reference level for termination calibration

31.1.15 MIPI_CAL_MIPI_BIAS_PAD_CFG2_0

MIPI Bias Pad Configuration Register 2

Offset: 0x60 | Read/Write: R/W | Reset: 0x00000002 (0bxxxxxxxxxxxxxx00000000000x000xx10)

Bit	Reset	Description
18:16	0x0	PAD_VCLAMP_LEVEL: VCLAMP level adjustment
15:8	0x0	PAD_SPARE: Spare bit for MIPI Bias Config
6:4	0x0	PAD_VAUXP_LEVEL: VAUXP level adjustment 00 = no adjustment, default 01 = 105% 10 = 110% 11 = 115% 100 = no adjustment 101 = 95% 110 = 90% 111 = 85%
1	0x1	PAD_PDVREG: Power down voltage regulator, 1=power down
0	0x0	PAD_VBYPASS: Bypass bang gap voltage reference

32.0 VIDEO INPUT (VI)

The Video Input block is normally used to receive pixels from an external device, such as a camera, and transfer them to memory. The MIPI CSI interface connects to the VI block and transfers received data to VI.

This section describes the VI registers; however, it is not intended to be a programming guide to VI, as it is expected that NVIDIA supplied drivers will always be used with it. However, the register interface is documented to aid with understanding those drivers.

32.1 VI Registers

Refer to “Reading Register Tables” in the Introduction section for the register table protocol as well as recommendations for accessing registers.

32.1.1 VI_CTXSW_0

Context Switch Register

Should be common to all modules. Includes the current channel/class (which is writable by software) and the next channel/class (which the hardware sets when it receives a context switch).

Context switch works like this:

Any context switch request triggers an interrupt to the host and causes the new channel/class to be stored in NEXT_CHANNEL/NEXT_CLASS. Software sees that there is a context switch interrupt and does the necessary operations to make the module ready to receive traffic from the new context. It clears the context switch interrupt and writes CURR_CHANNEL/CLASS to the same value as NEXT_CHANNEL/CLASS, which causes a context switch acknowledge packet to be sent to the host. This completes the context switch and allows the host to continue sending data to the module.

Context switches can also be preloaded. If CURR_CLASS/CHANNEL are written and updated to the next CLASS/CHANNEL before the context switch request occurs, an acknowledge will be generated by the module, and no interrupt will be triggered. This is one way for software to avoid dealing with context switch interrupts.

Another way to avoid context switch interrupts is to set the AUTO_ACK bit. This bit tells the module to automatically acknowledge any incoming context switch requests without triggering an interrupt. CURR_* and NEXT_* will be updated by the module so they will always be current.

Offset: 0x20 | Byte Offset: 0x80 | Read/Write: R/W | Reset: 0xXXXXf800 (0bxxxxxxxxxxxxxxxx11111x0000000000)

Bit	R/W	Reset	Description
31:28	RO	X	NEXT_CHANNEL: Next requested channel
25:16	RO	X	NEXT_CLASS: Next requested class
15:12	RW	0xf	CURR_CHANNEL: Current working channel, reset to 'invalid'
11	RW	0x1	AUTO_ACK: Automatically acknowledge any incoming context switch requests 0 = MANUAL 1 = AUTOACK
9:0	RW	0x0	CURR_CLASS: Current working class

32.1.2 VI_INTSTATUS_0

Offset: 0x21 | Byte Offset: 0x84 | Read/Write: RO | Reset: 0x00000000 (0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx0)

Bit	Reset	Description
0	0x0	CTXSW_INT: Context switch interrupt status (clear on write)

32.1.3 VI_VI_INPUT_CONTROL_0

VI Input Control

Software must always program parallel cameras in a way that avoids simultaneous HSYNC and VSYNC active edges.

Offset: 0x22 | Byte Offset: 0x88 | Read/Write: R/W | Reset: 0x00000000 (0bx00000000xxxxxxxxxx0000000000000)

Bit	Reset	Description
30	0x0	V_COUNTER: Vertical Counter. 0= Enabled. 1= Disabled (reset to 0) 0 = ENABLED 1 = DISABLED

Take from the CSC Unit 0000= 16-bit RGB (B5G6R5), all RGB data can be pre or post decimated depending on mux select programming on the input to the Color Space Converter 0001= 16-bit RGB (B5G6R5) Dithered (This is currently NOT supported) 0010= 24-bit RGB (B8G8R8) Take from the YUV422 Core output path: (Same thing as using YUV422PRE and YUV_SOURCE==CORE_OUTPUT) 0011= YUV422 stream after downscaling, POST Take from the YUV422 paths: (see YUV_SOURCE field) 0100= YUV422 stream before downscaling, PRE Take from the WriteBuffer interface logic, which is used for JPEG Stream 0101= JPEG Stream (Pattern A,B,C) 0110= Reserved 0111= CSI_PPA Bayer direct to memory as a 16-bit value {6'b0, CSI_SVD[15:6]} 1000= CSI_PPB Bayer direct to memory as a 16-bit value {6'b0, CSI_SVD[15:6]} 1010=Reserved 1011=YUV422 stream from the ALT mux 0 = RGB16 1 = RGB16D 2 = RGB24 3 = YUV422POST 4 = YUV422PRE 5 = JPEG_STREAM 7 = CSI_PPA_BAYER 8 = CSI_PPB_BAYER 10 = YUV422ALT

32.1.7 VI_HOST_INPUT_FRAME_SIZE_0

Host Input Frame Width

Input Frame Width and Height give the total input data dimensions. The VI input stage will cull/clip pixels outside the Active Region (see register VI_HOST_H_ACTIVE and VI_HOST_V_ACTIVE). The amount of data per frame is expected to be INPUT_WIDTH * INPUT_HEIGHT * the bytes per pixel (determined from the INPUT_HOST_FORMAT). For planar, the BPP is 1 for the Y FIFO and 1/2 for U and V. For non planar, it is 2.

The Bayer data is treated as 1 byte per pixel, so if it is more, then the input width and the H_ACTIVE should be scaled accordingly, so that internally generated HSYNC and VSYNCs for ISP are correct.

For Bayer input, it is important to insert blanking data for horizontal and vertical, allowing ISP to do sideband calculations.

Offset: 0x26 | Byte Offset: 0x98 | Read/Write: R/W | Reset: 0xXXXXXXXX (0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx)

Bit	Reset	Description
28:16	X	INPUT_FRAME_HEIGHT: Host Input Frame Height. Specifies in terms of lines the height of the input data coming from host.
12:0	X	INPUT_FRAME_WIDTH: Specifies in terms of pixels the width of the input data coming from host.

32.1.8 VI_HOST_H_ACTIVE_0

VI Horizontal Active

This register defines the horizontal active area of the input video source with respect to the internally generated horizontal sync. (This is for data coming in from host.)

Offset: 0x27 | Byte Offset: 0x9c | Read/Write: R/W | Reset: 0xXXXXXXXX (0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx)

Bit	Reset	Description
28:16	X	HOST_H_ACTIVE_PERIOD: Horizontal Active Period. This parameter specifies the number of pixels in the horizontal active area. H_ACTIVE_START + H_ACTIVE_PERIOD should be less than 2^NV_VI_H_IN (or 8192). This parameter should be programmed with an even number (bit 16 is ignored internally).
12:0	X	HOST_H_ACTIVE_START: Horizontal Active Start (offset to active). This parameter specifies the number of pixels to be discarded until the first active pixel. If programmed to 0, the first active pixel is the first pixel popped from the Host YUV FIFO.

32.1.9 VI_HOST_V_ACTIVE_0

Vertical Active

This register defines the vertical active area of the input video source with respect to the internally generated vertical sync. (This is for data coming in from the host.)

Offset: 0x28 | Byte Offset: 0xa0 | Read/Write: R/W | Reset: 0xXXXXXXXX (0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx)

Bit	Reset	Description
28:16	X	HOST_V_ACTIVE_PERIOD: Vertical Active Period. This parameter specifies the number of lines in the vertical active area. V_ACTIVE_START + V_ACTIVE_PERIOD should be less than 2^NV_VI_V_IN (or 8192).
12:0	X	HOST_V_ACTIVE_START: Vertical Active Start (offset to active) This parameter specifies the number of horizontal sync active edges from vertical sync active edge to the first vertical active line. If programmed to 0, the first active line starts after the first horizontal sync active edge following the vertical sync active edge.

32.1.10 VI_VIP_H_ACTIVE_0

This register is reserved.

Offset: 0x29 | Byte Offset: 0xa4 | Read/Write: R/W | Reset: 0xXXXXXXXX (0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx)

Bit	Reset	Description

Bit	Reset	Description
26:0	X	WB_STATUS: Status of the Host DMA write buffer

32.1.17 VI_HOST_DMA_WRITE_PEND_BUFCOUNT_0

Host DMA Write Buffer Pending Buffer Count

Offset: 0x30 | Byte Offset: 0xc0 | Read/Write: RO | Reset: 0x00000XXX (0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx)

Bit	Reset	Description
8:0	X	PEND_BUFCOUNT: Pending buffer count of the Host DMA write buffer.

32.1.18 VI_VB0_START_ADDRESS_FIRST_0

Video Buffer O Start Address for First Output

First Output Registers

These registers are used to setup the first of two memory outputs for VI Address Y, U, V; Frame size; Count; Size (line stride and block height); and Buffer Stride

Offset: 0x31 | Byte Offset: 0xc4 | Read/Write: R/W | Reset: 0xXXXXXXXX (0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx)

Bit	Reset	Description
31:0	X	VB0_START_ADDRESS_1: This is the byte address of video buffer 0 if output data format is RGB or YUV non-planar. This is the byte address of video buffer 0 Y-plane if output data format is YUV planar.

32.1.19 VI_VB0_BASE_ADDRESS_FIRST_0

Video Buffer O BASE Address for First Output

BASE address is used in Tiling mode. The BASE address always points to the left_upper corner of a surface. A surface can contain multiple buffers, in circular_buffer case.

Writes to the BASE address register will cause the corresponding internal buffer index to be reset to zero.

Offset: 0x32 | Byte Offset: 0xc8 | Read/Write: R/W | Reset: 0xXXXXXXXX (0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx)

Bit	Reset	Description
31:0	X	VB0_BASE_ADDRESS_1: This is the first byte address of video buffer 0. This is the byte address of video buffer 0 Y-plane if output data format is planar.

32.1.20 VI_VB0_START_ADDRESS_U_0

Video Buffer O Start Address U (linked to First Output)

Offset: 0x33 | Byte Offset: 0xcc | Read/Write: R/W | Reset: 0xXXXXXXXX (0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx)

Bit	Reset	Description
31:0	X	VB0_START_ADDRESS_U: This is the byte address of video buffer 0 U-plane, if output data format is YUV planar. Due to clock gating, the primary OUTPUT_TO_MEMORY must be enabled and the OUTPUT_FORMAT must be set to a planar format prior to writing this register

32.1.21 VI_VB0_BASE_ADDRESS_U_0

Video Buffer O BASE Address U (linked to First Output)

Offset: 0x34 | Byte Offset: 0xd0 | Read/Write: R/W | Reset: 0xXXXXXXXX (0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx)

Bit	Reset	Description
31:0	X	VB0_BASE_ADDRESS_U: This is the first byte address of video buffer 0 U-plane, if output data format is planar.

32.1.22 VI_VB0_START_ADDRESS_V_0

Video Buffer O Start Address V (linked to First Output)

Offset: 0x35 | Byte Offset: 0xd4 | Read/Write: R/W | Reset: 0xXXXXXXXX (0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx)

Bit	Reset	Description
31:0	X	VB0_START_ADDRESS_V: This is the byte address of video buffer 0 V-plane, if output data format is YUV planar. Due to clock gating, the primary OUTPUT_TO_MEMORY must be enabled and the OUTPUT_FORMAT must be set to a planar format prior to writing this register

32.1.23 VI_VB0_BASE_ADDRESS_V_0

Video Buffer O BASE Address V (linked to First Output)

Offset: 0x36 | Byte Offset: 0xd8 | Read/Write: R/W | Reset: 0xXXXXXXXX (0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx)

Bit	Reset	Description
31:0	X	VB0_BASE_ADDRESS_V: This is the byte address of video buffer 0 V-plane, if output data format is YUV planar.

32.1.24 VI_VB0_SCRATCH_ADDRESS_UV_0

Video Buffer O Scratch Address UV (linked to First Output)

Offset: 0x37 | Byte Offset: 0xdc | Read/Write: R/W | Reset: 0xXXXXXXXX (0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx)

Bit	Reset	Description
31:0	X	VB0_SCRATCH_ADDRESS_UV: If OUTPUT_FORMAT is YUV420PA, this is used. This is the byte address of video buffer 0. UV intermediate data is saved here during the YUV422 to YUV420PA conversion. The size allocated needs to match the FIRST_FRAME_WIDTH register setting.

32.1.25 VI_FIRST_OUTPUT_FRAME_SIZE_0

Width and height of first output frame

This is the size of the frame being written to memory. Apply decimation or averaging to calculate the output frame size. Whether or not downscaling is used specify whatever the size of the frame being written to memory.

Offset: 0x38 | Byte Offset: 0xe0 | Read/Write: R/W | Reset: 0xXXXXXXXX (0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx)

Bit	Reset	Description
28:16	X	FIRST_FRAME_HEIGHT: Frame height in lines which the VI needs to process
12:0	X	FIRST_FRAME_WIDTH: Frame width in pixel which the VI needs to process

32.1.26 VI_VB0_COUNT_FIRST_0

Video Buffer Set 0 Count for First Output

Offset: 0x39 | Byte Offset: 0xe4 | Read/Write: R/W | Reset: 0x000000XX (0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx)

Bit	Reset	Description
7:0	X	VB0_COUNT_1: Video Buffer Set 0 Count. This specifies the number of buffers in video buffer set 0.

32.1.27 VI_VB0_SIZE_FIRST_0

Video Buffer Set 0 Size for First Output

Offset: 0x3a | Byte Offset: 0xe8 | Read/Write: R/W | Reset: 0xXXXXXXXX (0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx)

Bit	Reset	Description
28:16	X	VB0_V_SIZE_1: Video Buffer Set 0 Vertical Size. This specifies the number of lines in each buffer in video buffer set 0. This value will be divided by 2 for chroma buffers for YUV420 planar formats
12:0	X	VB0_H_SIZE_1: Video Buffer Set 0 Horizontal Size. This parameter specifies the line stride (in pixels) for lines in the video buffer set 0. For YUV non-planar format, this parameter must be programmed as multiple of 2 pixels (bit 0 is ignored). For YUV planar format, this parameter must be programmed as multiple of 8 pixels (bits 2-0 are ignored) and it specifies the luma line stride or twice the chroma line stride. This value is divided by 2 for chroma buffers for YUV422 and YUV420 planar formats

32.1.28 VI_VB0_BUFFER_STRIDE_FIRST_0

Video Buffer Set 0 Buffer Stride

Offset: 0x3b | Byte Offset: 0xec | Read/Write: R/W | Reset: 0xXXXXXXXX (0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx)

Bit	Reset	Description
31:30	X	VB0_BUFFER_STRIDE_C: Video Buffer Set 0 Chroma Buffer Stride 00= Equal to Luma Buffer Stride 01= Equal to Luma Buffer Stride divided by 2 in this case Luma Buffer Stride should be multiple of 2 bytes. 10= Equal to Luma Buffer Stride divided by 4 in this case Luma Buffer Stride should be multiple of 4 bytes. 1x= Reserved 0 = CBS1X 1 = CBS2X 2 = CBS4X
29:0	X	VB0_BUFFER_STRIDE_L: Video Buffer Set 0 Luma Buffer Stride This is luma buffer stride (in bytes)

32.1.29 VI_VB0_START_ADDRESS_SECOND_0

Video Buffer O Start Address for Second Output

Second Output Registers

These registers are used to set up the second of two memory outputs for VI Address; Frame size; Count; Size (line stride and block height); and Buffer Stride.

Offset: 0x3c | Byte Offset: 0xf0 | Read/Write: R/W | Reset: 0xXXXXXXXX (0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx)

Bit	Reset	Description
31:0	X	VB0_START_ADDRESS_2: This is byte address of video buffer 0 if output data format is RGB or YUV non-planar. This is byte address of video buffer 0. This output data is read by the SB function of the GR2D block.

32.1.30 VI_VB0_BASE_ADDRESS_SECOND_0

Video Buffer O Base Address for Second Output

Offset: 0x3d | Byte Offset: 0xf4 | Read/Write: R/W | Reset: 0xXXXXXXXX (0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx)

Bit	Reset	Description
31:0	X	VB0_BASE_ADDRESS_2: This is the byte address of video buffer 0, if output data format is RGB or non-planar. This is the first byte address of the video buffer

32.1.31 VI_SECOND_OUTPUT_FRAME_SIZE_0

Width and Height of Second Output Frame

Offset: 0x3e | Byte Offset: 0xf8 | Read/Write: R/W | Reset: 0xXXXXXXXX (0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx)

Bit	Reset	Description
28:16	X	SECOND_FRAME_HEIGHT: frame height in lines which the VI needs to process
12:0	X	SECOND_FRAME_WIDTH: frame width in pixel which the VI needs to process

32.1.32 VI_VB0_COUNT_SECOND_0

Video Buffer Set 0 Count for Second Output

Offset: 0x3f | Byte Offset: 0xfc | Read/Write: R/W | Reset: 0x000000XX (0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx)

Bit	Reset	Description
7:0	X	VB0_COUNT_2: This specifies the number of buffers in video buffer set 0.

32.1.33 VI_VB0_SIZE_SECOND_0

Video Buffer Set 0 Size for Second Output

Offset: 0x40 | Byte Offset: 0x100 | Read/Write: R/W | Reset: 0xXXXXXXXX (0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx)

Bit	Reset	Description
28:16	X	VB0_V_SIZE_2: Video Buffer Set 0 Vertical Size. This specifies the number of lines in each buffer in video buffer set 0.
12:0	X	VB0_H_SIZE_2: Video Buffer Set 0 Horizontal Size. This parameter specifies the line stride (in pixels) for lines in the video buffer set 0. For YUV non-planar format, this parameter must be programmed as multiple of 2 pixels (bit 0 is ignored).

32.1.34 VI_VB0_BUFFER_STRIDE_SECOND_0

Video Buffer Set 0 Buffer Stride for Second Output

Offset: 0x41 | Byte Offset: 0x104 | Read/Write: R/W | Reset: 0xXXXXXXXX (0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx)

Bit	Reset	Description
29:0	X	VB0_BUFFER_STRIDE_2: Video Buffer Set 0 Luma Buffer Stride. This is luma buffer stride (in bytes)

32.1.35 VI_H_LPF_CONTROL_0

VI Horizontal Low-Pass Filter (LPF) Control

Offset: 0x42 | Byte Offset: 0x108 | Read/Write: R/W | Reset: 0x02400240 (0bxxx0001001000000xxx0001001000000)

Bit	Reset	Description
28:16	0x240	H_LPF_C: Horizontal LPF Chrominance filter. This controls low-pass filter for U V data.
12:0	0x240	H_LPF_L: Horizontal LPF Luminance filter. This controls low-pass filter for Y data.

32.1.36 VI_H_DOWNSCALE_CONTROL_0

VI Horizontal Downscaling Control

Horizontal pixel processing starts with horizontal low-pass filtering.

Following horizontal low-pass filtering, horizontal downscaling (decimation) can then be performed with or without horizontal averaging.

If horizontal downscaling (decimation) is performed without horizontal averaging, the down-scaling factor is specified by input active period and output frame size.

If horizontal downscaling is performed with horizontal averaging, the downscaling factors are limited to few factors determined by H_AVG_CONTROL. When enabling averaging PLEASE be careful that the input and output ratios match the formula for the averaging decimation ratio exactly to the pixel/line.

The formulae for each of the Averaging Decimation Ratio are as follows:

- x = input size
- y(x) = output size
- 2-pixel averaging and 1/2 downscaling: y(x) = Floor(x/2)
- 4-pixel averaging and 1/3 downscaling: y(x) = Floor((x-1)/3)
- 4-pixel averaging and 1/4 downscaling: y(x) = Floor(x/4)
- 8-pixel averaging and 1/7 downscaling: y(x) = Floor((x-1)/7)
- 8-pixel averaging and 1/8 downscaling: y(x) = Floor(x/8)

Horizontal Decimation Algorithm

The Horizontal Decimator decides which pixels to drop by using a simple DDA algorithm. The accumulator will continue to add the value of the output width (numerator) for each pixel until the sum is equal to or greater than the input width (denominator). When the sum is greater than or equal to the input width (denominator), the hardware will flag that pixel as a pixel to be written out to memory. At the same time, the input width (denominator) will be subtracted from the sum, and the difference will be loaded back into the accumulator for the next line. By default the accumulator is initialized with 0's upon reset. However, the user can set the H_DEC_INIT_VAL to initialize the accumulator with a certain value from 0 to the input width (denominator). Any H_DEC_INIT_VAL that is greater or equal to the difference of the input width (denominator) and the output width (numerator) will cause the first pixel to be written out to memory. This register shifts the phase of the decimation pattern.

Offset: 0x43 | Byte Offset: 0x10c | Read/Write: R/W | Reset: 0x00000X0X (0bxxx0000000000000xxxxxxxxxxxx00xx)

Bit	Reset	Description
28:16	0x0	H_DEC_INIT_VAL: Horizontal Decimation Accumulator Initial Value. The user may initialize the H-Dec accumulator with a value between 0-(H_ACTIVE_PERIOD) to change the phase of the decimation pattern. This will allow the user to decide which is the first pixel to keep.
10:8	X	H_AVG_CONTROL: Horizontal Averaging Control. This specifies the number of pixels to average and to decimate horizontally. 000= 2-pixel averaging and 1/2 downscaling 001= 4-pixel averaging and 1/3 downscaling 010= 4-pixel averaging and 1/4 downscaling 011= 8-pixel averaging and 1/7 downscaling 100= 8-pixel averaging and 1/8 downscaling other= reserved 0 = A2D2 1 = A4D3 2 = A4D4 3 = A8D7 4 = A8D8

Bit	Reset	Description
3:2	0x0	INPUT_H_SIZE_SEL_EXT: Selects input horizontal size into scalers (extension field) 00= Horizontal size selected with INPUT_H_SIZE_SEL field (backward compatible) 01= Horizontal size of CSI_PPA is provided by CSI_PPA_H_ACTIVE register 10= Horizontal size of CSI_PPB is provided by CSI_PPB_H_ACTIVE register 11= Horizontal size of ISP is provided by ISP_H_ACTIVE register 0 = USE_INPUT_H_SIZE_SEL 1 = CSI_PPA 2 = CSI_PPB 3 = ISP
1	X	OUTPUT_H_SIZE_SEL: Output Horizontal Size Select. Selects between the first and second memory output frame widths for the numerator in the downscaling ratio. Uses FIRST_FRAME_WIDTH or SECOND_FRAME_WIDTH. This is effective only when H_AVERAGING is DISABLED and H_DOWNSCALING is ENABLED. 0 = FIRST 1 = SECOND
0	X	INPUT_H_SIZE_SEL: Input Horizontal Size Select. The VIP option is deprecated. Only the HOST option is valid. Selects the HOST input active area width for the denominator in the downscaling ratio. Uses HOST_H_ACTIVE_PERIOD, which is the width of the data after cropping. This is effective only when H_AVERAGING is DISABLED and H_DOWNSCALING is ENABLED. 1 = HOST

32.1.37 VI_V_DOWNSCALE_CONTROL_0

VI Vertical Downscaling Control

Vertical processing consists of optional vertical downscaling (decimation) which can be performed with or without vertical averaging.

If vertical downscaling (decimation) is performed without vertical averaging, the down-scaling factor is specified by input active period and output frame size.

If horizontal down-scaling is performed with vertical averaging, the downscaling factors are limited to few factors determined by V_AVG_CONTROL. When enabling averaging, you must ensure that the input and output ratios match the formula for the averaging decimation ratio exactly to the pixel/line.

The formulae for each of the Averaging Decimation Ratio are as follows:

- x = input size
- y(x) = output size
- 2-pixel averaging and 1/2 downscaling: y(x) = Floor(x/2)
- 4-pixel averaging and 1/3 downscaling: y(x) = Floor((x-1)/3)
- 4-pixel averaging and 1/4 downscaling: y(x) = Floor(x/4)
- 8-pixel averaging and 1/7 downscaling: y(x) = Floor((x-1)/7)
- 8-pixel averaging and 1/8 downscaling: y(x) = Floor(x/8)

Vertical Decimation Algorithm (same as the Horizontal Decimation Algorithm)

The Vertical Decimator decides which pixels to drop by using a simple DDA algorithm. The accumulator will continue to add the value of the output height (numerator) for each line until the sum is equal to or greater than the input height (denominator). When the sum is greater than or equal to the input height (denominator), the hardware will flag that line as a line to be written out to memory. At the same time, the input height (denominator) will be subtracted from the sum, and the difference will be loaded back into the accumulator for the next line. By default the accumulator is initialized with 0's upon reset. However, the user can set the V_DEC_INIT_VAL to initialize the accumulator with a certain value from 0 to the input height (denominator). Any V_DEC_INIT_VAL that is greater or equal to the difference of the input height (denominator), and the output height (numerator) will cause the first line to be written out to memory. This register shifts the phase of the decimation pattern.

Offset: 0x44 | Byte Offset: 0x110 | Read/Write: R/W | Reset: 0x0000XX0X (0bxxx0000000000000xxxxxxxxxxxx00xx)

Bit	Reset	Description
28	X	IGNORE_FIELD: Specifies whether odd/even field affects vertical decimation. 0 = disabled - odd/even field affects the vertical downscaling 1 = enabled - field is ignored in vertical downscaling 0 = DISABLED 1 = ENABLED
28:16	0x0	V_DEC_INIT_VAL: Vertical Decimation Accumulator Initial Value The user may initialize the V-Dec accumulator with a value between 0-(V_ACTIVE_PERIOD) to change the phase of the decimation pattern. This will allow the user to decide which is the first line to keep.
13	X	MULTI_TAP_V_AVG_FILTER: Multi-Tap Vertical Averaging Filter 0 = disabled 1 = enabled. This will enable the Multi-Tap filtering when the Vertical Averaging is enabled. The filter settings will depend on the V_AVG_CONTROL value. 000 - 3 Taps (1,2,1)/4 001 - 5 Taps (1,2,2,2,1)/8 010 - 6 Taps (1,1,2,2,1,1)/8 011 - 11 Taps (1,1,1,2,2,2,2,2,1,1,1)/16 100 - 12 Taps (1,1,1,1,2,2,2,2,1,1,1,1)/16 0 = DISABLED 1 = ENABLED

10:8	X	V_AVG_CONTROL: Vertical Averaging Control. This specifies the number of lines to average and to decimate vertically. 000= 2-line averaging and 1/2 downscaling 001= 4-line averaging and 1/3 downscaling 010= 4-line averaging and 1/4 downscaling 011= 8-line averaging and 1/7 downscaling 100= 8-line averaging and 1/8 downscaling other= reserved 0 = A2D2 1 = A4D3 2 = A4D4 3 = A8D7 4 = A8D8
3:2	0x0	INPUT_V_SIZE_SEL_EXT: Selects input vertical size into scalers (extension field) 00= Vert. size selected with INPUT_V_SIZE_SEL field (backward compatible) 01= Vert. size of CSI_PPA is provided by CSI_PPA_V_ACTIVE register 10= Vert. size of CSI_PPB is provided by CSI_PPB_V_ACTIVE register 11= Vert. size of ISP is provided by ISP_V_ACTIVE register 0 = USE_INPUT_V_SIZE_SEL 1 = CSI_PPA 2 = CSI_PPB 3 = ISP
1	X	OUTPUT_V_SIZE_SEL: Output Vertical Size Select. Selects between the first and second memory output frame heights for the numerator in the downscaling ratio. Uses FIRST_FRAME_HEIGHT or SECOND_FRAME_HEIGHT. This is effective only when V_AVERAGING is DISABLED and V_DOWNSCALING is ENABLED. 0 = FIRST 1 = SECOND
0	X	INPUT_V_SIZE_SEL: Input Vertical Size Select. The VIP option is deprecated. Only the HOST option is valid. Selects the HOST input active area height for the denominator in the downscaling ratio. Uses HOST_V_ACTIVE_PERIOD, which is the height of the data after cropping. This is effective only when V_AVERAGING is DISABLED and V_DOWNSCALING is ENABLED. 1 = HOST

32.1.38 VI_CSC_Y_0

CSC Y Offset and Gain

Color Space Conversion coefficients.

The CSC can be used for YUV to RGB conversion with brightness and hue/saturation control.

For Y color, the Y offset is applied first and saturation (clipping) is performed immediately after the Y offset is applied.

R = sat(KYRGB * sat(Y + YOF) + KUR * U + KVR * V)

G = sat(KYRGB * sat(Y + YOF) + KUG * U + KVG * V)

B = sat(KYRGB * sat(Y + YOF) + KUB * U + KVB * V)

Saturation and rounding is performed in the range of 0 to 255 for the above equations.

Typical values are:

YOF = -16.000, KYRGB = 1.1644

KUR = 0.0000, KVR = -1.5960

KUG = -0.3918, KVG = -0.8130

KUB = 2.0172, KVB = 0.0000

KUR and KVB are typically 0.0000 but they may be programmed non-zero for hue rotation.

The CSC can also take RGB input, in which case YOF, KVB, KUG, KUR should be programmed to 0, and KYRGB will be forced to 0 by the hardware for generating R and B. KYRGB will not be forced to 0 for generating G. KVR, KYRGB, and KUB can be programmed to 1.0 or used as gain control for R, G, B correspondingly.

Note that color value ranges from 0 to 255 for Y, R, G, B and -128 to 127 for U and V.

Offset: 0x45 | Byte Offset: 0x114 | Read/Write: R/W | Reset: 0x0XXX00XX (0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx)

Bit	Reset	Description
25:16	X	KYRGB: Y Gain for R, G, B colors in 2.8 format
7:0	X	YOF: Y Offset in s.7.0 format

32.1.39 VI_CSC_UV_R_0

CSC U & V coefficient for R

Offset: 0x46 | Byte Offset: 0x118 | Read/Write: R/W | Reset: 0x0XXX0XXX (0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx)

Bit	Reset	Description
26:16	X	KVR: V coefficients for R in s.2.8 format
10:0	X	KUR: U coefficients for R in s.2.8 format

32.1.40 VI_CSC_UV_G_0

CSC U & V coefficient for G

Offset: 0x47 | Byte Offset: 0x11c | Read/Write: R/W | Reset: 0x0XXX0XXX (0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx)

Bit	Reset	Description
25:16	X	KVG: V coefficients for G in s.1.8 format
9:0	X	KUG: U coefficients for G in s.1.8 format

32.1.41 VI_CSC_UV_B_0

CSC U & V coefficient for B

Offset: 0x48 | Byte Offset: 0x120 | Read/Write: R/W | Reset: 0x0XXX0XXX (0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx)

Bit	Reset	Description
26:16	X	KVB: V coefficients for B in s.2.8 format
10:0	X	KUB: U coefficients for B in s.2.8 format

32.1.42 VI_CSC_ALPHA_0

RGB Color Space Converter Alpha value

Offset: 0x49 | Byte Offset: 0x124 | Read/Write: R/W | Reset: 0x00000000 (0bxxxxxxxxxxxxxxxxxxxxxxxx00000000)

Bit	Reset	Description
7:0	0x0	RGB888_ALPHA: When output format to memory is selected for RGB888, the pixel data is 32-bit aligned. The value programmed here will be appended to the RGB888 data as the 8 MSBs and can be used as an alpha value.

32.1.43 VI_HOST_VSYNC_0

Valid when INPUT_SOURCE is HOST

Offset: 0x4a | Byte Offset: 0x128 | Read/Write: RO | Reset: 0x0000000X (0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx)

Bit	Reset	Description
0	X	HOST_VSYNC_TRIGGER: This triggers VI's internal VSYNC generation. Always write once to this register with '1' before writing the Frame's data to Y_FIFO_DATA

32.1.44 VI_COMMAND_0

VI Command

This register is used initialize VI module when INPUT_SOURCE is HOST.

This register has a dual use purpose. Host input VSYNC is created by writing to this register.

Offset: 0x4b | Byte Offset: 0x12c | Read/Write: R/W | Reset: 0xXXXX0X00 (0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx0)

Bit	Reset	Description
28:16	X	V_COUNTER_THRESHOLD: Vertical Counter Threshold. This specifies a threshold which, when exceeded, would generate the vertical counter interrupt if the interrupt is enabled. This is used to detect the case when the host is sending too many input data than expected by VI module.
11:8	X	Y_FIFO_THRESHOLD: Y-FIFO Threshold. This specifies maximum number of filled locations in Y-FIFO for the Y-FIFO Threshold Status bit.
0	0x0	PROCESS_FIELD: Process Odd/Even field (effective when INPUT_SOURCE is HOST). Writing to this bit will initialize VI to receive one field of video. 0= odd field 1= even field 0 = ODD 1 = EVEN

32.1.45 VI_HOST_FIFO_STATUS_0

Host FIFO status

This is not needed if host input video goes through command buffer interface.

Offset: 0x4c | Byte Offset: 0x130 | Read/Write: RO | Reset: 0x0000XX0X (0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx)

Bit	Reset	Description
14:12	X	V_FIFO_STATUS: This indicates the number of filled locations in V-FIFO. If the returned value is 3'h0, the FIFO is empty and if the returned value is 3'h7 then the FIFO is full.
10:8	X	U_FIFO_STATUS: This indicates the number of filled locations in U-FIFO. If the returned value is 3'h0, the FIFO is empty and if the returned value is 3'h7 then the FIFO is full.
3:0	X	Y_FIFO_STATUS: This indicates the number of filled locations in Y-FIFO. If the returned value is 4'h0, the FIFO is empty and if the returned value is 4'hF then the FIFO is full.

32.1.46 VI_INTERRUPT_MASK_0

Interrupt Mask

Offset: 0x4d | Byte Offset: 0x134 | Read/Write: R/W | Reset: 0x00000000 (0bxxx00000000x00000000000000000000)

Bit	Reset	Description
28	0x0	SECOND_OUTPUT_DROP_MC_DATA_INT_MASK: This bit controls interrupt when VI drops data to MC. 0 = DISABLED 1 = ENABLED
27	0x0	FIRST_OUTPUT_DROP_MC_DATA_INT_MASK: This bit controls interrupt when VI drops data to MC. 0 = DISABLED 1 = ENABLED
26	0x0	TS_OTHER_PROTOCOL_ERROR_INT_MASK: This bit controls interrupt when the ISDB-T input get a packet which means FEC+BODY in total size but FEC and BODY do not match FEC_SIZE and BODY_SIZE 0 = DISABLED 1 = ENABLED
25	0x0	TS_OVERRUN_ERROR_INT_MASK: This bit controls interrupt when the ISDB-T input get an overrun error 0 = DISABLED 1 = ENABLED
24	0x0	TS_UNDERRUN_ERROR_INT_MASK: This bit controls interrupt when the ISDB-T input get an underrun error 0 = DISABLED 1 = ENABLED
23	0x0	TS_UPSTREAM_ERROR_INT_MASK: This bit controls interrupt when the ISDB-T VI input gets an upstream error. 0 = DISABLED 1 = ENABLED
22	0x0	RAISE_STREAM_2_INT_MASK: Stream 2 raise. This bit controls interrupt when the the Stream 2 Raise is enabled and returned 0 = DISABLED 1 = ENABLED
21	0x0	RAISE_STREAM_1_INT_MASK: Stream 1 raise. This bit controls interrupt when the the Stream 1 Raise is enabled and returned 0 = DISABLED 1 = ENABLED
19	0x0	DMA_STALL_INT_MASK: Write Buffer DMA to VI. Stalls VI and causes an error This bit controls interrupt when the VI drops raw 8-bit stream data because the Write Buffer DMA is stalling. 0 = DISABLED 1 = ENABLED

Bit	Reset	Description
18	0x0	SECOND_OUTPUT_PEER_STALL_INT_MASK: VI to Peer stall - Second Memory Output This bit controls interrupt when the VI drops peer bus packet(s) because the peer is stalling the second output peer bus and data is coming from the pins 0 = DISABLED 1 = ENABLED
17	0x0	FIRST_OUTPUT_PEER_STALL_INT_MASK: VI to Peer stall - First Memory Output. This bit controls interrupt when the VI drops peer bus packet(s) because the peer is stalling the first output peer bus and data is coming from the pins 0 = DISABLED 1 = ENABLED
16	0x0	YUV420PA_ERROR_INT_MASK: YUV420PA Error Interrupt Mask. This bit controls interrupt when the VI does not average data because the line buffer data is not ready from the memory controller. The VI will write unaveraged data and will write the U,V data from the even line in such cases. 0 = DISABLED 1 = ENABLED
15	0x0	EPP_ERROR_INT_MASK: VI to EPP Error Interrupt Mask. This bit controls interrupt when the VI drops data to the EPP because the EPP is stalling the vi2epp bus and data is coming from the pins 0 = DISABLED 1 = ENABLED
14	0x0	FRAME_SECOND_OUTPUT_INT_MASK: Buffer Done Second Output Interrupt Mask. This bit controls interrupt when the Second Output to memory has written a frame to memory. 0 = DISABLED 1 = ENABLED
13	0x0	BUFFER_SECOND_OUTPUT_INT_MASK: Buffer Done Second Output Interrupt Mask This bit controls interrupt when the Second Output to memory has written a buffer to memory. 0 = DISABLED 1 = ENABLED
12	0x0	FRAME_FIRST_OUTPUT_INT_MASK: Frame Done First Output Interrupt Mask This bit controls interrupt when the First Output to memory has written a frame to memory. 0 = DISABLED 1 = ENABLED
11	0x0	BUFFER_FIRST_OUTPUT_INT_MASK: Buffer Done First Output Interrupt Mask This bit controls interrupt when the First Output to memory has written a buffer to memory. 0 = DISABLED 1 = ENABLED
10	0x0	Y_THRESHOLD_INT_MASK: Y-FIFO Threshold Interrupt Mask This bit controls interrupt when the number of filled locations in Y-FIFO is equal or greater than the Y_FIFO_THRESHOLD value. This bit should be set to 1 only when INPUT_SOURCE is HOST. 0 = DISABLED 1 = ENABLED
9	0x0	V_COUNTER_INT_MASK: Vertical Counter Interrupt Mask (effective when VIDEO_SOURCE is HOST) This bit controls interrupt when the vertical counter threshold is reached. 0 = DISABLED 1 = ENABLED
8	0x0	VVS_INT_MASK: VVS pin Interrupt Mask This bit controls interrupt when VVS rising/falling edge is detected. 0 = DISABLED 1 = ENABLED
7	0x0	VHS_INT_MASK: VHS pin Interrupt Mask This bit controls interrupt when VHS rising/falling edge is detected. 0 = DISABLED 1 = ENABLED
6	0x0	VGP6_INT_MASK: VGP6 pin Interrupt Mask This bit controls interrupt when VGP6 rising/falling edge is detected. 0 = DISABLED 1 = ENABLED

Bit	Reset	Description
5	0x0	VGP5_INT_MASK: VGP5 pin Interrupt Mask This bit controls interrupt when VGP5 rising/falling edge is detected. 0 = DISABLED 1 = ENABLED
4	0x0	VGP4_INT_MASK: VGP4 pin Interrupt Mask. This bit controls interrupt when VGP4 rising/falling edge is detected. 0 = DISABLED 1 = ENABLED
3	0x0	VD11_INT_MASK: VD11 pin Interrupt Mask. This bit controls interrupt when VD11 rising/falling edge is detected. 0 = DISABLED 1 = ENABLED
2	0x0	VD10_INT_MASK: VD10 pin Interrupt Mask. This bit controls interrupt when VD10 rising/falling edge is detected. 0 = DISABLED 1 = ENABLED
1	0x0	VD9_INT_MASK: VD9 pin Interrupt Mask. This bit controls interrupt when VD9 rising/falling edge is detected. 0 = DISABLED 1 = ENABLED
0	0x0	VD8_INT_MASK: VD8 pin Interrupt Mask. This bit controls interrupt when VD8 rising/falling edge is detected. 0 = DISABLED 1 = ENABLED

32.1.47 VI_INTERRUPT_TYPE_SELECT_0

Interrupt Type Select

Offset: 0x4e | Byte Offset: 0x138 | Read/Write: R/W | Reset: 0x00000000 (0bxxxxxxxxxxxxxxxxxxxxxxxx000000000)

Bit	Reset	Description
8	0x0	VVS_INT_TYPE: VVS pin Interrupt Type. This bit controls interrupt VVS 0 = EDGE 1 = LEVEL
7	0x0	VHS_INT_TYPE: VHS pin Interrupt Type. This bit controls interrupt VHS 0 = EDGE 1 = LEVEL
6	0x0	VGP6_INT_TYPE: VGP6 pin Interrupt Type. This bit controls interrupt VGP6 0 = EDGE 1 = LEVEL
5	0x0	VGP5_INT_TYPE: VGP5 pin Interrupt Type. This bit controls interrupt VGP5 0 = EDGE 1 = LEVEL
4	0x0	VGP4_INT_TYPE: VGP4 pin Interrupt Type. This bit controls interrupt VGP4 0 = EDGE 1 = LEVEL
3	0x0	VD11_INT_TYPE: VD11 pin Interrupt Type. This bit controls interrupt VD11 0 = EDGE 1 = LEVEL
2	0x0	VD10_INT_TYPE: VD10 pin Interrupt Type. This bit controls interrupt VD10 0 = EDGE 1 = LEVEL
1	0x0	VD9_INT_TYPE: VD9 pin Interrupt Type. This bit controls interrupt VD9 0 = EDGE 1 = LEVEL

Bit	Reset	Description
0	0x0	VD8_INT_TYPE: VD8 pin Interrupt Type. This bit controls interrupt VD8 if edge or level type 0 = EDGE 1 = LEVEL

32.1.48 VI_INTERRUPT_POLARITY_SELECT_0

Interrupt Polarity Select

Offset: 0x4f | Byte Offset: 0x13c | Read/Write: R/W | Reset: 0x00000000 (0bxxxxxxxxxxxxxxxxxxxxxxxx000000000)

Bit	Reset	Description
8	0x0	VVS_INT_POLARITY: VVS pin Interrupt Type. This bit controls interrupt VVS 0= falling edge or low level 1= rising edge or high level 0 = LOW 1 = HIGH
7	0x0	VHS_INT_POLARITY: VHS pin Interrupt Type. This bit controls interrupt VHS 0= falling edge or low level 1= rising edge or high level 0 = LOW 1 = HIGH
6	0x0	VGP6_INT_POLARITY: VGP6 pin Interrupt Type. This bit controls interrupt VGP6 0= falling edge or low level 1= rising edge or high level 0 = LOW 1 = HIGH
5	0x0	VGP5_INT_POLARITY: VGP5 pin Interrupt Type. This bit controls interrupt VGP5 0= falling edge or low level 1= rising edge or high level 0 = LOW 1 = HIGH
4	0x0	VGP4_INT_POLARITY: VGP4 pin Interrupt Type. This bit controls interrupt VGP4 0= falling edge or low level 1= rising edge or high level 0 = LOW 1 = HIGH
3	0x0	VD11_INT_POLARITY: VD11 pin Interrupt Type. This bit controls interrupt VD11 0= falling edge or low level 1= rising edge or high level 0 = LOW 1 = HIGH
2	0x0	VD10_INT_POLARITY: VD10 pin Interrupt Type. This bit controls interrupt VD10 0= falling edge or low level 1= rising edge or high level 0 = LOW 1 = HIGH
1	0x0	VD9_INT_POLARITY: VD9 pin Interrupt Type. This bit controls interrupt VD9 0= falling edge or low level 1= rising edge or high level 0 = LOW 1 = HIGH
0	0x0	VD8_INT_POLARITY: VD8 pin Interrupt Type. This bit controls interrupt VD8 if edge or level type. 0= falling edge or low level 1= rising edge or high level 0 = LOW 1 = HIGH

32.1.49 VI_INTERRUPT_STATUS_0

Interrupt Enable

This register returns interrupt status when read. Except for bits 15-14, when this register is written, the interrupt status corresponding to the bits written with 1 will be reset.

Interrupt status corresponding to the bits written with 0 will be left unchanged.

Note that interrupt status bits can be set even when their corresponding interrupt enable bits, in VI10R, are cleared. When these bits are set and their corresponding interrupt enable bits are set, an interrupt is generated. The interrupt can be cleared, or left unchanged, by writing 1 or 0, respectively, to the corresponding bits in this register.

Clearing the interrupt status bits does not affect the interrupt enable bits.

Offset: 0x50 | Byte Offset: 0x140 | Read/Write: RO | Reset: 0xXXXXXXXX (0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx)

Bit	Reset	Description
28	X	SECOND_OUTPUT_DROP_MC_DATA_INT_STATUS: If SECOND_OUTPUT is dropping data to MC, INTR will be set. 0 = NOINTR 1 = INTR
27	X	FIRST_OUTPUT_DROP_MC_DATA_INT_STATUS: If FIRST_OUTPUT is dropping data to MC, INTR will be set. 0 = NOINTR 1 = INTR
26	X	TS_OTHER_PROTOCOL_ERROR_INT_STATUS: This bit shows the status of the condition when the ISDB-T input gets another protocol error (ex: total packet received is FEC_SIZE+BODY_SIZE but the individual FEC portion != FEC_SIZE and the individual BODY portion != BODY_SIZE 0= Interrupt not detected 1= Interrupt detected 0 = NOINTR 1 = INTR
25	X	TS_OVERRUN_ERROR_INT_STATUS: This bit shows the status of the condition when the ISDB-T input gets an overrun error (more bytes in packet than specified 0= Interrupt not detected 1= Interrupt detected 0 = NOINTR 1 = INTR
24	X	TS_UNDERRUN_ERROR_INT_STATUS: This bit shows the status of the condition when the ISDB-T input gets an underrun error (START condition detected prior to receiving a full packet) 0= Interrupt not detected 1= Interrupt detected 0 = NOINTR 1 = INTR
23	X	TS_UPSTREAM_ERROR_INT_STATUS: This bit shows the status of the condition when the ISDB-T VI input gets an upstream error (error from the tuner) 0= Interrupt not detected 1= Interrupt detected 0 = NOINTR 1 = INTR
22	X	RAISE_STREAM_2_INT_STATUS: This bit shows the status of the condition when the Raise Stream 2 returns to the Host 0= Interrupt not detected 1= Interrupt detected 0 = NOINTR 1 = INTR

Bit	Reset	Description
21	X	RAISE_STREAM_1_INT_STATUS: This bit shows the status of the condition when the Raise Stream 1 returns to the Host 0= Interrupt not detected 1= Interrupt detected 0 = NOINTR 1 = INTR
20	X	FIELD_STATUS: Top or Bottom Field Status This bit specifies whether the last received video data field is top field or bottom field as defined by FIELD_TYPE bit. This bit cannot be reset by software by writing a 1. 0= Bottom field received 1= Top field received 0 = BOTTOM 1 = TOP
19	X	DMA_STALL_INT_STATUS: This bit shows the status of the condition when the VI drops data to the Write Buffer DMA 0= Interrupt not detected 1= Interrupt detected 0 = NOINTR 1 = INTR
18	X	SECOND_OUTPUT_PEER_STALL_INT_STATUS: This bit shows the status of if the VI dropped a buffer packet to the peer communicating with the second memory output 0= Interrupt not detected 1= Interrupt detected 0 = NOINTR 1 = INTR
17	X	FIRST_OUTPUT_PEER_STALL_INT_STATUS: This bit shows the status of if the VI dropped a buffer packet to the peer communicating with the first memory output 0= Interrupt not detected 1= Interrupt detected 0 = NOINTR 1 = INTR
16	X	YUV420PA_ERROR_INT_STATUS: YUV420PA Error Interrupt Enable This bit shows the status of if the VI does not average data because the line buffer data is not ready from the memory controller. The VI will write unaveraged data and will write the U,V data from the even line in such cases. 0= Interrupt not detected 1= Interrupt detected 0 = NOINTR 1 = INTR
15	X	EPP_ERROR_INT_STATUS: VI to EPP Error Interrupt Enable This bit controls interrupt when the VI drops data to the EPP because the EPP is stalling the vi2epp bus and data is coming from the pins 0= Interrupt not detected 1= Interrupt detected 0 = NOINTR 1 = INTR
14	X	FRAME_SECOND_OUTPUT_INT_STATUS: Frame Done Second Output Interrupt Status. This bit is set when a frame has been written to memory by the second output. 0= Interrupt not detected 1= Interrupt detected 0 = NOINTR 1 = INTR
13	X	BUFFER_SECOND_OUTPUT_INT_STATUS: Buffer Done Second Output Interrupt Status. This bit is set when a buffer has been written to memory by the second output. 0= Interrupt not detected 1= Interrupt detected 0 = NOINTR 1 = INTR
12	X	FRAME_FIRST_OUTPUT_INT_STATUS: Frame Done First Output Interrupt Status. This bit is set when a frame has been written to memory by the first output. 0= Interrupt not detected 1= Interrupt detected 0 = NOINTR 1 = INTR

Bit	Reset	Description
11	X	BUFFER_FIRST_OUTPUT_INT_STATUS: Buffer Done First Output Interrupt Status. This bit is set when a buffer has been written to memory by the first output. 0= Interrupt not detected 1= Interrupt detected 0 = NOINTR 1 = INTR
10	X	Y_THRESHOLD_INT_STATUS: Y-FIFO Threshold Interrupt Enable. This bit controls interrupt when the number of filled locations in Y-FIFO is equal or greater than the Y_FIFO_THRESHOLD value. 0= Interrupt not detected 1= Interrupt detected 0 = NOINTR 1 = INTR
9	X	V_COUNTER_INT_STATUS: Vertical Counter Interrupt Status (effective when VIDEO_SOURCE is HOST). This bit controls interrupt when the vertical counter threshold is reached. 0 = NOINTR 1 = INTR
8	X	VVS_INT_STATUS: VVS pin Interrupt Status. This bit controls interrupt when VVS rising/falling edge is detected. 0= Interrupt not detected 1= Interrupt detected 0 = NOINTR 1 = INTR
7	X	VHS_INT_STATUS: VHS pin Interrupt Status. This bit controls interrupt when VHS rising/falling edge is detected. 0= Interrupt not detected 1= Interrupt detected 0 = NOINTR 1 = INTR
6	X	VGP6_INT_STATUS: VGP6 pin Interrupt Status. This bit controls interrupt when VGP6 rising/falling edge is detected. 0= Interrupt not detected 1= Interrupt detected 0 = NOINTR 1 = INTR
5	X	VGP5_INT_STATUS: VGP5 pin Interrupt Status. This bit controls interrupt when VGP5 rising/falling edge is detected. 0= Interrupt not detected 1= Interrupt detected 0 = NOINTR 1 = INTR
4	X	VGP4_INT_STATUS: VGP4 pin Interrupt Status. This bit controls interrupt when VGP4 rising/falling edge is detected. 0= Interrupt not detected 1= Interrupt detected 0 = NOINTR 1 = INTR
3	X	VD11_INT_STATUS: VD11 pin Interrupt Status. This bit controls interrupt when VD11 rising/falling edge is detected. 0= Interrupt not detected 1= Interrupt detected 0 = NOINTR 1 = INTR
2	X	VD10_INT_STATUS: VD10 pin Interrupt Status. This bit controls interrupt when VD10 rising/falling edge is detected. 0= Interrupt not detected 1= Interrupt detected 0 = NOINTR 1 = INTR
1	X	VD9_INT_STATUS: VD9 pin Interrupt Status. This bit controls interrupt when VD9 rising/falling edge is detected. 0= Interrupt not detected

Bit	Reset	Description
		1= Interrupt detected 0 = NOINTR 1 = INTR
0	X	VD8_INT_STATUS: VD8 pin Interrupt Status. This bit controls interrupt when VD8 rising/falling edge is detected. 0= Interrupt not detected 1= Interrupt detected 0 = NOINTR 1 = INTR

32.1.50 VI_VIP_INPUT_STATUS_0

This register is reserved.

Offset: 0x51 | Byte Offset: 0x144 | Read/Write: RO | Reset: 0xXXXXXXXX (0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx)

Bit	Reset	Description
31:16	X	FRAME_COUNT
15:0	X	LINE_COUNT

32.1.51 VI_VIDEO_BUFFER_STATUS_0

Interrupt Enable

Offset: 0x52 | Byte Offset: 0x148 | Read/Write: RO | Reset: 0x000XXXXX (0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx)

Bit	Reset	Description
19:16	X	RAW_STREAM_WRITE_COUNT: Write count of the Raw Stream Write FIFO. This is the FIFO used to synchronize the data coming from pads into the VI clock domain.
15:8	X	SECOND_VIDEO_BUFFER_STATUS: Buffer status. This specifies the buffer number of the last video data field written to memory
7:0	X	FIRST_VIDEO_BUFFER_STATUS: Buffer status. This specifies the buffer number of the last video data field written to memory

32.1.52 VI_SYNC_OUTPUT_0

VI H and V Sync Output control

This register is reserved.

Offset: 0x53 | Byte Offset: 0x14c | Read/Write: R/W | Reset: 0xXXXXXXXX (0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx)

Bit	Reset	Description
31:19	X	VVS_OUTPUT_PERIOD
18:16	X	VVS_OUTPUT_WIDTH
15:3	X	VHS_OUTPUT_PERIOD
2:0	X	VHS_OUTPUT_WIDTH

32.1.53 VI_VVS_OUTPUT_DELAY_0

VI V Sync Output Delay

Offset: 0x54 | Byte Offset: 0x150 | Read/Write: R/W | Reset: 0x0000000X (0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx)

Bit	Reset	Description
3:0	X	VVS_OUTPUT_DELAY: This specifies the number of VI clock cycles from leading edge of VHS to leading edge of VVS. Programmed value is actual value + 2 so valid value ranges from -2 to 13.

32.1.54 VI_PWM_CONTROL_0

VI Pulse Width Modulation Control

The PWM feature has been deprecated.This register is reserved.

Offset: 0x55 | Byte Offset: 0x154 | Read/Write: R/W | Reset: 0x00000000 (0b00000000xx00xxxx00000000xxx0xxx0)

Bit	Reset	Description
31:0	0x0	Reserved.

32.1.55 VI_PWM_SELECT_PULSE_A_0

PWM Pulse Select A

The next 4 registers select which of the internal 128 pulses to be output. Each bit in the four registers corresponds to one internal pulse.

Offset: 0x56 | Byte Offset: 0x158 | Read/Write: R/W | Reset: 0xXXXXXXXX (0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx)

Bit	Reset	Description
31:0	X	PWM_SELECT_A: PWM Select bits 31 to 0

32.1.56 VI_PWM_SELECT_PULSE_B_0

PWM Pulse Select B

Offset: 0x57 | Byte Offset: 0x15c | Read/Write: R/W | Reset: 0xXXXXXXXX (0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx)

Bit	Reset	Description
31:0	X	PWM_SELECT_B: PWM Select bits 63 to 32

32.1.57 VI_PWM_SELECT_PULSE_C_0

PWM Pulse Select C

Offset: 0x58 | Byte Offset: 0x160 | Read/Write: R/W | Reset: 0xXXXXXXXX (0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx)

Bit	Reset	Description
31:0	X	PWM_SELECT_C: PWM Select bits 95 to 64

32.1.58 VI_PWM_SELECT_PULSE_D_0

PWM Pulse Select D

Offset: 0x59 | Byte Offset: 0x164 | Read/Write: R/W | Reset: 0xXXXXXXXX (0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx)

Bit	Reset	Description
31:0	X	PWM_SELECT_D: PWM Select bits 127 to 96

32.1.59 VI_VI_DATA_INPUT_CONTROL_0

VI Input Mask

Offset: 0x5a | Byte Offset: 0x168 | Read/Write: R/W | Reset: 0x00000fff (0bxxxxxxxxxxxxxxxxxxxx111111111111)

Bit	Reset	Description
11:0	0xfff	VI_DATA_INPUT_MASK: Mask the VD[11:0] pin inputs to the VI core and ISP. The mask is not applied to the Host GPIO read value

32.1.60 VI_PIN_INPUT_ENABLE_0

VI pins Input Enable

Offset: 0x5b | Byte Offset: 0x16c | Read/Write: R/W | Reset: 0x00000000 (0bxxxxxxxxxxx000000x00x000000000000)

Bit	Reset	Description
21	0x0	VGP6_INPUT_ENABLE: VGP6 pin Input Enable This bit controls VGP6 pin input. 0 = DISABLED 1 = ENABLED
20	0x0	VGP5_INPUT_ENABLE: VGP5 pin Input Enable This bit controls VGP5 pin input. 0 = DISABLED 1 = ENABLED
19	0x0	VGP4_INPUT_ENABLE: VGP4 pin Input Enable This bit controls VGP4 pin input. 0 = DISABLED 1 = ENABLED
18	0x0	VGP3_INPUT_ENABLE: VGP3 pin Input Enable This bit controls VGP3 pin input. 0 = DISABLED 1 = ENABLED
17	0x0	VGP2_INPUT_ENABLE: VGP2 pin Input Enable This bit controls VGP2 pin input. 0 = DISABLED 1 = ENABLED
16	0x0	VGP1_INPUT_ENABLE: VGP1 pin Input Enable This bit controls VGP1 pin input. 0 = DISABLED 1 = ENABLED
14	0x0	VVS_INPUT_ENABLE: VVS pin Input Enable This bit controls VVS pin input. 0 = DISABLED 1 = ENABLED
13	0x0	VHS_INPUT_ENABLE: VHS pin Input Enable This bit controls VHS pin input. 0 = DISABLED 1 = ENABLED
11	0x0	VD11_INPUT_ENABLE: VD11 pin Input Enable This bit controls VD7 pin input. 0 = DISABLED 1 = ENABLED
10	0x0	VD10_INPUT_ENABLE: VD10 pin Input Enable This bit controls VD7 pin input. 0 = DISABLED 1 = ENABLED

Bit	Reset	Description
9	0x0	VD9_INPUT_ENABLE: VD9 pin Input Enable This bit controls VD7 pin input. 0 = DISABLED 1 = ENABLED
8	0x0	VD8_INPUT_ENABLE: VD8 pin Input Enable This bit controls VD7 pin input. 0 = DISABLED 1 = ENABLED
7	0x0	VD7_INPUT_ENABLE: VD7 pin Input Enable This bit controls VD7 pin input. 0 = DISABLED 1 = ENABLED
6	0x0	VD6_INPUT_ENABLE: VD6 pin Input Enable This bit controls VD6 pin input. 0 = DISABLED 1 = ENABLED
5	0x0	VD5_INPUT_ENABLE: VD5 pin Input Enable This bit controls VD5 pin input. 0 = DISABLED 1 = ENABLED
4	0x0	VD4_INPUT_ENABLE: VD4 pin Input Enable This bit controls VD4 pin input. 0 = DISABLED 1 = ENABLED
3	0x0	VD3_INPUT_ENABLE: VD3 pin Input Enable This bit controls VD3 pin input. 0 = DISABLED 1 = ENABLED
2	0x0	VD2_INPUT_ENABLE: VD2 pin Input Enable This bit controls VD2 pin input. 0 = DISABLED 1 = ENABLED
1	0x0	VD1_INPUT_ENABLE: VD1 pin Input Enable This bit controls VD1 pin input. 0= Disabled 1= Enabled 0 = DISABLED 1 = ENABLED
0	0x0	VD0_INPUT_ENABLE: VD0 pin Input Enable This bit controls VD0 pin input. 0 = DISABLED 1 = ENABLED

32.1.61 VI_PIN_OUTPUT_ENABLE_0

VI pins Output Enable

Offset: 0x5c | Byte Offset: 0x170 | Read/Write: R/W | Reset: 0x00000000 (0bxxxxxxxxxx000000x000000000000000)

Bit	Reset	Description
21	0x0	VGP6_OUTPUT_ENABLE: VGP6 pin Output Enable. This bit controls VGP6 pin output. 0 = DISABLED 1 = ENABLED
20	0x0	VGP5_OUTPUT_ENABLE: VGP5 pin Output Enable. This bit controls VGP5 pin output. 0 = DISABLED 1 = ENABLED
19	0x0	VGP4_OUTPUT_ENABLE: VGP4 pin Output Enable. This bit controls VGP4 pin output. 0 = DISABLED 1 = ENABLED
18	0x0	VGP3_OUTPUT_ENABLE: VGP3 pin Output Enable. This bit controls VGP3 pin output. 0 = DISABLED 1 = ENABLED
17	0x0	VGP2_OUTPUT_ENABLE: VGP2 pin Output Enable. This bit controls VGP2 pin output. 0 = DISABLED 1 = ENABLED

Bit	Reset	Description
16	0x0	VGP1_OUTPUT_ENABLE: VGP1 pin Output Enable. This bit controls VGP1 pin output. 0 = DISABLED 1 = ENABLED
14	0x0	VVS_OUTPUT_ENABLE: VVS pin Output Enable. This bit controls VVS pin output. 0 = DISABLED 1 = ENABLED
13	0x0	VHS_OUTPUT_ENABLE: VHS pin Output Enable. This bit controls VHS pin output. 0 = DISABLED 1 = ENABLED
12	0x0	VSCK_OUTPUT_ENABLE: VSCK pin Output Enable. This bit controls VSCK pin output. 0 = DISABLED 1 = ENABLED
11	0x0	VD11_OUTPUT_ENABLE: VD11 pin Output Enable. This bit controls VD7 pin output. 0 = DISABLED 1 = ENABLED
10	0x0	VD10_OUTPUT_ENABLE: VD10 pin Output Enable. This bit controls VD7 pin output. 0 = DISABLED 1 = ENABLED

32.1.64 VI_PIN_OUTPUT_DATA_0

VI Pins Output Data

This register contains output data when the video camera interface pins are used as general-purpose output pins. When a bit in this register is written, the data bits can be output on the corresponding pin if the corresponding pin output buffer is enabled, and the pin output control select bits are programmed to output the bit in this register.

The output signal at the pin is affected by the corresponding pin output inversion bit.

