- T_R5G6B5
- T_A4R4G4B4
- T_A1R5G5B5

For YCbCr data format, Cb and Cr are 8-bit unsigned values.

For YUV data format, U and V are 8-bit signed values.

YCbCr422R is similar to YCbCr422P but the Cb and Cr are shared vertically.

YUV422R is similar to YUV422P but the U and V are shared vertically.

YCbCr422RA is the same as YCbCr422R in memory, and YUV422RA is the same as YUV422R in memory. However, while reading from memory, for YCbCr422RA and YUV422RA, chroma averaging is applied for each pixel pair so that they can be processed as YUV422 by the display pipeline.

For YCbCr422R and YUV422R, every other chroma pixels are not used (discarded) by the display pipeline.

Some formats have NVCF_ or T_ prefix aliases for NVIDIA surface format naming convention, wherein left-to-right component names correspond to MSB to LSB bits within a word. In old names without NVCF_ or T_, left-to-right component names generally map LSB to MSB within a word. The T_ names are preferred.

28:16	X	<AD/BD/CD>_V_SIZE: Window AD/BD/CD V Size (lines). This is the vertical size after scaling.
12:0	X	<AD/BD/CD>_H_SIZE: Window AD/BD/CD H Size (pixels). This is the horizontal size after scaling.

24.10.6 DC_<A/B/C>_WIN_<AD/BD/CD>_PRESCALED_SIZE_0

Window AD/BD/CD Pre-scaled Size

This register defines Window AD/BD/CD pre-scaled size.

The H pre-scaled size is needed to determine how many bytes to fetch from memory per line and this parameter must be programmed exactly as needed taking into account the scaling factor. For planar YUV or YCbCr data formats, this parameter refer to the H pre-scaled of the Y plane.

The total number of lines to be fetched from memory is determined by post-scale V size but V pre-scaled size is needed to 'clamp' the last valid line if the vertical DDA is exactly or slightly beyond the specified V pre-scaled size.

H pre-scaled size ideally should be in terms of pixel but then hardware needs to convert this precisely to bytes to determine the amount of data to request from memory.

CD: Offset: 0xf88 | Byte Offset: 0x3e20 | Read/Write: R/W | Reset: 0x00000000 (0bxxxxxxxxxxxxxxxx0000000000000000)

Bit	Reset	Description
15:0	0x0	<AD/BD/CD>_V_INITIAL_DDA: Window AD/BD/CD V Initial DDA (4.12). This is typically programmed to 0.0 for both non-interlaced and interlaced sources.

24.10.9 DC_<A/B/C>_WIN_<AD/BD/CD>_DDA_INCREMENT_0

Window AD/BD/CD DDA Increment

DDA increment is typically calculated by dividing (Pre-scaled size in pixels - 1) by (Post-scaled size in pixels - 1). The result should be rounded up and expressed as 4.12 format (4-bit integer and 12-bit fraction). For non-filtered image this value can be slightly larger so that it is not missing the last row/column. Reference programming values (H and V should be calculated separately depending on filter on/off and sizes):

- Filter on: min(round((prescaled_size_in_pixels - 1) * 0x1000 / (post_scaled_size_in_pixels - 1)) + initial_dda_bias, MAX)
- Filter off: min(round(prescaled_size_in_pixels * 0x1000 / (post_scaled_size_in_pixels - 1) - 0.5) + initial_dda_bias, MAX)

Where the value of MAX is as follows:

For V_DDA_INCREMENT: 15.0 (0xF000)

For H_DDA_INCREMENT: 4.0 (0x4000) for 4 Bytes/pixel formats.

8.0 (0x8000) for 2 Bytes/pixel formats.

Where the value of initial_dda_bias is as follows:

For V_DDA_INCREMENT: initial_dda_bias = (v_intial_dda == negative) ? mod(v_initial_dda)/(post_scaled_size_in_pixels - 1) : 0 ;

For H_DDA_INCREMENT: initial_dda_bias = 0;

They are theoretically the biggest values that guarantee not displaying beyond an image boundary. If the DDA increment is less than 1.0, then the image is upscaled. If the DDA increment is more than 1.0, then the image is downscaled.

AD: Offset: 0xb89 | Byte Offset: 0x2e24 | Read/Write: R/W | Reset: 0x10001000 (0b00010000000000000001000000000000)

10:8	X	<AD/BD/CD>_DV_CONTROL_G: Digital Vibrance control for G
2:0	X	<AD/BD/CD>_DV_CONTROL_R: Digital Vibrance control for R

Class: Display Color Keying and Blending

Color keying and blending of the display windows are done prior to cursor blending.

Cursor always goes on top of the blended windows. Blending is controlled independently on each possible overlap area of the display windows. If 3 windows are enabled there are 7 possible overlap area combinations. For every window in each overlap area combination, color key can be disabled or enabled. Also, for every window in each overlap area combination, there is a corresponding window blend control parameter and a window blend weight parameter. The window blend control parameter is always effective but the window blend weight is not always used. The window blend weight can also be derived from pixel alpha value or from the reverse of other overlapping windows weight.

Color keying has the highest priority for display window blending. Color key consists of a range of color which is searched independently for each window. If more than 1 windows color key is enabled, then Window A color key has the highest priority, followed by Window B color key, and then followed by Window C color key. Two sets of color key ranges (Color Key 0 and Color Key 1) can be defined; they are shared for all windows. It is possible to use both color key sets for the same window or for two separate windows.

The two sets of color key ranges should not overlap. If they do, the overlapped colors are treated as if they are part of Color Key 0 and not part of Color Key 1.

Assuming that there is no overlap with other higher priority window with color key not matched, if a window color key is enabled for any overlap condition and the window pixel is not within the color key range (key not match), then the window pixel will not be blended with other overlapping window pixels but it will be weighted. The weight is not dependent on the overlap condition it is controlled by the same set of parameters for all overlapping condition.

Assuming that there is no overlap with other higher priority window with color key not matched, if a window color key is enabled for a particular overlap condition and the window pixel is within the color key range (key match), then the window pixel will be weighted and blended with other overlapping pixels and this is controlled separately for each overlap condition.

Assuming that there is no overlap with other higher priority window with color key not matched, if a window color key is disabled then the window pixel will be blended with other overlapping pixels and this is controlled separately for each overlap condition.

Display Color Key parameters

For B4G4R4A4, B5G6R5A, and B5G6R5 modes, the color key should be compared prior to color conversion to 24-bpp and unused least significant bits of the pixel are filled with zeros.

For palletized mode, the color key is compared prior to the color palette, and the palletized color is compared against the green color key values/mask.

For YUV mode, U and V are offset by +128 before performing the color key comparison. In all cases, the color key is compared prior to the horizontal/vertical scaling filter and prior to digital vibrance control.

Both upper and lower values are inclusive.

24.11.1 DC_<A/B/C>_WINBUF_<AD/BD/CD>_START_ADDR_0

Window AD/BD/CD Start Address

Overview

START_ADDR, BUF_STRIDE, LINE_STRIDE, ADDR_H_OFFSET, ADDR_V_OFFSET combined, specify the starting address of a window buffer in the memory surface. Generally, START_ADDR is programmed with the starting address of the memory surface. H/V_OFFSET specifies the address offsets of the pixel at the beginning of the window with respect to the starting address of the memory surface. (There is an exception to that when memory surface is not well aligned, see ”For linear address mode” in Programming Restrictions below.)

Note that “beginning of the window” here means the top-left corner of a window in normal mode, top-right corner in horizontal flipping, bottom-left corner in vertical flipping, and bottom-right in horizontal+vertical flipping.

Starting Address Calculation

These formulae are same for both tiled and linear modes. However, for linear mode, the addresses calculated are real physical addresses. For tiled mode, these addresses will be translated to the real physical addresses by the memory controller client before being used.

- When a window is host triggered, starting address of a window is calculated as follows by hardware:
  - non-YUV-planar modes:

    starting-address = START_ADDR + ADDR_V_OFFSET * LINE_STRIDE + ADDR_H_OFFSET
  - YUV-planar modes:

    Y-starting-address = START_ADDR + ADDR_V_OFFSET * LINE_STRIDE + ADDR_H_OFFSET

    U-starting-address = START_ADDR_U + ADDR_V_OFFSET * UV_LINE_STRIDE / denom1 + ADDR_H_OFFSET / denom2

    V-starting-address = START_ADDR_V + ADDR_V_OFFSET * UV_LINE_STRIDE / denom1 + ADDR_H_OFFSET / denom2 where denom1/denom2 equal to 1 or 2 depending on the actual planar format, derived natively by hardware.
- When a window is non-host triggered, starting address of a window buffer is calculated as below.
  - non-YUV-planar mode:

    starting-address = START_ADDR + BUF_STRIDE * buf_index + ADDR_V_OFFSET * LINE_STRIDE + ADDR_H_OFFSET
  - YUV-planar mode:

Y-starting-address = START_ADDR + BUF_STRIDE * buf_index + ADDR_V_OFFSET * LINE_STRIDE + ADDR_H_OFFSET

U-starting-address = START_ADDR_U + UV_BUF_STRIDE * buf_index + ADDR_V_OFFSET * UV_LINE_STRIDE / denom1 + ADDR_H_OFFSET / denom2

V-starting-address = START_ADDR_V + UV_BUF_STRIDE * buf_index + ADDR_V_OFFSET * UV_LINE_STRIDE / denom1 + ADDR_H_OFFSET / denom2 where denom1/denom2 equal to 1 or 2 depending on the actual planar format, derived natively by hardware.

buf_index is the index transmitted by the triggering module pointing to the first buffer of a frame.

Programming Restrictions

i. For tiled address mode:

Image surface can only be aligned to multiples of 256, thus the following restrictions.

- START_ADDR, START_ADDR_U, START_ADDR_V need to be multiples of 256.
- BUF_STRIDE, UV_BUF_STRIDE need to be multiples of 256
- LINE_STRIDE, UV_LINE_STRIDE need to be multiples of 16
- ADDR_H_OFFSET needs to be even in YUV planar format, or a multiple of bytes per pixel in other formats. If H_DIRECTION=DECREMENT, however, it should point to last valid byte, which is an odd offset.
- ADDR_V_OFFSET needs to be a multiple of 2 in YUV planar format, unless H_DIRECTION=DECREMENT, but with no restrictions on other color formats.

ii. For linear address mode:

Image surface can be aligned 2, 4 or 8 bytes, depending on the color formats.

As an additional restriction for display, START_ADDR, START_ADDR_U and START_ADDR_V need to be multiples of 16.

When a surface is not aligned to 16 bytes, program START_ADDR with the memory surface address with its least 4 significant bits zeroed out and add these 4 address bits to the original H_OFFSET. (So the formulae in Starting Address Calculation above still hold)

- For all formats:
  - START_ADDR, START_ADDR_U and START_ADDR_V need to be multiples of 16.
- For 16-bpp formats,
  - (START_ADDR+H_OFFSET) need to be a multiple of 2.
- For 32-bpp formats,
  - (START_ADDR+H_OFFSET) needs to be a multiple of 4.
- For YUV planar formats:
  - BUF_STRIDE, UV_BUF_STRIDE:

    BUF_STRIDE[2:1]=UV_BUF_STRIDE[1:0]

    or as a stricter constraint: BUF_STRIDE is a multiple of 8, UV_BUF_STRIDE is a multiple of 4.
  - LINE_STRIDE, UV_LINE_STRIDE:

    LINE_STRIDE and UV_LINE_STRIDE need to be at least 16.

    LINE_STRIDE needs to be a multiple of 8, UV_LINE_STRIDE needs to be a multiple of 4.
  - ADDR_H_OFFSET: Needs to be even unless H_DIRECTION=DECREMENT, in which case should point to the last byte pixel, which is at an odd offset. .
  - ADDR_V_OFFSET: Needs to be even unless V_DIRECTION=DECREMENT, in which case should point to the last valid line, which is at an odd offset. .

iii. Memory allocation for non-host triggered case:

When a window buffer is not controlled by host (software) then a frame may be stored in multiple buffers. In this case, the buffers must be contiguous in the memory because display will use the same luma or chroma line strides for all lines in the frame. Also buffer wraparound must not occur in the middle of the displayed part of the frame.

The controlling module will send frame start and frame end indicators (flags) to display module to indicate the beginning and end of frame. Buffer start address is latched when frame start flag is active but the actual buffer start address is not switched until frame end flag is active. In the case where one buffer corresponds to one frame then frame start and frame end flag are active every time a buffer index is sent.

12:0	0x0	<AD/BD/CD>_UFLOW_THRESHOLD

24.11.23 DC_<A/B/C>_WINBUF_<AD/BD/CD>_SPOOL_UP_0

Spool up time configuration for different windows related logic.

SPOOL_UP_CTRL = MAX - This is the current Tegra X1 behavior. This allows for memfetch to start fetching for a window (irrespective of its relative position on the screen), at the very beginning of the Vblank of the next frame. Since the spool up time is maximum, this should have the least probability of underflow of the display pipe. However, on the down side, since all three windows would start fetching at the same time, and since display is a high priority client for MC, it has a high potential to starve out other clients.

SPOOL_UP_CTRL = PROGRAMMABLE, SPOOL_UP_DURATION = 1 - This corresponds to the Tegra 3 behavior. Since the fetch starts only 1 line prior to the active scan line of a window, this has high probability of causing underflow, but has a lesser impact on the other MC clients.

So, this register programmability programs a method to modulate the spool up time between the best and worst, if required, when other MC clients are present. For example when GPU/VIC is active, we may not want a very aggressive spool up and program some definite spool up duration. So, spool up time is a general knob, which would be a function of the resolution, bpp, active clients, memory speed, etc.

SPOOL_UP_EDGE:- By default the memfetch start signal generated by the hvtgen logic is one line clock wide.

For SPOOL_UP_CTRL = MAX:

- In this case if SPOOL_UP_EDGE is programmed to NEGEDGE. This ensures that if any act_req is sent during the time vcounter = 0(at the beginning of the frame). The activate value is loaded into the active state and the memfetch would see the latest updated value. The downside of programming it to NEGDGE is that we lose out on 1 line clock worth of spool up. This is required based upon Tegra compatibility and the way tests are written.
- In this case if SPOOL_UP_EDGE is programmed to POSEDGE. Then the memfetch would start fetching at the very beginning of the frame start pulse (1 line clock wide) and would give maximum spool up time. However, this may give test failure and potential Tegra compatibility issues as described above

FOR SPOOL_UP_CTRL = PROGRAMMABLE:

- Special care must be taken here. If SPOOL_UP_DURATION is set to 1. SPOOL_UP_EDGE must be set to POSEDGE to allow for at least 1 line worth of spool up.
- If SPOOL_UP_DURATION is > 1. Then SPOOL_UP_EDGE can be either POSEDGE or NEGEDGE. If it is NEGEDGE, then the effective spool up duration would be 1 line clock less than the SPOOL_UP_DURATION.

15:0	0xffff	<AD/BD/CD>_SF_HWM_THRESHOLD

24.11.25 DC_<A/B/C>_WINBUF_<AD/BD/CD>_LATENCY_THRESHOLD_0

The LATENCY_THRESHOLD register controls the behavior of the rdy4_latency_event from the display to the MC.

If B_RDY4LATENCY_THRESHOLD_ENABLE is set to DISABLE, the sideband rdy4_latency_event is always asserted, indicating that the display is always ready for a DVFS event.

The B_RDY4LATENCY_THRESHOLD field indicates the required occupancy of line buffers of windows below which the sideband rdy4_latency_event is deasserted. The occupancy figure is in units of 64B atoms for memfetch windows and in units of scan lines for regular windows.

The B_RDY4LATENCY_SPOOLUP_DURATION field indicates the number of scan lines during when the sideband will remain asserted (DVFS is allowed). This takes affect only when B_RDY4LATENCY_SPOOLUP_CTRL is set to ALLOW.

If the B_RDY4LATENCY_SPOOLUP_CTRL field is set to DISALLOW, the above register field is not affected and DVFS is disallowed until the threshold is reached.

24.12 WINBUF_AD/BD/CD CDE Registers

Note: *In the register and field names, <A/B/C> indicates A, B, or C, and <AD/BD/CD> indicates AD, BD, or CD, depending on the window selection.*

24.12.1 DC_<A/B/C>_WINBUF_<AD/BD/CD>_CDE_CONTROL_0

These WINBUF A CDE registers control window (WIN) parameters.

Note that there are three copies of these registers for windows A, B, and C. Only comptag base address registers are triple-buffered to be consistent with display surface start address buffering (this is required to support immediate flips).All other registers are double-buffered so that flips can be atomic and consistent. Registers will be activated by the WIN_x_ACT_REQ/UPDATE in display.

This register implements per surface compression enables, drawing direction, scanning direction, surface traversal control, and diagnostics to reset Request and Response side on Frame Start.

AD: Offset: 0xbef | Byte Offset: 0x2fbc | Read/Write: R/W | Reset: 0x00000000 (0bxxxxxxxxxxxxxxxxxx00xxxxxxxxxx0)

Bit	Reset	Description
27:16	0x0	<AD/BD/CD>_YOFFSET. The YOFFSET bits identify the Y offset for surface N
11:0	0x0	<AD/BD/CD>_XOFFSET. The XOFFSET bits identify the X offset for surface N.

24.12.6 DC_<A/B/C>_WINBUF_<AD/BD/CD>_CDE_CTB_ENTRY_0_0

This register implements per surface Maximum CTB entry count (in terms of CTB entry pairs) for Surfaces 0-3. For Display only, surface 0 is implemented.

AD: Offset: 0xbf6 | Byte Offset: 0x2fd8 | Read/Write: R/W | Reset: 0x00000002 (0bxxxxxxxxxxxxxxxxxxxxxxxxx00000010)
BD: Offset: 0xdf6 | Byte Offset: 0x37d8 | Read/Write: R/W | Reset: 0x00000002 (0bxxxxxxxxxxxxxxxxxxxxxxxxx00000010)
CD: Offset: 0xff6 | Byte Offset: 0x3fd8 | Read/Write: R/W | Reset: 0x00000002 (0bxxxxxxxxxxxxxxxxxxxxxxxxx00000010)

Bit	Reset	Description
7:0	0x2	<AD/BD/CD>_MAXENTRYCOUNT0. The MAXENTRYCOUNT{i} bits identify the per surface Maximum CTB entry count(in terms of CTB entry pairs) for Surfaces 0-3.For Display only surface 0 is implemented.

24.12.7 DC_<A/B/C>_WINBUF_<AD/BD/CD>_CDE_CG_SW_OVR_0

This register implements SW override to enable/disable CDE clock-gating.

AD: Offset: 0xbf7 | Byte Offset: 0x2fdc | Read/Write: R/W | Reset: 0x00000001 (0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx1)
BD: Offset: 0xdf7 | Byte Offset: 0x37dc | Read/Write: R/W | Reset: 0x00000001 (0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx1)
CD: Offset: 0xff7 | Byte Offset: 0x3fdc | Read/Write: R/W | Reset: 0x00000001 (0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx1)

Bit	Reset	Description
0	0x1	<AD/BD/CD>_CG. The CG bit identifies the CG software override to enable/disable CDE clock gating: 0 = DISABLE 1 = ENABLE

24.12.8 DC_<A/B/C>_WINBUF_<AD/BD/CD>_CDE_PM_CONTROL_0

This register is a select for PM counters implemented in the CDE.

AD: Offset: 0xbf8 | Byte Offset: 0x2fe0 | Read/Write: R/W | Reset: 0x00000000 (0bxxxxxxxxxxxxxxxxxxxxxxxxxxxx0000)
BD: Offset: 0xdf8 | Byte Offset: 0x37e0 | Read/Write: R/W | Reset: 0x00000000 (0bxxxxxxxxxxxxxxxxxxxxxxxxxxxx0000)
CD: Offset: 0xff8 | Byte Offset: 0x3fe0 | Read/Write: R/W | Reset: 0x00000000 (0bxxxxxxxxxxxxxxxxxxxxxxxxxxxx0000)

Bit	Reset	Description
3:0	0x0	<AD/BD/CD>_SELECT. The SELECT bits identify the select lines for PM counters implemented in the CDE: 0 = CTB_LOOKUP_HIT 1 = CTB_LOOKUP_MISS 2 = UNCOMP_1TO1 3 = ARITHMETIC_2TO1 4 = REDUCTION_8TO1 5 = ZBC 6 = CSR_FETCH_64B 7 = CTB_FETCH_64B 8 = PIXEL_FETCH_64B 9 = PIXEL_FETCH_32B 10 = CTB_READS_SAMPLED 11 = CTB_READ_RSP_LATENCY 12 = PIXEL_READS_SAMPLED 13 = PIXEL_READ_RSP_LATENCY

24.12.9 DC_<A/B/C>_WINBUF_<AD/BD/CD>_CDE_PM_COUNTER_0

This register is one of the read-back PM counters implemented in the CDE. Selected based on CDE_PM_CONTROL_SELECT.

AD: Offset: 0xbf9 | Byte Offset: 0x2fe4 | Read/Write: RO | Reset: 0xXXXXXXXX (0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx)
BD: Offset: 0xdf9 | Byte Offset: 0x37e4 | Read/Write: RO | Reset: 0xXXXXXXXX (0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx)
CD: Offset: 0xff9 | Byte Offset: 0x3fe4 | Read/Write: RO | Reset: 0xXXXXXXXX (0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx)

Bit	Reset	Description
31:0	X	<AD/BD/CD>_VALUE. The VALUE bits identify the value of PM counter based on select lines.

24.13 Window DD/TD (WIN_DD/TD) Registers

These registers control window DD and window TD parameters.

The registers under DC_WIN are double buffered.

Window TD: only 2BPP and 4BPP pitched linear format. None of the features listed in Windows A/B/C. The registers under DC_WIN_T are only accessed directly and not triple buffered.

> ***Note:*** *In the register and field names, <D/T> indicates D or T, and <DD/TD> indicates DD or TD, depending on the window selection.*

24.13.1 DC_<D/T>_WIN_<DD/TD>_WIN_OPTIONS_0

Window DD/TD Options

Class: Display Window Settings

Display Window DD/TD parameters

DD: Offset: 0x80 | Byte Offset: 0x200 | Read/Write: R/W | Reset: 0x00000000 (0bx0xxxxxxxxxxxxxxxxxxxxxxx0xxxxxx)
TD: Offset: 0x100 | Byte Offset: 0x400 | Read/Write: R/W | Reset: 0x00000000 (0bx0xxxxxxxxxxxxxxxxxxxxxxx0xxxxxx)

Bit	Reset	Description
30	0x0	<DD/TD>_WIN_ENABLE: Window DD/TD Window enable 0 = DISABLE 1 = ENABLE
6	0x0	<DD/TD>_COLOR_EXPAND: Window DD/TD 12/15/16/18-to-24 bpp color expansion. This bit should be enabled only for 12-bpp B4G4R4A4, 15-bpp B5G5R5A, 16-bpp B5G6R5, 18-bpp B6G6R6 color modes. If enabled, the color conversion is performed prior to horizontal scaling. 0 = DISABLE 1 = ENABLE

24.13.2 DC_<D/T>_WIN_<DD/TD>_COLOR_DEPTH_0

Window DD/TD Color Depth

This register describes the Window DD/TD color surface format. Windows have different capabilities and support subsets of these formats.

Windows A/B/C can use BYTE_SWAP to support additional formats.

Windows D/T do not support BYTE_SWAP. They support only the following formats:

- T_A8R8G8B8
- T_A8B8G8R8
- T_R5G6B5

- T_A4R4G4B4
- T_A1R5G5B5

For the YCbCr data format, Cb and Cr are 8-bit unsigned values. For the YUV data format, U and V are 8-bit signed values. YCbCr422R is similar to YCbCr422P but the Cb and Cr are shared vertically.

YUV422R is similar to YUV422P, but the U and V are shared vertically. YCbCr422RA is the same as YCbCr422R in memory and YUV422RA is the same as YUV422R in memory but while reading from memory, for YCbCr422RA and YUV422RA, chroma averaging is applied for each pixel pair so that they can be processed as YUV422 by the display pipeline.

For YCbCr422R and YUV422R, every other chroma pixels are not used (discarded) by the display pipeline.

Some formats have NVCF_ or T_ prefix aliases for Nvidia surface format naming convention, wherein left-to-right component names correspond to MSB to LSB bits within a word. In old names without NVCF_ or T_, left-to-right component names generally map LSB to MSB within a word.

The T_ names are preferred.

Bit	Reset	Description
28:16	X	<DD/TD>_V_SIZE: Window DD/TD V Size (lines). This is the vertical size after scaling.

Bit	Reset	Description
12:0	X	<DD/TD>_H_SIZE: Window DD/TD H Size (pixels). This is the horizontal size after scaling.

24.13.5 DC_<D/T>_WIN_<DD/TD>_LINE_STRIDE_0

Window DD/TD Line Stride

DD: Offset: 0x8a | Byte Offset: 0x228 | Read/Write: R/W | Reset: 0x00000000 (0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx)
TD: Offset: 0x10a | Byte Offset: 0x428 | Read/Write: R/W | Reset: 0x00000000 (0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx)

Bit	Reset	Description
15:0	X	<DD/TD>_LINE_STRIDE: Window DD/TD Line Stride. This is stride (in bytes) for all non-planar data formats. If the memory surface is tiled, the stride needs to be a multiple of 16. If H_DIRECTION of window DD/TD is set to DECREMENT, the stride also needs to be a multiple of 16. For planar YUV or YCbCr data formats, this is stride (in bytes) for the luma plane with the restriction that it must be in multiples of 8 (16 if tiled or in horizontal flipping) For tiled surface this value may affect starting address of a window. Refer to the comment of START_ADDR for detail.

24.14 WINBUF_DD/TD Registers

Note: *In the register and field names, <D/T> indicates D or T, and <DD/TD> indicates DD or TD, depending on the window selection.*

24.14.1 DC_<D/T>_WINBUF_<DD/TD>_START_ADDR_0

Window DD/TD Start Address

Overview

START_ADDR, BUF_STRIDE, LINE_STRIDE, ADDR_H_OFFSET, ADDR_V_OFFSET combined, specify the starting address of a window buffer in the memory surface. Generally, START_ADDR is programmed with the starting address of the memory surface. H/V_OFFSET specifies the address offsets of the pixel at the beginning of the window, with respect to the starting address of the memory surface. (There is an exception to that when memory surface is not well aligned, see “For linear address mode” under Programming Restrictions below.)

Note that "beginning of the window" here means the top-left corner of a window in normal mode, top-right corner in horizontal flipping, bottom-left corner in vertical flipping, and bottom-right in horizontal+vertical flipping.

Starting Address Calculation

These formulae are same for both tiled and linear modes. However, for linear mode, the addresses calculated are real physical addresses. For tiled mode, these addresses will be translated to the real physical addresses by the memory controller client before being used.

- When a window is host triggered, the starting address of a window is calculated as follows by hardware.
  - non-YUV-planar modes

    starting-address = START_ADDR + ADDR_V_OFFSET * LINE_STRIDE + ADDR_H_OFFSET
  - YUV-planar modes

    Y-starting-address = START_ADDR + ADDR_V_OFFSET * LINE_STRIDE + ADDR_H_OFFSET

    U-starting-address = START_ADDR_U + ADDR_V_OFFSET * UV_LINE_STRIDE / denom1 + ADDR_H_OFFSET / denom2

    V-starting-address = START_ADDR_V + ADDR_V_OFFSET * UV_LINE_STRIDE / denom1 + ADDR_H_OFFSET / denom2 where denom1/denom2 equal to 1 or 2 depending on the actual planar format, derived natively by hardware.

- When a window is non-host triggered, starting address of a window buffer is calculated as below.
  - non-YUV-planar mode

    starting-address = START_ADDR + BUF_STRIDE * buf_index + ADDR_V_OFFSET * LINE_STRIDE + ADDR_H_OFFSET
  - YUV-planar mode:

    Y-starting-address = START_ADDR + BUF_STRIDE * buf_index + ADDR_V_OFFSET * LINE_STRIDE + ADDR_H_OFFSET

    U-starting-address = START_ADDR_U + UV_BUF_STRIDE * buf_index + ADDR_V_OFFSET * UV_LINE_STRIDE / denom1 + ADDR_H_OFFSET / denom2

    V-starting-address = START_ADDR_V + UV_BUF_STRIDE * buf_index + ADDR_V_OFFSET * UV_LINE_STRIDE / denom1 + ADDR_H_OFFSET / denom2

    where denom1/denom2 are equal to 1 or 2 depending on the actual planar format, derived natively by hardware.

    buf_index is the index transmitted by the triggering module pointing to the first buffer of a frame.

Programming Restrictions

- For tiled address mode

  Image surface can only aligned to multiples of 256, thus the following restrictions.
  - START_ADDR, START_ADDR_U, START_ADDR_V need to be multiples of 256.
  - BUF_STRIDE, UV_BUF_STRIDE need to be multiples of 256
  - LINE_STRIDE, UV_LINE_STRIDE need to be multiples of 16
  - ADDR_H_OFFSET needs to be even in yuv planar format, or a multiple of bytes per pixel in other formats. If H_DIRECTION=DECREMENT, however, it should point to last valid byte, which is an odd offset.
  - ADDR_V_OFFSET needs to be multiple of 2 in YUV planar format, unless H_DIRECTION=DECREMENT, but with no restrictions on other color formats
- For linear address mode

  Image surface can be aligned 2, 4, or 8 bytes, depending on the color formats.

  As an additional restriction for display, START_ADDR, START_ADDR_U and START_ADDR_V need to be multiples of 16. When a surface is not aligned to 16 bytes, program START_ADDR with the memory surface address with its least 4 significant bits zeroed out and add these 4 address bits to the original H_OFFSET. (So the formulae in Starting Address Calculation above still hold)
  - For all formats:

    START_ADDR, START_ADDR_U and START_ADDR_V need to be multiples of 16.
  - For 16-bpp formats,

    (START_ADDR+H_OFFSET) needs to be a multiple of 2.
  - For 32-bpp formats,

    (START_ADDR+H_OFFSET) needs to be a multiple of 4.
  - For YUV planar formats:
    - BUF_STRIDE, UV_BUF_STRIDE:
    - BUF_STRIDE[2:1]=UV_BUF_STRIDE[1:0]

    or as a stricter constraint: BUF_STRIDE is a multiple of 8, UV_BUF_STRIDE be a multiple of 4.
    - LINE_STRIDE, UV_LINE_STRIDE:

      LINE_STRIDE and UV_LINE_STRIDE need to be at least 16.

      LINE_STRIDE needs to be a multiple of 8, UV_LINE_STRIDE needs to be a multiple of 4.

- ADDR_H_OFFSET: Needs to be even unless H_DIRECTION=DECREMENT, in which case should point to the last byte pixel, which is at an odd offset.
- ADDR_V_OFFSET: Needs to be even unless V_DIRECTION=DECREMENT, in which case should point to the last valid line, which is at an odd offset

- Memory allocation for non-host triggered case:

  When a window buffer is not controlled by host (software) then a frame may be stored in multiple buffers. In this case, the buffers must be contiguous in the memory because display will use the same luma or chroma line strides for all lines in the frame.

  Also buffer wraparound must not occur in the middle of the displayed part of the frame. The controlling module will send frame start and frame end indicators (flags) to display module to indicate the beginning and end of frame. Buffer start address is latched when frame start flag is active but the actual buffer start address is not switched until frame end flag is active. In the case where one buffer corresponds to one frame then frame start and frame end flag are active every time a buffer index is sent.

DD: Offset: 0xc0 | Byte Offset: 0x300 | Read/Write: R/W | Reset: 0x00000000 (0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx)
TD: Offset: 0x140 | Byte Offset: 0x500 | Read/Write: R/W | Reset: 0x00000000 (0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx)

Bit	Reset	Description
31:0	X	<DD/TD>_START_ADDR: Window DD/TD Start Address. This is a byte address. The LSB is not used for 16-bpp non-planar pixel format and the last 2 LSBs are not used for 32-bpp non-planar pixel format. For YUV planar pixel format, this specifies start address for the Y plane.

24.14.2 DC_<D/T>_WINBUF_<DD/TD>_ADDR_H_OFFSET_0

Window DD/TD Horizontal address offset

DD: Offset: 0xc6 | Byte Offset: 0x318 | Read/Write: R/W | Reset: 0x00000000 (0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx)
TD: Offset: 0x146 | Byte Offset: 0x518 | Read/Write: R/W | Reset: 0x00000000 (0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx)

Bit	Reset	Description
31:0	X	<DD/TD>_ADDR_H_OFFSET: Window DD/TD Horizontal address offset. This is a byte address. The LSB is not used for 16-bpp non-planar pixel format and the last 2 LSBs are not used for 32-bpp non-planar pixel format. For YUV planar pixel format, this specifies horizontal offset of Y plane. The horizontal offsets of U/V plane is derived by hardware.

24.14.3 DC_<D/T>_WINBUF_<DD/TD>_ADDR_V_OFFSET_0

Window DD/TD Vertical address offset

DD: Offset: 0xc8 | Byte Offset: 0x320 | Read/Write: R/W | Reset: 0x00000000 (0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx)
TD: Offset: 0x148 | Byte Offset: 0x520 | Read/Write: R/W | Reset: 0x00000000 (0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx)

Bit	Reset	Description
31:0	X	<DD/TD>_ADDR_V_OFFSET: Window DD/TD Vertical address offset. This is the vertical coordinate. For YUV planar pixel format, this specifies the vertical coordinate of Y plane. The vertical coordinate of U/V plane is derived by hardware.

24.14.4 DC_<D/T>_WINBUF_<DD/TD>_UFLOW_STATUS_0

Window DD/TD FIFO Underflow Status Register

DD: Offset: 0xca | Byte Offset: 0x328 | Read/Write: R/W | Reset: 0x00000000 (0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx)
TD: Offset: 0x14a | Byte Offset: 0x528 | Read/Write: R/W | Reset: 0x00000000 (0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx)

Bit	Reset	Description
30	X	COUNT_OFLOW: Flag bit that indicates that the underflow event counter has overflowed. There were too many events. If COUNT_OFLOW is set, UFLOW_COUNT is meaningless. Cleared on write.
23:0	X	UFLOW_COUNT: Underflow count. This field indicates the number of contiguous groups of output pixels for which there was no data in the FIFO. For example, if the valid from the FIFO is low for 10 consecutive cycles and then goes high, the counter will increment by one. Reset to zero on write.

24.14.5 DC_<D/T>_WINBUF_<DD/TD>_START_ADDR_HI_0

Window DD/TD Higher 32 bits of Start Address

Makes the start address 64 bits by adding the higher 32 bits below.

DD: Offset: 0xcd │ Byte Offset: 0x334 │ Read/Write: R/W │ Reset: 0x00000000 (0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx00)
TD: Offset: 0x14d │ Byte Offset: 0x534 │ Read/Write: R/W │ Reset: 0x00000000 (0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx00)

Bit	Reset	Description
1:0	0x0	<DD/TD>_START_ADDR_HI: Window DD/TD Start Address. This is a byte address. The LSB is not used for 16-bpp non-planar pixel format and the last 2 LSBs are not used for 32-bpp non-planar pixel format. For YUV planar pixel format, this specifies start address for the Y plane.

24.14.6 DC_<D/T>_WINBUF_<DD/TD>_UFLOW_CTRL_0

When the underflow debug mode is enabled. Instead of sending out the last valid pixel, DBG_PIXEL is sent out.

If <DD/TD>_UFLOW_CYA is set, the underflow recovery logic for simple windows is bypassed and replaced with an overflow-pop logic present in Tegra 3 styled windows.

DD: Offset: 0xe4 │ Byte Offset: 0x390 │ Read/Write: R/W │ Reset: 0x00000000 (0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx00)
TD: Offset: 0x164 │ Byte Offset: 0x590 │ Read/Write: R/W │ Reset: 0x00000000 (0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx00)

Bit	Reset	Description
31:0	X	<DD/TD>_UFLOW_DBG_PIXEL

24.14.8 DC_<D/T>_WINBUF_<DD/TD>_SPOOL_UP_0

Spool up time configuration for different windows related logic.

SPOOL_UP_CTRL = MAX - This is the current Tegra X1 behavior. This allows for memfetch to start fetching for a window (irrespective of its relative position on the screen), at the very beginning of the VBlank of the next frame. Since the spool up time is maximum, this should have the least probability of underflow of the display pipe. However, on the down side, since all three windows would start fetching at the same time, and since display is a high priority client for the MC, it has a high potential to starve out other clients.

SPOOL_UP_EDGE:- By default the memfetch start signal generated by the hvtgen logic is one line clock wide.

For SPOOL_UP_CTRL = MAX:

- If SPOOL_UP_EDGE is programmed to NEGEDGE, it ensures that if any act_req is sent during the time vcounter = 0 (at the beginning of the frame). The activate value is loaded into the active state and the memfetch would see the latest updated value.

  The downside of programming SPOOL_UP_EDGE to NEGDGE is 1 line clock worth of spool up is lost. This is required based upon Tegra compatibility.

- If SPOOL_UP_EDGE is programmed to POSEDGE, the memfetch starts fetching at the very beginning of the frame start pulse (1 line clock wide) and gives maximum spool up time. However, this may give test failure and potential Tegra compatibility issues as described above.

CHAPTER 25: COLOR DECOMPRESSION ENGINE

The color decompression engine (CDE) provides for color decompression which supports end-to-end data compression from surface render to display. The CDE resides between the GPU surface consumers (Display Controller or VIC) and memory.

The CDE allows GPU surface consumers to read compressed surfaces. The CDE converts the uncompressed surface requests into compressed surface requests, decompresses the data, and returns it to the GPU surface consumer uncompressed.

Refer to Chapter 24: Display Controller and Chapter 15: Video Image Compositor (VIC) for more information.

25.1 Features

CDE features include support for:

- Decompression of 4BPP surface colors
- Decompression ratios of 1:2, 1:8
- Arithmetic decompression (2:1)
- Reduction decompression (8:1)
- ZBC (Zero Bandwidth Clear)
  - Single ZBC color per surface
- Up to 8 surfaces
  - Compression bit buffer sized to support up to 2:1 downscaling for 8 surfaces
- Compression bit prefetching
  - Hide latency of fetching compression bits then fetching compressed data
  - Amortized over multiple scan lines
  - 128B fetch granularity
- Decompression bypass
  - Override requests to compressed surfaces
- Up to 4Kx4K pixel surface support
  - Maximum panel resolution – 4096 x 2560
- Surface Occlusion support
  - Up to 8 surfaces
- Immediate Flip support
  - Flip delayed to align with ROP tile boundary scan line

25.2 Functional Description

25.2.1 CDE Overview

The design point of CDE illustrated in the figure below is as follows:

- The CDE is a unit that exists between the compressed surface consumer and memory controller
  - Either between display and MCCIF or VIC and MCCIF
- The surface consumer will make requests for uncompressed data

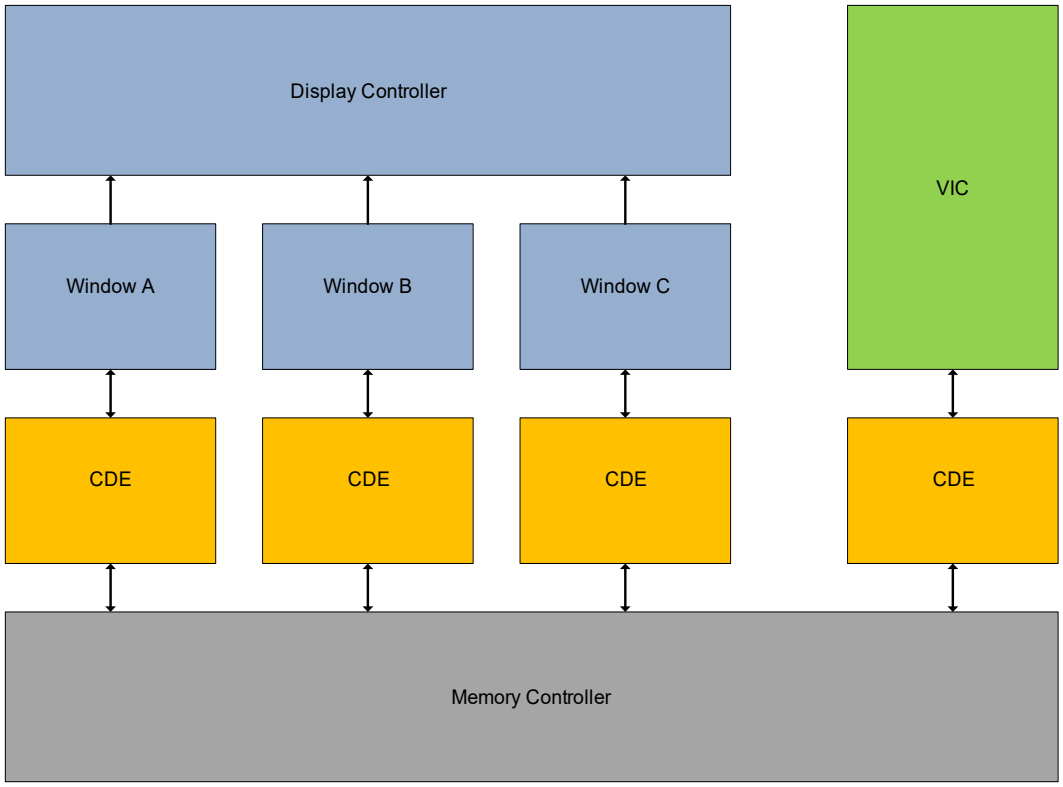
- The CDE determines whether the data is compressed.
  - If it is compressed, the CDE fetches the corresponding compressed data, decompresses it, and sends it to the GPU surface consumer
  - If it is uncompressed, the CDE passes the request and response through unmodified

The overall strategy for supporting decompression is as follows:

- GPU renders compressed surface
- Flush L2 cache and compression bit cache (CBC)
- Software running on GPU reformats CBC bits to allow for surface traversal either in horizontal or vertical fashion.
- Software updates registers in GPU surface consumer with respect to the new compressed surface
  - CDE registers part of surface fetch engine (i.e., VIC or display)
- GPU surface consumer reads from the compressed surface and CDE decompresses the surface as it returns the data

Note: *Since a surface flush and reformatting of CBC bits are required the surface must be at least double buffered. The GPU cannot render to a surface being displayed since display does not have access to the GPU L2 cache.*

Figure 100: CDE Design Point



25.3 CDE Registers

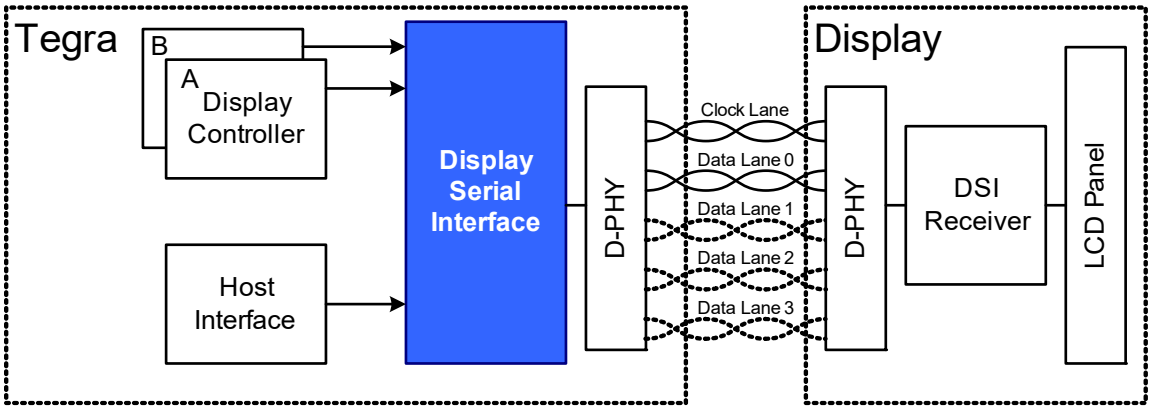
Refer to the following subsections in Chapter 24: Display Controller in this TRM for definitions of the CDE registers:

- WINBUF_A CDE Registers
- WINBUF_B CDE Registers
- WINBUF_C CDE Registers

CHAPTER 26: DISPLAY INTERFACES: MIPI-DSI

The Display Serial Interface (DSI) is a MIPI standard serial bitstream that provides a low pin-count interface to a display panel. DSI reduces both package pin-count and I/O power consumption compared with parallel solutions. It transfers pixel data from either one of the display controllers (internal to the Tegra® X1 device) to an external third-party LCD module. The physical positioning of the DSI module in relation to other units/devices in the system is shown below.

Figure 101: System Block Diagram of Single DSI Unit



DSI is a replacement for the MIPI DPI and DBI standards and follows the use cases of these interfaces. From a data transport point of view, MIPI DPI is an interface similar to a traditional raster-based isochronous display interface, and DBI is an asynchronous packet based transfer mechanism. DSI behaves like MIPI DPI when in Video Mode, and implements a Command Mode to handle the DBI interface. Any implementation must implement both these modes of operation.

26.1 Features

- Two DSI controllers, each drives the data on the respective D-PHY lanes
- Each DSI interface has 1 clock lane and 4 data lanes
- Maximum 1.5 GHz HS transmit rate
- Maximum 10 MHz LP receive rate
- Supports up to 8 PHY lanes with each DSI instance/channel supporting 1, 2, 3, 4 data lanes in Ganged mode configuration
- Video Mode with display controller as master
- Command Mode with host and/or display controller as masters
- Maximum Video Mode resolution is:
  - Uncompressed: 3480x1920, 60 fps at 24 bpp
  - Compressed: 4096x2304, 60 fps with 3:1 compression (8 bpp)
- Maximum Command Mode packet length is 1920 words
- Ganged Mode (Odd-Even/Left-Right)
- Dummy/Overlap mode

26.2 Functionality

26.2.1 Display Controller Interface

The interface between the display controller and the DSI unit consists of pixel data, Sync data, and a Line-Type code.

DSI captures the state of the line type code every line. This information is then used to look up a pre-programmed packet sequence that corresponds to that line type. There are several different line types to select from.

26.2.2 Packet Poster

The packet poster determines which packets will be sent on what video line when the DSI is in any of the 3 video modes and is being controlled by the display controller. The functions that this sub-unit performs are:

- Line type look-up
- Packet sequence generation
- Pixel data / packet stream integration

There are currently 6 valid line types that can be encoded on the 3 bits from the display controller. The other 2 line types are reserved for future use. The line type coding is shown in the following table.

Table 128: Line Type Descriptions

Line Type	Description
0	Blank line starting with VS
1	Blank line starting with VE
2	Blank line starting with HS
3	Active line
4	First blank line after active
5	First active line

The packet sequences corresponding to each line type are held in a pair of 32-bit registers. Each register holds three packet descriptors, and each packet descriptor has the following information:

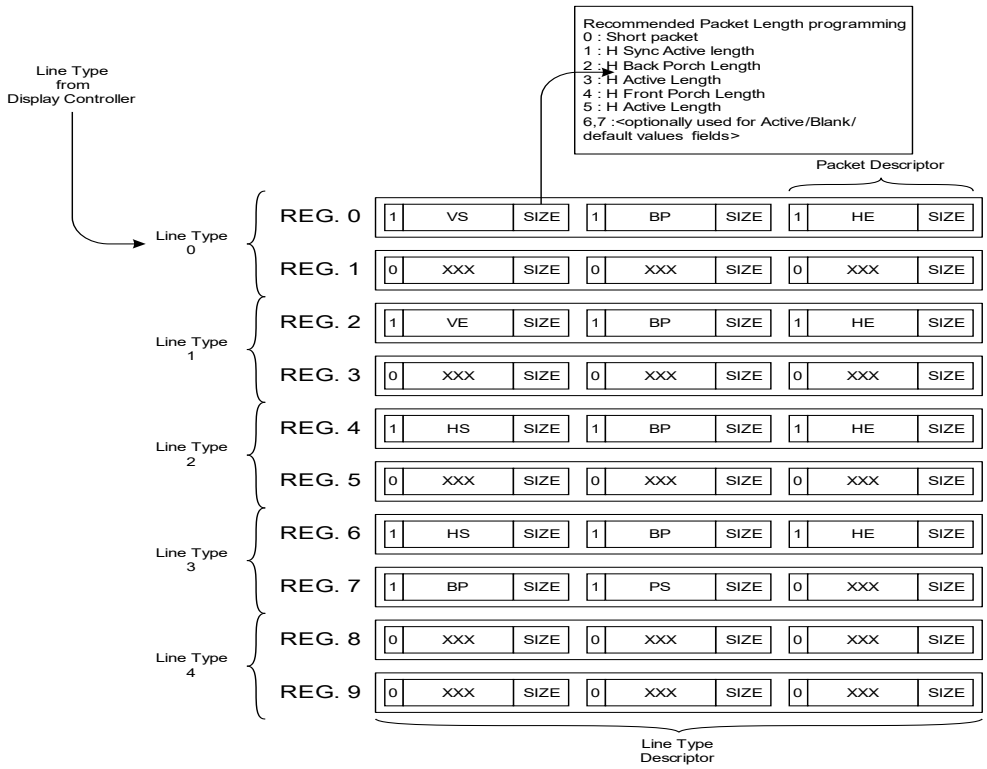
- Valid bit
- 6-bit packet ID
- 3-bit length index

The valid bit simply states whether or not a packet should be generated from that descriptor. A zero valid bit implies that no more packets in this packet sequence should be generated. Thus, the valid bit acts like a null terminator for the list of packet descriptors.

The packet ID is simply the MIPI DSI packet ID value. Software can therefore program any sequence of packets required for that line type.

Rather than have a 16-bit packet length field for every packet descriptor, the length is replaced by a 3-bit index which addresses the full 16-bit length for that packet type. This length is held elsewhere in separate length registers. A complete picture of the packet description data structures is shown in the following figure. This diagram shows typical packet mnemonics for the packets to be generated for video mode with sync pulses. By changing the programming of the packet sequences, any of the video modes, including burst mode, can be realized.

Figure 102: Line Type Look-up and Packet Sequence Descriptors



26.2.3 Host Interface

While many displays use a raster-based packet stream, in some applications it is more efficient to have a frame store in the display device itself and to only update the contents of the frame store when the required pixels have changed. For these types of displays, there is a software-accessible interface for sending command packets using the DSI command mode operation. This mode should also be used to access control and status registers within the display device.

The Host interface consists of a small FIFO for holding packet information and a special register for writing data into the FIFO. In this way, several packets may be queued up by software and sent in one HS burst. This is more efficient that sending the packets one at a time.

When very long sequences of packets are required to be sent – for example, when the host interface is emulating video mode, or where a large amount of data needs to be sent to the display device in one packet – it is possible for the host to use the large video line-store FIFO.

26.2.4 Clocking

The clocks in the DSI include:

- Host Clock = 300 MHz {Maximum frequency}
- Application/Lane Management Byte Clock = function of lanes, pixel clock, pixel depth. 10 to 187.5 Mbps
- Fixed LP receive clock = 20 to 216 MHz
- Lane Bit clock = 40 to 750 MHz differential clock, DDR data (80 to 1500 bps).
- DSI LP clock source is PLLP.

More details on pixel clock/byte_clock selection are explained in the next section.

Pixel Clock / DSI Byte Clock Ratios

When running the DSI interface in one of the two non-burst video modes, the relationship between the DSI D-PHY bit-rate clock, the DSI byte-rate lane clock, and the display controller pixel clock must be exact. This ensures that precise raster timing information is conveyed to the display peripheral.

There is always a fixed ratio of 8:1 between the D-PHY bit clock and the lane management layer byte clock since there are 8 bits in each byte that are serialized. Therefore, only relationships between pixel clock and byte clock and between pixel clock and bit clock will be discussed.

The relationship between pixel clock and byte clock is shown in the table below. As can be seen, for some modes, these ratios are not simple powers of 2.

Table 129: Pixel Clock: Byte Clock for Various Modes

Lanes	Pixel Data Format			
	16 bpp	18 bpp (packed)	18 bpp	24 bpp
1	1:2	4:9	1:3	1:3
2	1:1	8:9	2:3	2:3
3	3:2	12:9	1:1	1:1
4	2:1	16:9	4:3	4:3
5	5:2	20:9	5:3	5:3
6	3:1	8:3	2:1	2:1
7	7:2	28:9	7:3	7:3
8	4:1	32:9	8:3	8:3

Because the pixel clock is effectively derived from the D-PHY bit clock, it can be more instructive to look at the number by which you must divide the bit clock to get the correct pixel clock. This information is shown in the table below. Here, the numbers look reasonable except for the problematic cases of 16bpp over a 3-lane link and 18 bpp (packed) over a 4 lane link. For these two situations, you cannot simply divide the bit rate clock by some integer to arrive at the pixel clock. Moreover, if you need a 50:50 duty cycle for the pixel clock, then you will need to toggle the pixel clock every N/2 bit clock cycles, where N is the number in the table below. However, if you do this, 18 bpp (packed) over 2 lanes also becomes a problem.

Table 130: Value to Divide Bit Clock by to Get Pixel Clock

Lanes	Pixel Data Format			
	16 bpp	18 bpp (packed)	18 bpp	24 bpp
1	16	18	24	24
2	8	9	12	12
3	16 / 3	6	8	8
4	4	9 / 2	6	6
5	16/5	18/5	24/5	24/5
6	8/3	3	4	4
7	16/7	18/7	24/7	24/7
8	2	9/4	3	3

Table 131: Value of Shift Clock Divider to Get Pixel Clock (Non-Burst Mode

Lanes	Data Format (16 bpp)	Data Format (18 bpp)	Data Format (24 bpp)
1	14	16	22
2	6	7	10
3	3.333334	4	6
4	2	2.5	4

Table 131: Value of Shift Clock Divider to Get Pixel Clock (Non-Burst Mode

Lanes	Data Format (16 bpp)	Data Format (18 bpp)	Data Format (24 bpp)
5	1.6	1.8	2.4
6	0.666667	1	2
7	1.14285714	1.285714286	1.714285714
8	0	0.25	1

Note: *The fractional values in the above table cannot be supported through configuration fields because of a possible limitation in programming the shift divider for deriving the pixel clock from the byte clock in non-burst mode, that is, the SHIFT_CLK_DIVIDER field of the DC_DISP_DISP_CLOCK_CONTROL_0 field. This limitation occurs only in non-burst video mode.*

To resolve these issues, derive the display controller pixel clock from a separate PLL and then lock that PLL to the DSI D-PHY PLL using a phase comparator and the appropriate divide ratios obtained from the tables.

DSI PLL – Clock Mux

In the Tegra X1 device, the DSI implements a clock mux for the clock selection of the write clock domain to the line buffer and its upstream path in the DSI.

A single DSI instance receives a pixel data stream from either of the display controller heads. The single bit register field dsi_vid_src in the dsi_clk domain selects the active display head. The selected display pixel clock provides the necessary clocking to the front end of the DSI.

In cases where the Host transmission uses the line buffer, dsi_clk can provide the necessary clocking using the single bit register field pkt_wr_fifo_sel.

26.3 Modes of Operation

The DSI operates in two transmission modes: Video and Host/Command

26.3.1 Video Mode

Communication with the peripheral is by isochronous data transfer similar to a typical video interface. There is no Bus Turn Around permitted in Video Mode, though there is a mandatory period of LP operation at least once per frame. There are three different sub-modes of Video Mode. These are outlined below:

- Non-Burst Mode with Start and End

  In this mode, the DSI must match the timing of a traditional video raster as closely as possible. This means all information about the start and end of parameters like vertical and horizontal sync, front and back porches must be conveyed to the receiving peripherals via the timing of the transmission of the High-Speed sync packets.

- Non-Burst Mode without Start and End

  This is like Non-Burst Mode with Start and End, except that the Sync-Active and Sync-End packets are not sent. Pixels must still be delivered at the correct rate.

- Burst Mode

  Only the timing of Sync-Start packets is required to be accurately conveyed in this mode. The data rate of the pixel data is arbitrary and is typically higher than the pixel rate of the peripheral.

26.3.2 Host/Command Mode

Communication with the peripheral is by asynchronously timed and variable length packets. The packets may contain video data (Display Controller/Host) or control data. In Command Mode, return (read) data can be requested from the peripheral. The DSI will issue a Bus Turn Around (BTA) request and relinquish control of the bus to the peripheral.

26.4 FIFO Buffers

26.4.1 Video Mode Operation

26.4.1.1 Writing Data

The following packets are written into the large data FIFO based on the various triggering events described.

Table 132: FIFO Trigger Events

Trigger Event	Packet
Leading edge of Vertical Sync.	VSync Start
Trailing edge of Vertical Sync	VSync End
Leading edge of Horizontal Sync, *unless* simultaneous with leading or trailing edge of vertical sync	HSync Start
Trailing edge of Horizontal Sync	HSync End
Immediately following VS, HS, VE or HE packets. Packet Word Count determined by display controller timing parameters.	Blanking packet
Immediately following blanking packet	Pixel Stream packet (16, 18, or 24 bits/pixel)

26.4.1.2 Reading Data

The initiation of the reading of the FIFO is triggered by a delayed version of the horizontal sync pulse from the display controller. The delay should be sufficient that the FIFO will not completely drain as reading of the FIFO continues. However, the delay should not be so long as to cause the FIFO to overflow with data.

26.4.2 Command Mode Operation

26.4.2.1 Writing Data from the Display Controller

Upon receipt of the leading edge of Vertical Sync, the display controller sends whatever DCS command packets are required to initialize the display to receive pixels. Then, as pixels start to arrive from the display controller, a DCS Long Write packet is sent – one per line – which contains the pixel data for that line. No synchronization or blanking packets should be sent. Data packets continue to be sent until the end of the active period. Like video mode packets, there is no need to calculate ECC or CRC words, as this is performed by the hardware on the other side of the data FIFO.

The Packet Sequence registers behave in the same manner as they do for Video Mode packet generation with the following exceptions:

- For Long packets, a DCS command ID byte must be inserted as the first byte of the data payload of the packet, ahead of the pixel data. The packet header Word Count must be 1 more than the number of bytes in the pixel data to take into account this extra byte. It is the responsibility of software to make sure the packet length is programmed correctly.
- For Line Type 4, any data contained in the Host Data FIFO should be appended to the end of any packets defined in the Packet Sequence for Line Type 4. In this way, the Host may send DCS commands to the Display Peripheral while the Display Controller is sending pixel information to the Display Peripheral.

26.4.2.2 Writing Data from the Host

The host should choose which data FIFO – small or large – to use prior to sending packet information. The large data FIFO is only available if the display controller is not currently using it. The software is responsible for constructing whatever packets are

required for the desired operation and should be written into the FIFO via the host. There is no need for the software to compute ECC or CRC words, because this is performed by the hardware on the other side of the data FIFO.

26.4.2.3 Reading Data

The initiation of the reading of data from the FIFO is triggered by a FIFO threshold. Once the threshold is reached, the D-PHY starts to drain the FIFO, and the packets are sent to the display. The threshold should be set such that there is no danger of either FIFO overflow from excessive data from the host or display controller, or FIFO underflow caused by a lack of sufficient data in the FIFO.

26.5 Programming Guidelines

The packet timing diagrams in this section use the following key:

Figure 103: Video Mode Timing Diagram Key

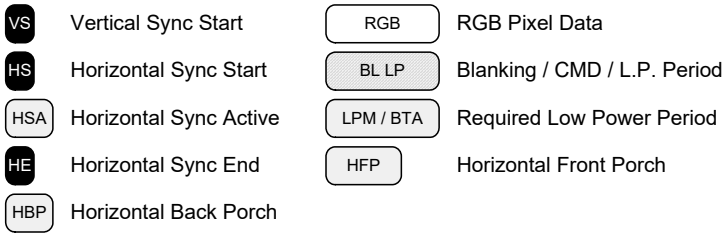


Table 133: Timing Diagram Parameter List

Parameter	Description
tHBP	Horizontal Back Porch period
tHACT	Horizontal Active period
tVBP	Vertical Back Porch period
tVACT	Vertical Active period
tVFP	Vertical Front Porch period
tL	Total line period

26.5.1 Initialization

The start-up and shut-down procedures vary depending on what mode of operation is required. Examples of programming sequences for the main modes are given below.

26.5.1.1 Video Mode Start-up

All 3 video modes – Burst, Non-Burst and Non-Burst with Sync Ends –have the same start-up sequence with a slight variation between Burst and Non-Burst modes:

- Set up the clocks. This involves configuring and enabling the DSI PLL (PLLD). For Non-Burst and Non-Burst with Sync End modes, the Display Controller must also be programmed to take its pixel clock from the DSI PLL. For Burst Mode, the Display Controller can take its pixel clock either from the DSI PLL or from another clock source. Program the PLLD registers with the correct OSC_FREQ and program the PLLD_BASE register. In addition, the PLLP must be running in order to provide the LP receive clock. Program the PLLP registers with the correct OSC_FREQ and program the PLLP_BASE register.
- Depending on the sub-mode, the various Packet Sequence registers and Packet Length registers must be programmed.
- Set the VID_TX_TRIG_SRC field in the DSI_CONTROL register to SOL. And program DSI_VID_SOURCE to select which display controller will source the video data.
- Enable the DSI

- Program the display controller to produce the raster size required
- Enable the display controller

When the display controller starts sending SOL and data, the DSI automatically starts creating and transmitting packets to the display device.

26.5.1.2 Command Mode Start-up

- Set up the clocks. Program and enable the DSI PLL (PLLD). In addition, the PLLP must be running in order to provide the LP receive clock. Program the PLLP registers with the correct OSC_FREQ and program the PLLP_BASE register. Unlike the Video modes, the selection of the PLLD output clock frequency is essentially arbitrary. The clock frequency should be based on the expected data throughput and the requirements of the particular display device. Program the PLLD registers with the correct OSC_FREQ and program the PLLD_BASE register. In addition, the PLLP must be running in order to provide the LP receive clock. Program the PLLP registers with the correct OSC_FREQ and program the PLLP_BASE register.
- Set the HOST_TX_TRIG_SRC field in the HOST_DSI_CONTROL registers to `IMMEDIATE`. Set any other state required.
- Enable DSI.

The DSI should now be ready to accept command packets written to the DSI_WR_DATA register.

26.5.2 Video Mode Programming

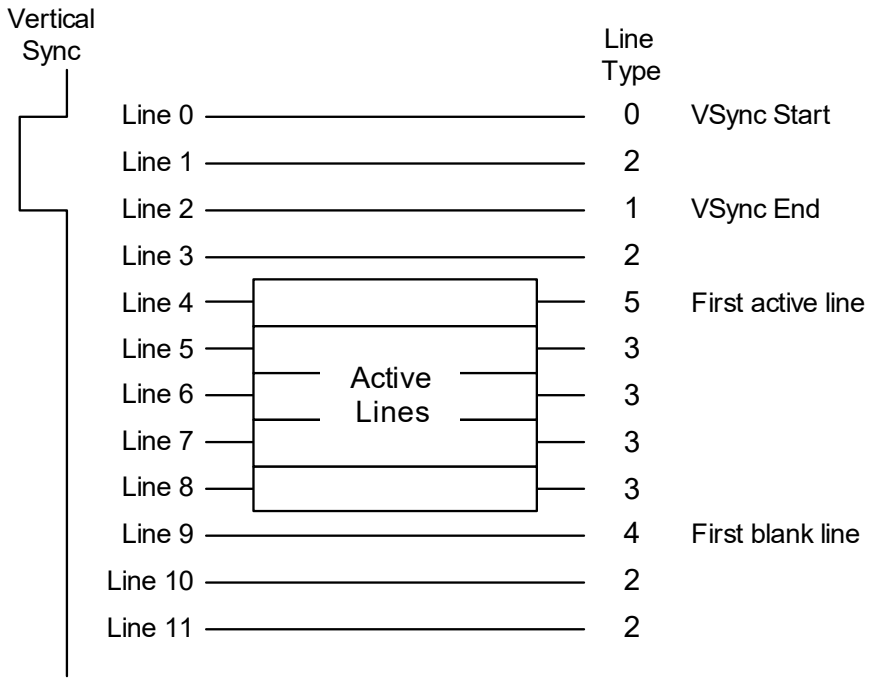
The programming model has been designed to accommodate current video mode sequences and potential future variations. Each line of video output is associated with a “line type”. This line type is automatically generated by the display controller hardware according to the following table.

Table 134: Recommended Line Types

Line Type	Description	Typical Raster Position
0	Blank line starting with VS	First line of the raster
1	Blank line starting with VE	Line corresponding to Vsync end.
2	Blank line starting with HS	Vertical blanking line
3	Active line starting with HS	Active line
4	First blank line after active	First blank line after active
5	First active line	First active line

The figure below illustrates a typical raster showing the relationship between various events in the raster and the line types.

Figure 104: Example Video Raster Showing Line Types



The line type acts like a pointer to a data structure containing the information about the "*packet sequence*" for that line type. The packet sequence information is actually held within a pair of registers. For example, the packet sequence for line type 0 is held in the pair of registers DSI_PKT_SEQ_0_LO and DSI_PKT_SEQ_0_HI. Each pair of packet sequence registers contains all the information required to generate up to 6 packets. This is sufficient to generate any packet sequence for any DSI video line. The information stored for each packet is shown in the following table:

Table 135: Packet Sequence Description Fields

Field	Number of bits	Description
PKT_*_SIZE	3	Pointer to packet size register
PKT_*_ID	6	Packet ID as defined in the MIPI DSI specification.
PKT_*_EN	1	Enable. Determines which packets are active.

Using the same pair of registers as an example, the table below shows how all six packet descriptors fit into the pair of 32-bit packet sequence registers.

Table 136: Packet Sequence 0 Registers

Register	Field	Bits	Description
DSI_PKT_SEQ_0_LO	PKT_00_SIZE	2:0	Packet 0 Size
	PKT_00_ID	8:3	Packet 0 ID
	PKT_00_EN	9	Packet 0 Enable
	PKT_01_SIZE	12:10	Packet 1 Size
	PKT_01_ID	18:13	Packet 1 ID
	PKT_01_EN	19	Packet 1 Enable
	PKT_02_SIZE	22:20	Packet 2 Size
	PKT_02_ID	28:23	Packet 2 ID
	PKT_02_EN	29	Packet 2 Enable
	SEQ_0_FORCE_LP	30	End in LP state

Table 136: Packet Sequence 0 Registers

Register	Field	Bits	Description
DSI_PKT_SEQ_0_HI	PKT_03_SIZE	2:0	Packet 3 Size
	PKT_03_ID	8:3	Packet 3 ID
	PKT_03_EN	9	Packet 3 Enable
	PKT_04_SIZE	12:10	Packet 4 Size
	PKT_04_ID	18:13	Packet 4 ID
	PKT_04_EN	19	Packet 4 Enable
	PKT_05_SIZE	22:20	Packet 5 Size
	PKT_05_ID	28:23	Packet 5 ID
	PKT_05_EN	29	Packet 5 Enable

Finally, the SIZE field in the packet descriptor is used as a pointer to a 16-bit "*packet length*" field in the packet length registers. An indirect pointer is used rather than storing the packet length directly in the packet descriptor because the packet lengths are physically large – 16 bits – but there is a lot of re-use. There are only a few different lengths used in a typical raster layout. Thus, it is more efficient to hold the lengths in separate length registers and then to simply refer to them with a short pointer. This allows the storing of 36 packet descriptors in only 6 pairs of packet sequence registers.

Note: *One of the packet length registers is reserved for short packets. If a* `SIZE` *field in the packet descriptor is programmed to 0, this packet is likely a short packet. Short packets are fixed in length to 4 bytes including the packet header byte and ECC byte. In the context of video mode, they are essentially reserved for timing packets. All other packet length registers can be used to determine the length of any associated long packet.*

The `SEQ_0_FORCE_LP` bit is used to determine if the link should be placed in the LP state at the end of the packet transmission. In Burst Mode operation, the link always drops back into LP state at the end of the HS packet transmission on a line. However, for Non-Burst Modes, the HS transmission may continue to the next line. It is important the that the hardware state machine that generates packets not attempt to go to the LP state, but should instead prepare for the next sequence of packets associated with the next video line and keep the line in the HS transmission state.

The packet length registers are shown in the table below. The packet size pointer in the packet descriptor can point to any of the available length registers – with the one exception of short packets, whose `SIZE` field must point to length register 0. It is recommended that the suggested packet length assignment for various length registers is followed to reduce confusion when debugging packet descriptors and packet sequences.

Table 137: Packet Length Registers and Assignments

Register	Field	Suggested Assignment
DSI_PKT_LEN_0_1	LENGTH_0	Must be used for short packets
	LENGTH_1	Horizontal sync active length (HSA)
DSI_PKT_LEN_2_3	LENGTH_2	Horizontal back porch length (HBP)
	LENGTH_3	Horizontal active length (ACTIVE)
DSI_PKT_LEN_4_5	LENGTH_4	Horizontal front porch length (HFP)
	LENGTH_5	–Horizontal active length (ACTIVE)
DSI_PKT_LEN_6_7	LENGTH_6/7	<EOTP/other packet IDs>

When programming the length registers, remember that these contain byte counts, not pixel counts. Therefore, the DSI pixel format, number of DSI lanes in use and the finite (non-zero) size of the packet header and CRC words should be taken into account when programming these values – especially for blanking packets since all of these parameters affect the number of bytes that should be used to emulate a specific blanking time. The equations required to determine the byte count in the packets are given in the examples that follow. The identification of the length given in the tables and equations has been included in three video mode examples so that the values in the examples can be easily tied to the registers.

26.5.2.1 SOL Delay Programming

In order to ensure that the pixel FIFO from display to DSI does not underflow when in video mode, it is necessary to delay the start of packet generation by the DSI by a fixed amount from the arrival of the SOL signal from the display. This is especially true of Burst-Mode, because the DSI byte clock can be very much faster than display pixel clock. If no delay is applied, the DSI will very quickly consume all the pixels in the FIFO and the FIFO will underflow. The SOL_DELAY registers are used to set this delay.

Non-Burst Mode

In non-burst mode, the rate at which the DSI consumes pixels is the same as the rate at which the display module produces them, so it is merely sufficient to ensure that enough pixels have been fed into the FIFO to overcome the internal latency. This internal latency is approximately 8 pixel clock cycles. However, `SOL_DELAY` is programmed in DSI byte clocks, so the pixel format and the number of lanes being used should be taken into account when programming this value. Contact your NVIDIA FAE for details on the relationship between display pixel clock and byte clock. These ratios are then used to determine the value of `SOL_DELAY` as follows (these equations are applicable for DCS in Non-burst configuration as well):

$$SOL\_DELAY = (((Sol2VldDly) + 14) * F_{DSI} / F_{pixel}) + FifoLatency$$

$$FifoLatency = Ceil\ (2 * (F_{DSI} / F_{pixel})) + 6$$

Sol2VldDly = Hsync start to Pixel valid delay

Where F_{DSI} and F_{pixel} are the DSI byte and pixel clocks, respectively.

Note: SOL toggle to valid assertion delay assumed to be fixed at 4 pixel clocks, in case the delay exceeds 4. The sum of additional clock cycles shall be added to the SOL delay equation.

Burst Mode

In Burst mode, not only must the pixel format, number of lanes, and the DSI / pixel clock ratio be taken into account, but also the horizontal back porch time (including Hsync) and the Horizontal active time.

The below equations are applicable for DCS in burst configuration as well.

So, for Burst mode:

- In case of End of Transmission packet, i.e., Eotp enabled, set Eotp = 1
- When the HFP packet is not transmitted, additional latency, i.e., AddLatency=20
- SOL toggle to valid assertion delay assumed to be fixed at 4 pixel clocks, in case the delay exceeds 4. The sum of additional clock cycles shall be added to SOL delay equation.
- When EOTp packets are enabled:

  $$SOL\_DELAY = (((Sol2VldDly + 6 + T_{active} + 1) * F_{DSI} / F_{pixel}) -$$

  $$((T_{active} + 1) * F_{DSI\_NB} / F_{pixel\_NB}))) + FifoLatency + AddLatency$$
- When EOTp packets are not enabled:

  $$SOL\_DELAY = (((Sol2VldDly + 6 + T_{active}) * F_{DSI} / F_{pixel}) -$$

  $$((T_{active}) * F_{DSI\_NB} / F_{pixel\_NB}))) + FifoLatency + AddLatency$$

  That is,

  $$FifoLatency = Ceil\ (2 * (F_{DSI} / F_{pixel})) + 6$$

  Sol2VldDly = Hsync start to Pixel valid delay

Notes:

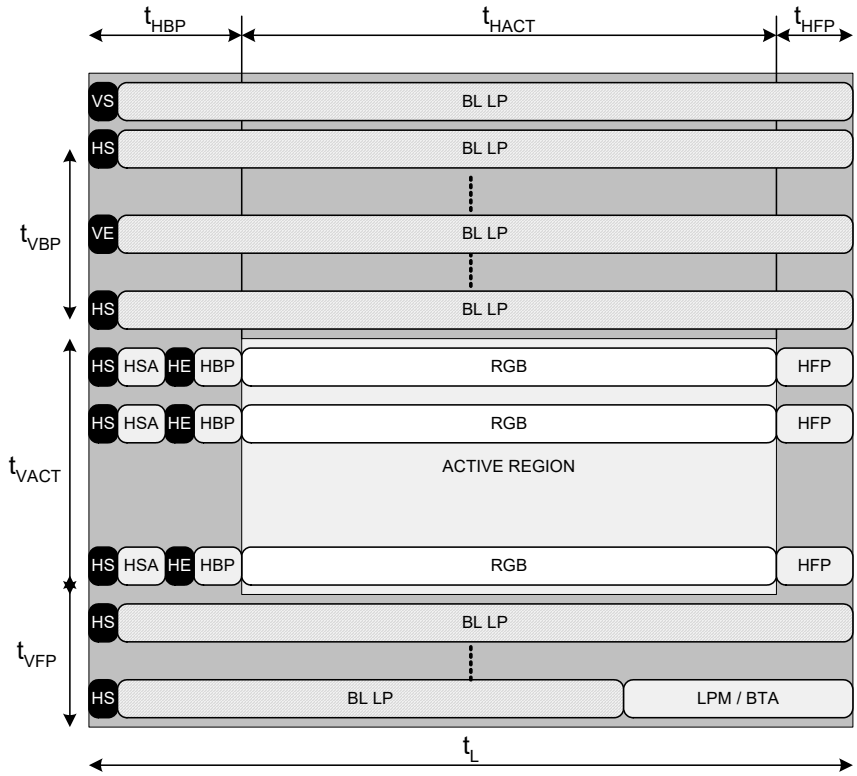
- *The ratio $F_{DSI\_NB} / F_{pixel\_NB}$ is determined by the clock ratio tables for Non-Burst mode, according to the pixel format used and the number of active lanes.*

- *If the overlap feature is enabled, the Tactive -> Effective Valid pixel length is inclusive of Overlap pixels.*

26.5.2.2 Non-Burst Mode with Start and End

This mode conveys traditional raster synchronization information across the link to the peripheral by sending both start and end sync packets.