Offset: 0x5f | Byte Offset: 0x17c | Read/Write: R/W | Reset: 0x00XXXXX (0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx)

Bit	Reset	Description
21	X	VGP6_OUTPUT_DATA: VGP6 pin Output Data (effective if VGP6_OUTPUT_ENABLE is ENABLED and VGP6_OUTPUT_SELECT is DATA)
20	X	VGP5_OUTPUT_DATA: VGP5 pin Output Data (effective if VGP5_OUTPUT_ENABLE is ENABLED and VGP5_OUTPUT_SELECT is DATA)
19	X	VGP4_OUTPUT_DATA: VGP4 pin Output Data (effective if VGP4_OUTPUT_ENABLE is ENABLED and VGP4_OUTPUT_SELECT is DATA)
18	X	VGP3_OUTPUT_DATA: VGP3 pin Output Data (effective if VGP3_OUTPUT_ENABLE is ENABLED and VGP3_OUTPUT_SELECT is DATA)

1	X	VD1_OUTPUT_DATA: VD1 pin Output Data (effective if VD1_OUTPUT_ENABLE is ENABLED and VD1_OUTPUT_SELECT is DATA)

Bit	Reset	Description
0	X	VD0_OUTPUT_DATA: VD0 pin Output Data (effective if VD0_OUTPUT_ENABLE is ENABLED and VD0_OUTPUT_SELECT is DATA)

32.1.65 VI_PIN_OUTPUT_SELECT_0

VI pins Output Select

This is the mux select used at the Pad Macro. For VCLK, VHSYNC, VVSYNC. Selects between the register programmed GPIO outputs (set to 0) and the internally generated VICLK, HSYNC, VSYNC (set to 1). For VGP1-VGP2, selects between the I2C outputs (set to 0) and the VI register programmed GPIO outputs (set to 1). For VD0-VD11, reserved for future use data pins output will be driven by GPIO outputs if enabled.

Offset: 0x60 | Byte Offset: 0x180 | Read/Write: R/W | Reset: 0x00000000 (0bxxxxxxxxxxx000000x000000000000000)

Bit	Reset	Description
21	0x0	PIN_OUTPUT_SELECT_vgp6: Pin Output Select VGP6 0= select VGP6 register data out 1= select PWM out 0 = DATA 1 = PWM

1	0x0	PIN_OUTPUT_SELECT_vd1: Pin Output Select VD1

Bit	Reset	Description
0	0x0	PIN_OUTPUT_SELECT_vd0: Pin Output Select VD0

32.1.66 VI_RAISE_VIP_BUFFER_FIRST_OUTPUT_0

This register is reserved.

A raise written when decimation or averaging is selected in the VI is not supported.

Offset: 0x61 | Byte Offset: 0x184 | Read/Write: R/W | Reset: 0x000X00XX (0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx)

Bit	R/W	Reset	Description
19:16	WO	X	RAISE_BUFFER_1_CHANNEL
4:0	RW	X	RAISE_BUFFER_1_VECTOR

32.1.67 VI_RAISE_VIP_FRAME_FIRST_OUTPUT_0

This register is reserved.

Offset: 0x62 | Byte Offset: 0x188 | Read/Write: R/W | Reset: 0x000X00XX (0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx)

Bit	R/W	Reset	Description
19:16	WO	X	RAISE_FRAME_1_CHANNEL
4:0	RW	X	RAISE_FRAME_1_VECTOR

32.1.68 VI_RAISE_VIP_BUFFER_SECOND_OUTPUT_0

This register is reserved.

Offset: 0x63 | Byte Offset: 0x18c | Read/Write: R/W | Reset: 0x000X00XX (0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx)

Bit	R/W	Reset	Description
19:16	WO	X	RAISE_BUFFER_2_CHANNEL
4:0	RW	X	RAISE_BUFFER_2_VECTOR

32.1.69 VI_RAISE_VIP_FRAME_SECOND_OUTPUT_0

This register is reserved.

Offset: 0x64 | Byte Offset: 0x190 | Read/Write: R/W | Reset: 0x000X00XX (0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx)

Bit	R/W	Reset	Description
19:16	WO	X	RAISE_FRAME_2_CHANNEL
4:0	RW	X	RAISE_FRAME_2_VECTOR

32.1.70 VI_RAISE_HOST_FIRST_OUTPUT_0

Raise Vector When from Host

Offset: 0x65 | Byte Offset: 0x194 | Read/Write: R/W | Reset: 0x000X00XX (0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx)

Bit	R/W	Reset	Description
19:16	WO	X	RAISE_HOST_1_CHANNEL
4:0	RW	X	RAISE_HOST_1_VECTOR

32.1.71 VI_RAISE_HOST_SECOND_OUTPUT_0

Raise Vector When from Host

Offset: 0x66 | Byte Offset: 0x198 | Read/Write: R/W | Reset: 0x000X00XX (0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx)

Bit	R/W	Reset	Description
19:16	WO	X	RAISE_HOST_2_CHANNEL
4:0	RW	X	RAISE_HOST_2_VECTOR

32.1.72 VI_RAISE_EPP_0

Raise Vector at Line End

The EPP receives the raise request via the Simple Stream Video Data bus

This raise needs to be written during the horizontal blanking period. (After end of line.)

This register is only valid if the input source is host.

Offset: 0x67 | Byte Offset: 0x19c | Read/Write: R/W | Reset: 0x000X00XX (0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx)

Bit	R/W	Reset	Description
19:16	WO	X	RAISE_EPP_CHANNEL
4:0	RW	X	RAISE_EPP_VECTOR

32.1.73 VI_CAMERA_CONTROL_0

VI camera control bits

Software must always program parallel cameras in a way that avoids simultaneous HSYNC and VSYNC active edges.

Offset: 0x68 | Byte Offset: 0x1a0 | Read/Write: R/W | Reset: 0x00000000 (0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxx000)

Bit	R/W	Reset	Description
2	RW	0x0	STOP_CAPTURE: Disables camera capturing VI_ENABLE after the next end of frame. 0 = DISABLED 1 = ENABLED
1	RW	0x0	TEST_MODE_ENABLE: Test Mode Enable 0 = DISABLED 1 = ENABLED
0	RO	0x0	VIP_ENABLE: Reserved.

32.1.74 VI_VI_ENABLE_0

VI Enables

Offset: 0x69 | Byte Offset: 0x1a4 | Read/Write: R/W | Reset: 0x00000001 (0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx01)

Bit	Reset	Description
1	0x0	SW_FLOW_CONTROL_OUT1: Software enable flow control for output1 0 = DISABLE 1 = ENABLE
0	0x1	FIRST_OUTPUT_TO_MEMORY: First Output to Memory 0 = ENABLED 1 = DISABLED

32.1.75 VI_VI_ENABLE_2_0

VI Enables second output

Offset: 0x6a | Byte Offset: 0x1a8 | Read/Write: R/W | Reset: 0x00000001 (0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx01)

Bit	Reset	Description
1	0x0	SW_FLOW_CONTROL_OUT2: Software enable flow control for output2 0 = DISABLE 1 = ENABLE
0	0x1	SECOND_OUTPUT_TO_MEMORY: Second Output to Memory Disabling output to memory may be set if only output to encoder pre-processor is needed. This will also power down all logic which is only used to send output data to memory. 0 = ENABLED 1 = DISABLED

32.1.76 VI_VI_RAISE_0

VI Enables second output

Offset: 0x6b | Byte Offset: 0x1ac | Read/Write: R/W | Reset: 0x00000000 (0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx0)

Bit	Reset	Description
0	0x0	RAISE_ON_EDGE: Makes Raises edge triggered not level sensitive, i.e., only return raise at the end of frame, not in the middle of the V-blank time. 0 = DISABLED 1 = ENABLED

32.1.77 VI_Y_FIFO_WRITE_0

YUV 4:2:0 Planar Y-FIFO, YUV 4:2:2 non-Planar YUV FIFO

Host YUV FIFO offsets. This register space is used for Host Video Data writes.

YUV 4:2:0 planar for re-encoding as well as YUV 4:2:2 data

Offset: 0x6c | Byte Offset: 0x1b0 | Read/Write: RO | Reset: 0xXXXXXXXX (0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx)

Bit	Reset	Description
31:0	X	Y_FIFO_DATA

32.1.78 VI_U_FIFO_WRITE_0

YUV 4:2:0 Planar U-FIFO

Offset: 0x6d | Byte Offset: 0x1b4 | Read/Write: RO | Reset: 0xXXXXXXXX (0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx)

Bit	Reset	Description
31:0	X	U_FIFO_DATA

32.1.79 VI_V_FIFO_WRITE_0

YUV 4:2:0 Planar V-FIFO

Offset: 0x6e | Byte Offset: 0x1b8 | Read/Write: RO | Reset: 0xXXXXXXXX (0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx)

Bit	Reset	Description
31:0	X	V_FIFO_DATA

32.1.80 VI_VI_MCCIF_FIFOCTRL_0

Memory Client Interface FIFO Control Register

> **Note:** The FIFO timing aspects of this register are not supported but are retained for software compatibility.

The clock enable fields of this register control the second-level clock gating for the MC side of the MCCIF.

A '1' written to the override field will result in that clock reverting to the legacy mode of operation (where the msc*clk is on whenever the client clock is enabled.

Offset: 0x6f | Byte Offset: 0x1bc | Read/Write: R/W | Reset: 0x00000000 (0bxxxxxxxxxxxxxxx00xxxxxxxxxxxxxx00)

Bit	Reset	Description
17	0x0	VI_RCLK_OVERRIDE
16	0x0	VI_WCLK_OVERRIDE
1	DISABLE	VI_MCCIF_RDMC_RDFAST: 0 = DISABLE 1 = ENABLE
0	DISABLE	VI_MCCIF_WRCL_MCLE2X: 0 = DISABLE 1 = ENABLE

32.1.81 VI_TIMEOUT_WCOAL_VI_0

Memory Client Interface FIFO Control Register

> **Note:** The FIFO timing aspects of this register are not supported but are retained for software compatibility.

The clock enable fields of this register control the second-level clock gating for the MC side of the MCCIF.

A '1' written to the override field will result in that clock reverting to the legacy mode of operation (where the msc*clk is on whenever the client clock is enabled.

Write Coalescing Time-Out Register

> **Note:** Write coalescing is not supported by the MCCIF clients.
> Registers are retained for backwards compatibility but are not used by the hardware.

Offset: 0x70 | Byte Offset: 0x1c0 | Read/Write: R/W | Reset: 0x32323232 (0b00110010000110010000110010000110010)

Bit	Reset	Description
31:24	0x32	VIWY_WCOAL_TMVAL
23:16	0x32	VIWV_WCOAL_TMVAL
15:8	0x32	VIWU_WCOAL_TMVAL
7:0	0x32	VIWSB_WCOAL_TMVAL

32.1.82 VI_MCCIF_VIWSB_HP_0

Memory Client Interface FIFO Control Register

> **Note:** The FIFO timing aspects of this register are not supported but are retained for software compatibility.

The clock enable fields of this register control the second-level clock gating for the MC side of the MCCIF.

A '1' written to the override field will result in that clock reverting to the legacy mode of operation (where the msc*clk is on whenever the client clk is enabled.

Memory Client High-Priority Control Register

> **Note:** High Priority mode is not supported by the MCCIF clients.
> Registers are retained for backwards compatibility but are not used by the hardware.

Offset: 0x72 | Byte Offset: 0x1c8 | Read/Write: R/W | Reset: 0x00000000 (0bxxxxxxxxxxxxxxxxxxxxxxxxxxx0000000)

Bit	Reset	Description
6:0	0x0	CBW_VIWSB2MC_HPTH

32.1.83 VI_MCCIF_VIWU_HP_0

Memory Client High-Priority Control Register

> **Note:** High Priority mode is not supported by the MCCIF clients.
> Registers are retained for backwards compatibility but are not used by the hardware.

Offset: 0x73 | Byte Offset: 0x1cc | Read/Write: R/W | Reset: 0x00000000 (0bxxxxxxxxxxxxxxxxxxxxxxxxxxx0000000)

Bit	Reset	Description
6:0	0x0	CBW_VIWU2MC_HPTH

32.1.84 VI_MCCIF_VIWV_HP_0

Memory Client High-Priority Control Register

> **Note:** High Priority mode is not supported by the MCCIF clients.
> Registers are retained for backwards compatibility but are not used by the hardware.

Offset: 0x74 | Byte Offset: 0x1d0 | Read/Write: R/W | Reset: 0x00000000 (0bxxxxxxxxxxxxxxxxxxxxxxxxxxx0000000)

Bit	Reset	Description
6:0	0x0	CBW_VIWV2MC_HPTH

32.1.85 VI_MCCIF_VIWY_HP_0

Memory Client High-Priority Control Register

> **Note:** High Priority mode is not supported by the MCCIF clients.
> Registers are retained for backwards compatibility but are not used by the hardware.

Offset: 0x75 | Byte Offset: 0x1d4 | Read/Write: R/W | Reset: 0x00000000 (0bxxxxxxxxxxxxxxxxxxxxxxxxxxx0000000)

Bit	Reset	Description
6:0	0x0	CBW_VIWY2MC_HPTH

32.1.86 VI_CSI_PPA_RAISE_FRAME_START_0

CSI Pixel Parser A Raise

CSI Raise vectors

Offset: 0x76 | Byte Offset: 0x1d8 | Read/Write: R/W | Reset: 0x000XXXXX (0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx)

Bit	Reset	Description
19:16	X	CSI_PPA_RAISE_FRAME_START_CHANNEL: Raise return channel
15:8	X	CSI_PPA_RAISE_FRAME_START_COUNT: Number of frame starts since the last raise >= count for raise to be returned
4:0	X	CSI_PPA_RAISE_FRAME_START_VECTOR: Raise returned by VI when CSI PPA issues a frame start to the consumer.

32.1.87 VI_CSI_PPA_RAISE_FRAME_END_0

CSI Pixel Parser A Raise

Offset: 0x77 | Byte Offset: 0x1dc | Read/Write: R/W | Reset: 0x000XXXXX (0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx)

Bit	Reset	Description
19:16	X	CSI_PPA_RAISE_FRAME_END_CHANNEL: Raise return channel
15:8	X	CSI_PPA_RAISE_FRAME_END_COUNT: Number of frame ends since the last raise >= count for raise to be returned
4:0	X	CSI_PPA_RAISE_FRAME_END_VECTOR: Raise returned by VI when CSI PPA issues a frame end to the consumer.

32.1.88 VI_CSI_PPB_RAISE_FRAME_START_0

CSI Pixel Parser B Raise

Offset: 0x78 | Byte Offset: 0x1e0 | Read/Write: R/W | Reset: 0x000XXXXX (0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx)

Bit	Reset	Description
19:16	X	CSI_PPB_RAISE_FRAME_START_CHANNEL: Raise return channel
15:8	X	CSI_PPB_RAISE_FRAME_START_COUNT: Number of frame starts since the last raise >= count for raise to be returned
4:0	X	CSI_PPB_RAISE_FRAME_START_VECTOR: Raise returned by VI when CSI PPB issues a frame start to the consumer.

32.1.89 VI_CSI_PPB_RAISE_FRAME_END_0

CSI Pixel Parser B Raise

Offset: 0x79 | Byte Offset: 0x1e4 | Read/Write: R/W | Reset: 0x000XXXXX (0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx)

Bit	Reset	Description
19:16	X	CSI_PPB_RAISE_FRAME_END_CHANNEL: Raise return channel
15:8	X	CSI_PPB_RAISE_FRAME_END_COUNT: Number of frame ends since the last raise >= count for raise to be returned
4:0	X	CSI_PPB_RAISE_FRAME_END_VECTOR: Raise returned by VI when CSI PPB issues a frame end to the consumer.

32.1.90 VI_CSI_PPA_H_ACTIVE_0

VI Horizontal Active

This register defines the horizontal captured (active) area of the input video source with respect to horizontal sync. (This is for CSI data.)

Offset: 0x7a | Byte Offset: 0x1e8 | Read/Write: R/W | Reset: 0xXXXXXXXX (0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx)

Bit	Reset	Description
28:16	X	CSI_PPA_H_ACTIVE_PERIOD: Horizontal Active Period. This parameter specifies the number of pixels in the horizontal active area. H_ACTIVE_START + H_ACTIVE_PERIOD should be less than 2^NV_VI_H_IN (or 8192). This parameter should be programmed with an even number (bit 16 is ignored internally).
12:0	X	CSI_PPA_H_ACTIVE_START: Horizontal Active Start (offset to active). This parameter specifies the number of clock active edges from horizontal sync active edge to the first horizontal active pixel. If programmed to 0, the first active line starts after the first active clock edge following the horizontal sync active edge.

32.1.91 VI_CSI_PPA_V_ACTIVE_0

Vertical Active

This register defines the vertical captured (active) area of the input video source with respect to vertical sync. (This is for CSI data.)

Offset: 0x7b | Byte Offset: 0x1ec | Read/Write: R/W | Reset: 0xXXXXXXXX (0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx)

Bit	Reset	Description
28:16	X	CSI_PPA_V_ACTIVE_PERIOD: Vertical Active Period. This parameter specifies the number of lines in the vertical active area. V_ACTIVE_START + V_ACTIVE_PERIOD should be less than 2^NV_VI_V_IN (or 8192).
12:0	X	CSI_PPA_V_ACTIVE_START: Vertical Active Start (offset to active). This parameter specifies the number of horizontal sync active edges from vertical sync active edge to the first vertical active line. If programmed to 0, the first active line starts after the first horizontal sync active edge following the vertical sync active edge.

32.1.92 VI_CSI_PPB_H_ACTIVE_0

VI Horizontal Active

This register defines the horizontal captured (active) area of the input video source with respect to horizontal sync. (This is for CSI data.)

Offset: 0x7c | Byte Offset: 0x1f0 | Read/Write: R/W | Reset: 0xXXXXXXXX (0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx)

Bit	Reset	Description
28:16	X	CSI_PPB_H_ACTIVE_PERIOD: Horizontal Active Period. This parameter specifies the number of pixels in the horizontal active area. H_ACTIVE_START + H_ACTIVE_PERIOD should be less than 2^NV_VI_H_IN (or 8192). This parameter should be programmed with an even number (bit 16 is ignored internally).
12:0	X	CSI_PPB_H_ACTIVE_START: Horizontal Active Start (offset to active). This parameter specifies the number of clock active edges from horizontal sync active edge to the first horizontal active pixel. If programmed to 0, the first active line starts after the first active clock edge following the horizontal sync active edge.

32.1.93 VI_CSI_PPB_V_ACTIVE_0

Vertical Active

This register defines the vertical captured (active) area of the input video source with respect to vertical sync. (This is for CSI data.)

Offset: 0x7d | Byte Offset: 0x1f4 | Read/Write: R/W | Reset: 0xXXXXXXXX (0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx)

Bit	Reset	Description
28:16	X	CSI_PPB_V_ACTIVE_PERIOD: Vertical Active Period. This parameter specifies the number of lines in the vertical active area. V_ACTIVE_START + V_ACTIVE_PERIOD should be less than 2^NV_VI_V_IN (or 8192).
12:0	X	CSI_PPB_V_ACTIVE_START: Vertical Active Start (offset to active). This parameter specifies the number of horizontal sync active edges from vertical sync active edge to the first vertical active line. If programmed to 0, the first active line starts after the first horizontal sync active edge following the vertical sync active edge.

32.1.94 VI_ISP_H_ACTIVE_0

Used when an image comes from ISP

Used only with input from ISP: defines input image horizontal size in pixels

Offset: 0x7e | Byte Offset: 0x1f8 | Read/Write: R/W | Reset: 0x0000XXXX (0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx)

Bit	Reset	Description
12:0	X	ISP_H_ACTIVE_PERIOD: Horizontal image size in pixels coming out of the ISP. Must be an even number (bit 0 is ignored).

32.1.95 VI_ISP_V_ACTIVE_0

Used when an image comes from ISP

Used only with input from ISP: defines input image vertical size in lines

Offset: 0x7f | Byte Offset: 0x1fc | Read/Write: R/W | Reset: 0x0000XXXX (0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx)

Bit	Reset	Description
12:0	X	ISP_V_ACTIVE_PERIOD: Vertical image size in lines coming out of the ISP. Must be an even number (bit 0 is ignored).

32.1.96 VI_STREAM_1_RESOURCE_DEFINE_0

This register defines resources used by stream 1.

The field definitions are:

- 0 = resource not used
- 1 = resource used.

Stream raises ("safe to reprogram VI" raises)

The I/O resources used by a data stream going through VI are indicated in STREAM_?_RESOURCE_DEFINE register.

Once resources are set in this register, and after the start of the following picture when ALL the stream's resources are done and idle processing that picture, a raise is generated. It is then safe to reprogram VI's functional units involved in processing that stream.

Two simultaneous data streams are supported, and they do not have to be mutually exclusive.

When no resources are indicated for a stream, no raise is generated.

Offset: 0x80 | Byte Offset: 0x200 | Read/Write: R/W | Reset: 0x00000000 (0bxxxxxxxxxxxxxxxxxxxx000000000000)

Bit	Reset	Description
11	0x0	HOST_DMA_BUFFER_OUTPUT_1: 0 = NOT_USED 1 = USED
10	0x0	EPP_OUTPUT_1: 0 = NOT_USED 1 = USED
9	0x0	HOST_DMA_VSYNC_OUTPUT_1: 0 = NOT_USED 1 = USED
8	0x0	SECOND_OUTPUT_1: 0 = NOT_USED 1 = USED
7	0x0	FIRST_OUTPUT_1: 0 = NOT_USED 1 = USED
6	0x0	ISP_INPUT_1: 0 = NOT_USED 1 = USED

4	0x0	CSI_PPB_CROPPED_INPUT_1: 0 = NOT_USED 1 = USED
3	0x0	CSI_PPA_UNCROPPED_INPUT_1: 0 = NOT_USED 1 = USED
2	0x0	CSI_PPA_CROPPED_INPUT_1: 0 = NOT_USED 1 = USED
1	0x0	HOST_INPUT_1: 0 = NOT_USED 1 = USED
0	0x0	VIP_INPUT_1: Reserved

32.1.97 VI_STREAM_2_RESOURCE_DEFINE_0

Defines resources used by stream 2.

The field definitions are:

- 0 = resource not used
- 1 = resource used.

Offset: 0x81 | Byte Offset: 0x204 | Read/Write: R/W | Reset: 0x00000000 (0bxxxxxxxxxxxxxxxxxxxx000000000000)

Bit	Reset	Description
11	0x0	HOST_DMA_BUFFER_OUTPUT_2: 0 = NOT_USED 1 = USED

Bit	Reset	Description
10	0x0	EPP_OUTPUT_2: 0 = NOT_USED 1 = USED
9	0x0	HOST_DMA_VSYNC_OUTPUT_2: 0 = NOT_USED 1 = USED
8	0x0	SECOND_OUTPUT_2: 0 = NOT_USED 1 = USED
7	0x0	FIRST_OUTPUT_2: 0 = NOT_USED 1 = USED

2	0x0	CSI_PPA_CROPPED_INPUT_2: 0 = NOT_USED 1 = USED
1	0x0	HOST_INPUT_2: 0 = NOT_USED 1 = USED
0	0x0	VIP_INPUT_2: Reserved.

32.1.98 VI_RAISE_STREAM_1_DONE_0

Raise vector when all stream 1 resources, as defined by the STREAM_1_RESOURCE_DEFINE register, become idle after the start of the following frame.

Offset: 0x82 | Byte Offset: 0x208 | Read/Write: R/W | Reset: 0x000X00XX (0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx)

Bit	R/W	Reset	Description
19:16	WO	X	RAISE_CHANNEL_STREAM_1
4:0	RW	X	RAISE_VECTOR_STREAM_1

32.1.99 VI_RAISE_STREAM_2_DONE_0

Raise vector when all stream 2 resources, as defined by the STREAM_2_RESOURCE_DEFINE register, become idle after the start of the following frame.

Offset: 0x83 | Byte Offset: 0x20c | Read/Write: R/W | Reset: 0x000X00XX (0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx)

Bit	R/W	Reset	Description
19:16	WO	X	RAISE_CHANNEL_STREAM_2
4:0	RW	X	RAISE_VECTOR_STREAM_2

32.1.100 VI_TS_MODE_0

ISDB-T Mode Selection Register

ISDB-T tuner mode register settuner/demodulator mode.

Offset: 0x84 | Byte Offset: 0x210 | Read/Write: R/W | Reset: 0x000000XX (0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx)

Bit	Reset	Description
5:4	X	FLOW_CONTROL_MODE: This field selects the buffer flow control for the Write DMA RDMA: The RDMA engine will release the buffers back to the WDMA as the buffers are consumed NONE: The VI will automatically release the buffer back to the WMDA after each buffer ready is generated. CPU: Software needs to write the TS_CPU_FLOW_CTL register to release each buffer to the WDMA 0 = RDMA 1 = NONE 2 = CPU 3 = RESERVED
3:2	X	PROTOCOL_SELECT: This field selected the pin configuration used for VD[1] NONE: TS_ERROR is tied to 0 TS_PSYNC is tied to 0 TS_ERROR: TS_ERROR is on VD[1] TS_PSYNC is tied to 0 TS_PSYNC: TS_ERROR is tied to 0. TS_PSYNC is on VD[1] 0 = NONE 1 = TS_ERROR 2 = TS_PSYNC 3 = RESERVED
1	X	INPUT_MODE: This field determines if input data is in serial or parallel format 0 = PARALLEL 1 = SERIAL
0	X	ENABLE: This field indicates the global enable for ISDB-T protocol handling 0 = DISABLED 1 = ENABLED

32.1.101 VI_TS_CONTROL_0

ISDB-T Mode Control Register

Offset: 0x85 | Byte Offset: 0x214 | Read/Write: R/W | Reset: 0xXXXX00XX (0bxxxxxxxxxxxxxxxxxxxxxxxxxxxx1xxx)

Bit	Reset	Description
30:24	X	FEC_SIZE: This field stores the number of FEC bytes to capture (after the BODY has been captured)
23:16	X	BODY_SIZE: This field stores the number of BODY bytes to capture (including PSYNC)
7	X	STORE_UPSTREAM_ERROR_PKTS: This field determines if VI should store packets to memory that have been flagged as UPSTREAM_ERROR packets. DISCARD: Do not store packets in memory STORE: Store UPSTREAM_ERROR packets in memory 0 = DISCARD 1 = STORE
6	X	BODY_VALID_SELECT: This field determines if VALID is used during BODY packet capture IGNORE: the VALID signal is ignored during the capture GATE: the VALID signal gates the capture of BODY data. 0 = IGNORE 1 = GATE

Bit	Reset	Description
5:4	X	START_SELECT: This field defines how the START of packet condition is determined PSYNC: PSYNC assertion rising edge VALID: VALID assertion rising edge BOTH: PSYNC && VALID asserted rising edge 0 = RESERVED 1 = PSYNC 2 = VALID 3 = BOTH
3	LOW	CLK_POLARITY: 0 = HIGH 1 = LOW
2	X	ERROR_POLARITY: 0 = HIGH 1 = LOW
1	X	PSYNC_POLARITY: 0 = HIGH 1 = LOW
0	X	VALID_POLARITY: This field indicates the polarity of TS_VALID. Only has affect when TS_MODE.ENABLE == ENABLED LOW indicates that the polarity of TS_VALID is active low. HIGH indicates that the polarity of TS_VALID is active high. 0 = HIGH 1 = LOW

32.1.102 VI_TS_PACKET_COUNT_0

ISDB-T Packet Count Register

Offset: 0x86 | Byte Offset: 0x218 | Read/Write: RO | Reset: 0x000XXXXX (0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx)

Bit	Reset	Description
16	X	TS_PACKET_COUNT_VALUE_OVERFLOW: This field is set to OVERFLOW when the value passes from 0xFFFF to 0x0000. It stays high until the CPU writes a zero to this bit to reset it. 0 = NONE 1 = OVERFLOW
15:0	X	TS_PACKET_COUNT_VALUE: This field holds the current value of the received packet counter. This counter increments in the presence of a new packet, regardless of whether it is flagged as an error. The counter can be cleared by writing this register with 0's and can also be preloaded to any value by writing the preload value to the register.

32.1.103 VI_TS_ERROR_COUNT_0

ISDB-T Error Count Register

Offset: 0x87 | Byte Offset: 0x21c | Read/Write: RO | Reset: 0x000XXXXX (0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx)

Bit	Reset	Description
16	X	TS_ERROR_COUNT_VALUE_OVERFLOW: This field is set to OVERFLOW when the value passes from 0xFFFF to 0x0000. It stays high until the CPU writes a zero to this bit to reset it. 0 = NONE 1 = OVERFLOW
15:0	X	TS_ERROR_COUNT_VALUE: This field holds the current value of the error packet counter. This counter increments in the presence of a packet flagged as error (see TS_ERROR) 0000 or a detected protocol violation. The counter can be cleared by writing this register with 0's and can also be preloaded to any value by writing the preload value to the register.

32.1.104 VI_TS_CPU_FLOW_CTL_0

ISDB-T CPU Flow Control Register

Offset: 0x88 | Byte Offset: 0x220 | Read/Write: RO | Reset: 0x0000000X (0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx)

Bit	Reset	Description
0	X	BUFFER_RELEASE: Used only when the FLOW_CONTROL_MODE register is set to CPU. Software must write this register to release each buffer back to WDMA. Failure to write this register when buffers are consumed will result in the WDMA stalling when it consumes all allocated/free buffers.

32.1.105 VI_VB0_CHROMA_BUFFER_STRIDE_FIRST_0

Video Buffer Set 0 Chroma Buffer Stride

This feature represents an alternative value to using VB0_BUFFER_STRIDE_C.

HOST_DMA_WRITE_BUFFER.BUFFER_SIZE (bytes) is used to hold the number of bytes in a buffer for ISDB-T mode.

Offset: 0x89 | Byte Offset: 0x224 | Read/Write: R/W | Reset: 0xXXXXXXXX (0b0xxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx)

Bit	Reset	Description
31	0x0	VB0_CHROMA_BUFFER_STRIDE_SELECT: select type of Chroma buffer stride: 0 = Use VB0_BUFFER_STRIDE_C, deriving chroma buffer stride from luma buffer stride (default). 1 = Use VB0_CHROMA_BUFFER_STRIDE. 0 = RATIO 1 = VALUE
29:0	X	VB0_CHROMA_BUFFER_STRIDE: Chroma buffer stride in bytes

32.1.106 VI_VB0_CHROMA_LINE_STRIDE_FIRST_0

Video Buffer Set 0 chroma line stride for First Output of planar YUV formats

Offset: 0x8a | Byte Offset: 0x228 | Read/Write: R/W | Reset: 0x0000XXXX (0b0xxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx)

Bit	Reset	Description
31	0x0	VB0_CHROMA_LINE_STRIDE_SELECT: select type of Chroma line stride: 0 = Use VB0_H_SIZE_1, deriving chroma line stride from luma line stride (default). 1 = Use VB0_CHROMA_H_SIZE_1. 0 = RATIO 1 = VALUE
12:0	X	VB0_CHROMA_H_SIZE_1: Video Buffer Set 0 chroma horizontal size This parameter specifies the chroma line stride (in pixels) for lines in the video buffer set 0. This parameter must be programmed as a multiple of 4 pixels (bits 1-0 are ignored).

32.1.107 VI_EPP_LINES_PER_BUFFER_0

Number of buffers per output frame in EPP

This register is used for VI2EPP syncpt only.

The VI will based on num_lines = frame_height/EPP_NUM_OF_BUFFER_PER_FRAME, send vi2epp_trigger for every num_lines

Offset: 0x8b | Byte Offset: 0x22c | Read/Write: R/W | Reset: 0x0000XXXX (0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx)

Bit	Reset	Description
12:0	X	LINES_PER_BUFFER: maximum 256 buffers per frame. linesPerBuffer = FLOOR(eppLineCount/eppBufferCount) linesPerBuffer must be > 2 eppLineCount must take into account any cropping in the EPP.

32.1.108 VI_BUFFER_RELEASE_OUTPUT1_0

Writes to this register will decrease BUFFER_COUNTER by 1

Offset: 0x8c | Byte Offset: 0x230 | Read/Write: R/W | Reset: 0x0000000X (0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx)

Bit	Reset	Description
0	X	BUFFER_RELEASE_OUTPUT1

32.1.109 VI_BUFFER_RELEASE_OUTPUT2_0

Offset: 0x8d | Byte Offset: 0x234 | Read/Write: R/W | Reset: 0x0000000X (0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx)

Bit	Reset	Description
0	X	BUFFER_RELEASE_OUTPUT2

32.1.110 VI_DEBUG_FLOW_CONTROL_COUNTER_OUTPUT1_0

Debug register

Offset: 0x8e | Byte Offset: 0x238 | Read/Write: RO | Reset: 0x000000XX (0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx)

Bit	Reset	Description
7:0	X	BUFFER_COUNT_OUTPUT1

32.1.111 VI_DEBUG_FLOW_CONTROL_COUNTER_OUTPUT2_0

Offset: 0x8f | Byte Offset: 0x23c | Read/Write: RO | Reset: 0x000000XX (0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx)

Bit	Reset	Description
7:0	X	BUFFER_COUNT_OUTPUT2

32.1.112 VI_TERMINATE_BW_FIRST_0

Writes to this register will terminate MC on BW operation in the FIRST output.

Offset: 0x90 | Byte Offset: 0x240 | Read/Write: R/W | Reset: 0x0000000X (0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx)

Bit	Reset	Description
0	X	TERMINATE_FIRST_BW

32.1.113 VI_TERMINATE_BW_SECOND_0

Writes to this register will terminate MC on BW operation in the SECOND output.

Offset: 0x91 | Byte Offset: 0x244 | Read/Write: R/W | Reset: 0x0000000X (0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx)

Bit	Reset	Description
0	X	TERMINATE_SECOND_BW

32.1.114 VI_VB0_FIRST_BUFFER_ADDR_MODE_0

Memory Controller Tiling Definitions

Offset: 0x92 | Byte Offset: 0x248 | Read/Write: R/W | Reset: 0x00000000 (0bxxxxxxxxxxxxxxxxxxxxxxxx0xxxxxxx0)

Bit	Reset	Description
8	0x0	UV1_TILE_MODE: 0 = LINEAR 1 = TILED
0	0x0	Y1_TILE_MODE: 0 = LINEAR 1 = TILED

32.1.115 VI_VB0_SECOND_BUFFER_ADDR_MODE_0

Offset: 0x93 | Byte Offset: 0x24c | Read/Write: R/W | Reset: 0x00000000 (0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx0)

Bit	Reset	Description
0	0x0	Y2_TILE_MODE: 0 = LINEAR 1 = TILED

32.1.116 VI_RESERVE_0_0

Reserved register

Offset: 0x94 | Byte Offset: 0x250 | Read/Write: R/W | Reset: 0x0000XXXX (0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx)

Bit	Reset	Description
15:12	X	nc_RESERVE_0_3
11:8	X	nc_RESERVE_0_2
7:4	X	nc_RESERVE_0_1
3:0	X	nc_RESERVE_0_0

32.1.117 VI_RESERVE_1_0

Reserved register

Offset: 0x95 | Byte Offset: 0x254 | Read/Write: R/W | Reset: 0x0000XXXX (0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx)

Bit	Reset	Description
15:12	X	nc_RESERVE_1_3
11:8	X	nc_RESERVE_1_2
7:4	X	nc_RESERVE_1_1
3:0	X	nc_RESERVE_1_0

32.1.118 VI_RESERVE_2_0

Reserved register

Offset: 0x96 | Byte Offset: 0x258 | Read/Write: R/W | Reset: 0x0000XXX0 (0bxxxxxxxxxxxxxxxxxxxxxxxxxxxx0000)

Bit	Reset	Description
15:12	X	nc_RESERVE_2_3

Bit	Reset	Description
11:8	X	nc_RESERVE_2_2
7:4	X	nc_RESERVE_2_1
3:0	0x0	nc_RESERVE_2_0

32.1.119 VI_RESERVE_3_0

Reserved register

Offset: 0x97 | Byte Offset: 0x25c | Read/Write: R/W | Reset: 0x0000XXXX (0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx)

Bit	Reset	Description
15:12	X	nc_RESERVE_3_3
11:8	X	nc_RESERVE_3_2
7:4	X	nc_RESERVE_3_1
3:0	X	nc_RESERVE_3_0

32.1.120 VI_RESERVE_4_0

Reserved register

Offset: 0x98 | Read/Write: R/W | Reset: 0x0000XXXX (0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx)

Bit	Reset	Description
15:12	X	nc_RESERVE_4_3
11:8	X	nc_RESERVE_4_2
7:4	X	nc_RESERVE_4_1
3:0	X	nc_RESERVE_4_0

32.1.121 VI_MCCIF_VIWSB_HYST_0

Memory Client Interface FIFO Control Register

> **Note:** The FIFO timing aspects of this register are not supported but are retained for software compatibility.

The clock enable fields of this register control the second-level clock gating for the MC side of the MCCIF.

A '1' written to the override field will result in that clock reverting to the legacy mode of operation (where the msc*clk is on whenever the client clock is enabled.

Memory Client Hysteresis Control Register

> **Note:** Hysteresis is not supported by the MCCIF clients.
> Registers are retained for backwards compatibility but are not used by the hardware.

Offset: 0x9a | Byte Offset: 0x268 | Read/Write: R/W | Reset: 0xc00001ff (0b1100xxxxxxxxxxxxxxx000111111111)

Bit	Reset	Description
31	ENABLE	CBW_VIWSB2MC_HYST_EN: 1 = ENABLE 0 = DISABLE
30:28	0x4	CBW_VIWSB2MC_HYST_REQ_TH

Bit	Reset	Description
11:0	0x1ff	CBW_VIWSB2MC_HYST_REQ_TM

32.1.122 VI_MCCIF_VIWU_HYST_0

Memory Client Hysteresis Control Register

> **Note:** Hysteresis is not supported by the MCCIF clients.
> Registers are retained for backwards compatibility but are not used by the hardware.

Offset: 0x9b | Byte Offset: 0x26c | Read/Write: R/W | Reset: 0xc00001ff (0b1100xxxxxxxxxxxxxxxx000111111111)

Bit	Reset	Description
31	ENABLE	CBW_VIWU2MC_HYST_EN: 1 = ENABLE 0 = DISABLE
30:28	0x4	CBW_VIWU2MC_HYST_REQ_TH
11:0	0x1ff	CBW_VIWU2MC_HYST_REQ_TM

32.1.123 VI_MCCIF_VIWV_HYST_0

Memory Client Hysteresis Control Register

> **Note:** Hysteresis is not supported by the MCCIF clients.
> Registers are retained for backwards compatibility but are not used by the hardware.

Offset: 0x9c | Byte Offset: 0x270 | Read/Write: R/W | Reset: 0xc00001ff (0b1100xxxxxxxxxxxxxxxx000111111111)

Bit	Reset	Description
31	ENABLE	CBW_VIWV2MC_HYST_EN: 1 = ENABLE 0 = DISABLE
30:28	0x4	CBW_VIWV2MC_HYST_REQ_TH
11:0	0x1ff	CBW_VIWV2MC_HYST_REQ_TM

32.1.124 VI_MCCIF_VIWY_HYST_0

Memory Client Hysteresis Control Register

> **Note:** Hysteresis is not supported by the MCCIF clients.
> Registers are retained for backwards compatibility but are not used by the hardware.

Offset: 0x9d | Byte Offset: 0x274 | Read/Write: R/W | Reset: 0xc00001ff (0b1100xxxxxxxxxxxxxxxx000111111111)

Bit	Reset	Description
31	ENABLE	CBW_VIWY2MC_HYST_EN: 1 = ENABLE 0 = DISABLE
30:28	0x4	CBW_VIWY2MC_HYST_REQ_TH
11:0	0x1ff	CBW_VIWY2MC_HYST_REQ_TM

32.1.125 VI_FIELD_STATUS_SHADOW1_0

This register contains a copy of the field status and frame counter registers at the end of the previous frame. The register is updated when the OP_DONE syncpt fires at the end of the frame. So the value should be "safe" to read for the entire "next" frame. There are 2 registers, each of which is tied to one of the 2 output channels

Offset: 0x9e | Byte Offset: 0x278 | Read/Write: RO | Reset: 0xXXXX000X (0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx)

Bit	Reset	Description
31:16	X	FRAME_COUNT_SHADOW1: Shadow copy of the number of frames received (VSYNCs)
0	X	FIELD_STATUS_SHADOW1: Shadow copy of the field count register - synced to channel 1

32.1.126 VI_FIELD_STATUS_SHADOW2_0

Offset: 0x9f | Byte Offset: 0x27c | Read/Write: RO | Reset: 0xXXXX000X (0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx)

Bit	Reset	Description
31:16	X	FRAME_COUNT_SHADOW2: Shadow copy of the number of frames received (VSYNCs)
0	X	FIELD_STATUS_SHADOW2: Shadow copy of the field count register - synced to channel 2

32.1.127 VI_COREMUX_CROP_H_ACTIVE_0

VI Horizontal Active

This register defines the horizontal captured (active) area of the input video source with respect to horizontal sync.

Offset: 0xa0 | Byte Offset: 0x280 | Read/Write: R/W | Reset: 0xXXXXXXXX (0b0xxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx)

Bit	Reset	Description
31	0x0	COREMUX_CROP_ENABLE: enable cropping after core-mux 0 = DISABLED 1 = ENABLED
28:16	X	COREMUX_CROP_H_ACTIVE_PERIOD: Horizontal Active Period. This parameter specifies the number of pixels in the horizontal active area. H_ACTIVE_START + H_ACTIVE_PERIOD should be less than 2^NV_VI_H_IN (or 8192). This parameter should be programmed with an even number (bit 16 is ignored internally).
12:0	X	COREMUX_CROP_H_ACTIVE_START: Horizontal Active Start (offset to active). This parameter specifies the number of clock active edges from horizontal sync active edge to the first horizontal active pixel. If programmed to 0, the first active line starts after the first active clock edge following the horizontal sync active edge.

32.1.128 VI_COREMUX_CROP_V_ACTIVE_0

Vertical Active

This register defines the vertical captured (active) area of the input video source with respect to vertical sync.

Offset: 0xa1 | Byte Offset: 0x284 | Read/Write: R/W | Reset: 0xXXXXXXXX (0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx)

Bit	Reset	Description
28:16	X	COREMUX_CROP_V_ACTIVE_PERIOD: Vertical Active Period. This parameter specifies the number of lines in the vertical active area. V_ACTIVE_START + V_ACTIVE_PERIOD should be less than 2^NV_VI_V_IN (or 8192).
12:0	X	COREMUX_CROP_V_ACTIVE_START: Vertical Active Start (offset to active). This parameter specifies the number of horizontal sync active edges from vertical sync active edge to the first vertical active line. If programmed to 0, the first active line starts after the first horizontal sync active edge following the vertical sync active edge.

32.1.129 VI_ALTMUX_CROP_H_ACTIVE_0

VI Horizontal Active

This register defines the horizontal captured (active) area of the input video source with respect to horizontal sync.

Offset: 0xa2 | Byte Offset: 0x288 | Read/Write: R/W | Reset: 0xXXXXXXXX (0b0xxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx)

Bit	Reset	Description
31	0x0	ALTMUX_CROP_ENABLE: enable cropping after core-mux 0 = DISABLED 1 = ENABLED
28:16	X	ALTMUX_CROP_H_ACTIVE_PERIOD: Horizontal Active Period. This parameter specifies the number of pixels in the horizontal active area. H_ACTIVE_START + H_ACTIVE_PERIOD should be less than 2^NV_VI_H_IN (or 8192). This parameter should be programmed with an even number (bit 16 is ignored internally).
12:0	X	ALTMUX_CROP_H_ACTIVE_START: Horizontal Active Start (offset to active). This parameter specifies the number of clock active edges from horizontal sync active edge to the first horizontal active pixel. If programmed to 0, the first active line starts after the first active clock edge following the horizontal sync active edge.

32.1.130 VI_ALTMUX_CROP_V_ACTIVE_0

Vertical Active

This register defines the vertical captured (active) area of the input video source with respect to vertical sync.

Offset: 0xa3 | Byte Offset: 0x28c | Read/Write: R/W | Reset: 0xXXXXXXXX (0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx)

Bit	Reset	Description
28:16	X	ALTMUX_CROP_V_ACTIVE_PERIOD: Vertical Active Period. This parameter specifies the number of lines in the vertical active area. V_ACTIVE_START + V_ACTIVE_PERIOD should be less than 2^NV_VI_V_IN (or 8192).
12:0	X	ALTMUX_CROP_V_ACTIVE_START: Vertical Active Start (offset to active). This parameter specifies the number of horizontal sync active edges from vertical sync active edge to the first vertical active line. If programmed to 0, the first active line starts after the first horizontal sync active edge following the vertical sync active edge.

32.1.131 VI_VI_STEREO_CONTROL_0

This register controls the aspects of stereo capture.

Offset: 0xa4 | Byte Offset: 0x290 | Read/Write: R/W | Reset: 0xXXXX0XX0 (0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx0)

Bit	Reset	Description
31:24	X	HBLANK_WIDTH: number of blank pixels inserted at the end of the super line.
21:16	X	SEAM_WIDTH: number of blank pixels inserted between lines
8	X	STEREO_BUFFER_1_SRC: source for stereo buffer 1 0 = CSIA 1 = CSIB
4	X	STEREO_BUFFER_0_SRC: source for stereo buffer 0 0 = CSIA 1 = CSIB
0	DISABLED	ENABLE_STEREO: enable stereo capture. Lines from two sources will be concatenated and sent to ISP 0 = DISABLED 1 = ENABLED

32.1.132 VI_VI_CSIA_PATTERN_GEN_SIZE_0

Control register for CSI-A Pattern Generator

Offset: 0xa5 | Byte Offset: 0x294 | Read/Write: R/W | Reset: 0xXXXXXXXX (0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx)

Bit	Reset	Description
29:16	X	CSIA_PG_V_COUNT_MAX: Maximum Y of pattern (program to 1 less than pattern height)
13:0	X	CSIA_PG_H_COUNT_MAX: Maximum X of pattern (program to 1 less than pattern width)

32.1.133 VI_VI_CSIA_PATTERN_GEN_CONTROL_0

Offset: 0xa6 | Byte Offset: 0x298 | Read/Write: R/W | Reset: 0x00000002 (0bxxxxxxxxxxxxxxxxxxxxxx00xxxx0010)

Bit	Reset	Description
9:8	0x0	CSIA_PG_UPDATE_CYCLES: "dead" cycles between updates of pattern generator, i.e., 0 = update every cycle, 1 = update every other cycle
3	0x0	CSIA_PG_ZERO_V_COUNT: Hold V count to zero when generating pattern data
2	0x0	CSIA_PG_ZERO_H_COUNT: Hold H count to zero when generating pattern data
1	BAYER	CSIA_PG_BAYER: Enable pattern generator 0 = YUV 1 = BAYER
0	DISABLED	CSIA_PG_ENABLE: enable pattern generator 0 = DISABLED 1 = ENABLED

32.1.134 VI_VI_CSIB_PATTERN_GEN_SIZE_0

Control Register for CSI-B pattern generator

Offset: 0xa7 | Byte Offset: 0x29c | Read/Write: R/W | Reset: 0xXXXXXXXX (0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx)

Bit	Reset	Description
29:16	X	CSIB_PG_V_COUNT_MAX: Maximum Y of pattern (program to 1 less than pattern height)
13:0	X	CSIB_PG_H_COUNT_MAX: Maximum X of pattern (program to 1 less than pattern width)

32.1.135 VI_VI_CSIB_PATTERN_GEN_CONTROL_0

Offset: 0xa8 | Byte Offset: 0x2a0 | Read/Write: R/W | Reset: 0x00000002 (0bxxxxxxxxxxxxxxxxxxxxxx00xxxx0010)

Bit	Reset	Description
9:8	0x0	CSIB_PG_UPDATE_CYCLES: "dead" cycles between updates of pattern generator, i.e., 0 = update every cycle, 1 = update every other cycle
3	0x0	CSIB_PG_ZERO_V_COUNT: hold V count to zero when generating pattern data
2	0x0	CSIB_PG_ZERO_H_COUNT: hold H count to zero when generating pattern data
1	BAYER	CSIB_PG_BAYER: enable pattern generator 0 = YUV 1 = BAYER
0	DISABLED	CSIB_PG_ENABLE: enable pattern generator 0 = DISABLED 1 = ENABLED

32.2 MIPI-CSI Registers

Refer to the CSI section in this document for descriptions of these registers.

33.0 SD/MMC CONTROLLER

The SD/MMC Controller can interface with SD, SDIO, or eMMC devices. It supports both on-board devices and plug-in cards.

Each Tegra® 4 device contains four instances of this controller, each of which is identical in its internal function, but they vary in I/O capabilities:

Controller	UHS-I Signaling Supported	8-bit eMMC Supported	Signaling Voltages
SDMMC1	Yes	No	1.8, 2.8-3.3 V
SDMMC2	Yes	Yes	1.8, 2.8-3.3 V
SDMMC3	Yes	No	1.8, 2.8-3.3 V
SDMMC4	Yes	Yes	1.2, 1.8 V

33.1 Standards Supported

The SD/MMC Controller supports the following industry standards at the stated levels.

- "SD Specifications Part E1 SDIO Specification", Technical Committee SD Card Association, Version 3.00, 16-December 2010
- "SD Specifications Part 1 Physical Layer Specification", Technical Committee SD Card Association, Version 3.01, 18-February 2010.
- "SD Specifications Part A2 SD Host Controller Standard Specification", Technical Committee SD Association, Version 3.00, 18-February 2010.
- JEDEC eMMC Electrical Interface Specification, Version 4.51, JEDEC Solid State Technology Association.

33.2 Speeds Supported

These tables show the maximum data rates available over the physical interface. The speeds achievable in actual use will be less than these rates, depending on the performance of the device itself, protocol limitations, and the software driver.

For SD 3.0 data transfer modes, these are the maximum data transfer speeds:

Speed Mode	(removable) Signal Voltage	I/O Frequency (MHz)	Bus Width	Maximum Throughput (MBytes/s)
Default speed	3.3	25	1,4	12.5
High Speed	3.3	50	1,4	25
SDR12	1.8	25	1,4	12.5
SDR25	1.8	50	1,4	25
SDR50	1.8	100	1,4	50
SDR104 UHS-I	1.8	208	1,4	104

For eMMC 4.51 data transfer modes, these are the maximum data transfer speeds:

Speed Mode	I/O Frequency (MHz)	Bus Width	Maximum Throughput (MBytes/s)
Legacy Speed	26	1,4,8	26
High Speed SDR	52	1,4,8	52
High Speed DDR	52	4,8	104
HS200 (SDR)	200	4,8	200

33.3 Operation

33.3.1 Hardware / Software Partitioning

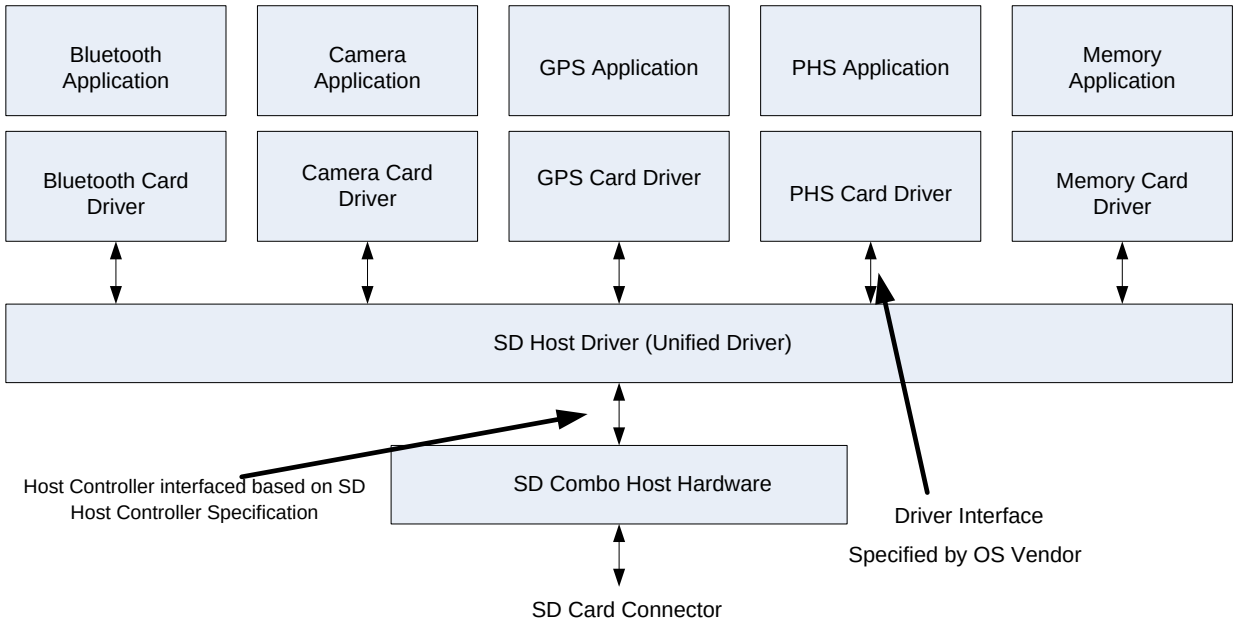
Hardware

The role of the hardware controller is to send out the programmed command, store the response, and make it visible to software. It updates the status registers and generates interrupts when attention is required. Software may also configure it for DMA operation.

Software

The software driver determines which type of card is inserted in the slot by sending the initialization commands and observing the responses received from the card. After identifying the card that is inserted, it should only program the corresponding set of commands that are applicable. It can enable interrupts for which notification is desired.

Figure 126: Host Hardware and Driver Architecture



33.4 Caveats and Assumptions

- A single SD/MMC controller handles only one device at a time.
- The software should configure SDMMC_VENDOR_CLOCK_CNTRL_0_SDMMC_CLK to _DISABLE before turning off the SD/MMC clock (and configure back to _ENABLE after turning on the SD/MMC clock). This is required in order to support asynchronous card interrupts when no clock is supplied to the card.
- PMC can be configured to wake the Tegra 4 device from the LP0 power state based on either:
  - Card Detection pin.
  - Asynchronous interrupt on the DAT1 line
- Write protect and Card detect logic is implemented in Tegra for SDMMC1 and SDMMC3 only.
- Off-card ECC, described in the MMC specification, is not supported.

33.5 Programming Guidelines

This section assumes a SD Host driver complying with the SD Specifications' Part A2, SD Host Control Standard Specification. The following subsections detail the necessary changes required for fully featured SD (and eMMC boot mode) operation.

33.5.1 Initialization

The following register writes should be done before the SD host driver is loaded. These register writes can be done in any order, and writes to different register fields within the same register should ideally be combined into a single write for efficiency:

33.5.1.1 General

These settings apply to all SDMMC controllers in use:

- Enable tuning in SDR50 by setting SDMMC_VENDOR_CLOCK_CNTRL_0_SDR50_TUNING_OVERRIDE.
- Enable SDR104 (HS200 for eMMC application) support by setting UHS_MODE_SEL to SDR104 in HOST_CONTROL_2 (offset 03Eh) register.
- Clamp clocks during resets by setting these two values:
  - SDMMC_VENDOR_CLOCK_CNTRL_0_PADPIPE_CLKEN_OVERRIDE_NORMAL
  - SDMMC_VENDOR_CLOCK_CNTRL_0_SPI_MODE_CLKEN_OVERRIDE_NORMAL

33.5.1.2 SDMMC1

These settings are specific to the SDMMC1 controller:

Supply Voltage	33 Ohm		50 Ohm		66 Ohm		100 Ohm	
	UP	DN	UP	DN	UP	DN	UP	DN
1.8 V	6'h46	6'h36	6'h2A	6'h20	6'h22	6'h17	6'h13	6'hB
3.3 V	-		6'h24	6'h14	-		-	

UP - APB_MISC_GP_SDIO1CFGPADCTRL_0_CFG2TMC_SDIO1CFG_CAL_DRVUP

DN - APB_MISC_GP_SDIO1CFGPADCTRL_0_CFG2TMC_SDIO1CFG_CAL_DRVDN

- APB_MISC_GP_SDIO1CFGPADCTRL_0_CFG2TMC_SDIO1CFG_CAL_DRVDN_SLWR **= 2'h0**
- APB_MISC_GP_SDIO1CFGPADCTRL_0_CFG2TMC_SDIO1CFG_CAL_DRVUP_SLWF **= 2'h0**
  SDMMC_SDMEMCOMPPADCTRL_0_SDMMC2TMC_CFG_SDMEMCOMP_VREF_SEL **= 4'h7**
- SDMMC_AUTO_CAL_CONFIG_0_AUTO_CAL_ENABLE_ENABLED
- SDMMC_AUTO_CAL_CONFIG_0_AUTO_CAL_PD_OFFSET = **8'h0**
- SDMMC_AUTO_CAL_CONFIG_0_AUTO_CAL_PU_OFFSET = **8'h0**

- If using the SDMMC1 interface, correctly enable the integrated pullup/down resistors there:
  - PINMUX_AUX_SDMMC1_CLK_0_PULL_UP_NORMAL
  - If using eMMC (a stronger external 4.7 kOhm pull-up is used on the CMD line):
    - PINMUX_AUX_SDMMC1_CMD_0_PULL_UP_NORMAL
  - If using SD or SDIO:
    - PINMUX_AUX_SDMMC1_CMD_0_PULL_UP_PULL_UP
  - PINMUX_AUX_SDMMC1_DAT3_0_PUPD_PULL_UP
  - PINMUX_AUX_SDMMC1_DAT2_0_PUPD_PULL_UP
  - PINMUX_AUX_SDMMC1_DAT1_0_PUPD_PULL_UP
  - PINMUX_AUX_SDMMC1_DAT0_0_PUPD_PULL_UP

33.5.1.3 SDMMC2

These settings are specific to the SDMMC2 controller:

Supply Voltage	33 Ohm		50 Ohm		66 Ohm		100 Ohm	
	UP	DN	UP	DN	UP	DN	UP	DN
1.8 V	6'h46	6'h36	6'h2A	6'h20	6'h22	6'h17	6'h13	6'hB
3.3 V	-		6'h24	6'h14	-		-	

UP - APB_MISC_GP_ATCFG6PADCTRL_0_CFG2TMC_ATCFG6_CAL_DRVUP

DN - APB_MISC_GP_ATCFG6PADCTRL_0_CFG2TMC_ATCFG6_CAL_DRVDN

- APB_MISC_GP_ATCFG6PADCTRL_0_CFG2TMC_SDIO2CFG_CAL_DRVDN_SLWR **= 2'h0**
- APB_MISC_GP_ATCFG6PADCTRL_0_CFG2TMC_SDIO2CFG_CAL_DRVUP_SLWF **= 2'h0**
- SDMMC_SDMEMCOMPPADCTRL_0_SDMMC2TMC_CFG_SDMEMCOMP_VREF_SEL **= 4'h7**
- SDMMC_AUTO_CAL_CONFIG_0_AUTO_CAL_ENABLE_ENABLED
- SDMMC_AUTO_CAL_CONFIG_0_AUTO_CAL_PD_OFFSET = **8'h0**
- SDMMC_AUTO_CAL_CONFIG_0_AUTO_CAL_PU_OFFSET = **8'h0**

- If using the SDMMC2 controller's external interface shared with the GMI pins, correctly enable the integrated pullup/down resistors there:
  - PINMUX_AUX_ GMI_CLK_0 _PUPD_PUUL_DOWN
  - If using eMMC (a stronger external 4.7 kOhm pull-up is used on the CMD line):

- PINMUX_AUX_GMI_AD15_0_PUPD_NORMAL

If using SD or SDIO:

- PINMUX_AUX_GMI_AD15_0_PUPD_PULL_UP

- PINMUX_AUX_GMI_IORDY_0_PUPD_PULL_UP
- PINMUX_AUX_GMI_AD12_0_PUPD_PULL_UP
- PINMUX_AUX_GMI_AD13_0_PUPD_PULL_DOWN
- PINMUX_AUX_GMI_AD14_0_PUPD_PULL_UP
- PINMUX_AUX_GMI_CS2_N_0_PUPD_PULL_UP
- PINMUX_AUX_GMI_CS3_N_0_PUPD_PULL_UP
- PINMUX_AUX_GMI_DQS_P_0_PUPD_PULL_UP
- PINMUX_AUX_GMI_CS7_N_0_PUPD_PULL_UP

33.5.1.4 SDMMC3

These settings are specific to the SDMMC3 controller:

Supply Voltage	33 Ohm		50 Ohm		66 Ohm		100 Ohm	
	UP	DN	UP	DN	UP	DN	UP	DN
1.8 V	6'h46	6'h36	6'h2A	6'h20	6'h22	6'h17	6'h13	6'hB
3.3 V	-		6'h24	6'h14	-		-	

UP - APB_MISC_GP_SDIO3CFGPADCTRL_0_CFG2TMC_SDIO3CFG_CAL_DRVUP

DN - APB_MISC_GP_SDIO3CFGPADCTRL_0_CFG2TMC_SDIO3CFG_CAL_DRVDN

- APB_MISC_GP_SDIO3CFGPADCTRL_0_CFG2TMC_SDIO3CFG_CAL_DRVDN_SLWR = **2'h0**
- APB_MISC_GP_SDIO3CFGPADCTRL_0_CFG2TMC_SDIO3CFG_CAL_DRVUP_SLWF = **2'h0**
- SDMMC_SDMEMCOMPPADCTRL_2_SDMMC2TMC_CFG_SDMEMCOMP_VREF_SEL = **4'h7**
  SDMMC_AUTO_CAL_CONFIG_0_AUTO_CAL_ENABLE_ENABLED
- SDMMC_AUTO_CAL_CONFIG_0_AUTO_CAL_PD_OFFSET = **8'h0**
- SDMMC_AUTO_CAL_CONFIG_0_AUTO_CAL_PU_OFFSET = **8'h0**

- If using the SDMMC3 interface, correctly enable the integrated pullup/down resistors there:
  - PINMUX_AUX_SDMMC3_CLK_0_PUPD_NORMAL
  - If using eMMC (a stronger external 4.7 kOhm pullup is used on the CMD line):
    - PINMUX_AUX_SDMMC3_CMD_0_PUPD_NORMAL
  - If using SD or SDIO:
    - PINMUX_AUX_SDMMC3_CMD_0_PUPD_PULL_UP
  - PINMUX_AUX_SDMMC3_DAT3_0_PUPD_PULL_UP
  - PINMUX_AUX_SDMMC3_DAT2_0_PUPD_PULL_UP
  - PINMUX_AUX_SDMMC3_DAT1_0_PUPD_PULL_UP
  - PINMUX_AUX_SDMMC3_DAT0_0_PUPD_PULL_UP

33.5.1.5 SDMMC4

These settings are specific to the SDMMC4 controller:

Supply Voltage	33 Ohms		50 Ohms	
	UP	DN	UP	DN
1.8 V	6'h07	6'h07	6'h02	6'h01
1.2 V	6'h0E	6'h0E	6'h05	6'h05

UP - APB_MISC_GP_GMACFGPADCTRL_0_CFG2TMC_GMACFG_CAL_DRVUP

DN - APB_MISC_GP_GMACFGPADCTRL_0_CFG2TMC_GMACFG_CAL_DRVDN

- APB_MISC_GP_GMACFGPADCTRL_0_CFG2TMC_GMACFG_CAL_DRVDN_SLWR **= 2'h0**
- APB_MISC_GP_GMACFGPADCTRL_0_CFG2TMC_GMACFG_CAL_DRVUP_SLWF **= 2'h0**
- SDMMC_SDMEMCOMPPADCTRL_0_SDMMC2TMC_CFG_SDMEMCOMP_VREF_SEL **= 4'h7**
- SDMMC_AUTO_CAL_CONFIG_0_AUTO_CAL_ENABLE_ENABLED
- SDMMC_AUTO_CAL_CONFIG_0_AUTO_CAL_PD_OFFSET = 8'h0
- SDMMC_AUTO_CAL_CONFIG_0_AUTO_CAL_PU_OFFSET = 8'h0
-
- If using the SDMMC4 interface, correctly enable the integrated pullup/down resistors there:
- PINMUX_AUX_SDMMC4_CLK_0_PUPD_PULL_DOWN
- If using eMMC (a stronger external 4.7 kOhm pullup is used on the CMD line):
  - PINMUX_AUX_SDMMC4_CMD_0_PUPD_NORMAL
- If using SD or SDIO:
  - PINMUX_AUX_SDMMC4_CMD_0_PUPD_PULL_UP
- PINMUX_AUX_SDMMC4_DAT7_0_PULL_UP_PULL_UP
- PINMUX_AUX_SDMMC4_DAT6_0_PULL_UP_PULL_UP
- PINMUX_AUX_SDMMC4_DAT5_0_PULL_UP_PULL_UP
- PINMUX_AUX_SDMMC4_DAT4_0_PULL_UP_PULL_UP
- PINMUX_AUX_SDMMC4_DAT3_0_PULL_UP_PULL_UP
- PINMUX_AUX_SDMMC4_DAT2_0_PULL_UP_PULL_UP
- PINMUX_AUX_SDMMC4_DAT1_0_PULL_UP_PULL_UP
- PINMUX_AUX_SDMMC4_DAT0_0_PULL_UP_PULL_UP

33.5.2 eMMC Boot Modes

The section of this document on the boot process describes the boot process in more detail, but note that only the SDMMC4 controller can be used as the e.MMC boot device.