Figure 105: Timing Diagram for Video Non-Burst Mode with Start and End



During the Vertical Active period, all packets should be concatenated into a single HS transmission for the duration of the Vertical Active period.

The figure below shows how a single line is constructed from multiple packets.

Figure 106: Non-Burst Mode with Start and End Packet Timing Detail

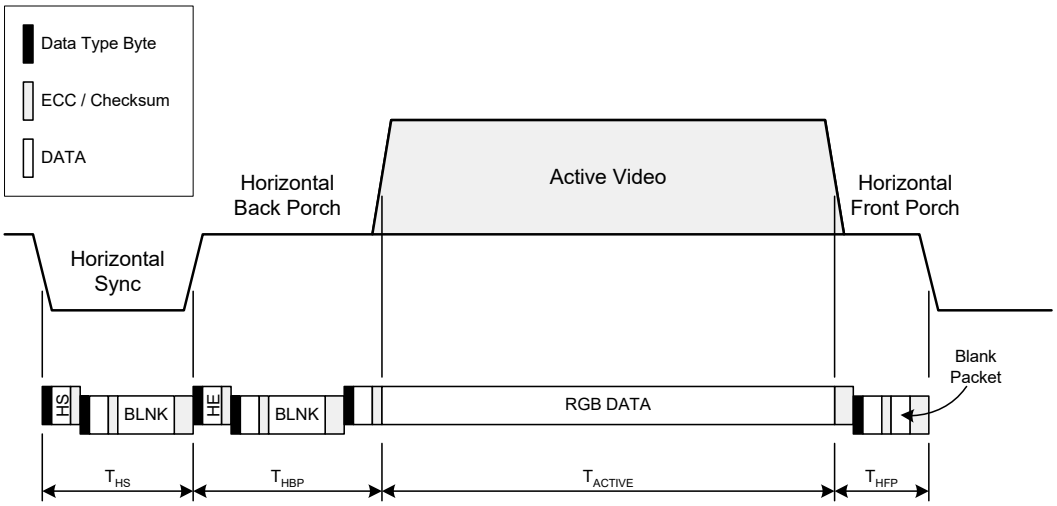


Table 138: Payload Size Table - Non-Burst Mode with Start and End

Packet	Payload Size (Bytes)
HSA	(T_{HS} * B) – 10
HBP	(T_{HBP} * B) – 14
ACTIVE	(T_{ACTIVE} * B)
HFP	(T_{HFP} * B) – 8

B = 2, 2.25 or 3, depending on pixel format.

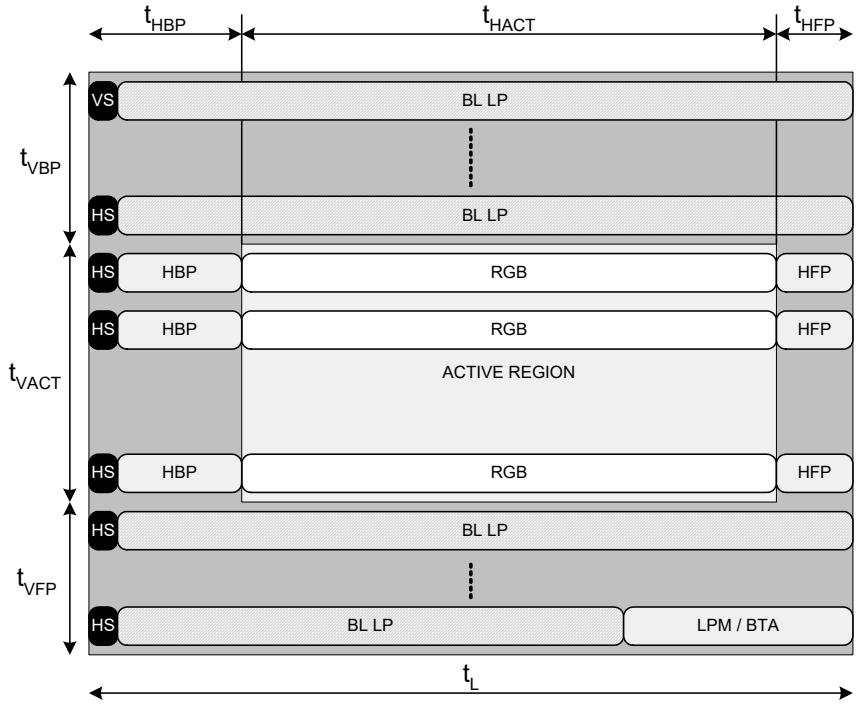
Table 139: Line Type Packet Sequences - Non-Burst with Sync Ends

LT	ID	Len	ID	Len	ID	Len	ID	Len	ID	Len	ID	Len
0	VS	0	EOT	7								
1	VE	0	EOT	7								
2	HS	0	EOT	7								
3	HS	0	BLNK	1	HE	0	BLNK	2	RGB	3	BLNK	4
4	HS	0	EOT	7								
5	HS	0	BLNK	1	HE	0	BLNK	2	RGB	3	BLNK	4

26.5.2.3 Non-Burst Mode (without Ends)

This mode relaxes the requirement to mimic the generation of sync pulses and merely mandates that the start of the line is indicated and that the pixels appear at the same rate and in the same area of the raster as a tradition raster structure.

Figure 107: Timing Diagram for Video Non-Burst Mode



During the Vertical Active period, all packets should be concatenated into a single HS transmission for the duration of the Vertical Active period.

The figure below shows how a single line is constructed from multiple packets.

Figure 108: Non-Burst Mode Packet Timing Detail

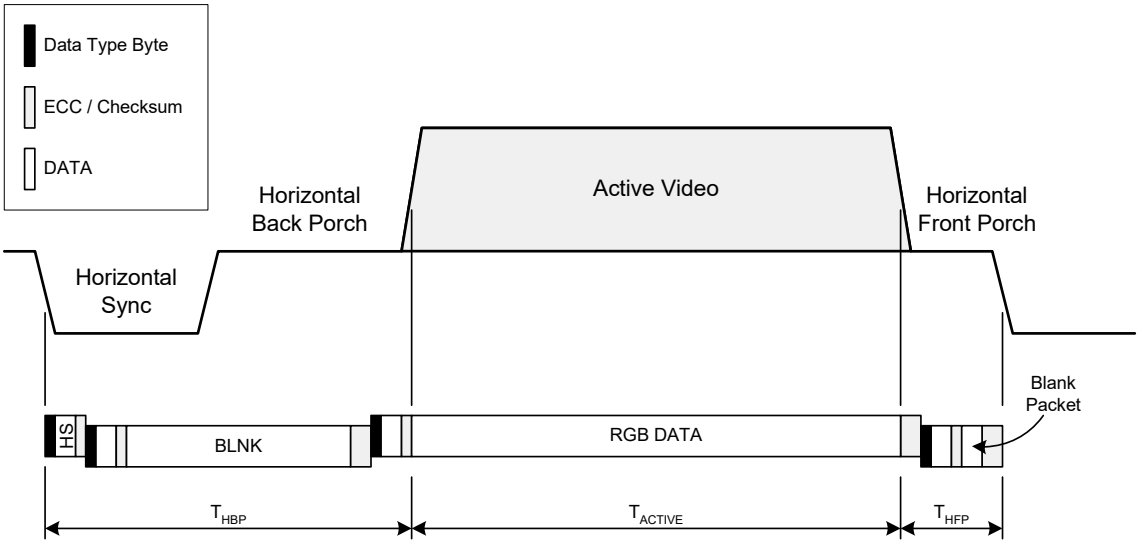


Table 140: Payload Size Table - Non-Burst Mode

Packet	Payload Size (Bytes)
HBP	$(T_{HBP} * B) - 14$
ACTIVE	$(T_{ACTIVE} * B)$
HFP	$(T_{HFP} * B) - 8$
1. B = 2, 2.25, or 3, depending on pixel format.	

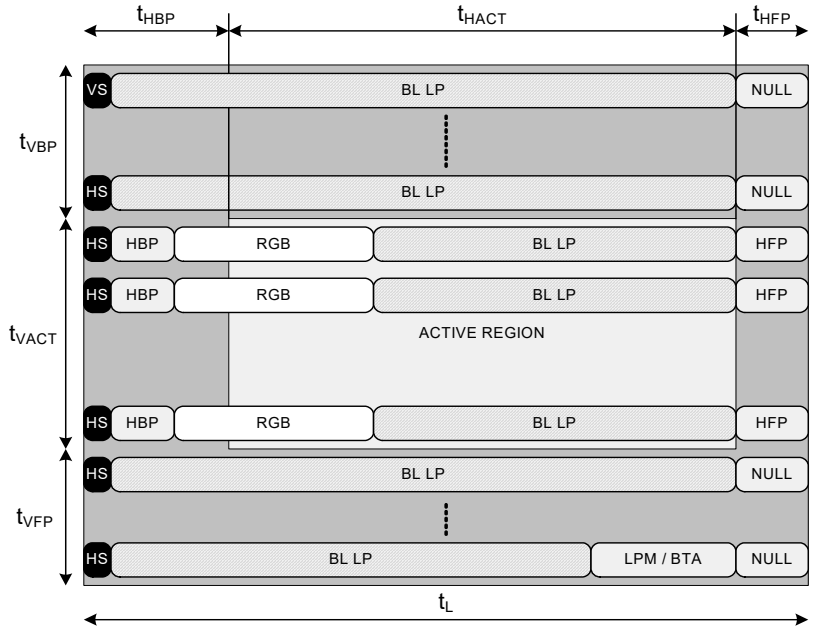
Table 141: Line Type Packet Sequences – Non Burst

LT	ID	Len	ID	Len	ID	Len	ID	Len	ID	Len	ID	Len
0	VS	0	EOT	7								
1	HS	0	EOT	7								
2	HS	0	EOT	7								
3	HS	0	BLNK	2	RGB	3	BLNK	4				
4	HS	0	EOT	7								
5	HS	0	BLNK	2	RGB	3	BLNK	4				

26.5.2.4 Burst Mode

In Burst Mode, the only attempt to match the raster structure is with the timing of the sync start events. The actual RGB pixel data is transmitted at whatever rate is convenient. This means that the HS, HBP, and RGB packets become compressed with respect to the timing of the underlying raster. This allows some period of idle time for each line that can be used for the transmission of other packets.

Figure 109: Timing Diagram for Video Burst Mode



During the Vertical Active period, packets on an individual line should be concatenated into a single HS transmission. However, unlike Non-Burst Mode, the bus should go idle – if possible – at the end of this transmission. This will allow additional non-video packets to be sent simultaneously with the video stream. The NULL and HFP packets may be optional. Check the latest MIPI DSI specification for clarification.

Table 142: Line Type Packet Sequences - Burst Mode

LT	ID	Len	ID	Len	ID	Len	ID	Len
0	VS	0	EOT	7				
1	HS	0	EOT	7				
2	HS	0	EOT	7				
3	HS	0	BLNK	2	RGB	3	EOT	7
4	HS	0	EOT	7				
5	HS	0	BLNK	2	RGB	3	EOT	7

Notes:

- *Burst mode always forces the LP packet field to LP mode. DSI_DSI_PKT_SEQ_0_LO/HI_0/1/2/3/4/5[SEQ_0_FORCE_LP] = 1'b1*
- *The register programming updates in video mode that impact the raster timing (DSI_DSI_PKT_SEQ_*_LO/HI_*, video mode control fields DSI_DSI_CONTROL_0) are assumed to be static with respect to the display controller. On-the-fly updates are not supported.*

26.5.2.5 Sequence while Switching the Modes/Updates to Raster Timing

This programming sequence must be followed when switching the modes/updates to raster timing:

1. Disable the DC2DSI interface path (DC_DISP_DISP_WIN_OPTIONS [DSI_ENABLE] = 1'b0)
2. Disable the DSI (DSI_LEG_EN disable)
3. Update the DSI configuration registers.
4. Enable the DC2DSI interface path (DC_DISP_DISP_WIN_OPTIONS [DSI_ENABLE] = 1'b1).

5. Enable the DSI (DSI_LEG_EN enable)

26.5.3 Command Mode Programming

There are two sources of command mode packet sequences:

- Display Controller
- Host Interface

Only one of these sources will be active at any particular time.

26.5.3.1 Command Mode from Host

In this mode of operation, all packets sent over the DSI interface are determined by software. There may be hardware assistance in the generation of error correction codes (ECCs) and cyclic redundancy checks (CRCs), but all other data is passed unaltered to the DSI physical layer.

Host Packet Writes

Packets are written to the hardware by writing to the DSI_WR_DATA register. The data written is passed into the DSI Host transmit FIFO. If the data is a packet header and the ECC_ENABLE field in the HOST_DSI_CONTROL register is set to ENABLE, then the MSBs of the 32-bit packet header word are replaced with a hardware-computed ECC byte prior to being written into the FIFO. If this field is set to DISABLE, then no action is taken by the hardware and the packet header is written unchanged.

If the packet is a long packet, then the packet payload should be written to the register after the packet header is written. If the CS_ENABLE field of the HOST_DSI_CONTROL register is set to ENABLE, then the hardware computes the check-sum and appends it to the packet information. If this field is set to DISABLE, then software must append the correctly computed check-sum to the packet data.

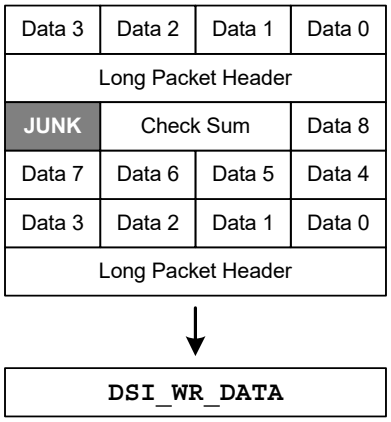
Rules:

1. Software should make sure packets are transmitted in their entirety and that once transmission starts, the FIFO contains enough data to finish a transition on a packet boundary. This can be achieved by only initiating a transmission – either explicitly or indirectly – once all data required for a transmission has been written to the transmit FIFO.
2. In Type-1 Display modules (i.e., the display device includes the full frame buffer to hold image data), the complete image data can be written to the frame buffer via the Host command mode. Software configures the register field to enable the Frame buffer selection for transfer of high-resolution image data.
   DSI_HOST_DSI_CONTROL[PKT_WR_FIFO_SEL]

   Note: *The maximum length of the long packet supported is 1920 words including header, payload, and CRC.*

3. Packets should be written such that the packet header is always written in one 32-bit word and is never split across writes. In other words, if the end of a packet does not fall on a 32-bit word boundary (if the payload has an odd length, for example), then the header for the next packet should not border the last packet, but should realign with the register. See the figure below for an example.

Figure 110: Packet Alignment for Writes to DSI_WR_DATA



Note: *For unaligned word transfers, the host transactions are split into multiple host transfers at the unaligned boundary.*

Host Packet Transmission

The source that controls when the Host write FIFO starts to drain (flush) is programmable. Selectable source is:

- Explicit FLUSH bit in a control register

  Immediate (HOST_TX_TRIG_SRC == IMMEDIATE**)**

As the name implies – if a '1' is written to the `DSI_HOST_TRIGGER` field of the `DSI_TRIGGER` register, then transmission of the data in the Host write FIFO will start immediately. It is recommended that all data required for transmission is written to the DSI_WR_DATA register prior to setting this bit.

26.5.3.2 Command Mode from Display Controller

This mode of operation allows the display controller to write pixel data packets to a DBI-like device that does not require data to be sent in an isochronous raster structure like a DPI device. The data coming from the display controller is sent in an isochronous manner, but the commands sent will be DCS control commands, rather than Video Mode timing and blanking packets.

Setup

There are six steps to operating in this mode:

1. Program the Peripheral display device using DCS commands via the Host Command interface. It is important to send the set_column_address, set_page_address, and set_pixel_format commands. These effectively define the area to which you will be writing pixels.
2. Program the DSI_INIT_SEQ_CONTROL and DSI_INIT_SEQ_DATA_* registers in the DSI interface with the appropriate values. Any commands required to be sent once per frame and *every* frame by way of setup prior to the pixel data being sent should be put in here.
3. Program the `DSI_DATA_FORMAT` field of the DSI_CONTROL register to the required pixel format. Note that `BIT18NP` should not be programmed – see the section below on pixel format restrictions.
4. Program the DSI_PKT_SEQ_* registers. Program the registers in the following way:
   - Packet Sequence registers for Line Types 0, 1, 2, and 4 should all be programmed with 0 in all the Packet Enable fields. In other words, there should not be any packets generated for these line types.
   - Packet Sequence registers for Line Types 3 and 5 should be programmed with a DCS Long Write packet.
   - To extend the support to transfer continuous HS packets (or) enable the Data lane in HS transmission during the entire active region (Line Type 3 and 5), additional Blank packets may be added to the packet sequence register. Refer to the table below for more information.

5. Program the DCS command ID register to have a write_start command associated with Line Type 5 (First line of active) and a write_continue command associated with Line Type 3 (all other active lines).
6. Enable the display. When Vertical syncs arrive from the display, the initialization sequence should be sent, and for every active line, the pixel data will be sent in a DCS Long Write packet.

Table 143: Line Type Packet Sequences for DCS Mode

LT	ID	Len	ID	Len	ID	Len	ID	Len	ID	Len
0	VS	0								
1	HS	0								
2	HS	0								
3	HS	0	RGB	3	BLNK	4				
4	HS	0								
5	HS	0	RGB	3	BLNK	4				

Note: *Blank packets are optional and would be enabled to have the data lane in HS transmission during the active region, i.e., (Line Type 3 and 5).*

Pixel Format Restrictions

The MIPI DCS specification allows for up to 6 different pixel data formats to be transmitted in a write_start or write_continue command. These pixel formats are listed in the table below. The DSI supports 3 of these pixel formats.

The formats supported are also shown in the “supported” column of the table below. Do not set `BIT18NP` as a pixel format. There is no DCS equivalent of this format, so undefined behavior may result.

Table 144: DCS Pixel Format Support

DCS ID	DCS Format	Supported	Name
0	reserved	N/A	-
1	3bpp	N	-
2	8bpp	N	-
3	12bpp	N	-
4	reserved	N/A	-
5	16bpp	Y	BIT16P
6	18bpp	Y	BIT18P
7	24bpp	Y	BIT24P

Simultaneous Host Command Packets

It may be necessary, from time to time, to send a DCS command to the display peripheral in a “side-band” fashion while the display controller is continuing to send DCS write commands with pixel information. Thus Line Type 4 (first blank line) is reserved to indicate to the hardware when it should attempt to send any DCS command packets requested by software.

If it is desired to send a DCS command in this way, the DCS command packet should be written in its entirety (header, ECC, DCS command, payload, CSC) into the Host Command FIFO. The HOST_TX_TRIG_SRC field should then be set to `IMMEDIATE`.

The DSI hardware will then send the entire contents of the FIFO out on the DSI interface on the first line of blanking. Sending the data on this line guarantees the Host packet transmission will have enough time to complete before the next packet generated by the Display Controller is generated.

Notes:

- *Though the Host FIFO can accommodate a 256-byte packet, maxHost transfer size should not exceed as given in the below expression (units in byte clock count):*

(host_pkt_data_size < HOST_FIFO_size) && (host_pkt_data_size < (line_time – (sol_delay + min HS-LP-HS blanking time needed + 10)))

- *Host packets shall be aligned to word boundaries. In case host packets end on an unaligned word boundary, a maximum of 1 is supported for such consecutive packets transfers.*
- *Additional sideband data can be sent using Init sequence registers as well*
- *If the host transfer is enabled during the frame video blanking interval, the following sequence needs to be performed at the end of the frame:*

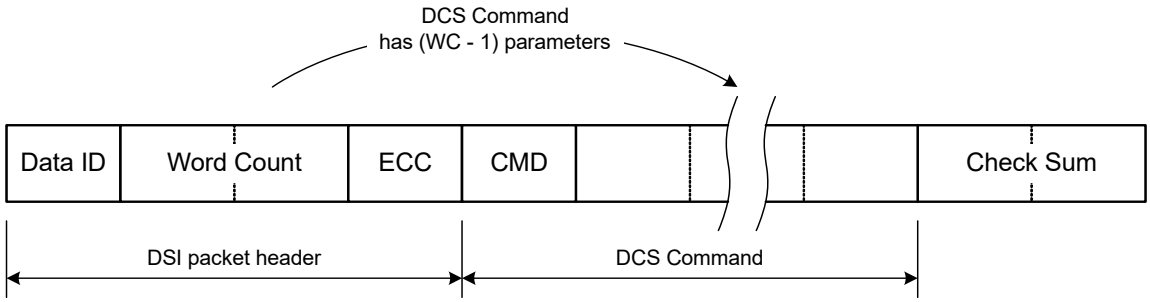
1. Wait for an end of frame event from the display controller.
2. Set the increment syncpt soft reset; that is, program the INCR_SYNCPT_SOFT_RESET field in the DSI_INCR_SYNCPT_CNTRL_0 register to 1'b1.
3. Clear the increment syncpt soft reset; that is, program the INCR_SYNCPT_SOFT_RESET field in the DSI_INCR_SYNCPT_CNTRL_0 register to 1'b0.
4. Continue with the subsequent configuration.

26.5.3.3 Display Command Set (DCS) Packets

DCS is a legacy control command set that is used to program various control registers present in typical LCD panels used in cell phones. Historically, the commands would be sent to the display over a MIPI DBI interface. Since MIPI DSI is meant to replace both DPI and DBI, it must also transport these control commands.

There are several DCS-specific commands in the MIPI DSI specification that can be used to send DCS commands to the Peripheral Display Device. However, the most useful is probably the DCS Long Write packet since it can be used to send commands with more than one parameter. The DCS command is embedded with an MIPI DSI Long Packet as follows: The DCS Command Byte and all the DCS Command Parameters (payload) are concatenated and sent in the Payload of the MIPI DSI Long Packet. The Word Count of the DSI packet conveys the total size of the DCS packet. As usual, a 2-byte CS footer is appended to the DSI Long Packet. The next figure below shows how a DCS Long Write packet is constructed.

Figure 111: DCS Command Placement in DSI Long Packet



26.5.3.4 16 bpp Byte Ordering in 16 bpp Format for Video/Command Mode

The DSI specification suggests a different byte order in the 16 bpp video and command mode data bit order, i.e., data packing in:

Video mode [16:0] -> {B[4-0],G[5-3]},{G[2-0],R[4-0]} (Default)

Command mode [16:0] -> {G[2-0],B [4-0]},{R[4-0],G[5-3]} (SwapEn)

The byte order can be configured through the DSI_DSI_CONTROL_0 register, DFMT_16BPP_SWAP_EN field. By default, the video mode order is selected and the command mode can be selected by the programing DFMT_16BPP_SWAP_EN to 1.

26.5.3.5 Frame Synchronization Between Identical Command Mode Displays

When stretching a single surface across multiple identical displays, frame synchronization can be achieved to avoid visual artifacts due to timing drifts across both the displays.

DCS command “adjust_vsync_timing” provides a mechanism for adjusting the command mode display vsync/frame sync timing with respect to another identical display. Vsync can be shifted, i.e., delayed/advanced by the specified number of scan lines.

26.5.3.6 Host Command Mode Byte Transmission

Command mode operation primarily involves sending the commands and data to the peripheral (the display device). The host processor indirectly controls activity at the peripheral by sending commands, parameters, and data to the display controller. Command Mode operation requires a bidirectional interface capabilities.

Command mode transfers are classified into,

- HS/LP mode

  Host command mode transmission can be enabled in High Speed and Low Power modes. Follow this programming sequence to configure the DSI to enable command mode transactions.

  - Configure DSI_DSI_CONTROL_0 [DSI_HOST_ENABLE]
  - LP/HS mode of transmission is selected by configuring the DSI_HIGH_SPEED_TRANS in the DSI_HOST_DSI_CONTROL_0 register.
  - Enable checksum/Ecc mode via DSI_HOST_DSI_CONTROL_0[CS_ENABLE], …, DSI_HOST_DSI_CONTROL_0[ECC_ENABLE].
  - Write the host data to the register DSI_DSI_WR_DATA_0. Once all the command packets are pushed into the FIFO, trigger the start of the transaction via the HOST_TX_TRIG_SRC field in the DSI_HOST_DSI_CONTROL_0 register.

- Raw Mode

  Host command mode transmission also supports RAW data bytes to be transferred to the display device. In Raw mode, the data written to the host is transferred with no concept of packets and the DSI hardware does not decode the packet headers and ECC/CS computation is not performed.

  In order to send the RAW data bytes (debug / diagnostic workaround mode):

  - Program the number of bytes to be transferred to the DSI_RAW_DATA_BYTE_COUNT register. The byte count programmed is equal to the total number of raw bytes (not to be interpreted as the byte count of a packet).
  - Write raw data bytes to the DSI Host.
  - Enable RAW_DATA in the DSI_HOST_DSI_CONTROL_0 register.

26.5.4 High-Speed Clock Configurations

In High Speed mode, the Host provides a low-swing, differential DDR clock signal for high-speed data transfers. The high-speed clock lane is configurable via the DSI_HS_CLK_CTRL] field in the DSI_DSI_CONTROL register.

- Free Running Mode /Continuous

The D-Phy clock lane operates in HS free running or continuous mode; i.e., used in systems where the D-Phy clock lane acts as a clock source to the display devices eliminating the need for an alternate oscillator clock source.

- TX Mode/Discontinuous Mode

The D-Phy clock lane operates in burst mode or discontinuous mode; i.e., the D-Phy clock lane remains active only during the HS transmission and stops the clock lane when there are no high-speed transmissions active in any of the data lanes.

Notes: *The Host programs the total horizontal blank period to meet the following criteria to provide enough time for HS <-> LP transitions.*
*(HBLANK) >= (number_of_lanes *(HS_Trail + HS-Exit + CLK_POST + CLK_TRAIL + HS_EXIT + TLPX + TLPX + TCLK_PREPARE + TCLK_ZERO + TCLK_PRE + 1 + TLPX + THS_PREPARE + TDAT_ZERO + 1))*
The parameters in this equation are defined in the DSI_DSI_PHY_TIMING registers.

- *The DSI_HS_CLK_CTRL field in the DSI_DSI_CONTROL_0 register control field for the HS clock lane is programmed when the DSI_HIGH_SPEED_TRANS control field in the DSI_DSI_CONTROL_0 register is programmed for HS packet transmission of packets.*

26.5.4.1 Switch Clock Lane between Continuous and Discontinuous Mode

The clock lane can be switched between continuous and dis-continuous mode DSI_DSI_CONTROL_0[DSI_HS_CLK_CTRL]

- 0: Continuous mode
- 1: Discontinuous mode (HS clock is only active during HS transmissions)

The following programming sequence need to be followed while switching the HS clock lane state:

- Wait for completion of the current transfers/transactions in the DSI and the idle status bit set.
- Update/switch the DSI_HS_CLK_CTRL field in the DSI configuration register DSI_DSI_CONTROL_0.

Note: *The clock lane shall be switched only when there are no high-speed transmissions active on any data lane.*

26.5.5 Ultra-Low Power Sequence

In this procedure, starting from the Stop state, the transmit side drives the TX-ULPS-Rqst state (LP-10) and then drives the TX-ULPS State (LP-00). After this, the clock lane enters the Ultra-Low Power state. If an error occurs, and an LP-01 or LP-11 is detected immediately after the TX-ULPS-Rqst state, the Ultra-Low Power state entry procedure is aborted, and the receive side waits for or returns to the Stop state, respectively.

The Clock lane and Data lanes can be configured to enter and exit ULPS independently/simultaneously:

- Independent control of the ULPS

  The Clock needs to be in the HS state, sending the active clock when data lanes are entering ULPS, When entering ULPS, the data lanes enter the ULPS first, followed by the clock lanes. Similarly, when exiting ULPS, the Data lanes exit the ULPS first, followed by the clock lanes.

  DSI_ULTRA_LOW_POWER_CONTROL register configures the control to enter the ULPS on particular clock/Data lane.

  ULPS Entry

  - Program the data lane to enter ULP sequence, wait for syncpt.
  - If the DSI_HIGH_SPEED_TRANS bit in the DSI_HOST_DSI_CONTROL_0 register is not equal to 0):

    Program the DSI_HIGH_SPEED_TRANS bit to a value less than or equal to 0.
  - Program the clock lane to enter ULP sequence and wait for syncpt

  ULPS Exit

  - Program the clock lanes to exit the sequence, wait for syncpt
  - Program the data lanes to exit the sequence, wait for syncpt

- Simultaneous control of the ULPS

  The DSI_ULTRA_LOW_POWER field in the HOST_DSI_CONTROL register is configured to control the ULPS for all the lanes, i.e., clock and data lanes 0-3 simultaneously.

  ULPS Entry:

  - If the DSI_HIGH_SPEED_TRANS bit in the DSI_HOST_DSI_CONTROL_0 register is not equal to 0:
    - Program DSI_HIGH_SPEED_TRANS to be less than or equal to 0.

- Program the DSI_ULTRA_LOW_POWER field in the HOST_DSI_CONTROL register to be less than or equal to ENTER_ULPM. The DSI_ULTRA_LOW_POWER field controls the ULPS for all lanes (clock and data lanes 0-3) simultaneously.

ULPS Exit:

- Program the DSI_ULTRA_LOW_POWER field in the HOST_DSI_CONTROL register to be less than or equal to EXIT_ULPM.

Notes: *The DSI_TWAKEUP field in the DSI_PHY_TIMING_2 register defines the length of the exit interval in multiples of 512 byte clocks common for all lanes (Clock/Data).*

- *The ULPM entry sequence always starts from the NORMAL state. Software should place the control fields in the NORMAL state after the exit sequence after the last operation is done. That is, in case of a ULPM sequence on clock, data lanes, you are recommended to program the register to the NORMAL state after the data lane exit sequence.*

26.5.6 End of Transmission Packet (EOTp)

The DSI specification defines a dedicated End of Transmission packet (EoTp) at the protocol layer to indicate the end of HS transmission. For backwards compatibility with earlier DSI systems, this EoTp can be enabled or disabled.

For host transactions during the video mode, EOTp should not be programmed in the Packet Sequence register. Software shall program the EOTP packet as part of the host data during host transactions during video mode.

26.5.7 Host Command Packet During Video Mode Transmission

DSI supports transmission of host command packets during vertical blanking in Video mode.

Host packet transmission during vertical blank time is possible with programmable control through the DSI_VID_MODE_CONTROL register to enable and select the line type to trigger the host command packets during video mode. The 0/1/2/4 line types with single short packet transmission as part of video raster can enable simultaneous host transfer in Video mode.

Video blank line types are:

- Line Type = 0 - Blank line starting with VS
- Line Type = 1 - Blank line starting with VE
- Line Type = 2 - Blank line starting with HS
- Line Type = 4 - First Blank line after active starting with HS.

The programming sequence to enable host transactions during Video mode is:

1. Choose the line type 0/1/2/4 (Video Blanking) for simultaneous host transfers during Video mode. Program the DSI_LINE_TYPE field in the DSI_DSI_VID_MODE_CONTROL_0 register to FOUR.
2. Write host data transactions to the host data buffer via the DSI_DSI_WR_DATA_0 register.
3. Simultaneous host transfers are enabled during Video mode via the Video mode control field. Program the DSI_CMD_PKT_VID_ENABLE field in the DSI_DSI_VID_MODE_CONTROL_0 to 1’b1.
4. Wait for FRAME_DONE syncpt from the display controller.
5. Set the increment syncpt soft reset; that is, program the INCR_SYNCPT_SOFT_RESET field in the DSI_INCR_SYNCPT_CNTRL_0 register to 1’b1.
6. Clear the increment syncpt soft reset; that is, program the INCR_SYNCPT_SOFT_RESET field in the DSI_INCR_SYNCPT_CNTRL_0 register to 1’b0.

Notes:

- The host packet data transmission cannot be enabled in Video burst mode, where NULL_PACKETs are included with the HSYNC packet.

- Checksum/ECC computation for the host packets can be performed by either the hardware or software by programming the CS/ECC_Enable fields in the DSI_HOST_DSI_CONTROL_0 register.
- After a single VSYNC/VSYNCEND/HSYNC short packet is transmitted, if the Host transmission is enabled, software-constructed Host data packets are transmitted.
- The length of the Host FIFO data is limited to 64 words deep.
- Host data should be pushed into the Host FIFO before the frame is triggered.
- Though the Host FIFO can accommodate a 256-byte packet, maxHost transfer size should not exceed as given in the below expression (units in byte clock count):

  (host_pkt_data_size < HOST_FIFO_size) && (host_pkt_data_size < (line_time – (sol_delay + min HS-LP-HS blanking time needed + 10)))
- Host packets must be aligned to a word boundary. For host packets ending on an unaligned word boundary, there is support for a maximum of 1 such consecutive packets transferring.

  For Unaligned word boundaries, if the end of a packet does not fall on a 32-bit word boundary then the header for the next packet should be posted to the next location of the FIFO. Refer to Figure 110.

  In the worst-case configuration scenario, the number of lanes is 4, and the Host packets end on Byte 0 (that is, a single byte is written in the last word).

26.5.8 Ganged Mode (Odd-Even/Left-Right) Programming

The Tegra X1 DSI supports Ganged mode. This section assumes that the reader is familiar with the DSI specification and normal video mode programing guidelines.

Odd-Even

For Odd-Even Ganged mode, the programming guidelines are based on these assumptions/limitations:

1. Both partitions have a single PLLD and clock source (DSI instances)
2. For VNB, all data lanes end in the same clock cycle aligned to the number of configured lanes.
3. The number of pixels in the 18 bpp packed case is always a multiple of four.
4. The number of active pixels from the display controller is not greater than 4096 pixels.

Programming guidelines/sequence and equations for Odd-Even Ganged mode are listed below:

1. Required inputs are: image resolution, data format, and optional number of lanes
2. Compute the pixel clock frequency from the given resolution:

   pixel frequency = (TotalHorizontalPeriod * TotalVerticalPeriod * FrameRate) / 10^6
3. Determine the shift clock divider value and ganged mode imagesplit information from the number of pixels, data format, and pixel frequency:

   pixel frequency = DSI clock (byte frequency) * 4/clock divider
4. Symmetrical split is possible for all resolutions. Determine the possibility of an asymmetrical split.

   Let n1 = number of lanes for the first partition, and n2 = number of lanes for the second partition from step 3.

   totalNumLanesInGangedMode = n1 + n2
5. Compute the correction pixels needed to align the totalNumPixels, totalNumBytes with totalNumLanesInGangedMode. From Limitation #2 and #3:
   - The pixelsNeededToInitiallyAlign should be such that updated totalNumPixels is a multiple of LCM (total Num Lane sInGangedMode,X)
   - totalNumBytes = totalNumPixels*bytesPerPixel is a multiple of totalNumLanesInGangedMode.

Notes:

- *LCM – least common multiple (X=4 for 18bpp packed, otherwise X=1)*
  If remainder is non-zero/ganged alignment and was not successful (from Step 9), add 'n' number of additional active pixels (zeros/random data) so that the updated image active width is divisible by the LCM above. This is needed to support image split as determined in (Step 4).
- *Add the additional correction/dummy pixels to HFP, determine the new pixel frequency, and compute the byte frequency using the clock divider. Use this information to program the PLLD and shift clock divider. It is okay to add dummy active pixels since panels provide an option using a register field that can be configured to drop/discard the padded pixels.*
- *Update the total number of pixels now with the newly added active pixels to ensure the total number of active pixels does not exceed 4096 pixels. In case the total number of pixels exceeds 4096 pixels, then the frame is considered to not support asymmetrically split for the given configuration (i.e., frame rate and split configurations).*
- *In the 18 bpp packed format case, you cannot achieve alignment over a definite set of iterations for a given frame rate. If the alignment is not achieved within 50-60 pixels, the pixel alignment is assumed to not be possible for the frame for symmetric split at that frame rate.*

6. Determine if the (first partition width) : (second partition width) ratio = n1/n2. If successful, proceed to the next step. If not, ganged width alignment is not successful. Repeat from step 5 by adding more active pixels that still meet the requirement mentioned there.

   splitFactor (for first partition)= n1/ totalNumLanesInGangedMode;

   First Partition Width (active pixels)= CEIL(spliFactor*image width)

   Pixels per line of first Partition = CEIL(splitFactor*totalNumPixels)

   second partition active width = imagewidth – first partition width

   pixels per line of second partition = totalNumPixels - Pixels per line of first Partition

Notes:

- *In consideration of constraint #4, software will ensure that the total number of pixels does not exceed 4096 pixels. If the total number of pixels exceeds 2570 pixels, then the frame does not support asymmetrically split for the given configuration, i.e., frame rate and split configurations.*
- *The number of active pixels added is limited to no more than 60 pixels. If this value exceeds 60 in these iterations, the input image cannot be split as per the split ratio (cannot deviate much from the selected frame rate).*

7. Determine the new pixel frequency (new active pixels and HFP correction) and compute the byte frequency using the clock divider. Use this information to configure the clock parameters for PLLD clock generation and the shift clock divider.
8. Determine the factors of the first partition width and second partition width.

   Select 'x' from the factors of the first partition and 'y' from the factors of the second partition such that x:y = n1/n2. The minimum of 1:1 (symmetrical) is possible for any image.

   - The first group of pixels: ganged start pointer = 0, valid width = x and low width = y
   - The second group: ganged start pointer = x, valid width = y, low width = x
9. In Ganged mode, the packet sequence programming includes HSYNC, HACT, and HFP (total Horizontal blanking period) packets.

   HACT payload size = Total Actual Image Bytes on Data lanes

Initial HFP payload size = totalNumBytesForTheSelectedPartition - numActBytesToBeSent - 16 (16 is because of 4 Bytes - HSYNC, (4+2) Bytes - HACT, (4+2) Bytes - HFP)

10. Compute the correction bytes (per line of partition) to align with the line width and number of lanes (per partition), limitation #2

    correctionBytesPerLane = CEIL(totalNoOfPixelsPerHorzLine *(FDSI/ Fpixel) – (BPP/ Gangedmode_lanes))

    totalNumBytesForTheSelectedPartition = (correctionBytesPerLane * numOfLanesForSelectedPartition)

    total Horizontal Blank(Bytes) = totalNumBytesForTheSelectedPartition - 16 + correctionBytesForAlignment

11. Ganged mode register programming

    - Even Partition Programming

      DSI_DSI_GANGED_MODE_CONTROL_0[DSI_GANGED_MODE_EN] = 1;

      DSI_DSI_GANGED_MODE_START_0[DSI_GANGED_START_POINTER] = 0

      DSI_DSI_GANGED_MODE_SIZE_0[DSI_GANGED_VALID_HIGH_WIDTH] = Even partition active width

      DSI_DSI_GANGED_MODE_SIZE_0[DSI_GANGED_VALID_LOW_WIDTH] = Even partition inactive/low width.

    - Odd Partition Programming

      DSI_DSI_GANGED_MODE_CONTROL_0[DSI_GANGED_MODE_EN] = 1;

      DSI_DSI_GANGED_MODE_START_0[DSI_GANGED_START_POINTER] = High width of Even partition

      DSI_DSI_GANGED_MODE_SIZE_0[DSI_GANGED_VALID_HIGH_WIDTH] = odd partition active width.

      DSI_DSI_GANGED_MODE_SIZE_0[DSI_GANGED_VALID_LOW_WIDTH] = odd partition inactive/low width

12. SOL delay calculation:

    SolFactor = ((Sol2VldDly + 6) * (FDSI / Fpixe)) + 6;

    sol_delay = Ceil (TotalHorzPixelWidth * (FDSI / Fpixel)) -

    Ceil (((SplitFactor * TotalHorzPixelWidth) * BPP) / Gangedmode_lanes) + SolFactor;

    Final_sol_delay = (dcs_mode) ? (sol_delay + 20) : sol_delay

    DSI_DSI_SOL_DELAY_0 = Final_sol_delay

Notes:

- *Sol2VldDly = Hsync start to Pixel valid delay*
- *totalNoOfPixelsPerHorzLine = Total Number of horizontal pixel count.*
- *SplitFactor = DSI_partition_lanes / Gangedmode_lanes.*
- *Gangedmode_lanes = Total number of lanes required in Ganged mode transfer*
- *DSI_partition_lanes = Total lanes in current partition/channel.*
- *BPP = Bytes per pixel*

Left-Right:

For Left-Right Ganged mode, the programming guidelines are based on these assumptions/limitations:

- Both partitions have a single PLLD and clock source (DSI instances)
- For VNB, all data lanes end in the same clock cycle aligned to the number of configured lanes (per DSI specification).
- The number of pixels in the 18 bpp packed case is always aligned to 4 pixels (per DSI specification).
- The number of active pixels from the display controller is not greater than 4096 pixels.

- For timing constraints that are applicable to overlap/dummy pixels, refer to the Overlap Pixels Packet Sequence subsection.

Programming guidelines/sequence and equations for Left-Right Ganged mode are listed below:

1. Required inputs are Image resolution,data format, and optional number of lanes
2. Compute the pixel clock frequency from the given resolution
   pixel frequency = (TotalHorizontalPeriod * TotalVerticalPeriod * FrameRate) / 10^6
3. Determine the possible shiftclock divider value and ganged mode image split the information from the number of pixels, data format, and pixel frequency.

   pixel frequency = DSI clock (byte frequency * 4/clock divider)
4. Symmetrical split is possible for all resolutions. Determine the possibility of the asymmetrical split.
5. Let n1=number of lanes for first partition and n2 = number of lanes for second partition from step 3

   Total number of DSI data lanes required for video refresh:
   totalNumLanesInGangedMode = n1 + n2
6. Compute the correction/additional pixels needed to align the total number of pixels and total number of bytes with totalNumLanesInGangedMode.

   From Limitation #3:

   - The pixelsNeededToInitiallyAlign should be such that an updated totalNumPixels is a multiple of LCM (totalNumLanesInGangedMode,X)
   - totalNumBytes = totalNumPixels*bytesPerPixel
     Ensure the total number of bytes is a multiple of totalNumLanesInGangedMode

   ---

   Note: *For the least common multiple (LCM), X = 4 for 18 bpp packed; otherwise X = 1*

   In the 18 bpp packed format, in case the alignment does not complete over a definite set of iterations for a given frame rate, check that the total additional pixels added to the align is not greater than 50-60 pixels. If this range is exceeded, the pixel alignment is not possible, and the frame is not considered to be asymmetrically split for the 18 bpp packed case (for that frame rate).

   Add the additional correction pixels to the HFP, determine a new pixel frequency, and compute the byte frequency using the clock divider. Use this information to configure the clock parameters for PLLD clock generation and the shift clock divider.
7. Determine the number of pixels per split on updatedPixelCount from step 6:

   - Determine the first partition width, and then the remaining pixels will be in the second partition.

     splitFactor (for first partition)= n1/ totalNumLanesInGangedMode

     First Partition Width (active pixels)= CEIL(splitFactor*image width)

     Pixels per line of the first partition = CEIL(splitFactor*totalNumPixels)

     second partition active width = imagewidth – first partition width

     pixels per line of the second partition = totalNumPixels - Pixels per line of the first partition.

   Note: *For 18 bpp packed, software should recheck if each of the widths determined above is multiple of 4. Otherwise, adjust the active pixels of the partition (increase) to align to 4 pixels and correspondingly decrease the pixels in the HFP (to still meet the line time) accordingly. Adjust pixels in the second partition as well.*

   ---

   numActBytesToBeSent = partition active width * bytesPerPixel

   totalNumBytesForTheSelectedPartition = pixels per line of selected partition * bytesPerPixel

8. In Ganged mode, the packet sequence programming includes HSYNC, HACT, and HFP (total horizontal blanking period) packets.

   HACT payload size = Total Actual Image Bytes on Data lanes

   Initial HFP payload size = totalNumBytesForTheSelectedPartition - numActBytesToBeSent - 16

   (16 is because of 4 bytes - HSYNC, (4+2) Bytes - HACT, (4+2) Bytes - HFP)

9. Compute the correction bytes (per line of partition) to align with line width and number of lanes (per partition) (limitation #2)

   Correction Bytes added per lane (correctionBytesPerLane) = CEIL(totalNoOfPixelsPerHorzLine *(FDSI/ Fpixel) – (BPP/ Gangedmode_lanes))

   Correction Bytes added per partition (totalNumBytesForTheSelectedPartition) = correctionBytesPerLane * numOfLanesForSelectedPartition

   total Horizontal Blank(Bytes) = totalNumBytesForTheSelectedPartition – 16 + correctionBytesForAlignment

10. Ganged mode register programming

    - Left Partition Programming

      DSI_DSI_GANGED_MODE_CONTROL_0[DSI_GANGED_MODE_EN] = 1;

      DSI_DSI_GANGED_MODE_START_0[DSI_GANGED_START_POINTER] = 0;

      DSI_DSI_GANGED_MODE_SIZE_0[DSI_GANGED_VALID_HIGH_WIDTH] = Total horizontal active width

      DSI_DSI_GANGED_MODE_SIZE_0[DSI_GANGED_VALID_LOW_WIDTH] = Total horizontal width – Total horizontal active width.

    - Right Partition Programming

      DSI_DSI_GANGED_MODE_CONTROL_0[DSI_GANGED_MODE_EN] = 1;

      DSI_DSI_GANGED_MODE_START_0[DSI_GANGED_START_POINTER] = leftPartitionWidth (for right partition)

      DSI_DSI_GANGED_MODE_SIZE_0[DSI_GANGED_VALID_HIGH_WIDTH] = Total horizontal active width

      DSI_DSI_GANGED_MODE_SIZE_0[DSI_GANGED_VALID_LOW_WIDTH] = Total horizontal width – Total horizontal active width.

11. SOL delay:

    SolFactor = ((Sol2VldDly + 8) * (FDSI / Fpixe)) + 6;

    sol_delay = Ceil (TotalHorzPixelWidth * (FDSI / Fpixel)) -

    Ceil (((SplitFactor * TotalHorzPixelWidth) * BPP) / Gangedmode_lanes) + SolFactor;

    Final_sol_delay = (dcs_mode) ? (sol_delay + 20) : sol_delay

    DSI_DSI_SOL_DELAY_0 = Final_sol_delay

Notes:

- *Sol2VldDly = Hsync start to Pixel valid delay*
- *totalNoOfPixelsPerHorzLine = Total Number of horizontal pixel count.*
- *SplitFactor = DSI_partition_lanes / Gangedmode_lanes.*
- *Gangedmode_lanes = Total number of lanes required in Ganged mode transfer*
- *DSI_partition_lanes = Total lanes in current partition/channel.*
- *BPP = Bytes per pixel*

Recommended Packet Sequence

26.5.9 Overlay Pixels Programming Guidelines

Overlay pixels refer to the additional number of active pixels sent per partition to meet the panel requirements with original line timing maintained.

Left partition:

- DSI_GANGED_START_POINTER = 0
- DSI_GANGED_VALID_HIGH_WIDTH = Actual High Width + overlay pixels count
- DSI_GANGED_VALID_LOW_WIDTH = Total width - DSI_GANGED_VALID_HIGH_WIDTH
- Hblank time adjusted per active line (since active time increased, blanking time reduced to maintain same line timing)
- Restriction on number of overlay pixels that can be added.
- No change in sol_delay
- For 18bpp packed case, even overlay pixels are consider to make sure total number of pixels is multiple of 4, alternatively, overlay pixels%4 == 0

Right partition:

- DSI_GANGED_START_POINTER = actual start pointer – overlay pixels count
- DSI_GANGED_VALID_HIGH_WIDTH = Actual High Width + overlay pixels count
- DSI_GANGED_VALID_LOW_WIDTH = Total width - DSI_GANGED_VALID_HIGH_WIDTH
- Hblank time adjusted per active line (since active time increased, blanking time reduced to maintain same line timing)
- Restriction on number of overlay pixels that can be added.
- No Change in sol_delay
- For 18bpp packed case, even overlay pixels are consider to make sure total number of pixels is multiple of 4, alternatively, overlay pixels%4 == 0

In asymmetric split cases, the number of overlay pixels is the same across left and right partitions and not in the ratio of asymmetric split ratio.

Example 1: (1080x1680 2x4 24 bpp)

- Image resolution: 1080x1680 @ 59.8fps (CVT reduced blanking)
- Data format: 24bpp
- Htotal = 1080+160 = 1240
- Vtotal = 1680+46 = 1726
- Pixel freq = 128MHz
- Line time = 9.6875us
- Split ratio: 2x4 (Symmetrical case)
- Split type: Left/right
- Video mode: Non burst video
- Actual left partition active width = 540, pixel index 0-539
  Ganged mode en = 1, start pointer = 0, high width =540, low width = 540
- Actual right partition active width = 540, pixel index 540-1079
  Ganged mode en = 1, start pointer =540, high width = 540, low width = 540
- Packet structure: HSYNC (4 bytes) + HACT (4 + 0x654 + 2) + HBLANK (4+0xe0+2) = 1860 bytes = 620 pixels = (540+80)
- Sol_delay: refer to Section 26.5.2.1: SOL Delay Programming.

Example for Overlay pixel count = 8:

- Left partition active width = 548, pixel index 0-547
  Ganged mode en = 1, start pointer = 0, high width =548, low width = 532
- Right partition active width =548, pixel index 532-1079
  Ganged mode en = 1, start pointer =532, high width =548, low width = 532
- Hblank timing = actual hblank timing-active width with overlay pixels timing included
- Packet structure: HSYNC (4 bytes) + HACT (4 + 0x66c + 2) + HBLANK (4+0xc8+2) = 1860 bytes = 620 pixels = (548+72)
- Sol_delay: no change in programming

Example 2:

- Image resolution: 2560x1600 @ 60fps (CVT reduced blanking)
- Data format: 24bpp
- Htotal = 2560+160 = 2720 pixels
- Vtotal = 1600+46 = 1646 lines
- Pixel clock frequency = 268.5MHz
- Line time = 10.13 µs
- Split ratio: 2x4 (Symmetrical case)
- Split type: Left/right
- Actual left partition active width = 1280, pixel index 0-1279
  Ganged mode en = 1, start pointer = 0, high width = 1280, low width = 1280
- Actual right partition active width = 1280, pixel index 1280-2559
  Ganged mode en = 1, start pointer = 1280, high width = 1280, low width = 1280
- Sol_delay: refer to Section 26.5.2.1: SOL Delay Programming.

Example for Overlay pixel count = 10:

- Left partition active width = 1290, pixel index 0-1289
  Ganged mode en = 1, start pointer = 0, high width = 1290, low width = 1270
- Right partition active width = 1290, pixel index 1270-2559
  Ganged mode en = 1, start pointer = 1270, high width = 1290, low width = 1270
- Hblank timing = actual Hblank timing-active width with overlay pixels timing included
- Sol_delay: no change in programming

26.5.10 Soft Reset Programming

Soft reset is asserted in the DSI through the LEG_DSI_ENABLE control field of the DSI_DSI_POWER_CONTROL_0 register. When soft reset is asserted, the DSI controller transitions the internal states to default mode. When it is asserted between valid transactions, the current transaction is halted, the internal states are moved to default mode, and a new transaction starts by programming the desired values following the programming sequence explained in the other sections.

Note: *For Host transmissions enabled through the DSI_HOST_TRIGGER field of the DSI_DSI_TRIGGER_0 register, soft reset cannot be issued between a transaction, and software will write 1'b0 to the register to clear the trigger bit.*

26.5.11 Function Programming

26.5.11.1 ECC Generation

For precise details on the calculation of the ECC field of the packet header, reference should be made to the MIPI Alliance Standard for Display Serial Interface. However, this is an overview of how the ECC can be created quite simply.

Each bit of the ECC byte is the result of XORing a number of bits from the packet header together. Which header bits contribute to which ECC bit is contained in a special table which can be used to calculate the ECC as follows:

```
const UCHAR ecc_parity[24] = { 0x07, 0x0b, 0x0d, 0x0e, 0x13, 0x15, 0x16, 0x19,
                               0x1a, 0x1c, 0x23, 0x25, 0x26, 0x29, 0x2a, 0x2c,
                               0x31, 0x32, 0x34, 0x38, 0x1f, 0x2f, 0x37, 0x3b
                             };
ULONG packet_header;
UCHAR ecc_byte;
UINT  i;

// Assume bottom 24 bits of packet_header
// contains header ID and byte count, then ...

ecc_byte = 0;
for (i = 0; i < 24; i++) {
  ecc_byte ^= ((packet_header >> i) & 1) ? ecc_parity[i] : 0x00;
}
packet_header |= (ULONG)(ecc_byte) << 24;
```

Note: *The table in the DSI specification actually contains 64 entries. Since short packets have been fixed in length to be the same as a long packet header since the original specification was written, there will now always be just 24 data bits in the packet header, so only 24 entries are needed.*

26.5.11.2 CRC Insertion

The DSI checksum used for long packets is derived using the generator polynomial $x^{16}+x^{12}+x^5+x^0$. Details of this can be found in Section 9.6 of the MIPI DSI specification. To understand how the CRC is generated, think of the packet data as consisting of a continuous serialized stream of bits, rather than a sequence of 8-bit bytes. When thought of in this way, it is relatively straight forward to generate the CRC. Reproduced below is an abridged version of the example C code contained in Appendix B of the MIPI DSI specification.

```
// Polynomial, bit reversed form (since DSI transmits LSB first) …
const unsigned short CRC16GenerationCode = 0x8408;

unsigned short CalculateCRC16( unsigned char *DataStream_ptr, unsigned short NumberOfDataBytes)

{
  unsigned short ByteCounter;
  unsigned char  BitCounter;
  unsigned char  CurrentData;
  unsigned short CRC16Result = 0xFFFF;

  if (NumberOfDataBytes > 0) {
    for (ByteCounter = 0; ByteCounter < NumberOfDataBytes; ByteCounteer++) {
      CurrentData = DataStream_ptr[ByteCounter];
      for (BitCounter = 0; BitCounter < 8; BitCounter++) {
        if ((CRC16Result & 0x0001) ^ (CurrentData ^ 0x0001))
          CRC16Result = ((CRC16Result >> 1) & 0x7FFF) ^ CRCGenerationCode;
        else
          CRC16Result =  (CRC16Result >> 1) & 0x7FFF;
        CurrentData = (CurrentData >> 1) & 0x7F;
      }
    }
  }
  return CRC16Result;
}
```

This code may not be very high-performance due to the inner for loop which iterates over bits, rather than bytes. While it is instructive and could form the basis of a reference piece of code, it is not recommended where performance is important. There are many documented methods of performing this calculation in parallel in order to speed up the computations. These methods are beyond the scope of this document.

26.5.12 Read Data Return

DSI is a bidirectional interface. Data is returned from the peripheral display device only after the display controller has requested information by issuing a Bus Turn Around (BTA). All returned data is written into a FIFO that can be read using Host reads of a DSI register.

26.5.12.1 Reading Peripheral Registers

A typical application of a BTA is in the reading of a register from the display peripheral. This is achieved in the following way:

1. Set up the DSI interface to be in Host-driven command mode.
2. Set the DSI_MAX_THRESHOLD to 3.
3. Set the HOST_TX_TRIG_SRC field of the HOST_DSI_CONTROL register to FIFO_LEVEL.
4. Set the PKT_BTA field of the HOST_DSI_CONTROL register to ENABLE.

5. Write a DCS READ command packet (see Section 8.8.8.2 of the MIPI DSI specification) into the Command FIFO by writing to the DSI_WR_DATA register.

This will result in the transmission of a DCS READ packet to the peripheral, the initiation of a BTA and – assuming the peripheral received the packet without error – the return of the requested data to the Host Read Return FIFO. The data can then be read from the FIFO by reading the DSI_RD_DATA register.

26.5.12.2 Bus Turn Around

- BTA is only supported for Host driven Command Mode interface. There will be no BTA during video mode transmission.
- Whether or not a BTA is initiated is controlled by the `PKT_BTA` field of the HOST_DSI_CONTROL register.
- The DSI Read Return FIFO is 4 bytes wide and 8 entries deep, so 32 bytes in total. this is enough to hold 8 short packets, or a mixture of short and long packets. The length of long packets must be severely restricted.
- Hardware does not perform ECC or CS checks on the read return data. Entire packets are simply made available to software to perform whatever checks they desire.
- There is the ability to increment a sync point counter on the arrival of the returned data or on the receipt of an error report in the event there was a problem with the read packet transaction.
- Software will ensure to program the byte clock frequency dsi_clk greater than 52 MHz, when performing BTA transactions.

26.5.12.3 BTA – Response Time Parameter

When a peripheral receives a READ Request, it is expected that a Bus Turn Around will immediately follow to extend support for the display device that cannot handle the request immediately after the Read request is issued.

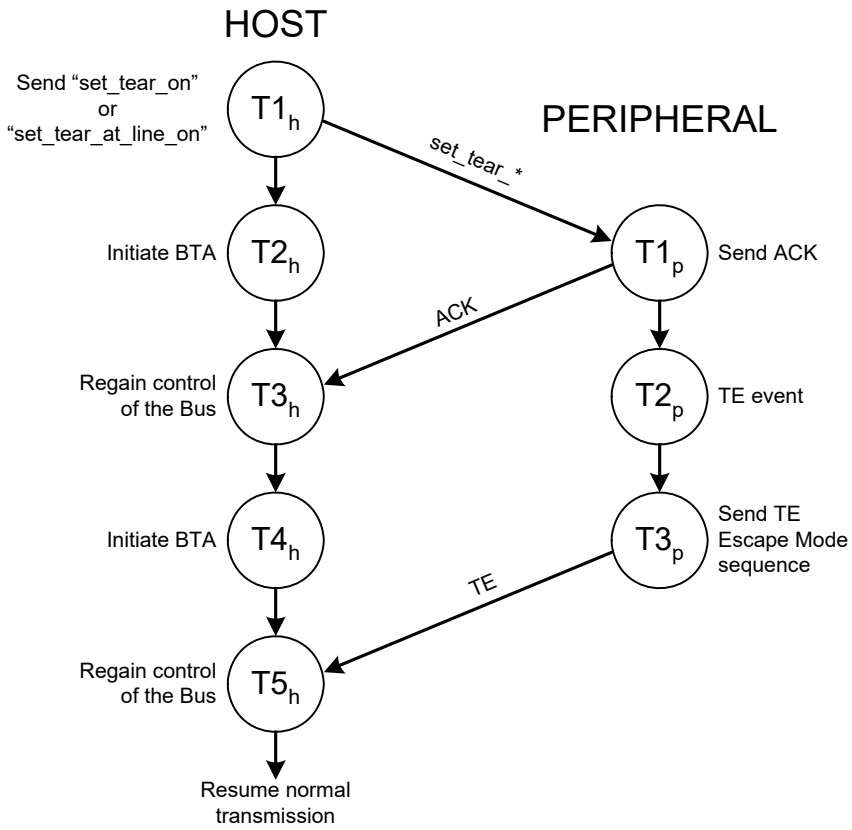
The DSI_DSI_BTA_TIMING_0 register defines DSI_TPKTBTA to allow a programmable delay between the end of host transmission and generation of BTA request for extending support for the display devices with slow response.

Note: *Valid programmable values for all the DSI_DSI_BTA_TIMING_0 register fields (DSI_TTAGO/ DSI_TTASURE/DSI_TTAGET/DSI_TPKTBTA) are 0 to 254. Invalid value is 255.*

26.5.13 Tearing Effect

In order to synchronize the update of a Command Mode display with data from the Host, a signal from the display can be sent to indicate when it is safe to proceed with the transmission of new data. This is the Tearing Effect reporting signal. Refer to Section 8.12 “TE Signaling in DSI” of the DSI specification for more details.

Figure 112: Tearing Effect State Transition Diagram



Programmatically, this is achieved in the following way:

1. Send SET_TEAR_ON or SET_TEAR_AT_LINE_ON command with the PKT_BTA field in the HOST_DSI_CONTROL register set to ENABLE. This is state T1h.
2. Wait for ACK to come back from the peripheral. This is states T2h and T3h.
3. Set the IMM_BTA field in the HOST_DSI_CONTROL register set to ENABLE. This will cause the D-PHY to go into BTA without having to send a command first. This is state T4h.
4. Wait for TE return byte from the peripheral. This is state T5h.

26.5.14 Pad Calibration Programming

- Configure the MIPI calibration clock to operate at 72 MHz via programming the register CLK_RST_CONTROLLER_CLK_SOURCE_UART_FST_MIPI_CAL_0.
- Enable the MIPI calibration clock via Set CLK_ENB_MIPI_CAL to 1.
- Release reset to mipi_cal logic by deasserting SWR_MIPI_CAL_RST to 0
- Configure the DSI pad/Bias pads to appropriate values

  DSI_PAD_CONTROL_3_0= 0x0

  DSI_PAD_CONTROL_4_0 = 0x0

  MIPI_CAL_MIPI_BIAS_PAD_CFG0_0 = 0x0;

  MIPI_CAL_MIPI_BIAS_PAD_CFG1_0 = 0x00020000

  MIPI_CAL_MIPI_BIAS_PAD_CFG2_0 = 0x00000000
- Configure MIPI calibration settings for DSI pads for setup MIPI_CAL_DSI* _MIPI_CAL_CONFIG [*SELDSI*/ *OVERIDEDSI*/ *HSPDOSDSI*/ *HSPUOSDSI*/ *TERMOSDSI*].

  MIPI_CAL_DSI*_MIPI_CAL_CONFIG_0

- Enable all the DSI lanes that require calibration driving LP_11 state.
- MIPI calibration start via - MIPI_CAL_MIPI_CAL_CTRL_0[MIPI_CAL_STARTCAL]
- Monitor the status via MIPI_CAL_CIL_MIPI_CAL_STATUS_0[*].

26.5.15 Error Reporting

There is no actual error recovery circuitry in the hardware, only error reporting. Any error that is reported via a protocol-level packet will be processed like all other return data and will be written to the data return FIFO for processing by the Host / Software.

Low level hardware errors such as bus contention will not be flagged, but will increment counters that can be queried by software so as to determine the reliability of the link.

26.5.15.1 Acknowledge with Error Report

The peripheral device (display) can be instructed to return an error report along with an acknowledge at the end of a transmission sequence. This is achieved by setting the PKT_BTA field in the HOST_DSI_CONTROL register to ENABLE. When this is done, there are several outcomes as shown in the table below.

Table 157: Peripheral Response to Various Conditions

Condition	Non-Read Packet	Read Packet
No error	ACK	Read Data
Corrected single bit error	ACK with ERR	Read Data + ACK with ERR
Non-corrected multi-bit error	ACK with ERR	ACK with ERR
SOT, EOT, VI ID or other D-PHY error	ACK with ERR	ACK with ERR

It is the responsibility of software to read this data from the packet returned in the packet return FIFO and process as required. No action will be taken by the hardware based on the error report returned in the ACK packet.

ACK Return

If a BTA request is enabled and there is no error, then the peripheral will return an ACK trigger to the DSI hardware. This single byte trigger has the value 0x84. Since the return FIFO is 32 bits wide, the 0x84 value will be placed in the bottom 8 bits of the FIFO.

Read Data

If a read command packet is sent, then BTA request should be enabled to allow the peripheral to return the read data. If no error occurs in the transmission of the read packet, or a corrected single bit error occurs, then the read data will be returned to the host DSI hardware in the form of a read packet. The precise form will depend on the type of read packet transmitted. Refer to the MIPI DSI specification Section 8.10 for details.

If a corrected error occurs during the transmission of the read command, the requested read data will be returned in the normal way, but an ACK with Error report packet will be appended to the read return data packet.

ACK with Error Report

The error report is contained in the 16 payload bits of a special short packet returned by the peripheral. The bits allocations of the packet data are detailed in Section 8.9.5 of the MIPI DSI specification but are repeated here for convenience.

Table 158: Error Report Bit Assignments

Bit	Description
0	SOT error
1	SOT sync error
2	EOT sync error
3	Escape Mode Entry Command error

Table 158: Error Report Bit Assignments

Bit	Description
4	Low-Power Transmit Sync Error
5	HS Receive Timeout error
6	False Control Error
7	RESERVED
8	ECC Error, single bit (corrected)
9	ECC Error, multi-bit (not corrected)
10	CS Error (long packet only)
11	DSI data type not recognized
12	DSI Virtual Channel ID invalid
13	RESERVED
14	RESERVED
15	RESERVED

26.5.16 Time Outs

There are three compulsory and one optional time out counters required by the MIPI DSI specification for Processors (display controller). Each timer will consist of a simple counter which will count DSI byte clocks. The counters will reset to 0 on an event and will then simply increment their count every DSI byte clock cycle. If the event that the time out is protecting occurs before the time out reaches its terminal count, the counter will simply stop counting and hold its value. If the counter reaches software programmed maximum count before the expected event occurs, the counter will stop counting and hold its count value. Any action that is required by the MIPI DSI specification upon reaching the time out will also be performed by the hardware.

Table 159: Time-out Counter Summary

Time Out Name	Abbreviation	Start Condition	Length Greater Than	Action
HS Transmit TO	HTX_TO	SOT	Longest HS sequence	EOT + LP-11
LP Receive TO	LRXH_TO	LP Rx start	LTXP_TO (on periph.)	LP-11
Turn Around TO	TA_TO	BTA start	BTA response time	LP-11
Peripheral Reset	PR_TO	Reset Entry CMD	Peripheral response time	None.

In the table, the Peripheral Reset time out is the only timer that is optional. All the other timers are required by the MIPI DSI specification. Note that under “Action”, the listed operations are forced on the interface by the D-PHY under the instruction of the protocol layer (hardware). In the case of the optional Peripheral Reset time out, there is no action since this time out simply exists to issue a reset to the peripheral. Once the reset command is issued, the only further action required is to wait for an appropriate length of time to allow the peripheral to go through its reset sequence.

In the case of the HTX_TO, LRXH_TO and TA_TO time outs, the reaching of a terminal count will not only cause the action as listed in the table below, but will also cause a tally counter to increment so that software can read the register and determine if any of the time outs have occurred. Software will be able to reset these tally counters to 0 by writing to the tally register. The value written will be irrelevant. The PR_TO will report its operation in a different manner. When the PR_TO counter is actually counting, there will be a status bit that reads as ‘0’. When the PR_TO terminal count is reached and time out ends, the status bit will become ‘1’. This will allow software to determine when the peripheral has been reset.

Table 160: Time Out and Tally Registers

Register	Field	Description
DSI_TIMEOUT_0	HTX_TO	High Speed Transmit time out duration
	LRXH_TO	Low Power Receive time out duration
DSI_TIMEOUT_1	TA_TO	Turn Around time out duration
	PR_TO	Peripheral Reset duration

Table 160: Time Out and Tally Registers

Register	Field	Description
DSI_TO_TALLY	HTX_TALLY	High Speed Transmit time out Tally
	LRXH_TALLY	Low Power Receive time out Tally
	TA_TALLY	Turn Around time out Tally
	P_RESET_STATUS	Peripheral Reset Status: 0= Reset, 1 = Ready

26.6 MIPI-DSI Registers

Refer to Section 1.4: Reading Register Tables in the Introduction chapter for the register table protocol as well as recommendations for accessing registers.

26.6.1 DSI_INCR_SYNCPT_0

Offset: 0x0 | Byte Offset: 0x0 | Read/Write: R/W | Reset: 0x00000000 (0bxxxxxxxxxxxxxxxx0000000000000000)

Bit	Reset	Description
15:8	0x0	COND: Condition mapped from raise/wait 0 = IMMEDIATE 1 = OP_DONE 2 = RD_DONE 3 = REG_WR_SAFE 4 = COND_4 5 = COND_5 6 = COND_6 7 = COND_7 8 = COND_8 9 = COND_9 10 = COND_10 11 = COND_11 12 = COND_12 13 = COND_13 14 = COND_14 15 = COND_15 16 = COND_16 17 = COND_17 18 = COND_18 19 = COND_19 20 = COND_20 21 = COND_21 22 = COND_22 23 = COND_23 24 = COND_24 25 = COND_25 26 = COND_26 27 = COND_27 28 = COND_28 29 = COND_29 30 = COND_30 31 = COND_31
7:0	0x0	INDX: syncpt index value

26.6.2 DSI_INCR_SYNCPT_CNTRL_0

Offset: 0x1 | Byte Offset: 0x4 | Read/Write: R/W | Reset: 0x00000000 (0bxxxxxxxxxxxxxxxxxxxxxxxx0xxxxxxx0)

Bit	Reset	Description
8	0x0	INCR_SYNCPT_NO_STALL: If NO_STALL is 1, then when FIFOs are full, INCR_SYNCPT methods will be dropped and the INCR_SYNCPT_ERROR[COND] bit will be set. If NO_STALL is 0, then when FIFOs are full, the client host interface will be stalled.
0	0x0	INCR_SYNCPT_SOFT_RESET: If SOFT_RESET is set, then all internal states of the client syncpt block will be reset. To do a soft reset, first set SOFT_RESET of all affected Host1x clients, then clear all SOFT_RESETs.

26.6.3 DSI_INCR_SYNCPT_ERROR_0

Offset: 0x2 | Byte Offset: 0x8 | Read/Write: R/W | Reset: 0x00000000 (0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx)

Bit	Reset	Description
31:0	X	COND_STATUS: COND_STATUS[COND] is set if the FIFO for COND overflows. This bit is sticky and will remain set until cleared. Cleared by writing 1.

26.6.4 DSI_CTXSW_0

Context switch register. Should be common to all modules. Includes the current channel/class (which is writable by software) and the next channel/class (which the hardware sets when it receives a context switch).

Any context switch request triggers an interrupt to the host and causes the new channel/class to be stored in NEXT_CHANNEL/NEXT_CLASS (see vmod/chexample). Software sees that there is a context switch interrupt and does the necessary operations to make the module ready to receive traffic from the new context. It clears the context switch interrupt and writes CURR_CHANNEL/CLASS to the same value as NEXT_CHANNEL/CLASS, which causes a context switch acknowledge packet to be sent to the host. This completes the context switch and allows the host to continue sending data to the module.

Context switches can also be pre-loaded. If CURR_CLASS/CHANNEL are written and updated to the next CLASS/CHANNEL before the context switch request occurs, an acknowledge will be generated by the module, and no interrupt will be triggered. This is one way for software to avoid dealing with context switch interrupts.

Another way to avoid context switch interrupts is to set the AUTO_ACK bit. This bit tells the module to automatically acknowledge any incoming context switch requests without triggering an interrupt. CURR_* and NEXT_* will be updated by the module so they will always be current.

Offset: 0x8 | Byte Offset: 0x20 | Read/Write: R/W | Reset: 0xf000f800 (0bxxxxxxxxxxxxxxxx11111x0000000000)

Bit	R/W	Reset	Description
31:28	RO	X	NEXT_CHANNEL: Next requested channel
25:16	RO	X	NEXT_CLASS: Next requested class
15:12	RW	0xf	CURR_CHANNEL: Current working channel, reset to 'invalid'
11	RW	0x1	AUTO_ACK: Automatically acknowledge any incoming context switch requests 0 = MANUAL 1 = AUTOACK
9:0	RW	0x0	CURR_CLASS: Current working class

Note: *PACKET DEFINITIONS*
Packet for Display Controller -> DSI communication:
Line Type is used to convey the type of video line from the display controller to the DSI block. The line type implies the generation of one of the associated packet sequences as defined in the DSI packet sequence registers (see below). Used to construct packet headers. All packet headers are now 32-bits wide regardless of whether they are short or long packets. Used for validation infrastructure only.

26.6.5 DSI_DSI_RD_DATA_0

DSI Read Return Data

Offset: 0x9 | Byte Offset: 0x24 | Read/Write: RO | Reset: 0xXXXXXXXX (0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx)

Bit	Reset	Description
31:0	X	DSI_RD_DATA: Each read to this register will pop 32 bits from the 32-bit wide read return data FIFO. The FIFO has NV_DSI_HOST_DATA_RETURN_FIFO_DEPTH entries.