33.5.3 Boot Option1

1. The clock to the card needs to be configured to 26 MHz.
2. Program the number of blocks. Configuring block length has no effect; it is always fixed to 512 bytes.
3. Configuring the data transfer direction has no impact, since it taken as CARD to HOST for boot mode.
4. Select either SDMA or PIO mode. (Tegra 4 devices do not support ADMA modes during boot option 1.)

5. Configure **SDMMC_VENDOR_BOOT_ACK_TIMEOUT_0** – The maximum timeout value that needs to be programmed is 50ms.The value programmed should exclude the 74 cycles that are required to enter boot mode.
6. Configure **SDMMC_VENDOR_BOOT_DAT_TIMEOUT_0** – The max timeout value that needs to be programmed is 1 second .The value programmed should exclude the 74cycles that are required to enter boot mode.
7. Configure **SDMMC_VENDOR_BOOT_CNTRL_0**[1] to 1 to ask the engine to look for boot_ack.
8. Configure **SDMMC_VENDOR_BOOT_CNTRL_0**[0] to trigger the engine.
9. If **SDMMC_INTERRUPT_STATUS_0**[31] = 1,the BOOT_ACK is not equal to 00101.The engine just informs the software and continues to fetch data from the card
10. If **SDMMC_INTERRUPT_STATUS_0**[30] = 1, the BOOT_ACK timeout has occurred. The engine just informs the software and continues to fetch data from the card.
11. The software should look for transfer complete interrupt. If “data_time_out” error has occurred, then the data transfer is not successful.
12. After successful data transfer from card, the software should look for “sdma_engine_busy” bit of **SDMMC_OBS_SDMMC_DBG0_0 [0].**Software shouldn’t program commands until this bit is zero.

33.5.4 Boot Option2

Boot option2 is treated like any normal read command. The BOOT_ACK should be enabled if the card supports boot acknowledgment. **SDMMC_VENDOR_BOOT_ACK_TIMEOUT_0, SDMMC_VENDOR_BOOT_DAT_TIMEOUT_0** should be programmed based on the frequency of operation.

33.5.5 Card Detect and Write Protect

Only SDMMC1 and SDMMC3 support removable SD cards. The standard SD Host, SDCD# pin acts as card detect pin and CDWP# pin acts as Write protect pin. The SD Card State registers can be ignored for embedded on-board devices.

PIN MUX detail for CD and WP pins for SDMMC1 and SDMMC3.

PINMUX_AUX_SDMMC1_WP_N_0_PUPD_PULL_UP

PINMUX_AUX_KB_COL4_0_PUPD_PULL_UP - This is the Pinmux option for SDMMC1 CD

PINMUX_AUX_KB_COL4_0_PUPD_PULL_UP - This is the Pinmux option for SDMMC3 WP

PINMUX_AUX_SDMMC3_CD_N_0_PUPD_PULL_UP

Additionally, an abort command should be issued if a card is removed during an SD transfer.

33.5.6 Improving Non-DMA (PIO) performance

When transferring more than a single 512 byte block size, PIO performance is reduced because the standard process waits for the buffer ready interrupt before beginning to move the next block of data.

Next block data movement can instead be pipelined on a four-byte word basis. To do this, software should waiting for SDMMC_PRESENT_STATE_0’s BUFFER_READ_EN or BUFFER_WRITE_EN fields to assert instead of the buffer ready interrupt. These status fields signify that the next four-byte word can be read from or written to the internal 512 byte buffer.

33.5.7 SD3.0 Signal Voltage Switching

Note:	This section is applicable only to the UHS-I SDMMC1, SDMMC2 and SDMMC3 controllers. The SDMMC4 controllers do not require these settings.

Signal Voltage Switching happens after setting 1.8V Signal enable in the host control 2 register. Switching the voltage from 3.3V to 1.8V, UHS-I signaling requires switching the external power supply.

After setting 1.8V Signal Enable in the *Host Control 2* register, the SD host driver communicates with the hardware platform to change the SDMMC1, SDMMC2 and SDMMC3 I/O voltage from 3.3 to 1.8V. This is typically via I2C control of an external "PMIC" (Power Management IC).

When resetting the controller (e.g., when an SD3.0 card in 1.8V mode has been removed), the SD host driver again communicates with the system software/platform to increase the SD I/O voltage back to 3.3V.

33.5.7.1 Initialization

Before the standard SD driver begins running:

1. Route the SDMMC controller's system interrupt to the appropriate driver.
2. Write 1 to SDMMC_VENDOR_SYS_SW_CNTRL_0_VOLT_SWITCH_INT_STATUS to clear any latent interrupts.
3. Set SDMMC_VENDOR_SYS_SW_CNTRL_0_VOLT_SWITCH_INT _ENABLE to enable the system interrupt on an SD3.0 UHS-I Voltage Switch event.

33.5.7.2 Entry

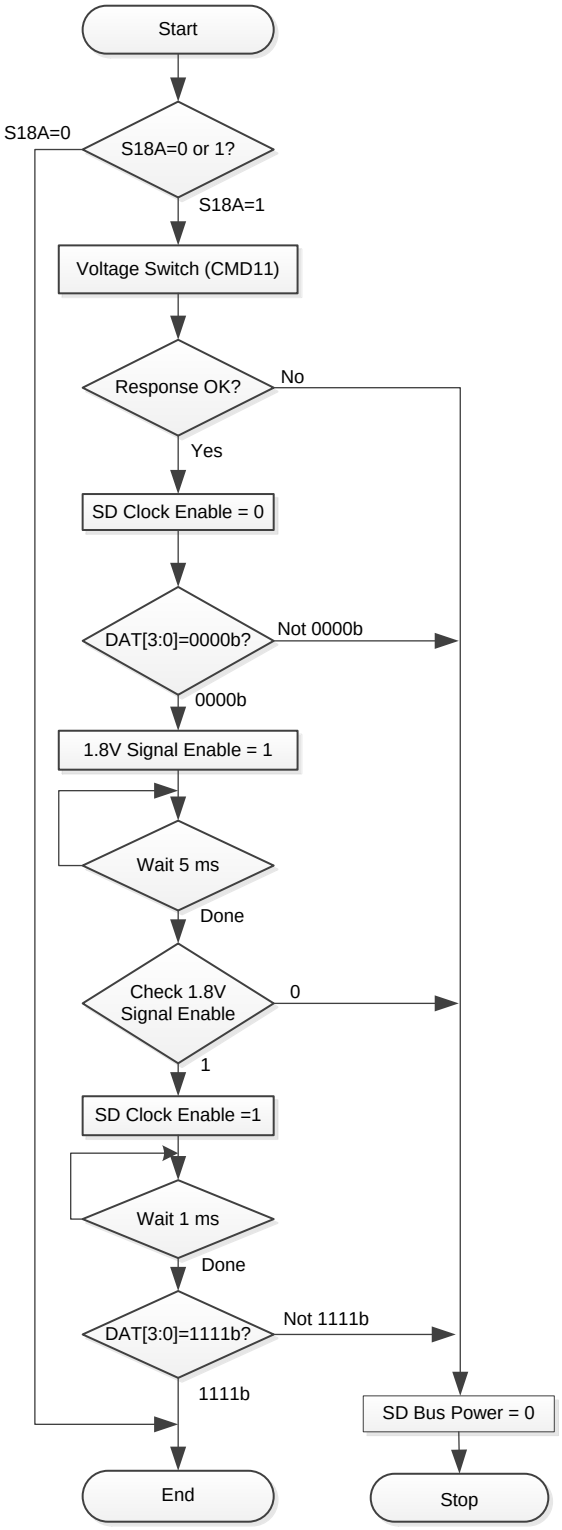
Once an SDMMC controller generates a system interrupt:

- Confirm the SDMMC System interrupt was from a voltage switch event by reading SDMMC_VENDOR_SYS_SW_CNTRL_0_VOLT_SWITCH_INT _STATUS.

33.5.7.3 Voltage Switch Procedure

The following figure shows the standard voltage switch procedure.

Figure 127: Voltage Switch Flowchart



33.5.7.1 Exit

Write 1 to SDMMC_VENDOR_SYS_SW_CNTRL_0_VOLT_SWITCH_INT _STATUS to clear the interrupt condition.

33.5.8 Tuning

Tuning is required because SD/MMC controllers do not automatically vary the RX clock trim each time Execute Tuning is set to 1; the SD Host driver must do this manually.

SD 3.0 cards can operate at frequencies up to 208 MHz. For the card to operate at high frequencies, the correct tap value must be programmed. The tap value in the vendor clock control register controls the track delay so that the input data is sampled correctly. The appropriate tap delay for the given platform is found using frequency tuning. The passing tap value range can be found by incrementing the tap value after each iteration and running frequency tuning.

In frequency tuning, CMD19 for SD and CMD21 for eMMC (emmc4.51) card is issued to the card and wait for the Buffer Read Ready interrupt. Once the interrupt is generated, in HOST_CONTROL_2 register (offset 03Ch), check whether EXECUTE_TUNING bit is cleared and the SAMPLING_CLK_SELECT bit is set. If both the conditions are met, treat tuning as successful and consider the tap value as working. After finding the passing tap range, the ideal tap value is calculated, which is 75% between the highest passing tap and the lowest passing tap. Set this tap value and run frequency tuning again to confirm that the tap value works. If the passing tap range falls in between 0 and 10, discount it and try to find a higher passing tap range.

During testing, the tap range between 0 and 10 was found to be insufficient for operating frequencies up to 208MHz.

33.5.8.1 Initialization

Before the standard SD drive begins running:

1. Route the SD/MMC controller's system interrupt to the appropriate driver.
2. Write 1 to SDMMC_VENDOR_SYS_SW_CNTRL_0_TUNING_SYS_INT_STATUS to clear any latent interrupts.
3. Set SDMMC_VENDOR_SYS_SW_CNTRL_0_TUNING_SYS_INT_ENABLE to enable the system interrupt on an SD3.0 UHS-I tuning start event.

33.5.8.2 Entry

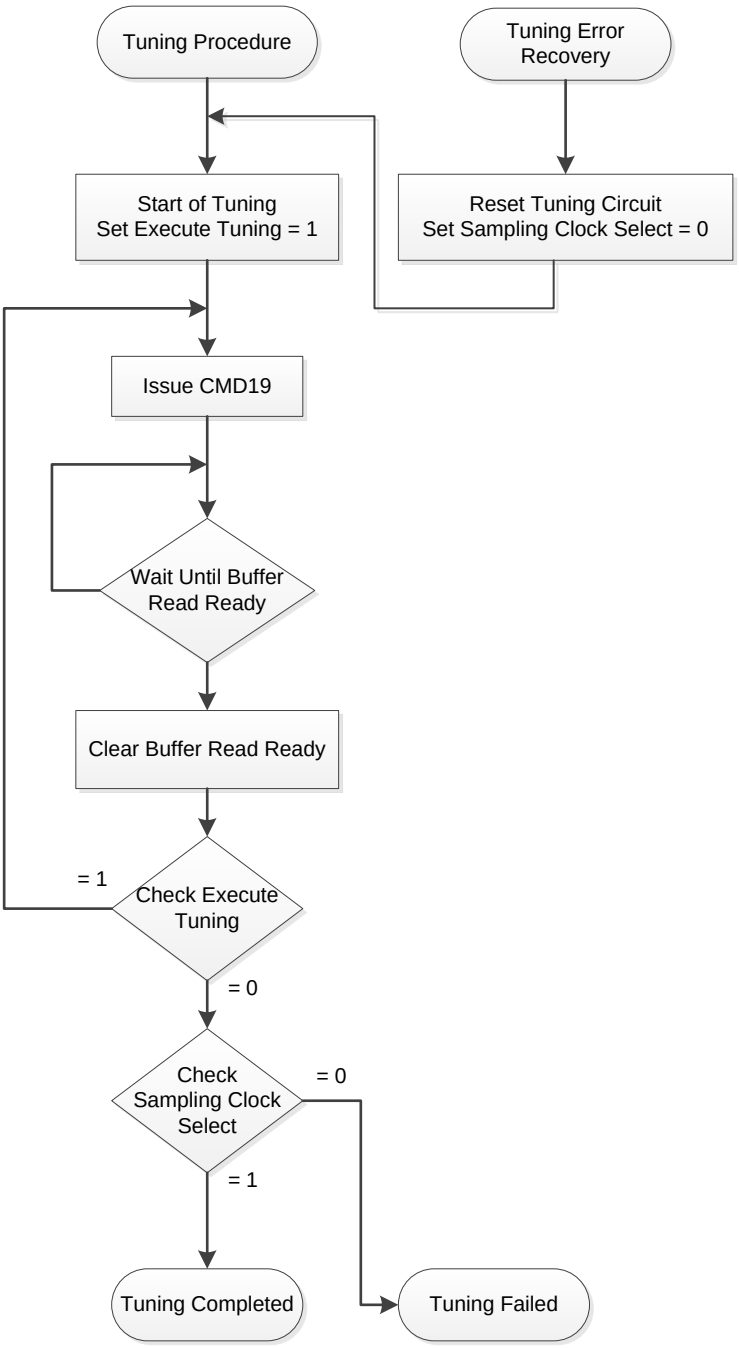
Once an SD/MMC system interrupt is received:

1. Confirm the SDMMC System interrupt was from a tuning event by reading SDMMC_VENDOR_SYS_SW__CNTRL_0_TUNING_SYS_INT_STATUS.
2. Disable the future tuning interrupts (to avoid interrupting yourself) by clearing SDMMC_VENDOR_SYS_SW_CNTRL_0_TUNING_SYS_INT_ENABLE.
3. Write 1 to SDMMC_VENDOR_SYS_SW_CNTRL_0_TUNING_SYS_INT_STATUS to clear the interrupt condition.
4. Disable the Buffer Read Ready interrupt to keep the standard SD Host Driver inactive until the tuning sequence is complete: Clear SDMMC_INTERRUPT_STATUS_ENABLE_0_ BUFFER_READ_READY.

33.5.8.3 Tuning Procedure

The figure below shows the standard tuning procedure.

Figure 128: Tuning Procedure



33.5.8.4 Exit

1. Write 1 to SDMMC_VENDOR_SYS_SW_CNTRL_0_TUNING_SYS_INT_STATUS to clear any pending tuning interrupts.
2. Set SDMMC_VENDOR_SYS_SW_CNTRL_0_TUNING_SYS_INT_ENABLE to enable the system interrupt on any future SD3.0 UHS-I tuning start events.
3. Signal to the SD Host driver that tuning has completed by asserting SDMMC_VENDOR_SYS_SW_CNTRL_0_ASSERT_BUFF_RD_RDY_INT.

33.5.9 SD Bus Power

When the standard SD driver changes the Power Control Register's SD Bus Power field, the hardware needs assistance from platform software to implement the change via the PMIC.

33.5.9.1 Initialization

Before the standard SD drive begins running:

1. Route the SD/MMC controller's system interrupt to the appropriate driver.
2. Write 1 to SDMMC_VENDOR_SYS_SW_CNTRL_0_SD_BUS_POWER_ON_OFF_INT_STATUS to clear any latent interrupts.
3. Set SDMMC_VENDOR_SYS_SW_CNTRL_0_SD_BUS_POWER_ON_OFF_INT_ENABLE to enable the system interrupt on an SD3.0 UHS-I Bus Power change event.

33.5.9.2 Entry

Once an SD/MMC system interrupt is received:

1. Confirm the SDMMC System interrupt was from a Bus Power change event by reading SDMMC_VENDOR_SYS_SW_CNTRL_0_SD_BUS_POWER_ON_OFF_INT_STATUS.
2. Write 1 to SDMMC_VENDOR_SYS_SW_CNTRL_0_SD_BUS_POWER_ON_OFF_INT_STATUS to clear the interrupt condition.
3. Read SDMMC_POWER_CONTROL_HOST_0_SD_BUS_POWER to determine the power state change request.

   If Bus Power is cleared, power off the SD power supply via the PMIC. Otherwise, if Bus Power is set, power on the SD power supply via the PMIC.

33.5.9.3 Exit

No actions required.

33.6 SD/MMC Registers

Refer to "Reading Register Tables" in the Introduction section for the register table protocol as well as recommendations for accessing registers.

33.6.1 Standard Registers

Note: For standard registers' usage, refer to the SD Host Controller Specification version 3.00.

There are a few vendor-specific register fields within the standard register offset range (0x00 through 0xff). (Future products will move these vendor-specific register fields out of the standard-defined register offset range.) These fields are described below:

33.6.1.1 Present State Register

Offset: 0x24 | Read/Write: R | Reset: 0x00000000 (0b00000000000000000000000000000000)

Bit	Reset	Description
28:25	X	DAT_7_4_LINE_LEVEL: This status reflects the DAT[7:4] lines' state for debug.

33.6.1.2 Interrupt Status Register

Offset: 0x30 | Read/Write: R/W | Reset: 0x00000000 (0b00000000000000000000000000000000)

Bit	Reset	Description
31:30	0	VEND_SPEC_ERR Bit 1: BOOT_ACK_ERR: Occurs When Boot Ack Status is not equal to '010' Bit 0: BOOT_ACK_TIMEOUT_ERR: Occurs When Boot Ack is not received within the programmed number of cycles.

33.6.1.3 Interrupt Status Enable Register

Offset: 0x34 | Read/Write: R/W | Reset: 0x00000000 (0b00000000000000000000000000000000)

Bit	Reset	Description
31:30	0	VENDOR_SPECIFIC_ERR 0 = Enable neither BOOT_ACK_ERR nor BOOT_ACK_TIMEOUT_ERR statuses. 1 = Enable only BOOT_ACK_TIMEOUT_ERR status. 2 = Enable only BOOT_ACK_ERR status. 3 = Enable both BOOT_ACK_ERR and BOOT_ACK_TIMEOUT_ERR statuses.

33.6.1.4 Interrupt Signal Enable Register

Offset: 038h | Read/Write: R/W | Reset: 0x00000000 (0b00000000000000000000000000000000)

Bit	Reset	Description
31:30	0	VENDOR_SPECIFIC_ERR 0 = Enable neither BOOT_ACK_ERR nor BOOT_ACK_TIMEOUT_ERR interrupts to CPU. 1 = Enable only BOOT_ACK_TIMEOUT_ERR interrupt to CPU. 2 = Enable only BOOT_ACK_ERR interrupt to CPU. 3 = Enable both BOOT_ACK_ERR and BOOT_ACK_TIMEOUT_ERR interrupts to CPU.

33.6.1.5 Force Event Register

Offset: 050h | Read/Write: R/W | Reset: 0x00000000 (0b00000000000000000000000000000000)

Bit	Reset	Description
31:30	0	VENDOR_SPECIFIC_ERR_STATUS 0 = no effect 1 = Force a BOOT_ACK_TIMEOUT_ERR event 2 = Force a BOOT_ACK_ERR event. 3 = Force both BOOT_ACK_ERR and BOOT_ACK_TIMEOUT_ERR events.

33.6.2 Vendor Registers

33.6.2.1 SDMMC_VENDOR_CLOCK_CNTRL_0

The following registers are Vendor Specific Registers and are mapped to Vendor Specific Address Space (0x100 - 0x1FF)

Vendor Clock Control Register

TAP_VAL - Tap Value for the input data path trimmer

This determines the tap value needed to sample the input data correctly. The delay per each tap can range from 70ps to 500ps. The following values are recommended on different SD/MMC interfaces for all modes up to SDR25:

- SDMMC1 - 2
- SDMMC2 - 2
- SDMMC3 - 3
- SDMMC4 - 5

For SDR50 and above modes, the tap value is determined by the tuning procedure.

BASE_CLK_FREQ: Software should program the actual clock frequency programmed in CAR registers CLK_RST_CONTROLLER_CLK_SOURCE_SDMMC*_0 for each SD/MMC controller. This should be done after every time SDMMC is reset and after every soft reset. This is important because all SD/MMC controllers follow the same register map, but could be programmed with different frequencies depending on the use case.

SPI_MODE_CLKEN_OVERRIDE: Software should always program this to 0 (NORMAL).

PADPIPE_CLKEN_OVERRIDE: Software should always program this to 0 (NORMAL).

Offset: 0x100 │ Read/Write: R/W │ Reset: 0x0005d00d (0b00000000000101110100000xx0x1101)

Bit	Reset	Description
28:24	0x0	TRIM_VAL: Reserved. Software should not change these bits.
23:16	0x5	TAP_VAL: Tap value for input data path trimmer.
15:8	0xd0	BASE_CLK_FREQ: System software programs the base SD/MMC clock frequency into this register before loading the SD/MMC driver. This value is readable in the standard, but not writeable, SDMMC_CAPABILITIES_0_BASE_CLOCK_FREQUENCY register field.
5	0x0	SDR50_TUNING_OVERRIDE: override the SDR50_TUNING capabilities bit. Software should only set this bit if it is required to use Tuning for SDR50. (only supported for SDMMC1 and SDMMC3) 0 = NORMAL : 0 -> No tuning support advertised for SDR50 mode. 1 = OVERRIDE: 1 -> Tuning support is enabled for SDR50 mode.
3	0x1	PADPIPE_CLKEN_OVERRIDE: Override for pad macro and pipe macro clken. 0 -> CLKEN is to pad macro and pipe macro can be deasserted along with internal CLKEN. 0 = NORMAL: 0 -> CLKEN is to pad macro and pipe macro can be deasserted along with internal CLKEN. 1 = OVERRIDE: 1 -> CLKEN is kept asserted to pad macro and pipe macro when internal CLKEN is deasserted.
2	0x1	SPI_MODE_CLKEN_OVERRIDE: Override for CLKEN during SPI_MODE during sw_reset. 0 = NORMAL: 0 -> CLKEN is deasserted while doing sw_reset. 1 = OVERRIDE: 1 -> CLKEN is kept asserted while doing sw_reset.
1	0x0	INPUT_IO_CLK: Feedback clock is selected by default. Software should not change this. Disabling the Feedback clock will select the Internal Clock that requires different tap value programming. 0 = FEEDBACK 1 = INTERNAL
0	0x1	SDMMC_CLK: This is set when sdmmc_clk is supplied by the CAR module. Prior to sdmmc_clk switch OFF. This bit should be written '0'. By writing zero, the asynchronous card interrupt is routed to the Interrupt controller.

Bit	Reset	Description
		0 = DISABLE 1 = ENABLE

33.6.2.2 SDMMC_VENDOR_SYS_SW_CNTRL_0

Vendor System SW Control Register

Offset: 0x104 │ Read/Write: R/W │ Reset: 0xX0018000 (0bxxxxxxxxxxxxxxxx11000xxxxx0000x00)

Bit	R/W	Reset	Description
31:28	RO	X	DAT_7_4_LINE_LEVEL: Line Signal Level. This status is used to check the DAT line level to recover from errors, and for debugging.
16	RW	0x1	SD_FENCE_RD_EN_AT_BLKGAP: set this to generate fence read at the blkgap ('stop at blkgap' should be enabled before setting this) 0 = DISABLE 1 = ENABLE
15	RW	0x1	SD_FENCE_RD_ENABLE: Fence Read request enable - need to set this to avoid data coherency issues when writing to system memory 0 = DISABLE 1 = ENABLE
14	RW	0x0	SD_BUS_POWER_ON_OFF_INT_STATUS: SD_BUS_POWER was changed. System software can use this interrupt to implement power switch. 0 = NO_INT 1 = GEN_INT
13	RW	0x0	VOLT_SWITCH_INT_STATUS: VOLT_18_EN was changed. System software can use this interrupt to implement a UHS-I voltage switch procedure for a standard SD Host driver 0 = NO_INT 1 = GEN_INT
12	RW	0x0	TUNING_SYS_INT_STATUS: CMD19 was issued while EXECUTE_TUNING was set. System software can use this interrupt to implement a UHS-I tuning procedure for a standard SD Host driver. 0 = NO_INT 1 = GEN_INT
6	RW	0x0	SD_BUS_POWER_ON_OFF_INT_ENABLE: Enables a separate system interrupt (i.e., not the standard SDHCI interrupt) when SD_BUS_POWER is changed. 0 = DISABLE 1 = ENABLE
5	RW	0x0	VOLT_SWITCH_INT_ENABLE: Enables a separate system interrupt (i.e., not the standard SDHCI interrupt) when VOLT_18_EN is changed. 0 = DISABLE 1 = ENABLE
4	RW	0x0	TUNING_SYS_INT_ENABLE: Enables a separate system interrupt (i.e., not the standard SDHCI interrupt) when CMD19 is issued while EXECUTE_TUNING is set. 0 = DISABLE 1 = ENABLE
3	RW	0x0	ASSERT_BUFF_RD_RDY_INT: Write a 1 to this field to assert sdmmc_interrupt_status_0_buffer_read_ready. Used by the system software that implements the tuning procedure to signal to the standard SD driver that the tuning process has completed 0 = DISABLE 1 = ENABLE
1	RW	0x0	INT_MASK_WHILE_TUNING: to avoid breaking software compatibility, interrupt generation behavior is changed when a this bit is set 0 = DISABLE 1 = ENABLE

Bit	R/W	Reset	Description
0	RW	0x0	SPI_MODE: This is a mirror bit. The SPI mode is set if this bit is set or CMD_XFER_MODE[7] is set. Writing 1 will drive the CS Low and writing zero will deassert the CS signal 0 = DISABLE : 0 -> SPI mode is disabled. 1 = ENABLE: 1 -> SPI mode is enabled.

33.6.2.3 SDMMC_VENDOR_CAP_OVERRIDES_0

Capabilities Override Bits

Offset: 0x10c │ Read/Write: R/W │ Reset: 0x00000007 (0b111)

Bit	Reset	Description
2	0x1	VOLTAGE_3_3_V_SUPPORT_OVERRIDE: Voltage support 3_3_V override
1	0x1	VOLTAGE_3_0_V_SUPPORT_OVERRIDE: Voltage support 3_0_V override
0	0x1	VOLTAGE_1_8_V_SUPPORT_OVERRIDE: Voltage support 1_8_V override

33.6.2.4 SDMMC_VENDOR_BOOT_CNTRL_0

Vendor Boot Control Register

This register is used to configure Boot Mode to support MMC v4.3 cards.

Offset: 0x110 │ Read/Write: R/W │ Reset: 0x00000000 (0b00)

Bit	Reset	Description
1	0x0	BOOT_ACK: This bit is used to support Boot Option in MMC 4.3 version cards. If set Boot acknowledgment is given by card else not given by card 0 = DISABLE 1 = ENABLE
0	0x0	BOOT: This bit enables/disable BootOption1. If set BootOption1 is enabled, hardware auto clears it when boot data is done. Writing 0 terminates the BootOption1 0 = DISABLE 1 = ENABLE

33.6.2.5 SDMMC_VENDOR_BOOT_ACK_TIMEOUT_0

Vendor Boot Acknowledgment Timeout Register

Offset: 0x114 │ Read/Write: R/W │ Reset: 0x00000000 (0b00000000000000000000)

Bit	Reset	Description
19:0	0x0	VALUE: If Boot Acknowledgment is not received within the programmed number of cycles, a Boot Acknowledgement Timeout error occurs (VENDOR_SPECIFIC_ERR[0])

33.6.2.6 SDMMC_VENDOR_BOOT_DAT_TIMEOUT_0

Boot Data Timeout Register

Offset: 0x118 │ Read/Write: R/W │ Reset: 0x00000000 (0b00000000000000000000000000)

Bit	Reset	Description
24:0	0x0	VALUE: If Boot Data is not received within the programmed number of cycles, a Data Timeout error occurs.

33.6.2.7 SDMMC_VENDOR_DEBOUNCE_COUNT_0

Debounce Counter Value Register

The Debounce Counter runs on a 32 KHz clock. Keeping the default value to 100ms = (100 * 32cycles/1ms) = 3200 cycles for 100ms = 0xC80

Offset: 0x11c │ Read/Write: R/W │ Reset: 0x00000c80 (0b00000000000000110010000000)

Bit	Reset	Description
23:0	0xc80	VALUE: The number of 32KHz clock cycles is programmed to meet the debounce period of the card slot.

33.6.2.8 SDMMC_VENDOR_MISC_CNTRL_0

Miscellaneous Vendor Control Register

- SDMMC_SPARE0: Spare register bits with reset value of 0
  - SDMMC_SPARE0[0]: SW_RESET_CLKEN_OVERRIDE, override the ‘sdmmc_clken’ when doing SW_RESET if set to 1.
  - SDMMC_SPARE0[1]: When set, allows SD clock to be stopped in the middle of a read data block while in SDR104 mode. Unsafe for at least some SD cards, but may improve SDR104 DMA read performance in some cases.
  - SDMMC_SPARE0[2]: When set, SDR104 support is advertised in SDMMC_CAPABILITIES_HIGHER_0_SDR104
  - SDMMC_SPARE0[3]: When set, SDR50 support is advertised in SDMMC_CAPABILITIES_HIGHER_0_SDR50
  - SDMMC_SPARE0[5]: When 0, masks the pad macro's "high speed" enable to 0, causing the pad macro to always launch data on the falling edge of the clock. This prevents the SD Host driver's setting of SDMMC_POWER_CONTROL_HOST_x_HIGH_SPEED_EN from undesirably affecting the output timing.
  - SDMMC_SPARE0 [7:6]: Number of pipe stages.
  - SDMMC_SPARE0[8]: When set, DDR50 support is advertised in SDMMC_CAPABILITIES_HIGHER_0_DDR50
  - SDMMC_SPARE1: Spare register bits with reset value of 1
  - SDMMC_SPARE1[0]: CMD_CONFLICT_DISABLE, disable command line conflict if set to 1.

Offset: 0x120 │ Read/Write: R/W │ Reset: 0xffff0098 (0b11111111111111110000000010011000)

Bit	Reset	Description
31:16	0xffff	SDMMC_SPARE1: Spare register bits with reset value of 1
15:1	0x4c	SDMMC_SPARE0: Spare register bits with reset value of 0x40
0	0x0	ERASE_TIMEOUT_LIMIT: Erase timeout value. 0 = FINITE: Finite, It is limited to the programmed value in the DATA_TIMEOUT_VALUE 1 = INFINITE: Infinite, Controller would be monitoring until the card is busy.

33.6.2.9 SDMMC_MAX_CURRENT_OVERRIDE_0

Offset: 0x124 │ Read/Write: R/W │ Reset: 0x00000000 (0b00000000000000000000000000)

Bit	Reset	Description
23:16	0x0	OVERRIDE_FOR_1_8V: Maximum override for 1.8V
15:8	0x0	OVERRIDE_FOR_3_0V: Maximum override for 3.0V
7:0	0x0	OVERRIDE_FOR_3_3V: Maximum override for 3.3V

33.6.2.10 SDMMC_SDMEMCOMPPADCTRL_0

SDMEMCOMP Pad control register

If AUTO_CAL_ENABLE is disabled (0), the values in this register are used to drive the DRVUP/DRVDN controls to the SDMMC comp pads.

Offset: 0x1e0 │ Read/Write: R/W │ Reset: 0x29318007 (0b01010010011x0011000000000000111)

Bit	Reset	Description
30:29	0x1	PU_PAD_DRV_TYPE
28:27	0x1	PD_PAD_DRV_TYPE
26:20	0x13	CFG_SDMEMCOMP_DRVUP: used if AUTOCAL is disabled
18:12	0x18	CFG_SDMEMCOMP_DRVDN: used if AUTOCAL is disabled
11	0x0	PU_PAD_E_TEST_OUT
10	0x0	PD_PAD_E_TEST_OUT
9:7	0x0	PU_PAD_TEST_SEL
6:4	0x0	PD_PAD_TEST_SEL
3:0	0x7	SDMMC2TMC_CFG_SDMEMCOMP_VREF_SEL

33.6.2.11 SDMMC_AUTO_CAL_CONFIG_0

SDMEMCOMP pad auto-calibration settings - Valid for SDMMC1/SDMMC3 Instances

AUTO_CAL_SLW_OVERRIDE

- 0 (Normal operation) pad DRVDN/UP_SLWR/F tied to AUTO_CAL output DRDVDN/UP_SLWR/F[1:0] = AUTO_CAL_PULLDOWN/UP[4:3]
- 1 (override) use CFG2TMC_SDIO[1|3]*_DRVDN/UP_SLWR/F pins to control pad slew inputs

AUTO_CAL_OVERRIDE

- 0 (normal operation): use AUTO_CAL_PU/PD_OFFSET as an offset to the calibration state machine setting
- 1 (override) : use AUTO_CAL_PU/PD_OFFSET register values directly

Offset: 0x1e4 │ Read/Write: R/W │ Reset: 0x00010000 (0b0000xxxxxxxxx001x0000000x0000000)

Bit	Reset	Description
31	0x0 –	AUTO_CAL_START: Writing a one to this bit starts the calibration state machine. This bit must be set even if the override is set in order to latch in the override value.
30	0x0	AUTO_CAL_OVERRIDE: AUTOCAL override. 0 = NORMAL : 0 (normal operation): use AUTO_CAL_PU/PD_OFFSET as an offset to the calibration state machine setting 1 = OVERRIDE : 1 (override) : use AUTO_CAL_PU/PD_OFFSET register values directly
29	DISABLED	AUTO_CAL_ENABLE: AUTOCAL enable. 0 = DISABLED : 0 (disabled): use sdmmc2tmc_cfg* register settings for pull-up/dn 1 = ENABLED : 1 (normal operation): use SDMMC generated pull-up/dn (override or AUTOCAL)
28	0x0	AUTO_CAL_SLW_OVERRIDE: AUTOCAL slew rate override. 0 = NORMAL : 0 (Normal operation) pad DRVDN/UP_SLWR/F tied to AUTO_CAL output DRDVDN/UP_SLWR/F[1:0] = AUTO_CAL_PULLDOWN/UP[4:3] 1 = OVERRIDE : 1 (override) use CFG2TMC_SDIO[1|3]*_DRVDN/UP_SLWR/F pins to control pad slew inputs
18:16	0x1	AUTO_CAL_STEP: calibration step interval (in microseconds)

Bit	Reset	Description
14:8	0x0	AUTO_CAL_PD_OFFSET: 2's complement offset for pull-down value
6:0	0x0	AUTO_CAL_PU_OFFSET: 2's complement offset for pull-up value

33.6.2.12 SDMMC_AUTO_CAL_INTERVAL_0

SDMEMCOMP Pad Calibration Interval

Offset: 0x1e8 │ Read/Write: R/W │ Reset: 0x00000000 (0b00000000000000000000000000000000)

Bit	Reset	Description
31:0	0x0	AUTO_CAL_INTERVAL: 0: Do calibration once. Otherwise, auto-calibration occurs at intervals equivalent to the programmed number of microseconds.

33.6.2.13 SDMMC_AUTO_CAL_STATUS_0

SDMEMCOMP Pad Calibration Status

Offset: 0x1ec │ Read/Write: RO │ Reset: 0xXXXXXXXX (0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx)

Bit	Reset	Description
31	X	AUTO_CAL_ACTIVE: One when auto calibrate is active - valid only after auto calibrate sequence has completed (AUTO_CAL_ACTIVE == 0)
30:24	X	AUTO_CAL_PULLDOWN_ADJ: Pull-down code sent to pads
22:16	X	AUTO_CAL_PULLUP_ADJ: Pull-up code sent to pads
14:8	X	AUTO_CAL_PULLDOWN: Pull-down code generated by auto-calibration
6:0	X	AUTO_CAL_PULLUP: Pull-up code generated by auto-calibration

[THIS PAGE INTENTIONALLY LEFT BLANK]

34.0 MIPI-HSI (HIGH SPEED SYNCHRONOUS SERIAL INTERFACE)

The MIPI High Speed Synchronous Serial Interface (“HSI”) connects a mobile application processor with the cellular baseband modem. It is a full duplex, point-to-point interface providing peer-to-peer communication between the two devices. The HSI provides for up to 16 channels of data transfer. The 16 channels share the same single flow control, so they cannot pass each other. This means different qualities of service (e.g., isochronous vs. low latency vs. bandwidth soak) are managed at a higher level.

In each direction, the HSI uses four wires to communicate a single bit of data:

- FLAG
- DATA
- READY
- WAKE

The data bit and clock are encoded into two of the wires, FLAG and DATA. These signals do not toggle when no data is being transferred. Although this complicates the receiver, it significantly reduces power compared to an interface that requires a continuous clock. READY and WAKE are used for flow control. WAKE signals the RX side that data transfer may be pending. READY signals the TX side when it may send data.

34.1 MIPI Standards Support

The MIPI HSI Controller implements the following MIPI standards:

- *High Speed Synchronous Serial Interface Specification, Version 1.0*, approved 23 March 2004
- *High-speed Synchronous Serial Interface (HSI) Physical Layer, Version 1.01.00*, approved 25 January 2009

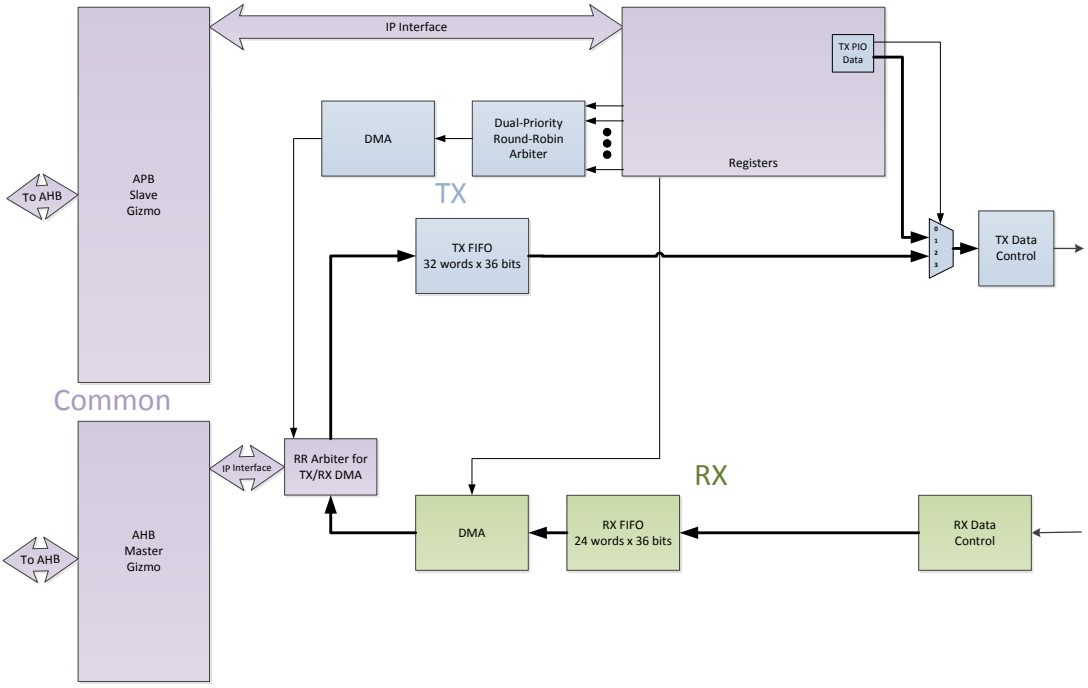
Refer to the MIPI website for further details of these specifications.

34.2 Overview and Architecture

The HSI Controller is a master on the AHB bus, using the standard AHB interface (Gizmo) for DMA to and from main memory. The register programming and PIO interface is a slave path on APB. The HSI controller implements TX and RX functions completely independently, so that both the TX and the RX paths can be active at the same time. The controller supports 16 TX and 16 RX channels. The driver software can setup additional DMA channels while one or more channels are already active. As both TX and RX are running simultaneously, DMA can have requests from both. A round robin arbiter is used to arbitrate the requests between TX and RX. Software has flexibility to provide the priority of channels. TX implements the PIO path as well which carries higher priority than any other DMA channel.

The transmitter logic runs at the TX clock provided from the system clock controller. The receiver has to retrieve its clock from the DATA and FLAG signals coming in from an external transmitter. The method to retrieve the receiver clock is explained in the Receiver section. The controller implements separate FIFOs for TX and RX.

Figure 129: HSI Controller Top-Level Block Diagram



34.2.1 DMA Functionality

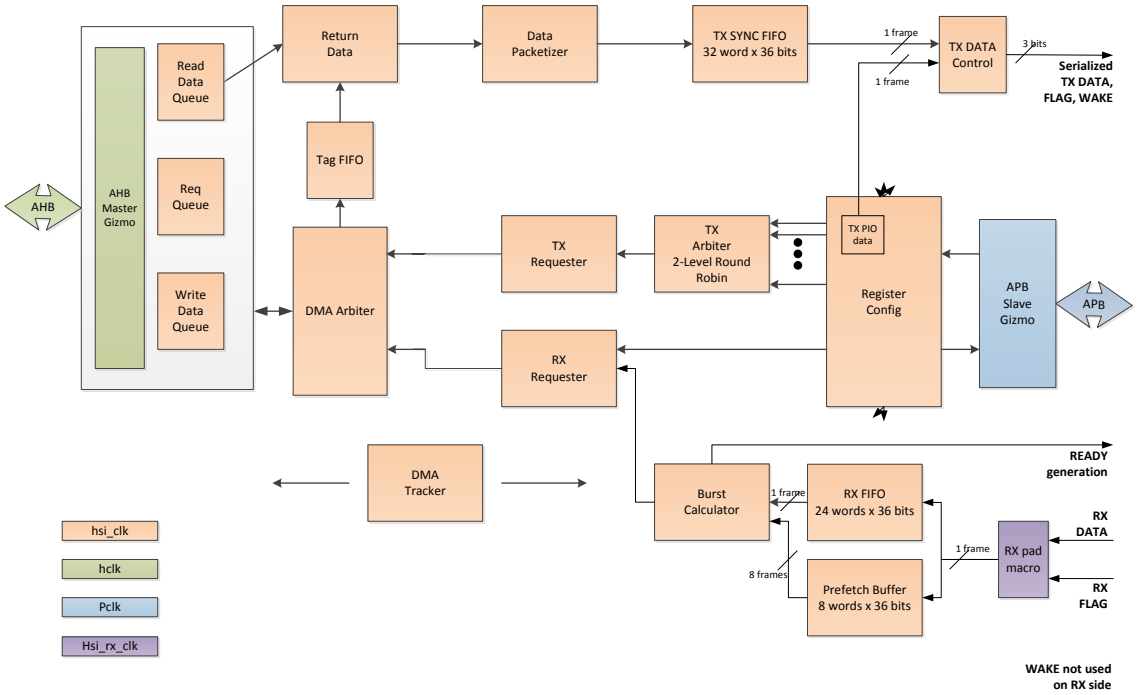
The HSI Controller is a master on AHB bus, using DMA to read HSI TX data and write HSI RX data. When both TX and RX DMA requests are pending internally, they are arbitrated using round-robin arbitration.

The controller implements a two-level (high and low priority) round robin arbitration to choose one channel out of 16 TX channels. The tag FIFO keeps track of AHB return data's HSI TX channel to push the channel information along with the data into the TX FIFO.

On the RX side, the RX Requester will coalesce successive frames into a single burst, up to the maximum allowed burst size. So, to maximize AHB write-to-system memory efficiency, the baseband modem should switch channels as little as possible.

DMA Tracker keeps track of all DMA TX and RX transactions.

Figure 130: HSI Controller Internal Micro Architecture



34.2.2 Transmitter Data Flow

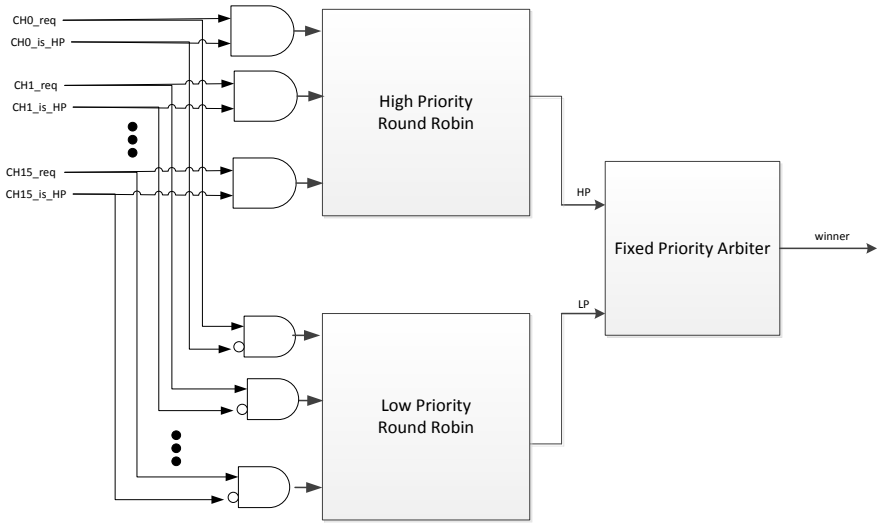
Software can configure up to 16 DMA channels to transmit data. A DMA channel can be set up, started, and stopped, even while other channels are actively DMA'ing. Setting up a DMA channel requires system memory address, DMA length, maximum burst size, and priority of that channel. To avoid bubbles between completing one DMA buffer and starting a new one, the HSI controller provides 2 DMA buffers per channel. That way, the HSI driver can set up the next DMA buffer for a channel while the other buffer can still service HSI traffic in that channel.

The HSI controller implements a two-level round robin arbiter to arbitrate between 16 TX channels. Re-arbitration occurs when the previous burst completes.

34.2.2.1 TX Two-Level Arbiter

The two level arbiter is implemented in such a way that High Priority channels always get through first and potentially starve low priority channels. The HSI host driver has the responsibility to avoid starving low-priority channels. Software can choose either priority for each channel independently. High priority channels are passed through a simple round-robin arbiter and similarly low-priority channels are also passed through a round robin and then the output of these two arbiters are given to a fixed priority arbiter which always make sure that HP goes out first.

Figure 131: Two-Level Arbiter used for TX



34.2.3 Receiver Data Flow

Software should set up a DMA buffer for each channel that may have RX data. For any data received in a channel without a DMA buffer allocated, the HSI controller:

- Interrupts software that an unexpected channel was received, and
- Halts further data (by deasserting READY) until software has drained the unexpected data

When allocating RX data buffers, software may not know the length of data expected ahead of time.

In case of unknown DMA length, controller generates the “new data write completion” interrupt on every word/burst completion (when successfully written to system memory). That way software knows when new data (of previously unknown length) has arrived.

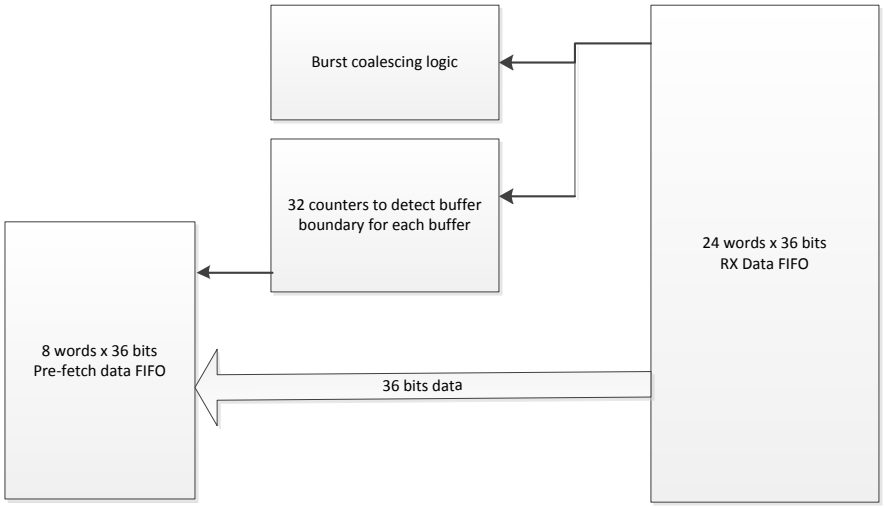
34.2.3.1 Receiver Burst Coalescing

Burst coalescing needs to be implemented to effectively use the system bus. Data coming in from external RX can be in any order in terms of channel number. The controller needs to make the maximum possible burst of incoming data before putting a request onto system bus.

As data is popped out of the RX data FIFO, its channel is compared against the next FIFO entries’ channels. If successive FIFO entries (HSI frames’ data) share the same channel, they will be coalesced into a single burst, up to the maximum burst size. (For AHB, the maximum burst size is eight 32-bit words.) Thus, AHB and system memory efficiency are strongly affected by RX data channel ordering.

The controller provides flexibility to software to switch between two system buffers in the runtime. Burst coalescing is invalid when software wants to switch the write location in the system memory. In that case controller needs to keep track of data length received associated for a particular buffer. The controller maintains counters for each buffer to detect the buffer boundary. The figure below shows the top level view of the burst coalescing scheme.

Figure 132: Burst Coalescing Scheme



34.3 Functional Description

34.3.1 Receiver Data Flow Modes

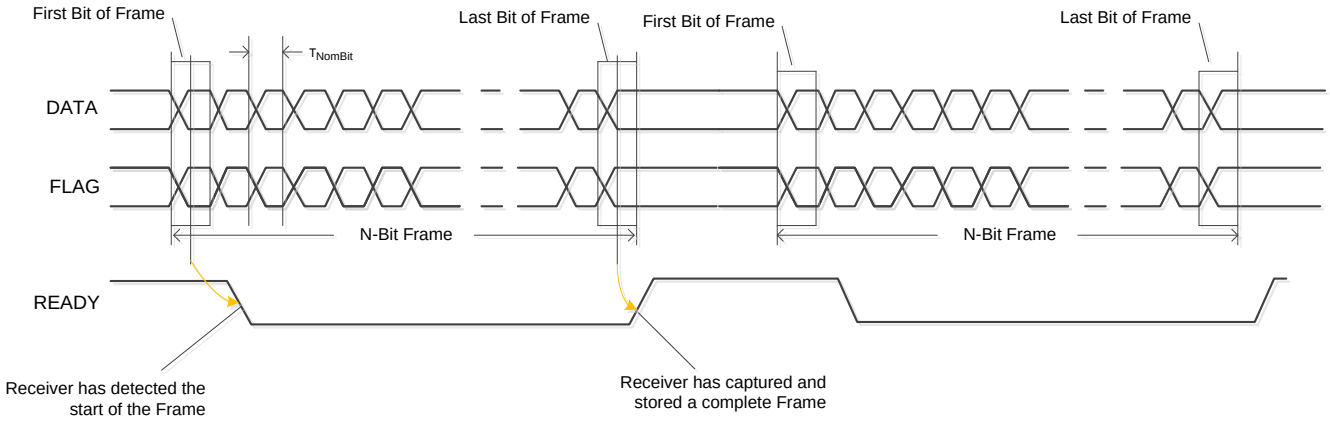
Data flow is a receiver feature. There are three different data flow types depending on the READY behavior -

34.3.1.1 Synchronized Data Flow

In the synchronized data flow, the receiver shall set READY to logic zero upon the reception of the first bit of frame and shall not set READY to logic one until enough bits have been received for the frame, and the frame has been stored in the buffer. The figure below shows the synchronized data flow READY signal timing.

Because of the idle time introduced by this handshake, synchronized data flow has lower interface efficiency, and should be avoided unless necessary.

Figure 133: Synchronized Data Flow Timing



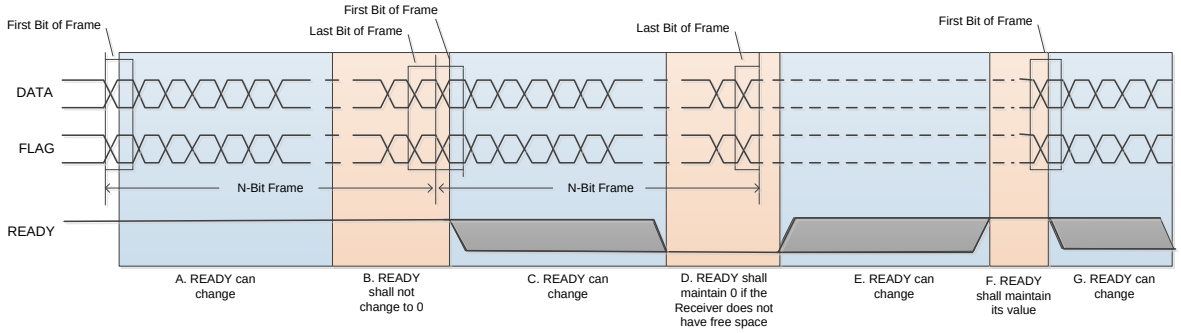
34.3.1.2 Pipelined Data Flow

In the pipelined data flow received shall only set the READY signal low when it has no storage available for a new frame. As long as the receiver can guarantee the successful reception of at least one more frame following the one being received, it

shall set READY to logic 1, and transmission can proceed in a pipelined manner. Pipelined data flow enables back-to-back frame transmission with no idle period on the line.

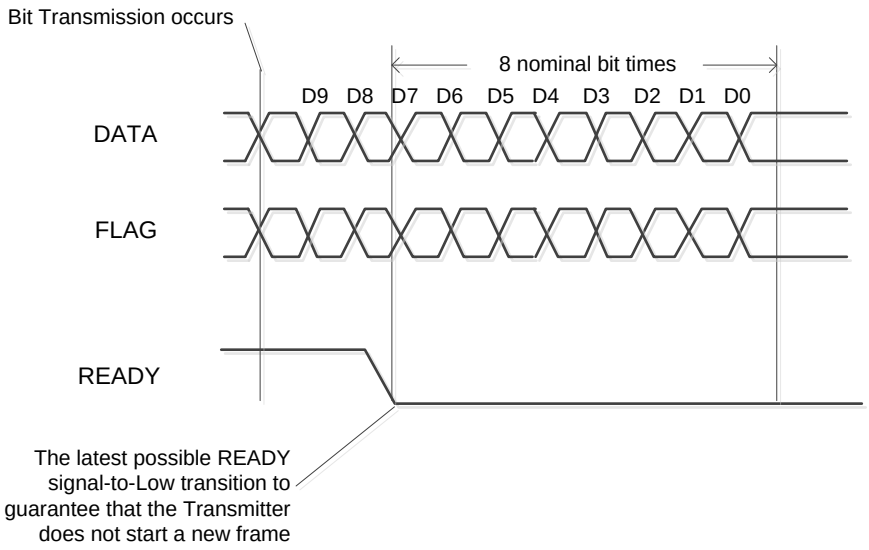
Because pipelined data flow allows for the highest performance, it should be used whenever possible.

Figure 134: Pipelined Data Flow Timing



The timing of the READY signal is asynchronous with respect to DATA and FLAG. However, the receiver shall drive READY to logic zero at least eight nominal bit times before the end of current frame in order to delay transmission of the next frame.

Figure 135: Pipelined Data Flow READY Signal-to-Low Detail

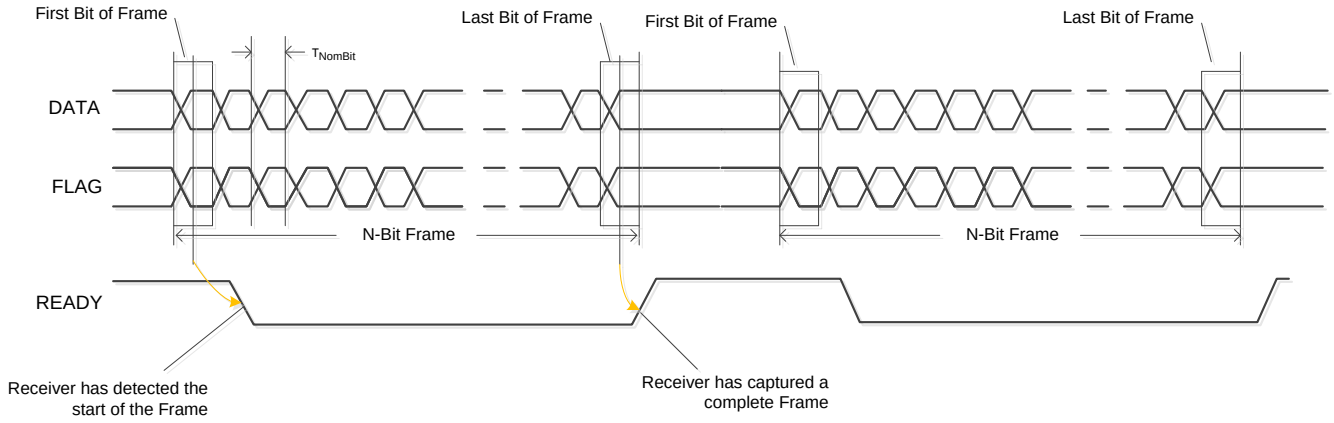


34.3.1.3 Receiver Real-time Data Flow

In receiver real-time data flow, a receiver shall drive READY to logic zero after the first bit of frame is found and high when the last bit of the frame is found. This READY signal behavior enables faster data transmission than in the synchronized data flow since the idle period between the frames are shorter.

Real-time data flow is used only for error recovery. (It provides a way for the TX side to see where in the frame the RX side is.) It should not be used for normal data transmission.

Figure 136: Receiver Real-Time Data Flow Timing



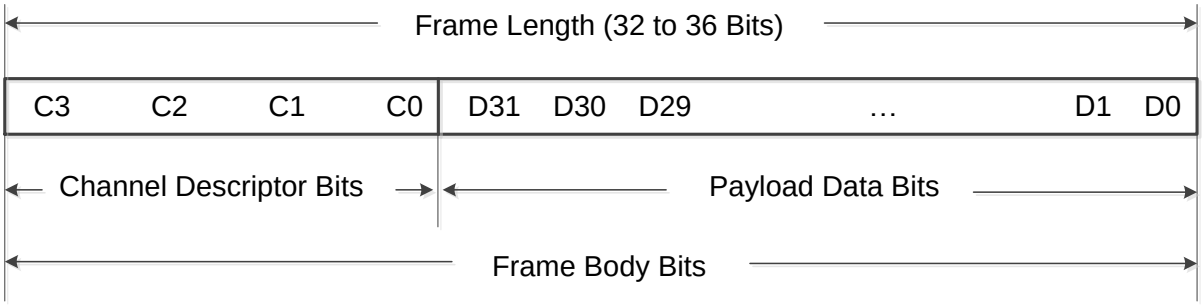
34.3.2 Bit Transmission Mode

HSI supports two transmission modes: Stream transmission mode and Frame transmission mode. The HSI receiver and transmitter implement Stream transmission mode with synchronized data flow, and Frame transmission mode with Synchronized Data Flow and Pipelined Data Flow.

34.3.2.1 Stream Transmission Mode

In this mode, the Physical layer data frame structure is made of 32 payload data bits, and 0 to 4 channel descriptor bits as shown below.

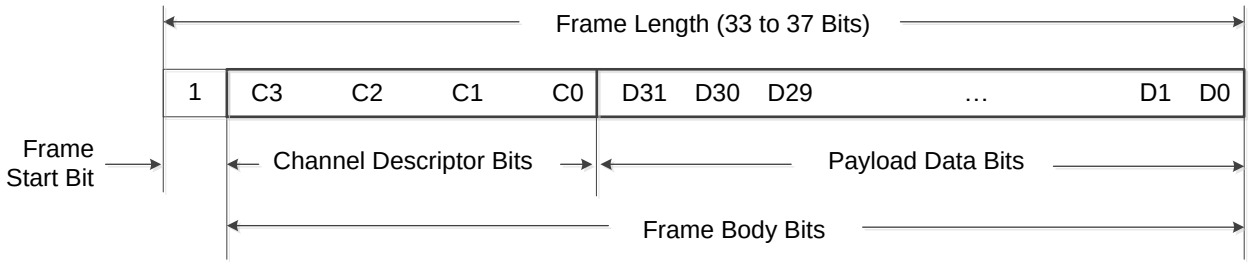
Figure 137: Frame Structure in Stream Mode



34.3.2.2 Frame Transmission Mode

In this mode, Frame boundaries shall be defined by a Frame start bit and a number of frame body bits.