26.6.6 DSI_DSI_WR_DATA_0

Host FIFO Write Input

Offset: 0xa | Byte Offset: 0x28 | Read/Write: R/W | Reset: 0xXXXXXXXX (0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx)

Bit	Reset	Description
31:0	X	DSI_WR_DATA: Each write to this register will push 32 bits into the 32-bit wide Host data FIFO. FIFO has NV_DSI_HOST_DATA_FIFO_DEPTH entries

26.6.7 DSI_DSI_POWER_CONTROL_0

Display Power Control

DSI Enable

Offset: 0xb | Byte Offset: 0x2c | Read/Write: R/W | Reset: 0x00000000 (0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx0)

Bit	Reset	Description
0	0x0	LEG_DSI_ENABLE: DSI interface Enable 0 = DISABLE: Disable DSI 1 = ENABLE: Enable DSI

26.6.8 DSI_INT_ENABLE_0

Interrupt Enable Register

Offset: 0xc | Byte Offset: 0x30 | Read/Write: R/W | Reset: 0x00000001 (0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx1)

Bit	Reset	Description
0	0x1	CTXSW_INT_ENABLE: Context Switch Interrupt Enable 0 = DISABLE: interrupt disabled 1 = ENABLE: interrupt enabled

26.6.9 DSI_INT_STATUS_0

Interrupt Status Register

Offset: 0xd | Byte Offset: 0x34 | Read/Write: R/W | Reset: 0x00000000 (0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx0)

Bit	Reset	Description
0	0x0	CTXSW_INT: Context switch interrupt status (clear on write)

26.6.10 DSI_INT_MASK_0

Interrupt Mask

Setting bits in this register mask the corresponding interrupt but does not clear a pending interrupt and does not prevent a pending interrupt to be generated. Masking an interrupt also does not clear a pending interrupt status and does not prevent a pending interrupt status to be generated.

Offset: 0xe | Byte Offset: 0x38 | Read/Write: R/W | Reset: 0x00000000 (0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx0)

Bit	Reset	Description
0	0x0	CTXSW_INT_MASK: Context Switch Interrupt Mask 0 = MASKED: interrupt masked 1 = NOTMASKED: interrupt not masked

26.6.11 DSI_HOST_DSI_CONTROL_0

DSI Control Register When Input is from HOST

Offset: 0xf | Byte Offset: 0x3c | Read/Write: R/W | Reset: 0x00000043 (0bxxxxxxxxxx00x000xx00xx0001000011)

Bit	Reset	Description
21	0x0	FIFO_STAT_RESET: write only bit to clear FIFO underflow/overflow flags. If a new underflow/overflow event occurs during the same time, current access cannot clear the status bits
20	0x0	CRC_RESET: Write only bit. When written with a 1, causes the Verification CRC generator to reset to 0xFFFF_FFFF. If written with 0, it has no effect.
18:16	0x0	DSI_PHY_CLK_DIV: Phy clock divider value for byte clock 0 = DIV1 1 = DIV2
13:12	0x0	HOST_TX_TRIG_SRC: Controls the source of the trigger to start sending packets. 0 = SOL: Start of Line signal from the Display Controller. 1 = FIFO_LEVEL: How full the FIFO is. Level determined elsewhere. 2 = IMMEDIATE: Determined by a write to the DSI_HOST_TRIGGER field of the DSI_TRIGGER register
9:8	0x0	DSI_ULTRA_LOW_POWER: Ultra Low Power 0 = NORMAL 1 = ENTER_ULPM 2 = EXIT_ULPM
7	0x0	PERIPH_RESET: Initiate an Escape Mode Peripheral Reset. 0 = DISABLE: Causes an Escape Mode Command to be sent to reset the 1 = ENABLE: External display device. Also starts the PR_TO counter. PR_TO state can be checked with the P_RESET_STATUS field in the DSI_TO_TALLY register. Hardware clears this bit upon completion of issuing "Trigger Reset" OR called "Reset Entry" command is sent out.
6	0x1	RAW_DATA: Host raw data mode. In this mode. All data is sent exactly as written. No attempt to decode packet headers is made. This bit will also override the function of the ECC and CS ENABLE fields. No ECC or CS will be generated. This mode is intended as a debug / diagnostic workaround mode only. 0 = DISABLE: Normal mode. 1 = ENABLE: Enable raw data transmission.
5	0x0	DSI_HIGH_SPEED_TRANS: DSI high speed transmission of packets 0 = LOW: Low speed - Note: Unlikely ever to be used. 1 = HIGH: High speed
4	0x0	PKT_WR_FIFO_SEL: Host Write FIFO Select. In video mode, software shall not program PKT_WR_FIFO_SEL=VIDEO. 0 = HOST: Write data to the small host data FIFO only. 1 = VIDEO: Write data to both the host and video line store FIFO, in series. Note: Software shall only program PKT_WR_FIFO_SEL field in Host mode.
3	0x0	IMM_BTA: Generate BTA immediately, e.g., for Tearing Effect reporting. Note: This will generate a BTA and pass control of the D-PHY to the remote peripheral without the need to send any packet. Once the BTA is initiated on interface this bit gets cleared. Later on Host syncpt opdone is returned when the remote peripheral has responded and relinquished control of the bus. 0 = DISABLE: Do not generate BTA 1 = ENABLE: Generate BTA immediately, without waiting for a packet.
2	0x0	PKT_BTA: Generate BTA at the end of Host packets 0 = DISABLE: Do not generate BTA 1 = ENABLE: Generate BTA after the next packet is sent.
1	0x1	CS_ENABLE: enable Hardware Check Sum (CS) for Host packets Note: when CS is disabled, Host is responsible for generating proper CRC and adding the 2-byte CRC to the end of the packet after the payload. 0 = DISABLE: Disable hardware generation of CS (Host must calculate CS). 1 = ENABLE: Enable hardware generation of CS.
0	0x1	ECC_ENABLE: Enable hardware Error Correction Code (ECC) for Host packets Note: when ECC is disabled, Host is responsible for generating proper ECC byte for header 0 = DISABLE: Disable hardware generation of ECC (Host must calculate ECC). 1 = ENABLE: Enable hardware generation of ECC.

26.6.12 DSI_DSI_CONTROL_0

General DSI Control Register

Offset: 0x10 | Byte Offset: 0x40 | Read/Write: R/W | Reset: 0x00000000 (0b00xxxxxxxxx0xx00xx00xx00xx000000)

Bit	Reset	Description
31	0x0	DSI_DBG_ENABLE: Control signal to turn off clock monitoring when enabled for debug, on every DSI byte clock debug signal toggle. Also TX CRC computation aid will turn on.
30	0x0	DFMT_16BPP_SWAP_EN: DSI specification supports different bit ordering (only 16 BPP) in command mode. Command Mode (Default): 16BPP[15:0] -> B[4-0]G[5-0]R[4-0]; Command Mode (SWAP_EN): 16BPP[15:0] -> G[2-0]B[4-0]R[4-0]G[5-3]
20	0x0	DSI_HS_CLK_CTRL: Control for the HS clock lane 0 = CONTINUOUS: HS clock is on all the time. 1 = TX_ONLY: HS clock is only active during HS transmissions.
17:16	0x0	DSI_VIRTUAL_CHANNEL: Virtual channel ID. The virtual channel is sent as part of the packet header and used to distinguish multiple displays.
13:12	0x0	DSI_DATA_FORMAT: Pixel Data format transmitted. Note that although the pixel format is specified in the packet header ID for RGB data packets, this information is ignored by the hardware. Only the information used in this register is used in the construction of RGB data packets. 0 = BIT16P: 16 bpp RGB Packed. 2 bytes used per pixel 1 = BIT18NP: 18 bpp RGB Not-packed. 3 bytes used per pixel 2 = BIT18P: 18 bpp RGB Packed. 2.25 bytes used per pixel 3 = BIT24P: 24 bpp RGB Packed. 3 bytes used per pixel
9:8	0x0	VID_TX_TRIG_SRC: Controls the source of the trigger to start sending packets. 0 = SOL: Start of Line signal from the Display Controller. 1 = FIFO_LEVEL: How full the FIFO is. Level determined elsewhere. 2 = IMMEDIATE: Determined by a write to the DSI_VID_TRIGGER field of the DSI_TRIGGER register
5:4	0x0	DSI_NUM_DATA_LANES: Number of D-PHY data lanes used by Display for HS transmission. 0 = ONE: 1 data lane. 1 = TWO: 2 data lanes. 2 = THREE: 3 data lanes. 3 = FOUR: 4 data lanes.
3	0x0	VID_DCS_ENABLE: Enable for insertion of DCS commands during Display Controller generated packets. When enabled, the DCS commands defined in the LT3_DCS_CMD and LT5_DCS_CMD fields of the DSI_DCS_CMDS register will be inserted in long packets defined in packet sequence 3 and 5. 0 = DISABLE: No DCS commands will be inserted. 1 = ENABLE: DCS command IDs will be inserted as described above.
2	0x0	DSI_VID_SOURCE: Source of video pixels 0 = DISPLAY_0: Pixels come from "display" 1 = DISPLAY_1: Pixels come from "displayb"
1	0x0	DSI_VID_ENABLE: Video DSI Interface Enable 0 = DISABLE: Disable 1 = ENABLE: Enable
0	0x0	DSI_HOST_ENABLE: Host DSI Interface Enable 0 = DISABLE: Disable 1 = ENABLE: Enable

26.6.13 DSI_DSI_SOL_DELAY_0

Number of Byte-Clock Counts to Wait after Reception

Offset: 0x11 | Byte Offset: 0x44 | Read/Write: R/W | Reset: 0x0000XXXX (0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx)

Bit	Reset	Description
15:0	X	SOL_DELAY: Start Of Line before generating output packets.

26.6.14 DSI_DSI_MAX_THRESHOLD_0

Maximum Threshold Registers for DSI Related Packets

Offset: 0x12 | Byte Offset: 0x48 | Read/Write: R/W | Reset: 0x0000XXXX (0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx)

Bit	Reset	Description
15:0	X	MAX_THRESHOLD: Start draining FIFO once this threshold is met. This register can be used for DBI mode when line packet data exceeds the size of the data FIFO.

26.6.15 DSI_DSI_TRIGGER_0

Manual Transmission Trigger Register

Offset: 0x13 | Byte Offset: 0x4c | Read/Write: R/W | Reset: 0x0000000X (0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx)

Bit	Reset	Description
1	X	DSI_HOST_TRIGGER: A 1 written to this bit will start host transmission when HOST_DSI_CONTROL.HOST_TX_TRIG_SRC is set to IMMEDIATE. Hardware auto clears on operation completion
0	X	DSI_VID_TRIGGER: A 1 written to this bit will start video transmission when DSI_CONTROL.VID_TX_TRIG_SRC is set to IMMEDIATE. Hardware auto clears on operation completion

26.6.16 DSI_DSI_TX_CRC_0

Transmission CRC

Offset: 0x14 | Byte Offset: 0x50 | Read/Write: RO | Reset: 0xXXXXXXXX (0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx)

Bit	Reset	Description
31:0	X	TX_CRC: Long Packet CRC appended to the end of long packets. This CRC is that result of generating a CRC from all transmitted bytes. If DSI_HOST_ENABLE == ENABLE, then a CRC is generated from all bytes transmitted from the Host interface in Command Mode. If DSI_VID_ENABLE == ENABLE, then a CRC is generated from all bytes transmitted during a frame of video when in Video Mode. Note that the hardware will capture the CRC into a separate internal register so that it can continue to calculate the CRC for the next frame without having to wait for software to read the current result.

26.6.17 DSI_DSI_STATUS_0

DSI Status Register

Offset: 0x15 | Byte Offset: 0x54 | Read/Write: RO | Reset: 0x00000XXX (0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx)

Bit	Reset	Description
10	X	DSI_IDLE: Indicated that the DSI is IDLE.
9	X	LB_UNDERFLOW: Indicates that a Line buffer underflow event happened
8	X	LB_OVERFLOW: Indicates that a Line buffer overflow event happened
4:0	X	RD_FIFO_COUNT: Count of how many data words are left in the Host Read Data Return FIFO. Typically, software knows how much data to read from the DSI_RD_DATA register after a Read packet / BTA has been sent / requested, since these transactions are initiated by software. However, under error conditions, insufficient data may have been read from the FIFO. Software should therefore check this field to make sure it is 0 after reading all the information it expected to get.

26.7 Initialization Sequence Registers

26.7.1 DSI_DSI_INIT_SEQ_CONTROL_0

DSI Initialization Sequence Control

Offset: 0x1a | Byte Offset: 0x68 | Read/Write: R/W | Reset: 0x0000XX00 (0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx0)

Bit	Reset	Description
14:8	X	DSI_FRAME_INIT_BYTE_COUNT: Frame Initialization Sequence Byte Count. This parameter specifies the number of frame initialization sequence cycles to send. If programmed to 0, there is no frame initialization cycle generated. Valid programmable values: 0 to 64. Invalid programmable values: 65 to 127.
0	0x0	DSI_SEND_INIT_SEQUENCE: Send Initialization Sequence (IS) 0 = DISABLE 1 = ENABLE

26.7.2 DSI_DSI_INIT_SEQ_DATA_0_0

DSI Init Sequence Write Data 0

Offset: 0x1b | Byte Offset: 0x6c | Read/Write: R/W | Reset: 0xXXXXXXXX (0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx)

Bit	Reset	Description
31:0	X	DSI_INIT_SEQ_DATA_0: DSI Init Sequence Write Data bits 31:0

26.7.3 DSI_DSI_INIT_SEQ_DATA_1_0

DSI Init Sequence Write Data 1

Offset: 0x1c | Byte Offset: 0x70 | Read/Write: R/W | Reset: 0xXXXXXXXX (0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx)

Bit	Reset	Description
31:0	X	DSI_INIT_SEQ_DATA_1: DSI Init Sequence Write Data bits 31:0

26.7.4 DSI_DSI_INIT_SEQ_DATA_2_0

DSI Init Sequence Write Data 2

Offset: 0x1d | Byte Offset: 0x74 | Read/Write: R/W | Reset: 0xXXXXXXXX (0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx)

Bit	Reset	Description
31:0	X	DSI_INIT_SEQ_DATA_2: DSI Init Sequence Write Data bits 31:0

26.7.5 DSI_DSI_INIT_SEQ_DATA_3_0

DSI Init Sequence Write Data 3

Offset: 0x1e | Byte Offset: 0x78 | Read/Write: R/W | Reset: 0xXXXXXXXX (0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx)

Bit	Reset	Description
31:0	X	DSI_INIT_SEQ_DATA_3: DSI Init Sequence Write Data bits 31:0

26.7.6 DSI_DSI_INIT_SEQ_DATA_4_0

DSI Init Sequence Write Data 4

Offset: 0x1f | Byte Offset: 0x7c | Read/Write: R/W | Reset: 0xXXXXXXXX (0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx)

Bit	Reset	Description
31:0	X	DSI_INIT_SEQ_DATA_4: DSI Init Sequence Write Data bits 31:0

26.7.7 DSI_DSI_INIT_SEQ_DATA_5_0

DSI Init Sequence Write Data 5

Offset: 0x20 | Byte Offset: 0x80 | Read/Write: R/W | Reset: 0xXXXXXXXX (0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx)

Bit	Reset	Description
31:0	X	DSI_INIT_SEQ_DATA_5: DSI Init Sequence Write Data bits 31:0

26.7.8 DSI_DSI_INIT_SEQ_DATA_6_0

DSI Init Sequence Write Data 6

Offset: 0x21 | Byte Offset: 0x84 | Read/Write: R/W | Reset: 0xXXXXXXXX (0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx)

Bit	Reset	Description
31:0	X	DSI_INIT_SEQ_DATA_6: DSI Init Sequence Write Data bits 31-0

26.7.9 DSI_DSI_INIT_SEQ_DATA_7_0

DSI Init Sequence Write Data 7

Offset: 0x22 | Byte Offset: 0x88 | Read/Write: R/W | Reset: 0xXXXXXXXX (0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx)

Bit	Reset	Description
31:0	X	DSI_INIT_SEQ_DATA_7: DSI Init Sequence Write Data bits 31-0

26.8 Packet Sequence Registers

These registers allow the construction of arbitrary packet sequences associated with various video line types as sent from the Display Controller to the DSI block.

The first digit of the pair of digits in each field below is the sequence number, and the second digit denotes the packet number within each sequence. For example, field PKT_23_ID, defines the ID for packet 3 in sequence 2.

26.8.1 DSI_DSI_PKT_SEQ_0_LO_0

DSI Packet Sequence 0 LO Half

Offset: 0x23 | Byte Offset: 0x8c | Read/Write: R/W | Reset: 0xXXXXXXXX (0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx0)

Bit	Reset	Description
30	X	SEQ_0_FORCE_LP: For packet sequence 0, forces the D-PHY to go to LP mode after the last packet of the sequence has been transmitted. 0 = DISABLE 1 = ENABLE
29	X	PKT_02_EN: Packet 2 enable 0 = DISABLE 1 = ENABLE
28:23	X	PKT_02_ID: Packet 2 Packet ID
22:20	X	PKT_02_SIZE: Packet 2 size pointer
19	X	PKT_01_EN: Packet 1 enable 0 = DISABLE 1 = ENABLE
18:13	X	PKT_01_ID: Packet 1 Packet ID
12:10	X	PKT_01_SIZE: Packet 1 size pointer
9	X	PKT_00_EN: Packet 0 enable 0 = DISABLE 1 = ENABLE
8:3	X	PKT_00_ID: Packet 0 Packet ID

Bit	Reset	Description
2:0	X	PKT_00_SIZE: Packet 0 size pointer

26.8.2 DSI_DSI_PKT_SEQ_0_HI_0

DSI Packet Sequence 0 HI Half

Line Type 0 is associated with the first line in the frame and should contain a packet sequence that starts with a VS packet.

Offset: 0x24 | Byte Offset: 0x90 | Read/Write: R/W | Reset: 0xXXXXXXXX (0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx0)

Bit	Reset	Description
29	X	PKT_05_EN: Packet 5 enable 0 = DISABLE 1 = ENABLE
28:23	X	PKT_05_ID: Packet 5 Packet ID
22:20	X	PKT_05_SIZE: Packet 5 size pointer
19	X	PKT_04_EN: Packet 4 enable 0 = DISABLE 1 = ENABLE
18:13	X	PKT_04_ID: Packet 4 Packet ID
12:10	X	PKT_04_SIZE: Packet 4 size pointer
9	X	PKT_03_EN: Packet 3 enable 0 = DISABLE 1 = ENABLE
8:3	X	PKT_03_ID: Packet 3 Packet ID
2:0	X	PKT_03_SIZE: Packet 3 size pointer

26.8.3 DSI_DSI_PKT_SEQ_1_LO_0

DSI Packet Sequence 1 LO Half

Line Type 1 is associated with the last line of Vertical Sync and should contain a packet sequence that starts with a VE packet.

Offset: 0x25 | Byte Offset: 0x94 | Read/Write: R/W | Reset: 0xXXXXXXXX (0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx0)

Bit	Reset	Description
30	X	SEQ_1_FORCE_LP: For packet sequence 1, forces the D-PHY to go to LP mode after the last packet of the sequence has been transmitted. 0 = DISABLE 1 = ENABLE
29	X	PKT_12_EN: Packet 2 enable 0 = DISABLE 1 = ENABLE
28:23	X	PKT_12_ID: Packet 2 Packet ID
22:20	X	PKT_12_SIZE: Packet 2 size pointer
19	X	PKT_11_EN: Packet 1 enable 0 = DISABLE 1 = ENABLE
18:13	X	PKT_11_ID: Packet 1 Packet ID
12:10	X	PKT_11_SIZE: Packet 1 size pointer
9	X	PKT_10_EN: Packet 0 enable 0 = DISABLE 1 = ENABLE
8:3	X	PKT_10_ID: Packet 0 Packet ID
2:0	X	PKT_10_SIZE: Packet 0 size pointer

26.8.4 DSI_DSI_PKT_SEQ_1_HI_0

DSI Packet Sequence 1 HI Half

Offset: 0x26 | Byte Offset: 0x98 | Read/Write: R/W | Reset: 0xXXXXXXXX (0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx0)

Bit	Reset	Description
29	X	PKT_15_EN: Packet 5 enable 0 = DISABLE 1 = ENABLE
28:23	X	PKT_15_ID: Packet 5 Packet ID
22:20	X	PKT_15_SIZE: Packet 5 size pointer
19	X	PKT_14_EN: Packet 4 enable 0 = DISABLE 1 = ENABLE
18:13	X	PKT_14_ID: Packet 4 Packet ID
12:10	X	PKT_14_SIZE: Packet 4 size pointer
9	X	PKT_13_EN: Packet 3 enable 0 = DISABLE 1 = ENABLE
8:3	X	PKT_13_ID: Packet 3 Packet ID
2:0	X	PKT_13_SIZE: Packet 3 size pointer

26.8.5 DSI_DSI_PKT_SEQ_2_LO_0

DSI Packet Sequence 2 LO Half

Line Type 2 is associated with any vertical blank line except the first one after active and should contain a packet sequence that starts with an HS packet.

Offset: 0x27 | Byte Offset: 0x9c | Read/Write: R/W | Reset: 0xXXXXXXXX (0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx0)

Bit	Reset	Description
30	X	SEQ_2_FORCE_LP: For packet sequence 2, forces the D-PHY to go to LP mode after the last packet of the sequence has been transmitted. 0 = DISABLE 1 = ENABLE
29	X	PKT_22_EN: Packet 2 enable 0 = DISABLE 1 = ENABLE
28:23	X	PKT_22_ID: Packet 2 Packet ID
22:20	X	PKT_22_SIZE: Packet 2 size pointer
19	X	PKT_21_EN: Packet 1 enable 0 = DISABLE 1 = ENABLE
18:13	X	PKT_21_ID: Packet 1 Packet ID
12:10	X	PKT_21_SIZE: Packet 1 size pointer
9	X	PKT_20_EN: Packet 0 enable 0 = DISABLE 1 = ENABLE
8:3	X	PKT_20_ID: Packet 0 Packet ID
2:0	X	PKT_20_SIZE: Packet 0 size pointer

26.8.6 DSI_DSI_PKT_SEQ_2_HI_0

DSI Packet Sequence 2 HI Half

Offset: 0x28 | Byte Offset: 0xa0 | Read/Write: R/W | Reset: 0xXXXXXXXX (0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx0)

Bit	Reset	Description
29	X	PKT_25_EN: Packet 5 enable 0 = DISABLE 1 = ENABLE
28:23	X	PKT_25_ID: Packet 5 Packet ID
22:20	X	PKT_25_SIZE: Packet 5 size pointer
19	X	PKT_24_EN: Packet 4 enable 0 = DISABLE 1 = ENABLE
18:13	X	PKT_24_ID: Packet 4 Packet ID
12:10	X	PKT_24_SIZE: Packet 4 size pointer
9	X	PKT_23_EN: Packet 3 enable 0 = DISABLE 1 = ENABLE
8:3	X	PKT_23_ID: Packet 3 Packet ID
2:0	X	PKT_23_SIZE: Packet 3 size pointer

26.8.7 DSI_DSI_PKT_SEQ_3_LO_0

DSI Packet Sequence 3 LO Half

Line Type 3 is associated with any active line except the first one and should contain a packet sequence that starts with an HS packet and includes an RGB data packet.

Offset: 0x29 | Byte Offset: 0xa4 | Read/Write: R/W | Reset: 0xXXXXXXXX (0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx0)

Bit	Reset	Description
30	X	SEQ_3_FORCE_LP: For packet sequence 3, forces the D-PHY to go to LP mode after the last packet of the sequence has been transmitted. 0 = DISABLE 1 = ENABLE
29	X	PKT_32_EN: Packet 2 enable 0 = DISABLE 1 = ENABLE
28:23	X	PKT_32_ID: Packet 2 Packet ID
22:20	X	PKT_32_SIZE: Packet 2 size pointer
19	X	PKT_31_EN: Packet 1 enable 0 = DISABLE 1 = ENABLE
18:13	X	PKT_31_ID: Packet 1 Packet ID
12:10	X	PKT_31_SIZE: Packet 1 size pointer
9	X	PKT_30_EN: Packet 0 enable 0 = DISABLE 1 = ENABLE
8:3	X	PKT_30_ID: Packet 0 Packet ID
2:0	X	PKT_30_SIZE: Packet 0 size pointer

26.8.8 DSI_DSI_PKT_SEQ_3_HI_0

DSI Packet Sequence 3 HI Half

Offset: 0x2a | Byte Offset: 0xa8 | Read/Write: R/W | Reset: 0xXXXXXXXX (0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx0)

Bit	Reset	Description
29	X	PKT_35_EN: Packet 5 enable 0 = DISABLE 1 = ENABLE
28:23	X	PKT_35_ID: Packet 5 Packet ID
22:20	X	PKT_35_SIZE: Packet 5 size pointer
19	X	PKT_34_EN: Packet 4 enable 0 = DISABLE 1 = ENABLE
18:13	X	PKT_34_ID: Packet 4 Packet ID
12:10	X	PKT_34_SIZE: Packet 4 size pointer
9	X	PKT_33_EN: Packet 3 enable 0 = DISABLE 1 = ENABLE
8:3	X	PKT_33_ID: Packet 3 Packet ID
2:0	X	PKT_33_SIZE: Packet 3 size pointer

26.8.9 DSI_DSI_PKT_SEQ_4_LO_0

DSI Packet Sequence 4 LO Half

Line Type 4 is associated with the first vertical blanking line after the last active line and should contain a packet sequence that starts with an HS packet. Ordinarily, this packet sequence should be identical to sequence 2.

Offset: 0x2b | Byte Offset: 0xac | Read/Write: R/W | Reset: 0xXXXXXXXX (0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx0)

Bit	Reset	Description
30	X	SEQ_4_FORCE_LP: For packet sequence 4, forces the D-PHY to go to LP mode after the last packet of the sequence has been transmitted. 0 = DISABLE 1 = ENABLE
29	X	PKT_42_EN: Packet 2 enable 0 = DISABLE 1 = ENABLE
28:23	X	PKT_42_ID: Packet 2 Packet ID
22:20	X	PKT_42_SIZE: Packet 2 size pointer
19	X	PKT_41_EN: Packet 1 enable 0 = DISABLE 1 = ENABLE
18:13	X	PKT_41_ID: Packet 1 Packet ID
12:10	X	PKT_41_SIZE: Packet 1 size pointer
9	X	PKT_40_EN: Packet 0 enable 0 = DISABLE 1 = ENABLE
8:3	X	PKT_40_ID: Packet 0 Packet ID
2:0	X	PKT_40_SIZE: Packet 0 size pointer

26.8.10 DSI_DSI_PKT_SEQ_4_HI_0

DSI Packet Sequence 4 HI Half

Offset: 0x2c | Byte Offset: 0xb0 | Read/Write: R/W | Reset: 0xXXXXXXXX (0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx0)

Bit	Reset	Description
29	X	PKT_45_EN: Packet 5 enable 0 = DISABLE 1 = ENABLE
28:23	X	PKT_45_ID: Packet 5 Packet ID
22:20	X	PKT_45_SIZE: Packet 5 size pointer
19	X	PKT_44_EN: Packet 4 enable 0 = DISABLE 1 = ENABLE
18:13	X	PKT_44_ID: Packet 4 Packet ID
12:10	X	PKT_44_SIZE: Packet 4 size pointer
9	X	PKT_43_EN: Packet 3 enable 0 = DISABLE 1 = ENABLE
8:3	X	PKT_43_ID: Packet 3 Packet ID
2:0	X	PKT_43_SIZE: Packet 3 size pointer

26.8.11 DSI_DSI_PKT_SEQ_5_LO_0

DSI Packet Sequence 5 LO Half

Line Type 5 is associated with the first active line. It should contain a packet sequence that starts with an HS packet and includes an RGB data packet. Ordinarily, this packet sequence should be identical to sequence 3.

Offset: 0x2d | Byte Offset: 0xb4 | Read/Write: R/W | Reset: 0xXXXXXXXX (0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx0)

Bit	Reset	Description
30	X	SEQ_5_FORCE_LP: For packet sequence 5, forces the D-PHY to go to LP mode after the last packet of the sequence has been transmitted. 0 = DISABLE 1 = ENABLE
29	X	PKT_52_EN: Packet 2 enable 0 = DISABLE 1 = ENABLE
28:23	X	PKT_52_ID: Packet 2 Packet ID
22:20	X	PKT_52_SIZE: Packet 2 size pointer
19	X	PKT_51_EN: Packet 1 enable 0 = DISABLE 1 = ENABLE
18:13	X	PKT_51_ID: Packet 1 Packet ID
12:10	X	PKT_51_SIZE: Packet 1 size pointer
9	X	PKT_50_EN: Packet 0 enable 0 = DISABLE 1 = ENABLE
8:3	X	PKT_50_ID: Packet 0 Packet ID
2:0	X	PKT_50_SIZE: Packet 0 size pointer

26.8.12 DSI_DSI_PKT_SEQ_5_HI_0

DSI Packet Sequence 5 HI Half

Offset: 0x2e | Byte Offset: 0xb8 | Read/Write: R/W | Reset: 0xXXXXXXXX (0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx0)

Bit	Reset	Description
29	X	PKT_55_EN: Packet 5 enable 0 = DISABLE 1 = ENABLE
28:23	X	PKT_55_ID: Packet 5 Packet ID
22:20	X	PKT_55_SIZE: Packet 5 size pointer
19	X	PKT_54_EN: Packet 4 enable 0 = DISABLE 1 = ENABLE
18:13	X	PKT_54_ID: Packet 4 Packet ID
12:10	X	PKT_54_SIZE: Packet 4 size pointer
9	X	PKT_53_EN: Packet 3 enable 0 = DISABLE 1 = ENABLE
8:3	X	PKT_53_ID: Packet 3 Packet ID
2:0	X	PKT_53_SIZE: Packet 3 size pointer

26.9 DCS Command and Packet Length Registers

26.9.1 DSI_DSI_DCS_CMDS_0

DCS command IDs used for Line Types 3 and 5. These command IDs are inserted at the start of the data payload of DCS long packets when the Display Controller is being used to transmit DCS commands.

Offset: 0x33 | Byte Offset: 0xcc | Read/Write: R/W | Reset: 0xXXXXXXXX (0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx0)

Bit	Reset	Description
15:8	X	LT5_DCS_CMD: DCS command for Line Type 5.
7:0	X	LT3_DCS_CMD: DCS command for Line Type 3.

26.9.2 DSI_DSI_PKT_LEN_0_1_0

DSI Packet Lengths 0 and 1

Offset: 0x34 | Byte Offset: 0xd0 | Read/Write: R/W | Reset: 0xXXXXXXXX (0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx)

Bit	Reset	Description
31:16	X	LENGTH_1: Packet length 1 (in bytes)
15:0	X	LENGTH_0: Packet length 0 (in bytes)

26.9.3 DSI_DSI_PKT_LEN_2_3_0

DSI Packet Lengths 2 and 3

Offset: 0x35 | Byte Offset: 0xd4 | Read/Write: R/W | Reset: 0xXXXXXXXX (0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx)

Bit	Reset	Description
31:16	X	LENGTH_3: Packet length 3 (in bytes)
15:0	X	LENGTH_2: Packet length 2 (in bytes)

26.9.4 DSI_DSI_PKT_LEN_4_5_0

DSI Packet Lengths 4 and 5

Offset: 0x36 | Byte Offset: 0xd8 | Read/Write: R/W | Reset: 0xXXXXXXXX (0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx)

Bit	Reset	Description
31:16	X	LENGTH_5: Packet length 5 (in bytes)
15:0	X	LENGTH_4: Packet length 4 (in bytes)

26.9.5 DSI_DSI_PKT_LEN_6_7_0

DSI Packet Lengths 6 and 7

Offset: 0x37 | Byte Offset: 0xdc | Read/Write: R/W | Reset: 0xXXXXXXXX (0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx)

Bit	Reset	Description
31:16	X	LENGTH_7: Packet length 7 (in bytes)
15:0	X	LENGTH_6: Packet length 6 (in bytes)

26.10 Physical Interface Timing Registers

The DSI PHY timing registers must be initialized before the interface is enabled. Based on the equations provided in the table below, all PHY timing parameters should be programmed in the timing registers. T_{byte} refers to just the DSI controller clock.

Table 161: D-PHY Timing Values

Parameter	MIPI D-PHY Spec Value	Programmed Value
THS-PREPARE	(40 ns + 4*UI , 85 ns + 6*UI)	Min - (40 + (4 T_{bit}))) / T_{byte} Max - ((85 + 6 T_{bit})) / T_{byte}
THS-ZERO	105 ns + 6*UI min.	(105 + (6 T_{bit})) / T_{byte} -2
THS-TRAIL	max(8*UI, 60 ns + 4*UI)	3 + max(8 T_{bit}, 60 + 4 T_{bit}) / T_{byte}
THS-EXIT	100 ns min.	100 / T_{byte}
TLPX	50 ns min.	50 / T_{byte}
TCLK-ZERO	300 ns along with TCLK-PREPARE	260/ T_{byte}
TCLK-PREPARE	(38 ns, 95 ns)	THS-PREPARE timing should guarantee to meet both these timing requirements
TCLK-POST	60 ns + 52*UI min.	(60 + (52 T_{bit})) / T_{byte} - 2
TCLK-TRAIL	60 ns min.	60 / T_{byte}
TCLK-PRE	8 UI	8 T_{bit}
TTA-GO	4 * TLPX	3 * TLPX
TTA-SURE	(TLPX, 2 * TLPX)	TLPX - 1
TTA-GET	5 * TLPX	4 * TLPX
TWAKEUP	1 ms	1 ms/10 ns x 512 {in terms of 512 byte clocks}

Notes:

- T_{byte} = Period of one byte clock in nanoseconds.
- T_{bit} = Period of one bit time in nanoseconds. (T_{bit} = T_{byte} / 8)
- All figures and time periods are in nanoseconds.
- All timing register values are multiples of byte clock period, T_{byte}.
- All fractional results are truncated. No rounding.

26.10.1 DSI_DSI_PHY_TIMING_0_0

DSI D-PHY Timing Register 0

Offset: 0x3c | Byte Offset: 0xf0 | Read/Write: R/W | Reset: 0xXXXXXXXX (0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx)

Bit	Reset	Description
31:24	X	DSI_THSDEXIT: Time to drive LP11 after HS **Note:** Valid programmable values for all the fields in this register (i.e., DSI_THSPREPR/ DSI_TDATZERO/DSI_THSTRAIL/DSI_THSDEXIT) are 0 to 254. Invalid value is 255.
23:16	X	DSI_THSTRAIL: Time to drive HS flipped bit at EOT
15:8	X	DSI_TDATZERO: Time to drive HS0 before SOT
7:0	X	DSI_THSPREPR: Time to drive LP00 before HS data

26.10.2 DSI_DSI_PHY_TIMING_1_0

DSI D-PHY Timing Register 1

Offset: 0x3d | Byte Offset: 0xf4 | Read/Write: R/W | Reset: 0xXXXXXXXX (0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx)

Bit	Reset	Description
31:24	X	DSI_TCLKTRAIL: Time to drive HS0 before the clock goes to LP1 **Note:** Valid programmable values for all the fields in this register (i.e., DSI_TTLPX/ DSI_TCLKZERO/DSI_TCLKPOST/ DSI_TCLKTRAIL) are 0 to 254 Invalid value is 255.
23:16	X	DSI_TCLKPOST: Time to drive clock after the last HS data
15:8	X	DSI_TCLKZERO: Time to drive LP00 before HS clock
7:0	X	DSI_TTLPX: LP period

26.10.3 DSI_DSI_PHY_TIMING_2_0

DSI D-PHY Timing Register 2

Offset: 0x3e | Byte Offset: 0xf8 | Read/Write: R/W | Reset: 0xXXXXXXXX (0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx0)

Bit	Reset	Description
23:16	X	DSI_TCLKPREPARE: Time to drive LP0 before CLK_ZERO starts off on the clock lane. **Note:** Valid programmable values for the following register fields (i.e., DSI_TCLKPRE/ DSI_TCLKPREPARE) are 0 to 254. Invalid value is 255
15:8	X	DSI_TCLKPRE: Time to run clock before enabling data lane
7:0	X	DSI_TWAKEUP: LP period when exiting ULPM, in units of 512 byte clocks.

26.10.4 DSI_DSI_BTA_TIMING_0

DSI D-PHY Bus-Turn-Around Timing

Offset: 0x3f | Byte Offset: 0xfc | Read/Write: R/W | Reset: 0xXXXXXXXX (0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx)

Bit	Reset	Description
31:24	X	DSI_TPKTBTA: Programmable Time delay between end of Host packet transmission and generation of Pkt BTA in PKT_BTA mode (i.e., HOST_DSI_CONTROL[2]) - Generate BTA at the end of Host packets **Note**: Valid programmable values for all the fields in this register (i.e., DSI_TTAGO/ DSI_TTASURE/DSI_TTAGET/ DSI_TPKTBTA) are 0 to 254. Invalid value is 255.
23:16	X	DSI_TTAGET: Time to Drive LP00 at end of BTA (5 * TTLPX)
15:8	X	DSI_TTASURE: Time to Receive LP00 at end of BTA (2 * TTLPX)
7:0	X	DSI_TTAGO: Time to drive LP00 at start of BTA (4 * TTLPX)

26.11 Contention Recovery Timers

These registers control the length of time - in units of 512 DSI byte clocks – that can elapse before the hardware will decide that a bus contention error has occurred.

There are several counters to deal with various forms of error that may occur. For details, refer to the MIPI DSI Specification, Section 7.2.2.

26.11.1 DSI_DSI_TIMEOUT_0_0

DSI Time Out Terminal Count Register 0

Offset: 0x44 | Byte Offset: 0x110 | Read/Write: R/W | Reset: 0xXXXXXXXX (0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx)

Bit	Reset	Description
31:16	X	LRXH_TO: Low Power Receive (Host) Time Out terminal count
15:0	X	HTX_TO: High Speed Transmit Time Out terminal count

26.11.2 DSI_DSI_TIMEOUT_1_0

DSI Time Out Terminal Count Register 1

Offset: 0x45 | Byte Offset: 0x114 | Read/Write: R/W | Reset: 0xXXXXXXXX (0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx)

Bit	Reset	Description
31:16	X	PR_TO: Peripheral Reset duration.
15:0	X	TA_TO: Turn Around Time Out terminal count

26.11.3 DSI_DSI_TO_TALLY_0

DSI Time Out Tally Register

Each time one of the time-out counters reaches its terminal count, it will increment the associated tally register.

Offset: 0x46 | Byte Offset: 0x118 | Read/Write: R/W | Reset: 0xXXXXXXXX (0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx0)

Bit	R/W	Reset	Description
24	RO	X	P_RESET_STATUS: Peripheral Reset time out status 0 = IN_RESET 1 = READY
23:16	RW	X	TA_TALLY: Turn Around time out tally
15:8	RW	X	LRXH_TALLY: LP Rx time out tally
7:0	RW	X	HTX_TALLY: HS Tx time out tally

26.12 Physical Pad Control Registers

26.12.1 DSI_PAD_CONTROL_0

DSI PHY Configuration Register

Software can program this register to work with different panels.

Offset: 0x4b | Byte Offset: 0x12c | Read/Write: R/W | Reset: 0x010f010f (0bxxxxxxx1xxxx1111xxxxxxx1xxxx1111)

Bit	Reset	Description
24	0x1	DSI_PAD_PULLDN_CLK_ENAB:1= Enable pad pulldown for clock bit at power on
19:16	0xf	DSI_PAD_PULLDN_ENAB:1= Enable pad pulldown for data bits at power on
8	0x1	DSI_PAD_PDIO_CLK: Power down for clock bit, drivers, receivers, and contention detectors
3:0	0xf	DSI_PAD_PDIO: Power down for data bit, drivers, receivers, and contention detectors

26.12.2 DSI_PAD_CONTROL_CD_0

Contention Detection Logic Enable Signals

Offset: 0x4c | Byte Offset: 0x130 | Read/Write: R/W | Reset: 0x00000000 (0bxxxxxxxxxxxxxx000xxxxxxx0xxxx0000)

Bit	Reset	Description
18:16	0x0	DSI_PAD_CDDNADJ: Level adjust on low limit of detection. Tie to 0 (DSI emu, miniTMC control). 000 = 0.3V 001 = 0.375V 010 = 0.45V 011 = 0.525V 100 = 0.3V 101 = 0.225V 110 = 0.15V 111 = 0.075V
8	0x0	DSI_PAD_CD_EN_CLK: Clock bit contention detector enable. 1 = Enable
3:0	0x0	DSI_PAD_CD_EN: Data bits contention detector enable. 1 = EnableCD_EN_[1] = 0 in DSI.

26.12.3 DSI_PAD_CD_STATUS_0

Contention Detection Status from MIPI PAD

Offset: 0x4d | Byte Offset: 0x134 | Read/Write: RO | Reset: 0x000X0X0X (0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx)

Bit	Reset	Description
18	X	DSI_PAD_CDN_CLK
16	X	DSI_PAD_CDP_CLK
11:8	X	DSI_PAD_CDN
3:0	X	DSI_PAD_CDP

26.12.4 DSI_DSI_VID_MODE_CONTROL_0

Host Command Packet During Video Mode

Offset: 0x4e | Byte Offset: 0x138 | Read/Write: R/W | Reset: 0x00000000 (0bxxxxxxxxxxxxxxxxxxxxxxxxxxxx0000)

Bit	Reset	Description
3:1	0x0	DSI_LINE_TYPE: Vertical blank. LINE TYPE on which the host command packet is to be transmitted, i.e., valid values are 0/1/2/4 0 = ZERO: Line type 0 1 = ONE: Line type 1 2 = TWO: Line type 2 3 = THREE: NA: Host command packets on line type 3 are invalid 4 = FOUR: Line type 4 5 = FIVE: NA: Host command packets on line type 5 are invalid 6 = SIX: NA: Host command packets on line type 6 are invalid 7 = SEVEN: NA: Host command packets on line type 7 are invalid
0	0x0	DSI_CMD_PKT_VID_ENABLE: 0 = DISABLE: Disable host command packet during video mode 1 = ENABLE: Enable host command packet during video mode

26.12.5 DSI_PAD_CONTROL_1_0

DSI PHY Configuration Register

Software can program this register to work with different panels.

Offset: 0x4f | Byte Offset: 0x13c | Read/Write: R/W | Reset: 0x00000000 (0bxxxxxxxxxxxxxxxxxx000x000x000x000)

Bit	Reset	Description
14:12	0x0	DSI_PAD_OUTADJ3: Input delay trimmer for data bit 3. Each tap delays 40 ps

Bit	Reset	Description
10:8	0x0	DSI_PAD_OUTADJ2: Input delay trimmer for data bit 2. Each tap delays 40 ps
6:4	0x0	DSI_PAD_OUTADJ1: Input delay trimmer for data bit 1. Each tap delays 40 ps
2:0	0x0	DSI_PAD_OUTADJ0: Input delay trimmer for data bit 0.Each tap delays 40 ps

26.12.6 DSI_PAD_CONTROL_2_0

DSI PHY Configuration Register

Software can program this register to work with different panels.

Offset: 0x50 | Byte Offset: 0x140 | Read/Write: R/W | Reset: 0x00000000 (0bxxxxxxxxxxxxx000x000x000x000x000)

Bit	Reset	Description
18:16	0x0	DSI_PAD_SLEWUPADJ: Pull-up slew rate adjust. 000 = 011: slew rate increases 100 = 000, 100 =111: skew rate decreases
14:12	0x0	DSI_PAD_SLEWDNADJ: Pull-down slew rate adjust. 000 = 011, slew rate increases 100 = 000, 100 = 111: skew rate decreases.
10:8	0x0	DSI_PAD_LPUPADJ: Driver pull-up impedance control. 00 = 130 ohms, default, 01 = 110 ohms 10 = 130 ohms 11 = 150 ohms
6:4	0x0	DSI_PAD_LPDNADJ: Driver pull-down impedance control. 00 = 130 ohms, default 01 = 110 ohms 10 = 130 ohms, same as 0 011 = 150 ohms
2:0	0x0	DSI_PAD_OUTADJCLK: Output trimmer delay for clock bit. Each tap delays 40 ps

26.12.7 DSI_PAD_CONTROL_3_0

DSI PHY Configuration Register

Software can program this register to work with different panels.

Offset: 0x51 | Byte Offset: 0x144 | Read/Write: R/W | Reset: 0x10000000 (0bxxx1xxxxxxxxxxx0xx00xx00xx00xx00)

Bit	Reset	Description
28	0x1	DSI_PAD_PDVCLAMP: Power down regulator which supplies current to serializer/ deserializer logic. Active high, 1=power down
16	0x0	DSI_PAD_BANDWD_IN: Increase bandwidth of differential receiver
13:12	0x0	DSI_PAD_PREEMP_PD_CLK: Clock bit HS driver pull down pre-emphasis. 00 = no_preemphasis 11= max
9:8	0x0	DSI_PAD_PREEMP_PU_CLK: Clock bit HS driver pull up pre-emphasis. 00 = no_preemphasis 11= max
5:4	0x0	DSI_PAD_PREEMP_PD: Data bit HS driver pull down pre-emphasis. 00 = no_preemphasis 11= max
1:0	0x0	DSI_PAD_PREEMP_PU: Data bit HS driver pull up pre-emphasis. 00 = no_preemphasis 11= max

26.12.8 DSI_PAD_CONTROL_4_0

DSI PHY Configuration Register

Software can program this register to work with different panels.

Offset: 0x52 | Byte Offset: 0x148 | Read/Write: R/W | Reset: 0x00000000 (0bxxx0xxxx0000xxx0xxxx0000xxx0xxx0)

Bit	Reset	Description
28	0x0	DSI_PAD_HS_BSO_CLK:1= Enables BIAS and power regulators on for HS mode

26.12.22 DSI_DUMMY_PIX_CNT_0

Offset: 0x60 | Byte Offset: 0x180 | Read/Write: R/W | Reset: 0x00XX00XX (0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx)

Bit	Reset	Description
23:16	X	RIGHT_DUMMY_PIX_CNT: Number of dummy pixels padded to the right of the active pixel stream i.e., [Min,Max] = [0,252] 0-> 1 pixels 251->252 pixels
7:0	X	LEFT_DUMMY_PIX_CNT: Number of dummy pixels padded to the left of the active pixel stream i.e., [Min,Max] = [0,252] 0-> 1 pixels 251->252 pixels

26.12.23 DSI_DSI_DSC_CONTROL_0

Note: *This feature is not supported.*

Display stream compression control register

Offset: 0x61 | Byte Offset: 0x184 | Read/Write: R/W | Reset: 0x00000300 (0bxxxxxxxxxxxxxxx00xxxx0011000000x0)

Bit	Reset	Description
17:16	0x0	NUM_COMPRESS_PKTS_PER_ROW: Number of compressed image packets per row between two sync events. Multiple packets option is for Video mode only. Always program ONE packet for Command mode. 0 = ONE: 1 compressed image packet for one slice per row 1 = TWO: 2 compressed image packets for two slices per row 2 = THREE: Reserved 3 = FOUR: 4 compressed image packets for four slices per row
11:2	0xc0	COMPRESS_RATE: Compression bit rate. Only 8/12/16 bpp compression rates are supported. Remaining values in this bit field are reserved. 128 = BPP_8 192 = BPP_12 256 = BPP_16
0	0x0	COMPRESS_MODE_EN: Enables compressed bitstream transport mode 0 = DISABLE: compression mode disabled 1 = ENABLE: compression mode enabled

CHAPTER 27: DISPLAY INTERFACES: HDMI AND DISPLAYPORT

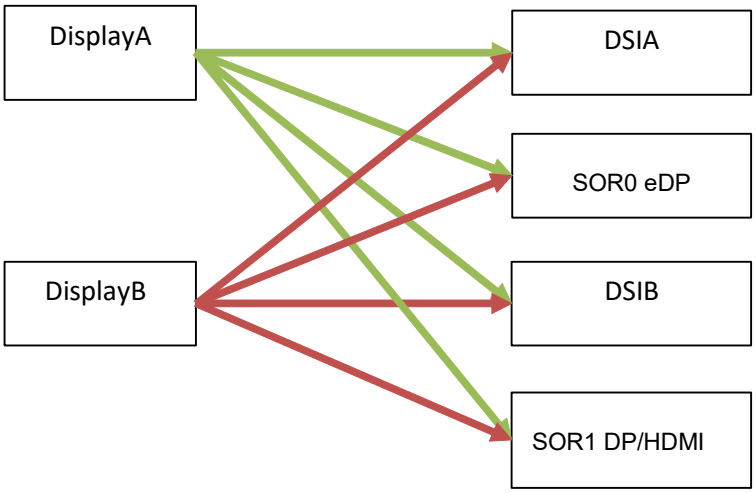
27.1 Overview

The Tegra X1 processor has two display serial output resources (SORs), which act as display interfaces: SOR0 and SOR1. They collect pixels from the output of a display pipeline, format/encode them to desired format, and then stream the data to various output devices. The SOR consists of several individual resources which can be used to interface with different display devices such as HDMI or DP. Each SOR can drive only a single device at any given time and can be connected to either display controller (Head).

SOR0 is for internal panels (no audio), and SOR1 is for either internal or external panels.

The Tegra X1 processor also has two MIPI-DSI interfaces, which support up to 2 x 4-lane mode. Refer to the Chapter 26: Display Interfaces: MIPI-DSI in this TRM for more information.

Figure 113: Output Connections



27.2 Features

SOR0 supports internal panels only, using eDP. Its features include:

- 1/2/4 lane eDP (eDP 1.4)
- Supports frame packed 3D stereo mode (not frame-sequential mode like dGPU)
- Supports generic infoframe
- ASSR copy protection
- 24-bit RGB pixel format only
- Supports up to HBR2 per DP 1.2 specification
- Supports eDP 1.4 features:
  - additional link rates (2.16, 2.43, 3.24, 4.32 Gbps)
  - enhanced framing
  - power sequencing
  - reduced auxiliary timing

- reduced main voltage swing

SOR1 supports DP and HDMI as well as eDP. Its features include:

- 1/2/4 lane DP (DP1.2) and eDP (eDP 1.4)
- HDMI 2.0, up to 594 MHz pixel clock
- HDCP 2.2 and 1.3 over either HDMI or DP
- ASSR (alternate seed scrambler reset) for internal eDP panels
- On HDMI, multichannel audio from HDA controller, up to 8 channels, 192 kHz, 24-bit.
- Supports frame-packed 3D stereo mode (not frame-sequential mode like dGPU)
- Supports generic infoframe transmission
- Supports HDMI Vendor Specific Infoframe (VSI) packet transmission
- Supports up to HBR2 link rate, per DP 1.2 specification
- Supports fuse calibration information for HDMI analog parameter(s)
- 24-bit RGB and 24-bit YUV444 (HDMI) pixel formats (YUV444 is mostly for 1080i support)
- 1080i output on HDMI (mostly implemented in the display controller)
- Supports DP or HDMI connectors via appropriate external level shifting
- Supports external Dual Mode standard (DP2HDMI passive or active adapters and adapter discovery)
- Supports eDP 1.4 features:
  - additional link rates (2.16, 2.43, 3.24, 4.32 Gbps)
  - enhanced framing
  - power sequencing
  - reduced auxiliary timing
  - reduced main voltage swing

27.3 eDP

The Tegra® X1 eDP block is a display output controller, supporting Embedded DisplayPort (eDP). It drives local panels only and does not support an external DP port. The eDP block has a pixel bus as an input from the display pipe of each head. It also has a small test pattern generator and formatter to encode pixels for specific output devices, a CRC generator, and a bundle interface to the display software interface.

The eDP block collects pixels from the output of the display pipeline, formats/encodes them to the eDP format, and then streams them to various output devices. The eDP block consists of individual resources that can interface with different display devices.

27.3.1 Features

These features are supported in the eDP block:

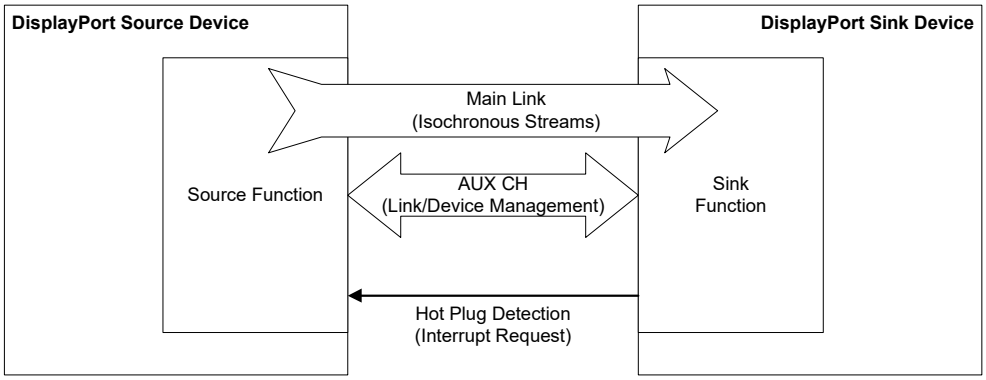
- eDP 1.4
  - 1/2/4 lanes, single link
  - RBR/HBR/HBR2
  - 18/24 bits color depth
  - Up to 540 MHz
  - Internal panel:

    - 4096 x 2160 @ 60Hz (2D – portrait/landscape)
    - 1920 x 1080 @ 60Hz (3D – portrait/landscape)
  - -0.5% down spread support
- Stereo mode
- Generic infoframe
- Supports DP AUX and HPD
- Single PHY to output eDP
  - 4-lane eDP
  - Supports 5.4 GHz eDP

27.3.2 DisplayPort Overview

The DisplayPort link consists of Main Link, Auxiliary Channel (AUX CH), and Hot Plug Detect (HPD) channels. Main Link is a unidirectional, high-bandwidth, and low-latency channel used for transport of isochronous streams such as uncompressed video and audio. Auxiliary Channel is a half-duplex, bidirectional channel used for link management and device control. The HPD signal serves as an interrupt request by the sink device. Main Link consists of AC-coupled, doubly terminated differential pairs (called lanes). Three link rates are supported: 5.4 Gbps, 2.7 Gbps, and 1.62 Gbps per lane. The Main Link supports 1, 2, or 4 lanes.

Figure 114: DisplayPort Link



27.4 HDMI

- HARDWARE_N feature enabled
- TMDS I/O macro with controls
- Interlaced video format support
- YUV444 output (BT.601 and BT.709 formats)
- HDMI in power-gated partition SOR
- Output range scaling for RGB
- Vendor-specific infoframe supported
- Audio features for HD audio include:
  - 2, 6, or 8 channels of LPCM (i.e., uncompressed linear PCM)
  - 16, 20, or 24 bits per sample
  - 32, 44.1, 48, 88.2, 96, 176.4, 192 K samples/second

27.5 HDCP

HDCP requires the presence of a correctly programmed KFUSE. Two main sequences are downstream authentication and upstream authentication. Downstream authentication permits encryption of the HDMI output, and involves a handshake between the HDMI module and the display device. Upstream authentication is more of a software convention between the application and HDMI driver, although the HDMI module does perform KFUSE operations to assist.

Communication with the downstream receiver uses DDC, which requires I^2C.

27.5.1 HDCP KFUSE Key Copying

HDCP keys are stored encrypted in the KFUSE module. Before starting HDCP, software must copy the keys (576 bytes) from the KFUSE to the HDMI registers.

Note: *KFUSE is just for HDCP 1.x. HDCP 2.0 does not use KFUSE.*

1. To enable use of KFUSE keys, set SOR_NV_PDISP_KEY_CTRL.LOCAL_KEYS = ENABLED.
2. Bring the KFUSE module out of reset and enable the clock, if not already enabled. This can be before or after HDMI is out of reset.
3. Wait for the KFUSE to read the keys from the fuse to its SRAM and perform error correction and CRC checking:
   a. Poll for KFUSE.STATE.DONE == 1
   b. Check KFUSE.STATE.CRCPASS == 1
   c. Check that SOR_NV_PDISP_KEY_CTRL.PKEY_LOADED == TRUE
4. Prepare to copy:
   a. KFUSE.KEYADDR.ADDR = 0
   b. KFUSE.KEYADDR.AUTOINC = 1
5. For each line in 0 .. 35 # 576 bytes = 144 words / 4 words-per-line = 36 lines
   a. For each word in 0..3:

      data[word] = KFUSE.KEYS # auto-increments read address
   b. SOR_NV_PDISP_KEY_HDCP_KEY_0 = data[0]
   c. SOR_NV_PDISP_KEY_HDCP_KEY_1 = data[1]
   d. SOR_NV_PDISP_KEY_HDCP_KEY_2 = data[2]
   e. SOR_NV_PDISP_KEY_HDCP_KEY_3 = data[3]
   f. SOR_NV_PDISP_KEY_HDCP_KEY_TRIG.LOAD_HDCP_KEY = TRIGGER # trigger decryption of 16 bytes
   g. If line == 0: SOR_NV_PDISP_KEY_CTRL.AUTOINC = DISABLED. Else:
      SOR_NV_PDISP_KEY_CTRL.AUTOINC = ENABLED
   h. SOR_NV_PDISP_KEY_CTRL.WRITE16 = TRIGGER # wait for decrypt, and copy decrypted 16 bytes to the local key store.
   i. Poll for SOR_NV_PDISP_KEY_CTRL.WRITE16 == DONE
6. Write SOR_NV_PDISP_KEY_SKEY_INDEX.IDX_VALUE with the AES key selector that was used to encrypt the keyglob data. This is currently fixed at 0.

27.5.2 Downstream Authentication

Note: *For register names containing "DP/TMDS", use DP in DP-HDCP mode and TMDS in HDMI-HDCP mode.*

This can be done before enabling transmission.

1. Set SOR_NV_PDISP_SOR_DP/TMDS_HDCP_CTRL.ONEONE = ENABLE. SOR_NV_PDISP_SOR_DP/TMDS_HDCP_CTRL.RUN = YES. Causes the RTL to access HDCP keys and compute AN and other parameters.
2. Poll for SOR_NV_PDISP_SOR_DP/TMDS_HDCP_CTRL.AN = VALID
3. Read Aksv from SOR_NV_PDISP_SOR_DP/TMDS_HDCP_AKSV_LSB/MSB and check validity (exactly 20 of 40 bits = 1). If invalid, the KFUSE might be blank.
4. Read Bksv from the receiver (via I2C), check validity (20 high bits), and write it into SOR_NV_PDISP_SOR_DP/TMDS_HDCP_BKSV_LSB/MSB.
5. Read AN from SOR_NV_PDISP_SOR_DP/TMDS_HDCP_AN_LSB/MSB, and write to the receiver via I^2C.
6. Read Aksv from SOR_NV_PDISP_SOR_DP/TMDS_HDCP_AKSV_LSB/MSB, check validity (20 high bits), and write to receiver via I^2C.
7. Poll for SOR_NV_PDISP_SOR_DP/TMDS_HDCP_CTRL.R0 = VALID
8. Read SOR_NV_PDISP_SOR_DP/TMDS_HDCP_RI and compare with the receiver's RI. They should match.

If the above procedure is successful, then SOR_NV_PDISP_SOR_DP/TMDS_HDCP_CTRL.CRYPT can be set to ENABLE.

To verify that encryption is enabled, check that SOR_NV_PDISP_SOR_DP/TMDS_HDCP_CTRL.RUN == YES.

27.5.3 Upstream Authentication

The HDMI module does not do the protocol itself. Rather, it provides primitives that software can use. These primitives access HDCP keys and status, and compute values.

Typically, downstream authentication has been completed before doing the upstream.

The "Upstream Setup" sequence is:

1. Set SOR_NV_PDISP_SOR_TMDS_HDCP_CMODE.MODE = READ_S
2. Poll for SOR_NV_PDISP_SOR_DP/TMDS_HDCP_CTRL.SPRIME = INVALID
3. Program SOR_NV_PDISP_SOR_TMDS_HDCP_CN_LSB/MSB and SOR_NV_PDISP_SOR_TMDS_HDCP_CKSV_LSB/MSB with Cn and Cksv. NOTE: CKSV_MSB must be last since it is a trigger.
4. Poll for SOR_NV_PDISP_SOR_DP/TMDS_HDCP_CTRL.SPRIME = VALID
5. Read Dksv from SOR_NV_PDISP_SOR_TMDS_HDCP_DKSV_LSB/MSB and verify validity
6. Read Cs from SOR_NV_PDISP_SOR_TMDS_HDCP_CS_LSB/MSB
7. Read S' from SOR_NV_PDISP_SOR_TMDS_HDCP_SPRIME_LSB1/LSB2/MSB

Software uses these read values to perform the authentication handshake with application software.

The "Upstream M" sequence is:

1. Set SOR_NV_PDISP_SOR_TMDS_HDCP_CMODE.MODE = READ_M.
2. Poll for SOR_NV_PDISP_SOR_DP/TMDS_HDCP_CTRL.MPRIME = INVALID.
3. Program SOR_NV_PDISP_SOR_TMDS_HDCP_CN_LSB/MSB and SOR_NV_PDISP_SOR_TMDS_HDCP_CKSV_LSB/MSB with Cn and Cksv. NOTE: CKSV_MSB must be last since it is a trigger.
4. Poll for SOR_NV_PDISP_SOR_DP/TMDS_HDCP_CTRL.MPRIME = VALID.
5. Read Dksv from SOR_NV_PDISP_SOR_TMDS_HDCP_DKSV_LSB/MSB and verify validity.
6. Read M' from SOR_NV_PDISP_SOR_TMDS_HDCP_MPRIME_LSB/MSB.

27.6 SOR Clocking

PLLDP used for eDP and DP link clock supports spread-spectrum.

PLLD2, used for the HDMI link and pixel clocks and the DP pixel clock, supports fractional-N for fine frequency control. The Fractional-N can be changed glitchlessly on the fly.

MAUD_CLK and HDA2CODEC_2X_CLK are used for audio and must remain synchronous; they can be driven from either PLLP or PLLA. PLLA allows fine frequency control (Fractional-N) to allow software to match the audio sample rate to an external broadcast stream.

I/O Cell/Pad clock input is selectable and depends on the protocol that is selected for output. For TMDS, this clock is equal to pclk, and for DP it is equal to 270 MHz PLLDP.

For both DP and TMDS, it is required to use the feedback clock from the macro for the digital logic. A glitchless 2:1 MUX needs to be added; one input is the feedback clock from the macro and is a fixed “safe” clock that is guaranteed to be running.

The feedback clock is needed because:

- For eDP/DP, the macro generates the clock that needs to be used by the SOR
- For TMDS, the PLL output and the macro clock might not be aligned in phase and requires “LOADADJ” calibration
- For some modes, the macro reference clock should be different from the pixel clock, for better performance

The following software programming sequence is recommended for clocks:

- Program the MUX to a safe clock
- Program/enable the PLLD2 or PLLDP reference PLL
- Program various macro registers to bring up the macro clock based on eDP/DP or TMDS mode. All of the macro registers are in the SOR.
- Program the MUX select to SOR clock.
- Program the rest of display to connect to the SOR.

27.6.1 DP Mode

The frequency of the SOR clock depends on the protocol, link training, pixel depth, and pixel replication. For DP, the SOR clock is generated in the SOR analog macro. The analog macro uses a 270 MHz differential reference clock from PLLDP. The macro multiplies this clock by 6, 10, or 20 to produce 1.62 GHz, 2.7 GHz, or 5.4 GHz link clock, respectively. The link clock is divided by 10 to produce the low speed SOR clock of 162 MHz, 270 MHz, or 540 MHz. The link clock frequency is chosen based on the bandwidth requirements of the stream, as described below.

The DP link can operate in 1, 2, or 4 lane mode and from 1.62 GHz to 5.4 GHz. In order to calculate the available bandwidth on the DP link, use the following equation:

```
Available Bandwidth = Link Rate/10 * bits per clock * number of lanes * 0.995
```

Link Rate/10 is the speed at which the SOR runs while in DP mode (for corner cases, you may need to account for spread). bits_per_clock is always 8. The number of lanes is 1, 2, or 4. In order to calculate the amount of bandwidth needed for a resolution, use the following equation:

```
Required Bandwidth = pixel clock * bits per pixel
```

If the Required Bandwidth is less than the Available Bandwidth, then that resolution can be supported at that link configuration. For example:

- 3840x2400x24bpp @60 Hz, 592.5 MHz pclk
  4 Lanes, 5.4 GHz

```
Available Bandwidth = 5400 MHz / 10 * 8 * 4 * 0.995 = 17193.6 Mbps
Required Bandwidth = 592.5 * 24 = 14220 Mbps
```

This resolution is supported at this link rate.

- 4096x2560x24bpp @60 Hz, 672.0 MHz pclk
  4 Lanes, 5.4 GHz

```
Available Bandwidth = 5400 MHz / 10 * 8 * 4 * 0.995 = 17193.6 Mbps
Required Bandwidth = 672 * 24 = 16128 Mbps
```

This resolution is supported at this link rate.

27.6.2 TMDS Mode

For single link TMDS (DVI/HDMI), the SOR clock and link clock are equal to the pixel clock frequency, because Tegra X1 does not support deep color or pixel replication. The I/O Cell generates the SOR clock by multiplying its pixel clock reference by 10 or 20, then dividing by 10.

27.6.3 Link Training

Link training can cause the link speed or lane count to change. Whenever OR clocks are changed, the Display Controller needs to be disconnected from the OR so that the OR pipeline can go idle. Changing the clocks while the OR pipeline is actively encoding pixels can leave the pipe in an unknown state. There are also many DP parameters that are dependent on the link rate, so if the link rate is changed on the fly, it could cause FIFO overflows/underflows and possibly hangs.

27.6.4 M_VID

In DP mode, the SOR1 must derive the ratio of link clock and pixel clock, so that the DP receiver can recover the pixel clock.

Each display head sends a version of its pixel clock to the SOR, used to transfer pixel data: display2sor1_clk, displayb2sor1_clk.

The M_VID ratio is derived separately for each display head. Then the correct head value is muxed along with the head's pixel data.

27.6.5 Audio Timestamp

In DP mode, the SOR1 must derive the ratio of link clock to audio sample clock. In Tegra X1 devices, the SOR logic uses a fixed 102 MHz clock called MAUD_CLK for this; derived from the same PLL as HDA2CODEC_2X clock uses. The 102 MHz MAUD_CLK must track the 48 MHz HDA2CODEC_2X_CLK (and thus the actual sample rate) and maintain the exact 2.125 ratio. That implies using the same PLL source (PLLP or possibly PLLA) for both.

Software programs N and D values to generate a 512*fs clock from the fixed 102 MHz clock:

512*fs / 102 = N/D

For 48 KHz, 512*48000/102000000 = 512/2125.

Thus, every 102 * 512/2125 MHz, the 512*fs counter increments. Every Naud=2^15 link clocks, the counter value is latched, giving Maud.

The following table shows the nominal N/D values for supported audio frequencies:

Table 162: MAUD N/D

Maudclk Freq	48 kHz		96 kHz		192 kHz		44.1 kHz		88.2 kHz		176.4 kHz	
	N	D	N	D	N	D	N	D	N	D	N	D
102 MHz	512	2125	1024	2125	2048	2125	2352	10625	4704	10625	9408	10625

The audio sample rate (and thus MAUD_CLK) need not be a fixed synchronous ratio to the link clock; this would be the case in spread-spectrum or frequency-hopping link clock, or when audio PLL uses fractional-N to lock to external source. In such cases, the Maud will vary from the nominal value. For example, if link clock slows down 0.5%, the computed Maud will increase by 0.5 %. If audio PLL slows down by 0.1% for 48 * 1000/1001 KHz sampling, the computed Maud will decrease by 0.1%.

27.6.6 SOR Clock Switch

The SOR clock should be disabled while doing SOR clock switching.

For SOR0:

- CLK_RST_CONTROLLER.CLK_OUT_ENB_X.CLK_ENB_SOR0 = DISABLE
- CLK_RST_CONTROLLER.CLK_SOURCE_SOR0.SOR0_CLK_SEL1 = …
- CLK_RST_CONTROLLER,CLK_SOURCE_SOR0.SOR0_CLK_SEL0 = …
- CLK_RST_CONTROLLER.CLK_OUT_ENB_X.CLK_ENB_SOR0 = ENABLE

SOR1 has similar settings.

27.7 Programming Guidelines

This subsection provides SOR programming guidance for software. It covers the following topics:

- The programming sequence for SOR start: attaching and powering up SOR (eDP/DP and HDMI)
- The programming sequence for SOR stop: detaching and powering down SOR (eDP/DP and HDMI)
- The programming requirements for display standard raster timing used in SOR

27.7.1 DP Mode

For eDP/DP without audio, programming is the same between SOR0 and SOR1. All the programming below refers to SOR. The same is applicable to SOR1 and the DPAUX modules as well. Controls in CAR and Display Controllers are mentioned explicitly.

Controls in Display

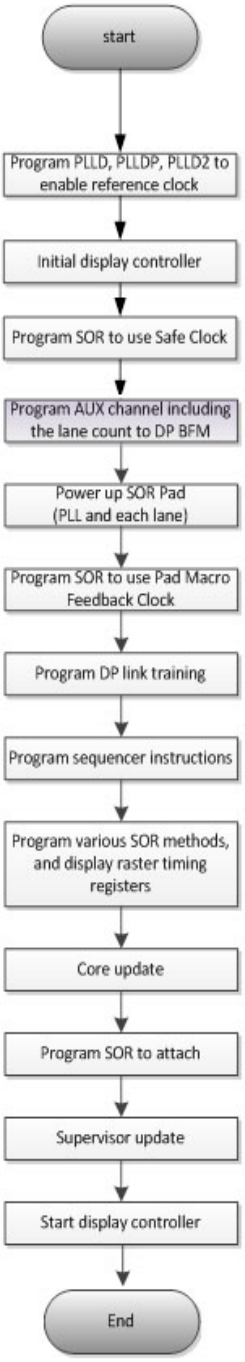
```
DISP_WIN_OPTIONS.SOR_ENABLE ENABLE
DISP_WIN_OPTIONS.SOR1_ENABLE ENABLE
```

Controls in CAR

```
CLK_OUT_ENB_X.CLK_ENB_SOR0
RST_DEV_X_SET.SET_SOR0_RST
CLK_OUT_ENB_X.CLK_ENB_SOR1
RST_DEV_X_SET.SET_SOR1_RST

CLK_OUT_ENB_X.CLK_ENB_DPAUX
RST_DEV_X_SET.SET_DPAUX_RST
CLK_OUT_ENB_Y.CLK_ENB_DPAUX1
RST_DEV_Y_SET.SET_DPAUX1_RST
```

27.7.1.1 SOR Start



27.7.1.2 eDP Start Sequence

Program PLLD□PLLDP and PLLD2 to Enable Reference Clock

Software has to program PLLD, PLLDP, and PLLD2 first to enable reference clock, because the reference clock should be stable before enabling the display controller and SOR.

Initialize the Display Controller

The Display Controller should be initialized before programming the SOR.

```
STATE_ACCESS.WRITE_MUX ACTIVE
```

Set display to use the active copy of shadow register. Any programming to display register will be active immediately.

```
DISP_WIN_OPTIONS.SOR_ENABLE ENABLE
DISP_WIN_OPTIONS.SOR1_ENABLE ENABLE
```

The above register controls the sor_enable signal in display which controls the enabling of display2sor clock gating and raster timing signals.

Program display pixel clock so dcpclk is valid. Program display window selection registers and window initial properties (can be overridden later).

The display pixel clock should be programmed to be valid at this stage. The pixel clock feeds to SOR pad CLOCKIN, which generates the CLOCKOUT that will be used later by the SOR as orclk in HDMI mode. Before the SOR switches to use pad CLOCKOUT as orclk, the CLOCKOUT should be stable.

```
WIN_OPTIONS.WIN_ENABLE ENABLE
Enables display window.
```

Program AUX Channel

Program AUX registers to control DP parameters.

Notes:

- *In Tegra X1, DPAUX pad macro's power mode is controlled by DPAUX register DPAUX_HYBRID_SPARE_0.PAD_PWR. The reset value of this register is POWER UP. Therefore the default power mode of DPAUX pad macro is POWER UP.*
- ***[For SW]** The programming on DPAUX_HYBRID_SPARE_0 register is not applicable to software. Software need use another approach to program the Aux channel.*

Power up SOR Pad

Power up PLLDP to generate the macro clock and start to run the lane sequencer.

The programming sequence should follow the SOR pad specification.