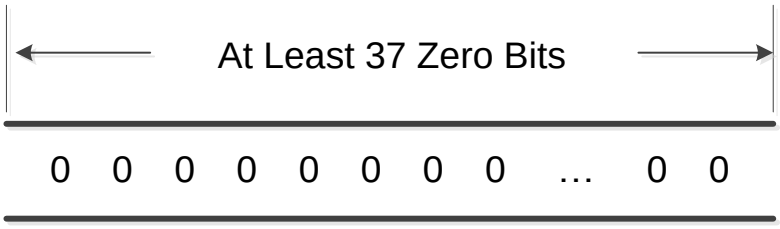
Figure 138: Frame Structure in Frame Mode



34.3.2.3 Physical Layer Break Frame

The transmitter shall be able to send a break frame regardless of the state of READY signal. Formally, the break transmission shall be defined as any sequence of logic zeros that is longer than can occur in normal transmission.

Figure 139: Minimum Break Transmission Size for Four Channel Descriptor Bits



34.4 Programming Guidelines

34.4.1 Transmitter

1. Program TX_MODE and tx channel_width in the TX_Global_Control_Register. Channel_width decides the Frame length. For example,if software wants to use up to 8 channels, channel_width must be programmed as 3. Software can use channel number 0 to 7 in this case.
2. Software can configure up to 2 DMA Buffers per channel. Provide the DMA length, Priority, and Starting address for each buffer and enable ready/in-use bit in TX_Control_Register for respective channel. Hardware will finish the running buffer first and then switch to the next buffer of same channel if that buffer is enabled.
3. Enable Buffer Complete Interrupt in TX_Buffer_Complete_Interrupt_Enable_Register. Hardware asserts the interrupt when total length for the corresponding buffer is transferred. Interrupt for the corresponding channel will be generated in TX_Buffer_Complete_Interrupt_Status_Register.
4. Software can initiate High priority PIO mode at any time. Program channel number in TX_Global_Control_Register through which PIO frame has to be transmitted, write 32 bit data in PIO_Word_Register. Writing data into this register initiates the PIO transfer. The next PIO write cannot be made until the TX PIO Complete Interrupt (“PIO_COMPLETE_INTR”) asserts.
5. Software can see the status of each buffer in TX_Buffer_Status_Register (shows how many words have been transmitted to TX) and can HALT any channel if need. **Hardware will clear the Ready/in-use bit in TX_Control_Register for that Buffer on Halt.** On Halt, DMA will stop fetching further data from that buffer.
6. Break frame feature is supported to get TX and RX in sync. Software can enable the TX to send break frame anytime (but only in frame mode). On asserting break frame, the controller will send a frame of all zeros (the frame length will depend on channel_length).

34.4.2 Receiver

1. Program the number of channels and enable the RX_ENABLE bit in RX_Global_Control_Register.
2. Software can set up up to 2 DMA Buffers per channel. Software needs to program the DMA Length (even if the total DMA length is not known ahead of time) and starting address for each buffer and enable/in-use bit in RX_control_register for respective channel.
3. Not setting up DMA will result in an Error Interrupt in RX_Error_Interrupt_Status_Register when a Frame is received by the RX for that particular channel. The received data can be read from the HSI RX Error Data register.
4. Enable “New Data Write Completion Interrupt” in RX_New_Data_Wr_Comp_Interrupt_Enable Register which will generate an interrupt every time a frame (OR maximum possible bursts of a frame) will be written to system memory. Interrupt for corresponding channel will be generated in RX_New_Data_Wr_Comp_Interrupt_Status_Register.
5. Enable Buffer Complete Interrupt in RX_Buffer_Complete_Interrupt_Enable_Register. Hardware asserts the interrupt when the total length for the corresponding buffer is transferred. Interrupt for the corresponding channel will be generated in RX_Buffer_Complete_Interrupt_Status_Register. In case of fence_enable, the controller waits until fence read data comes back before asserting the RX_Buffer_Complete_Interrupt. However when fence is disabled, as soon as data is written on AHB, controller will assert the interrupt.
6. Software can see the status of each Buffer in RX_Buffer_Status_Register (shows how many words have been successfully written to system memory) and Halt any channel if need. Hardware will clear Ready/in-use bit in RX_Control_Register for that Buffer on Halt. On Halt, the RX will not write data to system memory for that buffer and generates an Error Interrupt in RX_Error_Interupt_Register if any Frame is received for that Halted channel.

34.4.3 Halting Incomplete DMA

If desired, software could de-allocate an RX buffer that is only partially filled by:

- Asserting that buffer’s “halt” bit (need to add halt bits for both RX and TX buffers, not just TX)
- Polling on the semaphore until hardware releases it

Software can know how much data is in each buffer by:

- Looking at the per-buffer “# words written” status
- Knowing that the hardware will work on the buffer given to it first, first

This requires software to serially allocate DMA buffers to the same channel (i.e., two separate threads cannot simultaneously allocate DMA buffers to the same channel).

34.4.4 Miscellaneous Points

- The driver needs to make sure of the ratio between core clock and Rx clock for successful data reception. 2:1 is the ratio that needs to be maintained between core and Rx clock. For example, if Rx is running at 200 MHz, core must be running at minimum 100 MHz for successful reception.
- READY deassertion in synchronized Data Flow mode. READY deassertion behavior is under-constrained and the description only says “upon reception of the first bit of a physical frame”. This sequence of events cannot happen in zero time. Maximum deassertion delay is not given. No reasonable implementation could allow the delay to be longer than a frame time, and a reasonable maximum would be the 8 nominal bit times before the end of a frame used by the Pipelined Data Flow. Regardless, Synchronize Data Flow is a huge efficiency waste on the HSI interface, and any high-speed, low-power device should be using Pipelined Data Flow instead.
- The Tegra® 4 MIPI-HSI Controller does not implement following:
  - Receiver Frame Burst Counter
  - Receiver Tailing bit Counter
  - Missed clock cycle

- Additional Clock Cycle

The main reason for not implementing these error detection primitives is that the HSI environment is relatively error free and error detection is quite well and recovery time is relatively long. HSI relies on the physical interface's bit error rate to be significantly small for reliability.

- In case of an RX break frame – which is all zero frames, the controller asserts the RX Error interrupt for channel 0 if the ready bit for channel 0 is not set (which means channel 0 is not running) and also asserts RX break frame interrupt.
- The Tegra 4 HSI architecture does not support fence mechanism. Keep it disabled and apply the WAR for successful operation.
- Software should deassert the HSI_RX_SRC_RST bit of MIPIHSI_GLOBAL_RX_CONTROL_0 register before starting the transfer. This is needed to release the reset of rx_pad_macro.

34.5 MIPI-HSI Registers

Refer to "Reading Register Tables" in the Introduction section for the register table protocol as well as recommendations for accessing registers.

34.5.1 MIPIHSI_GLOBAL_TX_CONTROL_0

HSI Global TX Control Register

Offset: 0x0 │ Read/Write: R/W │ Reset: 0x00000000 (0bxxxxxxxxxxxxxxxxxxxx00000x0000000)

Bit	Reset	Description
12:9	0x0	PIO_CHANNEL_NUM: Baseband channel number to which PIO data has to be transmitted. As writing the PIO Data Initiates the PIO word transfer, this field must be written before PIO data. TX supports data transfer through PIO as well. The controller will insert the PIO frame after the current frame on HSI interface is done and generate the PIO done interrupt. 0 = CHANNEL_0 1 = CHANNEL_1 2 = CHANNEL_2 3 = CHANNEL_3 4 = CHANNEL_4 5 = CHANNEL_5 6 = CHANNEL_6 7 = CHANNEL_7 8 = CHANNEL_8 9 = CHANNEL_9 10 = CHANNEL_10 11 = CHANNEL_11 12 = CHANNEL_12 13 = CHANNEL_13 14 = CHANNEL_14 15 = CHANNEL_15
8	0x0	SEND_BREAK_FRAME: Injects Break Frame. Possible only in Frame Transmission Mode. Hardware clears it when a Break Frame is sent out. 0 = DISABLE 1 = ENABLE
6:3	0x0	CHANNEL_DESC_WIDTH: This defines the channel_width in the frame_length. The Channel descriptor field in the Frame will change accordingly. This field must be programmed correctly before any transfer starts. 0 = SINGLE_CHANNEL 1 = UPTO_TWO_CHANNELS 2 = UPTO_FOUR_CHANNELS 3 = UPTO_EIGHT_CHANNELS 4 = UPTO_SIXTEEN_CHANNELS

Bit	Reset	Description
2:1	0x0	WAKE: Normally, the WAKE signal is automatically controller by the controller, It would be controller "low" or "high" via software to work around any bug (either in the controller or the device). 0 = AUTOMATICALLY_ASSERTS 1 = LOW 2 = HIGH
0	0x0	TRANSMISSION_MODE: TX mode of transmission. Refer to section 4.2 of the MIPI_HSI specification, v1.01. 0 = STREAM_MODE 1 = FRAME_MODE

34.5.2 MIPIHSI_GLOBAL_RX_CONTROL_0

HSI Global RX Control Register

Offset: 0x4 │ Read/Write: R/W │ Reset: 0xc8000000 (0b1100100xxxxxxxxxxxxxxx0x00000000)

Bit	Reset	Description
31	0x1	HSI_RX_SRC_RST: RX pad macro reset. Needed, so that rx pad macro can be reset in case of recovery without touching of controller reset. Please note that other side link also need to be reset at the same time when RX pad_macro is applied reset. 0 : Deassert the rx pad macro reset 1 : Assert the rx pad macro reset. Default is 1 so that pad macro reset will automatically be reset on power on reset.
30	0x1	HSI_FENCE_RD_ENABLE: Fence Read request enable - need to set this to avoid data coherency issues when writing to system memory. Keep it disabled (program 1'b0 to this bit) for successful operation in Tegra 4 series devices.
29:25	0x4	RX_CLK_TRIM_VALUE: Needed for RX pad macro.
9	0x0	RX_INTERNAL_WAKE: Needed for the devices that don't implement WAKE. In that case RX will have to assume that WAKE is always asserted. 0 : Look for external WAKE signal. 1 : External WAKE is not implemented. Assume WAKE is always there.
7:4	0x0	NUM_OF_RX_CHANNELS: Number of RX channel that software wants to use. The Channel descriptor field in the Frame will change accordingly. The total frame_length depends on this and RX reception mode. 0 = ONE_CHANNEL 1 = TWO_CHANNELS 2 = FOUR_CHANNELS 3 = EIGHT_CHANNELS 4 = SIXTEEN_CHANNELS
3:2	0x0	RECEIVER_DATA_FLOW_MODE: READY Timing depends on Receiver Data Flow Mode. Refer to section 4.1.2 of the MIPI_HSI specification, v1.01, for receiver data flow modes. Receiver_real_time_mode is not supported as its used only in case of error recovery. 0 = SYNCRONIZED_DATA_FLOW_MODE 1 = PIPELINED_DATA_FLOW_MODE 2 = RECEIVER_REAL_TIME_MODE
1	0x0	RX_MODE: RX Bit Reception mode. Please refer section 4.2 of MIPI_HSI spec v1.01. 0 = STREAM_MODE 1 = FRAME_MODE
0	0x0	RX_ENABLE: Enable/Disable RX. RX will work only if it is enabled. 0 = DISABLE 1 = ENABLE

34.5.3 MIPIHSI_PIO_DATA_PORT_0

HSI PIO Data/Word Register

Offset: 0x8 | Read/Write: R/W | Reset: 0x00000000 (0b00000000000000000000000000000000)

Bit	Reset	Description
31:0	0x0	PIO_DATA: 32-bit data to be Transmitted through PIO. Only TX supports data transfers through PIO. The TX will start transmitting data as soon as software writes PIO word in this register.

34.5.4 MIPIHSI_DMA_CONTROL_TX_BUF_0_CH_0_0

HSI DMA TX Channel_0_Buffer_0 Control Register

Offset: 0xc | Read/Write: R/W | Reset: 0x00000000 (0bx000000000000000xxxxxxxxxxxxx000)

Bit	Reset	Description
30:16	0x0	LENGTH_DMA_BUF_0_TX_CH_0: Number of words to be transferred from Buffer_0. 0 = One 32-bit word. 0x7FFE = 127 KB.
2	0x0	PRIORITY_TX_CH_0: priority for this DMA channel. Affects both buffers of this channel. High priority channels are given preference over low priority. All the same priority channels follow the round robin scheme. 0 = HIGH 1 = LOW
1	0x0	HALT_DMA_BUF_0_TX_CH_0: Stop fetching data from BUF_0. Any data already fetched into the FIFO will still go out to the HSI Tx interface. 0 = DISABLE: Software needs to wait until hardware clears this bit before starting a new transaction. 1 = ENABLE
0	0x0	READY_BUF_0_TX_CH_0: Ready/in-use semaphore that software sets when ready, and hardware clears it when no longer in use. 0 = NO_LONGER_IN_USE 1 = IN_USE

34.5.5 MIPIHSI_DMA_CONTROL_TX_BUF_1_CH_0_0

HSI DMA TX Channel_0_Buffer_1 Control Register

Offset: 0x10 | Read/Write: R/W | Reset: 0x00000000 (0bx000000000000000xxxxxxxxxxxxxx00)

Bit	Reset	Description
30:16	0x0	LENGTH_DMA_BUF_1_TX_CH_0: Number of words to be transferred from Buffer_1. 0 = One 32-bit word. 0x7FFE = 127 KB.
1	0x0	HALT_DMA_BUF_1_TX_CH_0: Stop fetching data from BUF_1. Any data already fetched into the FIFO will still go out to the HSI Tx interface. 0 = DISABLE: Software needs to wait until hardware clears this bit before starting a new transaction. 1 = ENABLE
0	0x0	READY_BUF_1_TX_CH_0: Ready/in-use semaphore that software sets when ready, and hardware clears it when no longer in use. 0 = NO_LONGER_IN_USE 1 = IN_USE

34.5.6 MIPIHSI_DMA_CONTROL_TX_BUF_0_CH_1_0

HSI DMA TX Channel_1_Buffer_0 Control Register

Offset: 0x14 | Read/Write: R/W | Reset: 0x00000000 (0bx00000000000000xxxxxxxxxxxxx000)

Bit	Reset	Description
30:16	0x0	LENGTH_DMA_BUF_0_TX_CH_1: Number of words to be transferred from Buffer_0. 0 = One 32-bit word. 0x7FFE = 127 KB.
2	0x0	PRIORITY_TX_CH_1: Priority for this DMA channel. Affects both buffers of this channel. High priority channels are given preference over low priority. All the same priority channels follow the round robin scheme. 0 = HIGH 1 = LOW
1	0x0	HALT_DMA_BUF_0_TX_CH_1: Stop fetching data from BUF_0. Any data already fetched into the FIFO will still go out to the HSI Tx interface. 0 = DISABLE: Software needs to wait until hardware clears this bit before starting a new transaction. 1 = ENABLE
0	0x0	READY_BUF_0_TX_CH_1: Ready/in-use semaphore that software sets when ready, and hardware clears it when no longer in use. 0 = NO_LONGER_IN_USE 1 = IN_USE

34.5.7 MIPIHSI_DMA_CONTROL_TX_BUF_1_CH_1_0

HSI DMA TX Channel_1_Buffer_1 Control Register

Offset: 0x18 | Read/Write: R/W | Reset: 0x00000000 (0bx00000000000000xxxxxxxxxxxxx00)

Bit	Reset	Description
30:16	0x0	LENGTH_DMA_BUF_1_TX_CH_1: Number of words to be transferred from Buffer_1. 0 = One 32-bit word. 0x7FFE = 127 KB.
1	0x0	HALT_DMA_BUF_1_TX_CH_1: Stop fetching data from BUF_1. Any data already fetched into the FIFO will still go out to the HSI Tx interface. 0 = DISABLE: Software needs to wait until hardware clears this bit before starting new transaction. 1 = ENABLE
0	0x0	READY_BUF_1_TX_CH_1: Ready/in-use semaphore that software sets when ready, and hardware clears it when no longer in use. 0 = NO_LONGER_IN_USE 1 = IN_USE

34.5.8 MIPIHSI_DMA_CONTROL_TX_BUF_0_CH_2_0

HSI DMA TX Channel_2_Buffer_0 Control Register

Offset: 0x1c | Read/Write: R/W | Reset: 0x00000000 (0bx00000000000000xxxxxxxxxxxxx000)

Bit	Reset	Description
30:16	0x0	LENGTH_DMA_BUF_0_TX_CH_2: Number of words to be transferred from Buffer_0. 0 = One 32-bit word. 0x7FFE = 127 KB.

Bit	Reset	Description
2	0x0	PRIORITY_TX_CH_2: Priority for this DMA channel. Affects both buffers of this channel. High priority channels are given preference over low priority. All the same priority channels follow the round robin scheme. 0 = HIGH 1 = LOW
1	0x0	HALT_DMA_BUF_0_TX_CH_2: Stop fetching data from BUF_0. Any data already fetched into the FIFO will still go out to the HSI Tx interface. 0 = DISABLE: Software needs to wait until hardware clears this bit before starting new transaction. 1 = ENABLE
0	0x0	READY_BUF_0_TX_CH_2: Ready/in-use semaphore that software sets when ready, and hardware clears it when no longer in use. 0 = NO_LONGER_IN_USE 1 = IN_USE

34.5.9 MIPIHSI_DMA_CONTROL_TX_BUF_1_CH_2_0

HSI DMA TX Channel_2_Buffer_1 Control Register

Offset: 0x20 │ Read/Write: R/W │ Reset: 0x00000000 (0bx000000000000000xxxxxxxxxxxxxx00)

Bit	Reset	Description
30:16	0x0	LENGTH_DMA_BUF_1_TX_CH_2: Number of words to be transferred from Buffer_1. 0 = One 32-bit word. 0x7FFE = 127 KB.
1	0x0	HALT_DMA_BUF_1_TX_CH_2: Stop fetching data from BUF_1. Any data already fetched into the FIFO will still go out to the HSI Tx interface. 0 = DISABLE: Software needs to wait until hardware clears this bit before starting new transaction. 1 = ENABLE
0	0x0	READY_BUF_1_TX_CH_2: Ready/in-use semaphore that software sets when ready, and hardware clears it when no longer in use. 0 = NO_LONGER_IN_USE 1 = IN_USE

34.5.10 MIPIHSI_DMA_CONTROL_TX_BUF_0_CH_3_0

HSI DMA TX Channel_3_Buffer_0 Control Register

Offset: 0x24 │ Read/Write: R/W │ Reset: 0x00000000 (0bx000000000000000xxxxxxxxxxxxx000)

Bit	Reset	Description
30:16	0x0	LENGTH_DMA_BUF_0_TX_CH_3: Number of words to be transferred from Buffer_0. 0 = One 32-bit word. 0x7FFE = 127 KB.
2	0x0	PRIORITY_TX_CH_3: Priority for this DMA channel. Affects both buffers of this channel. High priority channels are given preference over low priority. All the same priority channels follow the round robin scheme. 0 = HIGH 1 = LOW
1	0x0	HALT_DMA_BUF_0_TX_CH_3: Stop fetching Data from BUF_0. Any data already fetched into the FIFO will still go out to the HSI Tx interface. 0 = DISABLE: Software needs to wait until hardware clears this bit before starting new transaction. 1 = ENABLE

Bit	Reset	Description
0	0x0	READY_BUF_0_TX_CH_3: Ready/in-use semaphore that software sets when ready, and hardware clears it when no longer in use. 0 = NO_LONGER_IN_USE 1 = IN_USE

34.5.11 MIPIHSI_DMA_CONTROL_TX_BUF_1_CH_3_0

HSI DMA TX Channel_3_Buffer_1 Control Register

Offset: 0x28 │ Read/Write: R/W │ Reset: 0x00000000 (0bx00000000000000xxxxxxxxxxxxxx00)

Bit	Reset	Description
30:16	0x0	LENGTH_DMA_BUF_1_TX_CH_3: Number of words to be transferred from Buffer_1. 0 = One 32-bit word. 0x7FFE = 127 KB.
1	0x0	HALT_DMA_BUF_1_TX_CH_3: Stop fetching data from BUF_1. Any data already fetched into the FIFO will still go out to the HSI Tx interface. 0 = DISABLE: Software needs to wait until hardware clears this bit before starting new transaction. 1 = ENABLE

HSI TX Channel_15 DMA Buffer_0 System Memory Address Register

Offset: 0x17c | Read/Write: R/W | Reset: 0x00000000 (0b00000000000000000000000000000000)

Bit	Reset	Description
31:0	0x0	SYSTEM_MEM_ADDR_BUF_0_TX_CH_15: System Memory Address for DMA Buffer-0 for TX

34.5.67 MIPIHSI_TX_CH_15_DMA_BUFFER_1_SYSTEM_MEMORY_ADDR_0

HSI TX Channel_15 DMA Buffer_1 System Memory Address Register

Offset: 0x184 | Read/Write: R/W | Reset: 0x00000000 (0b00000000000000000000000000000000)

Bit	Reset	Description
31:0	0x0	SYSTEM_MEM_ADDR_BUF_1_TX_CH_15: System Memory Address for DMA Buffer-1 for TX

34.5.68 MIPIHSI_TX_CH_0_DMA_BUFFER_STATUS_0

HSI TX Channel_0 DMA Buffer Status Register

Offset: 0x18c | Read/Write: RO | Reset: 0x00000000 (0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx)

Bit	Reset	Description
31:16	X	WORDS_READ_STATUS_FOR_BUFFER_1_TX_CH_0: Status indicating number of words received from the memory Buffer-1.Ranges from 0 to 128 KB (0x8000 words).
15:0	X	WORDS_READ_STATUS_FOR_BUFFER_0_TX_CH_0: Status indicating number of words received from the memory Buffer-0.Ranges from 0 to 128 KB (0x8000 words).

34.5.69 MIPIHSI_TX_CH_1_DMA_BUFFER_STATUS_0

HSI TX Channel_1 DMA Buffer Status Register

Offset: 0x190 | Read/Write: RO | Reset: 0x00000000 (0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx)

Bit	Reset	Description
31:16	X	WORDS_READ_STATUS_FOR_BUFFER_1_TX_CH_1: Status indicating number of words received from the memory Buffer-1. Ranges from 0 to 128 KB (0x8000 words).
15:0	X	WORDS_READ_STATUS_FOR_BUFFER_0_TX_CH_1: Status indicating number of words received from the memory Buffer-0. Ranges from 0 to 128 KB (0x8000 words).

34.5.70 MIPIHSI_TX_CH_2_DMA_BUFFER_STATUS_0

HSI TX Channel_2 DMA Buffer Status Register

Offset: 0x194 | Read/Write: RO | Reset: 0x00000000 (0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx)

Bit	Reset	Description
31:16	X	WORDS_READ_STATUS_FOR_BUFFER_1_TX_CH_2: Status indicating number of words received from the memory Buffer-1.Ranges from 0 to 128 KB (0x8000 words).
15:0	X	WORDS_READ_STATUS_FOR_BUFFER_0_TX_CH_2: Status indicating number of words received from the memory Buffer-0.Ranges from 0 to 128 KB (0x8000 words).

34.5.71 MIPIHSI_TX_CH_3_DMA_BUFFER_STATUS_0

HSI TX Channel_3 DMA Buffer Status Register

Offset: 0x198 | Read/Write: RO | Reset: 0x00000000 (0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx)

Bit	Reset	Description
31:16	X	WORDS_READ_STATUS_FOR_BUFFER_1_TX_CH_3: Status indicating number of words received from the memory Buffer-1.Ranges from 0 to 128 KB (0x8000 words).
15:0	X	WORDS_READ_STATUS_FOR_BUFFER_0_TX_CH_3: Status indicating number of words received from the memory Buffer-0.Ranges from 0 to 128 KB (0x8000 words).

34.5.72 MIPIHSI_TX_CH_4_DMA_BUFFER_STATUS_0

HSI TX Channel_4 DMA Buffer Status Register

Offset: 0x19c | Read/Write: RO | Reset: 0x00000000 (0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx)

Bit	Reset	Description
31:16	X	WORDS_READ_STATUS_FOR_BUFFER_1_TX_CH_4: Status indicating number of words received from the memory Buffer-1.Ranges from 0 to 128 KB (0x8000 words).
15:0	X	WORDS_READ_STATUS_FOR_BUFFER_0_TX_CH_4: Status indicating number of words received from the memory Buffer-0.Ranges from 0 to 128 KB (0x8000 words).

34.5.73 MIPIHSI_TX_CH_5_DMA_BUFFER_STATUS_0

HSI TX Channel_5 DMA Buffer Status Register

Offset: 0x1a0 | Read/Write: RO | Reset: 0x00000000 (0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx)

Bit	Reset	Description
31:16	X	WORDS_READ_STATUS_FOR_BUFFER_1_TX_CH_5: Status indicating number of words received from the memory Buffer-1.Ranges from 0 to 128 KB (0x8000 words).
15:0	X	WORDS_READ_STATUS_FOR_BUFFER_0_TX_CH_5: Status indicating number of words received from the memory Buffer-0.Ranges from 0 to 128 KB (0x8000 words).

34.5.74 MIPIHSI_TX_CH_6_DMA_BUFFER_STATUS_0

HSI TX Channel_6 DMA Buffer Status Register

Offset: 0x1a4 | Read/Write: RO | Reset: 0x00000000 (0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx)

Bit	Reset	Description
31:16	X	WORDS_READ_STATUS_FOR_BUFFER_1_TX_CH_6: Status indicating number of words received from the memory Buffer-1.Ranges from 0 to 128 KB (0x8000 words).
15:0	X	WORDS_READ_STATUS_FOR_BUFFER_0_TX_CH_6: Status indicating number of words received from the memory Buffer-0.Ranges from 0 to 128 KB (0x8000 words).

34.5.75 MIPIHSI_TX_CH_7_DMA_BUFFER_STATUS_0

HSI TX Channel_7 DMA Buffer Status Register

Offset: 0x1a8 | Read/Write: RO | Reset: 0x00000000 (0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx)

Bit	Reset	Description
31:16	X	WORDS_READ_STATUS_FOR_BUFFER_1_TX_CH_7: Status indicating number of words received from the memory Buffer-1.Ranges from 0 to 128B (0x8000 words).
15:0	X	WORDS_READ_STATUS_FOR_BUFFER_0_TX_CH_7: Status indicating number of words received from the memory Buffer-0.Ranges from 0 to 128 KB (0x8000 words).

34.5.76 MIPIHSI_TX_CH_8_DMA_BUFFER_STATUS_0

HSI TX Channel_8 DMA Buffer Status Register

Offset: 0x1ac | Read/Write: RO | Reset: 0x00000000 (0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx)

Bit	Reset	Description
31:16	X	WORDS_READ_STATUS_FOR_BUFFER_1_TX_CH_8: Status indicating number of words received from the memory Buffer-1.Ranges from 0 to 128 KB (0x8000 words).
15:0	X	WORDS_READ_STATUS_FOR_BUFFER_0_TX_CH_8: Status indicating number of words received from the memory Buffer-0.Ranges from 0 to 128 KB (0x8000 words).

34.5.77 MIPIHSI_TX_CH_9_DMA_BUFFER_STATUS_0

HSI TX Channel_9 DMA Buffer Status Register

Offset: 0x1b0 | Read/Write: RO | Reset: 0x00000000 (0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx)

Bit	Reset	Description
31:16	X	WORDS_READ_STATUS_FOR_BUFFER_1_TX_CH_9: Status indicating number of words received from the memory Buffer-1.Ranges from 0 to 128 KB (0x8000 words).
15:0	X	WORDS_READ_STATUS_FOR_BUFFER_0_TX_CH_9: Status indicating number of words received from the memory Buffer-0.Ranges from 0 to 128 KB (0x8000 words).

34.5.78 MIPIHSI_TX_CH_10_DMA_BUFFER_STATUS_0

HSI TX Channel_10 DMA Buffer Status Register

Offset: 0x1b4 | Read/Write: RO | Reset: 0x00000000 (0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx)

Bit	Reset	Description
31:16	X	WORDS_READ_STATUS_FOR_BUFFER_1_TX_CH_10: Status indicating number of words received from the memory Buffer-1.Ranges from 0 to 128 KB (0x8000 words).
15:0	X	WORDS_READ_STATUS_FOR_BUFFER_0_TX_CH_10: Status indicating number of words received from the memory Buffer-0.Ranges from 0 to 128 KB (0x8000 words).

34.5.79 MIPIHSI_TX_CH_11_DMA_BUFFER_STATUS_0

HSI TX Channel_11 DMA Buffer Status Register

Offset: 0x1b8 | Read/Write: RO | Reset: 0x00000000 (0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx)

Bit	Reset	Description
31:16	X	WORDS_READ_STATUS_FOR_BUFFER_1_TX_CH_11: Status indicating number of words received from the memory Buffer-1.Ranges from 0 to 128 KB (0x8000 words).
15:0	X	WORDS_READ_STATUS_FOR_BUFFER_0_TX_CH_11: Status indicating number of words received from the memory Buffer-0.Ranges from 0 to 128 KB (0x8000 words).

34.5.80 MIPIHSI_TX_CH_12_DMA_BUFFER_STATUS_0

HSI TX Channel_12 DMA Buffer Status Register

Offset: 0x1bc | Read/Write: RO | Reset: 0x00000000 (0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx)

Bit	Reset	Description
31:16	X	WORDS_READ_STATUS_FOR_BUFFER_1_TX_CH_12: Status indicating number of words received from the memory Buffer-1.Ranges from 0 to 128 KB (0x8000 words).
15:0	X	WORDS_READ_STATUS_FOR_BUFFER_0_TX_CH_12: Status indicating number of words received from the memory Buffer-0.Ranges from 0 to 128 KB (0x8000 words).

34.5.81 MIPIHSI_TX_CH_13_DMA_BUFFER_STATUS_0

HSI TX Channel_13 DMA Buffer Status Register

Offset: 0x1c0 | Read/Write: RO | Reset: 0x00000000 (0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx)

Bit	Reset	Description
31:16	X	WORDS_READ_STATUS_FOR_BUFFER_1_TX_CH_13: Status indicating number of words received from the memory Buffer-1.Ranges from 0 to 128 KB (0x8000 words).
15:0	X	WORDS_READ_STATUS_FOR_BUFFER_0_TX_CH_13: Status indicating number of words received from the memory Buffer-0.Ranges from 0 to 128 KB (0x8000 words).

34.5.82 MIPIHSI_TX_CH_14_DMA_BUFFER_STATUS_0

HSI TX Channel_14 DMA Buffer Status Register

Offset: 0x1c4 | Read/Write: RO | Reset: 0x00000000 (0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx)

Bit	Reset	Description
31:16	X	WORDS_READ_STATUS_FOR_BUFFER_1_TX_CH_14: Status indicating number of words received from the memory Buffer-1.Ranges from 0 to 128 KB (0x8000 words).
15:0	X	WORDS_READ_STATUS_FOR_BUFFER_0_TX_CH_14: Status indicating number of words received from the memory Buffer-0.Ranges from 0 to 128 KB (0x8000 words).

34.5.83 MIPIHSI_TX_CH_15_DMA_BUFFER_STATUS_0

HSI TX Channel_15 DMA Buffer Status Register

Offset: 0x1c8 | Read/Write: RO | Reset: 0x00000000 (0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx)

Bit	Reset	Description
31:16	X	WORDS_READ_STATUS_FOR_BUFFER_1_TX_CH_15: Status indicating number of words received from the memory Buffer-1.Ranges from 0 to 128 KB (0x8000 words).
15:0	X	WORDS_READ_STATUS_FOR_BUFFER_0_TX_CH_15: Status indicating number of words received from the memory Buffer-0.Ranges from 0 to 128 KB (0x8000 words).

34.5.84 MIPIHSI_DMA_CONTROL_RX_BUF_0_CH_0_0

HSI DMA RX Channel_0_Buffer_0 Control Register

Offset: 0x1cc | Read/Write: R/W | Reset: 0x00000000 (0bx0000000000000000xxxxxxxxxxxxxx00)

Bit	Reset	Description
30:16	0x0	LENGTH_DMA_BUF_0_RX_CH_0: Number of words to be transferred from Buffer_0 0 = One 32-bit word. 0x7FFE = 127 KB.
1	0x0	HALT_DMA_RX_CH_0: Stop writing data to BUF_0. Hardware will clear the READY_BUF bit on HALT. Software needs to wait until hardware clears this bit before starting new transaction.

34.5.157 MIPIHSI_RX_CH_9_DMA_BUFFER_STATUS_0

HSI RX Channel_9 DMA Buffer Status Register

Offset: 0x370 | Read/Write: RO | Reset: 0x00000000 (0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx)

Bit	Reset	Description
31:16	X	WORDS_READ_STATUS_FOR_BUFFER_1_RX_CH_9: Status indicating number of words received from the memory Buffer-0.Ranges from 0 to 128 KB (0x8000 words).
15:0	X	WORDS_READ_STATUS_FOR_BUFFER_0_RX_CH_9: Status indicating number of words received from the memory Buffer-0.Ranges from 0 to 128 KB (0x8000 words).

34.5.158 MIPIHSI_RX_CH_10_DMA_BUFFER_STATUS_0

HSI RX Channel_10 DMA Buffer Status Register

Offset: 0x374 | Read/Write: RO | Reset: 0x00000000 (0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx)

Bit	Reset	Description
31:16	X	WORDS_READ_STATUS_FOR_BUFFER_1_RX_CH_10: Status indicating number of words received from the memory Buffer-0.Ranges from 0 to 128 KB (0x8000 words).
15:0	X	WORDS_READ_STATUS_FOR_BUFFER_0_RX_CH_10: Status indicating number of words received from the memory Buffer-0.Ranges from 0 to 128 KB (0x8000 words).

34.5.159 MIPIHSI_RX_CH_11_DMA_BUFFER_STATUS_0

HSI RX Channel_11 DMA Buffer Status Register

Offset: 0x378 | Read/Write: RO | Reset: 0x00000000 (0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx)

Bit	Reset	Description
31:16	X	WORDS_READ_STATUS_FOR_BUFFER_1_RX_CH_11: Status indicating number of words received from the memory Buffer-0.Ranges from 0 to 128 KB (0x8000 words).
15:0	X	WORDS_READ_STATUS_FOR_BUFFER_0_RX_CH_11: Status indicating number of words received from the memory Buffer-0.Ranges from 0 to 128 KB (0x8000 words).

34.5.160 MIPIHSI_RX_CH_12_DMA_BUFFER_STATUS_0

HSI RX Channel_12 DMA Buffer Status Register

Offset: 0x37c | Read/Write: RO | Reset: 0x00000000 (0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx)

Bit	Reset	Description
31:16	X	WORDS_READ_STATUS_FOR_BUFFER_1_RX_CH_12: Status indicating number of words received from the memory Buffer-0.Ranges from 0 to 128 KB (0x8000 words).
15:0	X	WORDS_READ_STATUS_FOR_BUFFER_0_RX_CH_12: Status indicating number of words received from the memory Buffer-0.Ranges from 0 to 128 KB (0x8000 words).

34.5.161 MIPIHSI_RX_CH_13_DMA_BUFFER_STATUS_0

HSI RX Channel_13 DMA Buffer Status Register

Offset: 0x380 | Read/Write: RO | Reset: 0x00000000 (0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx)

Bit	Reset	Description
31:16	X	WORDS_READ_STATUS_FOR_BUFFER_1_RX_CH_13: Status indicating number of words received from the memory Buffer-0.Ranges from 0 to 128 KB (0x8000 words).
15:0	X	WORDS_READ_STATUS_FOR_BUFFER_0_RX_CH_13: Status indicating number of words received from the memory Buffer-0.Ranges from 0 to 128 KB (0x8000 words).

34.5.162 MIPIHSI_RX_CH_14_DMA_BUFFER_STATUS_0

HSI RX Channel_14 DMA Buffer Status Register

Offset: 0x384 | Read/Write: RO | Reset: 0x00000000 (0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx)

Bit	Reset	Description
31:16	X	WORDS_READ_STATUS_FOR_BUFFER_1_RX_CH_14: Status indicating number of words received from the memory Buffer-0.Ranges from 0 to 128 KB (0x8000 words).
15:0	X	WORDS_READ_STATUS_FOR_BUFFER_0_RX_CH_14: Status indicating number of words received from the memory Buffer-0.Ranges from 0 to 128 KB (0x8000 words).

34.5.163 MIPIHSI_RX_CH_15_DMA_BUFFER_STATUS_0

HSI RX Channel_15 DMA Buffer Status Register

Offset: 0x388 │ Read/Write: RO │ Reset: 0x00000000 (0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx)

Bit	Reset	Description
31:16	X	WORDS_READ_STATUS_FOR_BUFFER_1_RX_CH_15: Status indicating number of words received from the memory Buffer-0.Ranges from 0 to 128 KB (0x8000 words).
15:0	X	WORDS_READ_STATUS_FOR_BUFFER_0_RX_CH_15: Status indicating number of words received from the memory Buffer-0.Ranges from 0 to 128 KB (0x8000 words).

34.5.164 MIPIHSI_TX_DMA_BUFFER_COMPLETE_INTERRUPT_ENABLE_0

HSI TX DMA Buffer Complete Interrupt Enable Register

Offset: 0x38c │ Read/Write: R/W │ Reset: 0x00000000 (0b00000000000000000000000000000000)

34.5.175 MIPIHSI_RX_FRAME_TIMEOUT_CNTR_0

HSI RX Frame Timeout Counter Register

Offset: 0x3b8 │ Read/Write: R/W │ Reset: 0x00000fff (0bxxxxxxxxxxxxxxxxxxxxx111111111111)

Bit	Reset	Description
11:0	0xfff	RX_FRAME_TIMEOUT: Receiver Frame Timeout Counter Number of HSI controller clock cycles after a frame starts that the last piece of data for that frame is received. If not, software is interrupted to deal with the apparently lost frame. The RX clock is nominally the same frequency as the TX clock, but may have a lower frequency. The default value of 0xFFF cycles is long enough considering the minimum data rate of rx. 0x00: Disabled 0x01: Frame started is considered incomplete after 1 controller clock cycle 0x02: Frame started is considered incomplete after 2 controller clock cycles. 0xFFF: Frame started is considered incomplete after 4095 controller clock cycles

34.5.176 MIPIHSI_MISC_2_CONTROL_0

HSI Misc 2 Control Register

Offset: 0x3bc │ Read/Write: R/W │ Reset: 0x0000012c (0bxxxxxxxxxxxxxxxxxxxxxxxx100101100)

Bit	Reset	Description
8:0	0x12c	COALESCE_TIMEOUT_CNTR: Coalesce timeout counter This is used to attempt to coalesce burst even when there is no back pressure from AHB. Counter has 300 as the default value (8*(32+4+1) = 296) to attempt burst of 8. 300 internal controller clock cycles after the first word of a channel is received to attempt to coalesce with following words. Software can disable this feature by setting this counter value as 0.

[THIS PAGE INTENTIONALLY LEFT BLANK]

35.0 I2C CONTROLLER

The I^2C controller (I2C) implements an I^2C 3.0 specification-compliant I^2C master and slave controller. The I^2C controller supports multiple masters and slaves. It supports Standard mode (up to 100 Kbits/s), Fast mode (up to 400 Kbits/s), Fast mode plus (Fm+, up to 1 Mbits/s), and High-speed mode (up to 3.4 Mbits/s).

Tegra® 4 devices have five instances of this controller. All five instances have identical I2C master functionality.

The I^2C controller supports DMA over the APB bus, using the APB DMA controller, in addition to single byte transfers. The I^2C controller also supports packet mode transfers where the data to be transferred is encapsulated in a predefined packet format as payload and sent to the I^2C controller over APB bus via DMA. The header of the packet specifies the type of operation to be performed, the size and other parameters (described in detail in subsequent sections).

Features

- Supports Standard (up to 100 Kbits/s), Fast (up to 400 Kbits/s), Fm+ (up to 1 Mbits/s), and High-speed (up to 3.4 Mbits/s) modes of operation.
- Independent Master Controller and Slave Controller with separate register-based host interface
- Master supports clock stretching by the slave
- Supports one to eight-byte burst data transfers
- Supports 4 Kbyte transfers in packet mode. Can be extended beyond 4 Kbytes by breaking up transfers into multiple packets (in both DMA and non-DMA modes)
- Both master and slave support transactions with 7-bit or 10-bit addressing
- Master is capable of data transfers to/from two or more slaves consecutively with a repeated-start condition
- Fully programmable 7-bit or 10-bit address for the slave
- Supports bus clear operations to address SDA issues
- Supports general call addressing
- Supports recognition and transfer of data to peripherals that do not send an acknowledge (ACK)
- Slave can also be configured not to acknowledge
- Master supports packet based DMA

Clocking

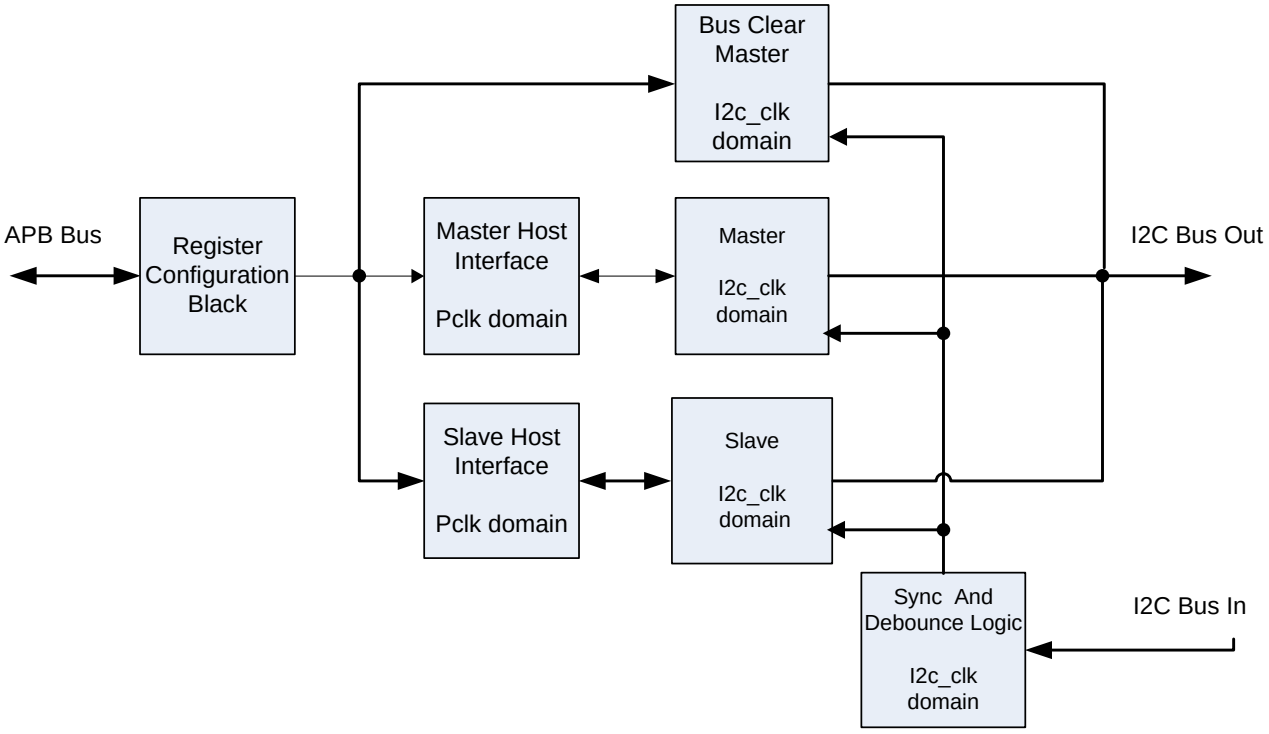
The I^2C controller has three clock domains:

- The Host interface runs on the APB clock (pclk). The APB clock is derived from the system clock and can be 1.0, ½, 1/3 or ¼ times the system clock (sclk).
- The I^2C interface controller runs on a fixed frequency clock running at 72 MHz. The 72 MHz clock is derived from PLLP. Even though you can mux between PLLP, PLLC, PLLM, and OSC clocks, PLLP is always selected and used in normal operation.
- The time-out logic runs on a 32 kHz clock.

35.1 Functionality

The I^2C controller can work as both a Master and a Slave. The Master can address the internal slave (for basic testing) or an external 7-bit or 10-bit addressed Slave device. The Master can be programmed for either a single slave transaction or a two-slave transaction. The two-slave transaction is generally useful in a random read from an external device. When reading from an external device, the random read-address needs to be set with an initial dummy-write to the device, followed by a repeated-start and a read transaction to the same device. The internal Slave address can be programmed to be either a 7-bit or a 10-bit address. Figure 140 below shows the I^2C controller in both the master and slave modes.

Figure 140: I²C Controller Block Diagram



35.1.1 Bus Clear Master Operation

Bus clear logic helps to resolve I2C bus hang issues. If the data line (SDA) is permanently stuck low because a slave device is pulling it low continuously for some unknown reason, the I2C master loses the arbitration and releases the I2C bus. In this case, software can use the Bus Clear master to get the SDA line released by sending clock pulses on the SCL line. Per the I2C specification, the device that held the bus Low should release it sometime within 9 clock pulses. But if the device needs more clock pulses than the default 9 pulses, software has an option to do so by programming a configurable register bit field (I2C_I2C_BUS_CLEAR_CONFIG_0[BC_SCLK_THRESHOLD]) to the required number of clock pulses.

Bus Clear Procedure

The Bus Clear operation starts with an ARB_LOST notification from the I^2C controller. The ARB_LOST notification could be due to other masters, if there are any master devices connected in the system and the I2C bus is already occupied by them. It could also be due to other configuration/setup issues such as pinmuxing, pin tri-state clear.

If it is determined that ARB_LOST notification is due to a slave device continuously pulling the SDA line low, the bus clear operation can be initiated to recover the bus with the following steps:

1. Reset the I^2C controller using module reset after the ARB_LOST notification from the controller.

2. Program the I2C_I2C_BUS_CLEAR_CONFIG_0[BC_SCLK_THRESHOLD] bit field to the required number of clock pulses.
3. Select the STOP or NO_STOP condition using the I2C_I2C_BUS_CLEAR_CONFIG_0[BC_STOP_COND] bit field.
4. Program I2C_I2C_BUS_CLEAR_CONFIG_0[BC_TERMINATE] as needed
5. Set the I2C_I2C_BUS_CLEAR_CONFIG_0[BC_ENABLE] bit field to start the bus clear operation. Hardware auto clears this bit after the bus clear operation is done.
6. Once enabled, the bus clear logic starts sending clock pulses on the SCL line.
7. Based on BC_TERMINATE settings, the Bus Clear logic:
   - Sends clock pulses until SDA is released or the threshold count is reached, whichever is earlier or
   - Sends the threshold number of clock pulses irrespective of SDA line release status (released before threshold is reached or not-released with threshold count reached)
8. If SDA is released within the programmed number of clock pulses:
   - The Bus Clear logic terminates the transaction with STOP/NO-STOP condition based on the BC_STOP_COND settings.
   - Then it sets the bus_clear operation status in the I2C_I2C_BUS_CLEAR_STATUS_0[BC_STATUS] register bit field.
   - Finally, it sets the BUS_CLEAR DONE bit field in I2C_INTERRUPT_STATUS_REGISTER_0 and also interrupts the system if the corresponding interrupt enable bit is set.

35.1.2 Low-Power Operation

I^2C is a low-speed serial interface with only two bus lines (SCL, SDA) required. So from the I^2C specification side, there is no low-power operation specifically defined for the interface. But to save the power, use the lowest possible speed, if performance is not needed. The following bus speeds are supported by I^2C:

- Standard mode (Sm), with a bit rate up to 100 kbit/s
- Fast mode (Fm), with a bit rate up to 400 kbit/s
- Fast mode Plus (Fm+), with a bit rate up to 1 Mbit/s
- High-speed mode (Hs mode), with a bit rate up to 3.4 Mbit/s

35.1.2.1 Low Power Programming

Program the CLK_SOURCE_I2C register (for example: I2C1instance clock source address 0x60006124) and the I2C_CLK_DIVISOR registers such that the required data rate can be achieved at the minimum possible module clock so that power can be saved.

Below are the data relations for various modes of operation. If the signal rise time is good in a system, use I2C_CLK_DIVISOR= 8 or above for Standard/Fast/Fm+ bus operations.

- Standard/Fast/Fm+:

  SCL = CLK_SOURCE.I2C / (N* (I2C_CLK_DIVISOR_STD_FAST_MODE+1)*I2C FREQUENCY DIVISOR)
- HS mode:

  SCL = CLK_SOURCE.I2C / (N * (I2C_CLK_DIVISOR_HSMODE+1)*I2C FREQUENCY DIVISOR)

The default N value is 8 for Standard/Fast/Fm+ modes and 12 for HS-mode. If there is a large rise time on the interface signals because of a weak pull-up or large capacitance, then N will increase. Also, N depends on I2C_CLK_DIVISOR_STD_FAST_MODE and I2C_CLK_DIVISOR_HSMODE values. It would be 9 and 13, respectively, for Standard and HS modes for I2C_CLK_DIVISOR_x values up to 2.

35.1.2.2 IDLE Power Programming

When the module is not used or the interface is idle, disable the module clock by clearing the CLK_ENB_I2C bits in the CAR module.

For example, the I2C1 clock enable bit is CLK_RST_CONTROLLER_CLK_OUT_ENB_L_0[CLK_ENB_I2C1]. Software can clear this bit when it is seen that no transfers are needed from the I2C1 instance.

35.1.3 CL-DVFS-I2C and I2C5 sharing PWR-I2C Bus

Because the I2C5 controller and CL-DVFS-I2C can try to access the PWR-I2C bus simultaneously in an application, there is the potential for a bus conflict. To avoid this, the CL-DVFS module grants the interface bus to either the CL-DVFS-I2C or I2C5 controller based on the requests in round-robin fashion. If software intends to disable the CL-DVFS clock for some reason (for example, power savings), the CL-DVFS must be put in the RESET state by programming its module reset to 1. The I2C5 controller always gets the bus grant this way.

For the I2C5 controller to work properly, one of the following must occur:

1. The CL-DVFS is in the RESET state.
2. The CL-DVFS is out of reset and its clocks are running

The I2C5 controller will not work if the CL-DVFS is out of reset and the clocks to the CL-DVFS module are disabled. The interface bus grant arbiter in the CL-DVFS cannot work because its clock is not toggling.

35.1.4 TSEC-I2C and I2C4 Sharing DDC-I2C Bus

There is no bus arbiter in this case. Only one I2C (TSEC-I2C or I2C4) controller can access the DDC interface at a time. The controllers should be operated in serial fashion to access the DDC-I2C interface.

35.2 Software Interfaces

A typical peripheral controller might require the following steps to communicate or control an external peripheral:

1. Set up the registers
2. Program the ‘GO’ bit to start the interaction with the external peripheral
3. The peripheral controller collects the response from the peripheral and interrupts software
4. Software reads the response

35.2.1 Packet Flow

The flow is a transport path that can be uniquely identified in the system. It is a virtual path or channel that carries a particular type of packets from a source to a destination. A flow carries logical information and is not dependent on the physical implementation.

Information exchange between the hardware peripheral controller and software as described above can be classified into:

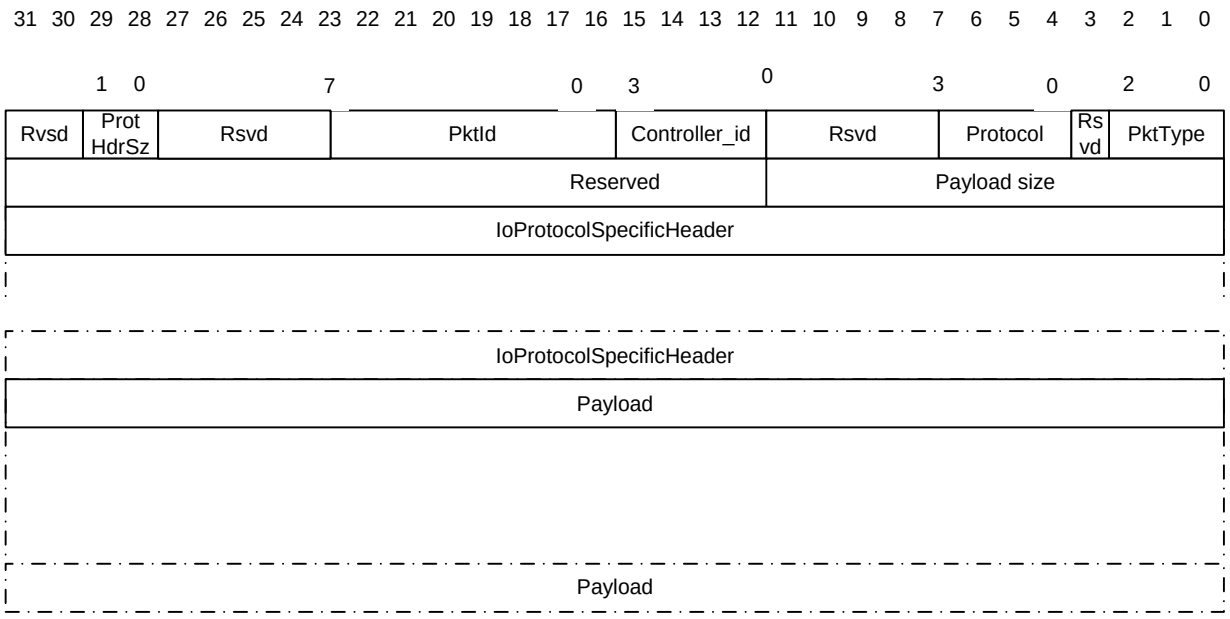
- ‘Request’ flow which can represent the register writes
- ‘Response’ flow for peripheral controller responses sent back to software, and
- ‘Interrupt’ flow for out-of-band handshakes between hardware and software

Packets within a flow can be exchanged in a manner that requires full intervention from the CPU (PIO mode) or least intervention from the CPU (DMA mode). The I/O packet described below is a structure that can be used to represent various flows in the system.

35.2.2 I/O Packet Format

An I/O packet consists of a header and payload. The header consists of two parts: two words of generic header and 1-4 words of protocol-specific header.

Figure 141: I/O Packet



35.2.2.1 I/O Packet Word 0

Word 0 of the I/O packet contains the Generic Header Word 0. The contents of generic header word 0 are described in the table below.

Table 107: Generic I/O Header Word 0

Bits	Field Value	Description
31:30	Reserved	Reserved
29:28	ProtHdrSz	Size of the protocol-specific header in words 0 = 1 words 1 = 2 words 2= 3 words 3 = 4 words For I2C, ProtHdrSz = 0 for request packets and 1 for response packets
27:24	Reserved	Reserved
23:16	PktId	PktId is an 8-bit field that identifies the packet. A peripheral controller might choose to log the packet ID for a packet that causes errors
15:12	Controller ID	There might be multiple controllers supporting any format. For example, there might be 4 I2C controllers. The Controller ID field specifies the controller for which this packet is destined.
11:8	Reserved	Reserved
7:4	Protocol	The protocol is indicated in this field 0 = reserved 1= I2C 2-15 = reserved
3	Reserved	Reserved

Bits	Field Value	Description
2:0	PktType	Packet type information 0 = request 1 = response 2 = interrupt 3 = stop 4-7 = reserved

35.2.2.2 I/O Packet Word 1

Word 1 of the I/O packet contains Generic Header Word 1. The contents of Generic Header Word 1 are described in the table below.

Table 108: Generic I/O Header Word 1

Bits	Field Value	Description
31:12	Reserved	Reserved
11:0	PayloadSize	Payload size in bytes

Note about Payload Size:

For request packets that transmit data, the total packet size is payload_size + 8 bytes of generic header + protocol-specific header. However, for request packets with a read command, the payload size indicates the amount of data to be received. Hence the packet size = 8 bytes of generic header + protocol-specific header, because there is no payload in this packet, just the receive command.

35.2.3 Transferring Packets

Packets can be transferred using PIO or DMA modes. A peripheral controller can choose to implement one or both modes. The header is a minimum of three words with the first two words reserved for packet information and the third word reserved for protocol-specific requirements. A minimum of four words is needed to transfer one byte to the external peripheral.

35.2.4 Protocol-Specific Header

Depending on the implementation of the peripheral controller and the interface protocol, the header words can be defined. No restriction is placed on the organization of the fields or the number of protocol-specific words (a minimum of one word and a maximum of four words) that a particular implementation chooses.

I2C has one word with the protocol-specific header. The contents of the I2C protocol-specific header are described in the next section.

35.2.5 I2C Master Packet Protocol Specific Headers

The I2C master supports two kinds of packets.

- Transmit packets that flow from Host to Controller.
- Receive data packets that flow from Controller to Host.

Table 109: I2C Master Transmit Packet Header

Bit	Name	Description
31:26	Reserved	Reserved
25	RESP_PKT_FREQ	Response packet frequency. This field is valid only if the I2C master is transmitting (READ/WRITE field below). If the I2C master is receiving, response packets are sent for every request packet received. 0: Send response packet at the end of last packet. 1: Send response packet for each packet transmitted.
24	RESP_PKT_ENABLE	Enable response packet. It qualifies RESP_PKT_FREQ field. 0: Do not send response packets (status has to be obtained via interrupt status bits). 1. Send response packet.
23	Reserved	Reserved
22	HS_MODE	Enable High speed mode (3.4 MHz operation)
21	CONTINUE_ON_NACK	Enable mode to handle devices that do not generate ACK upon the reception of a byte.
20	SEND_START_BYTE	1: Send a start byte at the beginning of the transaction
19	READ/WRITE	1: READ
18	Address mode	1: 10-bit mode 0: 7-bit mode
17	IE	Generate interrupt upon packet completion
16	REPEAT_START/STOP	1: Put a repeat start condition on the bus(to continue transaction) 0: Put a stop condition on the bus
15	ContinueXfer	This bit overrides the REPEAT_START/STOP command above. 0: Introduce repeat start or stop condition based on bit 16. 1: Continue with current transfer without stop or repeat start condition.
14:12	HS_MASTER_ADDR	High Speed mode Master code
11:10	Reserved	Reserved
9:0	SLAVE_ADDR	Slave address. Bit 0 is ignored for 7-bit addressing, but should always match bit 19 (READ/WRITE).

Response packets contain the status of the I^2C controller. To accommodate that, the response packet header contains two words of the protocol-specific header.

Table 110: I2C Master Response Packet Header Word 0

Bit	Name	Description
31:27	Reserved	Reserved
26	RFIFO_OVF	Receive FIFO overflowed.
25	TFIFO_OVF	Transmit FIFO overflowed.
24	TRANSFER_COMPLETE	All the packets have been transferred successfully. The packet for which the “LAST PACKET” field is set has been transferred.
23:16	TRANSFER_PKT_ID	The current packet ID for which the transaction is happening on the bus
15:4	TRANSFER_BYTENUM	The number of bytes transferred in the current packet

Bit	Name	Description
3	NOACK_FOR_ADDR	1 = No ACK received for the address byte
2	NOACK_FOR_DATA	1 = No ACK received for the current data byte
1	ARB_LOST	1 = Arbitration lost
0	CONTROLLER_BUSY	1 = Controller is busy

35.2.6 I2C Slave Protocol Specific Packet Headers

The I2C slave supports two packet types:

- Transmit packets flow from the Host to I^2C controller. These contain details of the transfer that need to be carried out, such as transfer direction (read/write) and mode of operation.
- Receive packets flow from the I^2C controller to Host. They contain the data (in case of the I2C receiving data) as well as the status that indicates the health of the I2C slave.

Note: For I2C slaves, the transmit packet can be of control type (generic header word 0, bits [2:0]). This can be used by the host to tell the I2C slave to acknowledge the last byte of the transfer.

Table 111: I2C Slave Transmit Packet Header

Bit	Name	Description
31:26	Reserved	Reserved
26	ACK_LAST_BYTE	This bit is set to indicate to the I2C slave that it can release the bus by acknowledging the last byte. 0: Withhold ACK for the last byte of transfer. 1: Acknowledge the last byte immediately.
25	RESP_PKT_FREQ	Response packet frequency. This field is valid only if the I2C Slave is transmitting. If the I2C slave is receiving, then it will send a response packet for each request packet received. 0: Send response packet at the end of last packet 1: Send response packet for each packet transmitted.
24	RESP_PKT_ENABLE	Enable response packet. 0: Do not send response packets (status has to be obtained via interrupt status bits). 1: Send response.
23	Reserved	Reserved
22	HS_MODE	Enable High speed mode (3.4 MHz operation)
21:20	Reserved	Reserved
19	READ/WRITE	1: READ
18	Address mode	1: 10-bit mode 0: 7-bit mode
17	IE	Generate interrupt upon packet completion
16:11	Reserved	Reserved.
10	SLAVE_ADDR_OVRIDE	Use the slave address field in the packet header (below) instead of the programmed value.
9:0	SLAVE_ADDR	Slave address

The I2C Slave Response Packet protocol-specific header contains two words.

Note: Slave response packet header word 0 contains what might seem redundant information; however, this information is useful if the external master operates in a mode different from what the host expects. For example, the external master while capable of High Speed mode can operate in Fast mode, which is helpful for the host to know.

The same is true for the slave address, because two slave addresses are supported.