1. Wait at least 5 µs
2. De-assert PDBG

   ```
   SOR.NV_PDISP_SOR_PLL2.AUX6          BANDGAP_POWERDOWN_DISABLE
   ```

3. Wait 20 µs
4. De-assert PDPLL, PLLVCOPD, PLLCAPPD to enable PLL

   ```
   SOR.NV_PDISP_SOR_PLL3.PLLVDD_MODE    V3_3
   SOR.NV_PDISP_SOR_PLL0.PWR            ON
   SOR.NV_PDISP_SOR_PLL0.VCOPD          RESCIND
   SOR.NV_PDISP_SOR_PLL2.AUX1           SEQ_PLLCAPPD_OVERRIDE
   SOR.NV_PDISP_SOR_PLL2.AUX8           SEQ_PLLCAPPD_ENFORCE_DISABLE
   ```

5. Wait 200 µs till PLL is locked

   ```
   SOR.NV_PDISP_SOR_PLL2.AUX2           OVERRIDE_POWERDOWN
   SOR.NV_PDISP_SOR_PLL2.AUX7           PORT_POWERDOWN_DISABLE
   ```

6. Power up SOR macro lanes
7. Power up 1, 2 or 4 lanes

   1 lane:

   ```
   SOR.NV_PDISP_SOR_DP_LINKCTL0.LANECOUNT ONE
   ```

```
SOR.NV_PDISP_SOR_DP_PADCTL0.PD_TXD_0 NO
SOR.NV_PDISP_SOR_DP_PADCTL0.PD_TXD_1 YES
SOR.NV_PDISP_SOR_DP_PADCTL0.PD_TXD_2 YES
SOR.NV_PDISP_SOR_DP_PADCTL0.PD_TXD_3 YES
```

2 lanes:

```
SOR.NV_PDISP_SOR_DP_LINKCTL0.LANECOUNT TWO
SOR.NV_PDISP_SOR_DP_PADCTL0.PD_TXD_0 NO
SOR.NV_PDISP_SOR_DP_PADCTL0.PD_TXD_1 NO
SOR.NV_PDISP_SOR_DP_PADCTL0.PD_TXD_2 YES
SOR.NV_PDISP_SOR_DP_PADCTL0.PD_TXD_3 YES
```

4 lanes:

```
SOR.NV_PDISP_SOR_DP_LINKCTL0.LANECOUNT FOUR
SOR.NV_PDISP_SOR_DP_PADCTL0.PD_TXD_0 NO
SOR.NV_PDISP_SOR_DP_PADCTL0.PD_TXD_1 NO
SOR.NV_PDISP_SOR_DP_PADCTL0.PD_TXD_2 NO
SOR.NV_PDISP_SOR_DP_PADCTL0.PD_TXD_3 NO
```

8. Start lane sequencer

```
SOR.NV_PDISP_SOR_LANE_SEQ_CTL -dirty
SOR.NV_PDISP_SOR_LANE_SEQ_CTL.DELAY             15
SOR.NV_PDISP_SOR_LANE_SEQ_CTL.NEW_POWER_STATE   PU
SOR.NV_PDISP_SOR_LANE_SEQ_CTL.SEQUENCE          DOWN
SOR.NV_PDISP_SOR_LANE_SEQ_CTL.SETTING_NEW       TRIGGER
```

9. Select to use single clock for macro

```
SOR.NV_PDISP_SOR_CLK_CNTRL.DP_CLK_SEL SINGLE_DPCLK
```

10. Other programming

```
SOR.NV_PDISP_SOR_DP_LINKCTL0.ENABLE YES
SOR.NV_PDISP_SOR_DP_LINKCTL0.TUSIZE <specified by test arguments>
SOR.NV_PDISP_SOR_DP_LINKCTL0.ENHANCEDFRAME <specified by test arguments>
SOR.NV_PDISP_SOR_DP_SPARE0.SEQ_ENABLE YES
```

Switch to Use Pad Macro Feedback Clock

The SOR clock needs to be switched to connect to feedback clock from the macro. This switching is done by programming the registers in the CAR. Assuming that we want to use a PLLD source for PCLK and want to use the feedback clock as SORCLK, the following program can be used.

```
CLK_RST_CONTROLLER_CLK_SOURCE_SOR0.SOR0_CLK_SEL1 0
CLK_RST_CONTROLLER_CLK_SOURCE_SOR0.SOR0_CLK_SEL0 1
CLK_RST_CONTROLLER_CLK_SOURCE_SOR1.SOR1_CLK_SRC PLLD
CLK_RST_CONTROLLER_CLK_SOURCE_SOR1.SOR1_CLK_SEL1 0
CLK_RST_CONTROLLER_CLK_SOURCE_SOR1.SOR1_CLK_SEL0 1
CLK_RST_CONTROLLER_CLK_SOURCE_SOR1.SOR1_CLK_DIVISOR
```

For SOR0, SOR0_CLK_SEL1 is optional. Since it supports only eDP, the only clocks are SAFECLK and FEEDBACK.

For SOR1, SOR1_CLK_SEL1 is used to mux between SAFECLK and HDMICLK in HDMI mode. The output of this mux is then muxed with FEEDBACK clock.

CLK_DIVISOR is used only in TMDS mode and is not available in SOR0.

Program Sequencer Instructions

Program SOR sequencer instructions to run and stop sequencer.

```
SOR.NV_PDISP_SOR_SEQ_CTL.PU_PC 0
SOR.NV_PDISP_SOR_SEQ_CTL.PU_PC_ALT 0
SOR.NV_PDISP_SOR_SEQ_CTL.PD_PC 8
SOR.NV_PDISP_SOR_SEQ_CTL.PD_PC_ALT 8
SOR.NV_PDISP_SOR_SEQ_CTL.SWITCH 0
SOR.NV_PDISP_SOR_LANE_SEQ_CTL.DELAY 0
```

For non-sequencer tests, only program basic sequence without switching.

1. Sequencer up instructions

```
SOR.NV_PDISP_SOR_SEQ_INST0.WAIT_TIME 0
SOR.NV_PDISP_SOR_SEQ_INST0.WAIT_UNITS VSYNC
SOR.NV_PDISP_SOR_SEQ_INST0.HALT TRUE
SOR.NV_PDISP_SOR_SEQ_INST0.PIN_A LOW
SOR.NV_PDISP_SOR_SEQ_INST0.PIN_B LOW
SOR.NV_PDISP_SOR_SEQ_INST0.DRIVE_PWM_OUT_LO TRUE
SOR.NV_PDISP_SOR_SEQ_INST0.TRISTATE_IOS ENABLE_PINS
SOR.NV_PDISP_SOR_SEQ_INST0.BLACK_DATA NORMAL
SOR.NV_PDISP_SOR_SEQ_INST0.BLANK_DE NORMAL
SOR.NV_PDISP_SOR_SEQ_INST0.BLANK_H NORMAL
SOR.NV_PDISP_SOR_SEQ_INST0.BLANK_V NORMAL
SOR.NV_PDISP_SOR_SEQ_INST0.ASSERT_PLL_RESET NORMAL
SOR.NV_PDISP_SOR_SEQ_INST0.POWERDOWN_MACRO NORMAL
SOR.NV_PDISP_SOR_SEQ_INST0.LANE_SEQ RUN
SOR.NV_PDISP_SOR_SEQ_INST0.SEQUENCE UP
```

2. Sequencer down instructions

```
SOR.NV_PDISP_SOR_SEQ_INST8.WAIT_TIME 0
SOR.NV_PDISP_SOR_SEQ_INST8.WAIT_UNITS VSYNC
SOR.NV_PDISP_SOR_SEQ_INST8.HALT TRUE
SOR.NV_PDISP_SOR_SEQ_INST8.PIN_A LOW
SOR.NV_PDISP_SOR_SEQ_INST8.PIN_B LOW
SOR.NV_PDISP_SOR_SEQ_INST8.DRIVE_PWM_OUT_LO TRUE
SOR.NV_PDISP_SOR_SEQ_INST8.TRISTATE_IOS ENABLE_PINS
SOR.NV_PDISP_SOR_SEQ_INST8.BLACK_DATA NORMAL
SOR.NV_PDISP_SOR_SEQ_INST8.BLANK_DE NORMAL
SOR.NV_PDISP_SOR_SEQ_INST8.BLANK_H NORMAL
SOR.NV_PDISP_SOR_SEQ_INST8.BLANK_V NORMAL
SOR.NV_PDISP_SOR_SEQ_INST8.ASSERT_PLL_RESET NORMAL
SOR.NV_PDISP_SOR_SEQ_INST8.POWERDOWN_MACRO NORMAL
SOR.NV_PDISP_SOR_SEQ_INST8.LANE_SEQ RUN
SOR.NV_PDISP_SOR_SEQ_INST8.SEQUENCE DOWN
```

Before Attaching Program SOR Methods

Program the following SOR state control registers.

```
SOR.NV_PDISP_SOR_STATE1. ASY_OWNER
SOR.NV_PDISP_SOR_STATE1.ASY_SUBOWNER
SOR.NV_PDISP_SOR_STATE1.ASY_PROTOCOL
```

```
SOR.NV_PDISP_SOR_STATE1.ASY_HSYNCPOL
SOR.NV_PDISP_SOR_STATE1.ASY_VSYNCPOL
SOR.NV_PDISP_SOR_STATE1.ASY_DEPOL
SOR.NV_PDISP_SOR_STATE1.ASY_CRCMODE
SOR.NV_PDISP_SOR_STATE1.ASY_PIXELDEPTH
```

Program Display Raster Timing Registers

Program head control registers for hsync, vsync, hblank, vblank, htotal, vtotal.

Program these registers for each head connected.

```
SOR.NV_PDISP_HEAD_STATE0[NUM_HEADS].INTERLACED PROGRESSIVE
SOR.NV_PDISP_HEAD_STATE0[NUM_HEADS].DYNRANGE <specified by test arguments>
SOR.NV_PDISP_HEAD_STATE0[NUM_HEADS].COLORSPACE RGB
SOR.NV_PDISP_HEAD_STATE1[NUM_HEADS].VTOTAL <specified by test arguments>
SOR.NV_PDISP_HEAD_STATE1[NUM_HEADS].HTOTAL <specified by test arguments>
```

The Tegra X1 display has constraints on raster timing register configurations, therefore the programming to the SOR.NV_PDISP_HEAD_STATE registers should also be constrained to match with display.

```
if (REF_TO_SYNC.H_REF_TO_SYNC + REF_TO_SYNC.H_REF_TO_SYNC) < 20 {
SOR.NV_PDISP_HEAD_STATE1.HTOTAL $head [expr 19 - [REF_TO_SYNC.H_REF_TO_SYNC] + $total_width -
$blank_endx]
   SOR.NV_PDISP_HEAD_STATE3.HBLANK_END $head [expr 19 - [REF_TO_SYNC.H_REF_TO_SYNC]]
   SOR.NV_PDISP_HEAD_STATE4.HBLANK_START $head [expr 19 - [REF_TO
}

SOR.NV_PDISP_SOR_CSTM.ROTCLK 2
```

Attach and Update Methods

- Core update (sor_update)

```
SOR.NV_PDISP_SOR_STATE0.UPDATE 0
SOR.NV_PDISP_SOR_STATE0.UPDATE 1
SOR.NV_PDISP_SOR_STATE0.UPDATE 0
```

- Attach SOR

```
SOR.NV_PDISP_SOR_SUPER_STATE1.ASY_HEAD_OPMODE SLEEP
SOR.NV_PDISP_SOR_SUPER_STATE1.ASY_ORMODE      SAFE
SOR.NV_PDISP_SOR_SUPER_STATE1.ATTACHED        YES
```

- Set OR mode to NORMAL

```
SOR.NV_PDISP_SOR_SUPER_STATE1.ASY_HEAD_OPMODE SLEEP
SOR.NV_PDISP_SOR_SUPER_STATE1.ASY_ORMODE      NORMAL
SOR.NV_PDISP_SOR_SUPER_STATE1.ATTACHED        YES
```

- Set Head OP mode to AWAKE

```
SOR.NV_PDISP_SOR_SUPER_STATE1.ASY_HEAD_OPMODE AWAKE
SOR.NV_PDISP_SOR_SUPER_STATE1.ASY_ORMODE      NORMAL
SOR.NV_PDISP_SOR_SUPER_STATE1.ATTACHED        YES
```

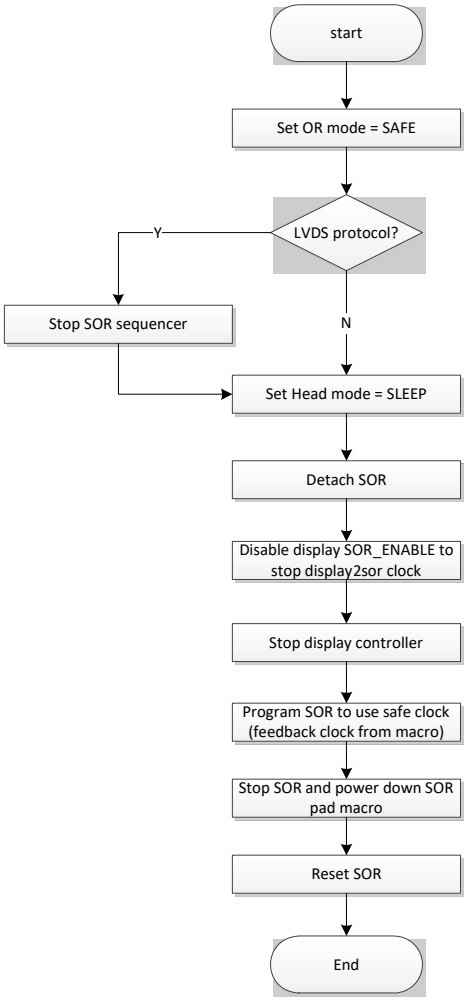
- Super update

```
SOR.NV_PDISP_SOR_SUPER_STATE0.UPDATE 0
SOR.NV_PDISP_SOR_SUPER_STATE0.UPDATE 1
SOR.NV_PDISP_SOR_SUPER_STATE0.UPDATE 0
```

Enable Display Controller

Now start the display controller by programming the display registers.

27.7.1.3 SOR Stop



27.7.1.4 eDP Stop Sequence

Set OR mode to SAFE

```
SOR.NV_PDISP_SOR_SUPER_STATE1.ASY_HEAD_OPMODE AWAKE
SOR.NV_PDISP_SOR_SUPER_STATE1.ASY_ORMODE      SAFE
SOR.NV_PDISP_SOR_SUPER_STATE1.ATTACHED        YES
sor_super_update
proc sor_super_update {} {
    SOR.NV_PDISP_SOR_SUPER_STATE0.UPDATE 0
    flush
    SOR.NV_PDISP_SOR_SUPER_STATE0.UPDATE 1
    flush
    SOR.NV_PDISP_SOR_SUPER_STATE0.UPDATE 0
    flush
}
```

Here OR mode can be polled for SAFE (SOR.NV_PDISP_SOR_PWR.MODE.SAFE).

Set Head Mode to SLEEP

```
SOR.NV_PDISP_SOR_SUPER_STATE1.ASY_HEAD_OPMODE SLEEP
SOR.NV_PDISP_SOR_SUPER_STATE1.ASY_ORMODE      SAFE
SOR.NV_PDISP_SOR_SUPER_STATE1.ATTACHED        YES
sor_super_update
```

Detach SOR

```
SOR.NV_PDISP_SOR_SUPER_STATE1.ASY_HEAD_OPMODE SLEEP
SOR.NV_PDISP_SOR_SUPER_STATE1.ASY_ORMODE      SAFE
SOR.NV_PDISP_SOR_SUPER_STATE1.ATTACHED        NO
sor_super_update
Here can poll SOR TEST to detach (SOR.NV_PDISP_SOR_TEST.ATTACHED.FALSE)
SOR.NV_PDISP_SOR_STATE1.ASY_OWNER NONE
SOR.NV_PDISP_SOR_STATE1.ASY_SUBOWNER NONE
SOR.NV_PDISP_SOR_STATE1.ASY_PROTOCOL LVDS_CUSTOM
sor_update
proc sor_update {} {
    SOR.NV_PDISP_SOR_STATE0.UPDATE 0
    flush
    SOR.NV_PDISP_SOR_STATE0.UPDATE 1
    flush
    SOR.NV_PDISP_SOR_STATE0.UPDATE 0
    flush
}
```

Disable Display SOR_ENABLE to Stop display2sor Clock

Set display to use the active copy of shadow register; this enables the disabling of PW* registers to take effect immediately (otherwise it will wait until the frame end since display uses the assembly copy of registers).

```
STATE_ACCESS.WRITE_MUX ACTIVE
DISP_WIN_OPTIONS.SOR_ENABLE DISABLE //this will stop display2sor pixel clock
```

Stop the Display Controller

```
DISPLAY_COMMAND.DISPLAY_CTRL_MODE STOP // stop sending frame at the next frame boundary
DISPLAY_POWER_CONTROL.PW0_ENABLE DISABLE
DISPLAY_POWER_CONTROL.PW1_ENABLE DISABLE
DISPLAY_POWER_CONTROL.PW2_ENABLE DISABLE
DISPLAY_POWER_CONTROL.PW3_ENABLE DISABLE
DISPLAY_POWER_CONTROL.PW4_ENABLE DISABLE
```

Program SOR to Use Feedback Clock from Macro (Safe Clock)

Requires CAR to be programmed for the SOR to use feedback clock from the macro.

System test implements the register programming by function:

```
sor_clk_sel safe
```

Stop SOR and Power Down SOR Pad Macro

- Power down each lane of SOR
- Set PDPLL, PLLVCOPD, PLLCAPPD to 1
- Wait for at least 5 µs

- Power down PDBG: set PDBG to 1
- Wait for at least 5 µs
- Power down E_DPD: set E_DPD to 1

1. Power down each lane for eDP

```
SOR.NV_PDISP_SOR_DP_PADCTL0.PD_TXD_0 YES
SOR.NV_PDISP_SOR_DP_PADCTL0.PD_TXD_1 YES
SOR.NV_PDISP_SOR_DP_PADCTL0.PD_TXD_2 YES
SOR.NV_PDISP_SOR_DP_PADCTL0.PD_TXD_3 YES
```

2. Stop lane sequencer

```
SOR.NV_PDISP_SOR_LANE_SEQ_CTL -dirty //enables config with the same value as is
SOR.NV_PDISP_SOR_LANE_SEQ_CTL.DELAY             15
SOR.NV_PDISP_SOR_LANE_SEQ_CTL.NEW_POWER_STATE   PD
SOR.NV_PDISP_SOR_LANE_SEQ_CTL.SEQUENCE          DOWN
SOR.NV_PDISP_SOR_LANE_SEQ_CTL.SETTING_NEW       TRIGGER
```

3. Here can poll SOR lane sequencer control status for SETTING_NEW done (SOR.NV_PDISP_SOR_LANE_SEQ_CTL.SETTING_NEW.DONE)
4. Power down PDPORT to power down all the output links and lanes

```
SOR.NV_PDISP_SOR_PLL2.AUX7          PORT_POWERDOWN_ENABLE
```

5. Wait for 20 µs
6. Power down PDPLL, PLLVCOPD, PLLCAPPD

```
SOR.NV_PDISP_SOR_PLL0.PWR           OFF
SOR.NV_PDISP_SOR_PLL0.VCOPD         ASSERT
SOR.NV_PDISP_SOR_PLL2.AUX1          SEQ_PLLCAPPD_OVERRIDE
SOR.NV_PDISP_SOR_PLL2.AUX8          SEQ_PLLCAPPD_ENFORCE_ENABLE
```

7. Wait for 20 us
8. Power down PDBG

```
SOR.NV_PDISP_SOR_PLL2.AUX6          BANDGAP_POWERDOWN_ENABLE
```

9. Set E_DPD to 1 (PWR)

Reset SOR

Tegra X1 requires SOR to be reset SOR after power down because after SOR is stopped, display's hvtgen does not clean the counters. Therefore if SOR is restarted, the counters will continue to count and result in a function error.

The reset is implemented by programming the following CAR register (Reset device SOR0).

```
CLK_RST_CONTROLLER_RST_DEVICES_X
```

27.7.2 HDMI

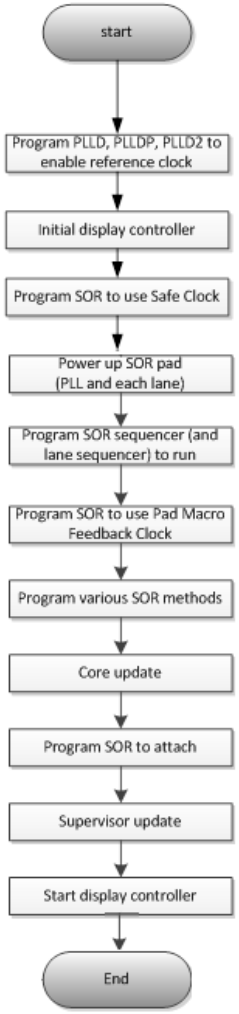
The overall sequence to start up HDMI is:

- Program power, pinmux, clocks, resets, etc.
- Copy HDCP keys from KFUSE to HDMI.
- Program display timing registers, etc.
- Program HDMI registers and SOR sequencer.
- Start HDMI SOR.

- Start display.

Since audio is entirely asynchronous to HDMI or the display, the HDA module can be started any time.

27.7.2.1 SOR Start



27.7.2.2 HDMI Start Sequence

Initialize Display Controller

Before programming the SOR, the display controller must be initialized.

```
STATE_ACCESS.WRITE_MUX ACTIVE
```

Set display to use the active copy of shadow register; therefore any programming to display register will be active immediately.

```
DISP_WIN_OPTIONS.SOR1_ENABLE ENABLE
```

This register controls the sor_enable signal in display which controls the enabling of display2sor1 clock gating and raster timing signals.

Program display pixel clock so dcpclk is valid

Program display window selection registers and window initial properties (can be overridden later)

The Display pixel clock should be programmed to be valid at this stage. The pixel clock feeds to the SOR pad CLOCKIN, which generates the CLOCKOUT, which will be used later by SOR as orclk in TMDS mode. Before SOR switches to use pad CLOCKOUT as orclk, the CLOCKOUT should be stable.

```
WIN_OPTIONS.WIN_ENABLE ENABLE
```

Enables display window.

Program Display Controller to Generate the Preamble as Expected by HDMI

Enforce display to send preamble signal as required by HDMI:

```
DISP_WIN_OPTIONS.SOR1_TIMING_CYA HDMI
```

Program HPULSE2 to Generate the Timing Signals for HDMI

Enforce display to send preamble signal as required by HDMI

```
DISP_SIGNAL_OPTIONS0.H_PULSE2_ENABLE ENABLE
H_PULSE2_CONTROL.H_PULSE2_MODE NORMAL
H_PULSE2_CONTROL.H_PULSE2_POLARITY HIGH
H_PULSE2_CONTROL.H_PULSE2_V_QUAL VACTIVE
H_PULSE2_CONTROL.H_PULSE2_LAST_END END_A
H_PULSE2_POSITION.H_PULSE2_START_A H_REF_TO_SYNC + H_SYNC_WIDTH + H_BACK_PORCH - 10
H_PULSE2_POSITION.H_PULSE2_END_A H_PULSE2_START_A + 8
```

Miscellaneous registers required:

```
DISP_TIMING_OPTIONS.VSYNC_H_POSITION 1
DISP_CLOCK_CONTROL.PIXEL_CLK_DIVIDER PCD1
DISP_COLOR_CONTROL.DITHER_CONTROL    DISABLE
```

- Dither

  Dithering should be disabled, since HDMI uses full 8 bits per component.

- Component Range
- For most HDMI resolutions (i.e., everything except VGA 640x480), R/G/B should be scaled to lie in the [16, 235] nominal range; see the HDMI specification, Section 6.6. The range scaling is recommended to be done in CSC2.

In the CSC2 block:

```
CSC2_CONTROL.OUTPUT_COLOR_SELECT = RGB
CSC2_CONTROL.LIMIT_RGB_COLOR = ENABLE
```

For most HDMI modes, pixel values 0 and 255 must be removed. HDMI's NV_PDISP_INPUT_CONTROL.ARM_VIDEO_RANGE = LIMITED enables this.

Gamma

Most content uses sRGB gamma which is not quite the same as Rec. 709 gamma used by HDMI for most modes. Post-composite gamma can be changed in CMU.

Program SOR to Use Safe Clock and Program refclk

In system level, it is required to program CAR for SOR to use safe clock (default).

```
CLK_RST_CONTROLLER_CLK_SOURCE_SOR1.SOR1_CLK_SEL1 0
CLK_RST_CONTROLLER_CLK_SOURCE_SOR1.SOR1_CLK_SEL0 0
```

Program SOR reference clock, based on HDMI pixel clock – see NV_PDISP_SOR_REFCLK in spec. For example,

```
dispclk_div_8_2 = int(dispclk_freq / 1000000.0 * 4)
NV_PDISP_SOR_REFCLK.DIV_INT = dispclk_div_8_2 >> 2
NV_PDISP_SOR_REFCLK.DIV_FRAC = dispclk_div_8_2 & 0x3
```

Power up SOR Pad

- Deassert E_DPD which is controlled by PMC module.
- Wait for at least 5 µs.
- Deassert PDBG.
- Wait for at least 20 µs.
- Deassert PDPLL, PLLVCOPD and PLLCAPPD.
- Enable SOR PLL.
- Wait for at least 200 µs to PLL lock.

1. Wait for 5 µs
2. Deassert PDBG SOR.NV_PDISP_SOR_PLL2.AUX6 BANDGAP_POWERDOWN_DISABLE
3. Wait for 20 µs
4. Deassert PLLVDD, VCOPD, and PLLCAPPD

```
SOR.NV_PDISP_SOR_PLL3.PLLVDD_MODE V3_3
SOR.NV_PDISP_SOR_PLL0.PWRON
SOR.NV_PDISP_SOR_PLL0.VCOPDRESCIND
SOR.NV_PDISP_SOR_PLL2.AUX8 SEQ_PLLCAPPD_ENFORCE_DISABLE //Force PLLCAPPD to be asserted
```

5. Wait for 200 µs

```
SOR.NV_PDISP_SOR_PLL2.AUX7 PORT_POWERDOWN_DISABLE
SOR.NV_PDISP_SOR_PLL2.AUX2 OVERRIDE_POWERDOWN
```

6. Wait for 20 µs
7. Enable power to the lane

```
SOR.NV_PDISP_SOR_DP_PADCTL0.PD_TXD_0  NO
SOR.NV_PDISP_SOR_DP_PADCTL0.PD_TXD_1  NO
SOR.NV_PDISP_SOR_DP_PADCTL0.PD_TXD_2  NO
SOR.NV_PDISP_SOR_DP_PADCTL0.PD_TXD_3  NO
```

8. Program SOR lane sequencer

```
SOR.NV_PDISP_SOR_LANE_SEQ_CTL.DELAY             15 //15us between each lane's power state change
SOR.NV_PDISP_SOR_LANE_SEQ_CTL.NEW_POWER_STATE   PU //power up when triggers
SOR.NV_PDISP_SOR_LANE_SEQ_CTL.SEQUENCE          DOWN
SOR.NV_PDISP_SOR_LANE_SEQ_CTL.SETTING_NEW       TRIGGER
```

9. Then can poll SOR.NV_PDISP_SOR_LANE_SEQ_CTL for a DONE status

CHECK TMDS Macro Programming

This field should only be changed when MODE_BYPASS is set to DP_SAFE or when the SOR is in safe mode.

```
If (pclk_freq < 340MHz)
SOR.NV_PDISP_SOR_CLK_CNTRL.DP_LINK_SPEED G2_7
Else
SOR.NV_PDISP_SOR_CLK_CNTRL.DP_LINK_SPEED G5_4

SOR.NV_PDISP_SOR_CLK_CNTRL.DP_CLK_SEL  SINGLE_PCLK
```

Program SOR Sequencer

Once loadv arrives, SOR sequencer can be kicked off.

Enable sequencer

```
SOR.NV_PDISP_SOR_DP_SPARE0.SEQ_ENABLE YES
SOR.NV_PDISP_SOR_SEQ_CTL.PU_PC 0
SOR.NV_PDISP_SOR_SEQ_CTL.PU_PC_ALT 0
SOR.NV_PDISP_SOR_SEQ_CTL.PD_PC 8
SOR.NV_PDISP_SOR_SEQ_CTL.PD_PC_ALT 8
SOR.NV_PDISP_SOR_SEQ_CTL.SWITCH 0
```

Sequencer settings for HDMI

```
For ip=0 and 8,

SOR.NV_PDISP_SOR_SEQ_INST${ip}.WAIT_TIME 1
SOR.NV_PDISP_SOR_SEQ_INST${ip}.WAIT_UNITS VSYNC
SOR.NV_PDISP_SOR_SEQ_INST${ip}.HALT TRUE
SOR.NV_PDISP_SOR_SEQ_INST${ip}.PIN_A LOW
SOR.NV_PDISP_SOR_SEQ_INST${ip}.PIN_B LOW
SOR.NV_PDISP_SOR_SEQ_INST${ip}.DRIVE_PWM_OUT_LO TRUE
SOR.NV_PDISP_SOR_SEQ_INST${ip}.TRISTATE_IOS ENABLE_PINS
SOR.NV_PDISP_SOR_SEQ_INST${ip}.BLACK_DATA NORMAL
SOR.NV_PDISP_SOR_SEQ_INST${ip}.BLANK_DE NORMAL
SOR.NV_PDISP_SOR_SEQ_INST${ip}.BLANK_H NORMAL
SOR.NV_PDISP_SOR_SEQ_INST${ip}.BLANK_V NORMAL
SOR.NV_PDISP_SOR_SEQ_INST${ip}.ASSERT_PLL_RESET NORMAL
SOR.NV_PDISP_SOR_SEQ_INST${ip}.POWERDOWN_MACRO NORMAL
```

Program SOR to Use Pad Macro Feedback Clock

When the previous programming is done, need to switch sor clock to connect to feedback clock.

This switching is done by using command “sor_clk_sel pad” to enable in top_peatrans.

```
CLK_RST_CONTROLLER_CLK_SOURCE_SOR1.SOR1_CLK_SRC PLLD
CLK_RST_CONTROLLER_CLK_SOURCE_SOR1.SOR1_CLK_SEL1 1
CLK_RST_CONTROLLER_CLK_SOURCE_SOR1.SOR1_CLK_SEL0 1
CLK_RST_CONTROLLER_CLK_SOURCE_SOR1.SOR1_CLK_DIVISOR
```

Program Other SOR Methods

Program general SOR setting related to head connected, hsync polarity, vsync polarity, de polarity, crc mode, bpp, display head control registers, display raster timing information.

To make display controller A as the primary driver for HDMI

To make display controller B as the primary driver for HDMI

```
SOR.NV_PDISP_INPUT_CONTROL.HDMI_SRC_SELECT DISPLAYB
SOR.NV_PDISP_INPUT_CONTROL.HDMI_SRC_SELECT DISPLAY (or) DISPLAYB
SOR.NV_PDISP_SOR_STATE1.ASY_PROTOCOL LVDS_CUSTOM //default value
```

Set asy_vsyncpol, asy_hsyncpol and asy_de according to panel requirements

```
if {0 == [string compare "positive" $hsync_polarity]} {
SOR.NV_PDISP_SOR_STATE1.ASY_HSYNCPOL POSITIVE_TRUE
} else {
```

```
SOR.NV_PDISP_SOR_STATE1.ASY_HSYNCPOL NEGATIVE_TRUE
}
if {0 == [string compare "positive" $vsync_polarity]} {
SOR.NV_PDISP_SOR_STATE1.ASY_VSYNCPOL POSITIVE_TRUE
} else {
SOR.NV_PDISP_SOR_STATE1.ASY_VSYNCPOL NEGATIVE_TRUE
}
if {0 == [string compare "positive" $DE_polarity]} {
SOR.NV_PDISP_SOR_STATE1.ASY_DEPOL POSITIVE_TRUE
} else {
SOR.NV_PDISP_SOR_STATE1.ASY_DEPOL NEGATIVE_TRUE
}
```

Set pixel depth. Only valid for HDMI is BPP_24_444 (5).

```
SOR.NV_PDISP_SOR_STATE1.ASY_PIXELDEPTH BPP_24_444
```

Program display head control registers

Set the dynamic range for the output. Display Port has a restriction that BPP_18_444 RGB mode must use VESA.

```
if {0 == [string compare "vesa" $dynamic_range]} {
SOR.NV_PDISP_HEAD_STATE0.DYNRANGE $head VESA
} else {
SOR.NV_PDISP_HEAD_STATE0.DYNRANGE $head CEA
}
SOR.NV_PDISP_HEAD_STATE0.COLORSPACE $head RGB //Only RGB is supported
```

Program Preamble timing in SOR

Enables SOR to use preamble signal generated by display:

```
SOR.NV_PDISP_SOR_DP_SPARE0.DISP_VIDEO_PREAMBLE_CYA ENABLE
```

Program display head control registers for raster timing

```
SOR.NV_PDISP_HEAD_STATE1.VTOTAL $head $total_height
SOR.NV_PDISP_HEAD_STATE1.HTOTAL $head $total_width
//sync_endy == v_ref_to_sync + v_sync_width
//constraint: sync_endy >= 1 (due to v_ref_to_sync >= 1)
SOR.NV_PDISP_HEAD_STATE2.VSYNC_END $head $sync_endy
//sync_endx == h_ref_to_sync + h_sync_width
SOR.NV_PDISP_HEAD_STATE2.HSYNC_END $head $sync_endx
//blank_endy == v_sync_width + v_backporch
SOR.NV_PDISP_HEAD_STATE3.VBLANK_END $head $blank_endy
//blank_endy == h_sync_width + h_backporch
SOR.NV_PDISP_HEAD_STATE3.HBLANK_END $head $blank_endx
//blank_starty == v_sync_width + v_back_porch + v_active (surface_height)
SOR.NV_PDISP_HEAD_STATE4.VBLANK_START $head $blank_starty
//blank_starty == h_sync_width + h_back_porch + h_active (surface_width)
SOR.NV_PDISP_HEAD_STATE4.HBLANK_START $head $blank_startx
```

Validate raster timing for display to meet Tegra X1 display constraints

Tegra X1 display Constraint 1: H_REF_TO_SYNC + H_SYNC_WIDTH + H_BACK_PORCH > 20.

If the raster config violates this constraint, will adjust htotal, hblank_end and hblank_start values to meet the constraint as: H_REF_TO_SYNC + H_SYNC_WIDTH + H_BACK_PORCH = 20.

```
if {$blank_endx + [REF_TO_SYNC.H_REF_TO_SYNC] < 20} {
            SOR.NV_PDISP_HEAD_STATE1.HTOTAL $head [expr 19 - [REF_TO_SYNC.H_REF_TO_SYNC] +
$total_width - $blank_endx]
            SOR.NV_PDISP_HEAD_STATE3.HBLANK_END $head [expr 19 - [REF_TO_SYNC.H_REF_TO_SYNC]]
            SOR.NV_PDISP_HEAD_STATE4.HBLANK_START $head [expr 19 - [REF_TO_SYNC.H_REF_TO_SYNC] -
$blank_endx + $blank_startx]
}
```

Attach SOR

1. Program head owner

```
if { use displayA } {
SOR.NV_PDISP_SOR_STATE1.ASY_OWNER HEAD0
} else {
      SOR.NV_PDISP_SOR_STATE1.ASY_OWNER HEAD1
}
SOR.NV_PDISP_SOR_STATE1.ASY_SUBOWNER BOTH
```

2. Core update

```
sor_update
proc sor_update {} {
    SOR.NV_PDISP_SOR_STATE0.UPDATE 0
    flush
    SOR.NV_PDISP_SOR_STATE0.UPDATE 1
    flush
    SOR.NV_PDISP_SOR_STATE0.UPDATE 0
    flush
}
```

3. Attach SOR

```
SOR.NV_PDISP_SOR_SUPER_STATE1.ASY_HEAD_OPMODE SLEEP
SOR.NV_PDISP_SOR_SUPER_STATE1.ASY_ORMODE    SAFE
SOR.NV_PDISP_SOR_SUPER_STATE1.ATTACHED      YES
sor_super_update
proc sor_super_update {} {
    SOR.NV_PDISP_SOR_SUPER_STATE0.UPDATE 0
    flush
    SOR.NV_PDISP_SOR_SUPER_STATE0.UPDATE 1
    flush
    SOR.NV_PDISP_SOR_SUPER_STATE0.UPDATE 0
    flush
}
```

4. Here can poll NV_PDISP_SOR_TEST for attach status (SOR.NV_PDISP_SOR_TEST.ATTACHED.TRUE)
5. Set OR mode to NORMAL

```
SOR.NV_PDISP_SOR_SUPER_STATE1.ASY_HEAD_OPMODE SLEEP
SOR.NV_PDISP_SOR_SUPER_STATE1.ASY_ORMODENORMAL
SOR.NV_PDISP_SOR_SUPER_STATE1.ATTACHED        YES
sor_super_update
```

6. Head awake

```
SOR.NV_PDISP_SOR_SUPER_STATE1.ASY_HEAD_OPMODE AWAKE
```

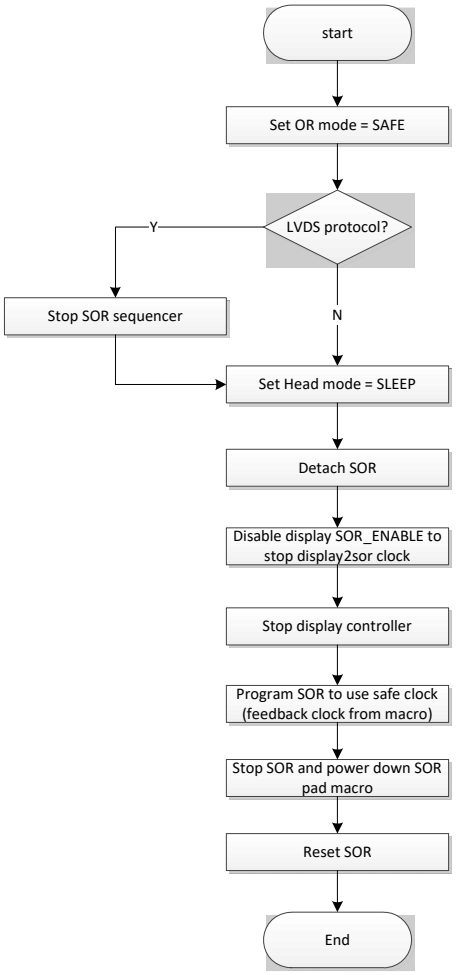
```
SOR.NV_PDISP_SOR_SUPER_STATE1.ASY_ORMODE      NORMAL
SOR.NV_PDISP_SOR_SUPER_STATE1.ATTACHED        YES
```

Start the Display Controller

Now start the display controller by programming the display registers.

27.7.2.3 SOR Stop

General sequence



27.7.2.4 HDMI Stop Sequence

Set OR mode to SAFE

```
SOR.NV_PDISP_SOR_SUPER_STATE1.ASY_HEAD_OPMODE AWAKE
SOR.NV_PDISP_SOR_SUPER_STATE1.ASY_ORMODE      SAFE
SOR.NV_PDISP_SOR_SUPER_STATE1.ATTACHED        YES
sor_super_update
proc sor_super_update {} {
    SOR.NV_PDISP_SOR_SUPER_STATE0.UPDATE 0
    flush
    SOR.NV_PDISP_SOR_SUPER_STATE0.UPDATE 1
    flush
    SOR.NV_PDISP_SOR_SUPER_STATE0.UPDATE 0
```

```
    flush
}
```

Here can poll OR mode for SAFE (SOR.NV_PDISP_SOR_PWR.MODE.SAFE)

Set Head mode to SLEEP

```
SOR.NV_PDISP_SOR_SUPER_STATE1.ASY_HEAD_OPMODE SLEEP
SOR.NV_PDISP_SOR_SUPER_STATE1.ASY_ORMODE      SAFE
SOR.NV_PDISP_SOR_SUPER_STATE1.ATTACHED        YES
sor_super_update
```

Detach SOR

```
SOR.NV_PDISP_SOR_SUPER_STATE1.ASY_HEAD_OPMODE SLEEP
SOR.NV_PDISP_SOR_SUPER_STATE1.ASY_ORMODE      SAFE
SOR.NV_PDISP_SOR_SUPER_STATE1.ATTACHED        NO
sor_super_update
```

Here can poll SOR TEST to detach (SOR.NV_PDISP_SOR_TEST.ATTACHED.FALSE)

Core update: promote SOR_SET_CONTROL to arm state

```
SOR.NV_PDISP_SOR_STATE1.ASY_OWNER NONE
SOR.NV_PDISP_SOR_STATE1.ASY_SUBOWNER NONE
SOR.NV_PDISP_SOR_STATE1.ASY_PROTOCOL LVDS_CUSTOM
sor_update
proc sor_update {} {
    SOR.NV_PDISP_SOR_STATE0.UPDATE 0
    flush
    SOR.NV_PDISP_SOR_STATE0.UPDATE 1
    flush
    SOR.NV_PDISP_SOR_STATE0.UPDATE 0
    flush
}
```

Disable Display SOR_ENABLE to Stop display2sor Clock

Set display to use the active copy of shadow register, this enables the disabling of PW* registers take effect immediately (otherwise it will wait till the frame end since display uses the assembly copy of registers)

```
STATE_ACCESS.WRITE_MUX ACTIVE
DISP_WIN_OPTIONS.SOR_ENABLE DISABLE //this will stop display2sor pixel clock
```

Stop the Display Controller

```
DISPLAY_COMMAND.DISPLAY_CTRL_MODE STOP // stop sending frame at the next frame boundary
DISPLAY_POWER_CONTROL.PW0_ENABLE DISABLE
DISPLAY_POWER_CONTROL.PW1_ENABLE DISABLE
DISPLAY_POWER_CONTROL.PW2_ENABLE DISABLE
DISPLAY_POWER_CONTROL.PW3_ENABLE DISABLE
DISPLAY_POWER_CONTROL.PW4_ENABLE DISABLE
```

Program SOR to switch from Feedback Clock to Safeclk

Requires CAR to be programmed for SOR to use safeclk.

```
CLK_RST_CONTROLLER_CLK_SOURCE_SOR1.SOR1_CLK_SEL1 0
CLK_RST_CONTROLLER_CLK_SOURCE_SOR1.SOR1_CLK_SEL0 0
```

Stop SOR and Power Down SOR Pad Macro

- Power down each lane of SOR.
- Set PDPLL, PLLVCOPD, PLLCAPPD to 1.
- Wait for at least 5 µs.
- Power down PDBG: set PDBG to 1.
- Wait for at least 5 µs.
- Power down E_DPD: set E_DPD to 1.

1. Power down each lane

```
SOR.NV_PDISP_SOR_DP_PADCTL0.PD_TXD_0 YES
SOR.NV_PDISP_SOR_DP_PADCTL0.PD_TXD_1 YES
SOR.NV_PDISP_SOR_DP_PADCTL0.PD_TXD_2 YES
SOR.NV_PDISP_SOR_DP_PADCTL0.PD_TXD_3 YES
```

2. Stop lane sequencer

```
SOR.NV_PDISP_SOR_LANE_SEQ_CTL -dirty //enables config with the same value as is
SOR.NV_PDISP_SOR_LANE_SEQ_CTL.DELAY             15
SOR.NV_PDISP_SOR_LANE_SEQ_CTL.NEW_POWER_STATE   PD
SOR.NV_PDISP_SOR_LANE_SEQ_CTL.SEQUENCE          DOWN
SOR.NV_PDISP_SOR_LANE_SEQ_CTL.SETTING_NEW       TRIGGER
```

3. Here can poll SOR lane sequencer ctrl status for SETTING_NEW done (SOR.NV_PDISP_SOR_LANE_SEQ_CTL.SETTING_NEW.DONE)
4. Power down PDPORT to power down all the output links and lanes

```
SOR.NV_PDISP_SOR_PLL2.AUX7          PORT_POWERDOWN_ENABLE
```

5. Wait for 20 µs
6. Power down PDPLL, PLLVCOPD, PLLCAPPD

```
SOR.NV_PDISP_SOR_PLL0.PWR           OFF
SOR.NV_PDISP_SOR_PLL0.VCOPD         ASSERT
SOR.NV_PDISP_SOR_PLL2.AUX1          SEQ_PLLCAPPD_OVERRIDE
SOR.NV_PDISP_SOR_PLL2.AUX8          SEQ_PLLCAPPD_ENFORCE_ENABLE
```

7. Wait for 20 µs
8. Power down PDBG

```
SOR.NV_PDISP_SOR_PLL2.AUX6          BANDGAP_POWERDOWN_ENABLE
```

9. Set E_DPD to 1 (PWR)
10. Program E_DPD to 1 in PMC registers.

Reset SOR

Tegra X1 requires SOR to be reset after power down. Because after stop SOR, display's hvtgen does not clean the counters. Therefore if SOR is restarted, the counters will continue to count and result in a function error.

The reset is implemented by programming the following CAR register (Reset device SOR0):

```
CLK_RST_CONTROLLER_RST_DEVICES_X
```

27.7.3 Audio

27.7.3.1 HDA Audio Codec Initialization

HDA is the only audio source, the codec must be initialized before audio can flow. The internal codec uses industry-standard verbs, so in theory, the out-of-box driver should correctly discover and configure the codec. See the HD Audio specification. Below is a summary of the necessary verbs:

1. AOC widget: SET_CONV_STREAM_CHAN with desired output stream ID
2. AOC widget: SET_CONV_FMT to desired audio format (sampling frequency, sample depth, number of channels)
3. AOC widget: SET_DIGITAL_CONV_CONTROL1
   - Bit 0: 1 (DigEn=1)
   - Bit 3..6: channel status pre/copy/audio/pro bits
   - Bit 7: channel status CC bit 7 (called GEN_LEVEL)
4. AOC widget: SET_DIGITAL_CONV_CONTROL2:
   - Bit 6:0: channel status CC bits 6:0
5. Pin widget: SET_CONVERTER_CHANNEL_TO_DIGITAL_SLOT_MAPPING= 0x22 and SET_CONVERTER_CHANNEL_TO_DIGITAL_SLOT_MAPPING= 0x33 to undo default swap of channels 2 and 3
6. AOC widget: SET_STRIPE_CONTROL to select number of lanes. Recommend programming to 2 lanes all the time.
7. Pin widget: SET_PIN_WIDGET_CTRL = 0x40, to enable output and use PCM packets.
8. If desired to use HDA for info packets, program them with SET_DIP_INDEX/SET_DIP_DATA and enable with SET_DIP_XMIT_CTRL.

27.7.3.2 HDMI Audio Settings

Two methods of generating the CTS portion of ACR packets are supported:

- In “Force SW CTS”, software computes CTS for the current audio and pixel clocks and writes it to registers.
- In “Hardware CTS”, hardware computes CTS automatically.

Likewise, two methods for generating N portion are supported.

- In “SW N”, software programs current desired N into 0441_SUBPACK_HIGH register and AUDIO_N.VALUE.
- In “HW N”, software programs all the ACR_*_SUBPACK_HIGH per-frequency N, then hardware chooses the one to use.

1. Set NV_PDISP_SOR_HDMI_ACR_CTRL (all fields) to 0
2. Program LOOKUP per table.
3. Based on pixel clock and audio sample clock frequencies, program the appropriate ACR N value into NV_PDISP_SOR_HDMI_ACR_0441_SUBPACK_HIGH (see HDMI 1.2a specification, Section 7.2.3). LSB of N goes in SB6, and MSB into SB4.
4. Likewise, program the appropriate ACR CTS value into NV_PDISP_SOR_HDMI_ACR_0441_SUBPACK_LOW. The LSB of CTS goes in SB3, and the MSB into SB1.
5. Program the computed AVAL into the appropriate SOR_AUDIO_AVAL_ register
6. Set NV_PDISP_SOR_HDMI_ACR_*_SUBPACK_HIGH.ENABLE = YES.
7. Set NV_PDISP_SOR_HDMI_SPARE = 0x10000 OR’d with bits 0 and 1
8. Program the audio source with SOR_AUDIO_CNTRL0.SOURCE_SELECT = HDAL for HDA, or AUTO. AUTO automatically selects HDA if HDMI’s internal HDA codec has been enumerated by HDA controller.
9. Enable HDMI audio: Set NV_PDISP_SOR_HDMI_CTRL.ENABLE = EN, NV_PDISP_SOR_HDMI_GENERIC_CTRL.AUDIO = EN, AUDIO_ENGINE.PWRDWN=0

Note: *CTS and N values depend on the ratio of the actual pixel clock and audio clock rates. The chip's clock generators cannot create every frequency exactly. For example 25.2 MHz (for 640x480p@60) cannot be exactly generated – 25.25 is the result. Thus CTS and N must be adjusted accordingly.*

27.7.4 Audio Codec

The HDMI block in Tegra X1 contains an audio codec that is connected to the HDA controller on the chip. The audio codec identifies as: 0x10de0029. Note that the audio codec is used in both DP and HDMI. The table below contains a list of all supported verbs for this codec:

Table 163: Supported Verbs for Audio Codec

Node	Verb (Verb ID)	Payload	Response (32 bits)	Default Power on Value/Notes
Root	Get Parameter (0xF00)	Parameter ID	Parameter Value	NA
Audio Function Group	Get Parameter (0xF00)	Parameter ID	Parameter Value	NA
	Get Power State (0xF05)	0	Bits [31:11] are 0 Bit [10] = PS-Settings Reset Bit [9] = PS-ClkStopOk Bit [8] = PS-Error Bits [7:4] = PS-Act Bits [3:0] = PS - Set	PS-Settings Reset: 1 PS-ClkStopOk: 0x1 PS-Error: 0x0 PS-Act: 0x3 (D3hot) PS-Set: 0x3 (D3hot) D3hot is chosen as the default power on state in accordance with Intel ECR HDA015-B
	Set Power State (0x705)	Bits [7:4] are 0 and Bits [3:0] = PS – Set Value	0	
	Get Sub-System ID (0xF20)	0	Bits [31:16] = Vendor ID Bit [15:8] = Board SKU Bits [7:0] = Assembly ID	Vendor ID: 0x10DE Board SKU: 0x01 Assembly ID: 0x01
	Set Sub-System ID -1 (0x720)	Bits [7:0] of subsystem ID	0	
	Set Sub-System ID -2 (0x720)	Bits [15:8] of subsystem ID	0	
	Set Sub-System ID -3 (0x720)	Bits [23:16] of subsystem ID	0	
	Set Sub-System ID -4 (0x720)	Bits [31:24] of subsystem ID	0	
	Reset	0	0	In accordance with Intel ECN, treated as single AFG reset.
	Set Scratch Reg0, Byte0 (0x FA7) Vendor Defined	Bits [7:0] transparent to hardware	0	Reg0, Byte0: 0x00 Reg0, Byte1: 0x00 Reg0, Byte2: 0x00 Reg0, Byte3: 0x00
	Set Scratch Reg0, Byte1 (0xFA8) Vendor Defined	Bits [7:0] transparent to hardware	0	
	Set Scratch Reg0, Byte2 (0xFA9) Vendor Defined	Bits [7:0] transparent to hardware	0	
	Set Scratch Reg0, Byte3 (0xFAA) Vendor Defined	Bits [7:0] transparent to hardware	0	
	Get Scratch Reg0 (0xFA6) Vendor Defined	0	Bits [31:24]=Reg0, Byte3 Bits [23:16]=Reg0, Byte2 Bits [15:8]=Reg0, Byte1 Bits [7:0]=Reg0, Byte0	

Table 163: Supported Verbs for Audio Codec

Node	Verb (Verb ID)	Payload	Response (32 bits)	Default Power on Value/Notes
Audio Function Group	Set Scratch Reg1, Byte0 (0xFAC) Vendor Defined	Bits [7:0] transparent to hardware	0	Reg1, Byte0: 0x00 Reg1, Byte1: 0x00 Reg1, Byte2: 0x00 Reg1, Byte3: 0x00

For interoperability between HDMI and HDMI codec drivers, the HDMI codec contains a pair of scratch registers that are reflected in the HDMI block's SOR_NV_PDISP_SOR_AUDIO_HDA_CODEC_SCRATCH0/1_0 registers. The HDMI codec driver can access these scratch registers using the following HDA verbs:

```
Get Scratch Reg0 (0xFA6)
Set Scratch Reg0, Byte 0 (0xFA7)
Set Scratch Reg0, Byte 1 (0xFA8)
Set Scratch Reg0, Byte 2 (0xFA9)
Set Scratch Reg0, Byte 3 (0xFAA)

Get Scratch Reg1 (0xFAB)
Set Scratch Reg1, Byte 0 (0xFAC)
Set Scratch Reg1, Byte 1 (0xFAD)
Set Scratch Reg1, Byte 2 (0xFAE)
Set Scratch Reg1, Byte 3 (0xFAF)
```

The content of these registers is defined entirely by software; hardware doesn't interpret it in any way. The only exception is that an interrupt is raised in the HDMI block whenever the most significant bit of either scratch register changes. The interrupt is reflected in the SOR_NV_PDISP_INT_STATUS_0 register's CODEC_SCRATCH0/1 bits.

A similar mechanism exists for communicating data from the HDMI driver to the HDMI codec driver. The SOR_NV_PDISP_SOR_AUDIO_HDA_SCRATCH0/1/2/3_0 registers in the HDMI block are reflected in the HDMI codec's display scratch registers, which in turn can be accessed using the following HDA verbs:

```
Get Display Scratch Registers (0xFA5)
```

Changing the most significant bit of these registers causes an unsolicited response event to be emitted for the HDMI codec. Otherwise the content is defined entirely by software; hardware doesn't interpret it in any way.

27.7.5 Miscellaneous

For Audio to HDMI signaling, the HDA Codec has SCRATCH verbs that are reflected in the HDMI SOR_AUDIO_HDA_CODEC_SCRATCH* registers and CODEC_SCRATCH* interrupts.

For HDMI to Audio signaling, HDMI SOR_AUDIO_HDA_SCRATCH* registers, when written, are reflected to the HDA Codec GET_NV_SCRATCH_REGN_FROM_DISP verb and cause an Unsolicited Response (interrupt in the HDA Controller).

27.7.6 Other HDMI Configurations

1. Set NV_PDISP_SOR_HDMI_CTRL.MAX_AC_PACKET based on horizontal blanking width. Using display timing registers, MAX_AC_PACKET = floor((H_SYNC_WIDTH + H_BACK_PORCH + H_FRONT_PORCH – HDMI_CTRL.REKEY – 18) / 32)
2. Program and enable Audio InfoFrames. When using HDA audio, its contents come from verbs sent to the internal codec.
3. Program and enable AVI InfoFrames. When using HDA Audio, this *may* come from the HDA Codec if desired, using one of its Generic packets. If so, do not enable the HDMI one:
   - Set PDISP_SOR_HDMI_AVI_INFOFRAME_HEADER = 0x000D0282
   - Program checksum, PB1, PB2, PB3 in HDMI_AVI_INFOFRAME_SUBPACK0_LOW. PB4 contains the video format code from the CEA-861-D specification. See HDMI and EIA/CEA-861-D for all the fields. CRC is computed over header and PB1…PB13 as above.
   - Program PB4…PB6 in HDMI_AVI_INFOFRAME_SUBPACK0_HIGH, and PB7..PB13 in HDMI_AVI_INFOFRAME_SUBPACK1_LOW / HIGH.
   - Set HDMI_AVI_INFOFRAME_CTRL.ENABLE = EN
4. For HDMI 1.4 3D, program and enable the GENERIC InfoFrame to send an HDMI Vendor-Specific InfoFrame. When using HDA Audio, this *might* come from the HDA Codec, if desired, using one of its Generic packets. If so, do not enable the HDMI one.
   - Set NV_PDISP_SOR_HDMI_GENERIC_HEADER = 0x00LL0181 where LL is length of packet – 0x05 for the basic version described here.
   - HDMI_GENERIC_SUBPACK0_LOW.PB1/PB2/PB3 = 0x03/0c/00 (IEEE registration ID)
   - PB4 = 0x40 (Hdmi_video_format = 3d_structure present)
   - PB5 = 0x00 (3D_Structure = Frame packing)
   - PB6...PB27 = 0 (no 3D_Ext_Data for Frame packing)
   - Compute checksum over header and PB1..PB27 and put in PB0, as above.
   - HDMI_GENERIC_CTRL.ENABLE=EN. OTHER, SINGLE, HBLANK= DIS.
   - Be sure to keep HDMI_GENERIC_CTRL.AUDIO = EN

To support DVI rather than HDMI, set NV_PDISP_SOR_HDMI_CTRL.ENABLE = NO.

27.7.7 Display Raster Timing Register Programming

The Tegra X1 display has a legacy constraint of V_REF_TO_SYNC, which requires programming display register V_REF_TO_SYNC >=1. However, on the SOR side, the SOR design has an assumption of V_REF_TO_SYNC = 0. To resolve such a conflict, the DC raster timing programming in Tegra X1 is required to change when connected to SOR. This change affects software programming for DC raster timing on V_BACK_PORCH and V_FRONT_PORCH.

SOR and DC timing parameters have following constraints:

```
SOR.HSYNC_END    = DC.H_SYNC_WIDTH - 1
SOR.VSYNC_END    = DC.V_SYNC_WIDTH - 1
SOR.HBLANK_END   = SOR.HSYNC_END  + DC.H_BACK_PORCH
SOR.VBLANK_END   = SOR.VSYNC_END  + DC.V_BACK_PORCH + DC.V_REF_TO_SYNC SOR.HBLANK_START =
SOR.HBLANK_END + DC. H_DISP_ACTIVE
SOR.VBLANK_START = SOR.VBLANK_END + DC. V_DISP_ACTIVE
```

Because eDP configuration must match the panel specification and SOR design specification:

```
SOR.HBLANK_END   = h_sync_width + h_back_porch - 1;
SOR.HBLANK_START = h_sync_width + h_back_porch + h_active_width - 1;
SOR.VBLANK_END   = v_sync_width + v_back_porch - 1;
```

```
SOR.VBLANK_START = v_sync_width + v_back_porch + v_active_width - 1;
```

Note: *sync_width, back_porch, active_width, front_porch are params defined in the panel specification.*

So DC raster timing parameters should be modified as following:

```
DC.V_BACK_PORCH  = v_back_porch - DC.V_REF_TO_SYNC;
DC.V_FRONT_PORCH = v_front_porch + DC.V_REF_TO_SYNC;
```

Usually, DC.V_REF_TO_SYNC can be forced to 1.

27.7.8 HDA

The Tegra HDA controller has two parts: a bus interface block to the rest of the system named IPFS, and the actual HDA core controller.

The HDA core is implemented to an industry standard host controller specification published by Intel and known as ‘HD Audio’. This standard is sometimes also referred by its earlier name which was ‘Azalia’. For programming information on the HDA core, refer to http://www.intel.com/content/www/us/en/chipsets/high-definition-audio.html/

27.7.8.1 Clock and Reset

1. HDA controller needs two clock sources: hda_clk and hda2codec_2x_clk for the HDA core logic and the HDA link logic, respectively. The typical clock frequency for hda_clk is 108 MHz, but hda2codec_2x_clk should be set to 48 MHz, specified by the protocol spec. In fact, the protocol spec only designates the frequency of 1x clock, 24 MHz, but CAR generates the 2x clock and uses a clock divider to generate the 1x clock.
2. Set the clock source of both clocks through CAR programming. A typical way is to program PLLP to generate 216 MHz pllp_out0 and set the clock source of HDA_CLK/HDA2CODEC_2X_CLK to pllp_out0 with divider values 2 and 4.5, respectively.
3. Once the clocks are up and running, the reset signals should be de-asserted through programming HDA_RST and HDA2CODEC_2X_RST.

27.7.8.2 IPFS and FPCI

1. While the HDA controller is connected to the APB bus, it is wrapped with protocol conversion logic because it was also used in other NVIDIA chips. To be able to access the core configuration registers, some wrapper registers should be programmed accordingly. IPFS converts transactions between both the slave APB interface and the master MC protocol, mapping them to a bus protocol referred to as ‘FPCI’ which is the native interface of the HDA core. Also, the FPCI wrapper has PCI configuration registers.
2. IPFS is a flexible block designed to support multiple IPs which need various BAR addresses and sizes. However, in this instance, the HDA core logic needs only a 16 KB BAR0 region, which is already set in the IPFS registers. Software does not have to move the preset BAR0 region.
3. Simply turn on IPFS with programming to HDA_CONFIGURATION_0 with EN_FPCI, bit 0, enabled. The actual address of the register is NV_ADDRESS_MAP_HDA_BASE + HDA_CONFIGURATION_0.
4. The PCI configuration register can be accessed through using addresses starting from NV_ADDRESS_MAP_HDA_BASE + NV_HDA_APB_DFPCI_CFG_OFFSET. The first register, T_AZA_CFG_0 has read-only information such as vendor ID and device ID etc. To turn on the FPCI bus master, turn on T_AZA_CFG_1 with IO_SPACE, bit 0, MEM_SPACE, bit1 and BUS_MASTER, bit 2.

27.7.8.3 Pinmux

There are 4 pinmuxing options for the external codec: DAP1, DAP2, PE0 and PE2. Depending on the use case/application, software can choose one among the options. Refer to the pinmux table for the option details. The configuration registers are defined in the Pinmux Registers section of the Multi-purpose I/O Pins and Pin Multiplexing (Pinmuxing) chapter in this TRM. Make sure that the pinmuxes for all 5 external signals, SYNC, SDO, SDI, BCLK and RESET are programmed accordingly.

27.7.8.4 HDA Configuration

1. From cold reset, the HDA is still in the reset state. The first thing is to wake up HDA by de-asserting CRST. The CRST bit is in AZA_GCTL_0 whose address is NV_ADDRESS_MAP_HDA_BASE + NV_HDA_APB_BAR0_START + AZA_GCTL_0. Writing 1 to the bit wakes up HDA. Since resetting takes time, software should check the status, waiting for read back of CRST becoming 1.
2. Once CRST becomes 1, the HDA controller is ready to send commands (verbs) to codecs.
3. Before sending any real audio data to the internal codec, software may want to check if HDMI is properly woken up.
4. For ring buffer programming for command and data, refer to the HD Audio specification.

27.7.8.5 Other Configurations

1. When CPU gets an interrupt from HDA, it should read the interrupt status register in HDA to resolve any potential data coherency. This is required because the write transactions issued before the interrupt can be still in-flight. Reading the interrupt status register flushes all the write transactions before the register read value is returned. If there are many pending write transactions in FIFO, a simple read transaction can take some time due to the write transaction performance. The latency can be adjusted through the priority change in the MC register. See for the MC register spec for the details. This feature is turned on by default, but it can be defeated by setting HDA_CONFIGURATION_DFPCI_RSPPASSPW.
2. MC does not guarantee the original ordering of write transactions issued by HDA; especially if their addresses are more than 1 KB apart. By default, IPFS maintains the ordering of write transactions with the cost of performance. Usually, the write ordering is not critical unless some memory flags/status bits are used. Since HDA software is not expected to use such memory flags, it is recommended to turn on HDA_CONFIGURATION_UFPCI_PWPASSPW, which improves the write performance.

27.7.9 HDCP

27.7.9.1 Enable Encryption

Microcode handles most parts of the authentication sequence. Once the panel is authenticated and Session key is established, microcode enables hardware to start encryption. Enabling encryption should follow the below sequence:

Start State: _ENABLE = _NO; CRYPT_STS = _INACTIVE

1. Write NV_PDISP_SOR_HDCP22_LC128_MSB_0
2. Write NV_PDISP_SOR_HDCP22_LC128_LSB1_0
3. Write NV_PDISP_SOR_HDCP22_LC128_LSB2_0
4. Write NV_PDISP_SOR_HDCP22_LC128_LSB3_0 Write NV_PDISP_SOR_HDCP22_AES_CTR_KEY_LSB3
5. Write NV_PDISP_SOR_HDCP22_AES_CTR_KEY_LSB2
6. Write NV_PDISP_SOR_HDCP22_AES_CTR_KEY_LSB1
7. Write NV_PDISP_SOR_HDCP22_AES_CTR_KEY_MSB
8. Write NV_PDISP_SOR_HDCP22_AES_CTR_DATA_LSB
9. Write NV_PDISP_SOR_HDCP22_AES_CTR_DATA_MSB
10. Write NV_PDISP_SOR_HDCP22_CTRL_INIT_TRIGGER
11. Poll NV_PDISP_SOR_HDCP22_CTRL_INIT_DONE
12. Write NV_PDISP_SOR_HDCP22_CTRL_ENABLE_YES
13. Poll NV_PDISP_SOR_HDCP22_CTRL_CRYPT_STS = _ACTIVE

End State: _ENABLE = _YES; CRYPT_STS = _ACTIVE

27.7.9.2 Toggling Encryption

Start State: _ENABLE = _YES; CRYPT_STS = _ACTIVE

1. Write _ENABLE = _NO
2. Optional: Software waits for _CRYPT_STS to indicate _INACTIVE
3. Sometime later Write _ENABLE = _YES

End State: _ENABLE = _YES; CRYPT_STS = _ACTIVE

Redo Authentication

Start State: _ENABLE = _YES; CRYPT_STS = _ACTIVE

1. Write _ENABLE = _NO
2. Poll CRYPT_STS = INACTIVE
3. Session Key can happen here
4. Follow sequence to Section 27.7.9.1: Enable Encryption.

End State: _ENABLE = _YES; CRYPT_STS = _ACTIVE

27.7.9.3 Programming Interface

Priv interface

To protect HDCP 2.2 registers from tampering, accesses to them are limited to the SE secure processors.

Control Register

The SOR_NV_PDISP_SOR_HDCP22_CTRL register controls the Encryption of the actual data and initializing the HDCP variables. Refer to Section 27.8.224: SOR_NV_PDISP_SOR_HDCP22_CTRL_0for a complete description of this register.

AES-CTR Key Bus

The SOR_NV_PDISP_SOR_HDCP22_AES_CTR_KEY_[MSB/LSB1/LSB2/LSB3]_0 registers hold the Key value to drive the AES-CTR. These registers are programmed by software to the Session key value. This value will be XORed with the Ic128. These registers must be set to correct Ks value before setting the NV_PDISP_SOR_HDCP22_CTRL_ENABLE to _YES.

Refer to Section 27.8.226: SOR_NV_PDISP_SOR_HDCP22_AES_CTR_KEY_MSB_0 through Section 27.8.229: SOR_NV_PDISP_SOR_HDCP22_AES_CTR_KEY_LSB3_0 for complete descriptions of these registers.

AES-CTR Data Bus

The SOR_NV_PDISP_SOR_HDCP22_AES_CTR_DATA_MSB_0 and SOR_NV_PDISP_SOR_HDCP22_AES_CTR_-DATA_LSB_0 registers hold the Data input value to drive the AES-CTR. These registers are programmed by software to 64 bits riv value. For HDMI, this value is concatenated by inputCtr value for specific protocol. For DP, this value is XORed with TYPE value. This register must be set to the correct riv value before setting NV_PDISP_SOR_HDCP22_CTRL_ENABLE to _YES.

Refer to Section 27.8.230: SOR_NV_PDISP_SOR_HDCP22_AES_CTR_DATA_MSB_0 through Section 27.8.231: SOR_NV_PDISP_SOR_HDCP22_AES_CTR_DATA_LSB_0 for complete descriptions of these registers.

AES-CTR DP Type

The SOR_NV_PDISP_SOR_HDCP22_SST_DP_TYPE_0 register is used when the SOR is set to DP protocol. It allows software to pass the Stream Type value to the hardware which is used during encryption.

Refer to Section 27.8.232: SOR_NV_PDISP_SOR_HDCP22_SST_DP_TYPE_0 for a complete description of this register.

27.7.10 Tegra X1 Display Timing Constraints

Programming of display timing registers must meet these restrictions:

- Constraint 1: H_REF_TO_SYNC + H_SYNC_WIDTH + H_BACK_PORCH > 20.
- Constraint 2: V_REF_TO_SYNC + V_SYNC_WIDTH + V_BACK_PORCH > 1.
- Constraint 3: V_FRONT_PORCH + V_SYNC_WIDTH + V_BACK_PORCH > 1 (vertical blank).

- Constraint 4: V_SYNC_WIDTH >= 1

  H_SYNC_WIDTH >= 1
- Constraint 5: V_REF_TO_SYNC >= 1

  H_REF_TO_SYNC >= 0
- Constraint 6: V_FRONT_PORCH >= (V_REF_TO_SYNC + 1)

  H_FRONT_PORCH >= (H_REF_TO_SYNC + 1)
- Constraint 7: H_DISP_ACTIVE >= 16

  V_DISP_ACTIVE >= 16

27.8 Display Interfaces Registers

Refer to Section 1.4: Reading Register Tables in the Introduction chapter for the register table protocol as well as recommendations for accessing registers.

27.8.1 SOR_CTXSW_0

Context switch register. Should be common to all modules. Includes the current channel/class (which is writable by software) and the next channel/class (which the hardware sets when it receives a context switch).

Context switch works like this: Any context switch request triggers an interrupt to the host and causes the new channel/class to be stored in NEXT_CHANNEL/NEXT_CLASS (see vmod/chexample). Software sees that there is a context switch interrupt and does the necessary operations to make the module ready to receive traffic from the new context. It clears the context switch interrupt and writes CURR_CHANNEL/CLASS to the same value as NEXT_CHANNEL/CLASS, which causes a context switch acknowledge packet to be sent to the host. This completes the context switch and allows the host to continue sending data to the module.

Context switches can also be pre-loaded. If CURR_CLASS/CHANNEL are written and updated to the next CLASS/CHANNEL before the context switch request occurs, an acknowledge will be generated by the module and no interrupt will be triggered. This is one way for software to avoid dealing with context switch interrupts. Another way to avoid context switch interrupts is to set the AUTO_ACK bit.

This bit tells the module to automatically acknowledge any incoming context switch requests without triggering an interrupt. CURR_* and NEXT_* will be updated by the module so they will always be current.

Offset: 0x0 | Byte Offset: 0x0 | Read/Write: R/W | Reset: 0xXXXXf800 (0bxxxxxxxxxxxxxxxx11111x0000000000)

Bit	R/W	Reset	Description
31:28	RO	X	NEXT_CHANNEL: Next requested channel
25:16	RO	X	NEXT_CLASS: Next requested class
15:12	RW	0xf	CURR_CHANNEL: Current working channel, reset to 'invalid'
11	RW	0x1	AUTO_ACK: Automatically acknowledge any incoming context switch requests 0 = MANUAL 1 = AUTOACK
9:0	RW	0x0	CURR_CLASS: Current working class

27.8.2 SOR_NV_PDISP_SOR_SUPER_STATE0_0

The following 2 registers are the equivalent for supervisor methods that dGPU DSI hardware generates. In Tegra X1, software must generate them.

Writing a 1 to this field cause a 1 cycle pulse which is used to activate the fields in registers NV_PDISP_SOR_STATE[1].

Offset: 0x1 | Byte Offset: 0x4 | Read/Write: R/W | Reset: 0x00000000 (0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx0)

Bit	Reset	Description
0	0x0	UPDATE

27.8.3 SOR_NV_PDISP_SOR_SUPER_STATE1_0

NV_PDISP_SOR_SUPER_STATE1 contains triple buffered registers. The values written to SUPER_STATE1 are assembly values.

These are promoted to ARMed state when SUPER_STATE0 UPDATE is written.

The ARMed values are then promoted to ACTIVE internally by HW when an internally generated LOADV signal arrives.

The active state is reported in DISP_SOR_PWR and DISP_SOR_TEST registers

Offset: 0x2 | Byte Offset: 0x8 | Read/Write: R/W | Reset: 0x00000000 (0bxxxxxxxxxxxxxxxxxxxxxxxxxxxx0000)

Bit	Reset	Description
3	NO	ATTACHED: YES: Attach SOR to a display head NO: Detach SOR from display head 0 = NO 1 = YES
2	SAFE	ASY_ORMODE: SAFE: SOR is in safe low power state and not sending any active data. NORMAL: SOR is actively sending data 0 = SAFE 1 = NORMAL
1:0	0x0	ASY_HEAD_OPMODE: SLEEP: Display is not sending pixels and SOR will stop reading pixels from FIFOs SNOOZE: This should never be set by SW AWAKE: Display is sending active pixels to SOR 0 = SLEEP 1 = SNOOZE 2 = AWAKE

27.8.4 SOR_NV_PDISP_SOR_STATE0_0

Writing a 1 to this field cause a 1 cycle pulse which is used to promote the activate the fields in registers NV_PDISP_SOR_STATE[1], NV_PDISP_HEAD_STATE[0-5].

Offset: 0x3 | Byte Offset: 0xc | Read/Write: R/W | Reset: 0x00000000 (0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx0)

Bit	Reset	Description
0	0x0	UPDATE

27.8.5 SOR_NV_PDISP_SOR_STATE1_0

SOR Control Register

Offset: 0x4 | Byte Offset: 0x10 | Read/Write: R/W | Reset: 0x00000040 (0bxxxxxxxxxxxx00000000000000001000000)

Bit	Reset	Description
20:17	DEFAULTVAL	ASY_PIXELDEPTH: This sets the pixel depth and the only valid values are DEFAULTVAL for HDMI mode and BPP_18_444 and BPP_24_444 for DP mode. 0 = DEFAULTVAL 2 = BPP_18_444 5 = BPP_24_444
16:15	OFF	ASY_REPLICATE: This used to enable/disable pixel replication for HDMI. 0 = OFF 1 = X2 2 = X4

Bit	Reset	Description
14	0x0	ASY_DEPOL: This field needs to be set based on the DE polarity as needed by the panel. 0 = POSITIVE_TRUE 1 = NEGATIVE_TRUE
13	0x0	ASY_VSYNCPOL: This field needs to be set based on the VSYNC polarity as needed by the panel. 0 = POSITIVE_TRUE 1 = NEGATIVE_TRUE
12	0x0	ASY_HSYNCPOL: This field needs to be set based on the HSYNC polarity as needed by the panel. 0 = POSITIVE_TRUE 1 = NEGATIVE_TRUE
11:8	LVDS_CUSTOM	ASY_PROTOCOL: 0 = LVDS_CUSTOM 1 = SINGLE_TMDS_A 2 = SINGLE_TMDS_B 8 = DP_A 9 = DP_B 15 = CUSTOM
7:6	COMPLETE_RASTER	ASY_CRCMODE: This field controls the symbols (eDP) that get CRCed. ACTIVE_RASTER --> Only active regions of the raster are CRCed COMPLETE_RASTER --> Entire raster (active + blanking) will be CRCed. NON_ACTIVE_RASTER --> Only non-active regions of the raster are CRCed 0 = ACTIVE_RASTER 1 = COMPLETE_RASTER 2 = NON_ACTIVE_RASTER
5:4	NONE	ASY_SUBOWNER: This field should always set to NONE. 0 = NONE 1 = SUBHEAD0 2 = SUBHEAD1 3 = BOTH
3:0	NONE	ASY_OWNER: This field controls the display pipe that is being connected to the SOR. Note that the ARMED value of this field is promoted only when SOR gets attached. HEAD0 --> When SOR needs to be connected to display internal head: displaya HEAD1 --> When SOR needs to be connected to display external head: displayb NONE --> When it is not connected to any heads 0 = NONE 1 = HEAD0 2 = HEAD1

27.8.6 SOR_NV_PDISP_HEAD_STATE0_0

Head Control Register

Note: *HEAD_STATE registers are valid in DP mode only.*

This is an array of 2 identical register entries; the register fields below apply to each entry.