Table 112: I2C Slave Receive Packet Header Word 0

Bit	Name	Description
31:23	Reserved	Reserved
22	HS_MODE	Enable High speed mode (3.4 MHz operation)
21:19	Reserved	Reserved
18	Address mode	1 = 10-bit mode 0 = 7-bit mode
17:10	Reserved	Reserved
9:0	SLAVE_ADDR	Slave address

Table 113: I2C Slave Receive Packet Header Word 1

Bit	Name	Description
31:30	Reserved	Reserved
29	ACK_WITHHELD	Indicates that the ACK is withheld for the last byte and the slave is waiting for the host to explicitly command the slave to acknowledge the last byte. 0: Bus is released. 1: ACK is withheld.
28:27	XFER_ERR_REASON	This bit describes the nature of packet transfer error. It is meaningful only if PKT_XFER_ERR is set. 0: Master terminated transaction before it was completed. 1: Master did not terminate transaction when all bytes were transferred. 2: Reserved 3: Reserved
26	PKT_XFER_ERR	0: Request was successful 1: Error has occurred during packet transfer.
25	TFIFO_OVF	Transmit FIFO overflowed
24	TFIFO_OVF	Transmit FIFO overflowed
23:16	TRANSFER_PKT_ID	The current packet ID for which the transaction is happening on the bus
15	Reserved	Reserved
14:8	HW_MS_ADDR	Hardware master address (received via hardware GCA)
7	Reserved	Reserved
6	HS_MST_IRQ	Slave received hardware master address via GCA
5	REPROG_SL	Slave received ReprogramSlaveAddress command via GCA (general call addressing)
4	RST_SL	Slave received ResetSlave command via GCA (general call addressing)
3:2	Reserved	Reserved
1	R/W	Slave Transaction Status 1: Read transaction happened. 0: Write to slave happened.
0	ZA	Zero Address Status: Reports if slave has responded to the general call address (zero address). Valid only during writes. 1: Yes, slave responded 0: No, slave did not respond

35.3 Programming Guidelines

35.3.1 I2C Frequency Divisor Register

The FREQUENCY DIVISOR register (CLK_SOURCE_I2C register, whose address is: 0x60006124 for I2C1) must be programmed as a function of the CLK_SOURCE selected for I2C as follows:

```
Standard/Fast-mode/Fm+:
SCL = CLK SOURCE.I2C / (N* (I2C CLK DIVISOR STD FAST MODE+1)*I2C FREQUENCY DIVISOR)
High Speed mode:
SCL = CLK SOURCE.I2C / (N * (I2C CLK DIVISOR HSMODE+1)*I2C FREQUENCY DIVISOR)
Note:  The default N value is 8 for Standard/Fast/Fm+ modes and 12 for High Speed mode.
If there is a large rise time on the interface signals because of a weak pull-up or large capacitance, N
will increase. Also, N depends on I2C CLK DIVISOR STD FAST MODE and I2C CLK DIVISOR HSMODE values. It
would be 9 and 13, respectively, for Standard and High Speed modes for I2C_CLK_DIVISOR_x values up to 2.
```

The I^2C bus specification defines the minimum low period for the I2C_CLK as 4.7µs in Standard mode and 1.3µs in Fast mode. Because of this, the maximum I2C_CLK frequency in the standard mode can be 100 KHz but in Fast mode, it is limited to 348 KHz, assuming I2C_CLK has rise and fall delays of 300 ns per the I^2C specification.

The clock enable (bit 12 of the CLK_OUT_ENB.L register) must also be given to the I^2C controller, before any of the registers are written.

35.3.2 I2C Slave ADDR Registers

There are two slave ADDR registers that are used to configure the address of the internal slave-- I2C_SL_ADDR1 and I2C_SL_ADDR2. Bit [0] of I2C_SL_ADDR2 determines the address size of the internal slave. When this bit is programmed to be zero, the 7-bit slave address is taken from I2C_SL_ADDR1 [6:0]. When this bit is programmed to be one, the two most significant bits of the 10-bit slave address are taken from I2C_SL_ADDR2[2:1], and the least significant bits are taken from I2C_SL_ADDR1[7:0].

35.3.3 I2C Command ADDR Registers

These registers, I2C_CMD_ADDR0 and I2C_CMD_ADDR1, contain the address of the slave with which a transaction is intended. The I^2C Master Controller can be programmed to transact with both 7-bit and 10-bit addressed slaves. Bit [0] of the I2C_CNFG register determines the size of the slave address to be transacted. If a 7-bit or a 10-bit slave address is chosen, the respective address is taken from I2C_CMD_ADDR0 [9:0], and the Read/Write command is taken from bits 6 and 7 of the I2C_CNFG Register. In a 2 Slave configuration, the slave 1 address (7-bit or 10-bit) is taken from I2C_CMD_ADDR0 [9:0] and Slave 2 address (7-bit or 10-bit) from I2C_CMD_ADDR1 [9:0].

35.3.4 I2C Data Registers

There are two data registers, I2C_CMD_DATA1and I2C_CMD_DATA2, each with 32-bit length, which are to be loaded with the data to be transmitted or received as an I^2C Master. When used as an I2C slave, the controller uses a separate byte-wide register to store the data to be transmitted (I2C_SL_SEND) or data received (I2C_SL_RCVD).

35.3.5 I2C Configuration Register

This register is to be configured with the following data:

- Number of bytes to be transmitted or received
- Select for 7-bit or 10-bit slave address
- Program to send a Start Byte
- Single or two slave operations
- Support of NOACK from an external peripheral

The I2C_CNGF [9] bit is used to issue a “Begin-Transaction” command to the I^{2}C Master Controller. This bit is reset by hardware, and other bits of the register are masked for writes, when this bit is programmed to be one. Hence, the firmware should first configure all the other registers and bits [8:0] of the I2C_CNFG register before the I2C_CNFG [9] bit is programmed to one.

35.3.6 I2C Controller Status Register

This register (I2C_STATUS) gives the status of the I^{2}C Master operation. It includes the busy status of the I^{2}C controller and the completion status of the command executed.

35.3.7 I2C Controller Slave Status Register

This register (I2C_SL_STATUS) contains the status bits as I^{2}C Slave.

The controller contains status bits as follows:

- Receive Interrupt
- New Transaction Received
- Direction of transfer
- Bit 4 contains the END_TRANS bit. This bit is set when an I^{2}C transfer is complete (as indicated by either a stop or repeat start condition).
- Bit 5 contains the RST_SL bit. The byte received following the receipt of the general call address is 0x06. Therefore the programmable part of the slave address needs to be reset and reprogrammed.
- Bit 6 contains the REPROG_SL bit. The byte received following the receipt of the general call address is 0x04. Therefore reprogram the programmable part of slave address.
- Bit 7 contains the HW_MSTR_INT bit. When set, this bit indicates that master address has been transmitted after the general call address.
- Bits [14:8] contain the hardware master address. The contents of this field are meaningful only when bit 7 (HW_MSTR_INT) is set.

The I^{2}C controller generates an interrupt at the completion of each data byte received. In response to this interrupt, firmware must read the I2C_SL_STATUS register to confirm the cause of the interrupt and the direction of data transfer. If the interrupt is due to a data byte received (R/W = 0), firmware must read the data register, I2C_SL_RCVD, in order to clear the SL.IRQ bit in the status register. The I^{2}C controller will delay the release of the ACK handshake on the I^{2}C bus until the SL.IRQ bit has been cleared by this firmware read operation.

Either I2C_SL_STATUS needs to be polled or the I2C interrupt must be enabled for transfers to occur in slave mode. The following steps outline slave operation in both read and write transactions:

If the controller is configured as a slave, and is receiving data,

- I2C_SL_STATUS.SL_IRQ bit being set indicates a data byte has been received.
- Read of I2C_SL_STATUS clears SL_IRQ and returns the transfer direction in the RNW field.
- The data byte is already present in the I2C_SL_RCVD register. This can be read which causes the bus to be released.
- SL_IRQ is set again upon reception of the next byte.

If the controller is configured as a slave, and is transmitting data,

- I2C_SL_STATUS.SL_IRQ bit being set indicates that an address has been received.
- Read of I2C_SL_STATUS clears SL_IRQ and returns the transfer direction in the RNW field.
- The data byte needs to be written to the I2C_SL_RCVD register. This write causes the bus to be released.
- SL_IRQ is set again upon transfer of the byte. Another byte can be written to continue the operation.

35.3.8 Interrupt Generation

The I^2C controller generates interrupts upon the completion of transmission or reception of the specified number of bytes. A Master interrupt is generated when the number of bytes in the transaction, as programmed in the LENGTH field of the I2C_CNFG register, is complete.

A Slave interrupt is generated at the transmission/reception of each byte of data by the internal slave. In addition, if the internal Slave is in transmitter mode (the Slave receives a Read command), an interrupt is generated for the address and read-command reception also, as shown in the next two figures below. Slave interrupts are to be cleared by the firmware as mentioned above.

Figure 142: Interrupt Generation: Master Transmits to Internal Slave

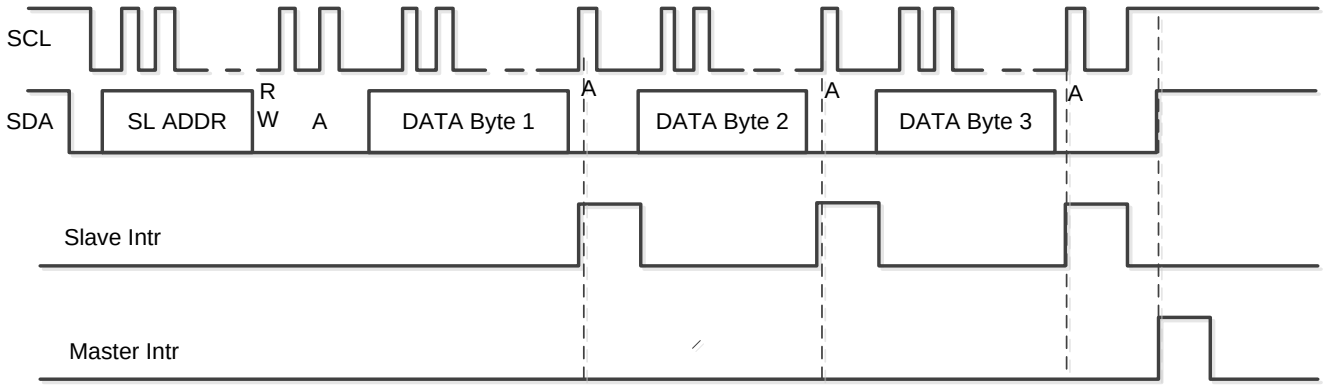


Figure 143: Interrupt Generation: Master Reads from Internal Slave

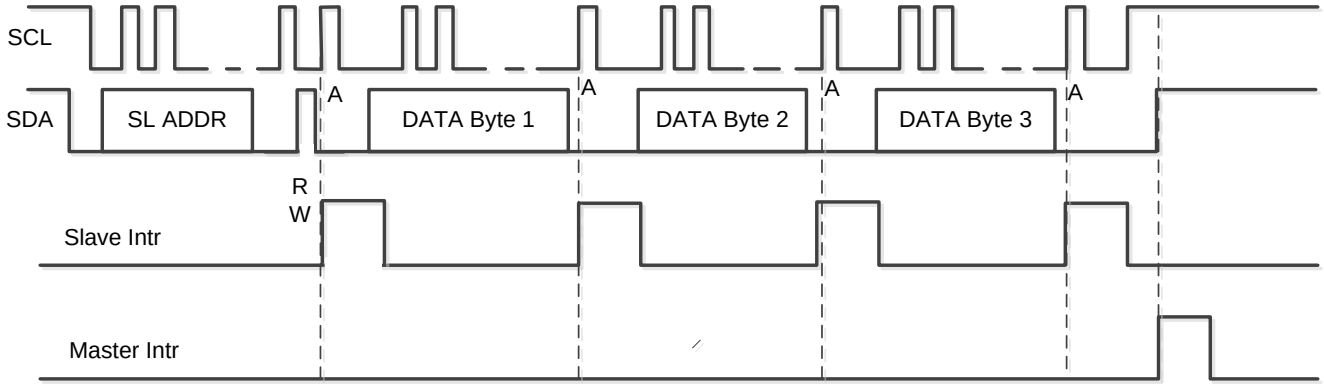

35.4 Programming Guidelines for Packet-Based Interface

35.4.1 Packet-Based Interface Registers

The following registers need to be programmed for a packet-based interface:

- I2C TX Packet FIFO
- I2C RX FIFO
- PACKET TRANSFER STATUS
- FIFO CONTROL
- FIFO STATUS
- Slave I2C TX FIFO
- Slave I2C RX FIFO
- Slave PACKET_TRANSFER_STATUS
- Slave FIFO CONTROL
- FIFO STATUS (common for both master and slave)
- INTERRUPT MASK REGISTER (common for both master and slave)
- INTERRUPT STATUS REGISTER (common for both master and slave)
- PACKET_MODE_EN, DEBOUNCE_CNT, and NEW_MASTER_FSM fields of I2C Controller Configuration Register

All other registers/fields have no meaning in packet mode and should be used only normal mode.

35.4.2 Programming Packet Header and Payload

Software should program the I2C_TX_PACKET_FIFO register. It writes the packet header followed by the payload. The header size can vary from 3 to 5 words. For I2C, the size is 3 words for request packets and 4 words for response packets. The first two words of the header contain a generic header. The third word of the packet (and fourth as well for response packets) contains I2C transaction-specific information. The payload contains the actual data to be written to the slave. In case of read operations, payload is nil, and hence, the packet contains only a header.

35.4.3 Reading from the RX FIFO

The data received on the bus is pushed into the RX FIFO. In PIO mode, a request interrupt is generated when the attention level is reached, and software reads the RX_FIFO register to get the data. In DMA mode, a DMA trigger is asserted after reaching the attention level.

35.4.4 Error Handling

The following steps describe what needs to happen when an error occurs due to a NACK, loss of arbitration, TX FIFO overflow, or RX FIFO overflow before proceeding with any further transactions:

- When an error occurred due to a NACK, a stop condition is put on the bus and interrupt is generated
- The status register is updated with the current error packet ID at which the error occurred
- Software should reset the controller
- In case of a DMA transfer, DMA needs to be restarted

In packet mode, special care should be taken to handle error recovery. If an error occurs during the transfer of a packet, then the controller should be reset, DMA needs to be restarted (if using DMA transfers), and the entire packet needs to be resent since there is no accurate way of knowing how many bytes made it to the I2C slave.

The repeat start bit in packet mode can complicate the situation further. When back-to-back packets are sent to a slave with the repeat start bit set, and an error occurs, it is not always known during which packet transfer the error occurred. Therefore, the entire stream of packets that were sent back to back using the repeat start bit need to be sent again.

Receives are simpler, since if an error occurs, and bytes for a packet have already been received, that packet can be deemed complete. Only incomplete transfers need to be retried.

35.4.5 Programming repeat_start/stop

This field indicates whether or not to put a stop condition after the current transaction. By default, this bit is zero and a stop condition is put on the bus. If this bit is set, a repeat start is put on the bus before proceeding with the next packet. The Repeat_start/stop bit can be used for combining read operations and write operations within a single transaction with a repeat start, or to do transfers beyond the 4 Kbyte limit. This bit is present in the protocol-specific header.

The I^2C controller supports transfer sizes beyond 4 Kbytes without a repeat start condition, again by combining multiple packets. This is in addition to ability to use repeat start condition to do continuous transfers over 4 Kbyte limit.

35.4.6 FIFO Control

In DMA mode, TX_FIFO_TRIG indicates the number of words that need to be empty in the TX FIFO for the DMA trigger to be asserted. RX_FIFO_TRIG indicates the number of words that need to be full in the RX FIFO for the DMA trigger to be asserted.

In PIO mode, TFIFO_DATA_REQ in the Interrupt Status Register will be set if the TX FIFO empty count is more than the value programmed in TX_FIFO_TRIG. Similarly RFIFO_DATA_REQ in the Interrupt Status Register will be set if the RX FIFO full count is more than the value programmed in RX_FIFO_TRIG. The CPU will be interrupted if the status bits are set and their corresponding INT_EN bit is set in the Interrupt Mask Register. The depth of the TX and RX FIFOs is 8.

35.4.7 FIFO Status

This register indicates the number entries that are empty in the TX FIFO (TX_FIFO_EMPTY_CNT) and the number of entries that are full in the RX FIFO(RX_FIFO_FULL_CNT).

35.4.8 Example Transfer

Here is a programming example for a 1 byte read followed by a 5-byte write

1. Program the PACKET_MODE_EN field to 1
2. Write the generic packet header
3. Write the payload size = 0x0 (1 byte)
4. Write the I2C specific header read/write = 1 and repeat_start/stop =1
5. Write the generic packet header
6. Write payload size = 0x4 (5 bytes)
7. Write the I2C specific header read/write = 0 and repeat_start/stop
8. Write the 12 bytes (word aligned)

35.4.9 Removal of Register Read Side Effects

The I^2C controller implements packet mode transfers for I2C slaves. In packet mode, the slave holds off sending an ACK on the very last byte of transfer until the host explicitly indicates to the I^2C controller to release the bus by acknowledging the last byte. The Host is responsible for providing this indication to the I2C slave in a timely fashion before the SMBUS time-outs happens.

After checking the packet contents, the Host needs to send a control packet with:

- ACK_LAST_BYTE in the protocol-specific header set to 1'b1
- PAYLOAD_SIZE in the generic packet header set to zero
- READ/WRITE in the protocol-specific header set to 1'b1 (READ).

The slave will release the bus as soon as it receives this control packet.

35.4.10 DMA Capability for I2C Slave

Packet mode capability of the slave combined with DMA transfer capabilities eliminates the need for byte-by-byte interactions between the driver and hardware.

35.4.11 Programming Guidelines for the Slave

The data is transmitted/received through the I2C_I2C_SL_RCVD_0 register.

To work in a mode where one byte can be transferred at a time, set the ENABLE_SL bit in the I2C_I2C_SL_CNFG_0 register.

Data can be transmitted and received through the I2C_I2C_SLV_TX_PACKET_FIFO_0 and I2C_I2C_SLV_RX_FIFO_0 registers, respectively when the FIFO_XFER_EN bit in the I2C_I2C_SL_CNFG_0 register is set.

In FIFO transfer mode, a slave by default works in one byte mode. That is, initially when a single byte is received, the ACK is withheld and an interrupt is generated. Software should indicate whether to acknowledge this byte or not by writing into ACK_LAST_BYTE field of the I2C_I2C_SL_CNFG_0 register. Note that the ACK_LAST_BYTE_VALID field also needs to be set to indicate to hardware that ACK_LAST_BYTE is being updated. When software receives an interrupt due to SLV_RX_BUFFER_FILLED, it can check ACK_WITHHELD of the I2C_I2C_SLV_PACKET_STATUS_0 register to see if the slave is withholding the ACK for the last byte.

Software can update the buffer size from default to any number by programming BUFFER_SIZE or by writing a packet where it updates the payload size.

The packet structure consists of header followed by data in case of a Read operation, whereas it consists of only header in case of a Write operation. Packets should be programmed into the I2C_I2C_SLV_TX_PACKET_FIFO_0 register .The data received will be stored in I2C_I2C_SLV_RX_FIFO_0 register. When software reads this register, it causes a pop.

The packet header consists of 3 words: a generic header, payload size, and a protocol-specific header.

A packet Write operation works as follows.

After enabling the packet, to work in packet mode for a Write operation (Master writing to slave):

- Set I2C_I2C_SL_CNFG_0.ENABLE_SL
- Set I2C_I2C_SL_CNFG_0.FIFO_XFER_EN
- Set I2C_I2C_SL_CNFG_0.PACKET_MODE_EN
- Wait for an SLV_RX_BUFFER_FILLED interrupt. By default, buffer_size is one. An interrupt will be generated after the first byte and the ACK is withheld.
- Clear the interrupt and indicate whether to acknowledge the last byte received by writing into the ACK_LAST_BYTE_VALID and ACK _LAST_BYTE bits of the I2C_I2C_SL_CNFG_0 register.
- Write the Generic Packet Header
- Write the Payload size
- Write the protocol-specific header.

The buffer_size will be updated with the payload size set in packet header. An interrupt will be generated again after receiving the number of bytes equal to buffer_size. The Slave will withhold the ACK for the last byte if the ACK_LAST_BYTE field in the protocol-specific header is not set or else it will acknowledge the last byte immediately.

Software should read the bytes received from SLV_RX_FIFO register. This will generate a trigger if the FIFO is above the threshold. See the FIFO_CONTROL register on how to program threshold levels. The last two steps are repeated every time there is a transfer equal to buffer_size.

To work in packet mode for Read operations (Master reading from slave):

- Set I2C_I2C_SL_CNFG_0.ENABLE_SL
- Set I2C_I2C_SL_CNFG_0.FIFO_XFER_EN
- Set I2C_I2C_SL_CNFG_0.PACKET_MODE_EN
- When a read transaction is received, an interrupt will be generated and TX_BUFFER_REQ will be set.
- Clear the interrupt and write the data to be transmitted into the I2C_I2C_SLV_TX_PACKET_FIFO_0.
- If a new transaction is received, an interrupt will again be generated and TX_BUFFER_REQ will be set.

The data can be sent or received without working in packet mode by only updating the following register field information. For example, a Write operation works as follows:

- Set I2C_I2C_SL_CNFG_0.ENABLE_SL
- Set I2C_I2C_SL_CNFG_0.FIFO_XFER_EN
- Set I2C_I2C_SL_CNFG_0.ACK_WITHHOLD_EN if hardware needs to withhold the ACK for the last byte.
- After receiving SLV_RX_BUFFER_FILLED interrupt, clear the interrupt and update the ACK_LAST_BYTE field. Also read the bytes from RX_FIFO.

35.5 I2C Registers

Refer to “Reading Register Tables” in the Introduction section for the register table protocol as well as recommendations for accessing registers.

35.5.1 I2C_I2C_CNFG_0

IC Controller Configuration Register (Master)

The I2C_CNFG register is used to configure:

- the number of bytes to be transmitted or received
- the slave device type (either a 7-bit device or a 10-bit device)
- enable mode to send Start-byte or not
- to select either a single slave transaction or two slave transaction
- enable mode to handle devices that do not generate an ACK.

Offset: 0x0 | Read/Write: R/W | Reset: 0x00000800 (0bxxxxxxxxxxxxxxxx0000100000000000)

Bit	Reset	Description
15	0x0	MSTR_CLR_BUS_ON_TIMEOUT: When this bit is set, the I2C master will force the clock low for an extended period of time (>TIMEOUT) to force all SMB slaves to release the bus. 0 = Don’t clear the bus on TLow: SEXT/TIMEOUT time-out 1 = Clear the bus on TLow: SEXT/TIMEOUT time-out

Bit	Reset	Description
14:12	0x0	DEBOUNCE_CNT: Debounce period for SDA and SCL lines. 0 = No debounce 1 = 2T 2 = 4T 3 = 6T, etc. where T is the period of the fix PLL clock source coming to I2C. Maximum debounce period is 14T. A debounce period of > 50 ns is desirable.
11	0x1	NEW_MASTER_FSM: Maintained for backward compatibility. 0 = DISABLE 1 = ENABLE
10	0x0	PACKET_MODE_EN: Write 1 to initiate transfer in packet mode. 0 = NOP 1 = GO
9	0x0	SEND: Writing a 1 causes the master to initiate the transaction in normal mode. Values of other bits are not affected when this bit is 1. Cleared by hardware. Other bits of the register are masked for writes when this bit is programmed to one. Thus, firmware should first configure all other registers and bits [8:0] of the I2C_CNFG register before the bit I2C_CNFG[9] is programmed to zero. 0 = NOP 1 = GO
8	0x0	NOACK: Enable mode to handle devices that do not generate an ACK. 1 = Do not look for an ACK at the end of the enable. 0 = DISABLE 1 = ENABLE
7	0x0	CMD2: Read/Write Command for Slave 2: 1 - Read Transaction; 0 - Write Transaction. For a 7-bit slave address, this bit must match with the LSB of address byte for slave 2. Valid only when bit 4 of this register is set. 0 = DISABLE 1 = ENABLE
6	0x0	CMD1: Read/Write Command for Slave 1: 1 - Read Transaction; 0 - Write Transaction. Command for Slave 1: For a 7-bit slave address, this bit must match with the LSB of address byte for slave 1. 0 = DISABLE 1 = ENABLE
5	0x0	START: 1 = Yes, a Start byte needs to be sent. 0 = DISABLE 1 = ENABLE
4	0x0	SLV2: 1 = Enables a two-slave transaction. 0 = No command for Slave 2 present. 0 = DISABLE 1 = ENABLE
3:1	0x0	LENGTH: The number of bytes to be transmitted per transaction. 000 = 1 byte ... 111 = 8 bytes. In a two slave transaction, the number of bytes should be programmed to be less than 011.
0	0x0	A_MOD: Address mode defines whether a 7-bit or a 10-bit slave address is programmed. 1 = 10-bit device address. 0 = 7-bit device address. 0 = SEVEN_BIT_DEVICE_ADDRESS 1 = TEN_BIT_DEVICE_ADDRESS

35.5.2 I2C_I2C_CMD_ADDR0_0

I2C Slave-1 Address

I2C_CMD_ADDR0 is programmed with the 7-bit or 10-bit address of slave 1 to which the transaction is intended.

Offset: 0x4 | Read/Write: R/W | Reset: 0x00000000 (0bxxxxxxxxxxxxxxxxxxxxxxxx0000000000)

Bit	Reset	Description
9:0	0x0	ADDR0: For 7-bit mode, the address is written in I2C_CMD_ADDR0[7:1], and I2C_CMD_ADDR0[0] indicates the read/write transaction. The I2C_CMD_ADDR0[0] bit must match the I2C_CNFG[6] bit. For 10-bit mode, the address is written in I2C_CMD_ADDR0[9:0], and I2C_CNFG[6] indicates the read/write transaction.

35.5.3 I2C_I2C_CMD_ADDR1_0

I2C Slave-2 Address

I2C_CMD_ADDR1 is programmed with the 7-bit or 10-bit address of slave 2 to which the transaction is intended.

Offset: 0x8 | Read/Write: R/W | Reset: 0x00000000 (0bxxxxxxxxxxxxxxxxxxxxxxxx0000000000)

Bit	Reset	Description
9:0	0x0	ADDR1: For 7-bit mode, the address is written in I2C_CMD_ADDR0[7:1], and I2C_CMD_ADDR0[0] indicates the read/write transaction. The I2C_CMD_ADDR0[0] bit must match the I2C_CNFG[7] bit. For 10-bit mode, the address is written in I2C_CMD_ADDR0[9:0], and I2C_CNFG[7] indicates the read/write transaction.

35.5.4 I2C_I2C_CMD_DATA1_0

I2C Controller Data 1: Transmit/Receive

The four least significant bytes of data to be transmitted are loaded into this register when the I2C Master is in Write mode.

The four least significant bytes of data are read through this register when the I2C Master is in Read mode.

Offset: 0xc | Read/Write: R/W | Reset: 0x00000000 (0b00000000000000000000000000000000)

Bit	Reset	Description
31:24	0x0	DATA4: Fourth data byte to be sent/received
23:16	0x0	DATA3: Third data byte to be sent/received
15:8	0x0	DATA2: Second data byte to be sent/received
7:0	0x0	DATA1: First data byte to be sent/received

35.5.5 I2C_I2C_CMD_DATA2_0

I2C Controller Data 2: Transmit/Receive

The four most significant bytes of data to be transmitted are loaded into the register when the I2C Master is in Write mode.

The four most significant bytes of data are read through this register when the I2C Master is in Read mode.

Offset: 0x10 | Read/Write: R/W | Reset: 0x00000000 (0b00000000000000000000000000000000)

Bit	Reset	Description
31:24	0x0	DATA8: Eighth data byte to be sent/received
23:16	0x0	DATA7: Seventh data byte to be sent/received
15:8	0x0	DATA6: Sixth data byte to be sent/received
7:0	0x0	DATA5: Fifth data byte to be sent/received

35.5.6 I2C_I2C_STATUS_0

I2C Controller Status (Master)

I2C_STATUS gives the status of the I2C Master operation.

Offset: 0x1c | Read/Write: RO | Reset: 0x00000XXX (0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx)

Bit	Reset	Description
8	X	BUSY: 0 = NOT_BUSY 1 = BUSY
7:4	X	CMD2_STAT: Slave 1 status: Transaction for Slave 1 for byte x failed. x is 'h0 to 'ha. All other combinations are invalid. 0 = SL1_XFER_SUCCESSFUL 1 = SL1_NOACK_FOR_BYTE1 2 = SL1_NOACK_FOR_BYTE2 3 = SL1_NOACK_FOR_BYTE3 4 = SL1_NOACK_FOR_BYTE4 5 = SL1_NOACK_FOR_BYTE5 6 = SL1_NOACK_FOR_BYTE6 7 = SL1_NOACK_FOR_BYTE7 8 = SL1_NOACK_FOR_BYTE8 9 = SL1_NOACK_FOR_BYTE9 10 = SL1_NOACK_FOR_BYTE10
3:0	X	CMD1_STAT: Slave 2 status: Transaction for Slave 2 for byte x failed. x is 'h0 to 'ha. All other combinations are invalid. 0 = SL2_XFER_SUCCESSFUL 1 = SL2_NOACK_FOR_BYTE1 2 = SL2_NOACK_FOR_BYTE2 3 = SL2_NOACK_FOR_BYTE3 4 = SL2_NOACK_FOR_BYTE4 5 = SL2_NOACK_FOR_BYTE5 6 = SL2_NOACK_FOR_BYTE6 7 = SL2_NOACK_FOR_BYTE7 8 = SL2_NOACK_FOR_BYTE8 9 = SL2_NOACK_FOR_BYTE9 10 = SL2_NOACK_FOR_BYTE10

35.5.7 I2C_I2C_SL_CNFG_0

I2C Controller Configuration (Slave)

I2C_SL_CNFG register is used to configure, enable mode of slave ACK.

Enable mode of the slave response to the general call address.

The register should be programmed when the I^2C controller is configured as a slave.

Offset: 0x20 | Read/Write: R/W | Reset: 0x00000004 (0bxxxxxxxxxxxx00000000000000000100)

Bit	Reset	Description
20	0x0	FIFO_XFER_EN: If this bit is disabled, data is always communicated via the I2C_SL_RCVD register. If enabled, data is communicated through FIFOs 0 = DISABLE 1 = ENABLE
19:8	0x0	BUFFER_SIZE: Payload size in bytes
7	0x0	ACK_LAST_BYTE_VALID: Acknowledge the last byte valid (write-only). This bit qualifies the ACK_LAST_BYTE field. 0 = DISABLE 1 = ENABLE
6	0x0	ACK_LAST_BYTE: Acknowledge the last byte. 0 = DISABLE 1 = ENABLE
5	0x0	ACK_WITHHOLD_EN: ACK Withhold Feature Enable 0 = DISABLE 1 = ENABLE
4	0x0	PKT_MODE_EN: Packet Mode Enable 0 = DISABLE 1 = ENABLE
3	0x0	ENABLE_SL: By writing zero to this field, the slave can be turned off 0 = DISABLE 1 = ENABLE
2	0x1	NEWSL: New Slave. 1 - Use new slave. 0 = DISABLE 1 = ENABLE
1	0x0	NACK: Disable Slave ACK. 1 – The slave will not acknowledge reception of address or data byte. 0 = DISABLE 1 = ENABLE
0	0x0	RESP: Slave response to the general call address (zero address). 0 = DISABLE 1 = ENABLE

35.5.8 I2C_I2C_SL_RCVD_0

I2C Controller Slave Receive/Transmit Data (Slave)

Offset: 0x24 | Read/Write: R/W | Reset: 0x00000000 (0bxxxxxxxxxxxxxxxxxxxxxxxx00000000)

Bit	Reset	Description
7:0	0x0	SL_DATA: Slave Received data

35.5.9 I2C_I2C_SL_STATUS_0

I2C Controller Slave Status (Slave)

Offset: 0x28 | Read/Write: R/W | Reset: 0x0000XX0X (0bxxxxxxxxxxxxxxxxxxxxxxxxx000000x0)

Bit	R/W	Reset	Description
14:8	RO	X	HW_MSTR_ADR: Hardware master address received via general call addressing. This field is meaningful only if HW_MSTR_INT is set.
7	RW	0x0	HW_MSTR_INT: 1 = Interrupt has been generated by slave. Hardware Master Address is received after General Call Address. Received Hardware Master Address. 0 = No event.
6	RW	0x0	REPROG_SL: 1 = Interrupt has been generated by the slave after the General Call Address is 0x04. Reprogram slave address. 0 = No action.
5	RW	0x0	RST_SL: 1 = Interrupt has been generated by slave after the General Call Address is 0x06. Reset and reprogram slave address. 0 = No action.
4	RW	0x0	END_TRANS: 1 = Interrupt has been generated by slave. Transaction completed as indicated by stop/repeat start condition. 0 = No transaction occurred or transaction in progress.
3	RW	0x0	SL_IRQ: 1 = Interrupt has been generated by slave. 0 = No interrupt generated. 0 = UNSET 1 = SET
2	RW	0x0	RCVD: New Transaction Received status. 1 = Transaction occurred. 0 = No transaction occurred. 0 = NO_TRANSACTION_OCCURED 1 = TRANSACTION_OCCURED
1	RO	X	RNW: Slave Transaction status. 0 = WRITE 1 = READ
0	RW	0x0	ZA: Zero Address Status 1 = Yes, slave responded. 0 = No, slave did not respond. 0 = NO_SLAVE_RESPONSE 1 = SLAVE_RESPONSE

35.5.10 I2C_I2C_SL_ADDR1_0

I2C Controller Slave Address 1 Register (Slave)

Offset: 0x2c | Read/Write: R/W | Reset: 0x00000000 (0bxxxxxxxxxxxxxxxx0000000000000000)

Bit	Reset	Description
15:8	0x0	SL_ADDR1: For a 10-bit slave address, this field is the least significant 8 bits.
7:0	0x0	SL_ADDR0: For a 10-bit slave address, this field is the least significant 8 bits.

35.5.11 I2C_I2C_SL_ADDR2_0

I2C Controller Slave Address 2 Register (Slave)

Offset: 0x30 | Read/Write: R/W | Reset: 0x00000000 (0bxxxxxxxxxxxxxxxx0xxxxx000xxxxx000)

Bit	Reset	Description
16	0x0	SELECT_SLAVE: 0 = Use slave addr0. 1 = Use slave addr1.
10:9	0x0	SL1_ADDR_HI: In 7-bit address mode, these bits are don't care. In 10-bit address mode, they represent the 2 MSBs of the address.
8	0x0	SL1_VLD: 0 = 7-bit addressing. 0 = SEVEN_BIT_ADDR_MODE 1 = TEN_BIT_ADDR_MODE
2:1	0x0	SL_ADDR_HI: In 7-bit address mode, these bits are don't care. In 10-bit address mode, they represent the 2 MSBs of the address.
0	0x0	VLD: 0 = 7-bit addressing. 1 - 10 bit addressing. 0 = SEVEN_BIT_ADDR_MODE 1 = TEN_BIT_ADDR_MODE

35.5.12 I2C_I2C_TLOW_SEXT_0

I2C Controller SMBUS Timeout Thresholds

Offset: 0x34 | Read/Write: R/W | Reset: 0x00000000 (0bxxxx00000000000000000000000000)

Bit	Reset	Description
27	0x0	RST_SL_ON_TIMEOUT: Reset Slave state machine on time-out
26	0x0	TLOW_MEXT_EN: Enable TLOW_MEXT counter
25	0x0	TLOW_SEXT_EN: Enable TLOW_SEXT counter
24	0x0	TIMEOUT_EN: Enable TIMEOUT counter
23:16	0x0	TLOW_MEXT: Cumulative clock low extend time (master device) accumulated over a byte transfer period in milliseconds (START to ACK, ACK to ACK, or ACK to STOP).
15:8	0x0	TLOW_SEXT: Cumulative clock low extend time (slave device) accumulated over a complete transfer (START till STOP)
7:0	0x0	TIMEOUT: Clock low time-out period in milliseconds

35.5.13 I2C_I2C_SL_DELAY_COUNT_0

I2C Slave Controller Delay Count

Offset: 0x3c | Read/Write: R/W | Reset: 0x0000001e (0bxxxxxxxxxxxxxxxx0000000000011110)

Bit	Reset	Description
15:0	0x1e	SL_DELAY_COUNT: The value determines the timing between an address cycle and a subsequent data cycle or two consecutive data cycles on the bus. The I2C_SL_DELAY_COUNT is valid only when an internal slave is accessed. I2C_SL_DELAY_COUNT has to be programmed such that TIMING = T * DLY, where T is the period of the clock source selected for I2C, DLY is I2C_SL_DELAY_COUNT, and TIMING is the desired timing. A value of >= 1250 ns is recommended.

35.5.14 I2C_I2C_SL_INT_MASK_0

I2C Controller Slave Mask (Slave)

Offset: 0x40 | Read/Write: R/W | Reset: 0x000000fd (0bxxxxxxxxxxxxxxxxxxxxxxxxx111111x1)

Bit	Reset	Description
7	0x1	HW_MSTR_INT: 0 = DISABLE 1 = ENABLE
6	0x1	REPROG_SL: 0 = DISABLE 1 = ENABLE
5	0x1	RST_SL: 0 = DISABLE 1 = ENABLE
4	0x1	END_TRANS: 0 = DISABLE 1 = ENABLE
3	0x1	SL_IRQ: 0 = DISABLE 1 = ENABLE
2	0x1	RCVD: 0 = DISABLE 1 = ENABLE
0	0x1	ZA: 0 = DISABLE 1 = ENABLE

35.5.15 I2C_I2C_SL_INT_SOURCE_0

I2C Controller Slave Source (Slave)

Offset: 0x44 | Read/Write: RO | Reset: 0x000000XX (0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx)

Bit	Reset	Description
7	X	HW_MSTR_INT: 0 = UNSET 1 = SET
6	X	REPROG_SL: 0 = UNSET 1 = SET
5	X	RST_SL: 0 = UNSET 1 = SET
4	X	END_TRANS: 0 = UNSET 1 = SET

2	X	RCVD: 0 = UNSET 1 = SET

Bit	Reset	Description
0	X	ZA: 0 = UNSET 1 = SET

35.5.16 I2C_I2C_SL_INT_SET_0

I2C Controller Slave Source (Slave)

Offset: 0x48 | Read/Write: R/W | Reset: 0x00000000 (0bxxxxxxxxxxxxxxxxxxxxxxxxx000000x0)

Bit	Reset	Description
7	0x0	HW_MSTR_INT: 0 = UNSET 1 = SET
6	0x0	REPROG_SL: 0 = UNSET 1 = SET
5	0x0	RST_SL: 0 = UNSET 1 = SET
4	0x0	END_TRANS: 0 = UNSET 1 = SET
3	0x0	SL_IRQ: 0 = UNSET 1 = SET
2	0x0	RCVD: 0 = UNSET 1 = SET
0	0x0	ZA: 0 = UNSET 1 = SET

Note: Program the field PACKET_MODE_EN of I2C_CNFG register while working in packet mode.

The set of registers given below describe the interface for packet mode only. With packet mode interface changes, normal mode registers and the operation are not affected. The transition from normal mode to packet mode is suggested because packet mode allows:

- There is no restriction on the number of bytes before and the after the repeated start
- The number of bytes that can be transferred with a single command is not limited to 8.

Though a packet can contain 4 Kbytes, because any number of packets can be pushed into the FIFO, there is no limit on the number of bytes that can be transferred.

- The transactions to different slaves can be chained together with repeat start and there is no limit on the number of slaves it can address.

35.5.17 I2C_I2C_TX_PACKET_FIFO_0

A packet contains header and payload. The header size is variable and could vary from 2 to 5 words. For I2C, the header size is 3 words. The first two words of the header contain generic information. The third word contains I2C transaction-specific information. The payload contains actual data to be written to the slave. For read operations, the payload is nil. Thus, the packet contains a header only.

Offset: 0x50 | Read/Write: R/W | Reset: 0x00000000 (0b00000000000000000000000000000000)

Bit	Reset	Description
31:0	0x0	TX_PACKET: Software writes packets into this register. A packet may contain generic information

35.5.18 I2C_I2C_RX_FIFO_0

Header or I2C Specific Header or Data

Offset: 0x54 | Read/Write: RO | Reset: 0xXXXXXXXX (0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx)

Bit	Reset	Description
31:0	X	RD_DATA: Software reads data from this register, causes a pop

35.5.19 I2C_PACKET_TRANSFER_STATUS_0

Offset: 0x58 | Read/Write: RO | Reset: 0x0XXXXXXX (0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx)

Bit	Reset	Description
24	X	TRANSFER_COMPLETE: The packet transfer for which the last packet is set has been completed 0 = UNSET 1 = SET
23:16	X	TRANSFER_PKT_ID: The current packet ID for which the transaction is happening on the bus
15:4	X	TRANSFER_BYTENUM: The number of bytes transferred in the current packet
3	X	NOACK_FOR_ADDR: No ACK received for the address byte 0 = UNSET 1 = SET
2	X	NOACK_FOR_DATA: No ACK received for the data byte 0 = UNSET 1 = SET
1	X	ARB_LOST: Arbitration lost for the current byte 0 = UNSET 1 = SET

35.5.23 I2C_INTERRUPT_STATUS_REGISTER_0

This register indicates the status bit for which the interrupt is set. If the interrupt is set, write a 1 to clear it. However, the TFIFO_DATA_REQ and RFIFO_DATA_REQ fields depend on the FIFO trigger levels and cannot be cleared.

Slv_rd2wr indicates there is a switch from read to write by repeat start and the current read transaction needs to be closed and started with a write transaction. Similarly, slv_wr2rd indicates a switch from write to read.

Offset: 0x68 | Read/Write: R/W | Reset: 0x000X000X (0bxxx000000000xxxxxxxx0000000000xx)

36.0 UART AND VFIR CONTROLLER

There are four Universal Asynchronous Receiver/Transmitters (UARTs) built into the Tegra® 4 devices. These UARTs support both 16450 and 16550 compatible modes. VFIR functionality is also supported.

36.1 Functional Description

36.1.1 UARTs A through D

All UARTs provide serial data synchronization and data conversion (parallel-to-serial and serial-to-parallel) for both receiver and transmitter sections. Synchronization for serial data stream is accomplished by adding start and stop bits to the transmit data to form a data character. Data integrity is accomplished by attaching a parity bit to the data character. The parity bit can be checked by the receiver for any transmission bit errors.

The COM-HOST interface is fully programmable through an 8-bit CPU interface. The registers are 32-bit word aligned. The interface supports word lengths from five to eight bits, an optional parity bit, and one or two stop bits. If enabled, parity can be odd, even, or forced to a defined state. Interrupts can be generated from any of 10 sources.

The UARTs support both 16450 and 16550 compatible modes. The default mode is 16450. This mode provides independent 16-byte FIFOs for transmit and receive operations and is selected by the FIFO control register. It also includes a 16-bit programmable baud rate generator and an 8-bit scratch register, 8 modem control lines, and 2 DMA handshake lines that are used to indicate when the FIFOs are ready to transfer data to the CPU.

The UARTs support a device clock of up to 72 MHz. The maximum baud rate is 16 clock cycles per symbol or 4.5 Megabits per second.

UART B is identical to UART A with the exception that only two signals are connected to its pins. UART A, C, and D are identical.

36.1.2 VFIR Controller

The VFIR controller in the Tegra 4 device implements the control and data sections of the IrDA Physical layer version 1.4, handling handshaking and basic networking between devices, and interfaces to an external Infrared transceiver.

This controller implements three distinct speed ranges and protocols: 2400 to 115,200 bits per second (Serial IR or SIR), 4 Megabits per second (called Fast Infrared or FIR), and 16 Megabits per second (called Very Fast Infrared or VFIR). Initial communication starts at 9600 bits per second, and negotiations proceed either faster or slower as the link strength allows. Each of the three speed ranges has different communication protocols and encoding schemes.

The following table lists the IrDA supported protocols.

Table 114: Protocols Supported by the IrDA

Signaling Rate (bps)	IrDA Name	Frame Wrapper and Encoding	IrDA Status	Tegra 4 Device Support?
9.6 K	SIR	Async RZI (3/16)	Mandatory	Yes
2400 - 115.2K	SIR	Async RZI (3/16)	Recommended	Yes
576.0 K	MIR	Sync HDLC RZI (4/16)	Optional	No
1.152 M	MIR	Sync HDLC RZI (4/16)	Optional	No
4.0 M	FIR	Sync 4PPM	Optional	Yes

Signaling Rate (bps)	IrDA Name	Frame Wrapper and Encoding	IrDA Status	Tegra 4 Device Support?
16.0 M	VFIR	Sync HHH(1,13)	Optional	Yes

The VFIR controller can operate in three different encodings; each is implemented separately. In SIR mode, a pulse encoder/decoder is inserted in the transmit/receive path of a standard UART. FIR and VFIR modes have their own control blocks. The outputs of the three blocks are multiplexed based on the current operating mode (SIR, FIR, or VFIR), before they leave the Tegra 4 device processor. The input signals are demultiplexed in a similar fashion.

Note: The operating mode is selected with the Mode [2:0] bits of the VFIR.CTL register

Figure 144: UART Block Diagram with SIR Decoder and Encoder

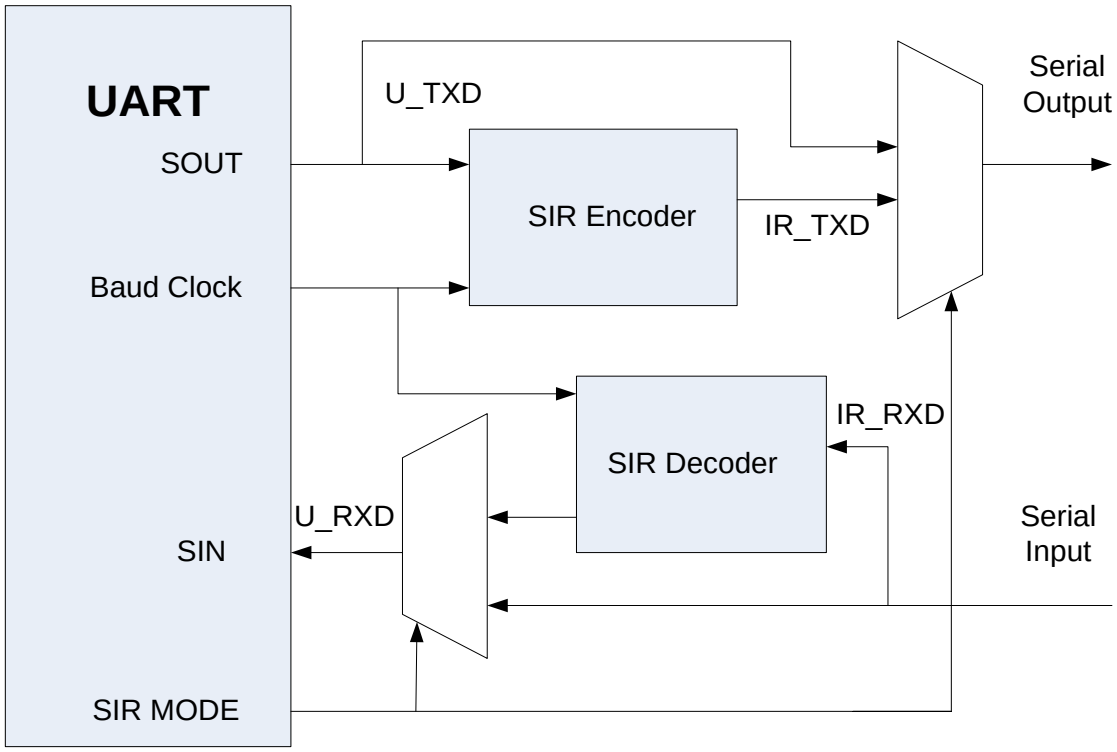

Figure 145: VFIR Controller Top-Level Block Diagram

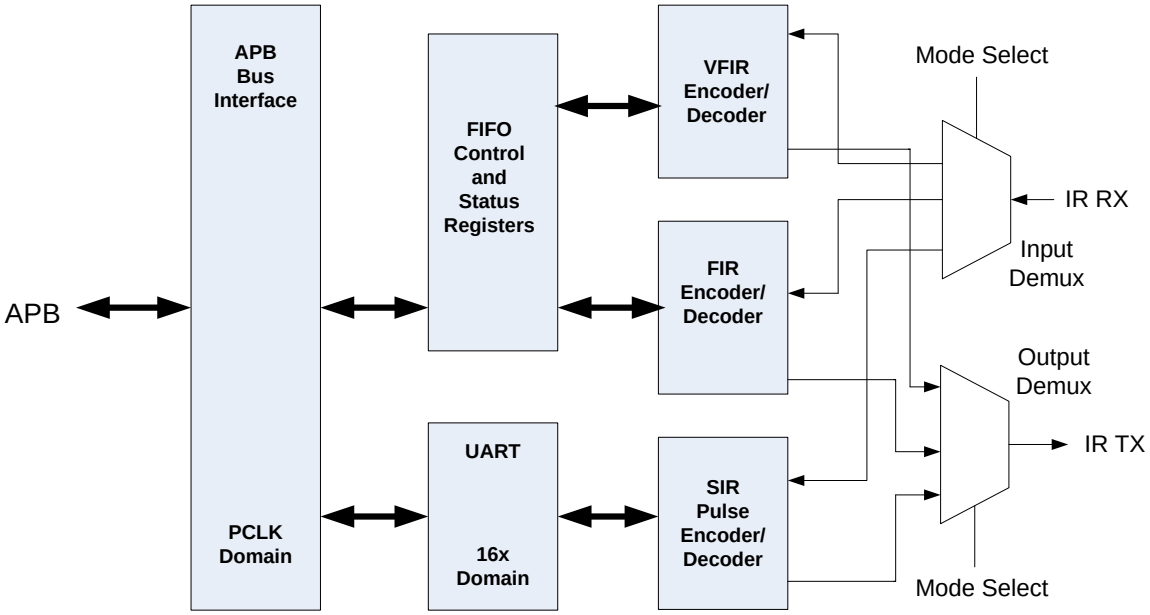


36.1.3 Hardware Features

The features supported by UART A, UART B, UART C, and UART D are:

- Synchronization for the serial data stream with start and stop bits to transmit data to and from a data character
- Data integrity by attaching a parity bit to the data character
- The COM-HOST interface is fully programmable through an 8-bit CPU interface
- Support for word lengths from 5 to 8 bits, an optional parity bit, and 1 or 2 stop bits
- The UART supports both 16450- and 16550-compatible modes. The default mode is 16450.
- DMA capable for both TX and RX
- 8 bit x 16 deep FIFO
- Auto sense baud detection
- Timeout interrupts to indicate if the incoming stream stopped
- Flow control support on RTS and CTS

The features supported by the VFIR controller are:

- Supports IrDA ver1.0 SIR protocol with maximum baud rate to 115.2 Kilobits per second
- Supports IrDA ver1.3 FIR protocol (4 Megabits per second)
- Supports IrDA ver1.4 VFIR protocol (16 Megabits per second)
- Programmable polarities on all the interface pins
- DMA capable for both TX and RX
- 32 bit x 16 deep FIFO
- Diagnostics for loopback and error insertion
- Interface control, such as transceiver signal strength, must be performed through GPIOs
- The maximum frequency of the device clock is 72 MHz

36.1.4 Hardware Signaling

All UARTs in the Tegra 4 device are implemented by a hardware block that supports modem control signals such as DTR, DSR, and DCD. UART A is, however, the only UART that allows those signals to be used externally.

For UART A, when the pin-mux is configured for 4- or 2-pin UART operation, the DSR and DCD input signals are tied low (active).

For UART B, the DTR output is routed back into the DSR and DCD inputs in hardware. This means that if software changes DTR state, the UART may raise an interrupt due to DSR/DCD changing state.

For UARTs C and D, the DSR and DCD inputs are tied to an inactive value.

Table 115: Serial Bus Interface Signals

Signal Name	Description
Outputs	
TXD	Transmit Data Port
RTS	Request to Send
DTR	Data Terminal Ready
Inputs	
RXD	Receiver Data Port
CTS	Clear to Send
DSR	Data Set Ready
DCD	Data Carrier Detect
RI	Ring Indicator

Note: The DSR, DCD and RI MODEM control signals do not control any hardware other than generating interrupts and status on change.

36.2 UART Programming Guidelines

36.2.1 16450 Mode Programming

1. Program pin mux settings to select a UART
2. Enable the UART clocks
3. For enabling internal loopback, program MCR[4] to 1
4. Program FCR[0] to 0
5. Enable interrupts in the IER register as needed
6. Write data into the THR register
7. Wait for a THR interrupt, if enabled, or poll for LSR[5]
8. During a receive, wait for an RBR interrupt or poll for LSR[0]
9. Read the UART.LSR register to clear interrupts

36.2.2 16550 Mode Programming

1. Program pin mux settings to select a UART
2. Enable the UART clocks
3. For enabling internal loopback, program MCR[4] to 1
4. Program FCR[0] to 1
5. Program trigger levels as required
6. Enable interrupts in the IER register as needed
7. Write data into the THR register
8. Wait for a THR interrupt, if enabled, or poll for LSR[5]
9. During a receive, wait for an RBR interrupt or poll for LSR[0]
10. Read the UART.LSR register to clear interrupts
11. The APB-DMA requestor numbers for UARTs A, B, and C are 8, 9, and 10, respectively

36.2.3 Transmitter and Receiver Holding Registers

The serial transmitter section consists of a Transmit Hold Register (THR) and Transmit Shift Register (TSR). The status of transmit hold register is provided in the Line Status Register (LSR). Writing to this register (THR) transfers the contents of data bus (D [7:0]) to the Transmit Holding Register whenever the Transmitter Holding Register or Transmitter Shift Register is empty. The Transmit Holding Register empty flag is set to 1 when the transmitter is empty or data is transferred to the transmit shift register. Note that a write operation is performed when the Transmit Holding Register empty flag is set.

The serial receiver section also contains an 8-bit Receiver Holding/Buffer Register (RBR). Receive data is removed from the UART and received by the processor by reading the RBR. The receiver contains a mechanism for preventing false starts as follows: On the falling edge of the start bit, the receiver internal counter starts to count 7.5 clocks (16x clock), which is the center of the start bit. The start bit is valid if the RX is still low at the mid-bit sample of the start bit. Verifying the start bit prevents the receiver from assembling a false data character due to a low going noise spike on the RX input. Receiver status codes are posted in the Line Status Register.

36.2.4 FIFO Interrupt Mode Operation

When the receive FIFO (FCR bit 0 = 1) and receive interrupts (IER bit 0 = 1) are enabled, a receiver interrupt occurs as follows:

- The receive data available interrupts are issued to the CPU when the FIFO has reached its programmed trigger level; it is cleared as soon as the FIFO drops below its programmed trigger level.
- The ISR receive data available indication also occurs when the FIFO trigger level is reached, and like the interrupt, it is cleared when the FIFO drops below the trigger level.
- The data ready bit (LSR bit 0) is set as soon as a character is transferred from the shift register to the receiver FIFO. It is reset when the FIFO is empty.

36.2.5 FIFO Polled Mode Operation

When FCR bit 0 = 1; clearing IER bits [3:0] to zero puts the UART in the FIFO polled mode of operation. Since the receiver and transmitter are controlled separately, either one or both can be in the polled mode operation by using the line status register as follows:

- LSR bit 0 is set as long as there is one byte in the receive FIFO
- LST bits [4:1] specifies which error(s) have occurred
- LSR bit 5 indicates when the transmit FIFO is empty
- LSR bit 6 indicates when both transmit FIFO and transmit shift registers are empty
- LSR bit 7 indicates when there are any errors in the receive FIFO

The UART requires a two-step FIFO enable operation in order to enable receive trigger levels.

36.2.6 Programmable Baud Rate Generator

The UART contains a programmable baud rate generator that can take the UART clock input and divide it by any divisor from 1 to 2^{16}-1. Refer to the Clocking and Reset Controller section for definitions of the UART clocks. The output frequency of baudout is equal to 16X the transmission baud rate (Baudout=16 X baud rate). Customized baud rates are achieved by selecting proper divisor values for the MSB and LSB bits of the baud rate generator.

36.2.7 Enable Register (IER)

There is an Interrupt Enable Register for each UART (UART A Interrupt Enable and UART B Interrupt Enable). The Interrupt Enable Register(s) masks the incoming interrupts from the receiver ready, transmitter empty, line status, and modem status registers to the INT output pin.

36.2.8 Interrupt Identification Register (IIR)

The UART provides four level prioritized interrupt conditions to minimize software overhead during data character transfers. The Interrupt Identification Register (IIR) provides the source of the interrupt in a prioritized manner.

During the read cycle, the 16550 provides the highest interrupt level to be serviced by the CPU. No other interrupts are acknowledged until the particular interrupt is serviced. The prioritized interrupt levels are shown in the following table. The Receive Data Time-out mode is enabled when the UART is operating in the FIFO mode.

Receive time-out does not occur if receive FIFO is empty. The time-out counter is reset at the center of each stop bit received or each time the Receive Holding Register is read. The actual time out value is:

- T (Time out length in bits) = 4 X P (Programmed work length) + 12

To convert the time-out value to a character value, divide this number to its complete word length + parity (if used) + number of stop bits and start bit.

Example

If you program the word length = 7 with no parity and one stop bit, the time-out is:

- T = 4X7 (programmed word length) + 12 = 40 bits.
- Character time = 40/9
- [(Programmed word length = 7) + (stop bit = 1) + (start bit = 1)] =4.4 characters

Table 116 Prioritized Interrupt Levels

Priority	D3	D2	D1	D0	Interrupt Source Description
1	0	1	1	0	LSR (Receiver Line Status Register)
2	0	1	0	0	RXRDY (Received Data Ready)
2	1	1	0	0	RXRDY (Received Data Timeout)
3	0	0	1	0	TXRDY (Transmitter Holding Register)
4	0	0	0	0	MSR (Modem Status Register)

36.2.9 FIFO Control Register (FCR) Modes

The FIFO control register is used to enable the FIFOs, clear the FIFOs, set the receiver FIFO trigger level, and select the type of DMA signaling. The operation of the FCR in the four DMA modes is given below.

36.2.9.1 Transmit Operation in DMA Mode 0 or Mode 1

When the UART is in the 16450 mode (FCR bit 0 = 0) or in the FIFO mode (FCR bit 0 = 1, FCR bit 3 = 0) and when there are no characters in the transmit FIFO or transmit holding register, the TXRDY* pin goes low. Once active, the TXRDY* pin goes high (inactive) after the first character is loaded into the Transmit Holding Register.

36.2.9.2 Receive Operation in DMA Mode 0

When the UART is in 16450 mode (FCR bit 0 = 0) or in the FIFO mode (FCR bit 0 = 1,FCR bit 3 = 0) and there is at least 1 character in the receive FIFO, the RXRDY* pin goes low. Once active, the RXRDY* pin goes high (inactive) when there are no more characters in the receiver.

36.2.9.3 Receive Operation in DMA Mode 1

When the UART is in the FIFO mode (FCR bit 0 = 1, FCR bit 3 = 1) and the trigger level or the timeout has been reached, the RXRDY* pin goes low. Once it is activated, it goes high (inactive) when there are no more characters in the FIFO.

36.2.10 Line Control Register (LCR)

The Line Control Register is used to specify the asynchronous data communication format. The word length, stop bits, and parity can be selected by writing appropriate bits in this register.

36.2.11 Modem Control Register (MCR)

This register controls the interface with the modem or a peripheral device (RS232).

Loopback Mode

If MCR[4] = 1, the loopback mode is enabled, and the following occurs:

The transmitter output (TX) is set high (Mark condition), and the receiver input (RX), CTS, DSR, CD, and RI are disabled. Internally, the transmitter output is connected to the receiver input and DTR, RTS, OP1, and OP2 are connected to modem control inputs.

In this mode, the receiver and transmitter interrupts are fully operational, but the interrupt sources are now the lower four bits of the modem control register instead of the four modem control inputs. The interrupts are controlled by the IER register.

Table 117: Modem Control Register (MCR)

Bit	Name	Description
7	N/A	Not used. Set to 0 internally.
6	RTS_EN	1 = Enable Hardware Flow Control using RTS 0 = Disable Hardware Flow Control
5	CTS_EN	1 = Enable Hardware Flow Control using CTS 0 = Disable Hardware Flow Control
4	LOOP	0 = Normal operating mode. 1 = Enable local loop-back mode (diagnostic).
3	OUT2	nOUT2 polarity
2	OUT1	nOUT1 polarity
1	RTS	1 = Force RTS (Request to Send) low 0 = Force RTS to high
0	DTR	1 = Force DTR (Data Terminal Ready) to low 1 = Force to high

36.2.12 Line Status Register (LSR)

The Line Status Register provides the status of data transfer to the CPU.

36.2.13 Modem Status Register (MSR)

The modem status register provides the current state of the control lines from the modem or peripheral to the CPU. Four bits of this register are used to indicate the changed information. These bits are set to 1 whenever a control input from the modem changes state. They are set to 0 whenever the CPU reads the register. The following table shows the bit format for the MSR register.

36.2.14 Scratchpad Register (SR)

Eight bits of information can be stored in this register. Information in this register does not affect the operation of the device in any way.

36.2.15 Autobaud Sense Register (ASR)

The UART can automatically determine the correct baud divisor by using the Autobaud Sense Register (UART offsets 0x3C). The most significant bit of this register is the valid flag. A write to this register will clear the valid flag and enable the autobaud process. When the first RX edge occurs, a counter running at 24 MHz starts counting. When another rx_edge occurs, the "complete" flag is set, the value is frozen, and the Autobaud Sense Value register is updated with the count value. The low 20 bits of the ASR give the number of clocks within a single bit. Because the UART uses 16x oversampling, the resulting value needs to be adjusted by shifting right 4 bits, then loading the resulting count in the divisor latch of the UART. (In the code snippet below, the lower 4 bits are rounded to give slightly greater accuracy.)

Because the speed determination is made by measuring the start bit, special characters must be sent by the transmitting UART to guarantee that the next character after the start bit is a 1. Since bit 0 (rightmost bit) is sent first, the ASCII Carriage Return character (CR) is sufficient to enable proper speed sense.

The following code snippet returns the values for DLH and DLL in r9, r8:

```
       MOV     r0, #1  ; dummy write data
       STRB    r0, [r3, #U_ASR]; Start autobaud sense (r3 as uart_base)
; now poll the autobaud sense register MSB until Valid is true
wait4valid
       LDR     r2, [r3, #U_ASR]; Read ASR
       TST     r2, #0x80000000 ; the Valid bit (active high)
       BEQ     wait4valid
; autobaud sense check complete...
; r2 as number of 1x clocks in one bit time
; representing the number of 24MHz clocks in the start bit
; Since this represents 16 of the baud (16x) clocks, we
; will be dividing by 16 to get baud divisor, but first
; round to nearest by adding 8 before the divide:
       ADD     r4, r2, #8 ; add 1/2 resolution
       MOV     r6, r4, LSR #4 ; divide by 16... R6 will have total divisor
       AND     r8, r6, #0xFF  ; copy DLL to r8
       MOV     r9, r6, LSR #8 ; copy DLM to r9
       AND     r9, r9, #0xff ; mask upper bytes
```

36.2.16 Baud Rate Generator

The following table given below is a divisor table for the baud rate, assuming the oscillator is 24.000 MHz.