Offset: 0x5..0x6 | Byte Offset: 0x14..0x18 | Read/Write: R/W | Reset: 0x00000000 (0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx000000)

Bit	Reset	Description
5:4	PROGRESSIVE	INTERLACED: Should always be set to PROGRESSIVE because INTERLACED is not supported. 0 = PROGRESSIVE 1 = INTERLACED
3	DISABLE	RANGECOMPRESS: Compresses the range of an RGB signal with black at 0, white at nominal 255 to the range required for CEA ranged RGB output, i.e., black at 16, white at 235. This control gives the driver a very quick way to compress RGB levels to be compatible with those required for output to TV via the TV encoder and/or to HDMI. 0 = DISABLE 1 = ENABLE
2	VESA	DYNRANGE: Sets the dynamic range for the output. VESA is the full 0 to maximum range. CEA mode will clip the output to fit within CEA range. Display Port has a restriction that BPP_18_444 RGB mode must use VESA. 0 = VESA 1 = CEA

Bit	Reset	Description
1:0	RGB	COLORSPACE: Should always be set to RGB. YUV_601/YUV_709 are not supported. 0 = RGB 1 = YUV_601 2 = YUV_709

27.8.7 SOR_NV_PDISP_HEAD_STATE1_0

This register sets the size of the raster

This is an array of 2 identical register entries; the register fields below apply to each entry.

Offset: 0x7..0x8 | Byte Offset: 0x1c..0x20 | Read/Write: R/W | Reset: 0x01011000 (0bx000000100000001x001000000000000)

Bit	Reset	Description
30:16	0x101	VTOTAL: This field is the total number of lines in a frame of the raster.
14:0	0x1000	HTOTAL: This field is the total number of pixels in a line of the raster.

27.8.8 SOR_NV_PDISP_HEAD_STATE2_0

This register sets the location of the horizontal and vertical sync end

This is an array of 2 identical register entries; the register fields below apply to each entry.

Offset: 0x9..0xa | Byte Offset: 0x24..0x28 | Read/Write: R/W | Reset: 0x00000001 (0bx000000000000000x000000000000001)

Bit	Reset	Description
30:16	0x0	VSYNC_END: This field is the total number of lines after which vertical sync ends
14:0	0x1	HSYNC_END: This field is the total number of pixels after which horizontal sync ends

27.8.9 SOR_NV_PDISP_HEAD_STATE3_0

This register sets the location of horizontal and vertical blank end.

This is an array of 2 identical register entries; the register fields below apply to each entry.

Offset: 0xb..0xc | Byte Offset: 0x2c..0x30 | Read/Write: R/W | Reset: 0x00010011 (0bx000000000000001x000000000010001)

Bit	Reset	Description
30:16	0x1	VBLANK_END: This field is the total number of lines after which vertical blank ends
14:0	0x11	HBLANK_END: This field is the total number of pixels after which horizontal blank ends.

27.8.10 SOR_NV_PDISP_HEAD_STATE4_0

This register sets the location of the horizontal and vertical blank start.

This is an array of 2 identical register entries; the register fields below apply to each entry.

Offset: 0xd..0xe | Byte Offset: 0x34..0x38 | Read/Write: R/W | Reset: 0x00110100 (0bx000000000010001x000000100000000)

Bit	Reset	Description
30:16	0x11	VBLANK_START
14:0	0x100	HBLANK_START

27.8.11 SOR_NV_PDISP_HEAD_STATE5_0

The following fields need to be set only for interlaced mode

This is an array of 2 identical register entries; the register fields below apply to each entry.

Offset: 0xf..0x10 | Byte Offset: 0x3c..0x40 | Read/Write: R/W | Reset: 0x00000001 (0bx000000000000000x000000000000001)

30:16	0x0	VBLANK_END_2
14:0	0x1	VBLANK_START_2

27.8.12 SOR_NV_PDISP_SOR_CRC_CNTRL_0

CRC_CONTROL

The main CRC enable bit flows along the pipeline. This register controls the injection of this bit at the top of the pipeline.

This register is double-buffered. The active value is updated at start of each frame from this 'arm' register.

Other registers such as SOR_STATE2.ASY_CRCMODE and SOR_*CRC* control the actual CRC logic, once enabled.

ARM_CRC_CONTROL enables or disables computation of CRC, effective at the start of next frame.

Offset: 0x11 | Byte Offset: 0x44 | Read/Write: R/W | Reset: 0x00000000 (0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx0)

Bit	Reset	Description
0	NO	ARM_CRC_ENABLE: 0 = NO 1 = YES 0 = DIS 1 = EN

27.8.13 SOR_NV_PDISP_SOR_CLK_CNTRL_0

LINK_SPEED

Programs the link speed for DP, i.e. it selects the multiplier used by the analog macro PLL.

For DP and TMDS, logic in the SOR will receive a version of this clock that is divided by 10. This field should only be changed when MODE_BYPASS is set to DP_SAFE or when the SOR is in safe mode.

It may take up to 200 microseconds for the PLLs in the analog macro to settle after this setting is changed.

Changing this field will require DP link re-training.

G1_62: Selects the 1.62 GHz link clock; PLL generates 1.62 GHz from 270MHz (multiplier = 6)

G2_7: Selects the 2.70 GHz link clock; PLL generates 2.70 GHz from 270MHz (multiplier = 10)

G5_4: Selects the 5.40 GHz link clock; PLL generates 5.40 GHz from 270MHz (multiplier = 20)

_LVDS: Link speed is 7*pixel clock used for LVDS (multiplier = 7)

CLK_SEL

The DP_SINGLE_LVDS macro has four input clocks. This field selects which clock is used for the internal logic. When the SOR is operating in DP mode, this should be set to one of the _DPCLK settings. When the SOR is operating in LVDS mode, this should be set to one of the _PCLK settings. This field should only be changed when the SOR is asleep or SOR_CLK_SEL is SAFE_SORCLK.

Please allow 200 microseconds for the PLLs in the macro to settle after changing this setting.

DIFF_PCLK and DIFF_PCLK inputs to macro are tied off. So software should only set to _SINGLE_(DP|P)CLK

_SINGLE_PCLK: Single ended pclk from the VPLLs

_DIFF_PCLK: Differential Pclk

_SINGLE_DPCLK: Single ended 270 MHz clock

_DIFF_DPCLK: Differential 270 MHz clock

Offset: 0x13 | Byte Offset: 0x4c | Read/Write: R/W | Reset: 0x0000001b (0bxxxxxxxxxxxxxxxxxxxxxxxxxxx0011011)

Bit	Reset	Description
6:2	G1_62	DP_LINK_SPEED: 6 = G1_62 10 = G2_7 7 = LVDS 20 = G5_4 29 = G8_1 8 = G2_16 9 = G2_43 12 = G3_24 16 = G4_32
1:0	DIFF_DPCLK	DP_CLK_SEL: 0 = SINGLE_PCLK 1 = DIFF_PCLK 2 = SINGLE_DPCLK 3 = DIFF_DPCLK

27.8.14 SOR_NV_PDISP_SOR_CAP_0

Serial output resource

The registers are defined as if all the SORs are fully featured (e.g., dual link). If a feature is not supported, the register remains accessible i.e., writes will not hang, reads will always return the default value.

Each SOR unit consists of two sub-links designated A and B. In single link operation, the A and/or B sub-link is active. In dual link modes, both links are active. SOR units consist of either one or two links operating in the following combinations:

Sub-link A (single link mode)

Sub-link B (single link mode)

Sub-link AB (dual single link copy mode)

Sub-links A+B (dual link mode)

Sub-links A,B (dual single link mode) planned for future enhanced mode.

Driver level control of the SOR is accomplished through methods in the core channel of the display engine. However, certain aspects of SOR operation are chip, process, voltage, and pixel clock dependent. These need to be controlled via registers by the VBIOS or RM during mode configuration.

This register reports the innate capabilities of the SOR. Note that depending on the actual board build configuration, these values may not be exactly the same ones reflected in the overall capabilities structure reported through the class. With the exception of the last bit, the values assumed by these fields are automatically produced by the hardware.

Note: *THIS REGISTER DEFINITION MUST BE KEPT COHERENT WITH DSI_SOR_CAP(i) !*

Usage: boot / initialization

27.8.15 SOR_NV_PDISP_SOR_PWR_0

This register contains bits that control the power state of the SOR. For simplicity, the sequencer will be used to perform all power control operations in the SOR (even in TMDS where the sequencing is relatively simple). This unifies the approach and makes it easier for the hardware and software to deal with the SOR's. At boot, the software must load and configure the SOR sequencer via the SOR_SEQ_CTL and SOR_SEQ_INST registers below. The sequencer must be properly programmed for power control to work.

NORMAL_STATE: Sets the normal operating state. There are two choices: powered up and powered down. To change this register, software should load in the new value and write SETTING_NEW=TRIGGER. Once the change has been successfully completed, SETTING_NEW will indicate DONE. This is the state that software will want to control in order to power up and down the interface.

NORMAL_START: The execution of the power up and power down sequence can be modified somewhat by choosing to use either the NORM or ALT program entry point.

SAFE_STATE: Sets the safe operating state. There are only two choices: powered up and powered down. To change this register, software should load in the new value and write SETTING_NEW=TRIGGER. Once the change has been successfully completed, the SETTING_NEW will indicate DONE. The execution of the power up and power down sequence can be modified somewhat by choosing to use either the standard or the alternate program entry point. This is the state that the hardware will use whenever it initiates the mode switch/shutdown procedure for HDMI. In general, this should be set to STATE_PD and left there always.

SAFE_START: The execution of the power up and power down sequence can be modified somewhat by choosing to use either the NORM or ALT program entry point.

HALT_DELAY: Once the sequencer gets to the instruction with the HALT=1, the program is essentially complete; that is, the attached unit is powered up or down as was requested. Some panels, however, have a minimum time before their state can be changed again. If the halt instruction has a non-zero delay, this bit will be set while that time expires.

MODE: The currently active state, normal or safe. After reset, the MODE is always SAFE.

SETTING_NEW: This bit is used to trigger a new setting of power mode to take effect. The typical procedure might be something like:

1. Make sure SETTING_NEW==DONE, i.e., not already an outstanding change request. If there is an outstanding change request, software must wait for it to complete.
2. Update the NORMAL and SAFE power mode fields.
3. Write SETTING_NEW=TRIGGER.
4. Poll for SETTING_NEW=DONE. If it does not happen within one frame time, then software may opt to accelerate the change by writing SOR_SEQ_CTL SWITCH=FORCE (be careful not to disturb other settings in that register!).

Note: *Software can start polling on SEQ_CTL_STATUS right after writing SETTING_NEW to trigger because SEQ_CTL_STATUS is set to RUNNING after 2 sorclk cycles which will always be less than the register read delay.*

Usage: boot / initialization / mode switch / normal operation / shutdown

Offset: 0x15 | Byte Offset: 0x54 | Read/Write: R/W | Reset: 0xXX000000 (0b0xxxxxxxxxxxxx00xxxxxxxxxxxxxx00)

Bit	R/W	Reset	Description

1	RW	NORMAL	NORMAL_START: 0 = NORMAL 1 = ALT
0	RW	PD	NORMAL_STATE: 0 = PD 1 = PU

27.8.16 SOR_NV_PDISP_SOR_PLL0_0

These registers configure the main SOR PLL and other frequency-dependent controls. The value loaded is a function of the pixel clock frequency, and whenever the pixel clock changes, these registers must be updated. In general, these registers will be updated during the second interrupt of a mode switch.

RESISTORSEL: Selects the internal resistor (0) or external resistor (1).

PULLDOWN: Weak pull-down enable

- 1 = 2Kohm pulldown on all outputs.
- 0 = Weak pulldown disabled.

Note: *Pulldown is also controlled by the sequencer. the pulldown is derived from an OR of:*

NV_PDISP_SOR_PLL0_PULLDOWN and the sequencer control of pulldown. This priv register field does not read the final pull-down value. In other words if software writes NV_PDISP_SOR_PLL0_PULLDOWN to DISABLED and sequencer pulldown is enabled, then an NV_PDISP_SOR_PLL0_PULLDOWN read will return DISABLED (while pulldown might be ENABLED due to sequencer control).

VCOCAP[3:0]: Selects the VCO capacitor and adjusts ring oscillator inter-stage load.

FILTER[3:0]

- Bits 2:0 select the loop filter and adjust the filter resistor value.
- Bit 3 controls this VCO startup bit for the TMDS_DUAL macro.
  - 0 - normal operation (default)
  - 1 - forced VCO oscillation mode

ICHPMP[3:0]: Specifies additions to the charge pump current in steps of 0.375 µA.

IOCURRENT[5:0]: Used for I/O control. This field has been replaced by the SOR_LANE_DRIVE_CURRENT registers.

TMDS_TERM: This bit is used to enable termination. Termination is only used in TMDS mode of operation, and may not be needed at lower operating frequencies (in which case, disabling it saves power).

TERMADJ[3:0]: Termination resistance control.

- 0000 - lowest

  ...
- 1000 - default

  ...
- 1111 - highest

COMPOUT: Termination calibration status. Only exists on DisplayPort SORs. This procedure should be performed on boot time to program TERMADJ correctly. Ideally this should be re-calibrated on Hot Plug Detect as well.

Procedure for termination calibration:

1. Start with the TERM_ADJ = 1000
2. Wait 100 µs and check COMPOUT
3. If COMPOUT=1, change the MSB to 0
4. Repeat for the next significant bits until all 4 bits are determined.

SUPPLYLEV[1:0]: Supply voltage level descriptor

LOADADJ[3:0]: Load pulse position adjust

LVDS_CM[1:0]: Reserved

COHERENTMODE: Output reference clock selector

0 = Non-coherent mode

1 = Coherent mode

BGAP_CNTL

Band-gap current setting control.

00 = Normal

01 = Positive coefficient

10 = Negative coefficient

11 = Normal + 12.5%

LOCKDET: Status signal indicating whether PLL is locked within the desired resolution.

0 = Not locked

1 = Locked

MISC_CNTL: Reserved.

DCIR_PLL_RESET: For the Display-over-PCIe® feature, a different type of analog macro was used in the SOR. The PLL in this macro needs to be held in reset during mode switches when the reference clock drops to safe-clock. A signal from the DCIR asserts this reset. NV_PDISP_SOR_PLL2_DCIR_PLL_RESET can be used to override this signal

OVERRIDE: The signal from the DCIR cannot power down the PLL.

ALLOW: The signal from the DCIR will be able to power down the PLL.

AUX0-AUX7: Most of these bits currently have no assigned function, but are provided to permit control of possible future features of the macro.

- AUX0: gate seq_2all_pll_pulldown from PULLDOWN. this can be used to remove sequencer control to PULLDOWN.
  - SEQ_PLL_PULLDOWN_OVERRIDE: Mask the pll_pulldown signal from the SOR sequencer so that it has no effect on the PLL_PULLDOWN port.
  - SEQ_PLL_PULLDOWN_ALLOW: Allow the pll_pulldown signal from the SOR sequencer to affect the PLL_PULLDOWN port.
- AUX1: Power on override for PLLCAPPD. The PLL in the analog macro will not run unless this is powered on. This can be used if the PLL needs to be powered on before the sequencer runs.
  - SEQ_PLLCAPPD_OVERRIDE: Mask the pll_reset signal from the SOR sequencer so that it has no effect on the PLLCPAPPD port of the SOR macro.
  - SEQ_PLLCAPPD_ALLOW: Allow the pll_reset signal from the SOR sequencer to assert PLLCAPPD.
- AUX2: gate PDBG from sequencer_pd_macro.

This can be used to force the Bandgap to power on.

  - OVERRIDE_POWERDOWN: gate the PDBG signal from the sequencer, PDBG can still be set by AUX6
  - ALLOW_POWERDOWN: normal operation, the PDBG signal from the sequencer can power down the bandgap
- AUX3: rotate green channel by 1 bit to reduce TMDS EMI
  - ROTATE_DISABLE: Do not rotate
  - ROTATE_ENABLE: Right-rotate green channel by 1 bit
- AUX4 has been used to enable duplicate controls for the Dual link HDCP. This is needed for some Dual Link panels.
  - DUPLICATE_CTRL_ENABLE: Copy the control bits from the primary link to the secondary.
  - DUPLICATE_CTRL_DISABLE: Zero out the ctrl bits on the secondary link.
- AUX5: No function
- AUX6: Main power down for bandgap and reference current setting circuitry
  (NOTE: This must be BANDGAP_POWERDOWN_DISABLE when in power down mode if 3.3V is seen on the IO_[A/B]_VDD rails)
  - BANDGAP_POWERDOWN_DISABLE: Allow the bandgap to powerup.
  - BANDGAP_POWERDOWN_ENABLE: Force the bandgap to powerdown.

- AUX7: Controls PDPORT in the analog macro which powers down all the output links/lanes; for instance, txd{n/p}0-9 for dual TMDS macro.
  - PORT_POWERDOWN_DISABLE: Allow the output ports to be turned on.
  - PORT_POWERDOWN_ENABLE: Force the output ports to power down. This will prevent any data from reaching the sink device.
- AUX8: No function.
- AUX9: No function.

27.8.19 SOR_NV_PDISP_SOR_PLL3_0

SOR_PLL3

This register directly controls the SOR analog macro. This register will either be programmed to fixed value on boot, or will need to be set in the SOR IED scripts.

KICKSTART

_DISABLE: Disable kickstart

_LOOP_40: short loop-filter 40% of avdd14

_LOOP_60: short loop-filter 60% of avdd14

_LOOP_50: short loop-filter 50% of avdd14

AVDD14_LEVEL

Internal regulated 1.4v voltage level control bits

_1_35V: 1.35V

_1_40V: 1.40V

_1_45V: 1.45V

_1_50V: 1.50V

No other values are valid for this field.

AVDD10_LEVEL

Internal regulated 1.0v voltage level control bits

_0_95V: 0.95V

_1_00V: 1.00V

_1_05V: 1.05V

_1_10V: 1.10V

No other values are valid for this field.

CLKDIST_MODE

Determining the clock distribution by CMOS buffer or CML buffers

_CMOS: CMOS buffers

_CML: CML buffers

PLLVDD_MODE

Field to determine the PLL voltage. Software needs to program this after power-on.

_3_3V: 3.3V --> For eDP

PLL_BYPASS

Set to DISABLE.

_ENABLE: Force the PLL output onto all lanes.

_DISABLE: Normal operation

TEST_REFCLK_EN

Software should not use this field.

BG_VREF_LEVEL

Control bits for the bandgap's output voltages

V(bandgap output) = 0.7v * (84% + BG_VREF_LEVEL*2%)

i.e.

0000 -> 0.588v

...

1000 -> 0.7v

...

1111 -> 0.798v

BG_TEMP_COEF

Control bits for the bandgap's temperature coefficient

Offset: 0x1a | Byte Offset: 0x68 | Read/Write: R/W | Reset: 0x38000440 (0b00111000000000000x00001000100xx00)

27.8.20 SOR_NV_PDISP_SOR_CSTM_0

The class permits the driver to select a number of operating modes for the SOR. Some of these modes (TMDS modes) are well defined and stable. Some modes may require customization by software before they will work. These registers are used for that customization. The fields available for customization are:

- PD_TXDA[3:0]: Bitwise control to power down the data pins of link A. Set to DISABLE to power down the pin.
- PD_TXDB[3:0]: Bitwise control to power down the data pins of link B. Set to DISABLE to power down the pin.
- PD_TXCA: Power down the clock pin of link A. Set to DISABLE to power down the pin.
- PD_TXCB: Power down the clock pin of link B. Set to DISABLE to power down the pin.

UPPER: Designates whether LVDS bank A is the upper, odd, or first pixel. Bank B is always set to !UPPER. The serial output from UPPER=1 will be Clock and A0-A3. The serial output from UPPER=0 (and DUALMODE) will be Clock and A4-A7. The default is bank A has UPPER=1, bank B has UPPER=0.

MODE[1:0]: Controls the digital output encoding applied to the data stream in custom mode and is only used for data muxing at the input of the SOR. This field does not control the TMDS macro.

- 0 = Reserved
- 1 = TMDS
- 2 = Reserved
- 3 = Reserved

LINKACTA, LINKACTB: Enables (1) or disables (0) the digital logic of links A and B

LVDS_EN: Output driver configuration for controlling the encoding of the data and the output common mode control. This does not control the internal clock dividers of the TMDS macro.

- 0 = TMDS
- 1 = Reserved

DUP_SYNC: Reserved

NEW_MODE: For backwards compatibility, set register to 0 so the old mode is used. In old mode, for the second link in dual link mode, all the control bits are zeroed out except for VSYNC. When a new mode is used, none of the control bits of the second link for dual-link mode are zeroed out.

BALANCED: Default is unbalanced. Has no effect in other modes.

PLLDIV: Controls the internal clock dividers of the TMDS_MACRO by setting the feedback divider for the high-speed PLL.

- 0 = Reserved
- 1 = divide by 10 (TMDS)

ROTCLK[3:0]: Skews the TXC clock to come out earlier. By changing this register value, you can configure the skew between output data (TX data) and output clock (TXC). This field specifies the number of sclk cycles which the output clock should come out earlier than its normal phase. For TMDS, sclk is a 10x pixel clock, so ROTVAL should be between 0-9. For LVDS, sclk is a 7x pixel clock, so ROTVAL should be between 0-7.

ROTDAT[2:0]: Before encoding the 8 bits of each color channel, the 8 bits within each color channel can be right rotated. All color channels are rotated by the same amount. For example, if ROTDAT = 6, then input channel data (r7,r6,r5,r4,r3,r2,r1,r0} would become {r5,r4,r3,r2,r1,r1,r7,r6}.

ROTDAT should be between 0 and 7.

TMDS modes of operation are standard and stable. The table below summarizes the fixed values the hardware uses for the above fields for TMDS operating modes.

	SINGLE TMDS_A	SINGLE TMDS_B	SINGLE TMDS_AB	SINGLE TMDS	Dual TMDS
PD_TXDA[2:0]	0	7	0	0	0
PD_TXDA[3]	1	1	1	1	1
PD_TXDB[2:0]	7	0	0	0	0
PD_TXDB[3]	1	1	1	1	1
PD_TXCA	0	1	0	0	0
PD_TXCB	1	0	0	0	1
UPPER	1	1	1	1	1
MODE[1:0]	1	1	1	1	1
LINKACTA	1	0	1	1	1
LINKACTB	0	1	1	1	1
LVDS_EN	0	0	0	0	0
DUP_SYNC	0	0	0	0	0
NEW_MODE	0?	1	1	1	0?
BALANCED	0	0	0	0	0
PLLDIV	1	1	1	1	1
ROTCLK[3:0]	0	0	0	0	0
ROTDAT[2:0]	0	0	0	0	0

Where X (ROTCLK[3:0]) = NV_PDISP_SOR_CSTM_ROTCLK;

The first register defines the total custom mode. This is useful for defining possible new modes of operation. Which is to say, this is a debug register set. Software should really never need to use it. Also, note that if LVDS_ONLY=TRUE, then this register cannot be used. This register is intended to have the same format as the second register.

Usage: boot / initialization / mode switch

Offset: 0x1b | Byte Offset: 0x6c | Read/Write: R/W | Reset: 0x0001c800 (0bx0000000xx0x000111001x0000000000)

27.8.21 SOR_NV_PDISP_SOR_BLANK_0

This register can be used to override the SOR output resource pixels with blank data.

OVERRIDE: Setting this field to true will override the pixel bus from the RG and output black pixels instead.

TRANSITION

This field controls the timing of the output resource blank override. The choices are

- IMMEDIATE The output resource will be blanked or restored to its previous output data immediately.

- NEXT_VSYNC The output resource will be blanked or restored to its previous output data at the next vsync.

STATUS This read-only field returns BLANKED when the output resource is sending blank pixels forced by the OVERRIDE bit, otherwise it returns NOT_BLANKED.

Usage: boot / initialization / mode switch / normal operation

Offset: 0x1f | Byte Offset: 0x7c | Read/Write: R/W | Reset: 0x0000000X (0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx00)

Bit	R/W	Reset	Description
2	RO	X	STATUS: 0 = NOT_BLANKED 1 = BLANKED
1	RW	IMMEDIATE	TRANSITION: 0 = IMMEDIATE 1 = NEXT_VSYNC
0	RW	FALSE	OVERRIDE: 0 = FALSE 1 = TRUE

27.8.22 SOR_NV_PDISP_SOR_SEQ_CTL_0

Sequencer control registers for SOR. Up to three pins can be assigned to an SOR for use in controlling the power to an attached LVDS flat panel. The meaning of any particular pin and whether it is actually available to this SOR is controlled in either the host or PCB manager. In addition, the sequencer can override the individual link clock and data power control pins, thereby forcing them all into disabled or tristate mode and it can override the DE signal from the RG (for TMDS mode) to force the link to become inactive.

PU_PC: The program counter for the start of the power up program sequence. Always 0.

PU_PC_ALT: The alternate entry point into the power up program sequence. Defaults to the same value as PU_PC.

PD_PC: The program counter for the start of the power down program sequence. Defaults to 8, evenly dividing the available program space.

PD_PC_ALT: The alternate entry point into the power down program sequence. Defaults to the same default value as PD_PC.

PC: The current value of the program counter (useful for status and debug).

STATUS: Indicates if the sequencer is STOPPED or RUNNING.

SWITCH: If a particular sequencer instruction is waiting for VSYNC to arrive, writing this bit to FORCE will cause the wait condition to be satisfied immediately.

The sequencer can be run both when the SOR is attached and detached. However, when sor is detached WAIT_UNITS_VSYNC is not honored. Also, BLANK_DATA, BLANK_DE, BLANK_V and BLANK_H are ignored.

NV_PDISP_SOR_DP_LINKCTL_ENABLE no longer controls PDBG or PLLCAPPD. The SOR sequencer or NV_PDISP_SOR_PLL2 should be used for these control bits.

Usage: boot / initialization / mode switch

Offset: 0x20 | Byte Offset: 0x80 | Read/Write: R/W | Reset: 0xX00X880X (0bxxxxxxxxxxxxxxxx100010000000xxxx)

Bit	R/W	Reset	Description
7:4	RW	0x0	PU_PC_ALT
3:0	RO	X	PU_PC

27.8.23 SOR_NV_PDISP_SOR_LANE_SEQ_CTL_0

The SOR_LANE_SEQ_CTL register is used to control the operation of the SOR lane sequencer. The lane sequencer is used to power up or power down the lanes in the analog macro one at a time to prevent spikes on the power rail.

LANE_STATE

This is the current status of each lane's power.

	DP	TMDS	LVDS
LANE0	DPA lane2	LinkA Lane0 LinkA Lane0	
LANE1	DPA lane1	LinkA Lane1	LinkA Lane1
LANE2	DPA lane0	LinkA Lane2	LinkA Lane2
LANE3	unused	unused	LinkA Lane3
LANE4	DPA lane3	LinkA clock	LinkA clock
LANE5	DPB lane2	LinkB Lane0	LinkB Lane0
LANE6	DPB lane1	LinkB Lane1	LinkB Lane1
LANE7	DPB lane0	LinkB lane2	LinkB Lane2
LANE8	unused	unused	LinkB Lane3
LANE9	DPB lane3	LinkB clock	LinkB clock

DELAY

Number of microseconds to delay between each lanes' power state change.

The recommended value is 1us.

NEW_POWER_STATE

This controls whether the lanes should be powered up or powered down when this sequencer is triggered by SETTING_NEW_TRIGGER.

PU: Power up the requested lanes

PD: Power down to the requested lanes

SEQUENCE

Controls the direction of the power up or power down sequence.

UP: Lanes are powered up in increasing order

DOWN: Lanes are powered up in decreasing order

STATE

Whenever this sequencer is running, this field will be set to _BUSY.

SETTING_NEW

This bit can be used to run this sequencer outside of the normal SOR sequencer operation. If the sequencer is already BUSY because of a request from the SOR sequencer, the lane sequencer will wait until that request is complete before servicing this request. It is recommended that this trigger should only be used when the SOR sequencer is not running in order to prevent this type of interaction.

The lane sequencer looks at the current protocol, NV_PDISP_SOR_DP_LINKCTL_ENABLE and whether the request is power-up or power-down to determine what the new lane state should be.

DP_LINKCTL.ENABLE	NEW_POWER_STATE	Protocol	New Lane State(1=POWER DOWN)
0	0	LVDS	LVDS.PD_TXD* | ~LVDS.LINKACT | SEQ_INST.TRISTATE_IOS
0	0	CSTM	CSTM.PD_TXD* | ~CSTM.LINKACT | SEQ_INST.TRISTATE_IOS
0	1	!DP	1
X	X	DP	~DP_PADCTL.PD_TXD*
1	X	X	~DP_PADCTL.PD_TXD*

Usage: boot / initialization / mode switch

Offset: 0x21 | Byte Offset: 0x84 | Read/Write: R/W | Reset: 0xX0011XXX (0b0xxxxxxxxxx0xxx10001xxxxxxxxxxx)

Bit	R/W	Reset	Description

0	RO	X	LANE0_STATE: 0 = POWERUP 1 = POWERDOWN

27.8.24 SOR_NV_PDISP_SOR_SEQ_INSTx_0

This register set is used to preload the power-up and power-down sequences. Each step of the program performs the following based on the fields below.

First, either delay for WAIT time or until the next leading edge of vertical sync from the RG. The range of WAIT is 0-1023 us or 0-1023 ms.

Second, set sequencer outputs (A, B, I/O pin powerdown override, etc.) to the values specified in the instruction. The meaning and use of pins A and B is chip and board dependent i.e., something the SW will need to know how to configure.

Lastly, if HALT==1, stop, otherwise, execute the next instruction.

WAIT_TIME: Amount of time to wait (in either us or ms). Note if WAIT_UNITS=VSYNC, the WAIT_TIME field is ignored.

WAIT_UNITS: Wait delay mode, us, ms, VSYNC.

PDPLL: Asserts the PDPLL port on the analog macro, powering down the pll. This sequencer control can be overridden by NV_PDISP_SOR_PLL2_AUX1_SEQ_PLLCAPPD_OVERRIDE. NV_PDISP_SOR_PLL0_PWR_OFF will force PDPLL to be asserted, regardless of the state of the sequencer.

YES: Power down the PLL.

NO: Do not power down the PLL

PDPORT: Asserts the PDPORT port on the SOR analog macro. This powers down all output lanes. This sequencer control can be overridden by NV_PDISP_SOR_DP_LINKCTL_ENABLE. NV_PDISP_SOR_PLL2_AUX7_PORT_POWERDOWN_ENABLE will force PDPORT to be asserted, regardless of the state of the sequencer.

YES: Power down the port

NO: Do not power down the port

LANE_SEQ: When set to _RUN, the sequencer will kick off the Lane Sequencer (see NV_PDISP_SOR_LANE_SEQ_CTL). The SOR sequencer will not continue to the next instruction until the lane sequencer completes. The lane sequencer will run before the other commands in the current instruction take effect and before the delay in the current instruction.

SEQUENCE: This field controls the direction of the lane power up or power down sequence.

UP: Lanes are powered up or down in increasing order

PDTXD_0, PDTXD_1 .... PDTXD_9

DOWN: Lanes are powered up or down in decreasing order

PDTXD_9, PDTXD_8 .... PDTXD_0

PIN_A, PIN_B: State to drive the external pin to. The connection state of these pins is controlled in either the host or the pcb manager.

DRIVE_PWM_OUT_LO: Drive the PWM circuit output lo. Note that this driven lo condition is applied before the optional PWM_POLARITY control, so that the external pin can actually be driven hi or lo.

TRISTATE_IOS: Coerce all output pins to tristate.

0 = enable output pins

1 = disable/tristate output pins

For chips with the SOR Lane Sequencer, this does not take effect until the Lane Sequencer is run. Since Lane Sequencer runs before the values in the current instruction take effect, TRISTATE_IOS should be set to the desired value on the instruction before LANE_SEQ_RUN.

BLACK_DATA: Override the pixel bus from the rg, and replace the pixels with black.

0 = normal data output

1 = force black output

BLANK_DE, BLANK_H, BLANK_V: Override the de, hsync, and vsync signals from the rg. The signals will be forced to the inactive i.e. deasserted state.

0 = normal output

1 = force signal inactive/deasserted

ASSERT_PLL_RESET: Assert reset to the PLL (PLLCAPPD) This sequencer control can be overridden by NV_PDISP_SOR_PLL2_AUX1_SEQ_PLLCAPPD_OVERRIDE.

NV_PDISP_SOR_PLL2_AUX8_SEQ_PLLCAPPD_ENFORCE_ENABLE will force PLLCAPPD to be asserted, regardless of the state of the sequencer.

0 = normal

1 = force reset

POWERDOWN_MACRO: Override LINKACTA, LINKACTB and force TMDS macro to powerdown state.

(Only controls PDBG)

0 = normal operation

1 = force powerdown

PULLDOWN: Weak pulldown enable (Only exists on TMDS SORs)

1 = 2Kohm pulldown on all outputs.

0 = Weak pulldown disabled.

Note: *These program examples are included here to illustrate the operation of the sequencer. They should not be assumed to be correct for actual operation.*

Power-up sequence LVDS (assume PIN_A controls panel power, PIN_B controls backlight).

Initial conditions (assume panel off = backlight off = 0):

HALT=0

PIN_A=0

PIN_B=0

DRIVE_PWM_OUT_LO=0

TRISTATE_IOS=1

BLACK_DATA=1

BLANK_DE=1

BLANK_H=1

BLANK_V=1

ASSERT_PLL_RESET=1

POWERDOWN_MACRO=1

Program

1. POWERDOWN_MACRO=0, WAIT ?

SOR PLL_PULLDOWN logic has been updated and allows either Sequencer controls it or a register write controls it. It can be best described as below:

```
-------------------------------------------------------------------------------------------------
|PLL_POWERDOWN  || NV_PDISP_SOR_PLL0_PULLDOWN   | NV_PDISP_SOR_PLL2_AUX0 |
NV_PDISP_SOR_SEQ_INST_PLL_PULLDOWN|
-------------------------------------------------------------------------------------------------
|SEQ Toggles it ||  DISABLE                 | PULLDOWN_ALLOW        |    1/0
|
-------------------------------------------------------------------------------------------------
|Always DISABLE ||  DISABLE                | PULLDOWN_OVERRIDE     |    Don't Care
|
-------------------------------------------------------------------------------------------------
|Always ENABLE  ||  ENABLE                 | Don't Care            |    Dont' Care
|
-------------------------------------------------------------------------------------------------
```

Note: *Register set can be accessed as an array as defined here or as individual registers as defined later.*

27.8.25 SOR_NV_PDISP_SOR_PWM_DIV_0

These two registers controls the optional PWM function for backlight intensity control. The PWM circuit will be driven off the buffered crystal clock. The first register (SOR_PWM_DIV) prescales the crystal clock and sets the resolution range.

DIVIDE: This field defines the period of the PWM output. Note that a value of 0 has the special meaning to disable pwm output.

pwm freq = reference clock / DIVIDE

DUTY_CYCLE: This specifies the duty cycle of PWM output. In other words, the number of cycles during pwm period (DIVIDE), hw will assert high (Hi_PERIOD).

CLK_SEL: Starting gt21x, sor pwm can be run at pixel clock. This field selects if PWM is run at crystal clock or pixel clock.

SETTING_NEW: Provides the mechanism to trigger a new configuration for both registers (SOR_PWM_DIV and SOR_PWM_CTL). When updating SOR_PWM_DIV, software must be careful to not overwrite an old value in duty cycle unless doing so is desired. Once a state change has been requested, it must be permitted to complete before attempting to trigger another one.

Examples of computation:

If Fs is the desired Frequency

DIV_DIVIDE = (reference freq / Fs); DIVIDE > 0 and integer.

DUTY_CYCLE Range: 1 to DIV_DIVIDE

To get minimum intensity: DUTY_CYCLE = 1

To get maximum intensity: DUTY_CYCLE = DIV_DIVIDE

Example 1:

For reference clock 27 MHz (Xtal)

Desired: 210 Hz (Fs)

DIV_DIVIDE = (27000000/210) = 128571.43

Round down to the 128571 causes desired Freq Fs = 210.0007 Hz

Round up to the 128572 causes desired Freq Fs = 209.999 Hz

Example 2:

For Crystal 120 MHz (pixel clock)

Desired: 50000 Hz (Fs)

DIV_DIVIDE = (120000000/50000) = 2400

Usage: boot / initialization

Offset: 0x32 | Byte Offset: 0xc8 | Read/Write: R/W | Reset: 0x00000000 (0bxxxxxxxx00000000000000000000000)

27.8.27 SOR_NV_PDISP_SOR_XBAR_CTRL_0

This register controls the xbar between the SOR and the TMDS analog macro. There are 2 links per SOR and 4/5 TMDS channels per link. Within the same link, the xbar are fully connected (i.e. each output channel can be connected to any channel). The xbar output can also be driven to zero by setting XSEL_* to XSEL_*_ZERO. Also, the two link can be swapped by setting LINK_SWAP to one. This xbar can also be bypassed by setting BYPASS to one.

Usage: boot / initialization

Offset: 0x4a | Byte Offset: 0x128 | Read/Write: R/W | Reset: 0x8d111a23 (0b10001101000100010001101000100011)

27.8.29 SOR_NV_PDISP_SOR_DP_LINKCTL0_0

PROGRAMMING NOTE:

The SOR_DP registers are doubly indexed. The first index selects the SOR, the second index selects port within the SOR. Some DP SORs will support DPA port and DPB port. The capability bits for each SOR will determine what ports exist.

The field NV_PDISP_SOR_DP_LINKCTL_ENABLE is used to enable a specific port on a given OR.

SOR_DP_LINKCTL

ENABLE

- _YES The current DP port is enabled and data will be driven to the associated pins
- _NO The current DP port is not enabled and the port will be powered down.

Each DP SOR has two DP ports, but only one can be active at any given time. Only one of the SOR_DP_LINKCTL_ENABLE fields should be set to _YES. Whichever set of SOR_DP registers has ENABLE set to YES will be the set that controls the DP hardware.

This field must be set to _YES before the first test pattern is sent out for link training. If this field is ever set to _NO, the link must be re-trained before it can be used again.

A certain number of active symbols are metered out every transfer unit to maintain a constant data rate. Since hardware has limited precision to represent the number to active symbols, an error will add up over the line width. TUSIZE is programmed to minimize the error to a value that is close to zero or can be handled by the buffer available in the hardware to sustain the slightly higher or lower data rate than the calculated value.

TUSIZE

Transfer unit size - Valid range 64 to 32

A certain number of active symbols are metered out every transfer unit to maintain a constant data rate. Since hardware has limited precision to represent the number to active symbols, an error will add up over the line width. TUSIZE is programmed to minimize the error to a value that is close to zero or can be handled by the buffer available in the hardware to sustain the slightly higher or lower data rate than the calculated value.

SYNCMODE

- _DISABLE = Link clock and stream clock asynchronous
- _ENABLE = Link clock and stream clock synchronous

This bit is used to specify whether the link clock and pixel clock are synchronous or not. This bit is included in the Main Stream Attribute data. The DP hardware treats all pixel clocks as asynchronous, so this should be left as _DISABLE.

ENHANCED_FRAME

- _DISABLE = Enhanced Framing symbol sequence for BS, SR, CPBS, and CPSR not supported.
- _ENABLE = Enhanced Framing symbol sequence for BS, SR, CPBS, and CPSR supported.

Enhanced Framing is required for HDCP over DP. This should be set to _ENABLE when the SOR is being used for DP and HDCP is enabled.

LANE_COUNT

- _ZERO = no lanes, DP disabled
- _ONE = One lane
- _TWO = Two lanes
- _FOUR = Four lanes

This field controls the lane configuration of the DP datapath. Power controls for individual lanes are in NV_PDISP_SOR_DP_PADCTL. For one-lane configuration, Lane0 is used. For 2-lane configuration, Lane0 and Lane1 are used. Source may choose any lane count as long as it does not exceed the capability of DisplayPort receiver as indicated in the receiver capability field. This field should only be changed when the SOR is asleep.

COMPLIANCE TEST PATTERN

This field is not implemented in Hardware

FORCE IDLE PATTERN

This is a diagnostics bit which when set will force the hardware to send idle pattern on all lanes enabled. By default, the DP hardware will automatically send out the idle pattern if the OR goes to sleep while the link is still trained. This field provides an additional override if needed.

- _NO - don't force idle pattern
- _YES - force idle pattern

Offset: 0x4c | Byte Offset: 0x130 | Read/Write: R/W | Reset: 0x00000100 (0b0xx0xxxxxxx00000x0xxx0x1000000x0)

27.8.31 SOR_NV_PDISP_SOR_LANE_DRIVE_CURRENT0_0

SOR_LANE_DRIVE_CURRENT

Transmitter main output drive level. Used to set transmitter main output drive level for each of the four lanes.

bit<7> is dummy

bit<6:3> is decoded into each 3.2mA unit

bit<2:0> are mapped to binary weighted units of 1.6mA, 0.8mA, 0.4mA. Each step is 400uA; the max setting=x100 0111=28mA

- x000 0000 -> 0mA

  ...

- x100 0111 -> 28mA max

  ...

- x111 1111 -> maxed out

Voltage is for single-ended output amplitude with double 50 ohm termination. Voltage is independent of termination control.

This register will be used during link training to set the voltage swing as requested by the sink device. The value to set for the drive current is dependent on the current value of the pre-emphasis in SOR_LANE_PREEMPHASIS. There is a separate LEVEL define for each valid pre-emphasis value.

Note: *When DP is active, the LANE0_DP_LANE2 field should be used for lane2 and LANE2_DP_LANE0 should be used for lane0.*

Offset: 0x4e | Byte Offset: 0x138 | Read/Write: R/W | Reset: 0x00000000 (0b00000000000000000000000000000000)

15:8	0x0	LANE1_DP_LANE1
7:0	0x0	LANE0_DP_LANE2

27.8.33 SOR_NV_PDISP_SOR_LANE4_DRIVE_CURRENT0_0

SOR_LANE4_DRIVE_CURRENT

Non-DP SORs contain five total lanes; four data lanes and one clock. There was not enough room in one register to fit all five lanes. LANE4 controls the fifth lane.

Offset: 0x50 | Byte Offset: 0x140 | Read/Write: R/W | Reset: 0x00000000 (0bxxxxxxxxxxxxxxxxxxxxxxxxxx00000000)

Bit	Reset	Description
7:0	0x0	LANE4

27.8.34 SOR_NV_PDISP_SOR_LANE4_DRIVE_CURRENT1_0

Offset: 0x51 | Byte Offset: 0x144 | Read/Write: R/W | Reset: 0x00000000 (0bxxxxxxxxxxxxxxxxxxxxxxxxxx00000000)

Bit	Reset	Description
7:0	0x0	LANE4

27.8.35 SOR_NV_PDISP_SOR_LANE_PREEMPHASIS0_0

SOR_LANE_PREEMPHASIS

Transmitter main output pre-emphasis for each of the four lanes.

bit<7> is dummy

bit<6:3> is decoded into each 1.6mA unit

bit<2:0> is mapped to binary weighted units of 0.8mA, 0.4mA, 0.2mA. Each step is 200 µA; the maximum setting=x010 1111 = 9.4mA, if the main driver is not borrowing; the main driver has higher priority to borrow.

- x000 0000 -> 0mA

  ...

- x010 1111 -> 9.4mA max

  ...

- x111 1111 -> maxed out

This register will be used during link training to set the pre-emphasis level of each lane as requested by the sink device. The sink device may request this value to be changed during Training Pattern 1 or Training Pattern 2 during link training.

The pre-emphasis value for a given level is dependent on the drive current setting.

There is a separate LEVEL define for each valid drive current setting.

Note: *When DP is active, the LANE0_DP_LANE2 field should be used for lane2 and LANE2_DP_LANE0 should be used for lane0.*

7:0	0x0	LANE0_DP_LANE2

27.8.41 SOR_NV_PDISP_SOR_DP_CONFIG0_0

SOR_DP_CONFIG

This register contains various other controls which affect the behavior of the DP logic.

WATERMARK

This field defines the number of symbols that the DP logic will wait for at the beginning of a line before ending blanking. This number will be based on the pixel rate, the link speed, bits per pixel, tusize and line active width.

IDLE_BEFORE_ATTACH

This field should be set to _ENABLE.

RD_RESET_VAL

When training pattern 2 begins, the running disparity of the 8B10B encoding is reset. The DP spec defines that the disparity of the first symbol sent out should be negative. By resetting the 8B10B running disparity to positive, the first symbol sent out will have a negative disparity.

- _POSITIVE: The internal running disparity is reset to positive, so the first 10b symbol sent out will have negative disparity.

- _NEGATIVE: The internal running disparity is reset to negative, so the first 10b symbol send out will have positive disparity.

This value is not expected to change unless a panel is encountered that expects a different disparity.

ACTIVESYM_COUNT, ACTIVESYM_FRAC and ACTIVESYM_POLARITY:

These three fields control the number of active symbols sent out every transfer unit. Hardware maintains a TU count which is used for metering. ACTIVESYM_COUNT is the number of symbols sent out every transfer irrespective of the tu count. Based on the ACTIVESYM_POLARITY which can be 0 or 1, we can send extra symbol for a particular TU based on the ACTIVESYM_FRAC (active fraction). If active polarity is 0 and ACTIVESYM_FRAC is say 5, hardware send an extra symbols every 5th TU. If active polarity is 1 and ACTIVESYM_FRAC is 5, hardware will send an extra symbols every TU except for the 5th TU.

For instance if the number of active symbols per TU is calculated to be 17.2, ACTIVESYM_COUNT is set to 17. Fractional value is 0.2 = 1/5 which translates to 1 symbol every 5 TUs. This translates to ACTIVESYM_FRAC of 5 and ACTIVESYM_POLARITY of 0.

For instance if the number of active symbols per TU is calculated to be 17.8, ACTIVESYM_COUNT is set to 17. Fractional value is 0.8 = 4/5 which translates to 1 symbol every TU except for the 5th TU. This translates to ACTIVESYM_FRAC of 5 and ACTIVESYM_POLARITY of 1.

ACTIVESYM_COUNT, ACTIVESYM_FRAC and ACTIVESYM_POLARITY:

These three fields control the number of active symbols sent out every transfer unit. Hardware maintains a TU count which is used for metering. ACTIVESYM_COUNT is the number of symbols sent out every transfer irrespective of the tu count. Based on the ACTIVESYM_POLARITY which can be 0 or 1, we can send extra symbol for a particular TU based on the ACTIVESYM_FRAC (active fraction). If active polarity is 0 and ACTIVESYM_FRAC is say 5, hardware send an extra symbols every 5th TU. If active polarity is 1 and ACTIVESYM_FRAC is 5, hardware will send an extra symbols every TU except for the 5th TU.

For instance if the number of active symbols per TU is calculated to be 17.2, ACTIVESYM_COUNT is set to 17. Fractional value is 0.2 = 1/5 which translates to 1 symbol every 5 TU's. This translates to ACTIVESYM_FRAC of 5 and ACTIVESYM_POLARITY of 0.

For instance if the number of active symbols per TU is calculated to be 17.8, ACTIVESYM_COUNT is set to 17. Fractional value is 0.8 = 4/5 which translates to 1 symbol every TU except for the 5th TU. This translates to ACTIVESYM_FRAC of 5 and ACTIVESYM_POLARITY of 1.

27.8.43 SOR_NV_PDISP_SOR_DP_MN0_0

SOR_DP_MN

This register contains controls to tweak the values used for M and N in the Main Stream Attribute data. These controls are for debugging purposes and possible workarounds. See Section 2.3.3 of the DisplayPort specification for more detailed descriptions of M and N.

N_VAL

This is the value that will be used for calculating M. This value is not used in the Main Stream Attributes. Main Stream attributes always send 2^15 for Nvid. This should not need to be programmed beyond its default value. If this value needs to be changed, it should be done while the OR is detached. Otherwise, the calculated M value will be incorrect for some time, or until the next mode switch.

M_DELTA: This defines an offset that will be used to modify the calculated M value. This should not need to be programmed beyond its default value.

M_MOD: Describes how the M_DELTA field should be applied to the M value.

- _NONE: The M_DELTA is ignored and not used.
- _INC: The M_DELTA value is added to M.
- _DEC: The M_DELTA value is subtracted from M.

This should not need to be programmed beyond its default value.

Offset: 0x5a | Byte Offset: 0x168 | Read/Write: R/W | Reset: 0x00008000 (0b00xx00000000000010000000000000000)

23:0	0x8000	N_VAL

27.8.45 SOR_NV_PDISP_SOR_DP_PADCTL0_0

SOR_DP_PADCTL

This register directly controls the DP pads. Some values in this register are only valid in DP mode when NV_PDISP_SOR_DP_LINKCTL_ENABLE == _YES.

PD_TXD_

Individual controls to power down the lanes. NV_PDISP_SOR_DP_LINKCTL_LANE_COUNT sets the number of lanes that are active in the DP datapath. These fields control power to the macro pins. When reducing the number of active lanes, the inactive lanes should be powered down before the lane configuration is changed. See Section 5.1.2 of the DP Specification.

If a lane is powered down, link training will need to be done before that lane can be used again.

- _YES: Force the lane to power down
- _NO: Enable power to the lane. Do not power down.

Only valid in DP mode when NV_PDISP_SOR_DP_LINKCTL_ENABLE == _YES.

COMMONMODE_TXD_

This is used to force the lanes to output the common mode voltage. This is required before link training begins. Section 3.5.3.3 of the DP specification dictates that the lanes must be precharged to the common mode voltage for at least 10 microseconds before beginning link training. Please see the DP specification for more information:

> ***Note:*** *When DP is active, the TXD_0_DP_TXD_2 field should be used for lane2 and TXD_2_DP_TXD_0 should be used for lane0.*

- _DISABLE: Normal operation
- _ENABLE: Force the lanes to output the common mode voltage

TX_PU_VALUE: TX pull-up current source drive

- x000xxxx -> 0mA
- x001xxxx -> 1mA
- x010xxxx -> 2mA
- x011xxxx -> 3mA
- x100xxxx -> 4mA
- x101xxxx -> 5mA
- x110xxxx -> 6mA

TX_PU

- _ENABLE: Pull-up current sources enabled

- _DISABLE: Pull-up current sources disabled

Currently it is unknown if this will be needed.

VCMMODE

VCM pin mode select

- _TRISTATE:tristate (default)
- _TEST_MUX:under test-mux control
- _WEAK_PULLDOWN:0 V weak pull-down
- _STRONG_PULLDOWN: 0V strong pull-down

This is a test mode pin, it does not need to be programmed by software.

REG_CTRL: Internal regulator control. These are spare input bits to the analog macro that have no defined function currently.

PAD_CAL_PD

Powerdown control for the pad calibration logic.

- _POWERDOWN: Power down
- _POWERUP:Normal operation

VCO_2X: This is a VCO startup diagnostics control input to the DP analog macro.

- _ENABLE: forced VCO oscillation mode
- _DISABLE: normal VCO operation

VCOLIMIT_SEL:

- When vcolimit_sel=0, the clamp counter counts 128 cycles <-> 474 ns @270 MHz;
- When vcolimit_sel=1, the clamp counter counts 32 cycles <-> 118 ns @ 270 MHz.

LOADADJ_SYNC_EN:

- When loadadj_sync_en=0,the loadadj-calibration code is reset to 0000;
- When loadadj_sync_en=1,the loadadj-calibration code is swept and the best value is used.

Used during LOADADJ calibration. Must be set to 0 and then to 1 to trigger the calibration sequence.

LOADADJ_BYPN:

- When loadadj_bypn=0, the loadadj-calibration block is bypassed;
- When loadadj_bypn=1, the loadadj-calibration block is being used.

Used during LOADADJ calibration to select the auto-cal value instead of the register value.

VCOCALIB_ENB:

- When vcocalib_enb=0,enable vco-calibration, sweep the vcogain code and the best value is used.
- When vcocalib_enb=1, reset the vco-calibration block.

Used during VCO Gain Calibration. Must be set to 1 and then back to 0 to trigger the calibration sequence.

VCOCALIB_OVERWRB:

- When vcocalib_overwrb=0, overwrite/disable the vco-calibration block;
- When vcocalib_overwrb=1, enable the vco-calibration block.

Used during VCO Gain Calibration.

VCOCALIB_TS0:

- When vcocalib_ts0=0, vco-calibration block counts 96 cycles <-> 355 ns @270 MHz
- When vcocalib_ts0=1, vco-calibration block counts 128 cycles <-> 474 ns @270 MHz

VCOLIMIT_DISABLE:

- When vcolimit_disable=0, enable the VCO-protection clamp;
- When vcolimit_disable=1, disable the VCO-protection clamp.

27.8.47 SOR_NV_PDISP_SOR_DP_SPARE0_0

NV_PDISP_SOR_DP_SPARE

Reserved for future features

SEQ_ENABLE

Used to enable the sequencer in DP mode. This needs to be set for eDP where we need to run sequencer to control backlight.

PANEL

Specify whether the DP panel is external or internal (notebook panel)

- EXTERNAL: An external DP panel is connected, normal operation
- INTERNAL: This port is connected to an internal panel. In this mode, the upstream status will report an internal link, and the scrambler will reset to 0xFFFE instead of 0xFFFF

SOR_CLK_SEL

This is used for SOR testbench. Specify whether to use a safe clock or the macro clock as the SOR clock.

- SAFE_SORCLK: Use the safe clock as the SOR clock
- MACRO_SORCLK: Use the macro clock as the SOR clock

DISP_VIDEO_PREAMBLE_CYA

This is used to select between video preamble from display versus the locally generated video preamble signal

- DISABLE: Use locally generated video preamble
- ENABLE: Use video preamble from display (To be used for legacy support of HDMI programming)

Offset: 0x60 | Byte Offset: 0x180 | Read/Write: R/W | Reset: 0x00000002 (0b00000000000000000000000000000010)

0	NO	SEQ_ENABLE: 0 = NO 1 = YES

27.8.49 SOR_NV_PDISP_SOR_DP_AUDIO_CTRL_0

SOR_DP_AUDIO_CTRL

ENABLE

This is the global enable/disable field for Audio over DisplayPort. When set to _NO, no audio stream packets, audio timestamp packets, or audio infoframes will be sent. When set to _YES, audio stream packets will be sent whenever audio arrives, and timestamp and infoframe packets will be sent once per frame during hblank.

MUTE

This field controls the AudioMute_Flag in the VB-ID. When muted, audio samples sent to the sink device are not played. This is an override to the audio mute signal coming from the Azalia Codec.

- DISABLE: The mute is not asserted, audio will be audible
- ENABLE: The mute is asserted. The sink device should not play any audio samples that are sent. If SW changes MUTE from ENABLE to AUTO, hardware will take control of unmuting after the new audio infoframe and audio timestamp have been sent.
- AUTO: The mute signal is controlled by hardware. Audio is muted during audio format or audio timing change and unmuted after the new audio infoframe and audio timestamp have been sent.

AUDIO INFOFRAME HEADER_OVERRIDE

HB1-HB3 are fixed values as defined by the DisplayPort specification. This field will let the values in NV_PDISP_HDMI_AUDIO_INFOFRAME_HEADER override the default values. This can be used for Debugging purposes and can be left at DISABLE for production.

- DISABLE: Use the default values of HB0=0x00, HB1=0x84, HB2=0x1B, HB3=0x44
- ENABLE: Replace the contents of the Audio Infoframe Header with the values in NV_PDISP_HDMI_AUDIO_INFOFRAME_HEADER

GENERIC_INFOFRAME_ENABLE

This field allows software to send infoframes (AVI, etc.) other than audio infoframe. When enabled NV_PDISP_SOR_DP_GENERIC_INFOFRAME_HEADER, NV_PDISP_SOR_DP_GENERIC_INFOFRAME_SUBPACK* priv regs is used as infoframe header and packet data. The infoframe is sent once per vertical blanking period.

PACKETID

This field can be left at 0.

CT_SELECT (Coding Type), CC_SELECT (Channel Count), SF_SELECT (Sampling Frequency), SS_SELECT (Sample Size), CA_SELECT (Channel/Speaker Allocation)

These fields control the values of several fields in the Audio Infoframe. The Azalia codec will detect these values, and can automatically place the correct values in the Infoframe.

- SW: The Audio Infoframe will contain the value from NV_PDISP_HDMI_AUDIO_INFOFRAME_SUBPACK0*
- HW: The Audio Infoframe will contain the value set by the Azalia codec.

- NEW_SETTINGS

All the fields/settings in this register will not take effect until NEW_SETTINGS is set to _TRIGGER. When the new settings are active, this field will automatically be set to _DONE. If hardware is sending an audio packet when this is set to trigger, then it will wait for the completion of the packet before the new settings are activated. Hence the maximum delay from TRIGGER to DONE will be time to complete an audio packet (56* (1/162 * 10^6) = 0.35 µs).

Offset: 0x62 | Byte Offset: 0x188 | Read/Write: R/W | Reset: 0x00Xf0001 (0b0xxxxxxxxxx1111100000000000xx00x1)

27.8.50 SOR_NV_PDISP_SOR_DP_AUDIO_HBLANK_SYMBOLS_0

SOR_DP_AUDIO_HBLANK_SYMBOLS

The packet generation logic needs to know the length of the hblank period. If there is no room in the current hblank for a new packet, it will be delayed until the next blanking period. This field should be programmed during the second Supervisor interrupt based on the new raster dimensions.

Y = 12/number of lanes

number of symbols/hblank = ((SetRasterBlankEnd.X + SetRasterSize.Width - SetRasterBlankStart.X - 7) * link_clk / pclk) - 3*enhanced_framing - Y

Y accounts for the time required to send BS, VBID, Mvid, Maud.

The value 7 is subtracted to account for reduction in hblank interval in the link clock domain due to uncertainties arising due to pixels crossing async boundary from pixel clock (rg_clk) to link clock (or_clk). Since we use two async FIFOs to transfer pixels from rg_clk to orclk, the uncertainties are effectively doubled. The value has been experimentally determined.

The following formulas can be used to calculate the maximum audio sampling rate that can be supported by DisplayPort given the current raster dimensions. DisplayPort has much more bandwidth during blanking periods than HDMI has, so hblank size is less of an issue.

- number of free symbols/hblank = ((SetRasterBlankEnd.X + SetRasterSize.Width - SetRasterBlankStart.X - 7) * link_clk / pclk - 2 - (3*enhanced_framing)) * #lanes - 12
- Size of a packet for 2ch audio = 20 symbols (up to 2 samples)
- Size of a packet for 8ch audio = 40 symbols
- Size of an audio packet header plus control symbols = 2*#lanes + 8 symbols (assuming < 32 samples per line)
- number of packets/hblank for 2ch audio = Floor ((number of free symbols/hblank - (2*#lanes + 8) / 20)
- number of packets/hblank for 8ch audio = Floor ((number of free symbols/hblank - (2*#lanes + 8) / 40)

Maximum audio sample rate possible:

- number of audio samples/line = SetRasterSize.Width * audio_fs / pclk
- number of audio packets needed for 2ch audio = Ceiling(SetRasterSize.Width * audio_fs / (pclk*2))
- number of audio packets needed for 3-8ch audio = SetRasterSize.Width * audio_fs / pclk

If the number of audio packets needed > number of packets/hblank, then that audio frequency is not supported.

Offset: 0x63 | Byte Offset: 0x18c | Read/Write: R/W | Reset: 0x00000000 (0bxxxxxxxxxxxxxxxx00000000000000000)

Bit	Reset	Description

27.8.51 SOR_NV_PDISP_SOR_DP_AUDIO_VBLANK_SYMBOLS_0

SOR_DP_AUDIO_VBLANK_SYMBOLS

The packet generation logic needs to know the length of a line during VBLANK. If there is no room in the current line for a new packet, it will be delayed until the next line. This field should be programmed during the second Supervisor interrupt based on the new raster dimensions.

Y accounts for the time required to send main stream attributes.

25 accounts for reduction of the vblank interval in the link clock domain due to active region transmission spilling on to the vblank region. Note this happen only on the first vblank line while transitioning from active to blanking. This value is experimentally determined. This might need some adjustment if NV_PDISP_SOR_AUDIO_DEBUG_BLANK_COUNT_ERROR is triggered. Note that this value will not exceed TUSIZE.

Y = (36/number of lanes) + 3;

number of symbols/line in vblank = ((SetRasterBlankStart.X - SetRasterBlankEnd.X - 25) * link_clk / pclk) - Y - 1

27.8.60 SOR_NV_PDISP_SOR_DP_TPG_0

This register is used to control the training patterns needed during link training. This should be set after the SOR clock has been set up and the lanes have been precharged.

There is one field per lane. If the same test pattern is to be sent on all lanes, they must all be switched to that pattern at the same time in order to stay in sync

Link Training Pattern Setting

- _NOPATTERN Training not in progress (or disabled)
- _TRAINING1 Training Pattern 1
- _TRAINING2 Training Pattern 2
- _TRAINING3 Training Pattern 3
- _D102 D10.2 test pattern (unscrambled) transmitted (same as Training Pattern 1)
- _SBLEERRATE Symbol Error Rate measurement pattern transmitted
- _PRBS7 PRBS7 transmitted
- _CSTM Custom 80 bit test pattern defined in NV_PDISP_SOR_DP_LQ_CSTM
- _HBR2_COMPLIANCE HBR2 Compliance Eye pattern. Repetition of scrambled 0s before 8b10b encoding. Sends SR periodically as defined in NV_PDISP_SOR_DP_TPG_CONFIG_HBR2_COMPLIANCE_PERIOD

  This is used for HBR2 electrical compliance.

SCRAMBLEREN

- _DISABLE - DisplayPort transmitter disables scrambler
- _ENABLE_GALIOS - DisplayPort transmitter scrambles data symbols before transmission

CHANNEL_CODING

This bit set to _ENABLE when DisplayPort receiver supports the Main Link channel coding specification as specified in ANSI X3.230-1994, clause 11. This is reserved for future expansion.

See Section 27.8.60: SOR_NV_PDISP_SOR_DP_TPG_0 for more information about the different test patterns. For convenience, the table below specifies the required SCRAMBLEREN and CHANNELCODING values for each pattern.

```
                | Requires        | Requres
Pattern         | Channel Coding? | Scrambling?
----------------+-----------------+------------
TRAINING1       | Yes             | No
TRAINING2       | Yes             | No
TRAINING3       | Yes             | No
D102            | Yes             | No
SBLERRATE       | Yes             | Yes
PRBS7           | No              | No
CSTM            | No              | No
HBR2_COMPLIANCE | Yes             | Yes
```

27.8.61 SOR_NV_PDISP_SOR_DP_TPG_CONFIG_0

NV_PDISP_SOR_DP_TPG_CONFIG

Additional controls for the DP Test Pattern Generator.

HBR2_COMPLIANCE_PERIOD

The HBR2 compliance pattern is a series of 0s that are scrambled and 8b10b encoded. Periodically, the Scrambler Reset Sequence is sent to keep the source and sink in sync. This field controls how many total symbols there are between the start of a new Scrambler Reset Sequence. This will be defined by a DPCD register on the sink test equipment.

16:0	0x0	HBR2_COMPLIANCE_PERIOD

27.8.62 SOR_NV_PDISP_SOR_DP_LQ_CSTM0_0

NV_PDISP_SOR_DP_LQ_CSTM

These registers are used to program a custom 80-bit test pattern used for link quality purposes in DP1.2. When NV_PDISP_SOR_DP_TPG is set to CSTM, the 80 bit pattern in these registers is send repetitively on the link. NV_PDISP_SOR_DP_TPG_LANE*_CHANNELCODING and NV_PDISP_SOR_DP_TPG_LANE*_SCRAMBLEREN should be set to _DISABLE in order to send out this pattern unaltered. For the HBR2 Compliance Eye Pattern, these three registers should all be set to 0, while NV_PDISP_SOR_DP_TPG_LANE*_CHANNELCODING and NV_PDISP_SOR_DP_TPG_LANE*_SCRAMBLEREN are set to _ENABLE.

- SOR_DP_LQ_CSTM0 contains bits 31:0

27.8.72 SOR_NV_PDISP_SOR_DP_HDCP_BKSV_MSB_0

HDCP BKSV MSB REGISTER

The BKSV_MSB register holds the 8 most significant bits of the receiver's key selection vector (KSV), as well as the receiver's REPEATER bit. See the HDCP specification and the Upstream Link for HDCP specification for more information.

Usage: normal operation

Offset: 0x79 | Byte Offset: 0x1e4 | Read/Write: R/W | Reset: 0x00000000 (0b0xxxxxxxxxxxxxxxxxxxxxxx00000000)

Bit	Reset	Description
31	0x0	REPEATER
7:0	ZERO	VALUE: 0 = ZERO

27.8.73 SOR_NV_PDISP_SOR_DP_HDCP_BKSV_LSB_0

HDCP BKSV LSB REGISTER

The BKSV_LSB register holds the 32 least significant bits of the receiver's key selection vector (KSV). See the HDCP specification and the Upstream Link for HDCP specification for more information.

Usage: normal operation

Offset: 0x7a | Byte Offset: 0x1e8 | Read/Write: R/W | Reset: 0x00000000 (0b00000000000000000000000000000000)

Bit	Reset	Description
31:0	ZERO	VALUE: 0 = ZERO

27.8.74 SOR_NV_PDISP_SOR_DP_HDCP_CTRL_0

HDCP CTRL REGISTER

The CTRL register is used to facilitate synchronization between the display driver and hardware.

- RUN: Set by the driver to start or stop the downstream protocol
- CRYPT: Set by the driver to turn encryption on.
- CRYPT_STATUS: This read only field reflects the encryption status of the link. Before entering DP flush mode, software has to disable encryption by setting RUN to NO. Encryption is turned off at the next scrambler reset. Hence software needs to wait until encryption is disabled by polling on CRYPT_STATUS to be _DISABLED before turning ON flush mode.
- AN: A bit set by hardware when a valid An value has been generated
- R0: A bit set by hardware when Km, Ks, M0, and R0 have been calculated
- SROM_EN: Set by hardware while the HDCP SROM is in use, cleared when not in use
- SROM_ERR: Set by hardware when an error occurs while using the HDCP SROM
- UPSTREAM: When the SOR is unattached state,
  - If this bit is set to _DP_MODE, SPRIME and MPRIME calculations will use AN,BKSV and M0 values from the DP HDCP block.
  - If this bit is set to _TMDS_MODE, SPRIME and MPRIME calculations will use AN,BKSV and M0 values from the TMDS HDCP block.

  If the SOR is attached to any HEAD, UPSTREAM SPRIME and MPRIME calculations would use AN,BKSV and M0 values from the HDCP block defined as below.

```
SOR ACTIVE PROTOCOL                                                    HDCP BLOCK
=======================================================================
SOR_SET_CONTROL_PROTOCOL_LVDS_CUSTOM              TMDS
SOR_SET_CONTROL_PROTOCOL_SINGLE_TMDS_A           TMDS
SOR_SET_CONTROL_PROTOCOL_SINGLE_TMDS_B           TMDS
SOR_SET_CONTROL_PROTOCOL_SINGLE_TMDS_AB        TMDS
SOR_SET_CONTROL_PROTOCOL_DUAL_SINGLE_TMDS     TMDS
SOR_SET_CONTROL_PROTOCOL_DUAL_TMDS                   TMDS
SOR_SET_CONTROL_PROTOCOL_DP_A                                 DP
SOR_SET_CONTROL_PROTOCOL_DP_B                                 DP
SOR_SET_CONTROL_PROTOCOL_CUSTOM                          TMDS
```

27.8.89 SOR_NV_PDISP_SOR_TMDS_HDCP_DKSV_LSB_0

HDCP DKSV LSB REGISTER

The DKSV_LSB register holds the 32 least significant bits of the transmitter's upstream key selection vector (KSV). See the HDCP specification and the Upstream Link for HDCP specification for more information.

Usage: normal operation

Offset: 0x8b | Byte Offset: 0x22c | Read/Write: RO | Reset: 0xXXXXXXXX (0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx)

Bit	Reset	Description
31:0	X	VALUE: 0 = ZERO

27.8.90 SOR_NV_PDISP_SOR_TMDS_HDCP_CTRL_0

HDCP CTRL REGISTER

The CTRL register is used to facilitate synchronization between the display driver and hardware.

- RUN: Set by the driver to start or stop the downstream protocol
- CRYPT: Set by the driver to turn encryption on.

  Write ENABLED to enable, but only after RUN == YES. Once enabled, it is disabled by writing RUN=NO.
- DUAL_LINK_EN: Set by the driver to turn dual-link mode on or off
- ONEONE: ONEONE_EN enables the HDCP 1.1 features. This enables HDCP EESS signaling and Advance_Cipher.

  Write ENABLED to enable, but only after RUN == YES. Once enabled, it is disabled by writing RUN=NO. This should be enabled if your receiver supports HDCP 1.1. See Chapter 2.7 in the HDCP 1.1 specification for EESS signaling. See Chapter 2.2 in the HDCP 1.1 specification for ADVANCE_CIPHER.
- AN: Set by hardware when a valid An value has been generated
- R0: Set by hardware when Km, Ks, M0, and R0 have been calculated
- SPRIME: Set by hardware when S' has been calculated
- MPRIME: Set by hardware when M' has been calculated
- SROM_EN: Set by hardware while the HDCP SROM is in use, cleared when not in use

- SROM_ERR: Set by hardware when an error occurs while using the HDCP SROM

Usage: normal operation

Offset: 0x8c | Byte Offset: 0x230 | Read/Write: R/W | Reset: 0x0000XX00 (0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx0000)

0	RW	0x0	RUN: 0 = NO 1 = YES

27.8.91 SOR_NV_PDISP_SOR_TMDS_HDCP_CMODE_0

HDCP CMODE REGISTER

The CMODE register indicates to hardware which upstream protocol calculation to perform. See the HDCP specification and the Upstream Link for HDCP specification for more information.

Writing to the CMODE register kicks off a "Read Status" or a "Read M" operation. When performing a "Read Status" operation, use the CMODE_INDEX field to identify the port for which you wish to obtain status.

Usage: normal operation

Offset: 0x8d | Byte Offset: 0x234 | Read/Write: R/W | Reset: 0x00000011 (0bxxxxxxxxxxxxxxxxxxxxxxxxx00010001)

Bit	Reset	Description

3:0	0x1	MODE: 1 = READ_S 2 = READ_M

27.8.92 SOR_NV_PDISP_SOR_TMDS_HDCP_MPRIME_MSB_0

HDCP MPRIME MSB REGISTER

The MPRIME_MSB register holds the 32 most significant bits of the encrypted M0 value. See the HDCP specification and the Upstream Link for HDCP specification for more information.

Usage: normal operation

Offset: 0x8e | Byte Offset: 0x238 | Read/Write: RO | Reset: 0xXXXXXXXX (0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx)

Bit	Reset	Description
31:0	X	VALUE: 0 = ZERO

27.8.93 SOR_NV_PDISP_SOR_TMDS_HDCP_MPRIME_LSB_0

HDCP MPRIME LSB REGISTER

The MPRIME_LSB register holds the 32 least significant bits of the encrypted M0 value. See the HDCP specification and the Upstream Link for HDCP specification document for more information.

Usage: normal operation

Offset: 0x8f | Byte Offset: 0x23c | Read/Write: RO | Reset: 0xXXXXXXXX (0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx)

Bit	Reset	Description
31:0	X	VALUE: 0 = ZERO

27.8.94 SOR_NV_PDISP_SOR_TMDS_HDCP_SPRIME_MSB_0

HDCP SPRIME MSB REGISTER

The SPRIME_MSB register holds the 8 most significant bits of the S' value. See the HDCP specification and the Upstream Link for HDCP specification for more information.

STATUS_READZ indicates whether or not this chip implements the HDCP Upstream Spec's "Read Z" operation. Currently, "Read Z" is not implemented.

STATUS_CS indicates whether or not this chip implements the connection state (CS) register. If this field is set to STATUS_CS_NOT_IMPL, it means this chip will always follow the standard "Read Status" protocol when reporting status. If this field is set to STATUS_CS_IMPLMNTD, it means this chip will always follow the "Read Status With Connection State" protocol when reporting status.

STATUS_SCOPE indicates how the chip will report the status for the STATUS_UNPROTECTED field. See the STATUS_UNPROTECTED description below for more information.

STATUS_INTPNL indicates if the port you are querying (identified by the CMode index) is transmitting to an internal panel on this head. If the port you are querying is not transmitting on this head (see the ** note below), or if it is transmitting on this head but to a device other than an internal panel, then STATUS_INTPNL_INACTV will be returned.

STATUS_MAX_CMODE_IDX identifies the maximum CMode index allowed for requesting status.

Note: *Unlike the STATUS_UNPROTECTED field, the other STATUS fields always use the _HA_ registers to report status for ports on head A and the _HB_ registers to report status on head B. If you use the _HA_ versions of the CMODE and SPRIME registers to query the status of a port that is actually being driven by head B, the status will indicate that the port isn't transmitting at all (everything will come back as INACTV).*

Usage: normal operation

Offset: 0x90 | Byte Offset: 0x240 | Read/Write: RO | Reset: 0x000000XX (0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx)

Bit	Reset	Description
7	X	STATUS_READZ: 0 = NOT_IMPL 1 = IMPLMNTD
6	X	STATUS_CS: 0 = NOT_IMPL 1 = IMPLMNTD
5	X	STATUS_SCOPE: 0 = SCOPE_TWO_HEADS 1 = SCOPE_1_HEAD
4	X	STATUS_INTPNL: 0 = INACTV 1 = ACTV
3:0	X	STATUS_MAX_CMODE_IDX

27.8.95 SOR_NV_PDISP_SOR_TMDS_HDCP_SPRIME_LSB2_0

HDCP SPRIME LSB2 REGISTER

The SPRIME_LSB2 register holds the 32 next-most significant bits of the S' value. See the HDCP specification and the Upstream Link for HDCP specification for more information.

STATUS_CMODE_IDX identifies the index of the port to which the status request was actually routed.
STATUS_UNPROTECTED indicates whether the port you queried (identified by the CMode index) is transmitting unprotected data. If STATUS_SCOPE is set to STATUS_SCOPE_1_HEAD, then make sure to use the _HA_ registers to see if any ports on head A are unprotected, and use the _HB_ registers to see if any ports on head B are unprotected. If STATUS_SCOPE is set to STATUS_SCOPE_2_HEADS, then STATUS_UNPROTECTED combines the status of both heads. In this case, both the _HA_ registers and the _HB_ registers will report the same value for the STATUS_UNPROTECTED field.

Value of STATUS_SCOPE	Meaning of STATUS_UNPROTECTED
_1_HEAD	UNPROTECTED_Y means that at least one port driven by this head is transmitting "unprotected" data. UNPROTECTED_N means that none of the ports driven by this head are transmitting "unprotected" data.

Value of STATUS_SCOPE	Meaning of STATUS_UNPROTECTED
_2_HEADS	UNPROTECTED_Y means that at least one port driven by either head is transmitting "unprotected" data. UNPROTECTED_N means that none of the ports driven by either head are transmitting "unprotected" data.

"Unprotected" data does not necessarily mean data that is not being encrypted. Data being transmitted out of a DAC is *always* considered unprotected. Data being transmitted out of a DVO is considered unprotected if it is not being encrypted. Data being transmitted by a TMDS link is also considered unprotected if it is not being encrypted,*except* for the case where the link feeds the internal panel of a laptop. The HDCP specification dictates that since the bus feeding an internal panel is essentially inaccessible to users, it can be considered "protected" even when sending clear data.

STATUS_EXTPNL is set to STATUS_EXTPNL_ACTV if the port identified by the CMode index is a digital interface (i.e., a DVO or TMDS interface), and it is transmitting on this head to something *other* than an internal panel. The STATUS_INTPNL field and the STATUS EXTPNL field will never be both set to ACTV for the same port. If a digital port is transmitting on this head, and it is physically connected to an internal panel, then the STATUS_INTPNL bit is set to ACTV and the STATUS_EXTPNL is set to INACTV; if it is transmitting on this head but it is *not* connected to an internal panel (even if it is not connected to anything at all), then STATUS_INTPNL is set to INACTV and STATUS_EXTPNL is set to ACTV.

STATUS_RPTR is set to STATUS_RPTR_ACTV if 1) the STATUS_EXTPNL field is set to ACTV, and 2) the REPEATER bit of the BKSV_MSB register is set to 0x1. This scenario should only occur after we are transmitting to an external HDCP-compliant device whose "repeater" bit is set.

STATUS_ENCRYPTING will be set to STATUS_ENCRYPTING_Y if the HDCP unit in this head is actually encrypting the data it receives. Note that if this bit is set, it means that *all* ports driven by this head whose data streams flow through the HDCP unit will be transmitting encrypted data, but any ports driven by this head whose data streams *bypass* the HDCP unit will be transmitting *clear* data. The DACs always use a data path that bypasses the HDCP unit and therefore must always be considered "unprotected".

Bit	Reset	Description
31:0	X	RDATA

27.8.101 SOR_NV_PDISP_SOR_HDMI_AUDIO_EMU1_0

HDMI_AUDIO_EMU1 and EMU2 allow control over S/PDIF transmitter clock ratios (which are fixed in the GPU). They do indirect addressing.

EMU1 has the address, and EMU2 has the data.

To write:

1. Write data register with data
2. Write address register with bit 31=1, and address in 15:0
3. Write address register with bit 31=0

To read:

1. Write address register with bit 31=0 and address in 15:0
2. Read back address register to introduce delay allowing read data to propagate
3. Read data register

Bit	Reset	Description
31:0	0x0	DATA

27.8.103 SOR_NV_PDISP_SOR_HDMI_AUDIO_INFOFRAME_CTRL_0

HDMI Registers

This is the register space for the HDMI block. Refer to these sections in the HDMI Version 1.1 specification:

- 5.3, Data Island Packet Definition

- 8.2.1, Auxiliary Video Information (AVI) InfoFrames
- 8.2.2, Audio InfoFrame

Also refer to IEC60958-1 for general information and IEC60958-3 for consumer specifications for related audio information.

Additional notes regarding the ACR packet:

There are several methods that can be used to generate the N and CTS values in the Audio Clock Regeneration packet. The details of these methods are described here.

Full Software control: Software controls the contents of the possible ACR packets. Software writes the contents of the ACR_XXXX_SUBPACK_HIGH and ACR_XXXX_SUBPACK_LOW for all seven audio frequencies.

Software selects a method in ACR_CTRL to determine the audio sampling frequency

1. Measured in the audio block (MEASURE)
2. Read from the channel status information encoded in the audio stream (PACKET)
3. Defined by software (FREQS)

Software writes _YES to the ENABLE field of the SUBPACK_HIGH registers to allow that pair of registers to be used as the ACR packet. The audio sampling frequency specified in ACR_CTRL will select one of the seven pairs of SUBPACK registers to use as the ACR packet. This packet is sent on every Frame 27 of the audio block if that pair's ENABLE field is _YES.

Hardware controlled CTS: Software provides the N value and the hardware measures the CTS value. This is described in the HDMI_SPARE comments and mentioned in all other affected registers.

Software writes _ENABLE to HDMI_SPARE_HW_CTS to enable this feature.

Software writes 1 to HDMI_SPARE_CTS_RESET_VAL. This controls what the internal CTS counter resets to when it starts the next round of measurement. Resetting to zero was not correct, and adding a few bits of control helped to fine tune the measurement.

Software sets all ENABLEs in ACR_CTRL to _NO. (The easy way to do this is just to write zero to the whole register.)

Software writes the value of N in two places:

1. ACR_0441_SUBPACK_HIGH_SB[4/5/6]: It is written here so that the ACR packet contains the correct information for N.
2. AUDIO_N_VALUE: It is written here so that the audio block knows what N to use while it is measuring CTS. (Software does not need to write N to these places if Hardware Selected N is used.)

Software enables the sending of ACR_0441_SUBPACK* by setting ACR_0441_SUBPACK_ENABLE to _YES. (This pair of registers is used for all audio frequencies when Hardware controlled CTS is enabled.)

Software writes _USE_HW_CTS_VAL to ACR_0441_SUBPACK_LOW_SB1.

Hardware selected N: Software provides the possible N values whenever the pixel clock frequency changes. Hardware looks up the correct N value from a table stored in priv registers.

Software writes the 7 possible N values into the 7 AUDIO_NVAL registers. This is based on pixel clock frequency.

Software enables this feature by setting AUDIO_N_LOOKUP to _ENABLE. Hardware will use the audio sampling frequency detected by the audio block to select the correct N value.

Note: *This is not the audio sampling frequency reported by the channel status information in the audio stream. Hardware will ignore whatever if written in the SUBPACK_HIGH registers when this feature is enabled and send the value of N it selected in these bytes of the ACR packet. CTS can come from the SUBPACK_LOW registers or the Hardware controlled CTS.*

Audio frequency notes: There are several places in the HDMI and Audio registers where the audio sampling frequency is reported or set. Here is a breakdown of all such fields.

In SPDIF audio encoding, one bit of each audio sample is part of the "channel status" information. The bits from all 192 audio samples combine to form the 192 bit channel status packet. For consumer applications, only the first 40 bits have defined values. These bits are included in the encoded HDMI audio packet. Four of these bits contain the audio sampling frequency as reported by the audio source. See the IEC60958-3 specification for more information.

SPDIF_CHN_STATUS1 and SPDIF_CHN_STATUS2 are read-only registers that contain the 40 bits of channel status data read from the last audio block. The audio frequency the audio stream reports can be read from SPDIF_CHN_STATUS1_SFREQ. This is the sampling frequency that ACR_CTRL refers to with _PACKET.

SPDIF_CHN_STATUS1_ORIGINAL is the original sampling frequency of the audio. If the source of the audio stream changed the sampling frequency from its original frequency for any reason, the original sampling frequency is reported here.

AUDIO_CNTRL0_SAMPLING_FREQ is the sampling frequency measured by the audio block. It counts the number of dispclks periods that occur between to specific points in the audio stream. It compares this count to the thresholds in the AUDIO_FS registers to determine what the audio sampling frequency is. This is the sampling frequency that ACR_CTRL refers to as _MEASURE. This is the sampling frequency used to determine the correct value of N when Hardware selected N is enabled (see AUDIO_N).

The CHANNEL_STATUS1 and CHANNEL_STATUS2 registers are for debug. They can be used to replace the channel status bits that were in the original SPDIF stream with user-defined bits. CHANNEL_STATUS1_SFREQ can be used to report a different sampling frequency to downstream devices.

ACR_CTRL_FREQS can be written to select a specific pair of SUBPACK registers to send as your ACR packet. ACR_CTRL_FREQS_ENABLE must be set to _YES for this to have any effect.

The HDMI Audio InfoFrame, AVI InfoFrame, and Generic InfoFrame have nearly identical priv register interfaces. The next five registers control the Audio InfoFrame as described in Section 8.2.2 of the HDMI specification.

HDMI_AUDIO_INFOFRAME_CTRL

This register controls the frequency and generation of audio InfoFrame packets. The contents of the packet should be written into the header (HDMI_AUDIO_INFOFRAME_HEADER) and subpacket (HDMI_AUDIO_INFOFRAME_SUBPACK0_LOW, HDMI_AUDIO_INFOFRAME_SUBPACK0_HIGH) registers.

ENABLE: Setting this field to _YES will initiate InfoFrame generation. Setting this bit to _NO will disable InfoFrame generation at the beginning of the next frame. The frequency of InfoFrame generation is controlled by OTHER and SINGLE fields.

OTHER: Setting this field to _EN while SINGLE is set to _DIS will cause InfoFrame to be transmitted to every other frame.

SINGLE: Setting this field to _EN while OTHER is set to _DIS will cause InfoFrame to be transmitted exactly once.

If OTHER and SINGLE fields are both set to _DIS, an InfoFrame will be generated every frame. Software should never set OTHER and SINGLE both to _EN.

See chapter 8.2.2 - Audio InfoFrame, in the HDMI specification for more information

CHKSUM_HW: Hardware provides a way to calculate the checksum for the InfoFrames.

_ENABLE will enable the hardware calculation to be passed to the packet

_DISABLE:

- Uses the register value defined in NV_PDISP_SOR_HDMI_AUDIO_INFOFRAME_SUBPACK0_LOW_PB0 for the S/PDIF
- Uses the checksum provided by the Azalia codec for the Azalia audio formats.

Usage: normal operation

Offset: 0x9a | Byte Offset: 0x268 | Read/Write: R/W | Reset: 0x00000200 (0bxxxxxxxxxxxxxxxxxxxxxxxx10xxx0xxx0)

Bit	Reset	Description
9	ENABLE	CHKSUM_HW: CHKSUM_HW is an optional feature for SW to use. Not required to be enabled. 0 = DISABLE 1 = ENABLE
8	0x0	SINGLE: 0 = DIS 1 = EN
4	0x0	OTHER: 0 = DIS 1 = EN
0	0x0	ENABLE: 0 = NO 1 = YES 0 = DIS 1 = EN

27.8.104 SOR_NV_PDISP_SOR_HDMI_AUDIO_INFOFRAME_STATUS_0

HDMI_AUDIO_INFOFRAME_STATUS

The SENT bit will be set to _DONE, after the first packet is sent. After the ENABLE bit in INFOFRAME_CTRL is set to _NO, the SENT bit will be set to _WAITING after the start of the next frame to indicate that it is safe to change the contents of the packet header and subpacket registers.

Usage: normal operation

15:8	0x0	PB1
7:0	0x0	PB0

27.8.107 SOR_NV_PDISP_SOR_HDMI_AUDIO_INFOFRAME_SUBPACK0_HIGH_0

HDMI_AUDIO_INFOFRAME_SUBPACK0_HIGH

This register should be written with the upper 2 bytes of the HDMI Audio InfoFrame. PB4 and PB5 are defined fields from the specification. See chapter 8.2.2 - Audio InfoFrame, Table 8-5, in the HDMI specification for more information

Offset: 0x9e | Byte Offset: 0x278 | Read/Write: R/W | Reset: 0x00000000 (0bxxxxxxxxxxxxxxxx0000000000000000)

Bit	Reset	Description
15:8	0x0	PB5
7:0	0x0	PB4

27.8.108 SOR_NV_PDISP_SOR_HDMI_AVI_INFOFRAME_CTRL_0

The following registers are used to send a 14-byte packet intended for sending AVI InfoFrame packet as described in Section 8.2.1 of the HDMI specification.

HDMI_AVI_INFOFRAME_CTRL

This register controls the frequency and generation of AVI InfoFrame packets. The fields of this register are identical to HDMI_AUDIO_INFOFRAME_CTRL. See Section 8.2.1 - Auxiliary Video information (AVI) InfoFrame, in the HDMI specification for more information.

Offset: 0x9f | Byte Offset: 0x27c | Read/Write: R/W | Reset: 0x00000200 (0bxxxxxxxxxxxxxxxxxxxxxxxx10xxx0xxx0)

Bit	Reset	Description
9	ENABLE	CHKSUM_HW: CHKSUM_HW is an optional feature for software to use. Not required to be enabled. 0 = DISABLE 1 = ENABLE
8	DIS	SINGLE: 0 = DIS 1 = EN
4	DIS	OTHER: 0 = DIS 1 = EN
0	NO	ENABLE: 0 = NO 1 = YES 0 = DIS 1 = EN

27.8.109 SOR_NV_PDISP_SOR_HDMI_AVI_INFOFRAME_STATUS_0

HDMI_AVI_INFOFRAME_STATUS

The SENT bit will be set to _DONE, after the first packet is sent. After the ENABLE bit in INFOFRAME_CTRL is set to _NO, the SENT bit will be set to _WAITING after the start of the next frame to indicate that it is safe to change the contents of the packet header and subpacket registers.

15:8	0x0	PB26
7:0	0x0	PB25

27.8.125 SOR_NV_PDISP_SOR_HDMI_ACR_CTRL_0

HDMI_ACR_CTRL

The Audio Clock Regeneration (ACR) packet contains the N and CTS values that the HDMI sink requires to recreate the audio clock. This mechanism is described in chapter 7.2 of the HDMI specification.

If software needs to specify N and CTS directly, this register is used to select the audio sampling frequency detection mechanism. The sampling rate is used to index one of the seven ACR_XXXX_SUBPACK_LOW/HIGH registers which must be written with the correct value of N and CTS. N and CTS are determined by the current audio sampling frequency and the pixel clock frequency:

CTS = (PixelClock*N) / (128*AudioSamplingFrequency)

The selected sampling rate must point to a valid entry (i.e., one of the 7 listed below) and the selected ACR_XXXX_SUBPACK_HIGH_ENABLE must be set to enable sending the packet.

When software is controlling N and CTS directly, the ACR packet is sent every 27th audio frame (of 0 to 191) of the audio block. The sampling frequency read from the channel status bits is not available until the 27th audio frame.

PACKET_ENABLE: Set this to _YES to use the channel status information read from the incoming SPDIF audio stream to determine the sampling frequency.

MEASURE_ENABLE: Set this to _YES to use the sampling frequency measured in the in the audio block to determine the sampling frequency. This is the sampling frequency that is read from AUDIO_CNTRL0_SAMPLING_FREQ.

FREQS_ENABLE: Set this to _YES to use the sampling frequency written into the _FREQS field of this register.

FREQS: This is the audio sampling frequency that will be used when FREQS_ENABLE is _YES.

When Hardware is used to measure CTS, all ENABLE fields of this register should be set to _NO.

All four subpackets contain the same ACR packet.

For more information, see the following in the HDMI specification:

- 7.2: Audio Sample Clock Capture and Regeneration use the other entry in tables 7-1, 7-2 and 7-3 to determine N
- 5.3.3: Audio Clock Regeneration Packet

Offset: 0xb1 | Byte Offset: 0x2c4 | Read/Write: R/W | Reset: 0x02010000 (0bxxxx0010xxxxxxx1xxxxxxx0xxxxxxx0)

15:8	0x0	SB3

27.8.127 SOR_NV_PDISP_SOR_HDMI_ACR_0320_SUBPACK_HIGH_0

HDMI_ACR_0320_SUBPACK_HIGH

Contains bytes 4-6 of the 32 kHz ACR packet. This is the N value. See table 5-11 in chapter 5.3.3 in the HDMI specification for more information.

ENABLE: _YES allows this packet to be sent. When set to _NO, this ACR packet will not be sent even if the sampling frequency defined in ACR_CTRL points to this register set.

Offset: 0xb3 | Byte Offset: 0x2cc | Read/Write: R/W | Reset: 0x00000000 (0b0xxxxxxx00000000000000000000000)

Bit	Reset	Description
31	NO	ENABLE: 0 = NO 1 = YES 0 = DIS 1 = EN
23:16	0x0	SB4
15:8	0x0	SB5
7:0	0x0	SB6

27.8.128 SOR_NV_PDISP_SOR_HDMI_ACR_0441_SUBPACK_LOW_0

HDMI_ACR_0441_SUBPACK_LOW

Contains bytes 1-3 of the 44.1 kHz ACR packet. This is the CTS value. If Hardware measured CTS is enabled, SB1 should be set to zero. See table 5-11 in chapter 5.3.3 in the HDMI specification for more information.

Offset: 0xb4 | Byte Offset: 0x2d0 | Read/Write: R/W | Reset: 0x00000000 (0b00000000000000000000000xxxxxxxx)

Bit	Reset	Description
31:24	0x0	SB1: 0 = USE_HW_CTS_VAL
23:16	0x0	SB2
15:8	0x0	SB3

27.8.129 SOR_NV_PDISP_SOR_HDMI_ACR_0441_SUBPACK_HIGH_0

HDMI_ACR_0441_SUBPACK_HIGH

Contains bytes 4-6 of the 44.1 kHz ACR packet. This is the N value. See table 5-11 in chapter 5.3.3 in the HDMI specification for more information.

If Hardware measured CTS is enabled, ACR_0441_SUBPACK_HIGH_N should be written with the N value for the current audio sampling frequency.

If the hardware N value selection is enabled, the N value does not need to be written to this register.

ENABLE: _YES allows this packet to be sent. This should be set to _YES when hardware measured CTS is being used. When set to _NO, this ACR packet will not be sent even if the sampling frequency defined in ACR_CTRL points to this register set.

Offset: 0xb5 | Byte Offset: 0x2d4 | Read/Write: R/W | Reset: 0x00000000 (0b0xxxxxxx00000000000000000000000)

15:8	0x0	SB5
7:0	0x0	SB6

27.8.140 SOR_NV_PDISP_SOR_HDMI_CTRL_0

HDMI_CTRL

REKEY: REKEY is the number of clocks required for HDCP rekey, starting from when DE is deasserted. No HDMI packets can be sent during this time. Due to a two cycle delay in hardware, REKEY should be set to two less than the desired value.

AUDIO_LAYOUT: AUDIO_LAYOUT controls layout (HB1[4]) of the Audio Sample Packet Header. Two different layouts are supported in the HDMI specification. The hardware only supports layout _2CH (2 channel audio). This should not need to be programmed beyond its init value of _2CH.

See Section 5.3.4 of the HDMI specification.

AUDIO_LAYOUT_SELECT: For projects with integrated audio codec, the AUDIO_LAYOUT information is automatically detected by hardware (default). We can override this capability and fall back on AUDIO_LAYOUT based selection by setting AUDIO_LAYOUT_SELECT to _SW_BASED.

If NV_CHIP_DISP_EXTENDED_AUD_FMT is not defined in the project specification, this field has no meaning, and only AUDIO_LAYOUT field will take effect.

SAMPLE_FLAT: SAMPLE_FLAT controls the values of (HB2[3:0]) of the Audio Sample Packet Header and should be _CLR. See Section 5.3.4 of the HDMI specification.

MAX_AC_PACKET: Set MAX_AC_PACKET to the maximum number of 32-pixel packets that will fit in the horizontal blanking interval. This controls the maximum number of audio packets, ACR packets, GCP packets, InfoFrames, etc. that will be sent during the horizontal blanking period.

MAX_AC_PACKET <= Floor[((HBLANK-REKEY-18)/32)]

CT_SELECT: Diagnostic workaround bit to decide whether the value of "coding type" will be hardware based or software based. The CT field is required in the construction of Audio InfoFrame packet (HDMI Specification, Section 8.2.2). By default, the CT field is constructed by software. However, by setting this bit, the CT field in the construction of the Audio InfoFrame packet comes as a sideband signal from the HDA codec. If NV_CHIP_DISP_EXTENDED_AUD_FMT is not defined in projects.spec, this field is reserved.

CC_SELECT: Diagnostic workaround bit to decide whether the value of "channel count" will be hardware based or software based. The CC field is required in the construction of Audio InfoFrame packet (HDMI Specification, Section 8.2.2). By default, the CC field is constructed by software. However,by setting this bit, the CC field in the construction of the Audio InfoFrame packet comes as a sideband signal from the HDA codec. If NV_CHIP_DISP_EXTENDED_AUD_FMT is not defined in projects.spec, this field is reserved.

SF_SELECT: Diagnostic workaround bit to decide whether the value of "sampling frequency" will be hardware based or software based. The SF field is required in the construction of Audio InfoFrame packet (HDMI Specification, Section 8.2.2). By default, the SF field is constructed by software. However, by setting this bit, the SF field in the construction of the Audio InfoFrame packet comes as a sideband signal from the HDA codec. If NV_CHIP_DISP_EXTENDED_AUD_FMT is not defined in projects.spec, this field is reserved.

SS_SELECT: Diagnostic workaround bit to decide whether the value of "sample size" will be hardware based or software based. The SS field is required in the construction of Audio InfoFrame packet (HDMI Specification, Section 8.2.2). By default, the SS field is constructed by software. However, by setting this bit, the SS field in the construction of the Audio InfoFrame packet comes as a sideband signal from the HDA codec. If NV_CHIP_DISP_EXTENDED_AUD_FMT is not defined in projects.spec, this field is reserved.

CA_SELECT: Diagnostic workaround bit to decide whether the value of "channel allocation" will be hardware based or software based. The CA field is required in the construction of Audio InfoFrame packet (HDMI Specification, Section 8.2.2). By default, the CA field is constructed by software. However, by setting this bit, the CA field in the construction of the Audio InfoFrame packet comes as a sideband signal from the HDA codec. If NV_CHIP_DISP_EXTENDED_AUD_FMT is not defined in projects.spec, this field is reserved.

ENABLE: Set to _YES to enable HDMI for this head. Set to _NO to disable HDMI for this head.

Offset: 0xc0 | Byte Offset: 0x300 | Read/Write: R/W | Reset: 0x00020038 (0bx0x00000xxx00010xxx0x0x0x0111000)

6:0	0x38	REKEY

27.8.141 SOR_NV_PDISP_SOR_HDMI_VSYNC_KEEPOUT_0

HDMI_VSYNC_KEEPOUT

Defines the start and end of the VSYNC keepout period where HDMI packets should not be sent. This is defined in chapter 2.7 the HDCP 1.1 specification.

END: Defines the end of the keepout period. This is measured in pixels after the active edge of VSYNC. This is defined in the specification and should not need to be written beyond its initialized value.

START: Defines the start of the keepout period. This is measured in pixels after the active edge of VSYNC. This is defined in the specification and should not need to be written beyond its initialized value.

ENABLE: When set to _YES, the keepout window is respected and no HDMI packets are sent in the period of time between START and END. This bit should be set to _YES. When set to _NO, the keepout window is ignored and HDMI packets may be sent regardless of the keepout window.

Offset: 0xc1 | Byte Offset: 0x304 | Read/Write: R/W | Reset: 0x819a028a (0b1xxxxx0110011010xxxxxx1010001010)

Bit	Reset	Description
31	YES	ENABLE: 0 = NO 1 = YES 0 = DIS 1 = EN
25:16	0x19a	START
9:0	0x28a	END

27.8.142 SOR_NV_PDISP_SOR_HDMI_VSYNC_WINDOW_0

HDMI_VSYNC_WINDOW

Defines the start and end of the window of opportunity where the HDCP EESS signaling occurs. This is defined in chapter 2.7 of the HDCP 1.1 specification.

END: Defines the end of the window of opportunity. This is measured in pixels after the active edge of VSYNC. This is defined in the specification and should not need to be written beyond its initialized value.

START: Defines the start of the window of opportunity. This is measured in pixels after the active edge of VSYNC. This is defined in the specification and should not need to be written beyond its initialized value.

ENABLE: _YES will allow EESS signaling during the window of opportunity. _NO will prevent EESS signaling.

Offset: 0xc2 | Byte Offset: 0x308 | Read/Write: R/W | Reset: 0x82000210 (0b1xxxxx1000000000xxxxxx1000010000)

Bit	Reset	Description
31	YES	ENABLE: 0 = NO 1 = YES 0 = DIS 1 = EN
25:16	0x200	START
9:0	0x210	END

27.8.143 SOR_NV_PDISP_SOR_HDMI_GCP_CTRL_0

The following registers are used to send a single-byte packet intended for sending the general control packet as described in Section 5.3.6 of the HDMI specification. This control packet is used to control the AVMUTE flag.

HDMI_GCP_CTRL

This register controls the frequency and generation of GCP packets. The fields of this register are identical to HDMI_AUDIO_INFOFRAME_CTRL.

All four subpackets contain the same GCP packet.

Offset: 0xc3 | Byte Offset: 0x30c | Read/Write: R/W | Reset: 0x00000000 (0bxxxxxxxxxxxxxxxxxxxxxxxx0xxx0xxx0)

Bit	Reset	Description
8	DIS	SINGLE: 0 = DIS 1 = EN
4	DIS	OTHER: 0 = DIS 1 = EN
0	NO	ENABLE: 0 = NO 1 = YES 0 = DIS 1 = EN

27.8.144 SOR_NV_PDISP_SOR_HDMI_GCP_STATUS_0

HDMI_GCP_STATUS

The SENT bit will be set to _DONE, after the first packet is sent. After the ENABLE bit in INFOFRAME_CTRL is set to _NO, the SENT bit will be set to _WAITING after the start of the next frame to indicate that it is safe to change the contents of the packet header and subpacket registers.

START_PP indicates the Pixel phase for the start fragment number of the ACTIVEVIDEO/VSYNC/HSYNC in case of the deep color:

- ACTIVE_START_PP: The first active pixel is packed in to this Phase
(e.g., if this value is 0 then 10P0,12P0,16P0)
- HSYNC_START_PP: The first pixel following the +ve transition of the VSYNC is packed in to this Phase (e.g. if this value is 0 then 10P0,12P0,16P0)
- VSYNC_START_PP: The first pixel following the +ve transition of the HSYNC is packed in to this Phase (e.g. if this value is 0 then 10P0,12P0,16P0)

END_PP indicates the Pixel phase for the end fragment number of the ACTIVEVIDEO/VSYNC/HSYNC in case of the deep color:

- ACTIVE_END_PP: The last active pixel is packed in to this Phase (e.g. if this value is 1 then 10P1,12P1,16P1)
- HSYNC_END_PP: The first pixel following the -ve transition of the VSYNC is packed in to this Phase (e.g. if this value is 1 then 10P1,12P1,16P1)
- VSYNC_END_PP: The first pixel following the -ve transition of the HSYNC is packed in to this Phase (e.g. if this value is 1 then 10P1,12P1,16P1)

Software can use above fields to set the DEFAULT PP FIELD or PP field of the GCP Packet. For more information, refer to the HDMI 1.3 specification, Section 6.5.3.

PP3 PP2 PP1 PP0 Pixel packing Phase

==========

0 0 0 0 Phase 4 (10P4)

0 0 0 1 Phase 1 (10P1, 12P1, 16P1)

0 0 1 0 Phase 2 (10P2, 12P2)

0 0 1 1 Phase 3 (10P3)

0 1 0 0 Reserved

All other values Reserved

To set the DEFAULT phase in the GCP packet, SW can use above values to make sure RASTER is setup right.

Default_Phase field of GCP SB2:

When Default_Phase is 0, the PP bits may vary and the first pixel of each Video Data Period may vary.

When Default_Phase is 1, the following will be true:

-- The first pixel of each Video Data Period shall always have a pixel packing phase of 0 (10P0, 12P0, 16P0).

Will be pointed by ACTIVE_START_PP field above

-- The first pixel following each Video Data Period shall have a pixel packing phase of 0 (10C0, 12C0, 16C0).

Will be pointed by ACTIVE_END_PP field above

-- The PP bits shall be constant for all GCPs and will be equal to the last packing phase (10P4, 12P2, 16P1).

Confirmed by HW.

-- The first pixel following every transition of HSYNC or VSYNC shall have a pixel packing phase of 0 (10C0, 12C0, 16C0).

Will be pointed by HSYNC_START_PP field above

Will be pointed by HSYNC_END_PP field above

Will be pointed by VSYNC_START_PP field above

Will be pointed by VSYNC_END_PP field above

27.8.146 SOR_NV_PDISP_SOR_HDMI_EMU0_0

HDMI_EMU0 and 1 do indirect addressing. EMU0 has the address, and EMU1 has the data.

To write:

1. Write the data register with data.
2. Write the address register with bit 31=1, and the address in bits 15:0.
3. Write the address register with bit 31=0.

To read:

1. Write the address register with bit 31=0 and the address in bits 15:0.
2. Read back the address register to introduce delay allowing the read data to propagate.
3. Read the data register.

27.8.149 SOR_NV_PDISP_SOR_HDMI_SPARE_0

HDMI_SPARE

HW_CTS - If this is set to _ENABLE, Hardware measured CTS will be enabled. This method is more accurate than using software controlled CTS. The HDMI block will count the number of TMDS clocks that occur during the interval 1/(128 * audio sample rate) and use the value as CTS and issue the ACR Packet at each interval. When hardware measured CTS is enabled, all ENABLE fields of ACR_CTRL must be set to _NO. Also, ACR_0441_SUBPACK_HIGH_ENABLE must be set to _YES.

ACR_0441_SUBPACK_HIGH_N should be written with the value of N for the current sampling frequency.

The N value must also be written into AUDIO_N_VALUE (See the AUDIO register section for more details).

The value of N can be determined from the current audio sampling frequency, the current pixel clock rate, and tables 7-1. 7-2, and 7-3 in the HDMI specification. In most cases the value in the "Other" row can be used.

FORCE_SW_CTS: When HW_CTS = ENABLE, it uses measured CTS. However, when the audio clock / video clock ratio is known, this is undesirable. Currently, HW_CTS cannot be disabled.

When FORCE_SW_CTS=ENABLE along with HW_CTS=ENABLE, the HW_CTS is used to control transmission of ACR packets, but the CTS is programmed by software in the ACR_0441_SUBPACK_LOW registers.

SUPRESS_SP_B: Default SUPRESS_SP_B=0 is to disable B bits in audio sample packets, for non-present samples. Setting SUPRESS_SP_B=1 restores the old behavior.

CTS_RESET_VAL: When an ACR packet is sent, the CTS counter is reset to the value in this field. This should be set to the INIT value of 1

ACR_PRIORITY: This controls the priority of the ACR packet with respect to Audio Sample packets. This should be set to _HIGH.

LOW: ACR packets will have lower priority than Audio Sample packets

HIGH: ACR packets will have higher priority than Audio Sample packets

Software needs to make sure these registers are set when audio is active:

- HDMI_SPARE_HW_CTS = _HW_CTS_ENABLE
- HDMI_SPARE_CTS_RESET_VAL = 1

27.8.150 SOR_NV_PDISP_SOR_HDMI_SPDIF_CHN_STATUS1_0

HDMI_SPDIF_CHN_STATUS1

HDMI_SPDIF_CHN_STATUS1/2 contains the value of the channel status bits extracted from the incoming S/PDIF audio data stream. See IEC60958-3 chapter 5 for more information on these fields.

USE Specifies consumer use (CONSUMER) or professional (PRO) use of the channel status block. SPDIF_CHN_STATUS1/2 assumes consumer use.

TYPE: Specifies the type of data the audio word represents.

- PCM: Audio sample word represents linear PCM samples
- OTHER: Audio sample word is something other than liner PCM (i.e., compressed audio)

COPYRIGHT: Copyright status of the audio.

- YES: Copyright is asserted
- NO: Copyright is not asserted

D: The values of these bits have different meanings based on the value of _TYPE.

If _TYPE==_PCM, then:

- NO_PREEMPHASIS: 2 audio channels without pre-emphasis
- PREEMPHASIS: 2 audio channels with 50 microseconds/15 microseconds pre-emphasis

All other states are reserved for future use.

MODE Defines one of four possible channel status formats for bytes 1-23 of channel status. Currently only the value "0" is defined. This format is assumed for the SPDIF_CHN_STATUS1/2.

CODE: This byte defines the Category Code of the input device. This code indicates what type of equipment is generating the input. See 5.3.1 of the IEC60958-3 specification for the values of codes.

SOURCE: Source number of the audio. If this value is zero then no source number was reported.

CHANNEL: Channel number of the audio. This reports the channel number reported for the first subframe of audio. If this value is zero then the channel number was not reported.

SFREQ: This is the reported sampling frequency of the input audio stream. The value UNDEFINED means that the sampling frequency was not indicated by the audio stream.

ACCURACY: Transmitter Clock accuracy.

- LVL1 High accuracy mode: Transmitted sampling frequency is within a tolerance of +/-50*10^-6
- LVL2 Normal accuracy mode: Transmitted sampling frequency is within a tolerance of +/-1000*10^-6
- LVL3 Variable pitch shifted clock mode: Only specially designed receivers can receive the signal in this mode
- OTHER: Interface frame rate not matched to sampling frequency: This is for all other modes that do not have an embedded sampling frequency clock.

27.8.151 SOR_NV_PDISP_SOR_HDMI_SPDIF_CHN_STATUS2_0

HDMI_SPDIF_CHN_STATUS2

MAX_LENGTH: Reports if the maximum audio sample word length is 20 bits or 24 bits.

LENGTH: Reports the audio sample word length of this block. The value of these bits is dependent on the value of MAX_LENGTH

- If MAX_LENGTH=_20 then refer to the MAX20_* defines.
- If MAX_LENGTH=_24 then refer to the MAX24_* defines.

All other bit combinations are reserved.

ORIGINAL: The original sampling frequency of the audio data. UNDEFINED indicates that the original sampling frequency was not defined

27.8.152 SOR_NV_PDISP_HDCPRIF_ROM_CTRL_0

HDCPRIF REGISTERS

This is the register space for the HDCP ROM interface control registers. These register control writing the contents of the HDCPRIF_KEY registers (56 bits) into the local key store. The keys are decoded by the CD, which outputs them on the internal key data bus. The key registers are then written by overloading the priv reg bus with the key data when a write to either key register is executed. The key data must then be input into the key store using the control commands below.As no access to key data from public buses is allowed, all these operations are performed as hardware controlled functions that are initiated by software.

Typical operation is as follows:

1. Write to the CTRL register with LOCAL_ENABLED, AUTOINC_DISABLED, WRITE5_INIT, WRITE7_INIT, WRITE1_INIT, LOAD_SELECT_ZERO, LOAD_ADDRESS_ZERO.
2. Decode the downstream KSV key data in the CD block.
3. Write NV_PDISP_HDCPRIF_KEY(0) and NV_PDISP_HDCPRIF_KEY(1) with zeroes. This operation will be overloaded with the key data from the CD block.
4. Write to the CTRL register with LOCAL_ENABLED, AUTOINC_ENABLED, WRITE5_TRIGGER, WRITE7_INIT, WRITE1_INIT, LOAD_SELECT_ZERO, LOAD_ADDRESS_ZERO. Poll for WRITE5_DONE.
5. Decode the downstream key in the CD block.
6. Write NV_PDISP_HDCPRIF_KEY(0) and NV_PDISP_HDCPRIF_KEY(1) with zeroes. This operation will be overloaded with the key data from the CD block.
7. Write to the CTRL register with LOCAL_ENABLED, AUTOINC_ENABLED, WRITE7_TRIGGER, WRITE5_INIT, WRITE1_INIT, LOAD_SELECT_ZERO, LOAD_ADDRESS_ZERO. Poll for WRITE7_DONE.
8. Repeat 5 through 7 39 more times. There are always 40 keys and one KSV value. If and only if upstream key authentication is required do the following:
9. Decode the upstream KSV key data in the CD block.
10. Write NV_PDISP_HDCPRIF_KEY(0) and NV_PDISP_HDCPRIF_KEY(1) with zeroes. This operation will be overloaded with the key data from the CD block.
11. Write to the CTRL register with LOCAL_ENABLED, AUTOINC_ENABLED,

WRITE5_TRIGGER, WRITE7_INIT, WRITE1_INIT, LOAD_SELECT_ZERO,

LOAD_ADDRESS_ZERO. Poll for WRITE5_DONE.

12. Decode the first upstream key in the CD block.
13. Write NV_PDISP_HDCPRIF_KEY(0) and NV_PDISP_HDCPRIF_KEY(1) with zeroes.

    This operation will be overloaded with the key data from the CD block.
14. Write to the CTRL register with LOCAL_ENABLED, AUTOINC_ENABLED, WRITE7_TRIGGER, WRITE5_INIT, WRITE1_INIT, LOAD_SELECT_ZERO,

    LOAD_ADDRESS_ZERO. Poll for WRITE7_DONE.
15. Repeat 12 through 14 39 more times. There are always 40 keys and one KSV value.

This leaves the store as follows (the required format):

- Byte 0 to Byte 4: downstream KSV
- Byte 5 to Byte 11: 1'st downstream key
- Byte 12 to Byte 18: 2'nd downstream key

  ...
- Byte 278 to Byte 284: 40'th downstream key
- Byte 285 to Byte 289: upstream KSV
- Byte 290 to Byte 296: 1'st upstream key

  ...
- Byte 563 to Byte 569: 40'th upstream key

HDCPRIF_ROM_CTRL

This register controls the number of Ack Attempts that the Crypto-ROM interface will try before timing out a Command transaction on the interface. This value is used to meet the tWr requirement of the Crypto-ROM, which limits the minimum time between these transactions. tWr is the minimum time between writes, and for Crypto-ROM operations the Commands are allowed to be issued two deep, so we need to wait 2 * tWr. The interface state machine will wait for a time of (Xp/2 * 949 * ACK_ATTEMPTS), where Xp is the Xtal clock period, and 949 is the number of Xtal clock edges the RTL needs to see to complete an Command/Acknowledge Poll sequence. The _INIT value will give a timeout of approximately 18 ms with a 27 MHz xtal (which will allow us to cope with Atmel parts that are out of spec on tWr).

Offset: 0xcf | Byte Offset: 0x33c | Read/Write: R/W | Reset: 0x000003ff (0bxxxxxxxxxxxxxxxx0000001111111111)

Bit	Reset	Description
15:0	0x3ff	ACK_ATTEMPTS

- AUDIO_CNTRL0
- ERROR_TOLERANCE: Because the (dispclk_audio_fs / audio sampling frequency) is a non-integer in general and due to the spdif input stream's jitter, THREE_HALF is not exactly equal to 3 times of HALF. ERROR_TOLERANCE is the error count in dispclk periods allowed for 3 x HALF vs THREE_HALF. Based on simulation, the value of 4 to 7 is a good value when dispclk_audio_fs = 416 MHz.

  It is anticipated that software doesn't need to change this field from its init value.
- SAMPLING_FREQ: This reports the incoming spdif audio stream sampling frequency. The HDMI specification only supports 7 audio sample frequency (fs); anything other than those 7 fs will be reported as UNKNOWN.

  See HDMI 1.1 specification Table 7-4 (page 77)
- SOURCE_SELECT: Determines whether to use the SPDIF or Azalia (HDAL) audio input.

This field has no effect on chips without the HDAL input. The default is AUTO: selects SPDIF audio until the HDAL audio input is initialized by the external controller

- FRAMES_PER_BLOCK: FRAMES_PER_BLOCK is number of frames per block. By specification each block has 192 (0xC0) frames.
- AUDIO_N
- N_VALUE: N_VALUE is the N parameter in HDMI Audio Clock Regeneration Packet. This value should be written when Hardware measured CTS is enabled. The correct N value can be read from tables 7-1, 7-2, and 7-3 in the HDMI specification.
- N_RESET: N_RESET is reset for N counter, If software is controlling the value of N, every time the audio stream changes sampling freq (fs), software (RM) need to reset the N counter by writing _ASSERT to N_RESET and follow by writing a _DEASSERT to N_RESET.

  If the Hardware selected N feature is enabled (N_LOOKUP = _ENABLE), Software only needs to reset the N counter when writing to the AUDIO_NVAL registers and when enabling/disabling N_LOOKUP.

  a. set N_RESET = _ASSERT

  b. modify N value registers

  c. set N_RESET = _DEASSERT

  Modifying N_VALUE can be done in step 1.
- N_LOOKUP

  When set to _ENABLE, the hardware will select the appropriate value of N to use from one of the AUDIO_NVAL registers. This selection is based on the audio sampling frequency detected by the audio block. This is not the sampling frequency reported in the channel status bits. N_RESET should be toggled when this feature is enabled.

  When set to _DISABLE, software must program the correct N value into AUDIO_N.

27.8.153 SOR_NV_PDISP_HDCPRIF_ROM_TIMING_0

This register controls the timing of the cryptorom interface. Any time the hdmi_clk period changes, the values here must be changed too. The cryptorom bit period must more than 1 uS. 500 KHz is a safe target. The hdmi_clk frequency is reduced by the scale factor defined by the PRESCALE divider; the period is equal to (PRESCALE+1) hdmi_clk ticks.

BIT_PERIOD defines the timing of the SCL (serial clock) output. The SCL pin will be driven high for counts 0.. (BIT_PERIOD >> 1), and will be driven low for counts (BIT_PERIOD >> 1)+1 .. BIT_PERIOD.

DATA_DLY defines how many scaled ticks pass before SDA (the data bit) makes a transition after the falling edge of SCL (for data writes and for ACK'ing after data reads).

START_DLY defines how many scaled ticks pass before SDA (the data bit) makes a transition after the rising edge of SCL (for START and STOP).

The defaults make sure even with an HDMI clock of 150 MHz that the bit clock will not be faster than 500 KHz.

In general, programming should be something like this. Given the hdmi_clk frequency and the target I2C bit rate, figure out the necessary prescale. The prescale must be large enough such that the BIT_PERIOD divisor fits into 8 bits, but it should otherwise be as small as possible in order to minimize the time quantization.

(PRESCALE+1)*(BIT_PERIOD+1)*(hdmi_clk period) >= (I2C bit period)

BIT_PERIOD+1 can be as large as 256. Rearranging,

PRESCALE = ceil[(I2C bit period)/(hdmi_clk period) / 256] - 1

= ceil[(hdmi_clk frequency)/(I2C frequency) / 256] - 1

This determines the time quantum of the other divisors.

prescale_period = (hdmi_clk period) / (PRESCALE + 1)

Next, determine the bit period:

BIT_PERIOD = ceil[(hdmi_clk frequency) / (PRESCALE+1) / (I2C frequency)] - 1

SDA (data) normally changes only while SCL is low. The Atmel datasheet says that SDA must hold for at least 10ns after SCL falls and must be set up at least 100 ns before SCL rises. Thus, DATA_DLY must be:

DATA_DLY > floor(BIT_PERIOD/2) + 10 ns

DATA_DLY < BIT_PERIOD - 100 ns

In most circumstances setting DATA_DLY to arrive 75% of the way through the cycle is OK.

DATA_DLY = floor((BIT_PERIOD+1) * 3 / 4) - 1

The start and stop conditions extend the SCL high time before the next falling SCL transition. One Atmel datasheet says that SDA (data) must not change within 200 ns of the rising or falling edge of SCL. A safe calculation is to assume that we wait a tick less than half a clock period:

START_DLY = floor(BIT_PERIOD / 2) - 2

Offset: 0xe5 | Byte Offset: 0x394 | Read/Write: R/W | Reset: 0x0f080e13 (0bxxxx11110000100000011000010011)

7:0	0x13	BIT_PERIOD

27.8.154 SOR_NV_PDISP_SOR_REFCLK_0

SOR_REFCLK

The HDMI clock is programmable and varies, depending on screen resolution. The NV_PDISP_SOR_SEQ_INSTn instructions (above) can wait for certain time intervals to elapse. Whenever hdmi_clk frequency is changed, this register must be reprogrammed to divide hdmi_clk to produce a 1 µs time reference, otherwise the time intervals requested by NV_PDISP_SOR_SEQ_INSTn will not be accurate.

The format of DIVISOR is an unsigned 8.2 divider. Because this is a simple digital divider, not a PLL, fractional values result in a jitter of one hdmi_clk between successive "1 µs" intervals, but the long-term average works out to the requested divisor. This jitter is OK because the NV_PDISP_SOR_SEQ_INST wait intervals do not need to be exact. If the integer part is written as 0, it will be interpreted the same as "1".

Offset: 0xe6 | Byte Offset: 0x398 | Read/Write: R/W | Reset: 0x00001900 (0bxxxxxxxxxxxxxxxxx0001100100xxxxxx)

27.8.155 SOR_NV_PDISP_CRC_CONTROL_0

CRC_CONTROL

The main CRC enable bit flows along the pipeline. This register controls the injection of this bit at the top of the pipeline. This register is double-buffered. The active value is updated at start of each frame from this 'ARM' register.

Other registers such as SOR_STATE2.ASY_CRCMODE and SOR_*CRC* control the actual CRC logic, once enabled.

ARM_CRC_CONTROL enables or disables computation of CRC, effective at the start of next frame.

Offset: 0xe7 | Byte Offset: 0x39c | Read/Write: R/W | Reset: 0x00000000 (0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx0)

Bit	Reset	Description
0	NO	ARM_CRC_ENABLE: 0 = NO 1 = YES 0 = DIS 1 = EN

27.8.156 SOR_NV_PDISP_INPUT_CONTROL_0

INPUT_CONTROL

HDMI_SRC_SELECT selects from which of the two display units to take input. This register should be changed only when HDMI is idle.

ARM_RGB_RANGE controls whether R/G/B values of 0 and 255 are permitted (FULL), or removed by clamping to [1,254] (LIMITED).

According to the EIA/CEA-861-B and HDMI specifications, the 640x480 VGA mode uses FULL, and all others use LIMITED.

Note that this does not scale the video or change the black and white points (VGA is [0,255], others are [16,235]). That must be done, if necessary, in display or at the source.

See the HDMI 1.2a specification, Section 6.6.

This register is double-buffered and will take effect on next frame boundary.

Offset: 0xe8 | Byte Offset: 0x3a0 | Read/Write: R/W | Reset: 0x00000000 (0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx00) | Default: 0x00000001

27.8.157 SOR_NV_PDISP_SCRATCH_0

SCRATCH

This register is not used by hardware. It is available for software to store the state or for testing purposes.

Offset: 0xe9 | Byte Offset: 0x3a4 | Read/Write: R/W | Reset: 0x00000000 (0b00000000000000000000000000000000)

Bit	Reset	Description
31:0	0x0	DATA

27.8.158 SOR_NV_PDISP_KEY_CTRL_0

HDCP KEY SRAM Register Control

This is the register space for the HDCP ROM interface control register. This register controls writing the contents of the hdcp_key_data bus (56 bits) into the local key store. The keys are decoded in the Crypto block, and then the key data is presented on the bus.

LOCAL: If this bit is ENABLED the on-chip HDCP key store will be used by the HDCP encryption block. If DISABLED, external Crypto-ROM will be used.

AUTOINC: If this bit is ENABLED, the address written to by the WRITE16 function will auto-increment after the operation is complete. This is the normal operating mode.

WRITE16: If this bit is set to TRIGGER, the HDCP keys module will write all 16 bytes of data from the hdcp_key_data bus (sourced by the CD module) into the local key store. The bytes are written into the store at contiguous bytes pointed to by the ADDRESS field in auto-increment mode, or contiguous bytes pointed to by the LOAD_ADDRESS field otherwise. Poll this bit until it reports DONE to ensure the write is complete.

PKEY_REQUEST_RELOAD: Requests that the private key be requested again from KFUSE. Will autoclear to zero as soon as the requested transfer of the key begins. Only PKEY_LOADED will indicate when the key is ready for use.

PKEY_LOADED: Indicates that the private key value has been received from KFUSE and is ready for use.

LOAD_ADDRESS: For the WRITE16 function, this field selects the start byte address of the contiguous locations in the local key store to be written with the hdcp_key_data. This field is ignored if the AUTOINC bit is ENABLED. Addresses start at 0.

ADDRESS: This read-only field reports the next byte address in the local key store to be written to once the TRIGGER bits are DONE. For the WRITE16 operation, the address will increment by 16. Addresses start at 0.

Typical operation is as follows:

1. Write to the register with LOCAL_ENABLED, AUTOINC_DISABLED, WRITE5_INIT, WRITE7_INIT, LOAD_ADDRESS_ZERO.
2. Write the downstream KSV key data into the CD module and decrypt the key (see dev_cd.ref - HDCP_KEY_REG(i) and NV_PCIPHER_CTL1).
3. Write to the register with LOCAL_ENABLED, AUTOINC_ENABLED, WRITE5_TRIGGER, WRITE7_INIT, LOAD_ADDRESS_ZERO. Poll for WRITE5_DONE.
4. Write the first downstream key data into the CD module and decrypt the key (see dev_cd.ref - HDCP_KEY_REG(i) and NV_PCIPHER_CTL1).
5. Write to the register with LOCAL_ENABLED, AUTOINC_ENABLED, WRITE7_TRIGGER, WRITE7_INIT, LOAD_ADDRESS_ZERO. Poll for WRITE7_DONE.
6. Repeat steps 4 and 5 39 more times. There are always 40 keys and one KSV value.

If upstream key authentication is required, do the following:

1. Write the upstream KSV key data into the CD module and decrypt the key.
2. Write to the register with LOCAL_ENABLED, AUTOINC_ENABLED, WRITE5_TRIGGER, WRITE7_INIT, LOAD_ADDRESS_ZERO. Poll for WRITE5_DONE.
3. Write the first upstream key data into the CD module and decrypt the key (see dev_cd.ref - HDCP_KEY_REG(i) and NV_PCIPHER_CTL1).
4. Write to the register with LOCAL_ENABLED, AUTOINC_ENABLED, WRITE7_TRIGGER, WRITE7_INIT, LOAD_ADDRESS_ZERO. Poll for WRITE7_DONE.
5. Repeat steps 9 and 10 39 more times. There are always 40 keys and one KSV value.

This will leave the store as follows (the required format):

- Byte 0 to Byte 4: downstream KSV
- Byte 5 to Byte 11: 1st downstream key
- Byte 12 to Byte 18: 2nd downstream key

...

- Byte 278 to Byte 284: 40th downstream key
- Byte 285 to Byte 289: upstream KSV
- Byte 290 to Byte 296: 1st upstream key

...

- Byte 563 to Byte 569: 40'th upstream key

27.8.165 SOR_NV_PDISP_SOR_AUDIO_CNTRL0_0

HD Audio (also known as Azalia)

PORT_CONNECTIVITY: This controls the behavior of the Port Connectivity field of the Azalia Configuration Defaults Verb. This can be used to disable a codec that is associated with an SOR that does not connect to a physical port.

- ENABLE: Report 00 in the Port Connectivity field by default. This corresponds to "The Port Complex is connected to a jack"
- DISABLE: Report 01 in the Port Connectivity field by default. This corresponds to "No physical connection for Port" See table 100 and table 101 of the High Definition Audio Specification (Revision 1.0) for more information.

AFIFO_FLUSH: When the DP and HDMI logic are not in the middle of sending an audio packet, they will flush out any entries at the head of the AFIFO that is not tagged as the beginning of a sample. This ensures that the next new audio packet sent will begin on the correct channel. This is a diagnostic workaround bit to disable the flushing.

- ENABLE: Automatically fix the AFIFO if it gets out of alignment
- DISABLE: Do not throw out any AFIFO entries.

SAMPLING_FREQ: This will report the incoming audio stream sampling frequency in the Azalia codec. The HDMI specification only supports 7 audio sample frequencies (fs). Anything other than those 7 fs will be reported as UNKNOWN. See the HDMI 1.1 specification, Table 7-4 (page 77).

SOURCE_SELECT: Determines whether to use the S/PDIF or Azalia (HDAL) audio input. This field has no effect on chips without the HDAL input. The default is AUTO: selects S/PDIF audio until the HDAL audio input is initialized by the external controller

INJECT_NULLSMPL: When the bit is enabled, if the audio format is stereo LPCM as indicated by the stream format in the corresponding output converter widget, the codec inserts null samples into the audio FIFO for each Azalia frame in which it did not receive any samples. This is done only for stereo LPCM and not for any other audio format. This bit should be disabled by default for backwards compatibility.

INPUT_MODE: This bit indicates what the audio data source is. HDA is Azalia data, S/PDIF is S/PDIF data.

SOR_AUDIO_CNTRL0

Offset: 0xfc | Byte Offset: 0x3f0 | Read/Write: R/W | Reset: 0xX01X1000 (0bxx0xxxxxxx01xxxxxxx1xxxxxxxxxx0)

27.8.166 SOR_NV_PDISP_SOR_AUDIO_NVAL_0320_0

SOR_AUDIO_NVAL

The following seven registers are used for HDMI N values for Azalia. These registers should be written with the correct N values for the current pixel clock frequency. These values can be found in tables 7-1, 7-2, and 7-3 of the HDMI specification. These registers are initialized to the value in the "other" row of these tables.

For DisplayPort audio, a value of 2^15 (0x8000) is always used.

VALUE: The correct N value for 32 kHz audio at the current pixel clock frequency should be written here.

SOR_AUDIO_HDA_ELD_BUFWR

Software Programming Model

In an integrated graphics chip, which includes an NVIDIA® Audio Controller, with support for an NVIDIA audio codec driver, the following is the background and the suggested programming model.

The audio software for the HDMI codec will need information about the audio capabilities of an attached HDMI sink device. This information is stored in the HDMI sink device's EDID. Typically, the EDID flows through a graphics adapter to graphics software, so the graphics adapter hardware will not have knowledge of the EDID contents.

To that end, a new mechanism is defined for passing the HDMI sink device's audio EDID information from the graphics software to the audio software. The data payload containing the audio information will be known as EDID-Like Data (or ELD) and will contain a subset of the HDMI sink devices EDID information.

The ELD information will be valid if the HDMI sink is attached and powered on and the ELD Valid bit is set. The Pin Widget that is associated with this HDMI widget will report if the device is attached and that the ELD memory is populated and valid by reporting Presence Detect of 1 and ELD Valid of 1 to a Pin Sense control command. As with the Presence Detect bit, the changes to the ELD Valid bit can also result in the generation of unsolicited responses.

Each codec implements a 96-byte ELD buffer that is written by the resource manager and read by the audio driver. Once the ELD buffer is written by the resource manager, the valid bit, NV_PDISP_SOR_AUDIO_HDA_PRESENSE_ELDV is set to

_VALID to indicate that ELD contents have been initialized by the resource manager. On hot unplug events, NV_PDISP_SOR_AUDIO_HDA_PRESENSE_ELDV is set to _INVALID to erase ELD programming in the audio driver.

Offset: 0x10c | Byte Offset: 0x430 | Read/Write: R/W | Reset: 0x00000000 (0bxxxxxxxxxxxxxxxx0000000000000000)

Bit	Reset	Description

27.8.182 SOR_NV_PDISP_SOR_AUDIO_AVAL_0320_0

AUDIO_AVAL

When using the Azalia codec, it is difficult to recover the 128*fs clock frequency from the incoming audio stream. Therefore, when using the Azalia codec, these registers must be programmed to emulate the N counter.

When using S/PDIF, the N counter will run at 128*fs (audio sampling frequency) and count to a value determined by the HDMI specification. The Azalia counter will run at 24 MHz at all times, and it needs to count for the same period of time as the N counter would have.

Refer to Section 7.2 of the HDMI specification, 1.2.

AVAL values do not need to be programmed by software. Their default values are OK. If the NVAL changes, it will change the N counter frequency. AVAL will need to be changed to match with this new NVAL. Certain resolutions may require different NVALs.

For Mobile chips, the clock is 24 MHz, not 54 MHz. For 44.1, the default N of 6272 gives non-integer AVAL. Choosing N of 4704 instead (nominal CTS 61875) gives an N frequency of 1200 Hz.

48k: 1ms 24000 azaclk cycles (0x5DC0)

44.1k: 1ms/1.2 20000 azaclk cycles (0x4E20)

But this is academic because CTS/N is hardcoded since the pixel clock / audio clock ratios are known and fixed.

At 27 MHz Pixel Clock			
	CTS	**N**	**AVAL**
44.1	22500	4704	20000
88.2	22500	9408	20000
176.4	22500	18816	20000
At 74.25 MHz Pixel Clock			
44.1	61875	4704	20000
88.2	61875	9408	20000
176.4	61875	18816	20000
At 148.5 MHz Pixel Clock:			
44.1	123750	4704	20000
88.2	123750	9408	20000

3:0	0xf	CHSTS_FS_3840

27.8.198 SOR_NV_PDISP_SOR_HDMI_VSI_INFOFRAME_CTRL_0

HDMI_VSI_CTRL

This register controls the frequency and generation of the Vendor Specific infoframe packets. The Vendor Specific Infoframe packet contains supplemental information about the raster type. The fields of this register are identical to HDMI_AVI_INFOFRAME_CTRL except where noted below.

The Vendor Specific Infoframe is described in Appendix H of the HDMI 1.4a specification.

- ENABLE

  Setting this field to _YES will initiate infoframe generation. Setting this bit to _NO will disable infoframe generation at the beginning of the next frame.

The frequency of infoframe generation is controlled by OTHER and SINGLE fields.

- OTHER

  Setting this field to _EN while SINGLE is set to _DIS will cause infoframe to be transmitted every other frame.

- SINGLE

  Setting this field to _EN while OTHER is set to _DIS will cause infoframe to be transmitted exactly once.

If OTHER and SINGLE fields are both set to _DIS, infoframe will be generated every frame. Software should never set both OTHER and SINGLE to _EN.

- CHKSUM_HW: Hardware provides a way to calculate the Checksum for the infoframes.
  - _ENABLE will enable the hardware calculation to be passed to the packet
  - _DISABLE will use the register value defined in SF_HDMI_VSI_SUBPACK0_LOW_PB0 for the checksum.
- VIDEO_FMT

  The Vendor Specific Infoframe contains an HDMI_Video_Format Field. This field specifies how the remaining bytes in the infoframe should be interpreted by the specification. When switching to a 3D stereo format, the HDMI_Video_Format field and the 3D_Structure field need to be set appropriately. This priv register field selects whether hardware or software will set those fields.
- _SW_CONTROLLED: The HDMI_Video_Format field and 3D_Structure field will be set by SF_HDMI_VSI_SUBPACK0_HIGH_PB4 and PB5.
- _HW_CONTROLLED: The HDMI_Video_Format field and 3D_Structure field will be set automatically by Hardware based on the state of the NV_917D_Core_Head_SetHdmiCtrl method.

Offset: 0x123 | Byte Offset: 0x48c | Read/Write: R/W | Reset: 0x00010200 (0bxxxxxxxxxxxxxxxx1xxxxxx10xxx0xxx0)

Bit	Reset	Description

15:8	0x0	PB1
7:0	0x0	PB0

27.8.211 SOR_NV_PDISP_SOR_DP_AUDIO_INFOFRAME_SUBPACK0_HIGH_0

DP_AUDIO_INFOFRAME_SUBPACK0_HIGH

This register should be written with the upper 2 bytes of the DP Audio InfoFrame. PB4 and PB5 are defined fields from the specification.

See Section 8.2.2 - Audio InfoFrame, Table 8-5, in the HDMI specification for more information

Offset: 0x132 | Byte Offset: 0x4c8 | Read/Write: R/W | Reset: 0x00000000 (0bxxxxxxxxxxxxxxxx0000000000000000)

Bit	Reset	Description
15:8	0x0	PB5
7:0	0x0	PB4

27.8.212 SOR_NV_PDISP_SOR_DP_AUDIO_TIMESTAMP_0320_0

SOR_DP_AUDIO_TIMESTAMP

Maud and Naud are defined as:

Maud / Naud = (512*fs) / link_clock

In other words, Maud is a measure of how many periods in the 512*fs domain would elapse in Naud link_clocks. Naud is fixed at 2^15. In order to simulate a counter running at 512*fs, a fractional counter running at 108 MHz is used.

For each of these registers, N and D-N should be set such that the following equation is satisfied exactly.

N/D = 512*fs / 108 MHz

32 KHz * 512 = 16.384 MHz

For Tegra X1:

16.384 MHz / 102 MHz = (2^14) / (17 * 3 * 2^4 * 5^3)

= 1024 (N) / 6375 (D)

Offset: 0x133 | Byte Offset: 0x4cc | Read/Write: R/W | Reset: 0x040014e7 (0b00000100000000000000010100111001111)

Bit	Reset	Description
31:16	0x400	N

27.8.219 SOR_NV_PDISP_HDMI_AUDIO_N_0

AUDIO_N

N_LOOKUP: When set to _ENABLE, the hardware will select the appropriate value of N to use from one of the AUDIO_NVAL registers. This selection is based on the audio sampling frequency detected by the audio block. This is not the sampling frequency reported in the channel status bits. N_RESET should be toggled when this feature is enabled. When set to _DISABLE, software must program the correct N value into AUDIO_N.

Offset: 0x13c | Byte Offset: 0x4f0 | Read/Write: R/W | Reset: 0x00000000 (0bxxx0xxxxxxxxxxxxxxxxxxxxxxxxxxx)

Bit	Reset	Description
28	0x0	LOOKUP: 1 = ENABLE 0 = DISABLE

27.8.220 SOR_NV_PDISP_HDMI_LANE_CALIB_FUSE_0

Register to read the lane calibration programmed in fuses to get a base line for lane parameters.

Offset: 0x13d | Byte Offset: 0x4f4 | Read/Write: RO | Reset: 0xXXXXXXXX (0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx)

Bit	Reset	Description
31:24	X	LANE3_CALIB

Bit	Reset	Description
15:0	0xfffd	LANE2_SEED

27.8.224 SOR_NV_PDISP_SOR_HDCP22_CTRL_0

HDCP 2.2 Control register

This register controls the Encryption of the actual data and initializing the HDCP vars.

_ENABLE: This bit will be set by the software when SKE has successfully completed and it needs to enable the encryption. Setting _YES would actually start encrypting the incoming data.

For HDMI, encryption would start after the EESS has been sent at the beginning of the next frame. For DP, encryption would start at the next SR. Setting this bit to _NO would stop encrypting the data. For HDMI ciphers would stop advancing at next EESS signaling. For DP, cipher would stop at the next CPSR. Hardware will retain internal state. The current status of the CIPHER block is reported in the _CRYPT_STATUS field.

Setting this bit to _NO doesn't reset any of the internal state of Counters so the encryption can be resumed.

_INIT: This bit is set by microcode at the end of the SKE success. Setting this field to _YES would reset inputCtr to its initial value to indicate a fresh start of a new session. Hardware clears this bit as soon as it is done initializing the state and generating the Ciphers.

> ***Note:*** *Software must not toggle this bit when link is already authenticated and encryption has been enabled at least once*

_LOCK_TYPE: This field indicates if the TYPE register can be written by unsecured software or not.

- _LOCKED indicates only Protected software can write to the TYPE
- _UNLOCKED indicates protected software cannot write to the TYPE

  Software needs the init value of the LOCK_TYPE field to be LOCKED.

_REPEATER: This bit is set by microcode normally before triggering the _INIT bit. This bit has no functional impact. It is used in reporting that the SOR is authenticated with a downstream REPEATER to the upstream logic.

_DISABLE_DETACH:HDCP2.2 code is executed in secure code using TSEC in Heavy secure mode. As RM is running in an unsecure environment, there is no "Disable Encryption Command". Currently RM disables HDCP during mode switch and reauthenticates after the mode switch is finished. This field enables HW to disable encryption when SOR is detached from the head. As the SOR is detached, there is no guarantee that the Panel would be in sync with cipher so a new fresh authentication is required. SOFTWARE MUST RESTABLISH THE KS/RIV.

_DISABLE_LANE_CNT:HDCP2.2 code is executed in secure code using TSEC in Heavy secure mode. As RM is running in an unsecure environment, there is no "Disable Encryption Command". Currently RM disables HDCP during Flush mode and reauthenticates after exit from the flush mode. This field enables HW to disable encryption when SOR lane count is set to 0 (which is the first step in Flush mode). As the SOR lane count goes to 0, there is no guarantee that the Panel would be in sync with cipher so a new fresh authentication is required. Software MUST RESTABLISH THE KS/RIV.

Offset: 0x141 | Byte Offset: 0x504 | Read/Write: R/W | Reset: 0x00000064 (0bxxxxxxxxxxxxxxxxxxxxxxxxxx110x100)

Bit	Reset	Description

0	0x0	CRYPT: 0 = DISABLE 1 = ENABLE

27.8.225 SOR_NV_PDISP_SOR_HDCP22_STATUS_0

HDCP 2.2 Status register

This register provides the status of the HDCP2.2 block.

_CRYPT_STATUS: This bit reports the actual link encryption status. This bit indicates whether HW is advancing the cipher or not.

_FRAME_CNT_OVERFLOW: This indicates if the Frame counter has overflowed.

_DATA_CNT_OVERFLOW: This indicates if the Data counter has overflowed.

_DETACHED_DISABLE: When NV_PDISP_SOR_HDCP22_CTRL_DISABLE_DETACH is set, HW would disable encryption when the SOR is detached. The status is reported in this bit. This will also indicate CRYPT_STATUS to _INACTIVE.

_LANE_CNT0_DISABLE: When NV_PDISP_SOR_HDCP22_CTRL_DISABLE_LANE_CNT0 is set, HW would disable encryption when the SOR lane count is set to 0 in DP mode. The status is reported in this bit. This will also indicate CRYPT_STATUS to _INACTIVE

Offset: 0x142 | Byte Offset: 0x508 | Read/Write: RO | Reset: 0x00000XXX (0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx)

27.8.232 SOR_NV_PDISP_SOR_HDCP22_SST_DP_TYPE_0

AES-CTR DP Type

Below 2 registers are used when the SOR is set to DP protocol. It allows SW to pass the Stream Type value to the HW which is used during encryption. This is a 64 bits value and indicates the type of the stream. If any bit is set to 1, then corresponding stream cannot be transmitted to HDCP1.x devices.

This communication is handled by microcode as a part of the Stream_Manage_Message to the repeater.

Hardware uses this value to generate the ciphers.

New settings in these registers are promoted to active at the same time as NV_PDISP_SOR_ECF0/1.

27.9 HDCP KFUSE Control Registers

Refer to Section 1.4: Reading Register Tables in the Introduction chapter for the register table protocol as well as recommendations for accessing registers.

27.9.1 KFUSE_STATE_0

Commands and status for ECC mode

Offset: 0x80 I Read/Write: R/W I Reset: 0xXX0XXXXX (0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx)

Bit	R/W	Reset	Description
31	RW	X	SOFTRESET
25	RW	X	STOP: Write 1 to abort decoding in progress, then wait for STATE=IDLE
24	RW	X	RESTART: Write 1 to re-start decoding, similar to deassertion of reset
17	RO	X	CRCPASS: After DONE, indicates CRC pass/fail
16	RO	X	DONE: When decode is complete, DONE=1
13:8	RO	X	ERRBLOCK: If any ERR_* are set, contains offset of first errored block
5:0	RO	X	CURBLOCK: Counter of current block during decode, for debugging

27.9.2 KFUSE_ERRCOUNT_0

ECC decode error count; valid after DONE=1

Offset: 0x84 I Read/Write: RO I Reset: 0xXXXXXXXX (0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx)

Bit	Reset	Description
30:24	X	ERR_FATAL: number of uncorrectable errors
22:16	X	ERR_3: number of correctable 3-bit errors
14:8	X	ERR_2: number of correctable 2-bit errors
6:0	X	ERR_1: number of correctable 1-bit errors

27.9.3 KFUSE_KEYADDR_0

For reading keyglob data after decode is DONE

Offset: 0x88 I Read/Write: R/W I Reset: 0x00010000 (0bxxxxxxxxxxxxxxx1xxxxxxx00000000)

Bit	Reset	Description
16	0x1	AUTOINC: when set, ADDR is incremented by 1 after each read of KEYS
7:0	0x0	ADDR: Word address (0..144)

27.9.4 KFUSE_KEYS_0

Decoded keyglob data; after each read, ADDR is incremented if AUTOINC==1

Offset: 0x8c I Read/Write: RO I Reset: 0xXXXXXXXX (0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx)

Bit	Reset	Description
31:0	X	DATA

27.9.5 KFUSE_PD_0

Offset: 0x24 I Read/Write: R/W I Reset: 0x0000000X (0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx0)

Bit	R/W	Reset	Description
1	RO	X	STATUS:PD STATUS BIT: Indicates the final value of PD going to the fuse macro. 0 = KFUSECELL_PWRUP 1 = KFUSECELL_PWRDOWN
0	RW	0x0	CTRL:PD (or POWER DOWN) feature: Writing this bit will assert kfusecell_pd pin to kfusecell macro and put it in a low leakage mode. 0 = POWERUP 1 = POWERDOWN

27.10 HDA Registers

Refer to Section 1.4: Reading Register Tables in the Introduction chapter for the register table protocol as well as recommendations for accessing registers.

27.10.1 HDA_AXI_BAR0_SZ_0

AXI BARi mapping

Offset: 0x0 I Read/Write: R/W I Reset: 0x00000004 (0bxxxxxxxxxxxxx00000000000000000100)

Bit	Reset	Description
19:0	0x4	AXI_BAR0_SIZE: The size of the address range associated with BARi is in 4K increments. Value of 0 signifies BARi is not used.

27.10.2 HDA_AXI_BAR1_SZ_0

Offset: 0x4 I Read/Write: R/W I Reset: 0x00000000 (0bxxxxxxxxxxxxx00000000000000000000)

Bit	Reset	Description
19:0	0x0	AXI_BAR1_SIZE: The size of the address range associated with BARi is in 4K increments. Value of 0 signifies BARi is not used.

27.10.3 HDA_AXI_BAR2_SZ_0

Offset: 0x8 I Read/Write: R/W I Reset: 0x00000000 (0bxxxxxxxxxxxxx00000000000000000000)

Bit	Reset	Description
19:0	0x0	AXI_BAR2_SIZE: The size of the address range associated with BARi is in 4K increments. Value of 0 signifies BARi is not used.

27.10.4 HDA_AXI_BAR3_SZ_0

Offset: 0xc I Read/Write: R/W I Reset: 0x00000000 (0bxxxxxxxxxxxxx00000000000000000000)

Bit	Reset	Description
19:0	0x0	AXI_BAR3_SIZE: The size of the address range associated with BARi is in 4K increments. Value of 0 signifies BARi is not used.

27.10.5 HDA_AXI_BAR0_START_0

Offset: 0x40 I Read/Write: R/W I Reset: 0x70038000 (0b01110000000000111000xxxxxxxxxxx)

Bit	Reset	Description
31:12	0x70038	AXI_BAR0_START: The start of AXI address space for BARi. The AXI target address is compared to start/size for each BAR to determine if the access is to that BAR.

27.10.6 HDA_AXI_BAR1_START_0

Offset: 0x44 I Read/Write: R/W I Reset: 0x00000000 (0b00000000000000000000xxxxxxxxxxx)

Bit	Reset	Description
31:12	0x0	AXI_BAR1_START: The start of AXI address space for BARi. The AXI target address is compared to start/size for each BAR to determine if the access is to that BAR.

27.10.7 HDA_AXI_BAR2_START_0

Offset: 0x48 I Read/Write: R/W I Reset: 0x00000000 (0b00000000000000000000xxxxxxxxxxx)

Bit	Reset	Description
31:12	0x0	AXI_BAR2_START: The start of AXI address space for BARi. The AXI target address is compared to start/size for each BAR to determine if the access is to that BAR.

27.10.8 HDA_AXI_BAR3_START_0

Offset: 0x4c I Read/Write: R/W I Reset: 0x00000000 (0b00000000000000000000xxxxxxxxxxx)

Bit	Reset	Description
31:12	0x0	AXI_BAR3_START: The start of AXI address space for BARi. The AXI target address is compared to start/size for each BAR to determine if the access is to that BAR.