Table 118: Baud Rate Generator Programming

Baud Rate	Divisor
300	5000
1200	1250
2400	625
4800	312
9600	156
19.2K	78
38.4K	39
57.6K	26
115.2K	13

36.2.17 Power-up Defaults

The following defines the Power-Up defaults:

- IER = 0
- ISR = 1
- LCR = 0
- MCR = 0
- LSR = 60 HEX
- MSR = Bits 0-3 = 0, Bits 4-7 = inputs
- FCR = 0
- TX = High

- OP1 = High
- OP2 = High
- RTS = High
- DTR = High
- RXRDY = High
- TXRDY = Low
- INT = Low

36.3 VFIR Programming Guidelines

36.3.1 IRDA (FIR/VFIR) and UART B

The IRDA module includes a fully functional 16550 compatible UART for implementing the SIR protocol. The UART pins will be selected automatically when the VFIR.CTL Mode bits are set to UART or SIR mode. Set the UART IRDA.CSR register to SIR mode to convert the UART signals to SIR signals.

If the IRDA.CTL Mode bits are set the FIR or VFIR modes, the UART pins will be disabled, and the FIR/VFIR pins will be used.

36.3.2 APB Bus Interface to Control/Status/FIFO

The Control and Status registers, and the FIFO reside on the APB bus. The processor programs the Control registers to begin transactions, and can read progress and error status from the Status Register. FIFO access is normally performed via the APB_DMA module.

36.3.3 FIR Mode Programming

1. Set the CLK_SOURCE_VFIR for 48 MHz and enable the UART_B Clock
2. Program IR.TX and IR.RX pin-mux settings to select IR (UART B)
3. Set the VFIR.CTL Mode to binary 100 (FIR)
4. FIR mode is half-duplex. Set the VFIR.CTL Transmit bit to '1' for transmits, '0' for receives
5. Read the VFIR.STS register to clear inputs
6. Program the APB_DMA to transfer data to/from the VFIR module
7. Enable the DMA bit in the VFIR.CTL register
8. Enable interrupts as needed
9. Set the GO bit in the VFIR.CTL register to start the action
10. Wait for DONE status or an interrupt which indicates that the transaction has completed
11. Check for errors when reading the VFIR Status and Interrupt Identification register
12. Clear the status bits by writing a '1' to them before starting the next packet.
13. For receive operations, the Incoming Frame Data Length (IFDL) register will contain the number of bytes received. DMA should have read this many bytes from the FIFO.

36.3.4 VFIR Mode Programming

1. Set the CLK_SOURCE_VFIR for 48MHz and enable the UART_B Clock
2. Program IR.TX and IR.RX pin mux settings to select IR (UART B)
3. Set the VFIR.CTL Mode to binary 101 (VFIR)
4. VFIR mode is half-duplex. Set the VFIR Control register Transmit bit to '1' for transmits, and '0' for receives

5. Read the VFIR.STS register to clear inputs
6. Program the APB_DMA to transfer data to/from the VFIR module
7. Enable the DMA bit in the VFIR.CTL register
8. Enable interrupts as needed
9. Set the GO bit in the VFIR.CTL register to start the action
10. Wait for DONE status or an interrupt which indicates that the transaction has completed
11. Check for errors when reading the VFIR Status and Interrupt Identification register
12. Clear the status bits by writing a '1' to them before starting the next packet.
13. For receive operations, the Incoming Frame Data Length (IFDL) register will contain the number of bytes received. DMA should have read this many bytes from the FIFO.

36.3.5 COM-SLAVE Interface (UART B)

The COM-SLAVE interface consists of a UART, which provides serial data synchronization and parallel-to-serial and serial-to-parallel data conversion for both receiver and transmitter sections. Synchronization for the serial data stream is accomplished by adding start and stop bits to the transmit data to form a data character. Data integrity is accomplished by attaching a parity bit to the data character. The parity bit can be checked by the receiver for any transmission bit errors.

The COM-SLAVE interface is fully programmable by an 8-bit CPU interface. The registers are 32-bit Word aligned. The interface supports word lengths from 5 to 8 bits, an optional parity bit, and 1 or 2 stop bits. If enabled, the parity can be odd, even, or forced to a defined state. Interrupts can be generated from any of 10 sources.

The UART supports both 16450 and 16550 compatible modes. The default mode is the 16450. The 16550 mode, which provides independent 16-byte FIFOs for transmits and receives, is selected via the FIFO control register. It also includes a 16-bit programmable baud rate generator and an 8-bit Scratch register, 8 modem control lines, and two DMA handshake lines that are used to indicate when the FIFOs are ready to transfer data to the CPU.

Table 119: Serial Bus Interface Signals for UART B

Signal Name	Direction	Description
UB3_RXD	I	Receiver Data Port
UB3_TXD	O	Transmit Data Port

36.3.6 SIR Pulse Encoder/Decoder

The UART transmit (TX) data is passed through this module prior to being muxed out to the IR transmitter. This module converts transmitted zeros into a 3/16 Return-To-Zero (RZ) pulse.

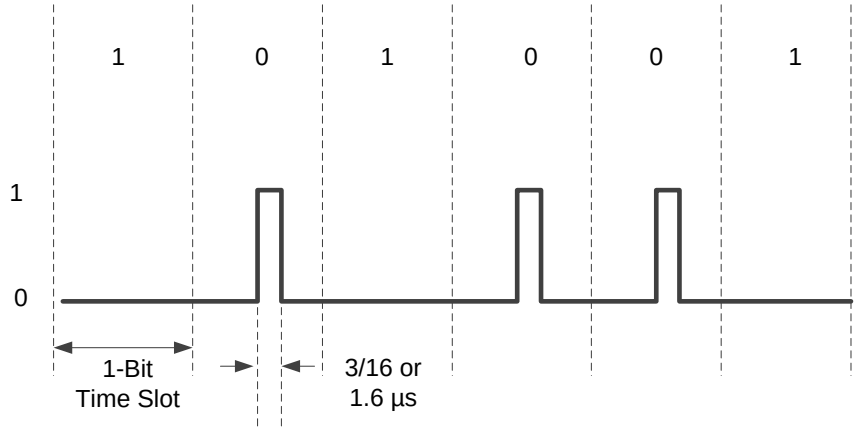
Similarly, received (RX) data is bit-synchronized using the 16X baud clock and the original serial data recovered from the IR bit stream. This data is then sent to the UART for reception.

The signal generated in SIR is as follows:

- On logic '1', the LED is off.
- On logic '0', a pulse is created starting the center of the bit time and lasting 3/16 of a bit time period or 1.6µs (3/16 bit times at 115.2 kbps) depending on the current settings.

The figure below displays the output for the input 101001 (in sending order) in SIR encoding.

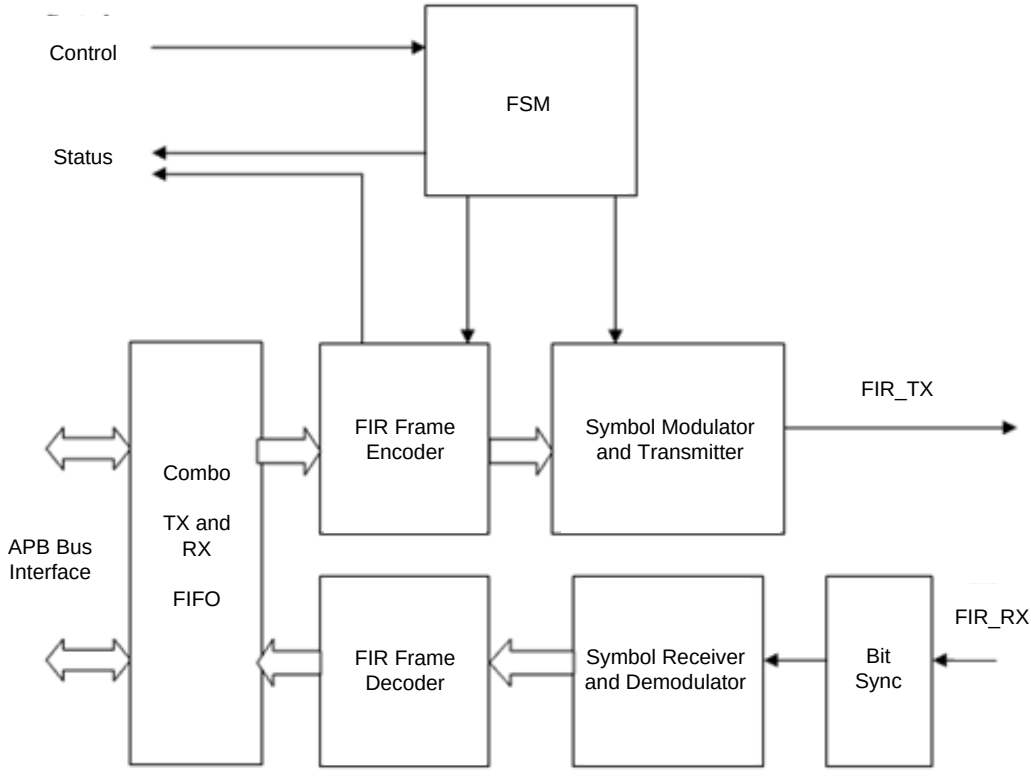
Figure 146: Output in Sending Order in SIR Encoding



36.3.7 FIR Encoder/Decoder

The figure below shows the micro-architecture for FIR and VFIR modes. Although the architecture is the same, the FIR and VFIR encoding schemes are very different.

Figure 147: Architecture for FIR and VFIR Modes



The Frame Level Encoder calculates CRC for the sent data, performs bit stuffing, creates start and stop sequences, and sends data down the line to the Data Shift Register. The Frame Level Decoder calculates the CRC on incoming data, performs bit de-stuffing, compares the calculated CRC to the received one, and reports any errors detected in the process.

The 1-symbol modulator creates the signal to be sent to the IR transceiver bit by bit as received from the UART in SIR mode, 2-bit signals in FIR mode, and 3-bit signals in VFIR mode.

FIR mode uses a Pulse Position Modulation code called 4PPM. The encoding sends one symbol every four time slices called "chips". Because there are four unique chip positions within each symbol in 4PPM, four independent symbols exist in which only one chip is logically a "one" while all other chips are logically a "zero." These four unique symbols are defined to be the only legal data symbols (DD) allowed in 4PPM. Each DD represents two bits of payload data, so that a byte of payload data can be represented by four DDs in sequence. The table below defines the chip pattern representation of the four unique DDs defined for 4PPM.

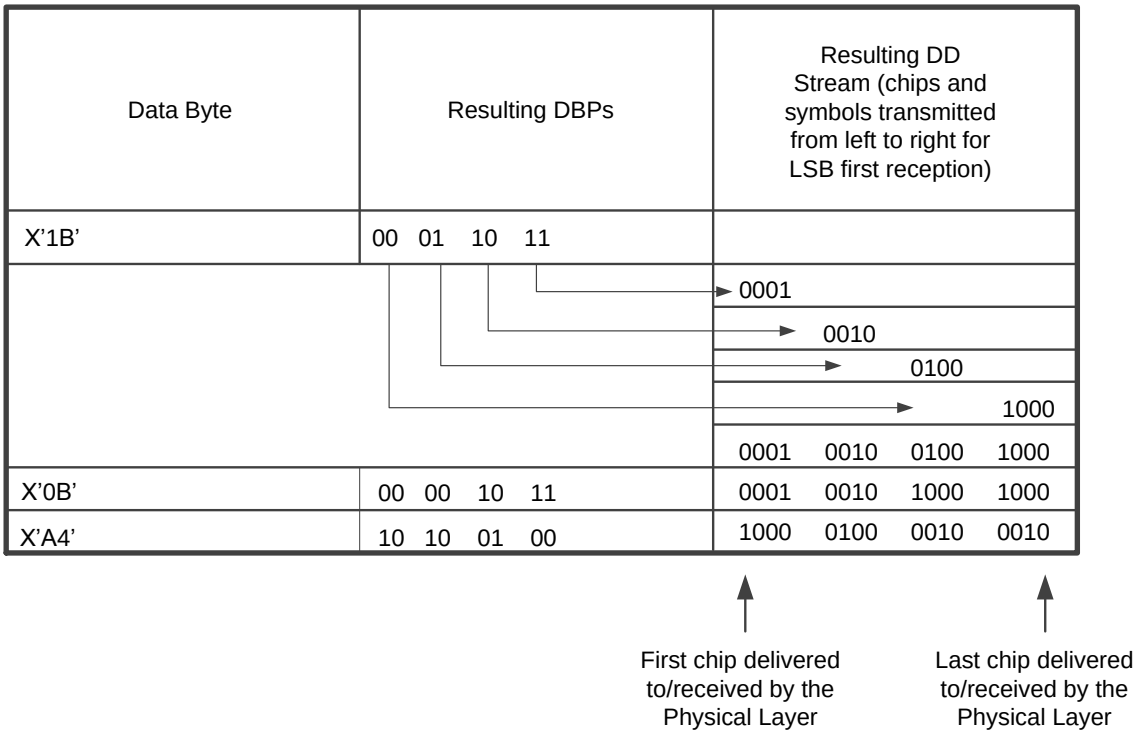
Table 120: Chip Pattern

Data Bit Pair	4PPM Data Symbol
00	1000
01	0100
10	0010
11	0001

A logical "1" represents a chip duration when the transmitting LED is emitting light, while a logical "0" represents a chip duration when the LED is off. Data encoding for transmission is done LSB first.

The figure below shows how various data bytes would be represented after encoding for transmission. In these examples transmission time increases from left to right so that chips and symbols farthest to the left are transmitted first.

Figure 148: Various Data Bytes After Encoding for Transmission



36.3.8 PPM Packet Format

For FIR 4PPM packets the data rate is 4 Megabits per second, and the signaling rate is 8.0 Mchips per second, where a chip is the smallest element of IrDA signaling. The packet format is defined below.

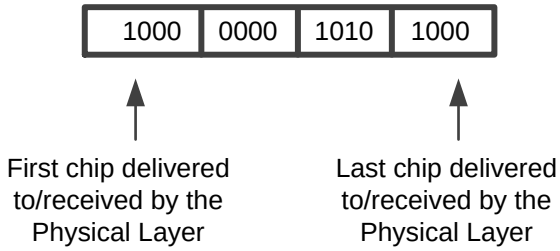
In this packet format, the payload data is encoded as described in the 4PPM encoding above, and the encoded symbols reside in the DD field. Maximum packet length is negotiated by the same mechanism as for the slower rates. The preamble field (PA) is used by the receiver to establish phase lock. During PA, the receiver begins to search for the start flag (STA) to establish symbol synchronization. If STA is received correctly, the receiver can begin to interpret the data symbols in the DD field. The receiver continues to receive and interpret data until the stop flag (STO) is recognized. STO indicates the end of a frame. The chip patterns and symbols for PA, STA, FCS field, and STO are defined below. Only complete packets that contain the entire format defined above are guaranteed to be decoded at the receiver (as for the lower rates, the information field, I, may be of zero length).

The 4PPM data encoding described above defines only the legal encoded payload data symbols. All other chip combinations are by definition illegal symbols for encoded payload data. Some of these illegal symbols are used in the definition of the preamble, start flag, and stop flag fields because they are unambiguously not data.

36.3.8.1 Preamble Field Definition

The preamble field (PA) consists of exactly 16 repeated transmissions of the following stream of symbols. In the PA field, transmission time increases from left to right so that chips and symbols on the left are transmitted first. See figure below.

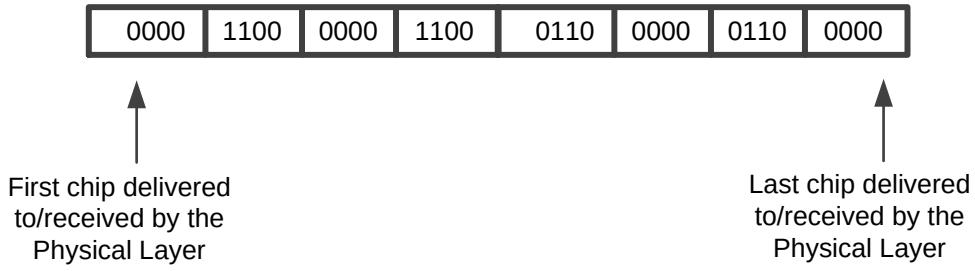
Figure 149: Preamble Field



36.3.8.2 Start Flag Definition

The start flag (STA) consists of exactly one transmission of the following stream of symbols. In the STA field, transmission time increases from left to right so that chips and symbols on the left are transmitted first. See figure below.

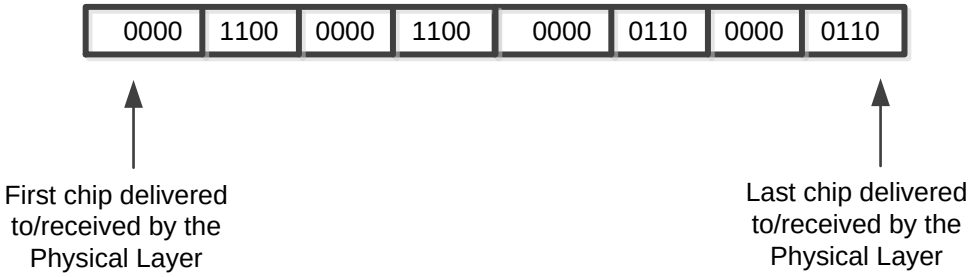
Figure 150: Start Flag



36.3.8.3 Stop Flag Definition

The stop flag (STO) consists of exactly one transmission of the following stream of symbols. In the STO field, transmission time increases from left to right so that chips and symbols on the left are transmitted first. See figure below.

Figure 151: Stop Flag



36.3.8.4 Frame Check Sequence Field Definition

The frame check sequence (FCS) field is a 32-bit field that contains a cyclic redundancy check (CRC) value. The CRC is a calculated, payload data dependent field, calculated before 4PPM encoding. It consists of the 4PPM encoded data resulting from the IEEE 802 CRC32 algorithm for cyclic redundancy check as applied to the payload data contained in the packet. The CRC32 polynomial is defined as follows:

$$CRC(x) = x^{32} + x^{26} + x^{23} + x^{22} + x^{16} + x^{12} + x^{11} + x^{10} + x^{8} + x^{7} + x^{5} + x^{4} + x^{2} + x + 1$$

The CRC32 calculated result for each packet is treated as four data bytes, and each byte is encoded in the same fashion as is payload data. Payload data bytes are input to this calculation in LSB first format. The 32-bit CRC register is preset to all "1's" prior to calculation of the CRC on the transmit data stream. When data has ended and the CRC is being shifted for transmission at the end of the packet, a "0" should be shifted in so that the CRC register becomes a virtual shift register.

Note:	The inverse of the CRC register is what is shifted as defined in the polynomial.

36.3.8.5 Aborted Packets

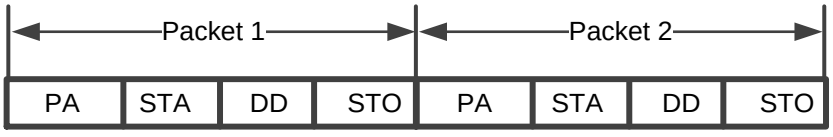
Receivers may only accept packets that have valid STA, DD, FCS, and STO fields as defined in the PPM Packet Format section. The PA field need not be valid in the received packet. All other packets are aborted and ignored.

Any packet may be aborted at any time after a valid STA but before transmission of a complete STO flag by two or more repeated transmissions of the illegal symbol "0000." Also, any packet may be aborted at any time after a valid STA by reception of any illegal symbol which is not part of a valid STO field.

36.3.8.6 Back to Back Packet Transmission

Back to back, or "brick-walled" packets are allowed, but each packet must be complete (i.e., containing PA, STA, DD, and STO fields). Brick-walled packets are illustrated in the figure below.

Figure 152: Back-to-Back (Brick-Walled) Packet Transmission



36.3.9 VFIR 16.0 Megabits per Second Rate

The 16.0 Megabits per second data transmission incorporates a new modulation code HHH (1,13) - low duty cycle, rate 2/3, (d,k) = (1, 13) run-length limited (RLL) code to achieve the specified data rate from a 24MHz reference clock. The HHH(1,13) code guarantees for at least one empty chip and at most 13 empty chips between chips containing pulses in the transmitted IR signal. The data transmission packet/frame is based on the 4.0 Megabits per second frame format with modifications introduced where necessary to accommodate the requirements that are specific to the new modulation code. The system includes a simple scrambling/descrambling scheme to randomize the duty cycle statistics. The signaling rate of the 16.0 Megabits per second data rate is 24.0 Mchips per second, where a chip is the smallest element of IrDA signaling.

36.3.10 HHH (1, 13) Modulation Code

The HHH (1, 13) modulation code has the following salient features:

- Code Rate: 2/3 ,
- Maximal Duty Cycle: 1/3 (~33%) ,
- Average Duty Cycle: ~26% ,
- Minimal Duty Cycle: 1/12 (~8.3%) ,
- Run-Length Constraints: (d, k) = (1, 13) ,
- Longest Run of '10's: yyy'000'101'010'101'000'yyy ,
- Chip Rate @ Data Rate 16 Megabits per second: 24 Mchips per second ,
- System Clock @ Data Rate 16 Megabits per second: N X 12 MHz (where N ≥ 4)

The HHH(1,13) code is a Run Length Limited (RLL) code that provides both power efficiency and bandwidth efficiency at the high data rate. The signaling rate of the code is 24 Mchips per second allowing a rise and fall time of 19 ns. LED on time is further improved by having a 26% average duty cycle for random data. The lower duty cycle is achieved by scrambling the incoming data stream. The run length constraints (d, k) = (1, 13) ensure an inactive chip after each active chip, i.e. only single-chip-width pulses occur. This feature allows a source or a receiver to exhibit a long tail property. To take full advantage of the d = 1 feature of HHH(1, 13) in strong signal conditions, clock and data recovery circuitry ignores the level of the chip following an active chip and assumes these chips are inactive. The modulation code is enhanced with simple frame-synchronized scrambler/descrambler mechanisms as defined and described in later in this chapter.

36.3.10.1 HHH Data Encoding Definition

The encoding definition of the HHH (1, 13) code is provided by a state transition table described as follows:

Specific data pair D ≡ □D* = (d1, d2) arriving at the encoder input is first associated with a corresponding next state N ≡□N*. This occurs as soon as the data D* bits have advanced into the positions of the internal data bits B1 = (b1, b2), i.e., when (b1, b2, b3, b4, b5, b6) is identical to (d1, d2, x, x, x, x). In a second step, during the next encoding cycle, the state S takes on the value of N*, i.e., S ≡ S* ← □N* so that S is now associated with (d1, d2). In the same cycle, the inner codeword C ≡ □C* now carrying the information of D* is computed. Thus, referring the figure below, a given internal input vector (b1, b2, b3, b4, b5, b6) associates the bits (b1, b2) with the next state N and a given state S associates the data pair ahead of (b1, b2) to the output C. In other words, the pair-wise values for N and C as listed in the figure below are not associated with the same input data pair.

Encoder initialization: The state S = (s1, s2, s3) = (1, 0, 0) is also used as the initial state of the encoder, i.e., denoting with (α, β), the first pair of data bits to be encoded, the state S is forced to take on the value (1, 0, 0) when the bits (α, β) have advanced into the encoding circuits such that the internal inputs B1 = (b1, b2) is identical to (α, β).

Table 121: Encoder Initialization

Present State: S = (s_1, s_2, s_3)	Next State/Internal Output: N = (n_1 n_2, n_3) / C = (c_1, c_2, c_3)							
	Internal Inputs: (b_1, b_2, b_3, b_4, b_5, b_6)							
	00xxxx	01xxxx	10xxxx	1100xx	1101xx	111011	1110(~~11~~)	1111xx
000	000/010	001/010	010/010	111/010	111/001	111/010	011/010	011/010
001	000/001	001/001	100/001	100/010	100/010	100/010	100/010	100/010
010	000/100	001/100	010/100	111/100	111/101	111/100	011/100	011/100
011	000/101	001/101	100/101	100/100	100/100	100/100	100/100	100/100
100	000/000	001/000	010/000	011/000	011/000	011/000	011/000	011/000
111	100/000	100/000	111/000	100/000	100/000	100/000	100/000	100/000

Note: Refer to the IrDA specification 1.4 for further details.

36.3.10.2 HHH (1, 13) Packet Format

The packet format for 16.0 Megabits per second HHH(1,13) has the following form.

Figure 153: HHH (1, 13) Packet Format

The payload data is encoded as described in the HHH (1,13) encoding above, and the encoded symbols reside in the IrLAP Frame field. The preamble field (PA) is used by the receiver to establish phase lock. During PA, the receiver begins to search for the start flag (STA) to establish symbol synchronization. If STA is received correctly, the receiver can begin to interpret the data symbols in the IrLAP Frame field. The receiver continues to receive and interpret data until the stop flag (STO) is recognized. STO indicates the end of a frame. The chip patterns and symbols for PA, STA, CRC field, and STO are defined below.

Only complete packets that contain the entire format defined above are guaranteed to be decoded at the receiver (as for the lower rates, the information field, I, that is part of the IrLAP field, may be of zero length).

The 16.0 Megabits per second packet contains several fields for the purposes of clock recovery, synchronization, and data transmission. In concept, the packet format is similar to that used in 4.0 Megabits per second; however, there are specific controller elements like clock recovery, synchronization, and encoding/decoding circuits that need to be implemented specifically for 16.0 Megabits per second data rate.

36.3.10.3 Preamble Field Definition

The transmitted PREAMBLE (PA) is constructed by concatenating ten times (10X) the 24-chip (1 µs) PREAMBLE PERIOD (PP), where

PP = '100'010'010'001'001'001'000'100'

to form the complete 240-chip (10 µs) preamble

PA = 'PP'PP'PP'PP'PP'PP'PP'PP'PP'PP'

The left-most/right-most chip of PP and PA, respectively, is transmitted first/last and a '1' in PP means an active chip (pulse) and a '0' means an empty chip (no pulse).

36.3.10.4 Start (STA) Flag Definition

The transmitted START (STA) delimiter is the 48-chip (2 µs) chip sequence

STA = '100'101'010'100'100'010'000'001'001'010'101'001'000'001'010'000'

The left-most/right-most chip of STA is transmitted first/last and a '1' in STA means an active chip (pulse) and a '0' means an empty chip (no pulse). The Start Flag Delimiter allows for packet synchronization. A delimiter detection circuit should declare a flag as having been found when there is a perfect match between the receiver chip stream and a particular delimiter. The Start and Stop delimiters contain a subsequence '1001010101001' that violates the HHH (1,13) code. This subsequence occurs twice in the Start Flag delimiter and never occurs within the main HHH code.

36.3.10.5 IrLAP Frame

The structure remains unchanged from that defined in the IrLAP Specification, Version 1.1. The content of the IrLAP frame is first scrambled and then encoded with HHH(1,13). Note that the 32 CRC bits for the IrLAP frame are calculated before the IrLAP frame is scrambled. For reference, the IrLAP frame as the following structure:

| Address (8 bits) | Control (8 bits) | Information (M times 8 bits) |

36.3.10.6 CRC

Computation remains unchanged from the 32-bit CRC defined for the 4 Megabits per second data rate. The content of the CRC field is first scrambled with the scheme described later and then encoded with HHH(1, 13) as described previously. Note that the 32 CRC bits for the IrLAP frame are calculated before the IrLAP frame is scrambled. The transmitted CRC field is a 48-chip (2 µs) sequence.

36.3.10.7 FLUSH BYTE (FB)

The Flush Byte (FB) is the 8-bit sequence:

FB = '00'00'00'00'.

These 8 bits are not scrambled but directly sent to the HHH(1,13) encoder. The transmitted FB field is a 12-chip (0.5 µ s) sequence. Note that the FB field is required to enable complete decoding of the CRC field. The flush byte denotes the end of the main body. Since the flush byte is not scrambled, a well-balanced HHH(1,13) sequence precedes the STOP delimiter. This sequence would be equivalent to the UART "Break" command.

36.3.10.8 STOP (STO)

The transmitted STOP (STO) delimiter is the 48-chip (2 µs) sequence:

STO = '001'001'010'101'001'000'100'000'100'101'010'100'100'000'100'000'.

The left-most/right-most chip of STO is transmitted first/last and a '1' in STO means an active chip (pulse) and a '0' means an empty chip (no pulse). As in the Start Flag delimiter, the Stop flag also contains a subsequence '1001010101001' that violates the HHH (1,13) code. This subsequence also occurs twice in the Stop Flag delimiter.

36.3.10.9 NULL Sequence

The transmitted NULL sequence is the 24-chip (1 µs) sequence

NULL = '000'000'000'000'000'000'000'000'.

The NULL field is a new field for the purpose of providing an HHH(1,13) code pattern violation that permits terminating reception of the packet in the event that the STO field is not recognized. The left-most/right-most chip in NULL is transmitted first/last and all chips of NULL are empty chips (no pulses). The NULL field increases the probability that the packet is terminated close to the STOP flag. The NULL field also reduces the probability that two back to back packets are interpreted as a single packet, should the STOP flag delimiter of the first packet be missed.

36.3.10.10 Scrambling and Descrambling Functions

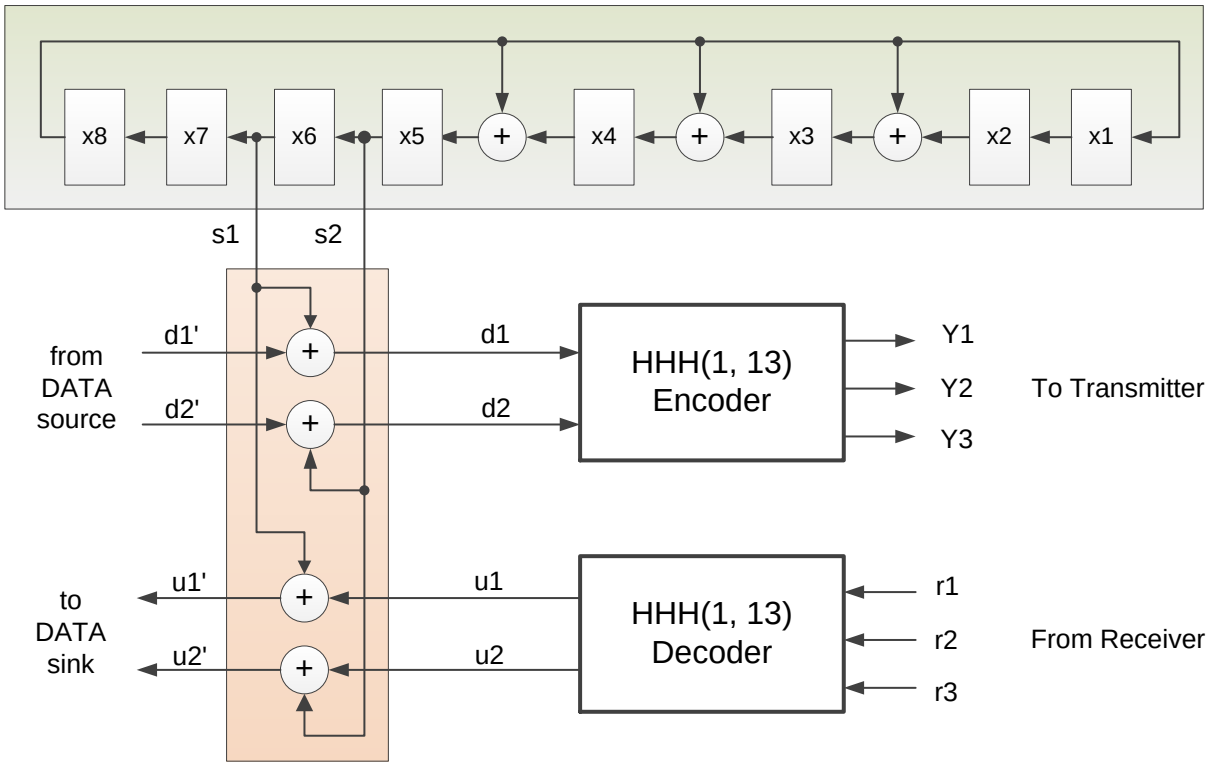
It is advantageous to enhance the encoder/decoder system with simple scrambler/descrambler functions.

The primitive polynomial: $x^8 \oplus x^4 \oplus x^3 \oplus x^2 \oplus 1$,

where $\oplus$ indicates a modulo-2 addition or, equivalently, a logic exclusive OR (XOR) operation. The operations of the proposed scrambling and descrambling functions are performed according to the principles of frame synchronized scrambling/descrambling (FSS) mechanisms. The scrambling/descrambling scheme is shown in the figure below. The linear feedback shift register (LFSR) produces a maximum-length pseudo-random sequence with period 255. The output of register cell x6 shown in the figure is defined to be the equivalent serial output of the LFSR.

The modulo-2 adders shown in the figure below correspond to logic XOR (exclusive OR) gates. During transmission, each new pair of source bits (d1', d2') is XOR-ed with a new pair of scrambling bits (s1, s2) to produce the scrambled data bit pair (d1, d2) entering the encoder. Similarly, during reception, each new pair of decoded bits (u1, u2) is XOR-ed with a new pair of descrambling bits (s1, s2) to produce the descrambled user bit pair (u1', u2') that is sent to the data sink. A scrambling/descrambling cycle has duration 3T seconds where T = 41.7 ns is the chip period.

Figure 154: Scrambling / Descrambling Scheme



36.3.10.11 Effects and Limits of Scrambling/Descrambling

By enhancing the system with scrambling/descrambling functions during data transmission/reception, one achieves generally better duty cycle statistics in the HHH(1,13) coded channel chip stream; the resulting duty cycle converges towards the average duty cycle of the code (≈ 26%) for typical payload data. Scrambling can greatly reduce the probability of occurrence of worst-case patterns.

36.3.10.12 Aborted Packets

Receivers may only accept packets that have valid STA, IrLAP frame, CRC, and STO fields as defined in the Packet Format section. The PA field need not be valid in the received packet. All other packets are aborted and ignored.

36.3.10.13 Back to Back Packet Transmission

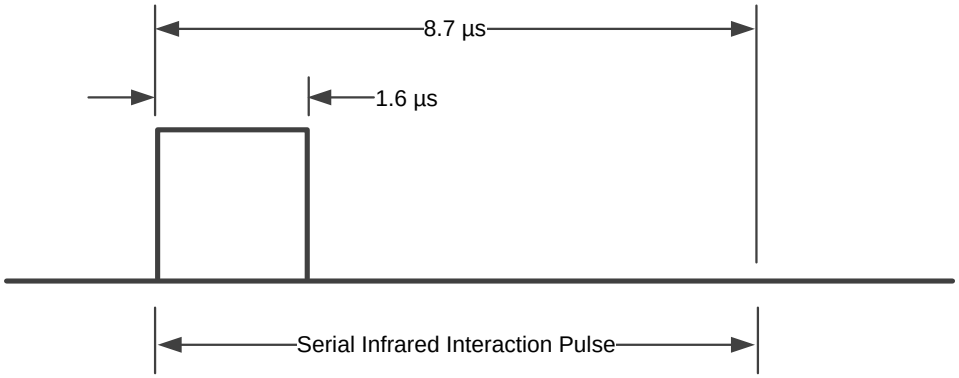
Back to back, or "brick-walled" packets are allowed, but each packet must be complete (i.e., containing PA, STA, IrLAP Frame, CRC and STO fields).

36.3.11 SIR - Serial Interaction Pulse

In order to guarantee non-disruptive coexistence with slower (up to 115.2 Kilobits per second) systems, once a higher speed (above 115.2 Kilobits per second) connection has been established, the higher speed system must emit a Serial infrared Interaction Pulse (SIP) at least once every 500 ms as long as the connection lasts to quiet slower systems that might interfere with the link. The pulse can be transmitted immediately after a packet has been transmitted. Initiation of this pulse will be performed by software by setting a bit in the VFIR Control register.

The pulse is shown below.

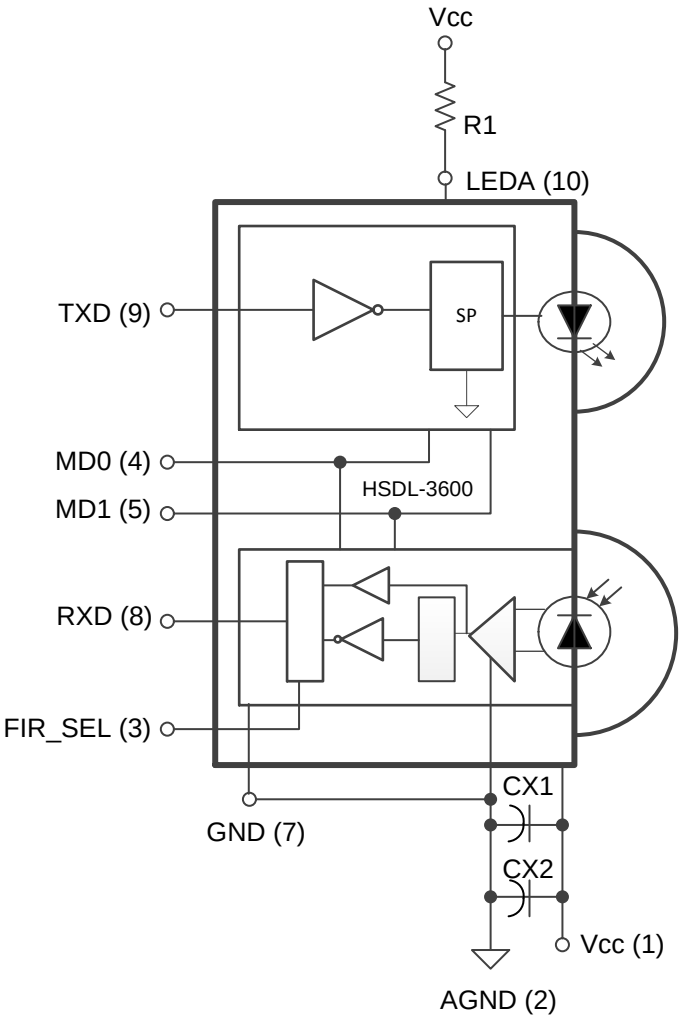
Figure 155: SIP



36.3.11.1 External Interface

The SIR/FIR/VFIR signals are muxed to the external transceiver. The transceiver has TX and RX pins, and may optionally have controls for receiver gain and transmitter power. This module provides the TX and RX pins, and each has a polarity control for compatibility with all vendors. Other transceiver pins are not directly supported, although they could be provided using GPIO signals. Refer to the drawing below for typical interface. TXD and RXD are VFIR module pins. MD and FIR_SEL pins would be GPIO. MD pins are for transmit power. FIR_SEL controls gain of receiver, and should be set to zero for SIR mode.

Figure 156: Typical Interface



36.4 UART Registers

Refer to “Reading Register Tables” in the Introduction section for the register table protocol as well as recommendations for accessing registers.

The Tegra 4 UART is based on the 16550 industry standard Universal Asynchronous Receiver/Transmitter (UART), with enhancements to support autobaud detection and End-of-Received Data timeout detection.

The UART supports a device clock of up to 72 MHz, for a maximum baud rate of 4.5 Megabits per second.

The THR, RBR and DLL registers all occupy the same address space.

- The Transmitter Holding Register (THR) is Write-Only, and can be accessed if the LSR.DLAB bit is clear.
- The Receiver Buffer Register (RBR) is Read-Only, and can be accessed if the LSR.DLAB bit is clear.
- The Divisor Latch LSByte Register (DLL) is Read/Write and can be accessed if the LSR.DLAB bit is set.

36.4.1 UART_THR_DLAB_0_0

UART Transmit Holding Register

Offset: 0x0 | Read/Write: R/W | Reset: 0x00000000 (0bxxxxxxxxxxxxxxxxxxxxxxxxx00000000)

Bit	R/W	Reset	Description
7:0	RO	0x0	THR_A: Transmit holding register, holds the character to be transmitted by the UART. In FIFO mode, a write to this FIFO places the data at the end of the FIFO.
7:0	RO	X	RBR_A: Receive Buffer Register. Rx Data read from here.
7:0	RO	0x0	DLL_A: Divisor Latch LSB (low 8 bits of 16-bit Baud Divisor)

36.4.2 UART_IER_DLAB_0_0

The IER and DLH registers occupy the same address space, selected by the LSR.DLAB bit. The Interrupt Enable Register (IER) is selected if the LSR.DLAB bit is clear. The Divisor Latch MSByte register (DLM) is selected if the LSR.DLAB bit is set. The DLM register holds the upper 8 bits of the 16-bit Baud Divisor (16x).

UART Interrupt Enable por=0x00000000

RX_TIMEOUT occurs when data has been sitting in the Rx FIFO for more than 4 character times without being read because there is not enough data to reach the trigger level. Interrupt needed to handle this case so that all data is received in a timely manner. Note that this normally occurs at the end of an incoming data stream.

EORD (End of Receive Data) Interrupt occurs when the receiver detects that data stops coming in for more than 4 character times. This interrupt is useful for determining that the sending device has completed sending all its data. EORD timeout will not occur if the receiving data stream is stopped because of hardware handshaking.

To clear the EORD timeout interrupt you must DISABLE the EORD interrupt enable (IE_EORD).

Interrupt Enable and Divisor Latch MSByte Registers

Offset: 0x4 | Read/Write: R/W | Reset: 0x00000000 (0bxxxxxxxxxxxxxxxxxxxxxxxxxx000000)

Bit	Reset	Description
5	0x0	IE_EORD: Interrupt Enable for End of Received Data 0 = DISABLE 1 = ENABLE
4	0x0	IE_RX_TIMEOUT: Interrupt Enable for Rx FIFO timeout 0 = DISABLE 1 = ENABLE
3	0x0	IE_MSI: Interrupt Enable for Modem Status Interrupt 0 = DISABLE 1 = ENABLE
2	0x0	IE_RXS: Interrupt Enable for Receiver Line Status Interrupt 0 = DISABLE 1 = ENABLE
1	0x0	IE_THR: Interrupt Enable for Transmitter Holding Register Empty interrupt 0 = DISABLE 1 = ENABLE
0	0x0	IE_RHR: Interrupt Enable for Received Data Interrupt 0 = DISABLE 1 = ENABLE

36.4.3 UART_IIR_FCR_0

The FCR and IIR registers occupy the same address space. The FIFO Control Register (FCR) is Write-Only. The Interrupt Identification Register (IIR) is Read-Only

UART FIFO Control Register por=0x00000000

The DMA can run in one of two modes:

- If Mode0 is selected (NO_CHANGE) the Rx DMA request will go active whenever the Rx FIFO is not empty. Only single byte transactions can be performed in this mode. If the FIFO is not enabled, Mode0 MUST be used.
- If Mode1 is selected (CHANGE) the Rx DMA request will go active whenever the Rx FIFO trigger level is reached.

For best performance, always enable the FIFO and select DMA Mode 1.

For RX_TRIG the FIFO_COUNT references the number of bytes in the receive FIFO.

For TX_TRIG the FIFO_COUNT references the number of empty bytes in the transmit FIFO. For example, FIFO_COUNT_GREATER_16 means that there are at least 16 empty byte slots in the TX_FIFO

UART Interrupt ID Register por=0x00000001

The Interrupt ID field indicates the current highest priority interrupt. If more than one interrupt is pending the one with the highest priority will be shown.

The table below shows the encoding. Priority flows from top (highest) to bottom (lowest).

Table 122 Interrupt ID Encoding

IIR[3:0]	Priority Level
0001	No interrupt
0110	Overrun Error, Parity Error, Framing Error, Break
0100	Receiver Data Available
1100	rx_timeout_intr
1000	eord_timeout_intr
0010	Transmitter Holding Register empty
0000	modem_status interrupt

UART FIFO Control and Interrupt Identification Registers

Offset: 0x8 │ Read/Write: R/W │ Reset: 0x00000000 (0bxxxxxxxxxxxxxxxxxxxxxxxxxx00000000)

Bit	Reset	Description
7:6	X	EN_FIFO: FIFO Mode Status 0=16450 mode(no FIFO) 1 = 16550 mode (FIFO) 1 = MODE_16550 0 = MODE_16450
7:6	0x0	RX_TRIG: 0 = FIFO_COUNT_GREATER_1 1 = FIFO_COUNT_GREATER_4 2 = FIFO_COUNT_GREATER_8 3 = FIFO_COUNT_GREATER_16

Bit	Reset	Description
5:4	0x0	TX_TRIG: 0 = FIFO_COUNT_GREATER_16 1 = FIFO_COUNT_GREATER_8 2 = FIFO_COUNT_GREATER_4 3 = FIFO_COUNT_GREATER_1
3	X	IS_PRI2: Encoded Interrupt ID Refer to IIR[3:0] table above 0 = DISABLE 1 = ENABLE
3	0x0	DMA: 0:DMA_MODE_0 1:DMA_MODE_1 0 = NO_CHANGE 1 = CHANGE
2	X	IS_PRI1: Encoded Interrupt ID Refer to IIR[3:0] table above 0 = DISABLE 1 = ENABLE
2	0x0	TX_CLR: 1 = Clears the contents of the transmit FIFO and resets its counter logic to 0 (the transmit shift register is not cleared or altered). This bit returns to 0 after clearing the FIFOs. 0 = NO_CLEAR 1 = CLEAR
1	X	IS_PRI0: Encoded Interrupt ID Refer to IIR[3:0] table above 0 = DISABLE 1 = ENABLE
1	0x0	RX_CLR: 1 = Clears the contents of the receive FIFO and resets its counter logic to 0 (the receive shift register is not cleared or altered). This bit returns to 0 after clearing the FIFOs. 0 = NO_CLEAR 1 = CLEAR
0	X	IS_STA: Interrupt Pending if ZERO 0 = INTR_PEND 1 = NO_INTR_PEND
0	0x0	FCR_EN_FIFO: 1 = Enable the transmit and receive FIFOs. This bit should be enabled 0 = DISABLE 1 = ENABLE

36.4.4 UART_LCR_0

UART Line Control Register

Offset: 0xc │ Read/Write: R/W │ Reset: 0x00000000 (0bxxxxxxxxxxxxxxxxxxxxxxxxx00000000)

Bit	Reset	Description
7	0x0	DLAB: Divisor Latch Access Bit (set to allow programming of the DLH, DLM Divisors) 0 = DISABLE 1 = ENABLE
6	0x0	SET_B: Set BREAK condition -- Transmitter will send all zeroes to indicate BREAK 0 = NO_BREAK 1 = BREAK

Bit	Reset	Description
5	0x0	SET_P: Set (force) parity to value in LCR [4] 0 = NO_PARITY 1 = PARITY
4	0x0	EVEN: Even parity format. There will always be an even number of 1s in the binary representation (PAR = 1) 0 = DISABLE 1 = ENABLE
3	0x0	PAR: 0 = No parity sent 0 = NO_PARITY 1 = PARITY
2	0x0	STOP: 0 = Transmit 1 stop bit 1 = Transmit 2 stop bits (receiver always checks for 1 stop bit) 0 = DISABLE 1 = ENABLE
1:0	0x0	WD_SIZE: 3=Word length of 8 0 = WORD_LENGTH_5 1 = WORD_LENGTH_6 2 = WORD_LENGTH_7 3 = WORD_LENGTH_8

36.4.5 UART_MCR_0

The RTS and CTS pins are used for hardware handshaking with and external serial device. RTS (Request-To-Send) informs the device that the UART is ready to accept data. CTS (Clear-To-Send) comes from the RTS of the external device and indicates that data can be sent.

The RTS pin can be controlled manually with the RTS bit in the MCR, or automatically by setting the RTS_EN bit.

If RTS_EN is set, the RTS pin will automatically remove the Request-To-Send when the FIFO reaches the trigger level.

If the CTS_EN bit is set, the UART transmitter will stop transmitting when the Clear-To-Send input is taken away.

UART Modem Control Register

Offset: 0x10 │ Read/Write: R/W │ Reset: 0x00000000 (0bxxxxxxxxxxxxxxxxxxxxxxxxxxx0000000)

Bit	Reset	Description
6	0x0	RTS_EN: 1 = Enable RTS Hardware Flow Control 0 = DISABLE 1 = ENABLE
5	0x0	CTS_EN: 1 = Enable CTS Hardware Flow Control 0 = DISABLE 1 = ENABLE
4	0x0	LOOPBK: 1 = Enable internal loop back of Serial Out to In 0 = DISABLE 1 = ENABLE
3	0x0	OUT2: nOUT2 (Not Used) 0 = DISABLE 1 = ENABLE

Bit	Reset	Description
2	0x0	OUT1: nOUT1 (Not Used) 0 = DISABLE 1 = ENABLE
1	0x0	RTS: 0 = Force RTS to high if RTS hardware flow control not enabled 0 = FORCE_RTS_HI 1 = FORCE_RTS_LOW
0	0x0	DTR: 1 = Force DTR to high 0 = FORCE_DTR_HI 1 = FORCE_DTR_LOW

36.4.6 UART_LSR_0

UART Line Status Register

Offset: 0x14 │ Read/Write: RO │ Reset: 0x00000XXX (0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx)

Bit	Reset	Description
8	X	TX_FIFO_FULL: Transmitter FIFO full status 0 = NOT_FULL 1 = FULL
7	X	FIFOE: 1 = Receive FIFO Error 0 = NO_ERR 1 = ERR
6	X	TMTY: Transmit Shift Register empty status 0 = NO_EMPTY 1 = EMPTY
5	X	THRE: 1 = Transmit Holding Register is Empty -- OK to write data 0 = FULL 1 = EMPTY
4	X	BRK: 1 = BREAK condition detected on line 0 = NO_BREAK 1 = BREAK
3	X	FERR: 1 = Framing Error 0 = NO_FRAME_ERR 1 = FRAME_ERR
2	X	PERR: 1 = Parity Error 0 = NO_PARITY_ERR 1 = PARITY_ERR
1	X	OVRF: 1 = Receiver Overrun Error 0 = NO_OVERRUN_ERROR 1 = OVERRUN_ERROR
0	X	RDR: 1 = Receiver Data Ready (Data available to read) 0 = NO_DATA_IN_FIFO 1 = DATA_IN_FIFO

36.4.7 UART_MSR_0

UART Modem Status Register

Offset: 0x18 | Read/Write: R/W | Reset: 0x00000000 (0bxxxxxxxxxxxxxxxxxxxxxxxxx00000000)

Bit	Reset	Description
7	0x0	CD: State of Carrier detect pin 0 = DISABLE 1 = ENABLE
6	0x0	RI: State of Ring Indicator pin 0 = DISABLE 1 = ENABLE
5	0x0	DSR: State of Data set ready pin 0 = DISABLE 1 = ENABLE
4	0x0	CTS: State of Clear to send pin 0 = DISABLE 1 = ENABLE
3	0x0	DCD: Change (Delta) in CD state detected 0 = DISABLE 1 = ENABLE
2	0x0	DRI: Change (Delta) in RI state detected 0 = DISABLE 1 = ENABLE
1	0x0	DDSR: Change (Delta) in DSR state detected 0 = DISABLE 1 = ENABLE
0	0x0	DCTS: Change (Delta) in CTS state detected 0 = DISABLE 1 = ENABLE

36.4.8 UART_SPR_0

UART Scratch Pad Register

Offset: 0x1c | Read/Write: R/W | Reset: 0x00000000 (0bxxxxxxxxxxxxxxxxxxxxxxxxx00000000)

Bit	Reset	Description
7:0	0x0	SPR_A: Scratchpad register (not used internally)

36.4.9 UART_IRDA_CSR_0

Bits [7:6] control the infrared (SIR) encoding. If enabled, each zero bit is transmitted as a short IR pulse. No pulse is sent during idle or '1' data bits. The IR pulse can be either 3/16 or 4/16 of a normal bit time.

The low 4 bits control signal polarity and apply whether or not SIR coding is enabled.

UART IrDA Pulse Coding CSR Register

Offset: 0x20 │ Read/Write: R/W │ Reset: 0x00000000 (0bxxxxxxxxxxxxxxxxxxxxxxxxxx00xx0000)

Bit	Reset	Description
7	0x0	SIR_A: 1 = Enable SIR coder 0 = Disable SIR coder 0 = DISABLE 1 = ENABLE
6	0x0	PWT_A: 0=3/16th Baud Pulse, 1=4/16 0 = BAUD_PULSE_3_14 1 = BAUD_PULSE_4_14
3	0x0	INVERT_RTS: Inverts the normally inactive high nRTS pin 0 = DISABLE 1 = ENABLE
2	0x0	INVERT_CTS: Inverts the normally inactive high nCTS pin 0 = DISABLE 1 = ENABLE
1	0x0	INVERT_TXD: Inverts the normally inactive high TXD pin 0 = DISABLE 1 = ENABLE
0	0x0	INVERT_RXD: Inverts the normally inactive high RXD pin 0 = DISABLE 1 = ENABLE

36.4.10 UART_RX_FIFO_CFG_0

Offset: 0x24 │ Read/Write: R/W │ Reset: 0x00000001 (0bxxxxxxxxxxxxxxxxxxxxxxxxxx0x000001)

Bit	Reset	Description
7	0x0	EN_RX_FIFO_TRIG: Enable use of RX_FIFO_TRIG count (obsoletes RX_TRIG when enabled) 0 = DISABLE 1 = ENABLE
5:0	0x1	RX_FIFO_TRIG: Set RX_FIFO trigger level (any value 1 thru 32)

36.4.11 UART_MIE_0

UART Modem Interrupt Enable Register

Offset: 0x28 │ Read/Write: R/W │ Reset: 0x0000000f (0bxxxxxxxxxxxxxxxxxxxxxxxxxxxx1111)

Bit	Reset	Description
3	0x1	DCD_INT_EN: Interrupt Enable for Change (Delta) in CD state detected 0 = DISABLE 1 = ENABLE
2	0x1	DRI_INT_EN: Interrupt Enable for Change (Delta) in RI state detected 0 = DISABLE 1 = ENABLE
1	0x1	DDSR_INT_EN: Interrupt Enable for Change (Delta) in DSR state detected 0 = DISABLE 1 = ENABLE

Bit	Reset	Description
0	0x1	DCTS_INT_EN: Interrupt Enable for Change (Delta) in CTS state detected 0 = DISABLE 1 = ENABLE

36.4.12 UART_ASR_0

The UART has autobaud sensing logic that can measure the width of the start bit of incoming data to determine baud rate. For this to work, the incoming character must have its LSB set. A <cr> works well (0x0d). The logic will use the UART device clock to count how wide the start pulse is and the BUSY bit will be set when the sensing is complete. The value in {RX_RATE_SENSE_H,RX_RATE_SENSE_L} should be divided by 16 with Round-to-Nearest, and the resulting value loaded into the DLM,DLL register pair to set the Baud Clock to 16X the Baud Rate.

UART Auto Sense Baud Register

Offset: 0x3c │ Read/Write: R/W │ Reset: 0x00000000 (0b00xxxxxxxxxxxxxx0000000000000000)

Bit	Reset	Description
31	0x0	VALID: This bit is set when the controller finishes counting the clocks between two successive clock edges after there is a write to ASR with don't care data. 0 = UN_SET 1 = SET
30	0x0	BUSY: This bit is set when there is a write to ASR and is reset when the controller finishes counting the clock edges between two successive clock edges. 0 = NO_BUSY 1 = BUSY
15:8	0x0	RX_RATE_SENSE_H: Shows bits [15:8] of the count of clock edges between two successive clock edges.
7:0	0x0	RX_RATE_SENSE_L: Shows bits [7:0] of the count of clock edges between two successive clock edges.

36.5 VFIR Registers

36.5.1 VFIR_CTL_0

The VFIR Control register is used to:

- enable/disable entire IRDA module
- configure the controller in FIR mode or VFIR mode or SIR or UART mode
- configure either in Transmit mode or Receive mode
- invert the polarity of Tx or Rx line
- invert the polarity of Tx or Rx line
- enable/disable DMA
- know the attention levels of Transmit FIFO and Receive FIFO
- start a transmit or receive operation
- select the frequency
- clear the Transmitter FIFO/Receiver FIFO

VFIR Control Register

Offset: 0x0 | Read/Write: R/W | Reset: 0x00000020 (0b000xxxx0x000x000xx00000000100000)

Bit	Reset	Description
31	0x0	GLOBAL_ENABLE: 0 = Entire IRDA module is disabled 0 = DISABLE 1 = ENABLE
30	0x0	GO: Set to 1 to start transmit or receive operation, self-clearing 0 = STOP 1 = START
29	0x0	AUTO_RESTART: Set to 1 to restart another operation when previous is done 0 = STOP 1 = RE_START
24	0x0	FORCE_BAD_CRC: Debugging bit to force a CRC error 0 = DISABLE 1 = ENABLE
22	0x0	TX_FIFO_CLR: Clear the Transmitter FIFO 0 = DISABLE 1 = ENABLE
21:20	0x0	TX_ATN_LVL: 00: when not full 3 = slots_empty_12 2 = slots_empty_8 1 = slots_empty_4 0 = not_full
18	0x0	RX_FIFO_CLR: Clear the Receiver FIFO 0 = DISABLE 1 = ENABLE
17:16	0x0	RX_ATN_LVL: 00: when not empty 3 = slots_full_12 2 = slots_full_8 1 = slots_full_4 0 = not_empty
13	0x0	START_SIP: Self-clearing bit to initiate a Serial Ir Interaction Pulse.
12	0x0	EN_PULSECORR: Fixes single pulse errors caused by VFIR propagation effects. 0 = DISABLE 1 = ENABLE
11	0x0	DMA_EN: DMA Enable Allow requests to go to the APB_DMA controller. 0 = DISABLE 1 = ENABLE
10	0x0	TX_TERM: of outgoing frame, i.e., the calculated CRC will be sent, followed by the frame stop sequence. The interrupt will be generated if enabled. 0 = ABORT 1 = NORMAL
9	0x0	COUNT_ODATA: When enabled, the controller will end the frame when the Outgoing Frame Data Length (OFDL) count is reached. Use in conjunction with TX_Term above so controller will know when and how to end the frame. 0 = DISABLE 1 = ENABLE
8	0x0	FORCEBRK: break state (zero) regardless of what the transmitter is doing. 0 = TX_ENABLE 1 = TX_DISABLE

Bit	Reset	Description
7	0x0	NEGATE_RX: Invert polarity on incoming RX pin (applies to all modes) 0 = DISABLE 1 = ENABLE
6	0x0	NEGATE_TX: Invert polarity on outgoing TX pin (applies to all modes) 0 = DISABLE 1 = ENABLE
5:4	0x2	FREQUENCY: The 8 and 24 MHz clocks can be used to save power during transmits. The 72 MHz clock can be used in case the 48 MHz clock is not available due to system constraints. 0 = F8MHz 1 = F24MHz 2 = F48MHz 3= F72MHz
3	0x0	TRANSMIT: 0 = Receive (FIR/VFIR modes) 1 = TRANSMIT 0 = RECEIVE
2:0	0x0	MODE: 000: UART uses the UART B module 7 = RSVD 6 = RSVD1 5 = VFIR 4 = FIR 3 = RSVD2 2 = MIR 1 = SIR 0 = UARTB

36.5.2 VFIR_STS_0

VFIR Status and Interrupt Identification Register is used to know the status of:

- Transmitter/Receiver FIFO Trigger level status
- Transmitter/Receiver FIFO FULL/EMPTY status
- Transmitter/Receiver FIFO empty slots
- whether a Transmit or Receive operation is done or not
- whether End of Frame is received or not
- whether there is any CRC error in received data or not
- whether there is any error in the received data
- whether the controller is busy with transmitting/receiving the data
- whether the VFIR interrupt is generated or not. To generate the interrupt, the corresponding enable bit has to be set in the VFIR Interrupt Enable Register

VFIR Status and Interrupt Identification Register

Offset: 0x4 │ Read/Write: R/W │ Reset: 0xXXXXX0X0 (0bxxxxxxxxxxxxxxxxxxxx0xxx0x000000)

Bit	R/W	Reset	Description
31	RO	X	TX_FTRIG: Transmitter FIFO Trigger level Reached
30	RO	X	TX_FIFO_FULL: Transmitter FIFO is Full
29	RO	X	TX_FIFO_EMPTY: Transmitter FIFO is Empty
28:24	RO	X	TX_FIFO_EMPTY_COUNT: Number of empty slots (words) in the Tx FIFO. The FIFO is a shared Rx/Tx FIFO with a total of decimal 20 entries

Bit	R/W	Reset	Description
23	RO	X	RX_FTRIG: Receiver FIFO Trigger level Reached
22	RO	X	RX_FIFO_FULL: Receiver FIFO is Full
21	RO	X	RX_FIFO_EMPTY: Receiver FIFO is Empty
20:16	RO	X	RX_FIFO_FULL_COUNT: Number of words available to read in the Rx FIFO. The FIFO is a shared Rx/Tx FIFO with a total of decimal 20 entries
15	RO	X	INTR: Global VFIR interrupt (OR of all FIR/VFIR interrupts)
14	RO	X	BUSY: transmitting or receiving data. It is clear when the controller is idle or transmits a Serial infrared Interaction Pulse (SIP)
11	RW	0x0	TX_UNDRN: break. This bit is cleared upon reading from the register.
7	RW	0x0	MISSED_PACKET: Another Rx arrived before the previous was serviced. Serviced is defined as clearing the Rx_EOF flag. This bit is cleared by writing a 1 to this bit.
6	RO	X	BITSYNC_LOCK: Debug status bit which indicates that receiver is Locked to incoming bitstream.
5	RW	0x0	RX_DETECT: Activity detected on Rx pin This bit is cleared by writing a 1 to this bit.
4	RW	0x0	RX_ERR: Receiver Error. This bit is set when an unexpected or illegal data has been received. This can be a break in transmission, illegal chip values or framing errors. This bit is cleared by writing a 1 to this bit.
3	RW	0x0	RX_FOVRN: Receiver FIFO overrun error occurred. This bit is cleared by writing a 1 to this bit.
2	RW	0x0	RX_CRC_ERR: CRC check on input data failed. This bit is cleared by writing a 1 to this bit.
1	RW	0x0	RX_EOF: Received End of Frame. Set when the last byte in frame is within the receiver FIFO. This bit is cleared by writing a 1 to this bit.
0	RW	0x0	DONE: Done flag. Set when controller completes a Transmit or Receive packet, even if the packet finished early due to errors. This bit is cleared by writing a 1 to this bit.