27.10.9 HDA_FPCI_BAR0_0

Offset: 0x80 I Read/Write: R/W I Reset: 0x00040001 (0b00000000000001000000000000000xxx1)

Bit	Reset	Description
31:4	0x4000	FPCI_BAR0_START: The start of FPCI address space mapped into the BARi range of PCI memory space. The 40-bit FPCI address is determined by a shift left 12 of the value of this register.
0	0x1	FPCI_BAR0_ACCESS_TYPE:Indicates if the address region is memory mapped versus configuration or I/O space. 0=memory mapped access (PW only) 1=I/O/config access (NPW only)

27.10.10 HDA_FPCI_BAR1_0

Offset: 0x84 I Read/Write: R/W I Reset: 0x00000001 (0b00000000000000000000000000000xxx1)

Bit	Reset	Description
31:4	0x0	FPCI_BAR1_START: The start of FPCI address space mapped into the BARi range of PCI memory space. The 40-bit FPCI address is determined by a shift left 12 of the value of this register.
0	0x1	FPCI_BAR1_ACCESS_TYPE:Indicates if the address region is memory mapped versus configuration or I/O space. 0=memory mapped access (PW only) 1=I/O/config access (NPW only)

27.10.11 HDA_FPCI_BAR2_0

Offset: 0x88 I Read/Write: R/W I Reset: 0x00000001 (0b00000000000000000000000000000xxx1)

Bit	Reset	Description
31:4	0x0	FPCI_BAR2_START: The start of FPCI address space mapped into the BARi range of PCI memory space. The 40-bit FPCI address is determined by a a shift left 12 of the value of this register.
0	0x1	FPCI_BAR2_ACCESS_TYPE:Indicates if the address region is memory mapped versus configuration or I/O space. 0=memory mapped access (PW only) 1=I/O/config access (NPW only)

27.10.12 HDA_FPCI_BAR3_0

Offset: 0x8c I Read/Write: R/W I Reset: 0x00000001 (0b00000000000000000000000000000xxx1)

Bit	Reset	Description
31:4	0x0	FPCI_BAR3_START: The start of FPCI address space mapped into the BARi range of PCI memory space. The 40-bit FPCI address is determined by a shift left 12 of the value of this register.
0	0x1	FPCI_BAR3_ACCESS_TYPE:Indicates if the address region is memory mapped versus configuration or I/O space. 0=memory mapped access (PW only) 1=I/O/config access (NPW only)

27.10.13 HDA_MSI_BAR_SZ_0

MSI BAR SIZE

Offset: 0xc0 I Read/Write: R/W I Reset: 0x00000000 (0bxxxxxxxxxxxxx00000000000000000000)

Bit	Reset	Description
19:0	0x0	MSI_BAR_SIZE: The size of the address range associated with MSI BAR is in 4K increments. Value of 0 signifies BAR is not used.

27.10.14 HDA_MSI_AXI_BAR_ST_0

MSI AXI BAR START

Offset: 0xc4 I Read/Write: R/W I Reset: 0x00000000 (0b00000000000000000000xxxxxxxxxxxx)

Bit	Reset	Description
31:12	0x0	MSI_AXI_BAR_START: The start of upstream AXI address space for MSI BAR.The upstream FPCI address is compared to start/1KB range for MSI BAR to determine if the access is MSI. Bits 31:12 of MSI BAR start correspond to AXI address bits 31:12.

27.10.15 HDA_MSI_FPCI_BAR_ST_0

MSI FPCI BAR START

Offset: 0xc8 I Read/Write: R/W I Reset: 0x00000000 (0b0000000000000000000000000000xxxx)

Bit	Reset	Description
31:4	0x0	MSI_FPCI_BAR_START: The start of upstream FPCI address space for MSI BAR. The upstream FPCI address is compared to start/1KB range for MSI BAR to determine if the access is MSI. Bits 31:4 of MSI BAR start correspond to UFPCI address bits 39:12.

27.10.16 HDA_MSI_VEC0_0

MSI VECTORi i in [0 7] RW

Offset: 0x100 I Read/Write: R/W I Reset: 0x00000000 (0b00000000000000000000000000000000)

Bit	Reset	Description
31:0	0x0	MSI_VECTOR0: Each vector register corresponds to 32 of the possible 256 MSI vectors.VECTOR0 corresponds to MSI vectors 31-0.Vector7 corresponds to MSI vectors 255-223.When an upstream MSI is sent, the bit corresponding to the MSI vector is set to 1 by hardware if the corresponding enable bit is 1.The bit is set to 0 if a 1 is written to its location.

27.10.17 HDA_MSI_VEC1_0

Offset: 0x104 I Read/Write: R/W I Reset: 0x00000000 (0b00000000000000000000000000000000)

Bit	Reset	Description
31:0	0x0	MSI_VECTOR1: Each vector register corresponds to 32 of the possible 256 MSI vectors.VECTOR0 corresponds to MSI vectors 31-0.Vector7 corresponds to MSI vectors 255-223.When an upstream MSI is sent, the bit corresponding to the MSI vector is set to 1 by hardware if the corresponding enable bit is 1.The bit is set to 0 if a 1 is written to its location.

27.10.18 HDA_MSI_VEC2_0

Offset: 0x108 I Read/Write: R/W I Reset: 0x00000000 (0b00000000000000000000000000000000)

Bit	Reset	Description
31:0	0x0	MSI_VECTOR2: Each vector register corresponds to 32 of the possible 256 MSI vectors.VECTOR0 corresponds to MSI vectors 31-0.Vector7 corresponds to MSI vectors 255-223.When an upstream MSI is sent, the bit corresponding to the MSI vector is set to 1 by hardware if the corresponding enable bit is 1.The bit is set to 0 if a 1 is written to its location.

27.10.19 HDA_MSI_VEC3_0

Offset: 0x10c I Read/Write: R/W I Reset: 0x00000000 (0b00000000000000000000000000000000)

Bit	Reset	Description
31:0	0x0	MSI_VECTOR3: Each vector register corresponds to 32 of the possible 256 MSI vectors.VECTOR0 corresponds to MSI vectors 31-0.Vector7 corresponds to MSI vectors 255-223.When an upstream MSI is sent, the bit corresponding to the MSI vector is set to 1 by hardware if the corresponding enable bit is 1.The bit is set to 0 if a 1 is written to its location.

27.10.20 HDA_MSI_VEC4_0

Offset: 0x110 I Read/Write: R/W I Reset: 0x00000000 (0b00000000000000000000000000000000)

Bit	Reset	Description
31:0	0x0	MSI_VECTOR4: Each vector register corresponds to 32 of the possible 256 MSI vectors.VECTOR0 corresponds to MSI vectors 31-0.Vector7 corresponds to MSI vectors 255-223.When an upstream MSI is sent, the bit corresponding to the MSI vector is set to 1 by hardware if the corresponding enable bit is 1.The bit is set to 0 if a 1 is written to its location.

27.10.21 HDA_MSI_VEC5_0

Offset: 0x114 I Read/Write: R/W I Reset: 0x00000000 (0b00000000000000000000000000000000)

Bit	Reset	Description
31:0	0x0	MSI_VECTOR5: Each vector register corresponds to 32 of the possible 256 MSI vectors.VECTOR0 corresponds to MSI vectors 31-0.Vector7 corresponds to MSI vectors 255-223.When an upstream MSI is sent, the bit corresponding to the MSI vector is set to 1 by hardware if the corresponding enable bit is 1.The bit is set to 0 if a 1 is written to its location.

27.10.22 HDA_MSI_VEC6_0

Offset: 0x118 I Read/Write: R/W I Reset: 0x00000000 (0b00000000000000000000000000000000)

Bit	Reset	Description
31:0	0x0	MSI_VECTOR6: Each vector register corresponds to 32 of the possible 256 MSI vectors.VECTOR0 corresponds to MSI vectors 31-0.Vector7 corresponds to MSI vectors 255-223.When an upstream MSI is sent, the bit corresponding to the MSI vector is set to 1 by hardware if the corresponding enable bit is 1.The bit is set to 0 if a 1 is written to its location.

27.10.23 HDA_MSI_VEC7_0

Offset: 0x11c I Read/Write: R/W I Reset: 0x00000000 (0b00000000000000000000000000000000)

Bit	Reset	Description
31:0	0x0	MSI_VECTOR7: Each vector register corresponds to 32 of the possible 256 MSI vectors.VECTOR0 corresponds to MSI vectors 31-0.Vector7 corresponds to MSI vectors 255-223.When an upstream MSI is sent, the bit corresponding to the MSI vector is set to 1 by hardware if the corresponding enable bit is 1.The bit is set to 0 if a 1 is written to its location.

27.10.24 HDA_MSI_EN_VEC0_0

MSI ENABLE VECTORi□i in [0□7]□RW

Offset: 0x140 I Read/Write: R/W I Reset: 0x00000000 (0b00000000000000000000000000000000)

Bit	Reset	Description
31:0	0x0	MSI_ENABLE_VECTOR0: Each vector register corresponds to the enable bit for 32 of the possible 256 MSI vectors. ENABLE VECTOR0 corresponds to enable bits for MSI vectors 31-0. Vector7 corresponds to enable bits for MSI vectors 255-223.When an upstream MSI is sent, the bit corresponding to the MSI vector is set to 1 by hardware if the corresponding enable bit is 1.

27.10.25 HDA_MSI_EN_VEC1_0

Offset: 0x144 I Read/Write: R/W I Reset: 0x00000000 (0b00000000000000000000000000000000)

Bit	Reset	Description
31:0	0x0	MSI_ENABLE_VECTOR1: Each vector register corresponds to the enable bit for 32 of the possible 256 MSI vectors. ENABLE VECTOR0 corresponds to enable bits for MSI vectors 31-0. Vector7 corresponds to enable bits for MSI vectors 255-223.When an upstream MSI is sent, the bit corresponding to the MSI vector is set to 1 by hardware if the corresponding enable bit is 1.

27.10.26 HDA_MSI_EN_VEC2_0

Offset: 0x148 I Read/Write: R/W I Reset: 0x00000000 (0b00000000000000000000000000000000)

Bit	Reset	Description
31:0	0x0	MSI_ENABLE_VECTOR2: Each vector register corresponds to the enable bit for 32 of the possible 256 MSI vectors. ENABLE VECTOR0 corresponds to enable bits for MSI vectors 31-0. Vector7 corresponds to enable bits for MSI vectors 255-223.When an upstream MSI is sent, the bit corresponding to the MSI vector is set to 1 by hardware if the corresponding enable bit is 1.

27.10.27 HDA_MSI_EN_VEC3_0

Offset: 0x14c I Read/Write: R/W I Reset: 0x00000000 (0b00000000000000000000000000000000)

Bit	Reset	Description
31:0	0x0	MSI_ENABLE_VECTOR3: Each vector register corresponds to the enable bit for 32 of the possible 256 MSI vectors. ENABLE VECTOR0 corresponds to enable bits for MSI vectors 31-0. Vector7 corresponds to enable bits for MSI vectors 255-223.When an upstream MSI is sent, the bit corresponding to the MSI vector is set to 1 by hardware if the corresponding enable bit is 1.

27.10.28 HDA_MSI_EN_VEC4_0

Offset: 0x150 I Read/Write: R/W I Reset: 0x00000000 (0b00000000000000000000000000000000)

Bit	Reset	Description
31:0	0x0	MSI_ENABLE_VECTOR4: Each vector register corresponds to the enable bit for 32 of the possible 256 MSI vectors. ENABLE VECTOR0 corresponds to enable bits for MSI vectors 31-0. Vector7 corresponds to enable bits for MSI vectors 255-223.When an upstream MSI is sent, the bit corresponding to the MSI vector is set to 1 by hardware if the corresponding enable bit is 1.

27.10.29 HDA_MSI_EN_VEC5_0

Offset: 0x154 I Read/Write: R/W I Reset: 0x00000000 (0b00000000000000000000000000000000)

Bit	Reset	Description
31:0	0x0	MSI_ENABLE_VECTOR5: Each vector register corresponds to the enable bit for 32 of the possible 256 MSI vectors. ENABLE VECTOR0 corresponds to enable bits for MSI vectors 31-0. Vector7 corresponds to enable bits for MSI vectors 255-223.When an upstream MSI is sent, the bit corresponding to the MSI vector is set to 1 by hardware if the corresponding enable bit is 1.

27.10.30 HDA_MSI_EN_VEC6_0

Offset: 0x158 I Read/Write: R/W I Reset: 0x00000000 (0b00000000000000000000000000000000)

Bit	Reset	Description
31:0	0x0	MSI_ENABLE_VECTOR6: Each vector register corresponds to the enable bit for 32 of the possible 256 MSI vectors. ENABLE VECTOR0 corresponds to enable bits for MSI vectors 31-0. Vector7 corresponds to enable bits for MSI vectors 255-223.When an upstream MSI is sent, the bit corresponding to the MSI vector is set to 1 by hardware if the corresponding enable bit is 1.

27.10.31 HDA_MSI_EN_VEC7_0

Offset: 0x15c I Read/Write: R/W I Reset: 0x00000000 (0b00000000000000000000000000000000)

Bit	Reset	Description
31:0	0x0	MSI_ENABLE_VECTOR7: Each vector register corresponds to the enable bit for 32 of the possible 256 MSI vectors. ENABLE VECTOR0 corresponds to enable bits for MSI vectors 31-0. Vector7 corresponds to enable bits for MSI vectors 255-223.When an upstream MSI is sent, the bit corresponding to the MSI vector is set to 1 by hardware if the corresponding enable bit is 1.

27.10.32 HDA_CONFIGURATION_0

Configuration

Offset: 0x180 I Read/Write: R/W I Reset: 0x800X8X40 (0b1xxxxxxxxxxx1xxx10xxxxxx01000000)

Bit	R/W	Reset	Description
31	RW	0x1	CLKEN_OVERRIDE: This can override the clock enable in case of malfunction.
19	RW	0x1	PW_NO_DEVSEL_ERR_CYA: Setting this bit disables detection of DECERR due to no DEVSEL for DS PWs only.
18	RO	X	INITIATOR_READ_IDLE: This read-only bit provides status reads on AFI upstream A value of 1b indicates there are no outstanding reads to initiator.
17	RO	X	INITIATOR_WRITE_IDLE: This read-only bit provides status writes on AFI upstream A value of 1b indicates there are no outstanding writes to initiator.
15	RW	0x1	WDATA_LEAD_CYA: Used to enable/disable the handling of write data ahead of requests on IPFS axi target
14	RW	0x0	WR_INTRLV_CYA: Used to enable/disable the handling of interleaved write requests on IPFS axi target
11	RO	X	TARGET_READ_IDLE: This read-only bit provides status reads to IPFS target. A value of 1b indicates there are no outstanding reads to downstream FPCI.
10	RO	X	TARGET_WRITE_IDLE: This read-only bit provides status writes to IPFS target. A value of 1b indicates there are no outstanding writes to downstream FPCI.
9	RO	X	MSI_VEC_EMPTY: This read-only bit provides status on whether MSI Vector registers have any active bits valid or not

Bit	R/W	Reset	Description
7	RW	0x0	UFPCI_MSIAW: MSI After Write ordering rule. 1 = whenever MSI is ready assert the interrupt 0 = default behavior, apply MSIAW ordering rule
6	RW	0x1	UFPCI_PWPASSPW: input to upstream FPCI 1 = whenever write is ready, send it; 0 = write goes only when outstanding PWs outside of new write's region are retired (default).
5	RW	0x0	UFPCI_PASSPW: Input to upstream FPCI. Allow upstream FPCI reads to pass writes.
4	RW	0x0	UFPCI_PWPASSNPW: used for upstream FPCI.Allow upstream FPCI PWs to pass NPWs.
3	RW	0x0	DFPCI_PWPASSNPW: used for downstream FPCI.Allow downstream FPCI PWs to pass NPWs.
2	RW	0x0	DFPCI_RSPPASSPW: input to downstream FPCI.Allow downstream FPCI responses to pass writes
1	RW	0x0	DFPCI_PASSPW: input to downstream FPCI.Allow downstream FPCI reads to pass writes.
0	RW	0x0	EN_FPCI: When the IPFS device block is disabled, it is completely invisible on the IPFS bus, i.e., it doesn't even process IPFS configuration accesses.

27.10.33 HDA_FPCI_ERROR_MASKS_0

FPCI Error Masks

Offset: 0x184 I Read/Write: R/W I Reset: 0x00000000 (0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxx000)

Bit	Reset	Description
2	0x0	MASK_FPCI_MASTER_ABORT: This bit allows FPCI error to be forwarded to AXI response when FPCI error response indicates Master Abort. 1 = forward error, 0 = return AXI OKAY response (2'b0)
1	0x0	MASK_FPCI_DATA_ERROR: This bit allows FPCI error to be forwarded to AXI response when FPCI error response indicates Data Error. 1 = forward error, 0 = return AXI OKAY response (2'b0)
0	0x0	MASK_FPCI_TARGET_ABORT: This bit allows FPCI error to be forwarded to AXI response when FPCI error response. This bit also covers decode error generated when there is no devsel received indicates Target Abort. 1 = forward error, 0 = return AXI OKAY response (2'b0)

27.10.34 HDA_INTR_MASK_0

Interrupt Masks

Offset: 0x188 I Read/Write: R/W I Reset: 0x00000000 (0bxxxxxxxxxxxxxxxx0xxxxxxx0xxxxxxx0)

Bit	Reset	Description
16	0x0	IP_INT_MASK:IP (SATA/AZA) interrupt to MPCORE gated by mask.
8	0x0	MSI_MASK:MSI to MPCORE gated by mask.
0	0x0	INT_MASK:Interrupt to MPCORE gated by mask.

27.10.35 HDA_INTR_CODE_0

Interrupt Control

Offset: 0x18c I Read/Write: R/W I Reset: 0x00000000 (0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxx00000)

Bit	Reset	Description
4:0	0x0	INT_CODE:Eight interrupt codesIf the code is 0, logging of the next interrupt is enabled 0 = INT_CODE_CLEAR: Clear interrupt code 1 = INT_CODE_INI_SLVERR: Interrupt code for MPCORE AXI SLVERR response to IPFS 2 = INT_CODE_INI_DECERR: Interrupt code for MPCORE AXI DECERR response to IPFS 3 = INT_CODE_TGT_SLVERR: Interrupt code for PCIE endpoint FPCI target abort or data error response to IPFS 4 = INT_CODE_TGT_DECERR: Interrupt code for PCIE2 FPCI master abort response to IPFS 5 = INT_CODE_TGT_WRERR: Interrupt code for bufferable write to non-posted write address region 6 = RSVD1: Reserved 7 = INT_CODE_DFPCI_DECERR: Interrupt code for PCIE2 response to downstream request when downstream FPCI address does not fall in a claimable downstream region 8 = INT_CODE_AXI_DECERR: Interrupt code for IPFS response to downstream request when axi target AXI addresss does not fall in any of IPFS downstream BARs 9 = INT_CODE_FPCI_TIMEOUT: Interrupt code for FPCI Timeout 10 = RSVD2: Reserved for future expansion 11 = RSVD3 12 = RSVD4 13 = RSVD5 14 = RSVD6 15 = INT_CODE_SM_FATAL_ERROR: Interrupt code for SM fatal error 16 = INT_CODE_SM_NON_FATAL_ERROR: Interrupt code for SM non-fatal error

27.10.36 HDA_INTR_SIGNATURE_0

Interrupt Signature

Offset: 0x190 I Read/Write: R/W I Reset: 0x00000000 (0b00000000000000000000000000000x0)

Bit	Reset	Description
31:2	0x0	INT_INFO: For interrupt codes 1-5/7-8, it contains address bits [31:2], either in FPCI memory space or AXI space. For FPCI generated errors, the info contains FPCI address.For AXI/IPFS generated errors, the info contains AXI address.
0	0x0	DIR: Indicates direction of the AXI/FPCI transaction. 1=rd/0=wrIf signature type is 6 (sideband message), this field is 1. 0 = WRITE: Interrupt due to a write transaction 1 = READ: Interrupt due to a read transaction

27.10.37 HDA_UPPER_FPCI_ADDR_0

Upper FPCI Address

Offset: 0x194 I Read/Write: R/W I Reset: 0x00000000 (0bxxxxxxxxxxxxxxxxxxxxxxxx00000000)

Bit	Reset	Description
7:0	0x0	INT_INFO_UPPER: These 8 bits are the upper byte of captured FPCI address (bits [39:32])when interrupt code is 3, 4 or 7. These bits determine the region in the Hypertransport Address Map that was accessed.

27.10.38 HDA_IPFS_INTR_ENABLE_0

IPFS Interrupt Enable

Offset: 0x198 I Read/Write: R/W I Reset: 0x00000000 (0bxxxxxxxxxxxxxxxxxx00xxxx00000000)

Bit	Reset	Description

27.10.49 HDA_HDA_MCCIF_FIFOCTRL_0

Memory Client Interface FIFO Control (where applicable) and Clock Gating Control Register.

Note: *The FIFO timing aspects of this register are no longer supported, but retained for software compatibility. The clock override/ovr_mode fields of this register control the 2nd-level clock gating for the client and mc side of the mccif. All clock gating is enabled by default.*

A '1' written to the rclk/wclk override field will result in one of the following:

With wclk/rclk override mode = LEGACY, the clock reverts to legacy mode of operation where the clock is on whenever the client clk is enabled. With wclk/rclk override mode = ON, the clock is always on inside mccif and PC.

A '1' written to the cclk override field keeps client's clk always on inside mccif.

27.11 DPAUX Registers

Refer to Section 1.4: Reading Register Tables in the Introduction chapter for the register table protocol as well as recommendations for accessing registers.

27.11.1 DPAUX_CTXSW_0

Context Switch Register

Should be common to all modules. Includes the current channel/class (which is writable by software) and the next channel/class (which the hardware sets when it receives a context switch).

Any context switch request triggers an interrupt to the host and causes the new channel/class to be stored in NEXT_CHANNEL/NEXT_CLASS (see vmod/chexample). Software sees that there is a context switch interrupt and does the necessary operations to make the module ready to receive traffic from the new context. It clears the context switch interrupt and writes CURR_CHANNEL/CLASS to the same value as NEXT_CHANNEL/CLASS, which causes a context switch acknowledge packet to be sent to the host. This completes the context switch and allows the host to continue sending data to the module.

Context switches can also be preloaded. If CURR_CLASS/CHANNEL are written and updated to the next CLASS/CHANNEL before the context switch request occurs, an acknowledge will be generated by the module and no interrupt will be triggered. This is one way for software to avoid dealing with context switch interrupts.

Another way to avoid context switch interrupts is to set the AUTO_ACK bit. This bit tells the module to automatically acknowledge any incoming context switch requests without triggering an interrupt. CURR_* and NEXT_* will be updated by the module so they will always be current.

Offset: 0x0 | Byte Offset: 0x0 | Read/Write: R/W | Reset: 0xXXXXf800 (0bxxxxxxxxxxxxxxxx11111x0000000000)

Bit	R/W	Reset	Description
31:28	RO	X	NEXT_CHANNEL: Next requested channel
25:16	RO	X	NEXT_CLASS: Next requested class
15:12	RW	0xf	CURR_CHANNEL: Current working channel, reset to 'invalid'
11	RW	0x1	AUTO_ACK: Automatically acknowledge any incoming context switch requests 0 = MANUAL 1 = AUTOACK
9:0	RW	0x0	CURR_CLASS: Current working class

27.11.2 DPAUX_INTR_EN_AUX_0

A DP SOR port can generate 4 types of interrupts:

- PLUG_EVENT: The HPD line has been high for at least DPAUX_HPD_CONFIG_0_PLUG_MIN_TIME microseconds
- UNPLUG_EVENT: The HPD line has gone low for at least DPAUX_HPD_CONFIG_0_UNPLUG_MIN_TIME microseconds
- IRQ_EVENT: After a DP device has been connected, it can generate an interrupt request. This will cause the DP hardware to read the Sink status and then notify the RM with an IRQ_EVENT interrupt.
- AUX_DONE: This interrupt will signify the completion of an AUX transaction.
- This is an array of 1 identical register entries; the register fields below apply to each entry.

Offset: 0x1..0x4 | Read/Write: R/W | Reset: 0x00000000 (0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx0000)

Bit	Reset	Description
3	DISABLED	AUX_DONE: 0 = DISABLED 1 = ENABLED

Bit	Reset	Description
31:0	X	REG

27.11.12 DPAUX_DP_AUXADDR_0

DP_AUXADDR

Address register for DisplayPort AUX channel transaction.

This address register describes the 20-bit address that the transaction reads from/writes to the sink AUX register address space. Refer to the DisplayPort specification for more details.

This is an array of 1 identical register entries; the register fields below apply to each entry.

Offset: 0x29..0x2c | Read/Write: R/W | Reset: 0x00000000 (0bxxxxxxxxxxxxx00000000000000000000)

Bit	Reset	Description
19:0	0x0	REG

27.11.13 DPAUX_DP_AUXCTL_0

DP_AUXCTL

Main control register for AUX transactions.

Refer to the DisplayPort specification for more information about AUX channel transactions.

The AUX bus can transmit data at 1Mbps. A single AUX transaction may take up to 648 microseconds to complete:

- 66 µs for precharge, SYNC, COMMAND, ADDRESS, and LENGTH
- 16*8 µs DATA
- 2 µs SYNC/STOP
- 400 µs maximum delay before reply begins
- 34 µs for precharge, SYNC
- 8 µs for REPLY_TYPE
- 8 µs LENGTH
- 2 µs SYNC/STOP

  ----

  648 microseconds

If an HPD_IRQ arrives just before an AUX request occurs, hardware will use the AUX channel to read the Link/Sink status, and then process the software request. This will incur an additional delay of up to 568 microseconds before the software request begins. This brings the total worst-case reply time to 1216 microseconds.

The AUXCTL_SEMA_REQUEST and AUXCTL_SEMA_GRANT bits are the semaphore for the DisplayPort AUX channel. Both VBIOS and RM need to use the AUX channel. The AUX semaphore is requested by writing to AUXCTL_SEMA_REQUEST. The client must check the value of AUXCTL_SEMA_GRANT to see if it was awarded the semaphore.

To obtain the semaphore:

For RM:

```
Write _RM to AUXCTL_SEMA_REQUEST
read AUXCTL_SEMA_GRANT
if (AUXCTL_SEMA_GRANT == _RM)
     RM grabbed the AUX channel successfully
else
     RM failed to control the AUX
```

For VBIOS:

```
Write _VBIOS to AUXCTL_SEMA_REQUEST
read AUXCTL_SEMA_GRANT;
if (AUXCTL_SEMA_GRANT == _VBIOS)
     VBIOS grabbed the AUX channel successfully;
else
     VBIOS failed to control the AUX;
```

To release the semaphore:

After the AUX transaction is finished, software must write _RELEASE to SEMA_REQUEST. This can be used to put the AUX channel back into a good state if it gets corrupted.

This is an array of 1 identical register entries; the register fields below apply to each entry.

Offset: 0x2d..0x30 | Read/Write: R/W | Reset: 0x0X000000 (0b0xxxxxxxxx00xxx00000xxx000000000)

Bit	R/W	Reset	Description
31	RW	DEASSERT	RST: This can be used to put the AUX channel back into a good state if it gets corrupted. Set to ASSERT to force a localized reset of the AUX logic. Set to DEASSERT to allow the AUX engine to run 0 = DEASSERT 1 = ASSERT
25:24	RO	X	SEMA_GRANT: The client must check the value of AUXCTL_SEMA_GRANT to see if it was awarded the semaphore. SEMA_GRANT_NONE: AUX channel available SEMA_GRANT_RM: AUX channel obtained by RM SEMA_GRANT_VBIOS: AUX channel obtained by VBIOS SEMA_GRANT_PMU: AUX channel obtained by PMU 0 = NONE 1 = RM 2 = VBIOS 3 = PMU
21:20	RW	RELEASE	SEMA_REQUEST: The AUX semaphore is requested by writing to AUXCTL_SEMA_REQUEST. The process for RM or VBIOS to obtain the AUX channel is: Set to _RM if aux is obtained by RM. Set to _VBIOS if aux is obtained by VBIOS. Set to RELEASE to relinquish control of the AUX channel. 0 = RELEASE 1 = RM 2 = VBIOS 3 = PMU
16	RW	DONE	TRANSACTREQ: Software uses this bit to request an AUX channel transaction. After CMD, CMDLEN, and AUXDATA_WRITE have been set, this field should be set to _TRIGGER (1). After the hardware receives the reply, the hardware clears the TRANSACTREQ to _DONE (0). If an unplug event is detected in the middle of a transaction, the current transaction is aborted, and the UNPLUG_EVENT bit will be set in DPAUX_INTR_4. Further transactions while unplugged will still be sent. If DPAUX_HYBRID_PADCTL_MODE is set to _I2C, or DPAUX_HYBRID_SPARE_PAD_PWR is set to _POWERDOWN, no transactions will be sent out. Any transactions in flight will complete. This prevents any interference with the I2C functionality of the pad. At the completion of an AUX transaction, the hardware will write the results into the DPAUX_DP_AUXSTAT register. The reply type should be checked as well as the error bits in this register to determine if the request was successful 0 = DONE 1 = PENDING
15:12	RW	I2CWR	CMD: AUX Command. Refer to Section 2.4, AUX channel syntax, in the DisplayPort specification. I2CWR: I2C write I2CRD: I2C read I2CREQWSTAT: I2C write status request I2CMOTWR: I2C write, Middle of transaction (MOT) I2CMOTRD: I2C read, MOT MOTREQWSTAT: I2C write status request, (MOT) AUXWR: AUX write AUXRD: AUX read 0 = I2CWR 1 = I2CRD 2 = I2CREQWSTAT 4 = MOTWR 5 = MOTRD 6 = MOTREQWSTAT 8 = AUXWR 9 = AUXRD

Bit	R/W	Reset	Description
8	RW	NO	ADDRESS_ONLY: Some I2C-over-AUX operations require address-only transactions. This bit modifies any AUX transaction into an address only transaction. The DP specification only uses Address-only transactions for I2CRD and I2CWR (with or without MOT set). NO: Send the AUX transaction normally. YES: Send an Address-only AUX transaction. Only Command and Address will be sent. The CMDLEN field is ignored; no data will be written. Since no data is written, the ACK/NACK for this command will not contain an M value. The values in DPAUX_DP_AUXSTAT_REPLY_M and DPAUX_DP_AUXSTAT_RX_ERROR will not be accurate after an Address-only transaction. 0 = NO 1 = YES
7:0	RW	0x0	CMDLEN: These bits determine the number of data bytes an AUX channel transaction writes or reads. An AUX transaction can read or write a maximum 16 bytes. Note: This field should be set to N-1, where N is the number of bytes in the transaction.

27.11.14 DPAUX_DP_AUXSTAT_0

DP_AUXSTAT

When an AUX command completes, it will update most fields in this register.

Refer to the DisplayPort specification for more information about AUX channel transaction.

This is an array of 1 identical register entries; the register fields below apply to each entry.

Offset: 0x31..0x34 | Read/Write: R/W | Reset: 0xX0XX00XX (0bxxxxxxxxxxxxxxxxxxxxx0000xxxxxxxx)

Bit	R/W	Reset	Description
28	RO	X	HPD_STATUS: Reports the current state of the HPD line, plugged or unplugged. This field is valid at all times, not just at the end of a transaction. This status is based on the value of the GPIO associated with this AUX channel. The connection between GPIO and AUX channel is hard coded, so they must be kept together when assigning them to an SOR link. AUX0 GPIO(1) AUX1 GPIO(19) AUX2 GPIO(15) AUX3 GPIO(21) 0 = UNPLUG 1 = PLUGGED
23:20	RO	X	AUXCTL_STATE: Reports the current state of the AUXCTL state machine. This field is valid at all times, not just at the end of a transaction. 0 = IDLE 1 = SYNC 2 = START1 3 = COMMAND 4 = ADDRESS 5 = LENGTH 6 = WRITE1 7 = READ1 8 = GET_M 9 = STOP1 10 = STOP2 11 = REPLY 12 = CLEANUP

Bit	R/W	Reset	Description
19:16	RO	X	REPLYTYPE: These bits are for status and describe the reply type of the AUX channel command. Refer to Section 2.4.1 of the DisplayPort specification for more information about how to handle each type of reply. ACK: Transaction successful NACK: Transaction failed or is incomplete DEFER: Try again later. I2CNACK: I2C transaction failed or is incomplete I2CDEFER: Try again later. 0 = ACK 1 = NACK 2 = DEFER 4 = I2CNACK 8 = I2CDEFER
11	RW	NOT_PENDING	NO_STOP_ERROR: If the AUX reply from the Sink device did properly terminate with a STOP signal (if the AUX line goes idle), this error bit will be set. There may have been some problem with the connection. The results of the most recent request cannot be guaranteed correct. This bit will remain set until 1 is written to it. 0 = NOT_PENDING 1 = PENDING
10	RW	NOT_PENDING	SINKSTAT_ERROR: After an HPD IRQ, the hardware will automatically read DPCD addresses 0x205-0x200 and place the results in the DPAUX_DP_AUX_SINKSTAT registers. REPLYTYPE is not updated on this type of read, so if the Sink device does not respond with an ACK, this bit will be set. RX_ERROR, TIMEOUT, and NO_STOP can still be set by the automatic read. This bit will remain set until 1 is written to it. 0 = NOT_PENDING 1 = PENDING
9	RW	NOT_PENDING	RX_ERROR: This error reporting bit is set if there is an undefined error detected by the AUX channel. Currently, this is only set if the logic was expecting the sink to send a length value (M), but one was not received. This bit will remain set until 1 is written to it. 0 = NOT_PENDING 1 = PENDING
8	RW	NOT_PENDING	TIMEOUT_ERROR: This error reporting bit is set to PENDING when a timeout has occurred while waiting for a reply. The AUX channel will wait for 400 µs before aborting the AUX transaction. The timeout value is programmable in the DPAUX_DP_AUX_CONFIG register. This bit will remain set until 1 is written to it. 0 = NOT_PENDING 1 = PENDING
7:0	RO	X	REPLY_M: These bits show the number of data bytes an AUX channel transaction receives. An AUX transaction can read or write 16 bytes maximum.

27.11.15 DPAUX_DP_AUX_SINKSTATLO_0

All bits of the SINKSTATLO and SINKSTATHI registers are combined into a 6-byte data buffer. This buffer contains sink/link status information from AUX address space from 00200h to 00205h, as specified in the DisplayPort specification. Hardware automatically issues an AUX read to the above address after a HPD IRQ is detected. The 6 bytes of read data are put into this buffer. The buffer is little endian.

This is an array of 1 identical register entries; the register fields below apply to each entry.

Offset: 0x35..0x38 | Read/Write: RO | Reset: 0xXXXXXXXX (0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx)

Bit	Reset	Description
31:0	X	REG

27.11.16 DPAUX_DP_AUX_SINKSTATHI_0

All bits of the SINKSTATLO and SINKSTATHI registers are combined into a 6-byte data buffer. This buffer contains sink/link status information from AUX address space from 00200h to 00205h, as specified in the DisplayPort specification. Hardware automatically issues an AUX read to the above address after a HPD IRQ is detected. The 6 bytes of read data are put into this buffer. The buffer is little endian.

This is an array of 1 identical register entries; the register fields below apply to each entry.

Offset: 0x39..0x3c | Read/Write: RO | Reset: 0x0000XXXX (0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx)

Bit	Reset	Description
15:0	X	REG

27.11.17 DPAUX_HPD_CONFIG_0

HPD_CONFIG

This register is used to configure the behavior of the HPD plug/unplug events. The INIT values are defined by the DisplayPort specification.

This is an array of 1 identical register entries; the register fields below apply to each entry.

Offset: 0x3d..0x40 | Read/Write: R/W | Reset: 0x07d000fa (0b00000111110100000000000011111010)

Bit	Reset	Description
31:16	0x7d0	UNPLUG_MIN_TIME: The HPD line must be low for this long before it is considered an unplug event. The units of this field are in microseconds.
15:0	0xfa	PLUG_MIN_TIME: The HPD line must be high for this long to be considered a plug event. The units of this field are in microseconds.

27.11.18 DPAUX_HPD_IRQ_CONFIG_0

HPD_IRQ_CONFIG

This register controls the size of the HPD IRQ pulse. The INIT value is defined by the DisplayPort specification.

This is an array of 1 identical register entries; the register fields below apply to each entry.

Offset: 0x41..0x44 | Read/Write: R/W | Reset: 0x000000fa (0bxxxxxxxxxxxxxxxx0000000011111010)

Bit	Reset	Description
15:0	0xfa	MIN_LOW_TIME: IRQ minimum time. The HPD line must be low for at least this amount of time to be an IRQ. An IRQ will occur if IRQ_MIN_TIME < duration of HPD low pulse < UNPLUG_MIN_TIME.

27.11.19 DPAUX_DP_AUX_CONFIG_0

AUX_CONFIG contains miscellaneous configuration parameters for the AUX channel.

This is an array of 1 identical register entries; the register fields below apply to each entry.

Offset: 0x45..0x48 | Read/Write: R/W | Reset: 0x00000190 (0bxxxxxxxxxxxxxxxx0000000110010000)

Bit	Reset	Description
15:0	0x190	TIMEOUT: Sets the wait time, in microseconds, before an AUX transaction will abort and report TIMEOUT in DPAUX_DP_AUXSTAT_TIMEOUT. The default value of 400 µs is specified in the DisplayPort specification.

27.11.20 DPAUX_HYBRID_PADCTL_0

HYBRID_PADCTL

Configuration for the hybrid pads that can be used as AUX/I2C.

This is an array of 1 identical register entries; the register fields below apply to each entry.

Offset: 0x49..0x4c | Read/Write: R/W | Reset: 0x00002462 (0bxxxxxxxxxxxxxxxx0010x10001100010)

Bit	Reset	Description
15	DISABLE	I2C_SDA_INPUT_RCV: Active high receiver enable for the I2C pad's DATA channel. 0 = DISABLE 1 = ENABLE

Bit	Reset	Description
14	DISABLE	I2C_SCL_INPUT_RCV: Active high receiver enable for the I2C pad's CLK channel. 0 = DISABLE 1 = ENABLE
13:12	V0_70	AUX_CMH: Active high 1.0V signal to control the output common mode voltage. 0_60V: VCM = 0.6V (default) 0_64V: VCM = 0.64V 0_70V: VCM = 0.70V 0_56V: VCM = 0.56V 0 = V0_60 1 = V0_64 2 = V0_70 3 = V0_56
10:8	OHM_50	AUX_DRVZ: Active high driver output impedance control. Increasing this value decreases the driver impedance. 0 = OHM_78 1 = OHM_60 2 = OHM_54 3 = OHM_45 4 = OHM_50 5 = OHM_42 6 = OHM_39 7 = OHM_34
7:2	0x18	AUX_DRVI: Active high output driver current control. Increasing the register value increases drive current.
1	ENABLE	AUX_INPUT_RCV: Active high receiver enable for the AUX CH pad. 0 = DISABLE 1 = ENABLE
0	AUX	MODE: Controls whether the pad is in I2C or AUX mode. 0 = AUX 1 = I2C

27.11.21 DPAUX_HYBRID_SPARE_0

PAD_PWR: When a HotPlug is detected on a given DP port, this bit must be set to _POWERUP before any AUX transactions are done. When an Unplug event is detected, this can be written to _POWERDOWN. As long as a DP monitor is connected, the AUX pads should remain powered on because the monitor may send an HPD IRQ, which will require the HW to initiate an AUX read without SW intervention. The logic assumes that the AUX pad will be powered on.

Offset: 0x4d..0x50 | Read/Write: R/W | Reset: 0x00000000 (0b00000000000000000000000000000000)

Bit	Reset	Description
0	POWERUP	PAD_PWR: Controls the E_PWRD port of the hybrid pad. The pads can consume a lot of power if enabled and should be disabled when not in use. POWERUP: pad has power and can be used for transactions. POWERDOWN: pad is powered down and cannot be used. 0 = POWERUP 1 = POWERDOWN

CHAPTER 28: HDMI CEC

The HDMI Consumer Electronics Control (CEC) block supports CEC standard communication over an HDMI connection. It supports both remote control of HDMI devices attached to the Tegra® X1 device, and also allows other HDMI devices to control Tegra functions. Refer to the CEC appendix of the HDMI specification for details of this link.

28.1 Functional Description

The CEC module is an APB slave. It is located at address NV_ADDRESS_MAP_APB_CEC_BASE (0x70015000).

The CEC consists of hardware state machines that send and receive bytes over the CEC wire. Its simple host interface allows one byte to be sent and received at a time.

The CEC has interrupts for interrupt-driven input and output, and also permits polling I/O.

28.2 Programming Guidelines

28.2.1 Initialization

28.2.1.1 Clock and Reset

The CEC uses a fixed clock source – the APB bus clock. It also has a clock enable and reset in the CAR block.

- CAR.RST_DEVICES_W.SWR_CEC_RST = DISABLE
- CAR.CLK_OUT_ENB_W.CLK_ENB_CEC = ENABLE

28.2.1.2 Interrupt

The CEC is on PRI interrupt controller bit 3.

CEC INT_MASK should be enabled for TX_* and RX_* interrupts. TX_REGISTER_EMPTY and RX_REGISTER_FULL are the key interrupts; most others are errors.

Refer to Chapter 3: Interrupt Controller for more information.

28.2.1.3 Pin Mux

The CEC is available on the HDMI_CEC pin. HDMI_CEC pin mux should be configured for:

- PM=0 (primary CEC function)
- PUPD=NORMAL
- TRISTATE=NORMAL
- E_INPUT=ENABLE
- OD=ENABLE.

28.2.2 CEC Timing

Timing parameters are in units of 32 microseconds. See the HDMI specification for CEC timing requirements. In Tegra X1 devices, the registers have default (reset) values as indicated in the following table.

Register	Field	Value	Comment
RX_TIMING_0	RX_START_BIT_MAX_LO_TIME	0x7a	
	RX_START_BIT_MIN_LO_TIME	0x6d	

Register	Field	Value	Comment
	RX_START_BIT_MAX_DURATION	0x93	
	RX_START_BIT_MIN_DURATION	0x86	
RX_TIMING_1	RX_DATA_BIT_MAX_LO_TIME	0x35	
	RX_DATA_BIT_SAMPLE_TIME	0x21	
	RX_DATA_BIT_MAX_DURATION	0x56	
	RX_DATA_BIT_MIN_DURATION	0x40	
RX_TIMING_2	RX_END_OF_BLOCK_TIME	0x50	
TX_TIMING_0	TX_START_BIT_LO_TIME	0x74	
	TX_START_BIT_DURATION	0x8d	
	TX_BUS_XITION_TIME	0x8	
	TX_BUS_ERROR_LO_TIME	0x71	
TX_TIMING_1	TX_LO_DATA_BIT_LO_TIME	0x2f	
	TX_HI_DATA_BIT_LO_TIME	0x13	
	TX_DATA_BIT_DURATION	0x4b	
	TX_ACK_NAK_BIT_SAMPLE_TIME	0x21	
TX_TIMING_2	BUS_IDLE_TIME_ADDITIONAL_FRAME	0x7	
	BUS_IDLE_TIME_NEW_FRAME	0x5	
	BUS_IDLE_TIME_RETRY_FRAME	0x3	

28.2.3 CEC Control

The CEC has several modes but only some are simulated or supported. TX_RX_MODE=ENABLE should be set last.

Register	Field	Value	Comment
SW_CONTROL	MODE	DISABLE	Use HW mode
INPUT_FILTER	FIFO_LENGTH	0	
	MODE	DISABLE	
HW_CONTROL	RX_LOGICAL_ADDRS	Slave addresses (bitmap)	If slave, holds addresses
	RX_SNOOP	DISABLE	
	RX_NAK_MODE	BLOCK	
	TX_NAK_MODE	BLOCK	
	FAST_SIM_MODE	DISABLE	SW should use DISABLE
	TX_RX_MODE	ENABLE	Enable last
INT_MASK	TX_*, RX_*	DISABLE/ENABLE	ENABLE to enable interrupt

28.2.4 Transmission

Each message is a series of bytes, and each byte has several flags associated with it.

Register	Field	Value	Comment
TX_REGISTER	DATA	byte	8-bit byte
	EOM	1 on last byte	End of message flag
	ADDRESS_MODE	DIRECT/BROADCAST	
	GENERATE_START_BIT	1	
	RETRY_FRAME	0/1	

In general, the first byte contains source and destination addresses, per the CEC specification. The source address is chosen by software as the Tegra address. The destination address is either 15 for broadcast, or less than 15 for a particular slave. The last byte contains EOM=1. When sending to address 15 (broadcast), ADDRESS_MODE must be BROADCAST so that ACK and NAK have correct polarity. If this transmission is a retry of a previous one, RETRY_FRAME should be 1 so that correct retry timing is used.

The TX register interface is unusual in that the interrupt (TX_REGISTER_EMPTY) controls transmission – it's not merely a status signal. To transmit a byte, TX_REGISTER is first written with data, then the INT_STAT.TX_REGISTER_EMPTY interrupt must be cleared. If interrupt service routines are used, they must be careful when clearing an interrupt, because doing so incorrectly could cause a spurious or lost byte.

Transmission pseudo-code:

```
Transmit(unsigned char data, bool eom?, bool broadcast?):
// enqueue byte
Write TX_REGISTER: DATA = data,
        EOM = eom?,
        ADDRESS_MODE = broadcast?,
        GENERATE_START_BIT = 1
// clear interrupt to enable transmission
Write INT_STAT: TX_REGISTER_EMPTY = 1
// wait for transmission
Either Poll INT_STAT.TX_* to go high, or wait for TX_* interrupt.
If TX_REGISTER_EMPTY=1, transfer is complete.
If other TX_* interrupts set, then error.
```

Transmission of multi-block frames requires the blocks (bytes) to be sent back-to-back with no idle space between. If software does not provide the bytes in time, hardware will signal a TX_REGISTER_UNDERRUN interrupt and halt transmission (see Section 28.2.6: Error Recovery below).

28.2.5 Reception

The RX_REGISTER_FULL interrupt indicates that a byte has been received and blocks further reception until cleared. If a subsequent byte is received while RX_REGISTER_FULL is high, an RX_REGISTER_OVERRUN error results.

When a byte is received, two additional EOM and ACK flags are provided as well.

Register	Field	Value	Comment
RX_REGISTER	DATA	byte	8-bit byte
	EOM	1 on last byte	End of message flag
	ACK	bit from bus	Expected value depends on whether broadcast or direct

Once INT_STAT indicates a byte has been received, first read the byte (and flags), and then clear the interrupt.

Reception pseudo-code:

```
Receive(unsigned char &data, bool &eom, bool &ack):
// wait for data
Either Poll INT_STAT.RX_REGISTER_FULL, or
        wait for CEC RX_REGISTER_FULL interrupt
If INT_STAT.RX_* error interrupts set, then error
data, eom, ack = Read RX_REGISTER.DATA/EOM/ACK
// clear interrupt to allow further reception
Write INT_STAT.RX_REGISTER_FULL = 1
```

28.2.6 Error Recovery

In case of transmission error such as UNDERRUN or NAKD, the transmission will stop. Alternatively, the soft reset sequence should be used:

```
tmp = CEC_HW_CONTROL
CEC_HW_CONTROL = 0
CEC_INT_STATUS = 0xffffffff
CEC_HW_CONTROL = tmp
```

28.3 CEC Registers

Refer to Section 1.4: Reading Register Tables in the Introduction chapter for the register table protocol as well as recommendations for accessing registers.

For more information on Consumer Electronics Control (CEC), refer to the CEC appendix of the HDMI specification.

28.3.1 CEC_SW_CONTROL_0

SW controlled mode is not supported. Leave disabled.

Offset: 0x0 | Read/Write: R/W | Reset: 0x000000XX (0b0xxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx)

Bit	R/W	Reset	Description
31	RW	DISABLE	MODE: 0 = DISABLE 1 = ENABLE
4	RO	X	FILTERED_RX_DATA_PIN
0	RO	X	RAW_INPUT_DATA_PIN

28.3.2 CEC_HW_CONTROL_0

The following steps are the best way to reset the CEC engine:

1. Set the CEC_HW_CONTROL_TX_RX_MODE to DISABLE
2. Set all the interrupt enable bits in CEC_HW_INTR_EN to DISABLE
3. Wait 1 second (1 second is the maximum CEC bus timeout period from the HDMI specification)
4. Set the CEC_HW_CONTROL_TX_RX_MODE to ENABLE and restart.

Other devices on the bus might have been communicating just fine. When the restart has completed, there might be a few spurious false start bits and other receive bus anomalies before normal operation is resumed.

The CEC_HW_CONTROL register contains the control bits and fields for operating and configuring the HW CEC engine.

> ***Note:*** *Once the block is enabled, software should not attempt to change these configuration parameters without first disabling the block, except for the RX_LOGICL_ADDRS and RX_SNOOP fields.*

RX_LOGICAL_ADDRS

The HDMI specification permits a single physical entity to claim logical addresses reserved for different functions (e.g., "Tuner x" and "Playback device y"). For a PC, it is entirely possible to be a multi-function device, so hardware might need to respond to 2 (or more) logical addresses (as many combinations as make sense). The next fields are used to configure the logical addresses that hardware will respond to. As per the specification, hardware will always respond to the broadcast address. This is a 15-bit field, where each bit position is associated with one of the logical addresses. A '1' in any bit position causes the hardware to respond to the associated logical address (i.e., capture data blocks/frames addressed to the address and properly

ack/nak said blocks). To keep things simple, the mapping of bit position to logical address is direct, i.e., bit N maps to logical address N.

RX_SNOOP

When enabled, the hardware will intercept and forward to software all traffic on the CEC bus. It will continue to ack/nak only those addresses that are assigned to it.

RX_NAK_MODE

The HDMI specification is a bit unclear about what the initiator is supposed to do if an intermediate block of a frame is NAK'd, i.e., should the initiator cease transmitting immediately or complete the rest of the frame. The HDMI specification says that a follower may NAK a frame at any time, but the concern is that some initiator might not recover from such an early NAK'd frame. This bit will permit the receive state machine to operate in either mode. The choices are:

- BLOCK which means that a frame will be NAK'd as soon as a RX_REGISTER_OVERRUN is detected
- FRAME which means that the hardware will keep track of any RX_REGISTER_OVERRUNs that occur during frame reception, and NAK only during the last block.

TX_NAK_MODE

The HDMI specification is a bit unclear about what the initiator is supposed to do if an intermediate block of a frame is NAK'd, i.e., should the initiator cease transmitting immediately or complete the rest of the frame. This bit will permit the transmit state machine to operate in either mode. The choices are:

- BLOCK which means transmission will cease at the first NAK'd block
- FRAME which means that transmission will always continue to the end of the frame.

TX_RX_INTERRUPT_ROUTING

The engine generates a single composite interrupt output signal which can then be routed to either PMU or HOST. This bit controls that routing.

TX_RX_MODE

This bit enables or disables the operation of the HW CEC engine. If the TX_RX_MODE is changed to DISABLE, then the HW engine returns to the IDLE state irrespective of what it is doing and drives a 1 onto the CEC bus. If CEC_SW_CONTROL_MODE is ENABLED, the HW CEC engine operation is automatically disabled.

Offset: 0x4 | Read/Write: R/W | Reset: 0x00000000 (0b00xxxxx0xxxxxxx00000000000000000)

Bit	Reset	Description
31	DISABLE	TX_RX_MODE: 0 = DISABLE 1 = ENABLE
30	DISABLE	FAST_SIM_MODE: 0 = DISABLE 1 = ENABLE
24	BLOCK	TX_NAK_MODE: 0 = BLOCK 1 = FRAME
16	BLOCK	RX_NAK_MODE: 0 = BLOCK 1 = FRAME
15	DISABLE	RX_SNOOP: 0 = DISABLE 1 = ENABLE
14:0	0x0	RX_LOGICAL_ADDRS: All logical addresses that should be matched. One bit per address.

28.3.3 CEC_INPUT_FILTER_0

The CEC_INPUT_FILTER register is used to configure the HW filtering that is required to deglitch the incoming receive data line. As data arrives into the chip, it is pushed into a 1 bit wide FIFO with a maximum of 64 entries deep. The actual used depth of the FIFO is set using the CEC_INPUT_FILTER_FIFO_LENGTH field. The used length is equal to CEC_INPUT_FILTER_FIFO_LENGTH+1. A datum is pushed into the FIFO once per microsecond tick. The FIFO bits should reset to '1' (the idle condition of the CEC bus).

The filtered output of the FIFO is computed roughly as follows:

```
filterMsk[63:0] = (1 << CEC_INPUT_FILTER_FIFO_LENGTH + 1) - 1;

if (reset || (CEC_INPUT_FILTER_MODE == CEC_INPUT_FILTER_MODE_DISABLE))
    fifo[63:0] = 0xffffffffffffffff;
else if (clock tick time)
    fifo[63:0] = (fifo[63:0] << 1) | rawInputDataPin;

if (reset || (CEC_INPUT_FILTER_MODE == CEC_INPUT_FILTER_MODE_DISABLE))
    filteredRxDataPin = 1;
else if ((clock tick time) && ((fifo & filterMsk) == filterMsk))
    filteredRxDataPin = 1;
else if ((clock tick time) && ((~fifo & filterMsk) == filterMsk))
    filteredRxDataPin = 0;
else
    filteredRxDataPin = filteredRxDataPin;
```

This logic should make sure that the filteredRxDataPin output only transitions to 0 or 1 when all the examined bits in the FIFO are also 0 or 1. Thus the filtered data line will not transition as long as there are glitches in the FIFO. The length of 64 provides a maximum operational length of 64 µs.

Every state transition on the filtered receive data line is reportable to software via the interrupt register described later.

Offset: 0x8 | Read/Write: R/W | Reset: 0x000000XX (0b0xxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx)

Bit	Reset	Description
31	DISABLE	MODE: 0 = DISABLE 1 = ENABLE
5:0	X	FIFO_LENGTH

28.3.4 CEC_SPARE_0

Spare register for future use.

Offset: 0xc | Read/Write: R/W | Reset: 0x00000000 (0bxxxxxxxxxxxxxxxx0000000000000000)

Bit	Reset	Description
15:0	0x0	SPARES

28.3.5 CEC_TX_REGISTER_0

CEC_HW_TX_REGISTER register

This register is used by software to provide the hardware with the actual data to be transmitted on the bus. Note that hardware will 'blindly' transmit what it is given. For example, it will not check to be sure that a proper legal initiator address has been

provided, it will not check to be sure that the maximum frame length of 16 is not violated, etc. These higher level protocol checks are the domain of the SW. In order to facilitate easier software programming and smoother operation, hardware will make its own working copy of the fields in this register, thus quickly freeing up the register for software to write the next block. (Basically, it is a one-deep FIFO with fullness reported via the TX_REGISTER_EMPTY bit).

DATA

The actual 8 bits of address/data to be transmitted on the bus. The data is always transmitted MSB (bit 7) first.

EOM

This is the "end of message" bit for this block of data. This bit is set at the last block of the frame.

ADDRESS_MODE

This bit indicates to the hardware whether this particular block is directly addressed or broadcast addressed (which in turn dictates how hardware is to interpret the ACK/NAK for the block).

GENERATE_START_BIT

Indicates to the hardware that it should precede the transmission of this block of data with a start bit.

RETRY_FRAME

Indicates if the current frame is a retry frame or not. Based on this value, hardware chooses an appropriate bus idle time programmed in TX_TIMING2 register and waits for the bus to be idle before it can attempt to send a start bit. This bit is only meaningful when TX_GENERATE_START_BIT is set.

RETRY FRAME	LAST_FRAM_ SENT_BY_US	WAIT TIME
1	YES	TIMING2_BUS_IDLE_TIME_RETRY_FRAME
1	NO	TIMING2_BUS_IDLE_TIME_RETRY_FRAME
0	NO	TIMING2_BUS_IDLE_TIME_NEW_FRAME
0	YES	TIMING2_BUS_IDLE_TIME_ADDITIONAL_FRAME

If a frame is being sent immediately following the previous frame, hardware waits for "TIMING2_BUS_IDLE_TIME_ADDITIONAL_FRAME". However, if someone else uses the bus before that time elapses, the hardware resets its wait time counter and waits for "TIMING2_BUS_IDLE_TIME_NEW_FRAME".

Offset: 0x10 | Read/Write: R/W | Reset: 0x00010000 (0bxxxxxxxxxxxxxxx01xxx0xxx000000000)

Bit	Reset	Description
17	DISABLE	RETRY_FRAME: 0 = DISABLE 1 = ENABLE
16	ENABLE	GENERATE_START_BIT: 0 = DISABLE 1 = ENABLE
12	DIRECT	ADDRESS_MODE: 0 = DIRECT 1 = BROADCAST
8	0x0	EOM
7:0	0x0	DATA

28.3.6 CEC_RX_REGISTER_0

CEC_HW_RX_REGISTER register

This register is used by hardware to buffer data to the software. When a block of data has been received from the bus, it is stored here for software (and the RX_REGISTER_FULL bit is set). The hardware also has a 'working copy' of the receive register to give software as much time as possible to empty it. When a full block is assembled, hardware places it into RX_REGISTER, so the register is like a 1 deep FIFO.

DATA

The 8 bits of data that were read from the bus.

EOM

The EOM bit read from the bus.

ACK_NAK

The ACK/NAK bit as read from the bus. In some cases (broadcast block) even though the device may have ACK'd the frame, some other device on the bus may NAK the frame, and software would need to know this.

Offset: 0x14 | Read/Write: RO | Reset: 0x00000XXX (0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx)

Bit	Reset	Description
9	X	ACK
8	X	EOM
7:0	X	DATA

28.3.7 CEC_RX_TIMING_0_0

CEC_HW_RX_TIMING0 register

Note: *All timing registers must be configured before the HW CEC engine is enabled.*

RX_START_BIT_MAX_LO_TIME

nominal 3.9 ms, (3900/32 = 122 intervals) = 3.904 ms

The maximum time the received bus can remain low, and still be considered the beginning of a proper start bit. If the start bit low time overruns this time, the start bit is considered invalid and is ignored.

RX_START_BIT_MIN_LO_TIME

nominal 3.5 ms, (3500/32 = 109 intervals) = 3.488 ms

The minimum time the received bus can remain low and still be considered the beginning of a proper start bit. If the start bit low time underruns this time, the start bit is considered invalid and is ignored.

RX_START_BIT_MAX_DURATION

nominal 4.7 ms, (4700/32 = 147 intervals) = 4.704 ms

The maximum total duration of the start bit from the first detected high-to-low transition to the high-to-low transition that begins the first address bit. If the start bit duration overruns this time, the start bit is considered invalid and is ignored.

RX_START_BIT_MIN_DURATION

nominal 4.3 ms (4300/32 = 134 intervals) = 4.288 ms

The minimum total duration of the start bit from the first detected high-to-low transition to the high-to-low transition that begins the first address bit. If the start bit duration underruns this time, the start bit is considered invalid and is ignored.

Offset: 0x18 | Read/Write: R/W | Reset: 0x86936d7a (0b10000110100100110110110101111010)

Bit	Reset	Description
31:24	0x86	RX_START_BIT_MIN_DURATION
23:16	0x93	RX_START_BIT_MAX_DURATION
15:8	0x6d	RX_START_BIT_MIN_LO_TIME
7:0	0x7a	RX_START_BIT_MAX_LO_TIME

28.3.8 CEC_RX_TIMING_1_0

CEC_HW_RX_TIMING1 register

> ***Note:*** *All timing registers must be configured before the HW CEC engine is enabled.*

RX_DATA_BIT_MAX_LO_TIME

nominal 1.7 ms, (1700/32 = 53 intervals) = 1.696 ms

The maximum time the received bus can remain low and still be considered the beginning of a proper start bit. If the start bit low time overruns this time, the start bit is considered invalid and is ignored.

RX_DATA_BIT_SAMPLE_TIME

nominal 1.05 ms, (1050/32 = 33 intervals) = 1.056 ms

The time to sample that data bit.

RX_DATA_BIT_MAX_DURATION

nominal 2.75 ms, (2750/32 = 86 intervals) = 2.752 ms

The maximum total duration of the start bit from the first detected high-to-low transition to the high-to-low transition that begins the first address bit. If the start bit duration overruns this time, the start bit is considered invalid and is ignored.

RX_DATA_BIT_MIN_DURATION

nominal 2.05 ms (2050/32 = 64 intervals) = 2.048 ms

The minimum total duration of the start bit from the first detected high-to-low transition to the high-to-low transition that begins the first address bit. If the start bit duration underruns this time, the start bit is considered invalid and is ignored.

Offset: 0x1c | Read/Write: R/W | Reset: 0x40562135 (0b01000000010101100010000100110101)

Bit	Reset	Description
31:24	0x40	RX_DATA_BIT_MIN_DURATION
23:16	0x56	RX_DATA_BIT_MAX_DURATION

28.3.9 CEC_RX_TIMING_2_0

CEC_HW_RX_TIMING2 register

RX_END_OF_BLOCK_TIME

> ***Note:*** *All timing registers must be configured before the HW CEC engine is enabled.*

nominal 1.9 ms, (1900/32 = 80 intervals) = 1.9 ms

The time to wait after the start of the final ACK/NAK phase of frame transmission before returning to the idle state. (Needed since the last ACK/NAK bit will not be followed by another high-to-low transition.)

Offset: 0x20 | Read/Write: R/W | Reset: 0x00000050 (0bxxxxxxxxxxxxxxxxxxxxxxxxx01010000)

Bit	Reset	Description
7:0	0x50	RX_END_OF_BLOCK_TIME

28.3.10 CEC_TX_TIMING_0_0

The next set of timing registers configures the CEC logic for HW assisted operation. To permit flexible configuration (to support possible semi-compliant devices), the bit timing control and check values are programmable (rather than just directly using the specification values).

While the block itself works on a 1 µs tick, in order to save register space, these timing numbers are specified in units of 32 µs.

First, the registers for the various timing intervals (there are quite a few of them).

CEC_HW_TX_TIMING0 register

> ***Note:*** *All timing registers must be configured before the HW CEC engine is enabled.*

For details of exact values and tolerances, refer to the CEC appendix of the HDMI specification.

TX_START_BIT_LO_TIME

nominal 3.7 ms, (3700/32 = 116 intervals) = 3.712 ms

How long to hold the bus lo during the start bit.

TX_START_BIT_DURATION

nominal 4.5 ms, (4500/32 = 141 intervals) = 4.512 ms

The total duration of the start bit

TX_BUS_XITION_TIME

nominal 250 µs, (250/32 = 8 intervals) = 256 µs

Time to wait for bus to settle after transitioning output.

TX_BUS_ERROR_LO_TIME

nominal 3.6 ms (3600/32 = 113 intervals) = 3.616 ms

Time to drive bus low when bus error must be signaled on the bus

Offset: 0x24 | Read/Write: R/W | Reset: 0x71088d74 (0b01110001xxxx10001000110101110100)

7:0	0x74	TX_START_BIT_LO_TIME

28.3.11 CEC_TX_TIMING_1_0

CEC_HW_TX_TIMING1 register

> ***Note:*** *All timing registers must be configured before the HW CEC engine is enabled.*

TX_LO_DATA_BIT_LO_TIME

nominal 1.5 ms, (1500/32 = 47 intervals) = 1.504 ms

How long to hold the bus low when transmitting a '0'.

TX_HI_DATA_BIT_LO_TIME

nominal 0.6 ms, (600/32 = 19 intervals) = 6.08 ms

How long to hold the bus low when transmitting a '1'.

TX_DATA_BIT_DURATION

nominal 2.4 ms, (2400/32 = 75 intervals) = 2.4 ms

The total duration of a data or ACK/NAK bit.

TX_ACK_NAK_BIT_SAMPLE_TIME

nominal 1.05 ms, (1050/32 = 33 intervals) = 1.056 ms

The time to sample that ACK/NAK bit.

Offset: 0x28 | Read/Write: R/W | Reset: 0x214b132f (0b00100001010010110001001100101111)

7:0	0x2f	TX_LO_DATA_BIT_LO_TIME

28.3.12 CEC_TX_TIMING_2_0

CEC_HW_TX_TIMING2 register

This register contains the bus idle time values for the various scenarios indicated in the HDMI specification (Section 9.1). Software indicates to the hardware the amount of delay in units of data bit periods, as defined by the CEC_HW_TX_TIMING1_TX_DATA_BIT_DURATION field.

ADDITIONAL_FRAME:

The amount of time the bus needs to be idle before a new frame can be sent immediately after sending a frame. The suggested value is greater than or equal to 7.

NEW_FRAME:

The amount of time the bus needs to be idle before a new frame can be sent if we were not the initiator for the previous frame. The suggested value is greater than or equal to 5.

RETRY_FRAME:

The amount of time the bus needs to be idle before the same frame can be resent. The suggested value is >= 3.

Offset: 0x2c | Read/Write: R/W | Reset: 0x00000357 (0bxxxxxxxxxxxxxxxxxxxxxx001101010111)

Bit	Reset	Description

7:4	0x5	BUS_IDLE_TIME_NEW_FRAME
3:0	0x7	BUS_IDLE_TIME_ADDITIONAL_FRAME

28.3.13 CEC_INT_STAT_0

CEC_HW_INTR register

This register contains the individual interrupt and status bits for the CEC HW unit. The CEC_HW_INTR_EN register contains the corresponding enable bit for each interrupt/status bit in the interrupt register. The interrupt enable determines whether the interrupt propagates to the PMIC as an interrupt, but the interrupt status bit itself is always set if the described condition occurs. Software writes a '1' to any interrupt/status bit in order to clear it.

Because the HW state machine also looks at the state of the interrupt bits when determining what action(s) to take, it is important for software to operate in roughly the following order when processing interrupts from this source:

1. Read the interrupt register to determine what caused the interrupt and what needs to be done.
2. Perform the operations required, e.g., reload TX register, read RX register.
3. Finally, clear the corresponding interrupt bits.

TX_REGISTER_EMPTY

The transmit register is empty, so software is free to write the next block of the frame into the register. For multi-block frames, software must in fact provide the next block before the current block is sent, otherwise a TX_REGISTER_UNDERRUN error will occur. When the TX engines reads from the TX_REGISTER register and stores a local copy, this interrupt is asserted.

TX_REGISTER_UNDERRUN

The transmit register was empty at the time the transmit hardware needed to have the next block ready to send. This is an error condition. The transmitter will have stopped transmitting, and recovery will require resending the entire frame from scratch.

TX_FRAME_OR_BLOCK_NAKD

Hardware sets this bit if any block/frame is NAK'd. If software sees this bit set, it knows it will have to resend the frame later.

TX_ARBITRATION_FAILED

Hardware sets this bit during the address block phase of transmitting a frame, if failed to win arbitration. In this case, transmission will cease, and the HW will flush any pending data in the TX_REGISTER. Software will need to retry the frame from scratch (after the appropriate signal free time, i.e., hardware will not automatically retry).

TX_BUS_ANOMALY_DETECTED

Sometime during block transmission, hardware detected anomalous behavior on the bus (e.g., the bus remained low after transmitter had signaled high). When such an anomaly is detected, the transmitter ceases operation, releases the bus high, and flushes any pending data in the TX_TRANSMIT register.

TX_FRAME_TRANSMITTED

This is asserted at the end of the last data bit, i.e., the ACK bit of the last block is sent. This is just an indication that the last block is sent but does not necessarily mean the transmission was successful. Software should still look for other interrupts to check for any errors.

RX_REGISTER_FULL

The hardware has assembled a complete block from the bus and placed it into the RX_REGISTER. Software should read the block immediately to ensure the RX_REGISTER is empty before hardware has the next block ready to load. When the HW RX engine writes RX data to the RX_REGISTER, this bit is set.

RX_REGISTER_OVERRUN

Software failed to read the RX_REGISTER before hardware had another block of data ready to transfer. Hardware will NAK the block/frame, and the initiator will need to retry later. Software will need to flush the partially accumulated frame.

RX_START_BIT_DETECTED

Whenever the receive engine detects a start bit, it will set this bit. This bit is used for debug.

RX_BUS_ANOMALY_DETECTED

The receiver detected some anomaly (including bus errors) on the bus. A bus error has a specific definition in the HDMI specification, but there are other kinds of anomalies that can occur. All anomalies and bus errors are reported here.

RX_BUS_ERROR_DETECTED

The receiver has detected the specific anomaly called a bus error and then signaled a bus error on the bus per the HDMI specification.

FILTERED_RX_DATA_PIN_TRANSITION_H2L

In direct SW bus drive mode, software needs to be interrupted whenever the state of the received data line transitions. This interrupt is asserted on a 1 to 0 transition.

FILTERED_RX_DATA_PIN_TRANSITION_L2H

In direct SW bus drive mode, software needs to be interrupted whenever the state of the received data line transitions. This interrupt is asserted on a 0 to 1 transition

CHAPTER 29: MIPI-CSI (CAMERA SERIAL INTERFACE)

This chapter describes the Tegra® X1 Camera Serial Interface (CSI), which is based on the MIPI CSI-2 v1.1 standard specification. The MIPI CSI-2 v1.1 standard is available from MIPI to its members at http://www.mipi.org/.

29.1 Functional Description

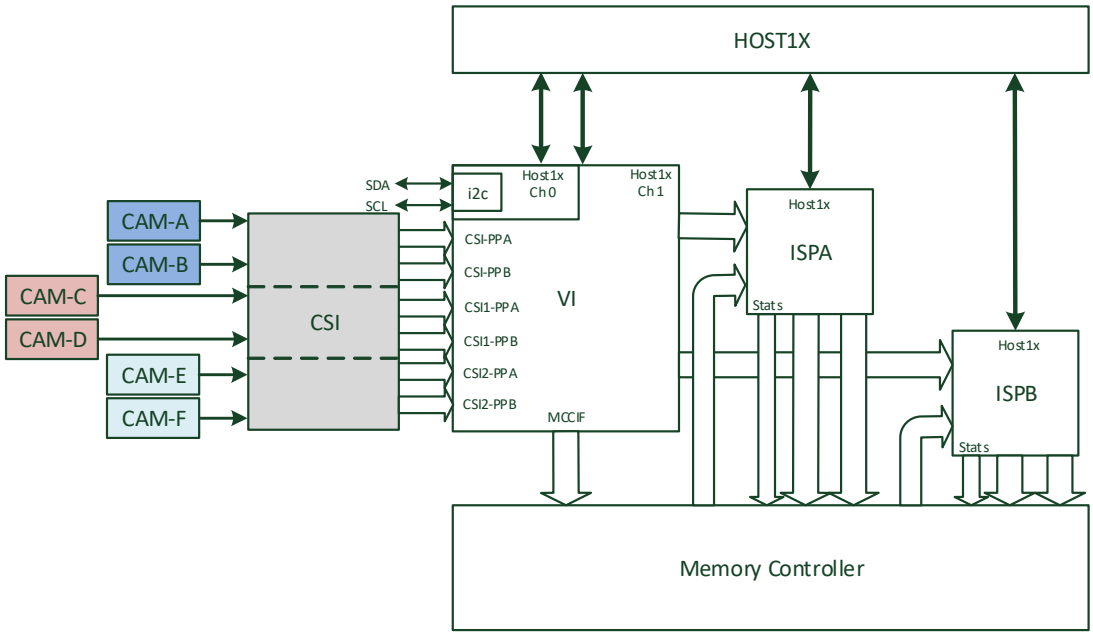
The Tegra X1 CSI unit implements MIPI compliant CSI receivers that may receive data from an external camera module with a CSI transmitter. The CSI unit provides for direct connection to six camera modules (A, B, C, D, E, and F), all of which may be active simultaneously: Internally, the CSI unit is composed of three identical instances referred to as CSI, CSI1, and CSI2 as follows:

- CSI: Supports up to 4 lanes for either Camera A or B with only one camera active, or up to 2 lanes for Cameras A and B when configured in the 2x2 mode with both camera's active. Two clock lanes are available to manage the Camera A and B streams.
- CSI1: Supports up to 4 lanes for either Camera C or D with only one camera active, or up to 2 lanes for Cameras C and D when configured in the 2x2 mode with both camera's active. Two clock lanes are available to manage the Camera C and D streams.
- CSI2: Supports up to 4 lanes for either Camera E or F with only one camera active, or up to 2 lanes for Cameras E and F when configured in the 2x2 mode with both camera's active. Two clock lanes are available to manage the Camera E and F streams.

The CSI unit offers both single and multi-camera configuration options. The single camera configuration option is supported with a 1-to-4 lane sensor connected to one of the CSI, CSI1, or CSI2 interfaces. Several multi-camera configuration options are also available by connecting up to two cameras to one of the CSI, CSI1, or CSI2 interfaces or by operating the interfaces simultaneously with multiple cameras connected. A maximum of six cameras can be supported by the CSI unit if all interfaces are utilized.

The following figure illustrates the datapaths associated with the Tegra X1 camera subsystem.

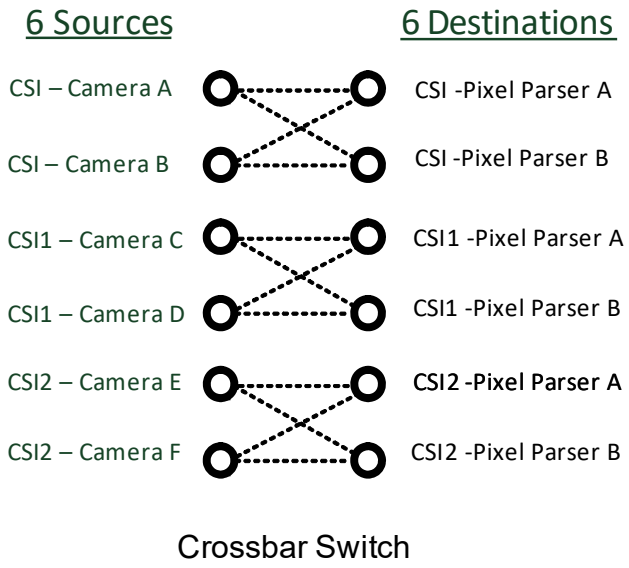
Figure 115: Datapath Through the Tegra X1 Camera Subsystem



A maximum of six data/pixel streams can be processed simultaneously at any given time. The streams can come from any of the six possible sources, as shown below. If the two streams come from a single source, then the streams are separated using

a filter indexed on different virtual channel numbers or data types. In case of separation using data types, the normal data type is separated from the embedded data type. Because there are only two pixel parsers for each CSI, CSI1, and CSI2 instance (PPA and PPB), the virtual channel and embedded data capability cannot be used at the same time.