36.5.3 VFIR_IER_0

VFIR Interrupt Enable Register is used to generate VFIR interrupt for different conditions. VFIR Interrupt bit is present in VFIR.

Status and Interrupt Identification Register

For example when the controller finishes the Transmitting/Receiving operation and if IE_DONE is set then Interrupt is generated. Similar is the case for other bits in this register

VFIR Interrupt Enable Register

Offset: 0x8 │ Read/Write: R/W │ Reset: 0x00000000 (0b0xxxxxxx0xxxxxxxxxxx0xxx0x000000)

Bit	Reset	Description
31	0x0	IE_TX_FTRIG: Enable Interrupt on Transmitter FIFO Trigger level reached 0 = DISABLE 1 = ENABLE
23	0x0	IE_RX_FTRIG: Enable Interrupt on Receiver FIFO Trigger level reached 0 = DISABLE 1 = ENABLE
11	0x0	IE_TX_UNDRN: transmit a break for the receiving side to abort reception. 0 = DISABLE 1 = ENABLE

Bit	Reset	Description
7	0x0	IE_MISSED_PACKET: Enable Interrupt for Missed Packet error 0 = DISABLE 1 = ENABLE
5	0x0	IE_RX_DETECT: Enable Interrupt on Activity on Rx Pin 0 = DISABLE 1 = ENABLE
4	0x0	IE_RX_ERR: Enable Interrupt on Receiver Error 0 = DISABLE 1 = ENABLE
3	0x0	IE_RX_FOVRN: Enable Interrupt on Receiver FIFO overrun 0 = DISABLE 1 = ENABLE
2	0x0	IE_RX_CRC: Enable Interrupt for input CRC check failure 0 = DISABLE 1 = ENABLE
1	0x0	IE_RX_EOF: Enable Interrupt for Received End of Frame 0 = DISABLE 1 = ENABLE
0	0x0	IE_DONE: Enable Interrupt for Done Status 0 = DISABLE 1 = ENABLE

36.5.4 VFIR_OFDL_0

VFIR Outgoing Frame Data Length is used to configure the number of bytes of data to be sent.

VFIR Outgoing Frame Data Length

Offset: 0xc │ Read/Write: R/W │ Reset: 0x00000000 (0bxxxxxxxxxxxxxxxx0000000000000000)

Bit	Reset	Description
15:0	0x0	OFDL: Set to the length in bytes of the outgoing frame. Length is calculated on the information field only (address, control and data fields only) without the CRC and flags. When in this mode, the amount of data transferred to the controller is counted and when the count is reached the controller finishes sending the frame in normal fashion by transmitting CRC field, STO flag and then the SIP.

36.5.5 VFIR_IFDL_0

VFIR Incoming Frame Data Length gives the information of the data received in bytes.

VFIR Incoming Frame Data Length

Offset: 0x10 │ Read/Write: RO │ Reset: 0x0000XXXX (0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx)

Bit	Reset	Description
15:0	X	IFDL: Running length in bytes of the incoming data stream. At the end of frame reception when the Received End of Frame interrupt occurs, this register reflects the length of the information field received in that frame, not counting the CRC field and other flags. Resets on the start of next frame reception, when a new STA field has been detected.

36.5.6 VFIR_FIFO_0

The VFIR FIFO is a shared FIFO. It holds the data in Transmitter/Receiver mode.

VFIR.FIFO (VFIR FIFO)

Offset: 0x40 │ Read/Write: R/W │ Reset: 0xXXXXXXXX (0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx)

Bit	Reset	Description
31:0	X	DATA: Shared FIFO. When transmitting, this FIFO holds the data to be transmitted. When receiving, this FIFO holds the received data.

37.0 SERIAL PERIPHERAL INTERFACE (SPI) CONTROLLER

The Serial Peripheral Interface (SPI) controller is a serial communications link between the processor and on-chip/off-chip serial peripheral devices such as sensors, ADC/DAC devices, and Flash controllers. Tegra® 4 devices support both Master and Slave modes of SPI operation on this interface.

In this section:

- *Word* refers to 32-bit data in the TX or RX FIFO
- *Packet* refers to variable length data that is transmitted or received
  - In Unpacked Mode, packet size can be any length from 1 to 32 bits
  - In Packed Mode, packet size can be 4, 8, 16, or 32 bits

37.1 Functionality

The Tegra 4 SPI Controller works as a Master/Slave on the SPI bus. It has independent transmit and receive FIFOs of 64 x 32 bits each. Software can program the controller to generate transactions of a required packet length on the SPI bus, where a transaction is a sequence of packets in either direction.

The controller supports either APB DMA or program transfer to read and write from the FIFOs as required. At the end of each transaction, an interrupt can be generated, if enabled. Software uses transmit and receive operations in combination with chip select (CS) control to generate commands on the SPI bus.

The interface consists of four signals: Chip Select/Slave Select (CS_N), Clock (SCLK), Master Data Out and Slave Data In (MOSI), and Master Data In and Slave Data Out (MISO).

Features

- Master and Slave functionality
  - Master: All transmission format modes are supported for both transmit and receive operations
  - Slave (transmits): Modes 1 and 3 are supported
  - Slave (receives): All modes are supported
- Independent Rx and Tx FIFOs
- FIFO depth of 64 x 32 bits
- Programmable bit lengths from 3 to 31 bits, resulting in packet sizes of 4 to 32 bits
- PIO or DMA Mode depending on packet size

  Options include Packed/Unpacked, Full-Duplex Mode, Both Enable Bit (x2 Mode), Both Enable Byte (x2 Mode), Bidirectional, Least Significant Bit, Least Significant Byte First (Endian-ness), software or hardware chip-select polarity selection
- Programmable clock phase and polarity
- Programmable delay between consecutive transfers
- Packed mode support for bit lengths of 3 (4-bit packet size), 7 (8-bit packet size), and 15 (16-bit packet size)
- Chip select (CS) can be controlled by software or can be generated automatically by hardware on packet boundaries
- Maximum 4-chip support with programmable CS polarity for each chip select
- DMA support
- Simultaneous receive and transmit operations supported
- The maximum frequency of the device clock is 50 MHz, so the maximum data rate is 50 Mbits/s

37.1.1 Transmission Format

Using the Mode field in the SPI Command1 Register, software sets one of the four modes in which the SPI controller works. The two bits of the Mode field specify the idle (inactive) state of SCLK before the chip select is asserted and the data transmitting/receiving edges of SCLK. Mode [1] determines the SCLK polarity. If the polarity is 0, then the SCLK signal is 0 when idle and transitions to 1 when data transfer starts. If the clock polarity is 1, then the SCLK signal is 1 when idle and transitions to 0 when data transfer starts. Mode [0] is the SCLK phase control bit. If the clock phase is 0, then the receiver latches the data on the first transition of SCLK from the idle state. If the clock phase is 1, then the receiver latches the data on the second transition of SCLK.

Modes supported by the SPI controller are:

- Master: All transmission format modes are supported both for transmitting and receiving
- Slave: Modes 1 and 3 are supported for transmitting
- Slave: All modes are supported for receiving

The following table defines the four modes for the SPI protocol.

Table 123: SPI Modes with Clock Polarity and Phase

SPI Mode	Clock Polarity	Clock Phase	SCLK Inactive State	Data Latch IN	Data Latch OUT
0	0	0	Low	Latched IN on the positive edge of clock	Latched OUT on the negative edge of clock
1	0	1	Low	Latched IN on the negative edge of clock	Latched OUT on the positive edge of clock
2	1	0	High	Latched IN on the negative edge of clock	Latched OUT on the positive edge of clock
3	1	1	High	Latched IN on the positive edge of clock	Latched OUT on the negative edge of clock

37.1.2 Modes of Operation

37.1.2.1 Master and Slave Modes

The SPI controller can be configured to operate as a Master or Slave. When the M/S bit in the SPI Command1 Register is set, Master mode is selected; when the M/S bit in the SPI Command1 Register is cleared, Slave mode is selected. Only the SPI Master can initiate a transaction.

In Master mode, data from the Tx FIFO is transmitted on the MOSI pin. The data from the slave is received on the MISO pin and sent to the Rx FIFO. The Master can simultaneously transmit and receive on MOSI and MISO in Full-Duplex Mode.

In Slave mode, once software enables the SPI controller by setting the PIO bit, it simply waits for the Master to initiate a transaction. Before the transaction begins, the slave logic continuously polls the CS input. When the Master asserts CS and SCLK is transmitted to the Slave, the Slave data is transmitted from the Tx FIFO on MISO and data from MOSI is received in the Rx FIFO. The Slave can also simultaneously transmit and receive on MOSI and MISO in Full-Duplex Mode.

Table 124: Master Mode Port Configuration

Name	Direction	Description
MOSI	Bidirectional	Output in Full-Duplex/Tx Mode Input in Both_Enable Rx Mode
MISO	Bidirectional	Input in Full-Duplex/Rx Mode
SCLK	Output	Output in Both_Enable TX Mode
CS_#x	Output	Slave select signal to x, where x is a number between 0 to 3

Table 125: Slave Mode Port Configuration

Name	Direction	Description
MISO	Bidirectional	Output in Full-Duplex/Tx Mode Input in Both_Enable Rx Mode
MOSI	Bidirectional	Input in Full-Duplex/Rx Mode Output in Both_Enable TX Mode
SCLK	Input	Synchronization clock received from the Master
CS_#	Input	Select signal

When the SPI controller is configured to interface with multiple slaves, the controller has one CS signal for each slave, up to a maximum of four slaves. During a transfer, the master asserts CS specified in the CS_SEL bits in SPI Command1 Register. There can be no more than one slave transmitting data during any particular transfer.

37.1.2.2 DMA and PIO Modes

PIO and DMA are the two main operational modes for the SPI controller. PIO mode is used when the number of packets to the transmitter or receiver is less than or equal to 64. DMA mode is used when the number of packets to the transmitter or receiver is greater than 64. In PIO or DMA mode, the SPI controller sends an interrupt to the processor at the end of each transfer. In this mode software configures the number of packets and number of bits in each packet to be transmitted/received. The limitation of PIO Mode is that it can be used only if the maximum number of packets that can be transferred is less than or equal to 64 packets (the FIFO depth is 64). If software wants to transmit/receive more than 64 packets in PIO Mode, it has to reconfigure the SPI controller every 64 packets.

To send/receive more than 64 packets, the SPI Controller can be configured in DMA mode (enabled by writing 1 to the DMA_EN bit in the SPI DMA Control Register). The SPI controller transmits or receives the number of packets as indicated by the BLOCK_SIZE field in the SPI Block Size Register. BLOCK_SIZE is a 16-bit field, so 2^{16} packets (amounting to 256 KB) can be transmitted/received in a single software configuration.

CS usage guideline: If a hardware-based CS is used, the CS goes to the inactive state after the transfer of packets as programmed in the BLOCK_SIZE register field is completed. If CS has to stay active in multiple consecutive transactions (for example, the first transaction – Tx: 64 Packets; the second transaction – Rx: 128 Packets), then the software based CS has to be used (in hardware-based CS, CS goes to the inactive state after the completion of the first transaction).

37.1.2.3 Packed and Unpacked Modes

SPI communication can be carried out in Packed or Unpacked Mode. These are both present in DMA and PIO Modes.

- Packed Mode: In Packed Mode, data can be transmitted/received with each packet size equal to 4, 8, 16, or 32 bits. The PACKED field and BIT_LEN field in the DMA Command1 Register determine if the mode Packed or Unpacked and the length of each packet. If the BIT_LEN field is set to 03h, each packet is 4 bits long and each word in the Tx/Rx FIFO contains 8 such packets. Similarly, if BIT_LEN is 07h, the packet length is 8. If BIT_LEN is 0Fh, the packet length is 16. If BIT_LEN is 1Fh, the packet length is 32. In Packed Mode, if BIT_LEN is set to 03h and if the number of packets is set to a non-multiple of 4 (for example, 5), the last word in FIFO contains only the fifth packet with 4 valid bits; 28 extra invalid bits will be ignored by the controller for transmits and will contain invalid data for receives.
- Unpacked Mode: If BIT_LEN is set to 03h, then each word in the Tx/Rx FIFO has 4 bits with the remaining bits in each word being ignored. BIT_LEN can be any value from 3 to 31 in Unpacked Mode.

37.1.2.4 Bidirectional Mode

Bidirectional mode is selected when the BIDIR bit is set in the SPI Command1 Register. In this mode, the SPI controller uses only one serial data pin for the interface with external device(s). The M/S bit decides which pin to use. The MOSI pin becomes the serial data I/O (MOMI) pin for the Master Mode, and the MISO pin becomes serial data I/O (SISO) pin for the Slave Mode. The SPI controller does not use the MISO pin in Master Mode and the MOSI pin in Slave Mode.

Table 126: Bidirectional Mode Port Configuration for Master (M/S Bit Set)

Name	Direction	Description
MOSI > MOMI	Bidirectional	Data Output and Input to Slave(s)
MISO > --	--	--
SCLK	Output	Synchronization clock to all Slaves
CS	Output	Slave select signal to x, where x is a number from 0 to 3, inclusive

Table 127: Bidirectional Mode Port Configuration for Slave (M/S Bit Cleared)

Name	Direction	Description
MOSI > --	--	--
MISO > SISO	Bidirectional	Data Output and Input from Slave(s)
SCLK	Input	Synchronization clock
CS	Input	Select signal

37.1.2.5 Both Enable Byte and Bit Modes (SPI x2 Mode)

The Both Enable Byte Mode is selected when the BOTH_EN_BYTE bit is set in the SPI Command1 Register. In this mode, the SPI controller uses both data pins only for transmitting or only for receiving. When the BOTH_EN_BYTE register field is set to 1, the Tx and Rx bits decide whether to transmit or receive. When the Tx bit is set, the MOSI and MISO pins are used to

transmit serial data from the Tx FIFO and Rx FIFO at the same time. When the Rx bit is set, the MISO and MOSI pins are used to receive serial data onto Tx FIFO and Rx FIFO at the same time.

Table 128: Both Enable Mode Port Configuration for Master (Tx Bit Set)

Name	Direction	Description
MOSI	Output	Data Output to Slave(s)
MISO	Output	Data Output to Slave(s)
SCLK	Output	Synchronization clock to all Slaves
CS_N_OUT	Output	Slave select signal to x, where x is a number from 0 to 3, inclusive

Table 129: Both Enable Mode Port Configuration for Slave (Rx Bit Set)

Name	Direction	Description
MOSI	Input	Data Input from Slave(s)
MISO	Input	Data Input from Slave(s)
SCLK	Input	Synchronization clock
CS_N	Input	Select signal

The Both Enable Bit Mode is selected when the BOTH_EN_BIT bit is set in the SPI Command1 Register. This feature is different from Both Enable Byte as follows: In Both Enable Byte Mode, a packet from the Tx FIFO is transmitted or received on the MOSI data line and a packet from the Rx FIFO is transmitted or received on the MISO data line. In Both Enable Bit Mode, a packet from the Tx FIFO is transmitted or received on both MOSI and MISO data lines. Even bits are transmitted or received on the MOSI data line and odd bits are transmitted or received on the MISO data line. This is the same in both Master and Slave Modes.

> **Note**: BOTH_EN_BYTE and BOTH_EN_BIT should not be set to 1 at the same time. BOTH_EN_BYTE or BOTH_EN_BIT should not be set to 1 when the BIDIR bit is set to 1.

37.1.2.6 LSBi_FE and LSBy_FE Modes

> **Note**: LSBi_FE is referred as En_LE_Bit (Enable Little Endian Bit), and LSBy_FE is referred as En_LE_Byte (Enable Little Endian Byte) for better understanding.

These two bits allow a data packet to be transmitted or received in Little Endian or Big Endian format. Once a data packet is read from the Tx FIFO, it undergoes a two-step pre-processing based on En_LE_Byte and En_LE_Bit.

> Step 1. In this step, En_LE_Byte configures whether a packet has to be arranged internally according to the Little Endian byte format or Big Endian byte format. For example, if a 2-byte packet is written into the FIFO by software as Byte 1,Byte 0, setting En_LE_Byte = 0 makes the SPI controller arrange the packet internally as Byte 0,Byte 1(Big Endian format). If En_LE_Byte = 1, the SPI controller internally arranges the packet as Byte 1,Byte 0 (Little Endian format) before the packet is transmitted.

Step 2. In this step, the output of Step 1 is taken, and data is put on the MOSI/MISO line according to En_LE_Bit. If En_LE_Bit is set to 0, the most significant bit of the output of Step 1 is put on the MOSI/MISO line first. If En_LE_Bit is set to 1, the least significant bit of Step 1 output is put on the MOSI/MISO line.

These steps are illustrated in the following table.

Step 1	**FIFO Packet (MSB - LSB)**	**Byte**	**Output of Step 1**
	Byte 1, Byte 0	0	Byte 0, Byte 1
		1	Byte 1, Byte 0
Step 2	**Output of Step 1**	**Bit**	**Data Transmitted on MOSI (Right-most Bit Sent First)**
	Byte 0, Byte 1	0	Byte 1 (0), Byte 1 (1), …, Byte 0 (6), Byte 0 (7)
	Byte 0, Byte 1	1	Byte 0 (7), Byte 0 (6), …, Byte 1 (1), Byte 1 (0)
	Byte 1, Byte 0	0	Byte 0 (0), Byte 0 (1), …, Byte 1 (6), Byte 1 (7)
	Byte 1, Byte 0	1	Byte 1 (7), Byte 1 (6), …, Byte 0 (1), Byte 0 (0)

Similarly for Receive operations, the first packet received will be internally rearranged first based on En_LE_Bit, then the output of the previous step will be rearranged based on En_LE_Byte before writing the final packet into the Rx FIFO.

The following examples explain the effect of these two bits:

- Unpacked Mode
  - Tx: The following example shows how a 20-bit length packet from the FIFO is transmitted. The right-most bit in Column D in the table below is transmitted first. B.7-B.0 indicates that bit 0 is transmitted first followed by bit 1 until bit 7, which is transmitted last.

A	B	C	D
FIFO WORD : 20 (MSB) - 0 (LSB)	**LSBi_FE**	**LSBy_FE**	**Data Tx'ed on MOSI/MISO Line**
	0	0	16, 17, 18, 19, 20, B.8-B-15, B.0 - B.7
	0	1	B.0 - B.7, B.8 - B-15, 16, 17, 18, 19, 20
	1	0	B.7 - B.0, B.15 - B-8, 20, 19, 18, 17, 16
	1	1	B.20 - B.0

  - Rx: The following example shows how a 20-bit length packet from the FIFO is received. The right-most bit in Column D in the table below is received last on the MOSI/MISO lines. B.7-B.0 indicates that bit 7 is received first followed by bit 6 until bit 0, which is received last. B.20 – B.0 are always written into the FIFO after the En_LE_Byte and En_LE_Bit transformations.

A	B	C	D
FIFO WORD : 20 (MSB) - 0 (LSB)	**LSBi_FE**	**LSBy_FE**	**Data Rx'ed on MOSI/MISO Line**
	0	0	B.7 - B.0, B.15 - B.8, 20, 19, 18, 17, 16
	0	1	20, 19, 18, 17, 16, B.15 - B.8, B.7 - B.0
	1	0	16, 17, 18, 19, 20, B.8 - B.15, B.0 - B7
	1	1	B.0 - B.20

- Packed Mode
  - Tx: The following example shows how 3 16-bit packets are transmitted. Column B indicates the valid packets to be transmitted. Because FIFO Word2 is not transmitted entirely, valid packets are only from B.15-

B.0. In Column D, P1(0 -15) indicates Packet1 of Column B is transmitted, B.15 is transmitted first, and B.0 is transmitted last.

A	B : Valid Packets	B	C	D
FIFO WORD1 : 31 (MSB) - 0 (LSB)	**P1(15-0), P0(15-0)**	**LSBi_FE**	**LSBy_FE**	**Data Tx'ed on MOSI/MISO Line**
FIFO WORD2 : 31 (MSB) - 0 (LSB)	**P2(15-0)**	0	0	P2(8-15), P2(0-7), P1(8-15), P1(0-7), P0(8-15), P0(0-7)
		0	1	P2(0-7), P2(8-15), P1(0-7), P1(8-15), P0(0-7), P0(8-15)
		1	0	P2(7-0), P2(15-8), P1(7-0), P1(15-8), P0(7-0), P0(15-8)
		1	1	P2(15-8), P2(7-0), P1(15-8), P1(7-0), P0(15-8), P0(7-0)

- Rx: The following example shows how 3 16-bit packets are received. Column B indicates the valid received packets in the Rx FIFO. In column D, P1(0 -15) indicates Packet1 of Column B is received, B.0 is received first, and B.15 is received last.

A	B : Valid Packets	B	C	D
FIFO WORD1 : 31 (MSB) - 0 (LSB)	**P1(15-0), P0(15-0)**	**LSBi_FE**	**LSBy_FE**	**Data Rx'ed on MOSI/MISO Line**
FIFO WORD2 : 31 (MSB) - 0 (LSB)	**P2(15-0)**	0	0	P0(7-0), P0(15-8), P1(7-0), P1(15-8), P2(7-0), P2(15-8)
		0	1	P0(15-8), P0(7-0), P1(15-8), P1(7-0), P2(15-8), P2(7-0)
		1	0	P0(8-15), P0(0-7), P1(8-15), P1(0-7), P2(8-15), P2(0-7)
		1	1	P0(15-8), P0(7-0), P1(15-8), P1(7-0), P2(15-8), P2(7-0)

37.2 SPI Programming Guidelines

There are two basic modes of operation: DMA and PIO modes. It is required that software sets up all parameters in the SPI Command1 and Command2 registers, SPI CS Timing 1 and 2 registers, SPI FIFO Control/Status register, SPI DMA Control register, and SPI Block Size register before enabling the PIO bit in any of these modes.

37.2.1 DMA Mode

This mode is enabled by writing 1 to the DMA bit in the SPI DMA Control register. In this mode, the SPI controller transmits or receives the number of packets as indicated by the BLOCK_SIZE field in the SPI Block Size register.

If the PACKED bit is set and BIT_LEN is set to 7, then all FIFO words contain 4 packets to transfer (transmit or receive). Packets will be transferred as per the LSBi_FE and LSBy_FE bit configurations (see the LSBi_FE and LSBy_FE Modes section), with packet 0 in byte 0 of the FIFO and packet 3 in byte 3 of the FIFO.

In Unpacked Mode, if BIT_LEN is set to N, each packet will consist of (N + 1) bits. These bits will be transmitted/received in the Tx_FIFO/Rx_FIFO as per the LSBi_FE and LSBy_FE bit configurations (see the LSBi_FE and LSBy_FE Modes section). Any remaining bits in the FIFO will be ignored by the hardware. The maximum packet length is 32, which can be selected by setting BIT_LEN to 31. In this case, all data bits in the FIFO contain valid packet data.

A DMA request will be generated to APB_DMA in this mode depending on the setting of Tx_TRIG and Rx_TRIG. If transmits are enabled, setting Tx_TRIG to 00 will generate a Tx DMA request whenever the Tx FIFO has one word of space available (if not full). Setting Tx_TRIG to 01 will generate a Tx DMA request whenever the Tx FIFO has 4 words of space available. If receives are enabled, setting Rx_TRIG to 00 will generate an Rx DMA request whenever the Rx FIFO has one word of data available (is not empty). Setting Rx_TRIG to 01 will generate an Rx DMA request whenever the Rx FIFO has 4 words of data available.

37.2.2 PIO Mode

This mode is enabled by writing 1 to the PIO bit in the SPI Command1 register. In this mode, the SPI controller transmits/ receives as many packets as configured by software in the SPI Block Size Register.

PIO Mode has the same features as DMA Mode. The difference between PIO Mode and DMA Mode is that in PIO Modek the maximum number of packets that can be transmitted or received is less than or equal to 64.

37.2.3 Interrupt Generation

The SPI controller generates an interrupt to the processor at the end of a transfer in PIO Mode or when an error is detected (both in PIO and DMA Modes) if the IE.TX or IE.RX bit in the SPI DMA Control register is enabled for transmit and receive modes of operation, respectively.

If IE.TX is enabled during transmits, an interrupt is generated whenever RDY or one of the FIFO status bits in the SPI FIFO Control/Status Register is set by the hardware. During transmits, when the SPI controller is configured as a Slave, if software/APB DMA cannot fill the transmit FIFO fast enough, hardware will set the Tx_FIFO_UNR bit and an underrun condition is generated. If software tries to write to a full Tx FIFO, hardware sets the Tx_FIFO_OVF bit as an indication that software attempted to overflow the Tx FIFO. Hardware makes sure that the overflowing data is never written to the Tx FIFO.

If IE.RX is enabled during receives, an interrupt is generated whenever RDY or one of the status bits in the SPI FIFO Control/Status Register is set by the hardware. During receives, when the SPI controller is configured as a Slave, if software/APB DMA cannot read the receive FIFO fast enough, hardware will set the Rx_FIFO_OVF bit and an overflow condition is generated. However, if software tries to read from an empty Rx FIFO, hardware sets the RXF_UNR bit as an indication that software attempted to underrun the Rx FIFO.

The interrupt can be cleared by writing a 1 to the source of the interrupt. If the interrupt is generated by assertion of RDY, then writing a 1 to the RDY bit clears the interrupt. If the interrupt is generated by assertion of Tx_FIFO_OVF, then writing a 1 to the TXF_OVF bit clears the interrupt. If the interrupt is generated by assertion of Rx_FIFO_UNR, then writing a 1 to RXF_UNR bit clears the interrupt.

> **Guideline for Automotive use cases**: In DMA Mode, if interrupts are enabled, the SPI software driver has to deal with 3 interrupts: one from the SPI controller and two from the Tx and Rx APB DMA channels. This might make it complicated for the driver and also stresses the system. In such cases, software can use the Rx DMA interrupt as the final one at which point all hardware activities can be assumed to be complete. But, in variable transfer lengths (continuous mode), software has to rely on the controller's interrupts.

37.2.4 Clock Initialization and Control

The SPI controller runs at 50 MHz at its interface to external SPI devices. The internal SPI controller clock should run at the same frequency as the outgoing Sclk_Out in Master Mode. In Slave Mode, the internal SPI interface clock frequency has to be 50% greater than the external clock (Sclk_in).

The SPI clock is selected from different clock sources using a generic clock switch module. The clock switch module supports glitch-free switching of clock from one source to another. There are 4 clock sources:

- osc_clk
- pllP_out
- pllC_out
- pllM_out0

The selected clock is divided by an 8-bit value written in the divider register. The clock is then trimmed, and gated branches are generated for the SPI instances.

The CLK_RST_CONTROLLER_CLK_OUT_ENB_H_0, CLK_RST_CONTROLLER_CLK_OUT_ENB_V_0, and CLK_RST_CONTROLLER_CLK_OUT_ENB_U_0 registers in the CAR (Clock and Reset) block contain the enable bits for the SPI controller. In addition, the clock source and divider registers (CLK_SOURCE_SBC1, CLK_SOURCE_SBC2, CLK_SOURCE_SBC3, CLK_SOURCE_SBC4, CLK_SOURCE_SBC5, and CLK_SOURCE_SBC6) contain the 2-bit field SBCx_CLK_SRC to determine the PLL clock source, while the SBCx_CLK_DIVISOR field determines the divide ratio.

See the Clock and Reset Controller section for more information on clock configuration.

Controller Reset

The SPI controller can be reset by writing 1 to SPI1 (bit 11) in the RST_DEVICES.H (0x6000:6008) register. Software needs to write a 0 to this bit to bring the SPI controller out of reset.

See the Clock and Reset Controller section for more information on SPI controller reset.

Slave Mode GPIO Synchronization

Because SPI does not support flow control, the GPIO is required to have the proper communication to avoid any clock loss from the Master. GPIO can be used in the following way for proper synchronization:

- SPI slave client software will write to the Config registers of the SPI controller and make the SPI slave ready.
- After that the slave client software will toggle GPIO to inform the Master that the Slave is ready.
- Then the SPI master sends SCLK to the slave device.

If there is no GPIO to tell the Master that the Slave is ready, there is a chance to lose clock/data.

Guidelines

This section provides guidelines for programming the SPI controller:

- First program all the required register fields (no particular order is required except for the PIO/DMA bit, which has to be programmed last):
  - Clock Mode
  - Packed/Unpacked Mode
  - Tx_EN/Rx_EN
  - BOTH_EN_BYTE/BOTH_EN_BIT
  - LSBi_FE/LSBy_FE
  - BIT_LEN and BLOCK_SIZE values
  - CS_SW_HW (software based or hardware based)
    - If CS_SW_HW is set, the value on CS_SW_VAL will be driven out.
    - When CS HW is used program the Setup & Hold Values in CS Timing Register.
  - Program the DMA Trig values appropriately, if DMA Mode is used
  - Enable interrupts if PIO Mode is used
- Lastly, program PIO or DMA to indicate the start of transfer.

Once software enables PIO/DMA, no required bits can be changed until the end of transfer except for PIO/DMA bit. Clearing the PIO/DMA bit will end the transaction. In case the SPI controller is configured to Receive Mode and software clears the PIO/DMA bit, then the partial data which the controller received until then will be written into the FIFO. This is true both for Master and Slave.

Do not enable conflicting features. For example, avoid enabling BOTH_EN_BIT (or) BOTH_EN_BYTE along with bidirectional (BIDIR) mode.

In Slave Mode after PIO or DMA is set, hardware first waits for the CS to go low by one of the 4 Masters. Then on reception of Sclk, transfer begins. If CS or Sclk is removed by the Master in the middle of a transfer, software must terminate the transaction by clearing the PIO/DMA bit. In case of Rx, hardware then writes the last received packet (incomplete packet) to the Rx FIFO. If software does not clear the PIO/DMA bit, the SPI controller will just keep waiting for the Sclk from the Master. If Sclk resumes later, the transaction continues from where it paused earlier.

If any error conditions occur, hardware will set the corresponding status bits in the SPI FIFO Control/Status register and stop the transfer. If IE is enabled, an interrupt is generated. Software has to clear the source of the interrupt by writing a 1 to it, after the completion of ISR.

Error Conditions

When the SPI controller is configured as a Master, the following error scenarios can happen:

- Tx_FIFO overflow

  Tx_FIFO overflow happens when the CPU/APB_DMA writes into the Tx FIFO when it is full. In this case, the SPI controller will end the transaction by setting the PIO/DMA_EN bit to 0, and flag the error bit along with the Tx_FIFO_OVF bit in the SPI FIFO Control/Status register. The SPI controller will generate an interrupt if interrupts are enabled. Software has to clear the error bit and the Tx_FIFO_OVF bit. To start a new transaction, software has to flush the FIFOs by writing to the TX_FIFO_FLUSH/RX_FIFO_FLUSH bits in the SPI FIFO Control/Status register.
- Rx_FIFO overflow

  Rx_FIFO overflow happens when the CPU/APB_DMA writes into the Rx FIFO when it is full in BOTH_EN Mode. In this case, the SPI controller will end the transaction by setting the PIO/DMA_EN bit to 0, and flag the error bit along with Rx_FIFO_OVF bit in the SPI FIFO Control/Status register. The SPI controller will generate an interrupt if interrupts are enabled. Software has to clear the error bit and the Rx_FIFO_OVF bit. To start a new transaction, software has to flush the FIFOs by writing to the TX_FIFO_FLUSH/RX_FIFO_FLUSH bits in the SPI FIFO Control/Status register.
- Tx_FIFO underrun

  Tx_FIFO underrun happens when the CPU/APB_DMA reads from the Tx FIFO when it is empty. In this case, the SPI controller will end the transaction by setting the PIO/DMA_EN bit to 0, and flag the error bit along with the Tx_FIFO_UNR bit in the SPI FIFO Control/Status register. The SPI controller will generate an interrupt if interrupts are enabled. Software has to clear the error bit and the Tx_FIFO_UNR bit. To start a new transaction, software has to flush the FIFOs by writing to the TX_FIFO_FLUSH/RX_FIFO_FLUSH bits in the SPI FIFO Control/Status register.
- Rx_FIFO underrun

  Rx_FIFO underrun happens when the CPU/APB_DMA reads from the Rx FIFO in BOTH_EN Mode. In this case, the SPI controller will end the transaction by setting the PIO/DMA_EN bit to 0, and flag the error bit along with the Rx_FIFO_UNR bit in the SPI FIFO Control/Status register. The SPI controller will generate an interrupt if interrupts are enabled. Software has to clear the error bit and the Rx_FIFO_UNR bit, along with the Interrupt bit. To start a new transaction, software has to flush the FIFOs by writing to the TX_FIFO_FLUSH/RX_FIFO_FLUSH bits in the SPI FIFO Control/Status register.

  > **Note**: In Master Mode, all the errors above can happen only when the CPU/APB_DMA reads/writes an empty/full FIFO. The SPI controller will never write/read a full/empty FIFO. Instead the controller will pause (stops sending clocks to the slave with chip select being in an active state) whenever the FIFOs are full/empty.

When the SPI controller is configured as a Slave, the following error scenarios can happen:

- Tx_FIFO overflow

  Tx_FIFO overflow happens when the CPU/APB_DMA or the SPI controller writes into the Tx FIFO when it is full. In this case, the SPI controller will end the transaction by setting the PIO/DMA_EN bit to 0, and flag the error bit along with Tx_FIFO_OVF bit in the status register. The SPI controller will generate an interrupt if interrupts are enabled. Software has to clear the error bit and Tx_FIFO_OVF bit. To start a new transaction, software has to disable the Master from sending clocks and then flush the FIFOs by writing to the TX_FIFO_FLUSH/RX_FIFO_FLUSH bits in the SPI FIFO Control/Status register.

- Rx_FIFO overflow

  Rx_FIFO overflow happens when the CPU/APB_DMA or the SPI controller writes into Rx FIFO when it is full in BOTH_EN Mode. In this case, the SPI controller will end the transaction by setting the PIO/DMA_EN bit to 0, and flag the error bit along with Rx_FIFO_OVF bit in the status register. The SPI controller will generate an interrupt if interrupts are enabled. Software has to clear the error bit and Rx_FIFO_OVF bit along with the Interrupt bit. To start a new transaction, software has to disable the Master from sending clocks and flush the FIFOs by writing to the TX_FIFO_FLUSH/RX_FIFO_FLUSH bits in the SPI FIFO Control/Status register.

- Tx_FIFO underrun

  Tx_FIFO underrun happens when the CPU/APB_DMA or the SPI controller reads from Tx FIFO when it is empty. In this case, the SPI controller will end the transaction by setting the PIO/DMA_EN bit to 0, and flag the error bit along with the TX_FIFO_UNR bit in the SPI FIFO Control/Status register. The SPI controller will generate an interrupt if interrupts are enabled. Software has to clear the error bit and TX_FIFO_UNR bit along with the Interrupt bit. To start a new transaction, software has to disable the Master from sending clocks and flush the FIFOs by writing to the TX_FIFO_FLUSH/RX_FIFO_FLUSH bits in the SPI FIFO Control/Status register.

- Rx_FIFO underrun

  Rx_FIFO underrun happens when the CPU/APB_DMA or the SPI controller reads from the Rx FIFO in BOTH_EN Mode. In this case, the SPI controller will end the transaction by setting the PIO/DMA_EN bit to 0, and flag the error bit along with the RX_FIFO_UNR bit in the SPI FIFO Control/Status register. The SPI controller will generate an interrupt if interrupts are enabled. Software has to clear the error bit and RX_FIFO_UNR bit along with the Interrupt bit. To start a new transaction, software has to disable the Master from sending clocks and flush the FIFOs by writing to the TX_FIFO_FLUSH/RX_FIFO_FLUSH bits in the SPI FIFO Control/Status register.

- CS_inactive

  When the SPI controller is configured as a Slave and cs_active between packets is set, if an external Master deasserts the chip select in the middle of a transaction, the SPI controller will end the transaction by setting the PIO/DMA_EN bit to 0, and sets the CS_INACTIVE bit in the SPI FIFO Control/Status register. The SPI controller will generate an interrupt if interrupts are enabled. Software has to clear the CS_INACTIVE bit. To start a new transaction, software has to disable the Master from sending clocks and flush the FIFOs by writing to the TX_FIFO_FLUSH/RX_FIFO_FLUSH bits in the SPI FIFO Control/Status register.

- Frame_End

  When the SPI controller is configured as a Slave and DMA-continuous and cs_active between packets is set, if an external Master stops sending clocks for more than slave_idle_clock_count programmed in the register, the SPI controller will end the transaction by setting the DMA bit to 0, and sets the FRAME_END bit in the SPI FIFO Control/Status register. The SPI controller will generate an interrupt if interrupts are enabled. Software has to clear the FRAME_END bit along with the Interrupt bit. To start a new transaction, software has to disable the Master from sending clocks and flush the FIFOs by writing to the TX_FIFO_FLUSH/RX_FIFO_FLUSH bits in the SPI FIFO Control/Status register. If the Master resumes the clk within “slave_idle_clock_count”, the SPI controller will also pause and resume the transaction whenever ext_clk is available.

Programming Trimmers

The 3 programmable trimmers in the SPI controller are used only in Master Mode:

- SPI-Tx trimmer

  This trimmer is used in Master Tx mode to adjust/center the outgoing data with respect to the outgoing clock.

- SPI-Rx trimmer

  This trimmer is used in Master Rx mode to delay the loopback clock to the Rx shift registers. This trimmer is used to adjust the Master SCLK with respect to the SPI slave device’s Tx data.

- SPI-Spare Control Register Byte1

This 3-bit trimmer controls the internal timing of the Master mode Rx datapath. This trimmer along with the SPI Rx trimmer may be set independently to adjust the loopback clock delay. This trimmer adjusts the programmable delay on the u_spi_slave_rx* flops in inbound paths. These are half cycle paths, and delays have been added to increase Setup margin on these paths.

- The SPI controller has a programmable delay chain with a 3-tap delay chain. The 3 taps use 100D, 100D, and 60D and are programmed as follows:
  - 000: Bypass through each mux: will see 3 muxes in path
  - 001: 60D
  - 010: 100D
  - 100: 100D
  - 011: 60D + 100D
  - 110: 100D + 100D
  - 101: 100D+60D
  - 111: 100D+100D+60D
- Spare cells used as control for these delay taps:
  - (u_spi1_shift_padmacro/spi_spare_control_byte1_in_reg_2_,
  - u_spi1_shift_padmacro/spi_spare_control_byte1_in_reg_1_,
  - u_spi1_shift_padmacro/spi_spare_control_byte1_in_reg_0_)

37.3 SPI Controller Registers

Refer to “Reading Register Tables” in the Introduction section for the register table protocol as well as recommendations for accessing registers.

There are six sets of the SPI controller registers, one for each of the six SPI controllers.

37.3.1 SPI_COMMAND1

SPI Command1 Register

This register is used to set the bit length and to select the transfer mode.

Chip Select can also be selected to be in hardware mode as software mode with both active high and active low polarities to support devices with varying CS polarities.

Offset: 0x0 │ Read/Write: R/W │ Reset: 0x43d00000 (0b01000011110100000000000xxxxx000000)

Bit	Reset	Description
31	0x0	PIO: Program 1 after all the other bits in the SPI_COMMAND2 and SPI_COMMAND1 registers are programmed to start the transfer. Hardware clears this bit automatically after the transfer is done. Clearing of this bit by software will stop the shifter and latch the partial data into the buffer (in Receive Mode). 0 = STOP (default) 1 = GO
30	0x1	M/S: Master/Slave mode select. 0 = Slave Mode (external clock) 1 = Master Mode (internal clock) (default)
29:28	0x0	MODE: The SPI interface clock mode has to be programmed according to the device with which it is communicating. 0 = Mode 0 (default) 1 = Mode 1 2 = Mode 2

Bit	Reset	Description
		3 = Mode 3 Master: All modes are supported both for Tx and Rx. Slave: Modes 1and 3 are supported for Tx Slave: All modes are supported for Rx.
27:26	0x0	CS_SEL: In Master Mode, these bits are programmed to select a slave in the multi-slave environment. 0 = Selects CS0 (default) 1 = Selects CS1 2 = Selects CS2 3 = Selects CS3
25	0x1	CS_POL_INACTIVE#3: In Master or Slave Mode, the inactive value of the external device's cs value, which is connected to CS3, needs to be programmed. 1 = CS3 Inactive value of External device is high, 0 = CS3 Inactive value of External device is low 0 = LOW 1 = HIGH (default)
24	0x1	CS_POL_INACTIVE#2: In Master or Slave Mode, the inactive value of the external device's cs value, which is connected to CS2, needs to be programmed, 1 = CS2 Inactive value of External device is high, 0 = CS2 Inactive value of External device is low 0 = LOW 1 = HIGH (default)
23	0x1	CS_POL_INACTIVE#1: In Master or Slave Mode, the inactive value of the external device's cs value, which is connected to CS1, needs to be programmed. 1 = CS1 Inactive value of External device is high, 0 = CS1 Inactive value of External device is low 0 = LOW 1 = HIGH (default)
22	0x1	CS_POL_INACTIVE#0: In Master or Slave Mode, the inactive value of the external device's cs value, which is connected to CS0, needs to be programmed. 1 = CS0 Inactive value of External device is high, 0 = CS0 Inactive value of External device is low 0 = LOW 1 = HIGH (default)
21	0x0	CS_SW_HW: Software control of the SPI_CS signal in Master Mode. In Slave Mode, this bit need not be programmed. 1 = CS controlled by software; 0 = CS controlled by hardware 0 = SPI _CS#(CS_SEL) is driven to the active state during packet transfers by the hardware (default) 1 = SPI _CS#(CS_SEL) is driven with the value in the CS_SW_VAL bit
20	0x1	CS_SW_VAL: CS signal value in Master Mode. In Slave Mode, this bit need not be programmed. If CS_SW_HW is 1, then the value in CS_SW_VAL is driven out on CS. If CS_SW_HW is 0, then this bit has no effect. 0 = CS is LOW 1 = CS is HIGH (default)
19:18	0x0	IDLE.SDA: Inactive data signal format. Controls the output enable of the SDA line when the controller is inactive and not doing data transfers. 0 = Drive low. (Master Mode) (default) 1 = Drive high. (Master Mode) 2 = External Pull Down. (Slave Mode) 3 = External Pull high. (Slave Mode)
17	0x0	BIDIR: Bidirectional Transfer Control Bit: This bit enables the bidirectional mode of the transfer. 0 = Normal Mode (default) 1 = Bidirectional Mode
16	0x0	LSBi_FE: Least Significant Bit First Enable. This bit works in combination with the LSBy_FE bit. Refer to the LSBi_FE and LSBy_FE Modes section for the encodings. The default is 0.
15	0x0	LSBy_FE: Least Significant Byte First Enable. This bit works in combination with the LSBi_FE bit. Refer to the LSBi_FE and LSBy_FE Modes section for the encodings. The default is 0.
14	0x0	BOTH_EN_BIT (x2 Mode): Both MISO and MOSI can also be used to transmit or receive at the same time when this bit is set. Even bits from the Tx FIFO packet are

Bit	Reset	Description
		transmitted/received on MOSI, and Odd bits from the Tx FIFO packet are transmitted/received on MISO. Refer to the Both Enable Byte and Bit Modes (SPI x2 Mode) section for more information. 0 = Normal Mode (default) 1 = Transmit/Receive on both MISO and MOSI at the same time when the Tx_EN and Rx_EN bits are set
13	0x0	BOTH_EN_BYTE (x2 Mode): The 2 FIFOs can also be used to transmit or receive at the same time when this bit is set. Refer to the Both Enable Byte and Bit Modes (SPI x2 Mode) section for more information. **Note**: the BIDIR bit has to be 0 before this bit is set. 0 = Normal Mode (default) 1 = Transmit/Receive on both MISO and MOSI at the same time when the Tx_EN and Rx_EN bits are set
12	0x0	Rx_EN: Receive enable. Setting this bit to 1 enables the controller to receive the data. 0 = DISABLE (default) 1 = ENABLE
11	0x0	Tx_EN: Transmit enable. Setting this bit to 1 enables the controller to transmit the data. 0 = DISABLE (default) 1 = ENABLE
10:6	N/A	Reserved for future use. Always write zeros.
5	0x0	PACKED: Packed mode enable bit.. 0 = Unpacked Mode (default) 1 = Packed Mode. This is only valid if the BIT_LEN field is set to either 3 (4-bit transfer), 7 (8-bit transfer), 15 (16-bit transfer), or 31 (32-bit transfer).
4:0	0x0	BIT_LEN: This field is used during PIO and DMA transfers. It represents the number of bits transmitted/received in either Packed or Unpacked Mode. The minimum bit length in Master Mode is 4 and the minimum length in Slave Mode is 1 byte (BIT_LEN = 7). The default is 0. 3 = 4-bit transfer N = N+1-bit transfer 31 = 32-bit transfer

37.3.2 SPI_COMMAND2

SPI Command2 Register

Offset: 0x4 │ Read/Write: R/W │ Reset: 0x00000000 (0bxxxxxxxxxxxxxxxxxxxxx000000000000)

Bit	Reset	Description
31:12	N/A	Reserved for future use. Always write zeros.
11:6	0x0	Tx_Clk_TAP_DELAY: Delays the clock going out to the external device with these tap values. Useful only in Master Mode. The default is 0.
5:0	0x0	Rx_Clk_TAP_DELAY: Delays the clock coming in from the external device with these tap values. Useful only in Master Mode. The default is 0. In Slave Mode, this value should always be 0.

37.3.3 SPI_CS_TIM1

SPI CS Timing1 Register

Offset: 0x8 │ Read/Write: R/W │ Reset: 0x00000000 (0b00000000000000000000000000000000)

Bit	Reset	Description
31:28	0x0	CS_SETUP_TIME#3: Specifies the setup time of the chip select to the data being transmitted or received on CS#3 in numbers of cycles (16 cycles maximum). The default is 0.

Bit	Reset	Description
		1 = 2 clock cycle delay 2 = 3 clock cycle delay, etc.
27:24	0x0	CS_HOLD_ TIME#3: Specifies the hold time of the chip select to the data being transmitted or received on CS#3 in numbers of cycles (16 cycles maximum). The default is 0. 1 = 2 clock cycle delay 2 = 3 clock cycle delay, etc.
23:20	0x0	CS_SETUP_ TIME#2: Specifies the setup time of the chip select to the data being transmitted or received on CS#2 in numbers of cycles (16 cycles maximum). The default is 0. 1 = 2 clock cycle delay 2 = 3 clock cycle delay, etc.
19:16	0x0	CS_HOLD_ TIME#2: Specifies the hold time of the chip select to the data being transmitted or received on CS#2 in numbers of cycles (16 cycles maximum). The default is 0. 1 = 2 clock cycle delay 2 = 3 clock cycle delay, etc.
15:12	0x0	CS_SETUP_ TIME#1: Specifies the setup time of the chip select to the data being transmitted or received on CS#1 in numbers of cycles (16 cycles maximum). The default is 0. 1 = 2 clock cycle delay 2 = 3 clock cycle delay, etc.
11:8	0x0	CS_HOLD_ TIME#1: Specifies the hold time of the chip select to the data being transmitted or received on CS#1 in numbers of cycles (16 cycles maximum). The default is 0. 1 = 2 clock cycle delay 2 = 3 clock cycle delay, etc.
7:4	0x0	CS_SETUP_ TIME#0: Specifies the setup time of the chip select to the data being transmitted or received on CS#0 in numbers of cycles (16 cycles maximum). The default is 0. 1 = 2 clock cycle delay 2 = 3 clock cycle delay, etc.
3:0	0x0	CS_HOLD_ TIME#0: Specifies the hold time of the chip select to the data being transmitted or received on CS#0 in numbers of cycles (16 cycles maximum). The default is 0. 1 = 2 clock cycle delay 2 = 3 clock cycle delay, etc.

37.3.4 SPI_CS_TIM2

SPI CS Timing2 Register

Offset: 0xc │ Read/Write: R/W │ Reset: 0x20202020 (0bxx100000xx100000xx100000xx100000)

Bit	Reset	Description
31:30	N/A	Reserved for future use. Always write zeros.
29	0x1	CS_ACTIVE_BETWEEN_PACKETS#3: Specifies if CS stays active between two packets on CS#3 1 = CS active between two packets (default) 0 = CS inactive between two packets
28:24	0x0	CYCLES_BETWEEN_PACKETS#3: Specifies the number of cycles between two packets in the PIO/DMA Mode for communication on CS#3. The default is 0. 1 = 2 clock cycle delay 2 = 3 clock cycle delay, etc.
23:22	N/A	Reserved for future use. Always write zeros.

Bit	Reset	Description
21	0x1	CS_ACTIVE_BETWEEN_PACKETS#2: Specifies if CS stays active between two packets on CS#2 1 = CS active between two packets (default) 0 = CS inactive between two packets
20:16	0x0	CYCLES_BETWEEN_PACKETS#2: Specifies the number of cycles between two packets in the PIO/DMA Mode for communication on CS#2. The default is 0. 1 = 2 clock cycle delay 2 = 3 clock cycle delay, etc.
15:14	N/A	Reserved for future use. Always write zeros.
13	0x1	CS_ACTIVE_BETWEEN_PACKETS#1: Specifies if CS stays active between two packets on CS#1 1 = CS active between two packets (default) 0 = CS inactive between two packets
12:8	0x0	CYCLES_BETWEEN_PACKETS#1: Specifies the number of cycles between two packets in the PIO/DMA Mode for communication on CS#1. The default is 0. 1 = 2 clock cycle delay 2 = 3 clock cycle delay, etc.
7:6	N/A	Reserved for future use. Always write zeros.
5	0x1	CS_ACTIVE_BETWEEN_PACKETS#0: Specifies if CS stays active between two packets on CS#0 1 = CS active between two packets (default) 0 = CS inactive between two packets
4:0	0x0	CYCLES_BETWEEN_PACKETS#0: Specifies the number of cycles between two packets in the PIO/DMA Mode for communication on CS#0. The default is 0. 1 = 2 clock cycle delay 2 = 3 clock cycle delay, etc.

37.3.5 SPI_TRANS_STATUS

SPI TRANSFER Status Register

Read this register for the status of the transfer.

Offset: 0x10 │ Read/Write: R/W │ Reset: 0x00ff0000 (0bx0xxxxx11111111xxxxxxxxxxxxxxx)

Bit	R/W	Reset	Description
31	N/A		Reserved for future use. Always write zeros.
30	RW	0x0	RDY: Ready bit. This bit is set to 1 at the end of every transfer, and an interrupt is also generated if the corresponding interrupt enable is set in PIO/DMA Mode. Software writes a 1 to clear it. The interrupt is also cleared when this bit is cleared. 0 = NOT_READY (default) 1 = READY
29:24	N/A		Reserved for future use. Always write zeros.
23:16	RW	0xff	SLV_IDLE_COUNT: Slave Continuous Mode. If Sclk is not received for this number of cycles, then Slave Continuous mode is terminated, and the status bit FRAME_END is set. The default is 255 (8'hff).
15:0	RO	X	BLOCK_COUNT: Counts the number of packets in a transaction (Tx or Rx) in DMA/PIO Mode. In DMA Continuous Mode, this field gives the number of packets only if the number of packet is less than 2^{16}.

37.3.6 SPI_FIFO_STATUS

SPI Control/Status FIFO Status Register

SPI STATUS register: Read this register to know the status of the transfer. Error bit is set whenever we encounter Errors such as Underflow/Overflow

Offset: 0x14 | Read/Write: R/W | Reset: 0x00400005 (0b00xxxxxxxxxxxxxx00xxxxx00000xxxx)

Bit	R/W	Reset	Description
31	RW	0x0	CS_INACTIVE: When the SPI is in Slave Mode, if CS is deasserted, this bit is set to indicate an error and the received number of bits is written in the Rx FIFO. An interrupt is generated if IE.Tx or IE.Rx is set. The default is 0.
30	RW	0x0	FRAME_END: When the SPI is in Slave Continuous mode, if Sclk is not received for the number of clocks specified in the SLV_IDLE_COUNT field, the continuous mode is terminated and this status bit is set. The default is 0.
29:23	RO	X	RX_FIFO_FULL_COUNT: Indicates the number of slots in the receive FIFO remaining before the FIFO is empty. This field is used by software for debugging purposes.
22:16	RO	X	TX_FIFO_EMPTY_COUNT: Indicates the number of slots in the transmit FIFO remaining before the FIFO is full. This field is used by software for debugging purposes.
15	RW	0x0	RX_FIFO_FLUSH: Software writes a 1 to this bit to flush the Rx FIFO. This bit reads as 1 when the flush operation is in progress and returns to 0 when it is finished. 0 = NOP (default) 1 = FLUSH
14	RW	0x0	TX_FIFO_FLUSH: Software writes a 1 to this bit to flush the Tx FIFO. This bit reads as 1 when the flush operation is in progress and returns to 0 when it is finished. 0 = NOP (default) 1 = FLUSH
13:9	N/A		Reserved for future use. Always write zeros.
8	RW	0x0	ERR: Will be set to 1 by hardware when errors such as underflow/overflow occur. Software writes a 1 to clear the flag. 0 = OK (default) 1 = ERROR
7	RW	0x0	TX_FIFO_OVF: TX FIFO Overflow. This bit is set to 1 whenever the SPI controller or software tries to write to a full Tx FIFO. An interrupt is generated if the interrupt enable is set for transmit operations (IE.TX in the SPI_DMA_CTL register). Software writes a 1 to clear this bit. 0 = OK (default) 1 = ERROR
6	RW	0x0	TX_FIFO_UNR: TX FIFO Underrun. This bit is set to 1 whenever the SPI controller or software tries to read from an empty Tx FIFO. An interrupt is generated if the interrupt enable is set for transmit operations (IE.TXC in the SPI_DMA_CTL register). Software writes a 1 to clear this bit. 0 = OK (default) 1 = ERROR
5	RW	0x0	RX_FIFO_OVF: RX FIFO Overflow. This bit is set to 1 whenever the SPI controller or software tries to write into a full Rx FIFO. An interrupt is generated if the interrupt enable is set for receive operations (IE.RXC in the SPI_DMA_CTL register). Software writes a 1 to clear this bit. 0 = OK (default) 1 = ERROR
4	RW	0x0	RX_FIFO_UNR: RX FIFO Underrun. This bit is set to1 whenever the SPI controller or software tries to read from an empty Rx FIFO. An interrupt is generated if the interrupt enable is set for receive operations (IE.RXC in the SPI_DMA_CTL register). Software writes a 1 to clear this bit. 0 = OK (default) 1 = ERROR

Bit	R/W	Reset	Description
3	RO	X	TX_FIFO_FULL: TX FIFO Full Status. Hardware sets this bit to 1 if the Tx FIFO is full; otherwise this bit is 0. The Tx FIFO is empty at power on reset (POR). 0 = NOT_FULL (default) 1 = FULL
2	RO	X	TX_FIFO_EMPTY: TX FIFO Empty Status. Hardware sets this bit to 1 if the Tx FIFO is empty; otherwise this bit is 0. The Tx FIFO is empty at POR. 0 = NOT_EMPTY 1 = EMPTY (default)
1	RO	X	RX_FIFO_FULL: RX FIFO Full Status. Hardware sets this bit to 1 if the Rx FIFO is full; otherwise this bit is 0. The Rx FIFO is empty at POR. 0 = NOT_FULL (default) 1 = FULL
0	RO	X	RX_FIFO_EMPTY: RX FIFO Empty Status. Hardware sets this bit to 1 if the Rx FIFO is empty; otherwise this bit is 0. The Rx FIFO is empty at POR. 0 = NOT_EMPTY 1 = EMPTY (default)

37.3.7 SPI_TX_DATA

SPI Transmit Data Register

Offset: 0x18 │ Read/Write: RO │ Reset: 0x00000000 (0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx)

Bit	Reset	Description
31:0	X	SPI_Tx_DATA. Transmit Data. This register holds the last data that was transmitted by the SPI controller.

37.3.8 SPI_RX_DATA

SPI Receive Data Register

Offset: 0x1c │ Read/Write: RO │ Reset: 0x00000000 (0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx)

Bit	Reset	Description
31:0	X	SPI_Rx_DATA. Receive Data. This register holds the last data that was received by the SPI controller.

37.3.9 SPI_DMA_CTL

SPI DMA Control Register

SPI DMA Control Register: Used in the DMA transfers. We can set trigger levels in this register

Offset: 0x20 │ Read/Write: R/W │ Reset: 0x00000000 (0b0000xxxxxxx00xx00xxxxxxxxxxxxxxx)

Bit	Reset	Description
31	0x0	DMA: Enable DMA Mode transfer. Software writes a 1 to this bit to start a transfer in the DMA mode. All fields in the SPI_COMMAND1 and SPI_DMA_CTL register must be set before writing a 1 to this bit. This bit is cleared by the SPI controller after all packets have been transferred as indicated by the DMA_BLOCK_SIZE field. Clearing this bit by software will stop the shifter and latch the partial data into buffer. 0 = DMA Mode is disabled (default) 1 = DMA Mode is enabled
30	0x0	CONT: Enable Continuous Mode transfer. 0 = Continuous Mode is disabled (default) 1 = Continuous Mode is enabled

Bit	Reset	Description
29	0x0	IE.RX: Interrupt enable on receive completion. 0 = Disable interrupt generation for receives (default) 1 = Enable interrupt generation at the end of a receive transfer
28	0x0	IE.TX: Interrupt enable on transmit completion. 0 = Disable interrupt generation for transmits (default) 1 = Enable interrupt generation at the end of a transmit transfer
27:21	N/A	Reserved for future use. Always write zeros.
20:19	0x0	RX_TRIG: Receive FIFO trigger level. 00: 1 word. DMA trigger is asserted whenever there is at least 1 packet in the RX FIFO. (default) 01: 4 words. DMA trigger is asserted when there are at least 4 packets in the RX FIFO. 10: 8 words. DMA trigger is asserted when there are at least 8 packets in the RX FIFO. 11: 16 words. DMA trigger is asserted when there are at least 16 packets in the RX FIFO. (Presently, the APB DMA does not support this trigger level.)
18:17	N/A	Reserved for future use. Always write zeros.
16:15	0x0	TX_TRIG: Transmit FIFO trigger level. 00: 1 word. DMA trigger is asserted whenever there is space for at least 1 packet in the TX FIFO. (default) 01: 4 words. DMA trigger is asserted when there is space for at least 4 packets in the TX FIFO. 10: 8 words. DMA trigger is asserted when there is space for at least 8 packets in the TX FIFO. 11: 16 words. DMA trigger is asserted when there is space for at least 16 packets in the TX FIFO. (Presently, the APB DMA does not support this trigger level.)

37.3.10 SPI_DMA_BLK

SPI Block Size Register

Offset: 0x24 │ Read/Write: R/W │ Reset: 0x00000000 (0bxxxxxxxxxxxxxxxx0000000000000000)

Bit	Reset	Description
31:16	N/A	Reserved for future use.
15:0	0x0	BLOCK_SIZE: Size of data block to be transferred in PIO/DMA Mode. The default is 0. In DMA Mode, the maximum number of 32-bit packets that can be transferred is 2^{16} = 65536. In PIO Mode, the maximum number of 32-bit packets that can be transferred is 64 (FIFO depth). The Block Size has to be programmed 1 packet lower than intended; for example, a value of 3 indicates 4 packets are to be transferred.

37.3.11 SPI_FIFO1

SPI TX FIFO Register

Offset: 0x108 │ Read/Write: R/W │ Reset: 0x00000000 (0b00000000000000000000000000000000)

Bit	Reset	Description
31:0	0x0	SPI Tx_FIFO. Tx FIFO.

37.3.12 SPI_FIFO2

SPI RX FIFO Register

Offset: 0x188 | Read/Write: R/W | Reset: 0x00000000 (0b00000000000000000000000000000000)

Bit	Reset	Description
31:0	0x0	SPI Rx_FIFO. Rx FIFO.

37.3.13 SPI_SPARE_CTLR

SPI Spare Control Register

Offset: 0x18c | Read/Write: R/W | Reset: 0x00000000 (0b00000000000000000000000000000000)

Bit	Reset	Description
31:11	0x0	Reserved for future use, always write zero.
10:8	0x0	SPI_SPARE_CONTROL_REGISTER_BYTE2. Program these bits with Rx_Clk_TAP_DELAY in the COMMAND2 register to adjust the clock delay on internal registers. Useful in Master Mode only. The default is 0. In Slave Mode, this value should always be 0.
7:0	0x0	Reserved for future use, always write zero.

38.0 ONE WIRE BATTERY CONTROLLER

The One Wire Controller (OWR) implements a device communications bus system that provides low-speed data, signaling, and power over a single signal. The OWR interface uses two wires for this – one for ground and the other for power and data. (However, the ground can be shared with power delivery.)

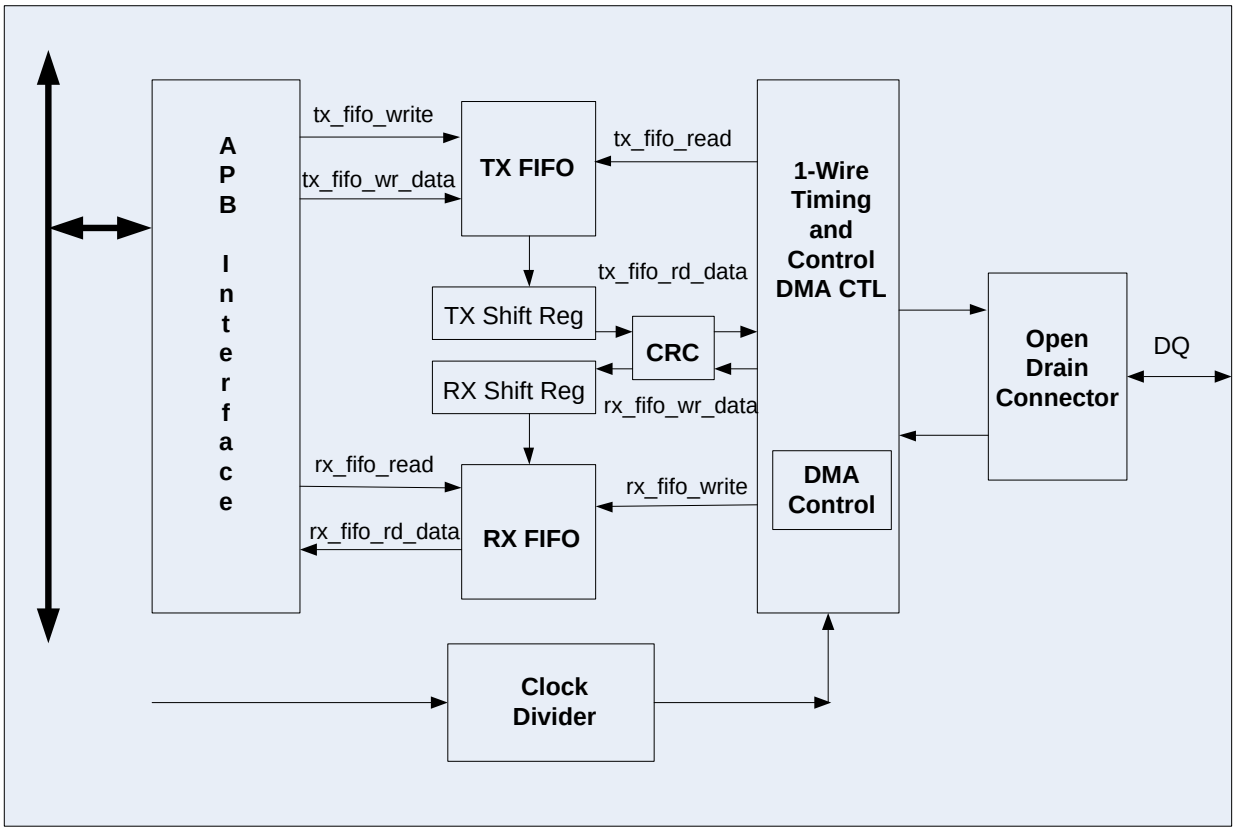
In Tegra® 4 devices, the one-wire protocol is intended to communicate with battery controller chips.

Features

- Independent RX and TX FIFOs
- FIFO depth of 32 x 32 bits
- Hardwired implementation of one-wire protocol to eliminate the need for an external bridge chip
- Software programmable registers
- Software readable status registers
- Receive transmission with interrupt-based operation
- Can run at 1 MHz and higher frequencies; provided timing parameters are programmed
- Deglitch support
- Byte transfers or 1-bit transfers
- Supports the following commands: Read ROM, Skip ROM, Read Memory, Read Status, Read Data/Generate 8-bit CRC, Write Memory, Write Status
- CRC 8-/16-bit implementation support
- Supports different battery devices, up to a memory size of 256K in byte transfer
- Also supports generic devices, such as DS2784. The features supported in DS2784 are:
  - Command
  - Command and Address
  - Command, Address and Write Command
  - Command, Address and Read Command

38.1 Functionality

Figure 157: OWR Block Diagram



Specific command sequences as per the OWR protocol have to be followed for any data transaction over the OWR interface.

The protocol involves first issuing a reset command where the controller looks for a presence from the device, and then issuing ROM commands before the EPROM is accessible, once the presence pulse is received.

The following ROM commands are supported:

- Read ROM (33hex command)
- Skip ROM (CChex command)

When the read ROM command is issued, the controller receives a 64-bit ID from the device. This is an optional command, in case there is only a single slave present. One can directly issue a Skip ROM Command and issue memory commands to access EPROM. When more than one slave is connected, then issue Search ROM and Match ROM commands, to search the particular slave and enable it to interact with the controller implemented using 1-bit mode.

EPROM accessible commands are:

- Read Memory (F0hex command)
- Read Status (AAhex command)
- Read Data/Generate 8 Bit CRC (C3hex command)
- Write Memory (0Fhex command)
- Write Status (55hex command)

Other commands can be used with 1-bit read/write. Contact your NVIDIA FAE for more details.

38.1.1 CRC Generation

To ensure data integrity, the controller has 8-bit and 16-bit CRC calculations. The equivalent polynomial function of this CRC is: $X^8 + X^5 + X^4 + 1$.

The CRC is calculated on the data being received from the device. During a Read Memory command, the software has a provision to enable the CRC check bit where the CRC is calculated on the data received from the device (RD_MEM_CRC_REQ bit in the Control register). When this bit is enabled, after the data is read from the EPROM, the device sends the CRC to the controller .The controller then checks the received CRC against the calculated CRC and sets a crc_error flag in case of mismatch. The CRC can be 8 bits or 16 bits wide depending on the CRC_16BIT_EN bit in the Control register. By programming the BY_PASS_CRC_ERR bit in the Control register, the crc_error is ignored by the controller and continues with the command operation.

For other commands, such as read data CRC, read status, and write memory commands, the CRC checks are done by default as part of the protocol, unlike in read memory where it is optional.

Note: CRC 16-bit is also supported in some battery devices.

38.1.2 OWR Data Transfer Sequence

The OWR protocol consists of five types of data transfer:

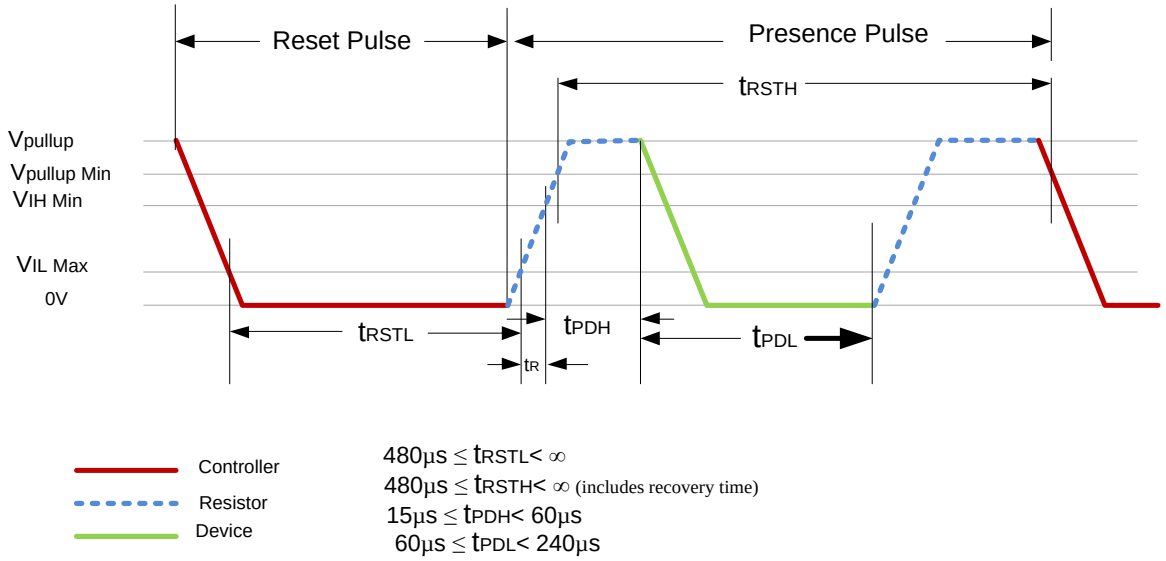
- Reset and presence pulse
- Write 0
- Write 1
- Read Data
- Program Pulse

All data transfers (except presence pulse) are initiated by the controller. The communication should always begin with the initialization sequence, shown in Figure 158 below.

38.1.2.1 Initialization Procedure

To begin any communications on OWR, initialization procedure must be issued. A reset pulse of t_{RSTL} is issued by the controller, and then the controller releases the 1-wire bus, until t_{RSTH} time. After reset pulse, controller detects for rising edge and waits for t_{PDH} time and transmits the presence pulse of t_{PDL}. .

Figure 158: Initialization Sequence



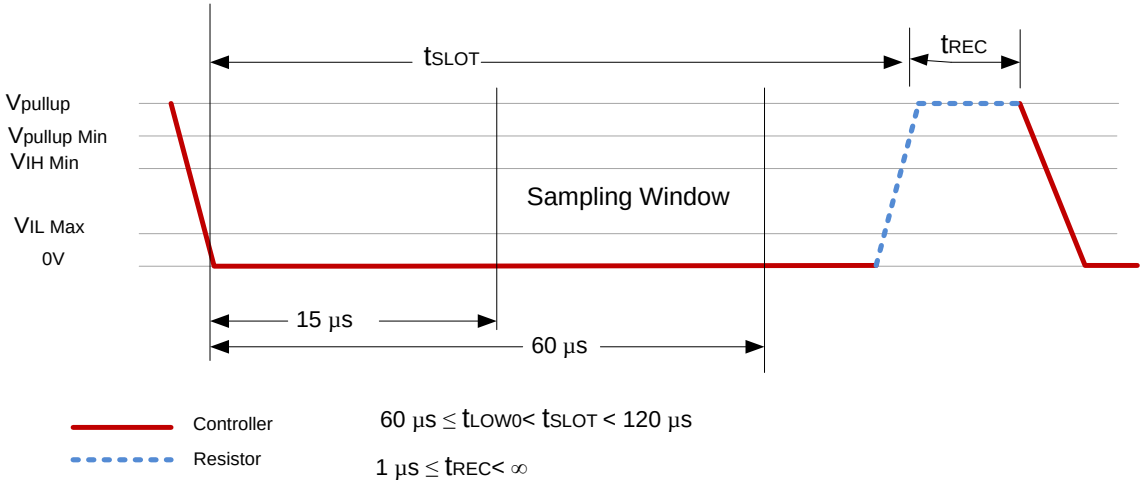
The reset pulse begins the initialization sequence. It is initiated when the GO bit in the Control register (Control.GO) is set.

38.1.2.2 Read/Write Time Slots

Write 0 Timing Slot

During a write memory command, for writing a bit 0, the data can be sampled and written into the scratchpad any time between t_{LOW0} and t_{SLOT} duration as shown in Figure 159 below.

Figure 159: Write 0 Timing



Write 1/Read Data Timing Slot

The Write 1 and Read timing slots are identical. The data bus is pulled low for t_{LOW1} time. The device can sample the data in sampling window (Figure 160). Similarly, during a read slot, the controller can read the data from the device in the sampling window (Figure 161)

Figure 160: Write 1 Timing

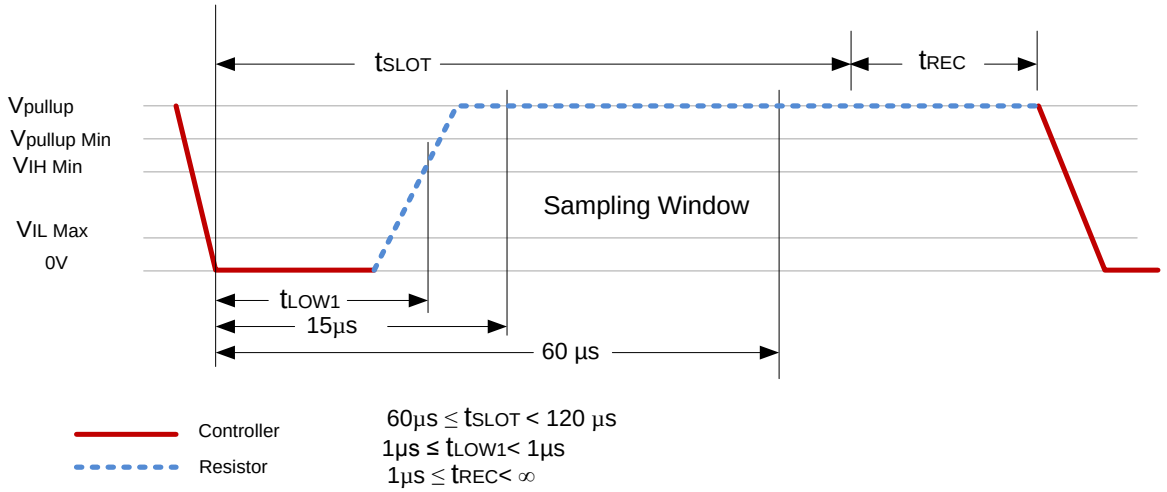


Figure 161: Read Timing

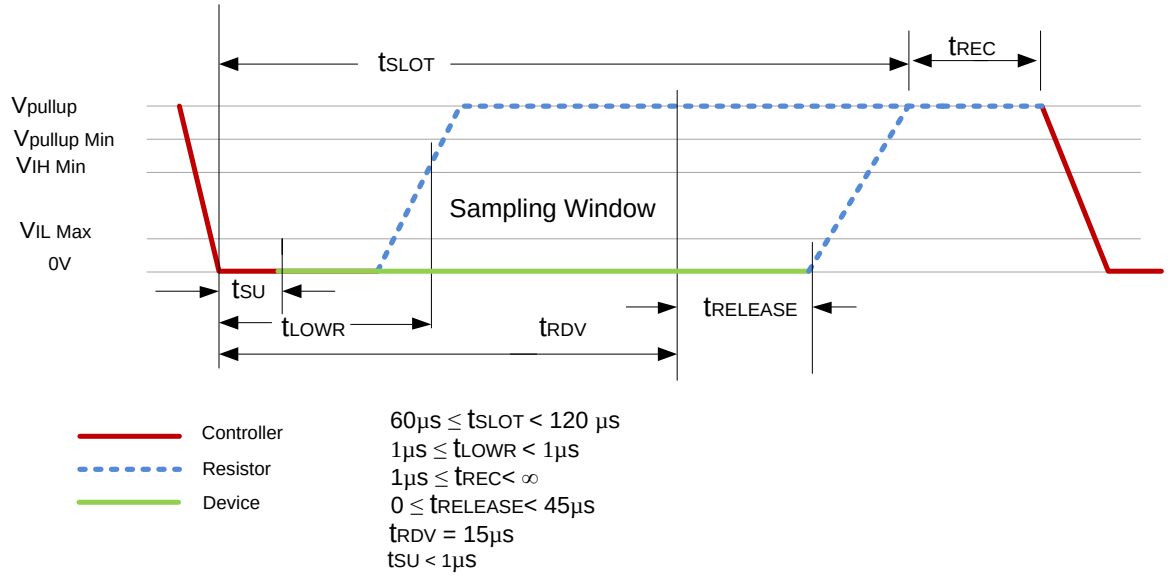
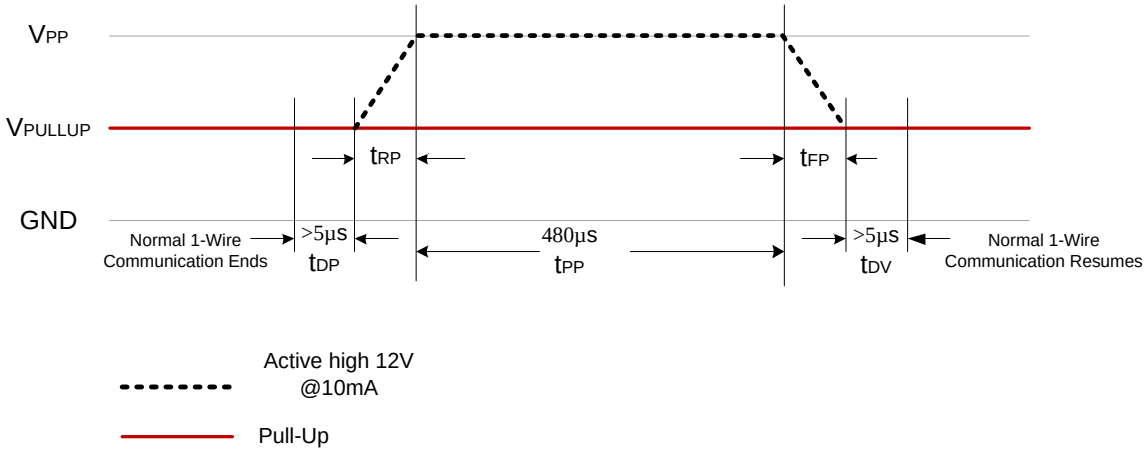


38.1.2.3 Programming Pulse

During a write memory command, data is first copied to the scratchpad. To shift the data from the scratchpad to the EPROM, a program pulse of 12 volts is applied to the data line after the controller has confirmed that the CRC is correct.

- In byte mode transfers, the controller controls the generation of programming pulse.
- In single-bit Write mode, the programming pulse is generated using GPIOs
- In Programming pulse window, the OWR bus is controlled by 12V voltage providing a minimum 10 mA of current.

Figure 162: Programming Timing Pulse

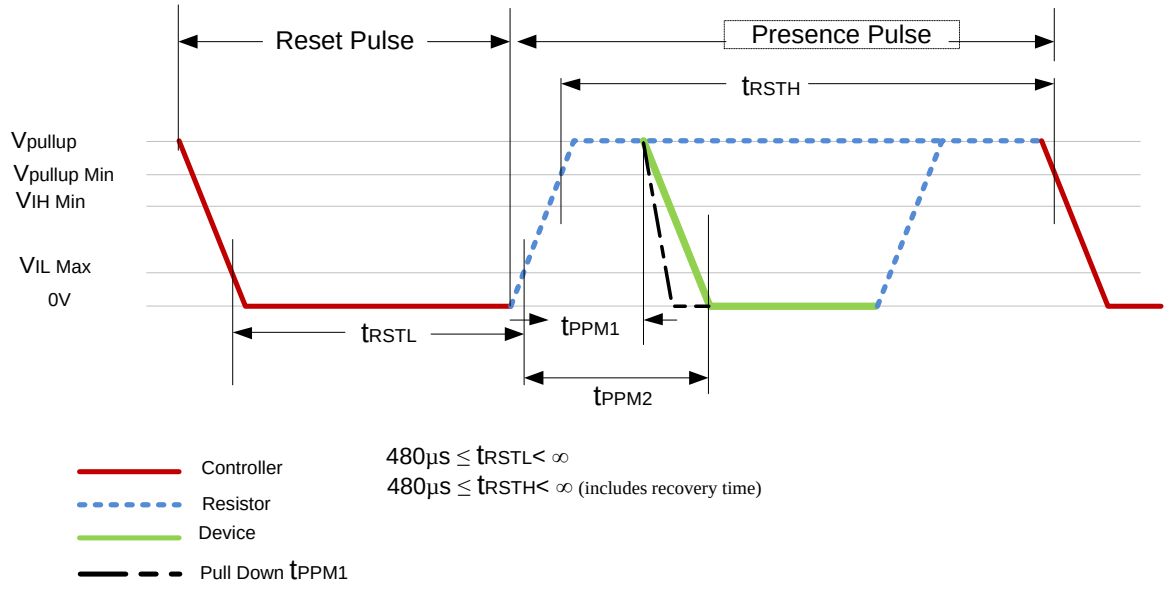


38.1.2.4 Presence-Pulse Masking (PPM)

Presence-Pulse Masking is used when battery devices are propagated through networks and get reflected. Glitches may occur due to reflections in network which may cause slave devices to lose synchronization.

When Presence-Pulse Masking is enabled, the controller pulls the OWR bus to low at t_{PPM1} until t_{PPM2}. At t_{PPM2} battery device further pulls down to low.

Figure 163: Presence-Pulse Masking



38.1.3 Interrupts

Interrupts are used to indicate the status of the design at different stages, so that the next data transfer can be determined.

Done signals indicate the data transfer is done without any interruptions.

Error signals indicate an error has occurred and data transfer should start again. An error can be a CRC error, a presence error, a memory write error, etc.

Overflow/underrun indicates the FIFO status.

Data request indicates FIFOs are ready to accept or send the data.

All the interrupts can be controlled by Interrupt MASK enables and the Interrupt SET register.

38.1.4 Error Handling

If the OWR controller receives an error such as a CRC error, presence error, memory write error, or an error command, a reset pulse must be issued, and the entire sequence must be repeated.

The OWR controller can bypass these errors by enabling register bits in the Control register.

CTL.BYPASS_CRC_ERR: Transfer does not stop on a CRC error

CTL.BYPASS_DGLITCH: Stops the execution of deglitch logic

CTL.PRESENCE_PULSE_MASKING: Transfer does not stop on a presence error.

38.1.5 Clock Control

OWR controller clocking has following clock source options:

Option 0: pllP_out0 = 432 MHz (Fixed 432 MHz directly from PLLP)

Option 1: pllC_out0 = Up to 600 MHz, Programmable clock output directly from PLLC.

Option 2: pllM_out0 = Up to 400 MHz, Programmable clock output directly from PLLM.

Option 3: dbg_oscout = External clock source determined by the customer. 12 MHz, 13 MHz, 19.2 MHz, or 26 MHz are supported frequencies.

An 8-bit divider is used to generate a 1 MHz clock

The clock divider generates a 1 MHz clock that is used as a time reference by the state machine. Transitions between the states of the state machine as well as actions triggered at precise time deadlines are expressed using the 1-MHz clock. The state machine performs all required actions to dialog with the external device.

38.1.6 Deglitch/Debounce

To overcome the glitches on the input DQ line, deglitch logic is used to make sure the data is stable for at least one microsecond. If a glitch occurs, an interrupt is generated and the transfer should start again. There is a bit to bypass deglitch logic. If that bit is set, deglitch is bypassed, and, if glitches occur, they are not reported.

When to sample the data is determined by programming the control register presence_sample_clk for reset initialization and read_data_sample_clk for read time slots.

There is a limitation to the value programmed in the presence/read_data sample clock: the hardware requires 6 clock cycles to implement deglitch generation logic The synchronizer output requires 2 clocks and deglitch requires 1 clock. If there is a glitch on the DQ line, hardware samples the data on the next clock edge, 2 clocks later, to store the sampled data’s 1 clock pulse).

Presence sample clk = Tpdl - 6 clocks

Rd_data_sample_clk = Trdv - 6 clocks

38.1.7 Read/Write 1 Bit

The controller also supports sending or receiving data bit by bit. In a bit-by-bit transfer, the software:

- calculates all the required calculations like when to send the wr0/wr1/rd
- calculates the CRC for received data
- checks CRC and
- preserves the received data

The hardware does not preserve any data in registers, except the received 1 bit data, in the RD_SAMPLE_DATA register.

The controller can only send the Time slots (Wr1/Wr0/Rd) and store the received sampled data in a register. Time slots are controlled by the value programmed in the timing registers.

In case of writes, the program pulse generation can be done using GPIO pins.

38.1.7.1 Programming Sequence

OWR communication always begins with reset initialization. To start reset initialization, program the CTRL.GO bit in the control register. Program all the timing registers before the GO bit. If device presence is detected, program the ROM command and then program the Memory Command.

Programming the ROM Command

Transmit LSB first to send the Read ROM Command (33h, 0011-0011).

Time Slots

- The LSB of the Read ROM command is 1'b1. Program CTRL.WR1_BIT (if 1'b0, program the CTRL.WR0_BIT) in the control register. After the controller generates the write-1 time slot, wait for the write-1 time slot to be completed by looking at INTR_STATUS.BIT_TRANSFER_DONE. Continue this until all the bits are transferred.
- After the Read ROM Command is sent, read 64 bits of ROM data. To receive 64 bits, 64 read time slots have to be sent. To generate the Read time slot, program CTRL.RD_BIT in the control register. After the controller generates the read time slot, the read bit is stored in READ_SAMPLED_BIT. The sampled bit should always be read after the bit transfer is done.
- Next, program the CTRL.RD_BIT, to read the second bit. The read time slot is generated by the controller. Wait for done and read the sampled bit.

Repeat the sequence for the remaining bits.

After all 64 bits are received, Memory data has to be read.

Reading EPROM Data using the Read Memory Command

- To read Memory data, first send the memory command followed by memory address. After the memory command and address are sent, verify the data sent. This can be done by checking the CRC of the command and address sent. To receive CRC, send 8 read slots, read the CRC data, and check for a match with the computed value. Read the EPROM data from memory or else start with initialization procedure.
- To read data from EPROM, send read time slots. The number of read time slots should be memory address – EPROM end offset. After reading EPROM data, read the CRC and check the received data, if CRC is required. Normally, the CRC is embedded within the EPROM data. To receive 8-bit CRC data, send 8 read time slots.

38.2 Programming Guidelines

38.2.1 Programming Registers

All the registers should be programmed and the CTL.GO bit should be programmed to start the controller.

Registers to Program Prior to the Control Register

- **All timing registers**: Program the timing values according to the battery device data sheet
- **Command register**: Program the device ROM Command, Memory Command, EPROM starting address
- **EPROM size offset**: Program the number of bytes to transfer
- **Interrupt mask enables**: Program the respective interrupt mask enables to enable the interrupts to CPU/COP
- **Control Register**: Programming this register depends on the type of execution required.

Program the GO bit only after programming all of the above.

Registers to Monitor

- **Interrupt Status & Source**: These are used to monitor the design status (like done, error, etc.).
- **CRC**: Stores the calculated CRC 8/16-bit value
- **Byte Count**: Indicates the number of bytes transferred/received
- **Read_ROM0/ROM1**: Stores the received ROM Family code, Serial Number, CRC.

FIFO Registers

- **Tx/Rx FIFO**: Data to transmit/receive data.

Notes:

- The Rd_data_crc bit needs to be enabled with both Read and Write commands in case of generic CRC Read and Write
- For Write commands, the CmdAddr CRC bit should be disabled
- Read memory command for both DS2502 and DS2784 can be supported in generic mode.
- DS2502 requires a programming pulse which is not supported by generic mode.

38.2.2 Byte Data Transfer Sequence

Reset Initialization → ROM Command → Memory Command → Reset Initialization → ROM Command → Memory Command, etc.

In case of an error, the entire sequence should start again from the beginning:

Reset Initialization → Error → Reset Initialization →ROM Command → Error → Reset Initialization → ROM Command → Memory Command, etc.

38.3 OWR Registers

Refer to “Reading Register Tables” in the Introduction section for the register table protocol as well as recommendations for accessing registers.

The 1-wire interface provides the communication line to a 1-Kbit Add-Only Memory (DS2502). The required protocol for accessing the DS2502 is defined by Dallas Semiconductor.

The DS2502 holds battery characteristics information. The interface sends or receives one bit or byte at a time.

- Supports 2 ROM commands: Skip ROM, Read ROM.
- Supports 5 Memory commands: Write Memory, Write Status Byte, Read Status Byte, Read Memory, and Read Data/Generate 8-bit CRC
- Different battery devices are also supported, with memory size 256k
- Battery devices with EPROM only are supported, devices with NV_RAMS are not supported

Programming Guidelines

The Controller supports two modes:

- Byte transfer mode
- Bit transfer mode

If the interface sends or receives a byte at a time: All the Timing registers, the command register, and the required fields in control registers should be programmed and then the GO bit in the control register should be programmed. ROM CMD data is stored in the ROM registers. EPROM data/status is stored in FIFOs. Interrupt bits know the status of the design and can be enabled or disabled.

If the interface sends or receives one bit at a time: This mode is enabled by enabling DATA_TRANSFER_MODE in the control register. All the timing registers should be programmed. Software writes WR0_BIT, WR1_BIT, or RD_BIT to enable the write one time slot, write zero time slot, or read time slot, wr0_busy, wr1_busy, and rd_busy to indicate the data transfer of the bit.

To read the sampled data: the sampled data is valid only after rd_busy goes low and an interrupt bit to indicate bit transfer is ready to accept the next bit. In one bit transfer mode, CRC calculations to detect errors and when to send write slots and read slots is decided by software only. One bit transfer mode supports only read commands.

38.3.1 OWR_CONTROL_0

OWR Control Register

This register is the main control register. It should be configured last after all other settings are configured.

Offset: 0x0 | Read/Write: R/W | Reset: 0x00000000 (0b00000000000000000000000000000000)

Bit	Reset	Description
31	0x0	RD_BIT: If 0, no transfer is done. If 1, the read time slot is executed. Reads of this write-only bit will return 0. 0 = NO_TRANSFER 1 = TRANSFER_READ_SLOT
30	0x0	WR0_BIT: If 0, no transfer is done. If 1, write zero time slot is executed. Reads of this write-only bit will return 0. 0 = NO_TRANSFER 1 = TRANSFER_ZERO
29	0x0	WR1_BIT: If 0, no transfer is done. If 1, write one time slot is executed. Reads of this write-only bit will return 0. 0 = NO_TRANSFER 1 = TRANSFER_ONE
28	0x0	BY_PASS_CRC_ERR: This bit is set to 1, if the transfer needs to continue on CRC error. Otherwise, on error the transfer stops, and the transfer should start on setting RPP reset (GO bit). 0 = STOP_TRANSFER_ON_CRC_ERR 1 = CONTINUE_TRANSFER_ON_CRC_ERR

Bit	Reset	Description
27	0x0	BY_PASS_DGLITCH: This bit is used to bypass the deglitch logic. If 1, just the sync output is taken. If 0, looks for any glitch in the sample window for at least 1 µs, Deglitch requires a minimum of 6 clocks (2 for sync, 2 for deglitch, and if glitch, checks for 2 more clocks). If glitch still exists, an error interrupt is asserted and the data transfer should start from first. 0 = START_DGLITCH 1 = NO_DGLITCH
26:23	0x0	RD_DATA_SAMPLE_CLK: Read the data sample window. The master samples data_in, which should be less than or equal to (tlow1 - 6) clocks. 6 clocks are used for deglitch, if deglitch is bypassed, 3 clocks should be enough.
22:15	0x0	PRESENCE_SAMPLE_CLK: Presence pulse sample clock. The master samples data_in, which should be less than or equal to (tpdl - 6) clocks. 6 clocks are used for deglitch, if deglitch is bypassed, 3 clocks should be enough.
14	0x0	RD_MEM_CRC_REQ: This bit is set to 1, if CRC is required for read memory command at the end of memory. 0 = NO_CRC_READ 1 = CRC_READ
13:9	0x0	RX_FIFO_ATTEN_LEVEL: Receive FIFO attention level. 000 = 1 word, FIFO request is asserted when at least one word is full in the FIFO. 001 = 2 word, FIFO request is asserted when at least 2 words are full in the FIFO, etc.
8:4	0x0	TX_FIFO_ATTEN_LEVEL: Transmit FIFO attention level. 000 = 1 word, FIFO request is asserted when at least one word is empty in the FIFO. 001 = 2 word, FIFO request is asserted when at least 2 words are empty in the FIFO, etc.
3	0x0	CRC_16BIT_EN: If set to 1, 16-bit CRC is executed. If set to 0, 8-bit CRC is executed. 0 = CRC_8BIT_EN 1 = CRC_16BIT_EN
2	0x0	DATA_TRANSFER_MODE: If set to 1, data transfer is done bit by bit. If set to 0, data transfer is done in bytes. 0 = BYTE_TRANSFER_MODE 1 = BIT_TRANSFER_MODE
1	0x0	PRESENCE_PULSE_MASKING: When set, DQ is driven to low by the master before the slave does. Clearing this bit disables the PPM. 0 = NO_PPM 1 = START_PPM
0	0x0	GO: Generate Reset Presence Pulse write only bit. Reads to this register will return 0. This bit should be programmed after all the registers are programmed. 0 = NO_PRESENCE_PULSE 1 = START_PRESENCE_PULSE

38.3.2 OWR_COMMAND_0

OWR Command Register

ROM_CMD, MEM_CMD, and MEM_ADDR should be programmed at the same time.

Offset: 0x4 | Read/Write: R/W | Reset: 0x00000000 (0b00000000000000000000000000000000)

Bit	Reset	Description
31:16	0x0	MEM_ADDR: EPROM Starting Address[15:0] to write/read data into EPROM
15:8	0x0	MEM_CMD: 1-wire MEM commands
7:0	0x0	ROM_CMD: 1-wire ROM commands

38.3.3 OWR_EPROM_0

OWR EPROM Size Offset

This register indicates the number of bytes to transfer. Up to 256k EPROM size is supported.

MEM_ADDR and MEMORY_BYTES_TRANSFER/STATUS_BYTES_TRANSFER should always be in sync. For example, if the EPROM end offset address is 0x7f, and we want to read data from the fourth location address of EPROM, the programming should be as follows:

- MEM_ADDR = 0x4;
- MEMORY_BYTES_TRANSFER = 0x7B; (0x4 - 0x7f)

The steps are similar for status bytes.

Offset: 0x8 | Read/Write: R/W | Reset: 0x00000000 (0b00000000000000000000000000000000)

Bit	Reset	Description
31:16	0x0	STATUS_BYTES_TRANSFER: Number of EPROM Status bytes to transfer: Mem_Addr - Status bytes end address
15:0	0x0	MEMORY_BYTES_TRANSFER: Number of EPROM memory bytes to transfer: Mem_Addr - EPROM end address

38.3.4 OWR_WR_RD_TCTL_0

OWR Write Read Timing Control Register

Controls the one-wire DQ output (Pullup or Pulldown) to write and read time slots. Timings are in microseconds.

Note : <= means less than or equal to.

Offset: 0xc | Read/Write: R/W | Reset: 0x00000000 (0bxx000000000000000000000000000000)

Bit	Reset	Description
29:28	0x0	TSU: Read Data Setup, Tsu = N OWR clocks, Range = tsu < 1
27:22	0x0	TRELEASE: Release 1-wire Time, Trelease = N OWR clocks, Range = 0 <= trelease < 45
21:18	0x0	TRDV: Read data valid time, Trdv = N+1 OWR clocks, Range = Exactly 15
17:11	0x0	TLOW0: Write Zero time Low, Tlow0 = N+1 OWR clocks, Range = 60 <= tlow0 < tslot < 120
10:7	0x0	TLOW1: Write one time Low, or TLOWR both are same. Tlow1 = N+1 OWR clocks, Range = 1 <= tlow1 < 15. TlowR = N+1 OWR clocks, Range = 1 <= tlowR < 15
6:0	0x0	TSLOT: Active time slot for write or read data, Tslot = N+1 OWR clocks, Range = 60 <= tslot < 120

38.3.5 OWR_RST_PRESENCE_TCTL_0

OWR Reset Presence Timing Control Register

Controls the one-wire DQ output (Pullup or Pulldown) to reset initialization time slots. Timings are in microseconds.

Note : <= means less than or equal to.

Offset: 0x10 | Read/Write: R/W | Reset: 0x00000000 (0b00000000000000000000000000000000)

Bit	Reset	Description
31:24	0x0	TPDL: PRESENCE_DETECT_LOW Tpdl = N OWR clocks, Range = 60 <= tpdl < 240
23:18	0x0	TPDH: PRESENCE_DETECT_HIGH Tpdh = N+1 OWR clocks, Range = 15 <= tpdh < 60

Bit	Reset	Description
17:9	0x0	TRSTL: RESET_TIME_LOW Trstl = N+1 OWR clocks, Range = 480 <= trstl < infinity
8:0	0x0	TRSTH: RESET_TIME_HIGH, Trsth = N+1 OWR clocks, Range = 480 <= trsth < infinity

38.3.6 OWR_PPM_CORRECTION_TCTL_0

OWR PRESENCE PULSE MASKING TIMING CONTROL

Drives the DQ line to low before the slave does.

Offset: 0x14 | Read/Write: R/W | Reset: 0x00000000 (0bxxxxxxxxxxxxxxxx0000000000000000)

Bit	Reset	Description
15:6	0x0	TPPM2: PRESENCE PULSE MASK STOP
5:0	0x0	TPPM1: PRESENCE PULSE MASK START

38.3.7 OWR_PROG_PULSE_TCTL_0

OWR PROGRAM PULSE TIMING CONTROL Register

Controls the 12V programming pulse used to write data to EPROM. Timings are in microseconds.

Offset: 0x18 | Read/Write: R/W | Reset: 0x00000000 (0b00000000000000000000000000000000)

Bit	Reset	Description
31:16	0x0	TPP: Program Pulse Width. Tpp = N OWR clocks. Range = 480 to 5000
15:12	0x0	TFP: Program Voltage Fall Time. Tfp = N OWR clocks. Range = 0.5 to 5
11:8	0x0	TRP: Program Voltage Rise Time. Trp = N OWR clocks. Range = 0.5 to 5
7:4	0x0	TDV: Delay to verify. Tdv = N OWR clocks. Range = > 5
3:0	0x0	TPD: Delay to program. Tpd = N+1 OWR clocks. Range = > 5

38.3.8 OWR_READ_ROM0_0

The Read ROM Command reads the 8-bit family code, 48-bit serial number, and 8-bit CRC for a total of 64 bits. Read ROM Command data is split into two 32-bit registers: READ_ROM0 and READ_ROM1.

OWR READ ROM DATA0 Register

Offset: 0x1c | Read/Write: RO | Reset: 0xXXXXXXXX (0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx)

Bit	Reset	Description
31:8	X	SERIAL_NUM0: Reads the first 24 bits of the ROM serial number
7:0	X	FAMILY_CODE: Reads the 8-bit family code of the ROM

38.3.9 OWR_READ_ROM1_0

OWR READ ROM DATA1 Register

Offset: 0x20 | Read/Write: RO | Reset: 0xXXXXXXXX (0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx)

Bit	Reset	Description
31:24	X	CRC_BYTE: Reads the 8-bit CRC code of the ROM
23:0	X	SERIAL_NUM1: Reads the next 24 bits of the ROM serial number

38.3.10 OWR_INTR_MASK_0

OWR INTR Mask Register

This register stores the masks for the interrupts. If a bit is set to 1 and the corresponding interrupt condition is satisfied, the interrupt line to the system interrupt controller is asserted.

Offset: 0x24 | Read/Write: R/W | Reset: 0x00000000 (0bxxxxxxxxxxxxxxxxxx00000000000000)

Bit	Reset	Description
13	0x0	BIT_TRANSFER_DONE_INT_EN: 0 = DISABLE 1 = ENABLE
12	0x0	RXFIFO_DATA_REQ_INT_EN: 0 = DISABLE 1 = ENABLE
11	0x0	TXFIFO_DATA_REQ_INT_EN: 0 = DISABLE 1 = ENABLE
10	0x0	DGLITCH_INT_EN: 0 = DISABLE 1 = ENABLE
9	0x0	RXF_UNR_INT_EN: 0 = DISABLE 1 = ENABLE
8	0x0	TXF_OVF_INT_EN: 0 = DISABLE 1 = ENABLE
7	0x0	MEM_CMD_DONE_INT_EN: 0 = DISABLE 1 = ENABLE
6	0x0	ROM_CMD_DONE_INT_EN: 0 = DISABLE 1 = ENABLE
5	0x0	PRESENCE_DONE_INT_EN: 0 = DISABLE 1 = ENABLE
4	0x0	RESET_DONE_INT_EN: 0 = DISABLE 1 = ENABLE
3	0x0	ERR_CMD_INT_EN: 0 = DISABLE 1 = ENABLE

Bit	Reset	Description
2	0x0	MEM_WR_ERR_INT_EN: 0 = DISABLE 1 = ENABLE
1	0x0	CRC_ERR_INT_EN: 0 = DISABLE 1 = ENABLE
0	0x0	PRESENCE_ERR_INT_EN: 0 = DISABLE 1 = ENABLE

38.3.11 OWR_INTR_STATUS_0

OWR Status Register

Offset: 0x28 | Read/Write: R/W | Reset: 0x0000XX00 (0bxxxxxxxxxxxxxxxxxxx0xx00000000000)

Bit	R/W	Reset	Description
13	RW	0x0	BIT_TRANSFER_DONE: This bit is set when the transfer of each bit is done. This is set in one bit transfer mode. Software writes a 1 to clear this bit. 0 = NOT_DONE 1 = DONE
12	RO	X	RXFIFO_DATA_REQ: RX FIFO data request 0 = RX_NOT_RDY 1 = RX_RDY
11	RO	X	TXFIFO_DATA_REQ: TX FIFO data request 0 = TX_NOT_RDY 1 = TX_RDY
10	RW	0x0	DGLITCH: This bit is set when data is not stable for at least 1 µs. Software writes a 1 to clear this bit. If deglitch is detected, the data transfer should start from first. 0 = DGLITCH_NOT_DETECTED 1 = DGLITCH_DETECTED
9	RW	0x0	RXF_UNR: RX FIFO Under run. This bit is set to 1 whenever software tries to read from an empty RX FIFO. Software writes a 1 to clear this bit. 0 = NOT_EMPTY 1 = EMPTY
8	RW	0x0	TXF_OVF: TX FIFO Overflow. This bit is set to 1 whenever software tries to write to a full TX FIFO. Software writes a 1 to clear this bit. 0 = NOT_EMPTY 1 = EMPTY
7	RW	0x0	MEM_CMD_DONE: This indicates the master has written data into EPROM or data was received from EPROM without any error. Software writes a 1 to clear it. 0 = NOT_DONE 1 = DONE
6	RW	0x0	ROM_CMD_DONE: This indicates the master has received the ROM data from the battery. Software writes a 1 to clear it. 0 = NOT_DONE 1 = DONE
5	RW	0x0	PRESENCE_DONE: This indicates the presence is done, and the master has detected the device. Software writes a 1 to clear it. 0 = NOT_DONE 1 = DONE
4	RW	0x0	RESET_DONE: This indicates the master has sent the reset, then waits for presence. Software writes a 1 to clear it. 0 = NOT_DONE 1 = DONE

Bit	R/W	Reset	Description
3	RW	0x0	ERR_CMD: ERROR CMD: Indicates an error command was written in the register. It should be ignored when the transfer is in single bit mode. Software writes a 1 to clear it. 0 = CORRECT_CMD 1 = ERROR_CMD
2	RW	0x0	MEM_WR_ERR: MEM WR Error: Indicates whether the received data from EPROM is correct or not. Software writes a 1 to clear it. 0 = N0_ERROR 1 = ERROR
1	RW	0x0	CRC_ERR: CRC Error: Indicates whether the received data is correct or not. Software writes a 1 to clear it. 0 = N0_ERROR 1 = ERROR
0	RW	0x0	PRESENCE_ERR: Presence Error. This bit is set when device presence is not found. 0 = SLAVE_DETECTED 1 = NO_SLAVE_DETECTED

38.3.12 OWR_INTR_SOURCE_0

OWR INTR Source Register

This read-only register returns the AND of the Interrupt Source and Interrupt Mask registers.

Offset: 0x2c | Read/Write: RO | Reset: 0x0000XXXX (0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx)

Bit	Reset	Description
13	X	BIT_TRANSFER_DONE: 0 = NOT_DONE 1 = DONE
12	X	RXFIFO_DATA_REQ: 0 = RX_NOT_RDY 1 = RX_RDY
11	X	TXFIFO_DATA_REQ: 0 = TX_NOT_RDY 1 = TX_RDY
10	X	DGLITCH: 0 = DGLITCH_NOT_DETECTED 1 = DGLITCH_DETECTED
9	X	RXF_UNR: 0 = NOT_EMPTY 1 = EMPTY
8	X	TXF_OVF: 0 = NOT_EMPTY 1 = EMPTY
7	X	MEM_CMD_DONE: 0 = NOT_DONE 1 = DONE
6	X	ROM_CMD_DONE: 0 = NOT_DONE 1 = DONE
5	X	PRESENCE_DONE: 0 = NOT_DONE 1 = DONE
4	X	RESET_DONE: 0 = NOT_DONE 1 = DONE

Bit	Reset	Description
3	X	ERR_CMD: 0 = CORRECT_CMD 1 = ERROR_CMD
2	X	MEM_WR_ERR: 0 = N0_ERROR 1 = ERROR
1	X	CRC_ERR: 0 = N0_ERROR 1 = ERROR
0	X	PRESENCE_ERR: 0 = SLAVE_DETECTED 1 = NO_SLAVE_DETECTED

38.3.13 OWR_INTR_SET_0

Interrupt Set Register

This write-only register can be used to set the interrupt status bit. A write to this register causes the bits in the status register to be set to 1. Reads always return 0.

Offset: 0x30 | Read/Write: R/W | Reset: 0x00000000 (0bxxxxxxxxxxxxxxxxxxx0xx00000000000)

Bit	Reset	Description
13	0x0	BIT_TRANSFER_DONE: 0 = NOT_DONE 1 = DONE
10	0x0	DGLITCH: 0 = DGLITCH_NOT_DETECTED 1 = DGLITCH_DETECTED
9	0x0	RXF_UNR: 0 = NOT_EMPTY 1 = EMPTY
8	0x0	TXF_OVF: 0 = NOT_EMPTY 1 = EMPTY
7	0x0	MEM_CMD_DONE: 0 = NOT_DONE 1 = DONE

2	0x0	MEM_WR_ERR: 0 = N0_ERROR 1 = ERROR

Bit	Reset	Description
1	0x0	CRC_ERR: 0 = N0_ERROR 1 = ERROR
0	0x0	PRESENCE_ERR: 0 = SLAVE_DETECTED 1 = NO_SLAVE_DETECTED

38.3.14 OWR_STATUS_0

Offset: 0x34 | Read/Write: R/W | Reset: 0x00XXXXXX (0bxxxxxxxxxxxxxxxxxxxxxxxxxx00xxxxx)

Bit	R/W	Reset	Description
23	RO	X	READ_SAMPLED_BIT: The bit is valid only when RD_BUSY is cleared. 0 = READ_ZERO 1 = READ_ONE
22	RO	X	RD_BUSY: READ : This self-clearing bit is cleared when a read time slot completes on the read sequence, and the sampled read bit is stored in READ_BIT 0 = IDLE 1 = BUSY
21	RO	X	WR1_BUSY: WRITE1: This self-clearing bit is cleared when a write one time slot completes on write sequence 1. 0 = IDLE 1 = BUSY
20	RO	X	WR0_BUSY: WRITE 0: This self-clearing bit is cleared when a write zero time slot completes on write sequence 0. 0 = IDLE 1 = BUSY
19	RO	X	RPP: This is set when the RPP reset bit is set in the control register (GO), auto-cleared on completion of the reset initialization sequence. 0 = IDLE 1 = RESET_PRESENCE_PULSE
18:13	RO	X	TX_FIFO_EMPTY_CNT: The number of slots that can be written to the TX FIFO.
12:7	RO	X	RX_FIFO_FULL_CNT: The number of slots to be read from the RX FIFO.
6	RW	0x0	RX_FLUSH: Flushes the RX FIFO, cleared after the FIFO is empty. 0 = DISABLE 1 = ENABLE
5	RW	0x0	TX_FLUSH: Flushes the TX FIFO, cleared after the FIFO is empty. 0 = DISABLE 1 = ENABLE
4	RO	X	RXF_EMPTY: RX FIFO empty status: RO. Hardware sets this bit to 1, if the RX FIFO is empty. Otherwise, this bit is set to 0. 0 = NOT_EMPTY 1 = EMPTY
3	RO	X	RXF_FULL: RX FIFO full status: Hardware sets this bit to 1, if the RX FIFO is full. Otherwise, this bit is set to 0. 0 = NOT_FULL 1 = FULL
2	RO	X	TXF_EMPTY: TX FIFO empty status: Hardware sets this bit to 1, if the TX FIFO is empty. Otherwise, this bit is set to 0. 0 = NOT_EMPTY 1 = EMPTY
1	RO	X	TXF_FULL: TX FIFO full status: Hardware sets this bit to 1 if the TX FIFO is full. Otherwise, this bit is set to 0. 0 = NOT_FULL 1 = FULL

Bit	R/W	Reset	Description
0	RO	X	RDY: Ready bit. This bit is set at the end of every transfer, and it is cleared by hardware when the next transfer starts. 0 = NOT_READY 1 = READY

38.3.15 OWR_CRC_0

OWR CRC Register

Offset: 0x38 | Read/Write: RO | Reset: 0xXXXXXXXX (0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx)

Bit	Reset	Description
31:16	X	CRC_CALC: CRC calculated by OWR current Write/Read operation
15:0	X	CRC_RECEV: CRC received on read data

38.3.16 OWR_BYTE_CNT_0

OWR BYTE_CNT Register

Offset: 0x3c | Read/Write: RO | Reset: 0xXXXXXXXX (0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx)

Bit	Reset	Description
31:16	X	TRANSMITTED: Number of bytes transmitted on write commands or address sent
15:0	X	RECEIVED: Number of bytes received on read data includes CRC byte count

38.3.17 OWR_TX_FIFO_0

OWR TX FIFO Register

Offset: 0x40 | Read/Write: R/W | Reset: 0x00000000 (0b00000000000000000000000000000000)

Bit	Reset	Description
31:0	0x0	WR_DATA: TX FIFO

38.3.18 OWR_RX_FIFO_0

OWR RX FIFO Register

Offset: 0x44 | Read/Write: RO | Reset: 0xXXXXXXXX (0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx)

Bit	Reset	Description
31:0	X	RD_DATA: RX FIFO

38.3.19 OWR_RECOVERY_TIME_TCTL_0

OWR RECOVERY TIME Register

Offset: 0x4c | Read/Write: R/W | Reset: 0x00000000 (0bxxxxxxxxxxxxxxxx0000000000000000)

Bit	Reset	Description
15:0	0x0	TREC: Recovery time slot for write or read data. Trec= N+1 OWR clocks

38.3.20 OWR_RST_TIME_TCTL_0

OWR RST PRESENCE HIGH AND LOW TIME Register

Offset: 0x50 | Read/Write: R/W | Reset: 0x00000000 (0b00000000000000000000000000000000)

Bit	Reset	Description
31:16	0x0	TRSTL: RESET_TIME_LOW Trstl = N+1 OWR clocks
15:0	0x0	TRSTH: RESET_TIME_HIGH, Trsth = N+1 OWR clocks

38.3.21 OWR_RST_PRESENCE_DETECT_TCTL_0

OWR RST PRESENCE DETECT HIGH AND LOW TIME Register

Offset: 0x54 | Read/Write: R/W | Reset: 0x00000000 (0b00000000000000000000000000000000)

Bit	Reset	Description
31:16	0x0	TPDL: PRESENCE_DETECT_LOW Tpdl = N OWR clocks
15:0	0x0	TPDH: PRESENCE_DETECT_HIGH Tpdh = N+1 OWR clocks

38.3.22 OWR_WRITE_ONE_ZERO_TCTL_0

OWR WRITE 1 OR WRITE 0 TIME Register

Offset: 0x58 | Read/Write: R/W | Reset: 0x00000000 (0b00000000000000000000000000000000)

Bit	Reset	Description
31:16	0x0	TLOW0: Write zero time Low. Tlow0 = N+1 OWR clocks
15:0	0x0	TLOW1: Write one time Low, or TLOWR both are same. Tlow1 = N+1 OWR clocks. TlowR = N+1 OWR clocks

38.3.23 OWR_TIME_SLOT_RELEASE_TCTL_0

OWR TIME SLOT OR RELEASE TIME Register

Offset: 0x5c | Read/Write: R/W | Reset: 0x00000000 (0b00000000000000000000000000000000)

Bit	Reset	Description
31:16	0x0	TRELEASE: Release 1-wire time. Trelease = N OWR clocks
15:0	0x0	TSLOT: Active time slot for write or read data. Tslot = N+1 OWR clocks

38.3.24 OWR_READ_DATA_TCTL_0

OWR WRITE 1 OR WRITE 0 LOW TIME Register

Offset: 0x60 | Read/Write: R/W | Reset: 0x00000000 (0b00000000000000000000000000000000)

Bit	Reset	Description
31:16	0x0	TRDV: Read data valid time. Trdv = N+1 OWR clocks
15:0	0x0	TSU: Read Data Setup. Tsu = N OWR clocks

38.3.25 OWR_PROGRAM_PULSE_TCTL_0

OWR PROGRAM PULSE TIMING CONTROL Register

Offset: 0x64 | Read/Write: R/W | Reset: 0x00000000 (0b00000000000000000000000000000000)

Bit	Reset	Description
31:24	0x0	TFP: Program Voltage Fall Time. Tfp = N OWR clocks
23:16	0x0	TRP: Program Voltage Rise Time. Trp = N OWR clocks
15:8	0x0	TDV: Delay to verify. Tdv = N OWR clocks
7:0	0x0	TPD: Delay to program. Tpd = N+1 OWR clocks

38.3.26 OWR_PROGRAM_PULSE_WIDTH_TCTL_0

OWR PROGRAM PULSE TIMING CONTROL Register

Offset: 0x68 | Read/Write: R/W | Reset: 0x00000000 (0bxxxxxxxxxxxxxxxx0000000000000000)

Bit	Reset	Description
15:0	0x0	TPP: Program Pulse Width. Tpp = N OWR clocks. Range = 480 to 5000.

38.3.27 OWR_PPM_TCTL_0

OWR PRESENCE PULSE MASKING TIMING CONTROL

Offset: 0x6c | Read/Write: R/W | Reset: 0x00000000 (0b00000000000000000000000000000000)

Bit	Reset	Description
31:16	0x0	TPPM2: PRESENCE PULSE MASK STOP
15:0	0x0	TPPM1: PRESENCE PULSE MASK START

38.3.28 OWR_SAMPLE_DATA_0

OWR SAMPLE DATA Register

Offset: 0x70 | Read/Write: R/W | Reset: 0x00000000 (0b00000000000000000000000000000000)

Bit	Reset	Description
31	0x0	RD_DATA_SAMPLE_CLK_EN: 0 = DISABLE 1 = ENABLE
30:16	0x0	RD_DATA_SAMPLE_CLK: Read data sample window. The master samples data_in, which should be less than or equal to (tlow1 - 6) clocks. 6 clocks are used for deglitch. If deglitch is bypassed, 3 clocks should be enough
15	0x0	PRESENCE_SAMPLE_CLK_EN: 0 = DISABLE 1 = ENABLE
14:0	0x0	PRESENCE_SAMPLE_CLK: Presence pulse sample clock. The master samples data_in, which should be less than or equal to (tpdl - 6) clocks. 6 clocks are used for deglitch. If deglitch is bypassed, 3 clocks should be enough.

38.3.29 OWR_GENERIC_CTL_0

GENERIC OWR COMMAND TRANSFER CONTROL

Offset: 0x74 | Read/Write: R/W | Reset: 0x00000000 (0bxxxxxxxxxxxxxxxxxxxxxx00000000000)

Bit	Reset	Description
10	0x0	RD_DATA_CRC: 0 = NO_READ 1 = READ

1	0x0	CMD_XFER_WDATA: 0 = NO_WRITE 1 = WRITE
0	0x0	CMD_XFER: 0 = NO_SEND 1 = SEND

38.3.30 OWR_CMD_XFER_TCTL_0

OWR COMMAND TRANSFER TIMING CONTROL Register

Offset: 0x78 | Read/Write: R/W | Reset: 0x00000000 (0b00000000000000000000000000000000)

Bit	Reset	Description
31:0	0x0	TWAIT

38.3.31 OWR_ADDR_XFER_TCTL_0

OWR ADDRESS TRANSFER TIMING CONTROL Register

Offset: 0x7c | Read/Write: R/W | Reset: 0x00000000 (0b00000000000000000000000000000000)

Bit	Reset	Description
31:0	0x0	TWAIT

38.3.32 OWR_DATA_XFER_TCTL_0

OWR DATA TRANSFER TIMING CONTROL Register

Offset: 0x80 | Read/Write: R/W | Reset: 0x00000000 (0b00000000000000000000000000000000)

Bit	Reset	Description
31:0	0x0	TWAIT

[THIS PAGE INTENTIONALLY LEFT BLANK]

39.0 PWM CONTROLLER

The Pulse Width Modulator (PWM) controller is a four channel frequency divider whose pulse width varies. Each channel has a programmable frequency divider and a programmable pulse width generator.

Frequency division is a 13-bit programmable value, and pulse division is an 8-bit value.

The PWM runs off a device clock, which is programmed in the Clock and Reset controller, and can be any frequency up to the device clock maximum speed of 48 MHz.

The device clock frequency is always subject to a minimum divide by 256 to generate the PWM output frequency, and may also be subdivided to slow it down further based on the programmable value locally.

There is an APB interface that interfaces the register logic to the APB bus.

The PWM contains four independently programmable pulse width modulators. Each generated pulse has an n/256 duty cycle. PWM signals are useful for LCD contrast and brightness control, VCO-generated clocks and other analog voltage references where high precision is not required.

39.1 Functionality

There are four PWM controllers on four individual pins on the chip. The pinmux corresponding to these are SDC primary pin groups. For the four PWM controllers there are four corresponding registers:

- PWM_CSR0
- PWM_CSR1
- PWM_CSR2
- PWM_CSR3

Each PWM must be enabled (bit [31]) to be operational. Pulse Width [23:16] determines the output pulse width and must be programmed appropriately. Pulse Width [30:24] is not used and must be 0. Frequency Divider [12:0] determines the Divided clock.

39.2 PWM Registers

Refer to “Reading Register Tables” in the Introduction section for the register table protocol as well as recommendations for accessing registers.

39.2.1 PWM_CONTROLLER_PWM_CSR_0_0

PWM Output-0 Configuration Control Register

Offset: 0x0 | Read/Write: R/W | Reset: 0x00000000 (0b00000000000000000xxx0000000000000)

Bit	Reset	Description
31	0x0	ENB: Enable Pulse width modulator 0 = DISABLE 1 = ENABLE
30:16	0x0	PWM_0: pulse width that needs to be programmed. 0=Always low. 1=1/256 Pulse high. 2=2/256 Pulse high. N=N/256 Pulse high
12:0	0x0	PFM_0: Frequency divider that needs to be programmed.

39.2.2 PWM_CONTROLLER_PWM_CSR_1_0

PWM Output-1 Configuration Control Register

Offset: 0x10 | Read/Write: R/W | Reset: 0x00000000 (0b0000000000000000xxx0000000000000)

Bit	Reset	Description

12:0	0x0	PFM_3: Frequency divider that needs to be programmed.

40.0 THERMAL SENSOR AND THERMAL THROTTLING CONTROLLER

40.1 Thermal Throttling Controller (SOC_THERM)

The goals of the thermal throttling controller include:

- Thermal sensing: Access, capture and processing data from thermal sensors which are located in multiple locations around the SOC.
- Thermal throttling: Providing a means of reducing the chip performance to manage power consumption in response to thermal events. Provide support for several possible software and hardware throttling mechanisms.
- External OC Alarm Slowdown: Providing a means of reducing chip performance to manage power consumption on detecting over-current alarms from outside the Tegra® 4 SOC. Examples of such OC alarms include “AC power unplug” event, PMIC over-current, battery over-current, radio power amplifier over-current events. Some events require the system to be throttled to lower power/performance within latencies that cannot be handled by software alone.
- Throttling in a di/dt safe manner: Providing hardware support to ensure that throttling in response to over-temp and over-current events happens in a di/dt safe manner. The support is implemented in SOC_THERM (for pulse skipper) and in CAR (for PLL slowdown).

The intention of this section is not to provide a full programmer’s guide, but solely to document the register interface to allow better understanding of NVIDIA® provided drivers.

40.2 Thermal Sensor

Thermal and voltage sensors are used to constantly monitor the temperature and voltage on the chip. Sensors are placed across the die to gauge the temperature of the whole chip. The TSensor module:

- Generates interrupt to software to lower temperature via DVFS, on reaching a certain thermal/voltage threshold
- Generates signal to CAR to reduce CPU frequency by half, on reaching a certain thermal/voltage threshold
- Generates signal to PMC when temperature reaches dangerously high levels to reset the chip and sets a flag in PMC

40.3 TSensor Registers

Refer to “Reading Register Tables” in the Introduction section for the register table protocol as well as recommendations for accessing registers.

40.3.1 SOC_THERM_THERMCTL_LEVEL0_GROUP_CPU_0

Offset: 0x0 │ Read/Write: R/W │ Reset: 0x0000000X (0bxxxxxxx00000000000000000000000xx)

Notice

The information provided in this specification is believed to be accurate and reliable as of the date provided. However, NVIDIA Corporation (“NVIDIA”) does not give any representations or warranties, expressed or implied, as to the accuracy or completeness of such information. NVIDIA shall have no liability for the consequences or use of such information or for any infringement of patents or other rights of third parties that may result from its use. This publication supersedes and replaces all other specifications for the product that may have been previously supplied.

NVIDIA reserves the right to make corrections, modifications, enhancements, improvements, and other changes to this specification, at any time and/or to discontinue any product or service without notice. Customer should obtain the latest relevant specification before placing orders and should verify that such information is current and complete.

NVIDIA products are sold subject to the NVIDIA standard terms and conditions of sale supplied at the time of order acknowledgement, unless otherwise agreed in an individual sales agreement signed by authorized representatives of NVIDIA and customer. NVIDIA hereby expressly objects to applying any customer general terms and conditions with regard to the purchase of the NVIDIA product referenced in this specification.

NVIDIA products are not designed, authorized or warranted to be suitable for use in medical, military, aircraft, space or life support equipment, nor in applications where failure or malfunction of the NVIDIA product can reasonably be expected to result in personal injury, death or property or environmental damage. NVIDIA accepts no liability for inclusion and/or use of NVIDIA products in such equipment or applications and therefore such inclusion and/or use is at customer’s own risk.

NVIDIA makes no representation or warranty that products based on these specifications will be suitable for any specified use without further testing or modification. Testing of all parameters of each product is not necessarily performed by NVIDIA. It is customer’s sole responsibility to ensure the product is suitable and fit for the application planned by customer and to do the necessary testing for the application in order to avoid a default of the application or the product. Weaknesses in customer’s product designs may affect the quality and reliability of the NVIDIA product and may result in additional or different conditions and/or requirements beyond those contained in this specification. NVIDIA does not accept any liability related to any default, damage, costs or problem which may be based on or attributable to: (i) the use of the NVIDIA product in any manner that is contrary to this specification, or (ii) customer product designs.

No license, either express or implied, is granted under any NVIDIA patent right, copyright, or other NVIDIA intellectual property right under this specification. Information published by NVIDIA regarding third-party products or services does not constitute a license from NVIDIA to use such products or services or a warranty or endorsement thereof. Use of such information may require a license from a third party under the patents or other intellectual property rights of the third party, or a license from NVIDIA under the patents or other intellectual property rights of NVIDIA. Reproduction of information in this specification is permissible only if reproduction is approved by NVIDIA in writing, is reproduced without alteration, and is accompanied by all associated conditions, limitations, and notices.

ALL NVIDIA DESIGN SPECIFICATIONS, REFERENCE BOARDS, FILES, DRAWINGS, DIAGNOSTICS, LISTS, AND OTHER DOCUMENTS (TOGETHER AND SEPARATELY, “MATERIALS”) ARE BEING PROVIDED “AS IS.” NVIDIA MAKES NO WARRANTIES, EXPRESSED, IMPLIED, STATUTORY, OR OTHERWISE WITH RESPECT TO THE MATERIALS, AND EXPRESSLY DISCLAIMS ALL IMPLIED WARRANTIES OF NONINFRINGEMENT, MERCHANTABILITY, AND FITNESS FOR A PARTICULAR PURPOSE. Notwithstanding any damages that customer might incur for any reason whatsoever, NVIDIA’s aggregate and cumulative liability towards customer for the products described herein shall be limited in accordance with the NVIDIA terms and conditions of sale for the product.