Figure 116: Data Source/Destination Options



The CSI unit may receive data from camera modules through the MIPI serial interface. A test pattern generator has been implemented to assist validation.

The CSI unit supports single-shot mode and burst capture mode.

The CSI unit is designed with error resilience.

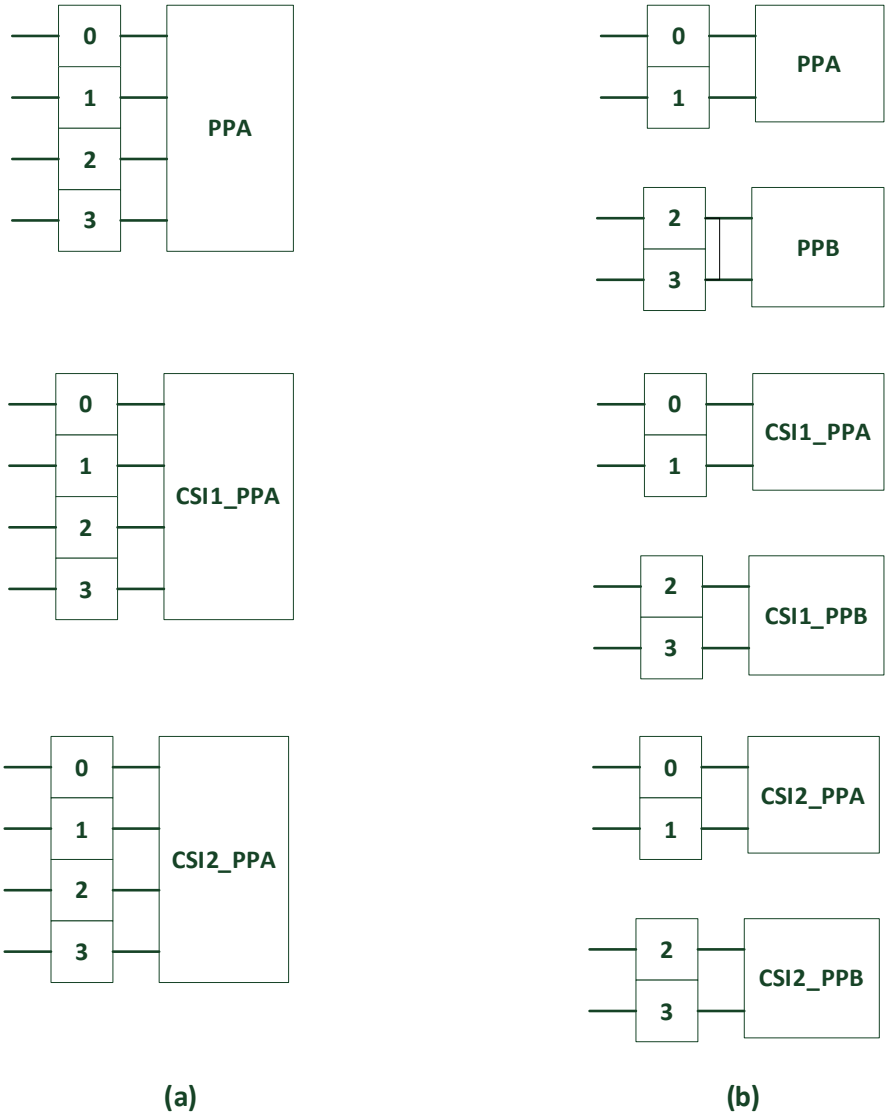
29.1.1 Lane Configurations

The number of MIPI lanes supported provides flexibility in the support of both single and dual camera user models. The typical single and dual camera application targets include high-resolution mono image capture in addition to dual camera image capture configurations:

- 1 x 4 (Single camera with 4 lane sensor using CSI_PPA, CSI1_PPA, or CSI2_PPA)
- 2 x4 (Stereo pair with 4 lanes for each camera using any pair of CSI_PPA, PPA, CSI1_PPA, and CSI2_PPA)
- 2 x 2 (Dual camera mode for CSI, CSI1, and CSI2 supporting 2,4, or 6 camera streams)

The following figure summarizes the typical camera configurations.

Figure 117: CSI MIPI Lane Configurations



Note: *Dual camera streams may be routed to either PPA or PPB when operating in 2x2 mode for each instance (CSI, CSI1, or CSI2) but cannot cross the CSI instance boundaries.*

There are several possible configuration options depending on the system configuration. A summary of the lane configuration options for various 1x4 and 2x4 configurations is provided in the following table.

Table 164: Pin Connections for Lane Configuration Options for 1x4 and 2x4

MIPI Pads		Pin Connects for Lane Configuration Options					
		1x4 (Option A)	1x4 (Option B)	1x4 (Option C)	2x4 (Option A)	2x4 (Option B)	2x4 (Option C)

csief_pad	CLK	-	-	csi_e_clk_n csi_e_clk_p	csi_e_clk_n csi_e_clk_p	-	csi_e_clk_n csi_e_clk_p
	Data Lanes	-	-	csi_e_d0_n csi_e_d0_p	csi_e_d0_n csi_e_d0_p	-	csi_e_d0_n csi_e_d0_p
		-	-	csi_e_d1_n csi_e_d1_p	csi_e_d1_n csi_e_d1_p	-	csi_e_d1_n csi_e_d1_p
		-	-	csi_f_d0_n csi_f_d0_p	csi_f_d0_n csi_f_d0_p	-	csi_f_d0_n csi_f_d0_p
		-	-	csi_f_d1_n csi_f_d1_p	csi_f_d1_n csi_f_d1_p	-	csi_f_d1_n csi_f_d1_p
	CLK	-	-	csi_f_clk_n csi_f_clk_p	csi_f_clk_n csi_f_clk_p	-	csi_f_clk_n csi_f_clk_p

Each of the MIPI x4 bricks may also be configured as a 1x2 or as a 2x2, resulting in the ability to configure from 1 to 6 2-lane cameras.

29.2 Use Cases

The use cases supported by the CSI unit include basic single camera, multiple cameras, embedded data, and virtual channel. The still and video capture sequences involve different single camera and multi-camera configuration options.

The table below summarizes the use case categories.

Table 165: Summary of CSI Camera Use Cases

Case	Description	Sources	Destinations
Single Camera Video Capture	Basic preview or video capture using single camera	Camera A, B, C, D, E, or F	PPA, PPB, CSI1_PPA,CSI1_PPB, CSI2_PPA,or CSI2_PPB

Table 165: Summary of CSI Camera Use Cases

Case	Description	Sources	Destinations
Stereo Camera Video Capture	Stereo pair video capture	Camera AB, CD, or EF	PPA and PPB, CSI1_PPA and CSI1_PPB, or CSI2_PPA and CSI2_PPB
Single Camera Still Capture and Preview	Basic high resolution still capture supporting single shot and burst capture and preview	Camera A, B, C, D, E, or F	PPA, PPB, CSI1_PPA,CSI1_PPB, CSI2_PPA,or CSI2_PPB
Stereo Camera Still Capture and Preview	Stereo camera high resolution still capture and preview	Camera AB,CD, or EF	PPA and PPB, CSI1_PPA and CSI1_PPB, or CSI2_PPA and CSI2_PPB
Dual Camera Mono Video Capture	Video feed of front facing camera and user facing camera for video annotation or video preview during Video Conference	Any camera pair	Any pair or pixel parsers
Video Conference Mono Still Capture & Preview*	Video feed of user facing camera for video conference and mono still capture from front facing camera.	Any camera pair	Any pair or pixel parsers
Multi-Camera Automotive	Low resolution YUV or RGB video feed from two cameras.	Any grouping of the 6 cameras	Any grouping of the 6 pixel parsers
Virtual Channel(1)	One stream goes to both parsers.	Camera AB,CD, or EF	PPA and/or PPB CSI1_PPA and CSI1_PPB, or CSI2_PPA and CSI2_PPB
Embedded Data	One stream goes to one parser and has normal and embedded data	Camera AB,CD, or EF	PPA and PPB, CSI1_PPA and CSI1_PPB, or CSI2_PPA and CSI2_PPB
Virtual channel based interleaving is not supported.			

The CSI unit supports both progressive and interlaced video captures. The interlaced capture is targeted toward the automotive use case and will always be either RGB or YCbCr data. During interlaced video capture, the Top and Bottom frames are signaled to the VI2 during the SOF by togging the LSB on the CSI[A,B]2VI_DATA bus. Refer to Chapter 31: Video Input (VI) in this TRM for more information.

29.3 Performance

The following table describes the various MIPI lane configurations and the theoretical maximum Mpixels/s achievable at 100% efficiency for several RAW Bayer pixel precisions and YCbCr 4:2:2.

Table 166: Maximum Capture Rate in MPixels/s for Various CSI Configurations

Link Speed	Number of Lanes	Maximum Mpixels/s with 100% Efficiency				
		RAW8	RAW10	RAW12	RAW14	YCbCr422
600 Mbps	1	75	60	50	42.9	37.5
	2	150	120	100	85.7	75
	3	225	180	150	128.6	112.5
	4	300	240	200	171.4	150
800 Mbps	1	100	80	66.7	57.1	50
	2	200	160	133.3	114.3	100
	3	300	240	200	171.4	150
	4	400	320	266.7	228.6	200
1 Gbps	1	125	100	83.3	71.4	62.5
	2	250	200	166.7	142.9	125
	3	375	300	250	214.3	187.5
	4	500	400	333.3	285.7	250

Table 166: Maximum Capture Rate in MPixels/s for Various CSI Configurations

Link Speed	Number of Lanes	Maximum Mpixels/s with 100% Efficiency				
1.5 Gbps	1	187.5	150	125	107.1	93.8
	2	375	300	250	214.3	187.5
	3	562.5	450	375	321.4	281.3
	4	750	600	500	428.6	375

The maximum throughput supported by the CSI unit using all available lanes is described by the following equation:

Maximum BW in bits/s = (1.5 Gbps/lane)*(12 lanes) = 18 Gbps

For RAW10 (10bpp), a total of 1.8G pixels/s can be delivered to the VI/ISP subsystem; similarly for YCbCr422 (16bpp), a total of 1.125 Gpixels per second can be delivered. Typically, overhead due to blanking and protocol will reduce these numbers by approximately 15%.

The following table translates the maximum pixel rate into the maximum achievable frame rate for different sensor resolutions and bit depths.

Table 167: Maximum Capture Rate in FPS for Various CSI Configurations

Frame Size	Pixel Type	Maximum Frame Capture Rate (FPS) with 100% Efficiency											
		800 Mbps				1 Gbps				1.5 Gbps			
		1	2	3	4	1	2	3	4	1	2	3	4
8MP	RAW10	10	20	30	40	12.5	25	37.5	50	18.8	37.6	56.4	75.2
	RAW12	8.3	16.7	25	33.4	10.4	20.8	31.1	41.6	15.6	31.2	46.8	62.4
	RAW14	7.2	14.3	21.5	28.6	8.9	17.9	26.8	35.7	13.4	26.8	40.2	53.6
14MP	RAW10	5.5	10.9	16.4	21.9	6.8	13.7	20.5	27.3	10.7	21.4	32.1	42.8
	RAW12	4.6	9.1	13.7	18.2	5.7	11.4	17.1	22.8	8.9	17.8	26.7	35.6
	RAW14	3.9	7.8	11.7	15.6	4.9	9.8	14.7	19.5	7.7	15.4	23.1	30.8

To minimize the rolling shutter artifacts, a generally accepted minimum still capture target of $1/15^{th}$ of a second is desired. The Zero Shutter Lag (ZSL) user model in which a preview stream and a still capture circular buffer are maintained makes it desirable to achieve the highest frame rate possible to provide good motion video for scene composition.

29.4 Supported CSI to VI Data Formats

The formats of the pixel data presented from the CSI to the VI across the 24-bit bus for each of the pixel parsers are summarized in the table below.

The Tegra X1 device presents all Raw data to the VI/ISP in its original bit order.

Table 168: CSI to VI Pixel Formats

Format Name		23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

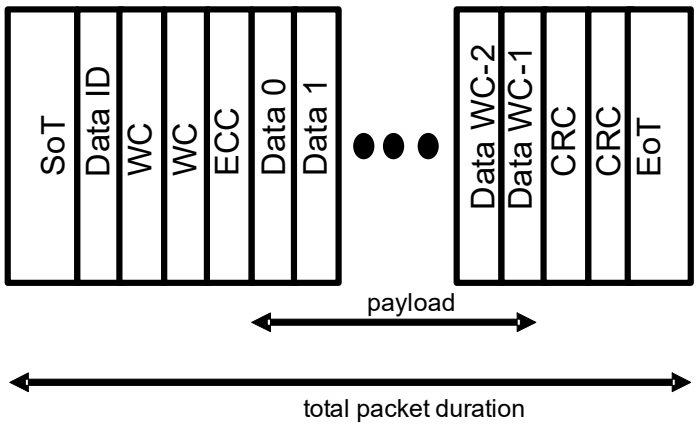
1. The bits marked as '0' are actually don't cares.
2. Odd Line refers to the first line from the CSI unit.

29.5 CSI Packet Structure

The CSI packet structure is illustrated below. It has a start-of-transmission sequence (SoT), which contains a 1-byte preamble sequence. The packet is composed of a 4-byte header, a body of word count (WC) bytes, and a 2-byte CRC check. The end-of-transmission (EoT) is indicated by the line state going from high-speed transmission to the LP11 state.

Figure 118: CSI Packet Structure



29.6 CSI Implementation

The CSI interface consists of:

- MIPI D-PHY block
- Control Interface Logic (CIL) for Serial Clock Receiver
- CSI datapath module which is implemented as a sub-module of VI module

In the Tegra X1 implementation, three CSI bricks including the csiab_pad with 4x data lanes, the csicd_pad with 4x data lanes and the csief_pad with 4x data lanes receive serial data from cameras, deserialize them into 8-bit parallel data, and send them to the CSICIL block. The CSICIL block performs packet boundary detection by searching for the packet preamble. The main CSI module receives an 8-bit packet aligned data from CSICIL, performs parity checking on the header, header decoding, CRC check, and pixel parsing. The output is sent out to the VI through the 28-bit bus, which outputs 1 pixel per VI clock.

29.7 Performance Limitations

The performance of the CSI interface is subject to several factors that must all be met. The performance factors that are directly related to the CSI interface are the serial data rate and the internal pixel rate. Maximum serial data rate is expected to be 1.5 Gbps/lane given the ideal system condition. This data rate may be degraded depending on system design and may also be limited by the CSI transmitter in the camera.

For each CSI data lane, the serial data stream received by the CSI PHY is internally converted to a byte stream by the CSI Control Interface Logic (CIL) before further processed by the CSI module that resides as part of the Video Input (VI) module. The CSI byte clock is used to transfer this data byte stream (1 byte per data lane) between the CIL and the CSI datapaths. This CSI byte clock is derived from the received CSI serial clock by dividing the CSI serial clock by 4. So for 1 Gbps serial CSI data rate, the serial clock frequency is 500 MHz and the byte clock frequency is 125 MHz.

The byte stream received by the CSI CIL logic is converted to a pixel stream at 1 pixel per clock in the CSI module. This pixel stream output is further processed by other modules (ISP or the rest of the VI datapath). Depending on where the CSI pixel stream is processed (ISP or VI), the maximum pixel clock frequency is limited by the pixel clock frequency of the modules that process this pixel stream.

Note: *VI/ISP pixel frequency may be lower than CSI output pixel clock frequency and therefore, may limit the actual pixel data rate. Please refer to the ISP and VI specifications.*

With multiple data lanes per CSI interface, the maximum serial data link speed may not be achievable due to pixel clock frequency limitations. Also, if two data streams come from the same CSI interface, since the streams are interleaved in time, the pixel clock frequency limitations may also limit the frame rate of the combined streams.

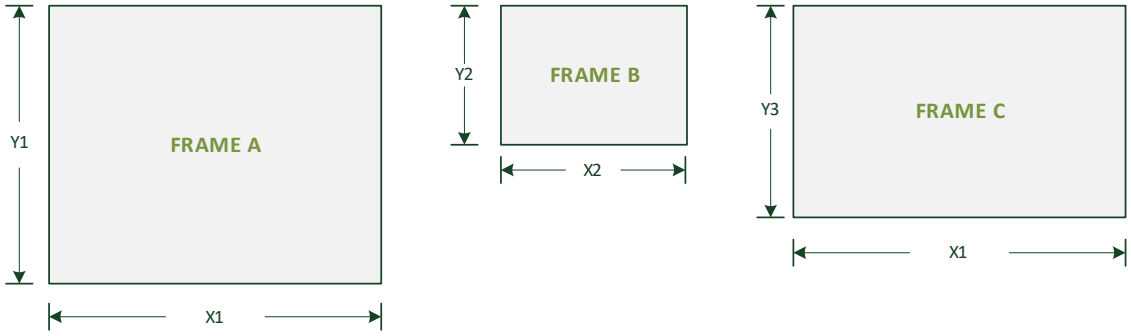
Table 169: Packet Efficiency

	Best* WC=65536	Typical* WC=1024
Payload	524 µs	8192 ns
Overhead	356 ns	356 ns
Efficiency	99.9%	96%

29.8 Frame Size Mismatch Scenarios

Several frame mismatch scenarios can occur during image capture. In these situations, a frame might not have the expected dimensions as shown in the following figure.

Figure 119: Frame Size Variations



Frame A = Full Resolution Image of size (X1,Y1)
Frame B - Preview image of size (X2,Y2) where, Y2 < Y1 & X2 < X1
Frame C - Preview image of size (X1,Y3) where, Y3 < Y1

The following subsections describe the behavior of the CSI unit (and VI/ISP) in the various frame size mismatch scenarios:

29.8.1 Received Frame Width and Height Matches Programmed Width and Height

When the CSI unit receives any frame size, it starts capturing the frame. The VI will raise the sync point when it receives the EoF at the right time.

29.8.2 Received Frame Width Does Not Match Programmed Width

Packet Width Mismatch Error

If the CSI unit receives any frame size in which the width of the incoming frame does not match the programmed value, the error is detected and signaled to the VI. The VI will drop the frame in the case of packet width mismatch errors.

29.8.3 Received Frame Height Does Not Match Programmed Height

CASE 1: Frame Height Mismatch Error - Fewer Rows Than Expected

Example: The CSI unit is instructed to capture Frame A:

When the sensor receives Frame C, it starts capturing the frame as the width of the frame matches the expected frame width. The CSI unit will encounter an early EoF. At this time, it will rearm the pixel parser state-machine with the same set of frame capture parameters and wait for the next frame.

If this frame was to be sent to memory, the VI unit will not detect that it is not the right frame and will not raise the sync point. When it receives the next frame from the CSI unit, it will overwrite the memory buffer (at the buffer location pointed by previous frame parameter).

If this frame was to be sent to the ISP, the VI forwards the EoF control packet to the ISP and indicates that the Frame was too short. The CSI and VI will not pad the frame to make the frame the right size. The ISP unit needs to detect the error condition and should not update the parameter for the next frame and apply the same parameters (as the previous frame) for the next incoming frame from the VI.

CASE 2: Frame Height Mismatch Error - More Rows Than Expected

Example 2: The CSI unit is instructed to capture Frame C:

When the CSI unit receives Frame A, it starts capturing the frame as the width of the frame is matched.

For the frame to be sent to memory, the VI marks the last atom of the frame to the memory as a non-posted write. The VI then raises a sync point when the WrAck and EoF at the expected frame size if received. In this case, instead of EoF, the VI will receive more pixel data. On detecting this condition, the VI will not raise the sync point; it drops the rest of the frame and does not corrupt the memory buffer. The CSI unit will rearm the pixel parser state machine with the same set of frame capture parameters and waits for the next frame. Because the VI is also aware of the expected frame height and detects the frame to be erroneous, it will overwrite the memory buffer with the next frame.

In case this frame was to be sent to the ISP, the VI, when it receives the regular pixel data instead of EoF flag from the CSI unit, will drop the data and generate an EoF flag to the ISP to terminate the frame and mark it as frame-too-big. The ISP unit needs to detect the error condition; it should not update the parameter for the next frame and will apply the same parameters (as the previous frame) for the next incoming frame from the VI.

29.8.4 Double Buffering of the Configuration Registers

There are two copies of configuration registers: operational and the shadow registers. The shadow registers are updated from the Host1x input when it does not have a pending capture command. The shadow register is copied to the operational register when a frame is successfully captured (at the EoF received at the right time). In the event of a frame size mismatch, the shadow registers are not copied and the current settings remain active for the next incoming frame:

1. Successful Frame Capture: The CSI pixel parser (and header parser) sub-units copy the shadow configuration register to the operational configuration register, if it needs to capture the next frame. This configurations need to move along the pipeline with the SoF marker.
2. Failed Frame Capture (Dropped): When a frame is dropped for being too big or too small, the shadow registers are not copied over to the operational register and the CSI remains armed for the next frame.

Whenever the CSI drops an incoming frame, whether due to a mismatch in virtual channel, data type, width, or the height, this information is appropriately logged in the status register. This would help in debugging any system issues where the software arms the CSI to capture the frame but eventually times out due to a missing sync point. There is only one copy of this register (per CSI channel) and every subsequent dropped frame will update this status register.

29.9 Error Handling

The CSI unit is required to tolerate and/or recover stream errors at various levels.

Table 170: CSI Error Categories

Error Categories	Classification	Type	Description
D-PHY Level Errors	Start of Transmission (SoT) Error	Single-bit error	Corrected an error condition signal from PHY/CIL
		Multi-bit error	Packet discarded
	Control Error	Incorrect line state sequence	XError signal asserted
	Escape Entry Error	Escape command different from 8-bits and escape handshaking incorrect	XError signal asserted
	End of Transmission (EoT) Error	A bit of the payload not on a byte boundary	Unrecoverable error condition signaled to the application layer
Packet Level Errors	Packet Header Error	Single bit error	Detected and corrected by the ECC code
		Multi-bit error	Detected but not corrected; error is flagged and interrupt generated
	Packet Payload Errors	Signaled through CRC Code	Detected but not corrected; error is flagged and interrupt generated
Protocol Decoding Errors	Frame Sync Error	FE is not matched to FS	Frame data is supplied to the VI and an error is signaled as a stream error to the application layer.
	Unrecognized ID	Data ID Error	Packet discarded
CSI Block Specific Errors	Packet Header Mismatch Error	Data ID Error	If the virtual channel ID does not match the programmed value for the corresponding pixel parser then the packet is discarded
		Data Type Error	If the data-type does not match the programmed value for the corresponding pixel parser then the packet is discarded
	FIFO Overflow	Backpressure	Frame is dropped
	Packet Word Count Mismatch	Packet longer than word count	Packet is dropped
		Packet shorter than word count	Packet is dropped
	Frame Height Mismatch	Frame larger than programmed size	Frame data is supplied to the VI until EoF and then the pixel parser is re-armed. VI will receive or drop the additional data depending on destination (MEMC or ISP)
		Frame smaller than programmed size	The pixel parser is rearmed on EoF and waits for the next frame

29.10 Other Architectural Constraints

The following specifies other architectural constraints for this design:

- Because there are only 2 pixel parsers for the CSI, CSI1, or CSI2 instance, embedded data and virtual channel cannot be supported simultaneously.
- Embedded data in a frame can be output in the same output port as the pixel data stream; however, in some cases where image processing or data reformatting is performed in VI/ISP, this embedded data may be accidentally processed in VI/ISP. Currently, VI/ISP cannot differentiate between embedded data or pixel data. Refer to the VI chapter for more information on the options for managing embedded data.

29.11 CSI Datapath Module

The CSI, CSI1, and CSI2 instance datapaths consist of two input ports and two output ports. For each instance, there are two datapaths for pixel stream processing; therefore, at any time, a maximum of two input ports may be active simultaneously.

The components of the CSI, CSI1, and CSI2 datapaths include:

- Two input ports for each instance: CSI A interface and CSI B interface, CSI1 A and CSI1 B, and CSI2 A and CSI2 B. Each port is capable of carrying a stream with CSI compatible data format.
- Two asynchronous input buffers (FIFOs) for each instance to receive streams from the CSI, CSI1, and CSI2 A interface and the CSI, CSI1, and CSI2 B interface.
- Two header parsers for CSI, CSI1, and CSI2 for searching packet header and to perform error detection and correction of CSI header.
- Two pixel parsers with corresponding output ports for CSI, CSI1, and CSI2. Each pixel parser can convert a CSI packet data stream to output a pixel stream. Each output port consists of a maximum 24 bits of data per clock. Depending on the output data format options, one or two pixels per clock may be sent.

29.11.1 Header Parser

CSI pixel stream processing mainly consists of header parser and pixel parser. There are 2 header parsers: header parser A and header parser B.

Header parser A is enabled when CSI A interface is selected as input source. Similarly, header parser B is enabled when CSI B interface is selected as input source.

In general the header parser is used for:

- Detecting long and short packet headers and deciding what to do with the packet. This includes performing error detection and correction on the packet header prior to making decision and dealing with uncorrectable packet header.
- Skipping extra data on longer than expected data packets.
- Skipping next packet on imminent input buffer overflow when the pixel parser is busy processing current packet.

When enabled, the header parser will interpret CSI packet header, perform error detection and correction. If the packet header is uncorrectable, then an error is flagged and interrupt generated. If good or correctable CSI packet header is found, then the header parser will check the Data Identifier (DI) byte in the packet header and check the 2-bit Virtual Channel (VC) identifier and the 6-bit Data Type (DT) within this Data Identifier byte and will also check the 2-byte Word Count (WC) value in the packet header. If the virtual channel ID does not match the expected (programmed) value for the corresponding pixel parser then the packet is discarded. If the virtual channel ID matches the expected (programmed) value for the corresponding pixel parser then the header parser must decide what to do with the packet depending on the Data Type and the Word Count value. For long packet, if the Data Type does not match the expected (programmed) value for the corresponding pixel parser then the packet is discarded. If the Data Type of the long packet matches the expected (programmed) value for the corresponding pixel parser, then the corresponding pixel parser is notified to process the remaining packet data and checksum.

When first enabled, the header parser must always search for Frame Start packet which is a CSI short packet. When frame start packet/signal is found, the header parser will notify the corresponding pixel parser so that it can prepare to process a new frame and output frame start code.

29.11.1.1 Data Type

There are 64 possible data types based on the 6-bit Data Type value.

Table 171: Possible Data Types

Data Type	Description
0x00 – 0x07	Synchronization Short Packet Data Types
0x08 – 0x0F	Generic Short Packet Data Types
0x10 – 0x17	Generic Long Packet Data Types
0x18 – 0x1F	YUV Data
0x20 – 0x27	RGB Data
0x28 – 0x2F	RAW Data
0x30 – 0x37	User Defined Byte-based Data
0x38 – 0x3F	Reserved

29.11.1.2 Short Packets

There are 16 possible short packets based on Data Type value.

Table 172: Possible Short Packets

Data Type	Description
0x00	Frame Start Code
0x01	Frame End Code
0x02	Line Start Code (Optional)
0x03	Line End Code (Optional)
0x04 – 0x07	Reserved

29.11.1.3 Long Packets

CSI long packets are data packets which always consist of 1 line of data per packet with exception of arbitrary data packets. There are various data types defined. Please refer to the Input Data Format section for a summary of CSI data formats and their corresponding CSI module internal output format.

Generic long packets need special handling. There are 3 generic long packet types defined: null packet (DT=0x10), blanking data packet (DT=0x11), and embedded data packet (DT=0x12). There are also 5 reserved generic long packet types (DT=0x13 to 0x17). The header parser should discard all null packets and all reserved generic long packets.

Blanking data packets may contain blank color or blank image information. The transmission of blanking data packet is optional in the CSI2.0 specification. Null and blanking data are defined in the CSI2.0 specification mainly to accommodate a receiver which is timing sensitive and requires line start/end for every line in the frame. As a CSI receiver, this product does not have such blank timing sensitivity and it typically does not process blank data and does not store it to memory. Blanking data packet can therefore be discarded by the header parser.

However, some modules may have a requirement for specific number of “blank” or extra lines at the end of vertical active area, such as the ISP module, which requires input active scan area to be about 6 lines larger than output active area. If a module that takes CSI output stream requires extra lines at the end of active image then blanking packet data can be used to generate these additional lines. In the future, there might be other reasons to process blank data. So, an option should be provided to accept and process blanking data. In the absence of better definition of blanking data format in the CSI specification, if software decides that blanking data cannot be discarded then, the pixel parser should assume that the blanking data format is the same as the programmed expected data type of the pixel stream.

The current CSI2.0 specification specifies that embedded data packets consists of 8-bit arbitrary data. This embedded data is, typically not the same pixel color as the image data. It might be used to send headers/status for JPEG/MPEG compressed data at the beginning or end of image data or in between image data lines. It might also be used to send closed caption text information or other type of information.

The exact use of embedded data is not clear, and therefore in most cases, embedded data is probably not used, or if sent by the transmitter, the embedded data packets can simply be discarded. If for some reason, it is important to receive the embedded data, there are other options that should be supported. Since there are two pixel parsers, if there is only one video source, it is best to direct embedded data to the other pixel parser which does not process the normal image data. In this way, the embedded data can be treated the same way as 8-bit arbitrary/compressed image data and can be output in 8-bit/clock or 16-bit/clock format. If there are two video sources that occupy both the pixel parsers, then embedded data if it has to be stored to memory, needs to be output in the same channel as the image data as 8-bit/16-bit data. But this also means that the module that receives output of CSI module and does image processing must have the ability to differentiate embedded data and not do image processing on this data prior to writing it to memory.

29.11.1.4 Top or Bottom Field Tag

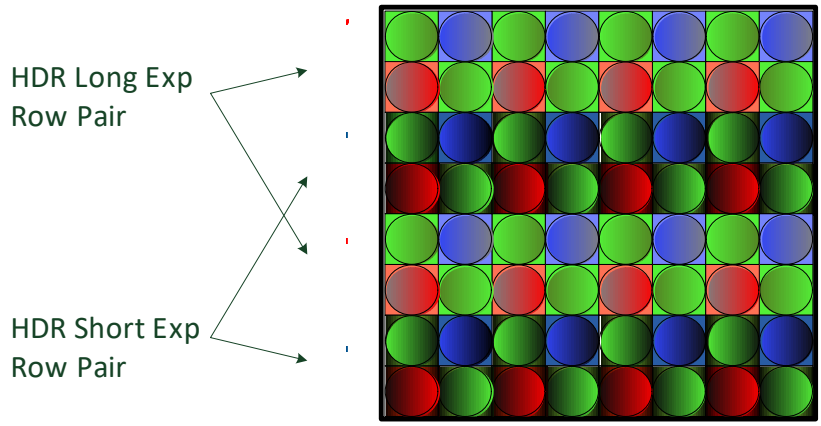
During frame start, a tag is passed from CSI to VI to indicate top or bottom field. The 1-bit tag is at the least significant bit of the CSI output bus. If the bit is “1”, the field is top, but bottom otherwise.

29.12 Test Pattern Generator (TPG)

The test pattern generator is a configurable resource introduced to improve hardware verification capability for the Tegra CSI. Because a provision for inserting pixel data from the Host interface is not available, the hardware verification of the CSI and VI units is difficult. The only sources of pixel data that can exercise the CSI are image sensors. In general, the sensor data cannot be controlled, making any self-checking test impossible. Test pattern generation modes offered by sensors are also ineffective because they have limited control.

The Tegra X1 CSI block introduces the AO-HDR feature in which data may be presented with alternate gain and exposure settings on each row as shown in the following figure.

Figure 120: Long and HDR Long and Short Exposure Rows Interleaved



The TPG will allow the scaling of the test patterns based on configuration settings. The first row pair is considered the long exposure row pair, and the second is the short exposure pair. In order to provide some flexibility, the option to either scale the short row pairs up or down is supported, which allows the simulation of HDR images while either allowing saturation or preventing it.

Table 173: TPG HDR Configuration Parameter

Register	Field	Bits	Format	Description
CSI_PG_AOHDR_[A..B]	ENABLE	0	U1	Controls whether the AT is operational. 0: DISABLED 1: ENABLED
	GAIN_RATIO	2:1	U2	Gain ratio for channel balancing; Short exposure gain: Long Exposure gain 0: 2:1 Gain ratio (short rows <<1) 1: 4:1 Gain Ratio (short rows << 2) 2: 0.5:1 Gain Ratio (short rows >> 1) 3: 0.25:1 Gain Ratio (short rows >> 2)
CSI1_PG_AOHDR_[A..B]	ENABLE	0	U1	Controls whether the AT is operational. 0: DISABLED 1: ENABLED
	GAIN_RATIO	2:1	U2	Gain ratio for channel balancing; Short exposure gain: Long Exposure gain 0: 2:1 Gain ratio (short rows <<1) 1: 4:1 Gain Ratio (short rows << 2) 2: 0.5:1 Gain Ratio (short rows >> 1) 3: 0.25:1 Gain Ratio (short rows >> 2)

Table 173: TPG HDR Configuration Parameter

Register	Field	Bits	Format	Description
CSI2_PG_AOHDR_[A..B]	ENABLE	0	U1	Controls whether the AT is operational. 0: DISABLED 1: ENABLED
	GAIN_RATIO	2:1	U2	Gain ratio for channel balancing; Short exposure gain: Long Exposure gain 0: 2:1 Gain ratio (short rows <<1) 1: 4:1 Gain Ratio (short rows << 2) 2: 0.5:1 Gain Ratio (short rows >> 1) 3: 0.25:1 Gain Ration (short rows >> 2)

29.12.1 TPG Limited Error Status

When enabled, the TPG will disable the following errors and associated interrupts for each instance of the CSI:

- Pixel Parser A:
  - HPA_UNC_HDR_ERR
  - PPA_PL_CRC_ERR
  - PPA_HDR_ERR_COR
- Pixel Parser B:
  - HPB_UNC_HDR_ERR
  - PPB_PL_CRC_ERR
  - PPB_HDR_ERR_COR

There are two separate test pattern generators for the CSI, CSI1, and CSI2 instances that can be configured to provide for the generation of synthetic image data, which is delivered to the PPA and PPB input FIFOs. The image data is multiplexed into the CSI, CSI1, and CSI2 datapaths between lane-merging logic and the data FIFOs. Programmable configuration parameters are available to allow variation in pixel data, data type, and spacing between various packets. In the real system, the LP state transition between any two CSI packets guarantees some idle time between the lines. This spacing between the lines from the pattern generator should be programmed to a minimum of 8 cycles, as the later stages of VI expects some idle cycles between the lines in order for it not to overflow.

A difference engine architecture is employed which can generate almost arbitrary patterns that consist of frequency sweeps or intensity ramps in both the horizontal and vertical directions. In addition, by using selected bits from the difference engine variables as addresses, a color patchwork pattern can be generated. The output from the difference engine is modeled off of a second-order partial differential equation of the form:

Where:

$$\varphi_{out} = \varphi + x \cdot \frac{d\varphi}{dx} + x^2 \cdot \frac{d^2\varphi}{dx^2}$$

$$\varphi = PHASE$$

$$\frac{d\varphi}{dx} = FREQ$$

$$\frac{d^2\varphi}{dx^2} = FREQ\_RATE$$

The PHASE, FREQ, and FREQ_RATE variables may be programmed to create a variety of different test patterns and are either used directly or as an index into a look-up table (LUT). The table below summarizes the configuration parameters for the TPG.

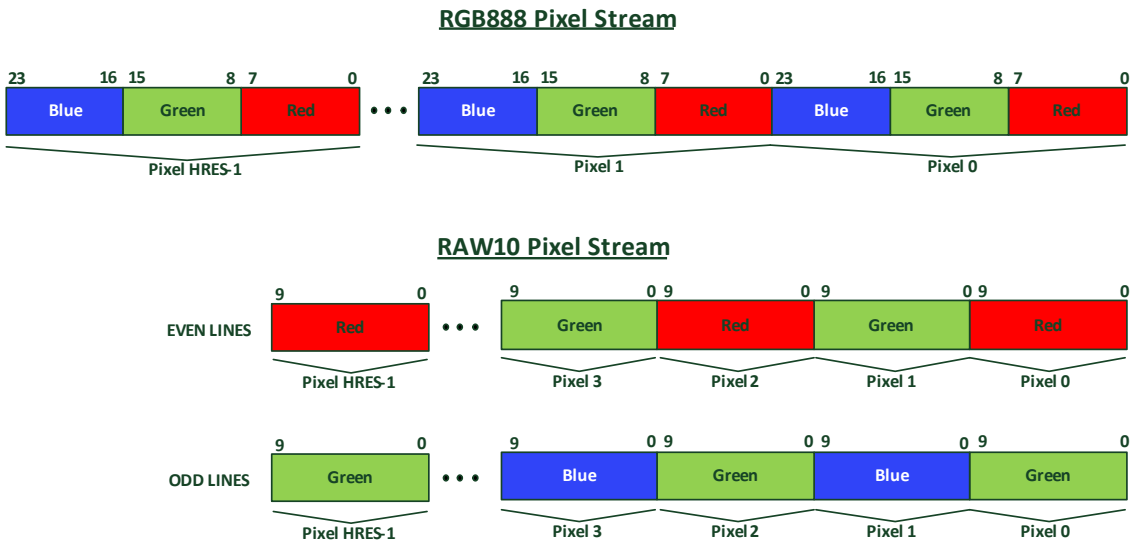
Table 174: Description of TPG Configuration Parameters

Configuration Variables for CSI_0, CSI1_0, CSI2_0 and CSI_1, CSI1_1, CSI2_1 Test Pattern Generators	TPG Frame Configuration	Image Height	Lines per frame
		Image Width	Pixels per line
		Vertical Blanking	Blank lines between frames
		Horizontal Blanking	Blank pixels between lines
		Initial Phase	Initial phase
		Mode	Direct or color patch
		Format	RGB888 or RAW10 support
	TPG Channel Configurations (R, G, and B)	Vertical Initial Frequency	Initial frequency
		Horizontal Initial Frequency	Initial frequency
		Vertical Frequency Rate	Rate of change for vertical frequency
		Horizontal Frequency Rate	Rate of change for horizontal frequency

29.12.2 TPG Frame Configuration Parameters

The TPG can be configured to provide the test images in either an RGB888 or Bayer RAW10 data format. The RGB888 data is delivered to the lane merging logic as a sequence of bytes representing the RGB triads for each pixel in an HRESxVRES image frame. For the Bayer RAW10 data, the color components of the RGB pixel are sampled in an alternating fashion, depending on whether the current row and pixel within the row is even or odd.

Figure 121: RGB888 and RAW10 TPG Pixel Streams



Note: *Byte ordering for RGB888 and RAW10 on the CSI2VI interface follows the same convention as data received over the MIPI interface.*

The data from the test pattern generator has the same format (with the packet header, CRC, ECC, etc.) as received on the output of lane-merging logic during normal operation.

29.12.3 Modes of Operation

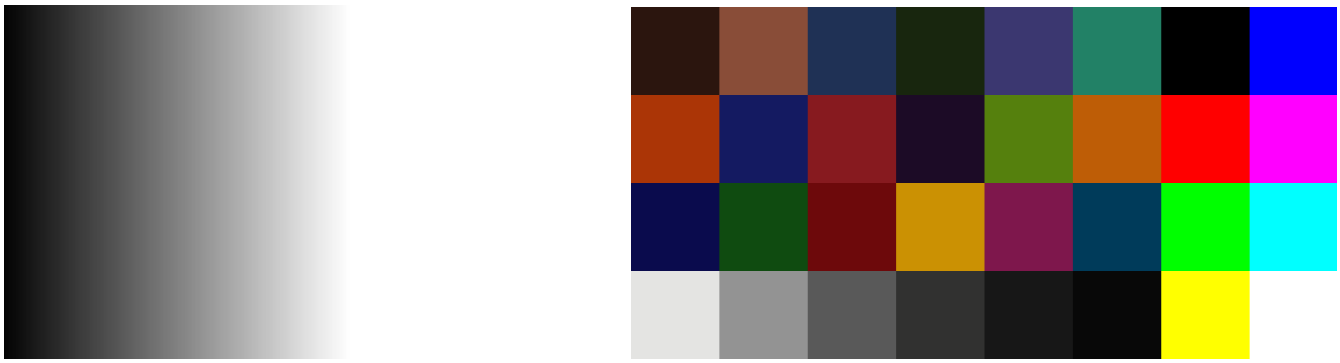
The test pattern generator operates in two modes:

- Direct — The output of the difference engine computation will be viewed directly.
- Color Patch — The difference engine output will be used to generate a patchwork of colors.

In Direct mode, the output comes directly from the value of the phase accumulator in the difference engine. An example of the kind of pattern that can be made is shown in (a) of the figure below. In Color Patch mode, the output comes from indexing a 32-element LUT.

The various bits from both the horizontal and vertical phase accumulators are used as address bits into a LUT of standard color values, allowing a patchwork of color test patterns to be generated. The colors in the pattern consist of linear RGB space representations of the 24 “Macbeth” test chart colors, shown on the left side of Figure 122(b), and the 8 “100% saturation” colors of a TV test pattern, on the right side of Figure 122(a). This gives a total of 32 color patches.

Figure 122: Example of (a) Direct Mode (b) Color Patch Generator Output



(a) (b)

29.13 Differential Pulse Code Modulation Support

The use of Differential Pulse Code Modulation (DPCM) compression schemes to reduce the data bandwidth requirements have been approached in both the SMIA and MIPI camera serial interface standards. The MIPI CSI-2 specification, v1.1, introduced a new data type for compressed data. In this format, RAW-10 and RAW-12 data can be transmitted as 6/7/8 bits per pixel. The SMIA also introduces a compression for RAW14 data providing transmission as 8/10 bits per pixel. The DPCM support is an optional feature, and the data compression is not mandated. However, if data compression is used, it must be implemented as described in annex E of the MIPI CSI-2 specification v01-01-00.

The MIPI and SMIA data compression schemes use an X–Y–Z naming convention, where:

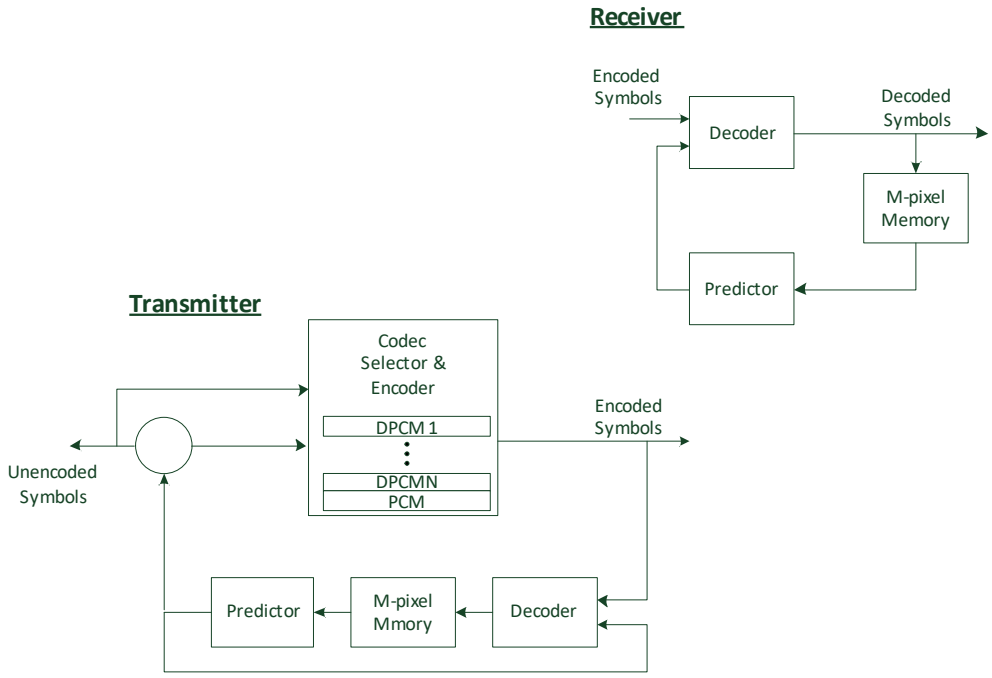
- X is the number of bits per pixel in the original image
- Y is the encoded (compressed) bits per pixel
- Z is the decoded (uncompressed) bits per pixel.

The following data compression schemes are defined for the Tegra X1 CSI unit:

- 14-bit RAW Compression Support (SMIA): 14-8-14; 14-10-14
- 12-bit RAW Compression Support (MIPI): 12–8–12; 12-7-12; 12-6-12
- 10-bit RAW Compression Support (MIPI): 10–8–10; 10-7-10; 10-6-10

To identify the type of data on the CSI-2 interface, packets with compressed data have a user-defined data type value. The encoder uses a simple algorithm to encode the pixel values. A fixed number of pixel values at the beginning of each line are encoded without using prediction. These first few values are used to initialize the predictor block. The remaining pixel values on the line are encoded using prediction. The following figure illustrates the data compression system for the transmitter and receiver.

Figure 123: Data Compression System Block Diagram



29.14 Software Requirements

29.14.1 Error Counters

To help debug, three 32-bit error counters have been implemented. Software can program each counter to increment at the event of any one of many error conditions or status change. The error conditions are:

- Header errors corrected
- Header uncorrectable errors
- CRC errors
- Packets too short, actual length less than WC
- Overflow errors due to padding packets too short
- FIFO overflow errors
- Illegal word count
- SoT single-bit error
- SoT multi-bit error, packet discarded
- EoT sequence error
- LP-CTRL error

The statistics that can be monitored include:

- Line packets processed
- Total packets processed

29.14.2 Programming Sequence

The following sequence is recommended for capturing a single frame:

1. Set up CSI registers for use case such as number of lanes, virtual channel, etc.
2. Initialize and power up CSI interface
3. Wait for initialization time or done signal from calibration logic
4. Power up camera through the I^2C interface
5. All CSI data and clock lanes are in stop state, LP11
6. Initiate frame capture through the I^2C
7. Frame done, CSI goes back to stop state, LP11

29.14.3 Escape Mode Handling

In the MIPI PHY specification, an escape mode is available for low speed command and data transfer. In our implementation, the escape mode entry is detected inside CSICIL. The command byte will be deposited in a register and interrupt generated from CSI. Software reads the register and decodes. CSI supports only one escape mode command which is Ultra-Low Power Mode (ULPM).

ULPM Command

Upon receiving the ULPM, software will synchronously power down the CSI interface and the camera as follows:

1. Software puts the camera in sleep mode through I^2C
2. The camera sends a ULPM command to CSI
3. CSI receives the ULPM command and raises an interrupt
4. Software powers down CSI, which goes to sleep in sync with the camera's CSI transmitter

29.15 DPHY Modes of Operation

The MIPI DPHY has 3 basic modes of operation. High speed mode employs differential signaling and achieves data rate of 1.5 Gbps. Both the driver and receiver are matched to 100 ohms differential. The driver is voltage mode for lower power consumption as opposed to current mode.

Low power control mode employs single-ended CMOS signaling for handshaking between camera and host. In this mode, there is no clock and no maximum symbol time defined in the specification. The receiver samples the input using both edges of the internal pixel clock, so the timing resolution is half the clock period of the pixel clock period.

Table 175: MIPI DPHY Mode of Operations

Modes	Description	Clock
High speed (HS)	High speed differential signaling. Up to 1.5 Gbps. Burst transmission for low power.	750 MHz differential
Low Power (LP) Control	Single-ended 1.2V CMOS level. Low speed signaling for handshaking. Supports ULPM sleep state.	No Clock

29.16 MIPI-CSI Registers

Refer to Section 1.4: Reading Register Tables in the Introduction chapter for the register table protocol as well as recommendations for accessing registers.

29.16.1 CSI_INPUT_STREAM_A_CONTROL_0

CSI Input Stream A Control

Offset: 0x20e | Byte Offset: 0x838 | Read/Write: R/W | Reset: 0x00ff0004 (0bxxxxxxx011111111xxxxxxxxxx0x100)

Bit	Reset	Description
24:16	0xff	CSI_A_SKIP_PACKET_THRESHOLD: CSI-A Skip Packet Threshold. This value is compared against the internal FIFO that buffers the input streams. A packet will be skipped (discarded) if the pixel stream processor is busy (probably due to padding process of a short line) and the number of entries in the internal FIFO exceeds this threshold value. Note that each entry in the internal FIFO buffer is four bytes. To turn off this feature, set the value to its maximum value (all ones).
4	0x0	CSI_A_SKIP_PACKET_THRESHOLD_ENABLE: Enables skip packet threshold feature. Skip packet feature is enabled. 0 = DISABLE: Skip packet feature is disabled. 1 = ENABLE
2	0x1	CSI_A_BYPASS_ALIGN: Bypass aligning CSIA and CSIB lanes if the valids for the lanes are out of sync by one cycle
1:0	0x0	CSI_A_DATA_LANE: CSI-A Data Lane. 0= 1 data lane; 1= 2 data lanes; 2= 3 data lanes; 3= 4 data lanes Note: Three data lanes are not supported in Test Pattern Generation mode.

29.16.2 CSI_PIXEL_STREAM_A_CONTROL0_0

CSI Pixel Stream A Control 0

Offset: 0x20f | Byte Offset: 0x83c | Read/Write: R/W | Reset: 0xXXXX01X0 (0bxxxxxxxxxxxxxxxxxxxxxxxx1xxxxx000)

Bit	Reset	Description
29:28	X	CSI_PPA_PAD_FRAME: CSI Pixel Parser A Pad Frame. This specifies how to deal with frames that are shorter (fewer lines) than expected. Short frames are usually caused by line packets being dropped because of packet errors. Expected frame height is specified in PPA_EXP_FRAME_HEIGHT. To do padding the value in CSI_PPA_WORD_COUNT needs to be set to the number of input bytes in each line's payload. 0 = PAD0S: Lines of all zeros will be used to pad out frames that are shorter than expected height. PPA_EXP_FRAME_HEIGHT must be programmed to an appropriate value if this field is set to PAD0S. 1 = PAD1S: Lines of all ones will be used to pad out frames that are shorter than expected height. PPA_EXP_FRAME_HEIGHT must be programmed to an appropriate value if this field is set to PAD1S. 2 = NOPAD: Short frames will not be padded out.
27	X	CSI_PPA_HEADER_EC_ENABLE: CSI Pixel Parser A Packet Header Error Correction Enable. This parameter specifies whether single bit errors in the packet header will be automatically corrected, or not. 0 = ENABLE: Single bit errors in the header will be automatically corrected. 1 = DISABLE: Single bit errors in the header will not be corrected. Header ECC check will still set header ECC status bits and the packet will be processed by Pixel Parser A. DISABLE should not be used when processing interleaved streams (Same stream going to both PPA and PPB).
25:24	X	CSI_PPA_PAD_SHORT_LINE: CSI Pixel Parser A Pad Short Line. This specifies how to deal with shorter than expected line (the number of bytes received is less than the specified word count). 0 = PAD0S: short line is padded by pixel of zeros such that the expected number of output pixels is correct. Due to the time required to do the padding, subsequent line packet may be discarded and therefore may cause a short frame (total number of lines per frame is less than expected). 1 = PAD1S: short line is padded by pixel of ones such that the expected number of output pixels is correct. Due to the time required to do the padding, subsequent line packet may be discarded and therefore may cause a short frame (total number of lines per frame is less than expected). 2 = NOPAD: A short line is not padded (will output less pixels than expected). This option is not recommended and may cause other modules that receives CSI output stream to hang up.

Bit	Reset	Description
21:20	X	CSI_PPA_EMBEDDED_DATA_OPTIONS: CSI Pixel Parser A Embedded Data Options. This specifies how to deal with embedded data within the specified input stream assuming that the CSI_PPA_DATA_TYPE is not embedded data and assuming that embedded data is not already processed by other CSI pixel stream processor. 0 = DISCARD: discard (throw away) embedded data 1 = EMBEDDED: Output embedded data as an 8-bpp arbitrary data stream.
19:16	X	CSI_PPA_OUTPUT_FORMAT_OPTIONS: CSI Pixel Parser A Output Format Options. This parameter specifies options for output data format. 0 = ARBITRARY: Output as 8-bit arbitrary data stream This may be used for compressed JPEG stream 1 = PIXEL: Output the normal 1 pixel/clock. Undefined LS color bits for RGB_666, RGB_565, RGB_555, and RGB_444, will be zeroed. 2 = PIXEL_REP: Same as PIXEL except MS color bits, for RGB_666, RGB_565, RGB_555, and RGB_444, will be replicated to their undefined LS bits. 3 = STORE: Output for storing RAW data to memory through ISP. Undefined LS color bits for RGB_666, RGB_565, RGB_555, and RGB_444 will be zeroed.
8	0x1	CSI_PPA_WC_CHECK: CSI Pixel Parser A Data WC Check. This parameter specifies whether the word count is checked. 0 = DISABLE: Wordcount Check is disabled 1 = ENABLE: Wordcount Check is enabled.
7	X	CSI_PPA_CRC_CHECK: CSI Pixel Parser A Data CRC Check. This parameter specifies whether the last 2 bytes of packet should be treated as CRC checksum and used to perform CRC check on the payload data. Note that in case there are 2 bytes of data CRC at the end of the packet, the packet word count does not include the CRC bytes. 0 = DISABLE: Data CRC Check is disabled regardless of whether there are CRC checksum at the end of the packet. 1 = ENABLE: Data CRC Check is enabled.
6	X	CSI_PPA_WORD_COUNT_SELECT: CSI Pixel Parser A Word Count Select. This parameter is effective only if packet header is sent as part of the stream. 0 = REGISTER: Word Count in packet header is ignored and the number of bytes per line/ packet is specified by CSI_PPA_WORD_COUNT. Payload CRC check will not be valid if the word count in CSI_PPA_WORD_COUNT is different than the count in the packet header. Interlaced support relies on frame number and will not work in REGISTER mode. 1 = HEADER: The number of bytes per line is to be extracted from Word Count field in the packet header. Note that if the serial link is not error free, programming this bit to HEADER may be dangerous because the word count information in the header may be corrupted. It is recommended to always program this bit to HEADER.
5	X	CSI_PPA_DATA_IDENTIFIER: CSI Pixel Parser A Data Identifier (DI) byte processing. This parameter is effective only if packet header is sent as part of the stream. 0 = DISABLED: Disabled - Data Identifier byte in packet header should be ignored (not checked against CSI_PPA_DATA_TYPE and against CSI_PPA_VIRTUAL_CHANNEL_ID). In this case, CSI_PPA_DATA_TYPE specifies the stream data format. 1 = ENABLED: Enabled - Data Identifier byte in packet header should be compared against the CSI_PPA_DATA_TYPE and the CSI_PPA_VIRTUAL_CHANNEL_ID.
4	X	CSI_PPA_PACKET_HEADER: CSI Pixel Parser A Packet Header processing. This specifies whether packet header is sent in the beginning of packet or not. 0 = NOT_SENT: Packet header is not sent. This setting should not be used if the stream source is CSI Interface A or B. Unless CSI-A, or CSI-B, is operating in a stream capture debug mode. In this case, CSI_PPA_DATA_TYPE specifies the stream data format and the number of bytes per line/packet is specified by CSI_PPA_WORD_COUNT. This implies that a packet footer is also not sent. In this case, no packet footer CRC check should be performed. 1 = SENT: Packet header is sent. This setting should be used if the stream source is CSI Interface A or B.
2:0	0x0	CSI_PPA_STREAM_SOURCE: CSI Pixel Parser A Stream Source 0 = CSI_A: CSI Interface A 1 = CSI_B: CSI Interface B

29.16.3 CSI_PIXEL_STREAM_A_CONTROL1_0

CSI Pixel Stream A Control 1

Offset: 0x210 | Byte Offset: 0x840 | Read/Write: R/W | Reset: 0x00000000 (0bxxxxxxxxxxxxxxxxxxxxxxxxx00000000)|

Bit	Reset	Description
7:4	0x0	CSI_PPA_TOP_FIELD_FRAME_MASK: CSI Pixel Parser A Top Field Frame Mask

Bit	Reset	Description
3:0	0x0	CSI_PPA_TOP_FIELD_FRAME: CSI Pixel Parser A Top Field Frame. This parameter specifies the frame number for top field detection for interlaced input video stream. Top Field is indicated when each of the least significant four bits of the frame number that has a one in its mask bit matches the corresponding bit in this parameter. In other words, Top Field is detected when the bitwise OR of ~(CSI_PPA_TOP_FIELD_FRAME ^ <frame number>) & CSI_PPA_TOP_FIELD_FRAME_MASK is one. Frame Number is taken from the WC field of the Frame Start short packet. Due to the reliance on WC field in packet header, interlaced support will not work if WC is selected from REGISTER mode.

29.16.4 CSI_PIXEL_STREAM_A_GAP_0

CSI Pixel Stream A Gap

Offset: 0x211 | Byte Offset: 0x844 | Read/Write: R/W | Reset: 0x00000000 (0b00000000000000000000000000000000)

Bit	Reset	Description
31:16	0x0	PPA_FRAME_MIN_GAP: Minimum number of viclk cycles from end of frame (Video_control = EF) to start of next frame (Video_control = SF). This parameter ensures that the minimum V-blank time requirement of VI/ISP is satisfied. This field takes effect only when the frame gap of the input stream is less than the specified value.
15:0	0x0	PPA_LINE_MIN_GAP: Minimum number of viclk cycles from end of previous line (Video_control = EL_DATA) to start of next line (Video_control = SL). This parameter ensures that the minimum H-blank time requirement of VI/ISP is satisfied. This field takes effect only when the line gap of the input stream is less than the specified value.

29.16.5 CSI_PIXEL_STREAM_PPA_COMMAND_0

CSI Pixel Parser A Command

Offset: 0x212 | Byte Offset: 0x848 | Read/Write: R/W | Reset: 0x0000XXX4 (0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx100)

Bit	Reset	Description
15:12	X	CSI_PPA_START_MARKER_FRAME_MAX: CSI Pixel Parser A Start Marker Maximum. Start Frame is indicated when the Minimum condition above is met and the least significant four bits of the frame number are less than or equal to this value.
11:8	X	CSI_PPA_START_MARKER_FRAME_MIN: CSI Pixel Parser A Start Marker Minimum. Start Frame is indicated when the Maximum condition below is met and the least significant four bits of the frame number are greater than or equal to this value.
4	X	CSI_PPA_VSYNC_START_MARKER: CSI Pixel Parser A VSYNC Start Marker. The start of frame is indicated when the VSYNC signal is received. When the input stream is from the VIP path and the data mode is PACKET, then this field may be programmed to VSYNC. 0 = FSPKT: Start of frame is indicated when a Frame Start short packet is received with a frame number whose least significant four bits are greater than or equal to CSI_PPA_START_MARKER_FRAME_MIN and less than or equal to CSI_PPA_START_MARKER_FRAME_MAX. When the input stream is from a CSI port, or from the host path, or from the VIP path and the data mode is PAYLOAD_ONLY, then this field may be programmed to FSPKT. 1 = VSYNC
2	0x1	CSI_PPA_SINGLE_SHOT: CSI Pixel Parser A Single Shot Mode. Software should clear it along with disabling the CSI_PPA_ENABLE, once a frame is captured 0 = DISABLE 1 = ENABLE
1:0	0x0	CSI_PPA_ENABLE: CSI Pixel Parser A Enable. This parameter controls CSI Pixel Parser A to start or stop receiving data. Reset (disable immediately) Enabling the pixel parser does not enable the corresponding input source to receive data. If the pixel parser is enabled later than the corresponding input source, the CSI will keep on rejecting incoming stream, until it encounters a valid SF. 0 = NOP: no operation 1 = ENABLE: enable at the next frame start as specified by the CSI Start Marker 2 = DISABLE: disable after current frame end and before next frame start. 3 = RST

29.16.6 CSI_PIXEL_STREAM_A_EXPECTED_FRAME_0

CSI Pixel Stream A Expected Frame

Offset: 0x213 | Byte Offset: 0x84c | Read/Write: R/W | Reset: 0x0000XXX0 (0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx0)

Bit	Reset	Description
15:4	X	PPA_MAX_CLOCKS: Maximum Number of viclk clock cycles between line start requests. The value in this field is in terms of 256 viclk clock cycles.
0	0x0	PPA_ENABLE_LINE_TIMEOUT: When set to one enables checking of the time between start line requests from the Header Parser to CSI-PPA. A fake EF will be outputted by CSI-PPA if this time between line starts exceeds the value in MAX_CLOCKS_BETWEEN_LINES. Padding lines can be inserted before the fake EF, if the number of lines outputted, when the fake EF is generated is less than the expected frame height. The type of padding is specified using CSI_PPA_PAD_FRAME.

29.16.7 CSI_CSI_PIXEL_PARSER_A_INTERRUPT_MASK_0

CSI Pixel Parser A Interrupt Mask

Offset: 0x214 | Byte Offset: 0x850 | Read/Write: R/W | Reset: 0x00000000 (0bxxxxxxxxxxxxxxxxx0xx000000000000)

Bit	Reset	Description
14	0x0	HPA_UNC_HDR_ERR_INT_MASK: Interrupt Mask for HPA_UNC_HDR_ERR. 0 = DISABLED: Do not generate an interrupt when HPA_UNC_HDR_ERR is set. 1 = ENABLED: Generate an interrupt when HPA_UNC_HDR_ERR is set.
10	0x0	PPA_SPARE_STATUS_1_INT_MASK: Interrupt Mask for PPA_SPARE_STATUS_1. 0 = DISABLED: Do not generate an interrupt when PPA_SPARE_STATUS_1 is set. 1 = ENABLED: Generate an interrupt when PPA_SPARE_STATUS_1 is set.
9	0x0	PPA_INTERFRAME_LINE_INT_MASK: Interrupt Mask for PPA_INTERFRAME_LINE. 0 = DISABLED: Do not generate an interrupt when PPA_INTERFRAME_LINE is set. 1 = ENABLED: Generate an interrupt when PPA_INTERFRAME_LINE is set.
8	0x0	PPA_EXTRA_SF_INT_MASK: Interrupt Mask for PPA_EXTRA_SF. 0 = DISABLED: Do not generate an interrupt when PPA_EXTRA_SF is set. 1 = ENABLED: Generate an interrupt when PPA_EXTRA_SF is set.
7	0x0	PPA_SHORT_FRAME_INT_MASK: Interrupt Mask for PPA_SHORT_FRAME. 0 = DISABLED: Do not generate an interrupt when PPA_SHORT_FRAME is set. 1 = ENABLED: Generate an interrupt when PPA_SHORT_FRAME is set.
6	0x0	PPA_STMERR_INT_MASK: Interrupt Mask for PPA_STMERR. 0 = DISABLED: Do not generate an interrupt when PPA_STMERR is set. 1 = ENABLED: Generate an interrupt when PPA_STMERR is set.
5	0x0	PPA_FIFO_OVRF_INT_MASK: Interrupt Mask for PPA_FIFO_OVRF. 0 = DISABLED: Do not generate an interrupt when PPA_FIFO_OVRF is set. 1 = ENABLED: Generate an interrupt when PPA_FIFO_OVRF is set.
4	0x0	PPA_PL_CRC_ERR_INT_MASK: Interrupt Mask for PPA_PL_CRC_ERR. 0 = DISABLED: Do not generate an interrupt when PPA_PL_CRC_ERR is set. 1 = ENABLED: Generate an interrupt when PPA_PL_CRC_ERR is set.
3	0x0	PPA_SL_PKT_DROPPED_INT_MASK: Interrupt Mask for PPA_SL_PKT_DROPPED. 0 = DISABLED: Do not generate an interrupt when PPA_SL_PKT_DROPPED is set. 1 = ENABLED: Generate an interrupt when PPA_SL_PKT_DROPPED is set.
2	0x0	PPA_SL_PROCESSED_INT_MASK: Interrupt Mask for PPA_SL_PROCESSED. 0 = DISABLED: Do not generate an interrupt when PPA_SL_PROCESSED is set. 1 = ENABLED: Generate an interrupt when PPA_SL_PROCESSED is set.
1	0x0	PPA_ILL_WD_CNT_INT_MASK: Interrupt Mask for PPA_ILL_WD_CNT. 0 = DISABLED: Do not generate an interrupt when PPA_ILL_WD_CNT is set. 1 = ENABLED: Generate an interrupt when PPA_ILL_WD_CNT is set.
0	0x0	PPA_HDR_ERR_COR_INT_MASK: Interrupt Mask for PPA_HDR_ERR_COR. 0 = DISABLED: Do not generate an interrupt when PPA_HDR_ERR_COR is set. 1 = ENABLED: Generate an interrupt when PPA_HDR_ERR_COR is set.

29.16.8 CSI_CSI_PIXEL_PARSER_A_STATUS_0

Pixel Parser A Status

Each status bit is cleared to zero when its bit position is written with one. For example writing 0x2 to CSI_PIXEL_PARSER_STATUS will clear only PPA_ILL_WD_CNT.

Offset: 0x215 | Byte Offset: 0x854 | Read/Write: RO | Reset: 0x0000XXXX (0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx)

Bit	Reset	Description
14	X	HPA_UNC_HDR_ERR: Uncorrectable Header Error. Set when header parser A parses a header with a multi bit error. This error will be detected by the headers ECC, but can't be corrected. The packet will be discarded.
10	X	PPA_SPARE_STATUS_1: PPA Spare Status bit. This bit will get set when Pixel Parser A has a line timeout. Line timeout needs to be enabled by setting PPA_ENABLE_LINE_TIMEOUT and programming PPA_MAX_CLOCKS for the MAX clocks between lines.
9	X	PPA_INTERFRAME_LINE: Set when CSI-PPA receives a request to output a line that is not in the active part of the frame output. That is after EF and before SF, or before start marker is found. The interframe line will not be outputted by the Pixel Parser.
8	X	PPA_EXTRA_SF: Set when CSI-PPA receives a SF when it is expecting an EF. This happens when EF of the frame gets corrupted before arriving CSI. CSI-PPA will insert a fake EF and the drop the current frame with Correct SF.
7	X	PPA_SHORT_FRAME: Set when CSI-PPA receives a short frame. This bit gets set even if CSI_PPA_PAD_FRAME specifies that short frames are to be padded to the correct line length.
6	X	PPA_STMERR: Stream Error, set when the control output of PPA does not follow the correct sequence. The correct sequence for CSI is: SF -> (SL_DATA or EF), SL_DATA -> (DATA or EL_DATA), DATA -> EL_DATA, EL_DATA -> (SL_DATA or EF), EF -> SF. Stream Errors can be caused by receiving a corrupted stream.
5	X	PPA_FIFO_OVRF: FIFO Overflow, set when the FIFO that is feeding packets to PPA overflows.
4	X	PPA_PL_CRC_ERR: PayLoad CRC Error. Set when a packet that was processed by PPA had a payload CRC error.
3	X	PPA_SL_PKT_DROPPED: Short Line Packet Dropped. Set when an incoming packet gets dropped because the input FIFO level reaches CSI_A_SKIP_PACKET_THRESHOLD when padding a short line.
2	X	PPA_SL_PROCESSED: Short Line Processed, Set when a line with a payload that is shorter than its packet header word count is processed by PPA.
1	X	PPA_ILL_WD_CNT: Illegal Word Count, set when a line with a word count that does not generate an integer number of pixels (Unused bytes at the end of payload) is processed by PPA.
0	X	PPA_HDR_ERR_COR: Header Error Corrected, Set when a packet that was processed by PPA has a single bit header error. This error will be detected by the headers ECC, and corrected by it if header error correction is enabled (CSI_A_HEADER_EC_ENABLE = 0). This flag will be set and the packet will be processed even if the error is not corrected.

29.16.9 CSI_CSI_SW_SENSOR_A_RESET_0

Offset: 0x216 | Byte Offset: 0x858 | Read/Write: R/W | Reset: 0x00000000 (0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx0)

Bit	Reset	Description
0	0x0	CSI_SENSOR_A_RESET: Reset CSI sensor A

29.16.10 CSI_INPUT_STREAM_B_CONTROL_0

CSI Input Stream B Control

Offset: 0x21b | Byte Offset: 0x86c | Read/Write: R/W | Reset: 0x00ff0004 (0bxxxxxxx011111111xxxxxxxxxx0x100)

Bit	Reset	Description
24:16	0xff	CSI_B_SKIP_PACKET_THRESHOLD: CSI-B Skip Packet Threshold. This value is compared against the internal FIFO that buffers the input streams. A packet will be skipped (discarded) if the pixel stream processor is busy (probably due to padding process of a short line) and the number of entries in the internal FIFO exceeds this threshold value. Note that each entry in the internal FIFO buffer is four bytes. To turn off this feature, set the value to its maximum value (all ones).

Bit	Reset	Description
4	0x0	CSI_B_SKIP_PACKET_THRESHOLD_ENABLE: Enables skip packet threshold feature. 0 = DISABLE: Skip packet feature is disabled. 1 = ENABLE: Skip packet feature is enabled.
2	0x1	CSI_B_BYPASS_ALIGN: Bypass aligning CSIB lanes if valids for the lanes are out of sync by a cycle
1:0	0x0	CSI_B_DATA_LANE: CSI-B Data Lane 0= 1 data lane, 1= 2 data lanes, 2= 3 data lanes (not supported), 3= 4 data lanes (not supported) Note: 3 data lanes is not supported in Test Pattern Generation mode.

29.16.11 CSI_PIXEL_STREAM_B_CONTROL0_0

CSI Pixel Stream A Control 0

Offset: 0x21c | Byte Offset: 0x870 | Read/Write: R/W | Reset: 0xXXXX01X0 (0bxxxxxxxxxxxxxxxxxxxxxxxx1xxxxx000)

Bit	Reset	Description
29:28	X	CSI_PPB_PAD_FRAME: CSI Pixel Parser B Pad Frame. This specifies how to deal with frames that are shorter (fewer lines) than expected. Short frames are usually caused by line packets being dropped because of packet errors. Expected frame height is specified in PPB_EXP_FRAME_HEIGHT. To do padding the value in CSI_PPB_WORD_COUNT needs to be set to the number of input bytes in each lines payload. 0 = PAD0S: Lines of all zeros will be used to pad out frames that are shorter than expected height. PPB_EXP_FRAME_HEIGHT must be programmed to an appropriate value if this field is set to PAD0S. 1 = PAD1S: Lines of all ones will be used to pad out frames that are shorter than expected height. PPB_EXP_FRAME_HEIGHT must be programmed to an appropriate value if this field is set to PAD1S. 2 = NOPAD: Short frames will not be padded out.
27	X	CSI_PPB_HEADER_EC_ENABLE: CSI Pixel Parser B Packet Header Error Correction Enable. This parameter specifies whether single bit errors in the packet header will be automatically corrected or not. 0 = ENABLE: Single bit errors in the header will be automatically corrected. 1 = DISABLE: Single bit errors in the header will not be corrected. Header ECC check will still set header ECC status bits and the packet will be processed by Pixel Parser B. DISABLE should not be used when processing interleaved streams (Same stream going to both PPA and PPB).
25:24	X	CSI_PPB_PAD_SHORT_LINE: CSI Pixel Parser B Pad Short Line. This specifies how to deal with shorter than expected line (the number of bytes received is less than the specified word count) short line is not padded (will output less pixels than expected). 0 = PAD0S: short line is padded by pixel of zeros such that the expected number of output pixels is correct. Due to the time required to do the padding, subsequent line packet may be discarded and therefore may cause a short frame (total number of lines per frame is less than expected). 1 = PAD1S: short line is padded by pixel of ones such that the expected number of output pixels is correct. Due to the time required to do the padding, subsequent line packet may be discarded and therefore may cause a short frame (total number of lines per frame is less than expected). 2 = NOPAD: This option is not recommended and may cause other modules that receive CSI output stream to hang up.
21:20	X	CSI_PPB_EMBEDDED_DATA_OPTIONS: CSI Pixel Parser B Embedded Data Options. This specifies how to deal with embedded data within the specified input stream assuming that the CSI_PPB_DATA_TYPE is not embedded data and that embedded data is not already processed by another CSI pixel stream processor. 0 = DISCARD: discard (throw away) embedded data 1 = EMBEDDED: Output embedded data as 8-bpp arbitrary data stream.
19:16	X	CSI_PPB_OUTPUT_FORMAT_OPTIONS: CSI Pixel Parser B Output Format Options. This parameter specifies output data format. 0 = ARBITRARY: Output as 8-bit arbitrary data stream This may be used for compressed JPEG stream 1 = PIXEL: Output the normal 1 pixel/clock. Undefined LS. color bits for RGB_666, RGB_565, RGB_555, and RGB_444, will be zeroed. 2 = PIXEL_REP: Same as PIXEL except MS color bits, for RGB_666, RGB_565, RGB_555, and RGB_444, will be replicated to their undefined LS bits. 3 = STORE: Output for storing RAW data to memory through ISP. Undefined LS color bits for RGB_666, RGB_565, RGB_555, and RGB_444, will be zeroed.

Bit	Reset	Description
8	0x1	CSI_PPB_WC_CHECK: CSI Pixel Parser B Data WC Check. This parameter specifies whether the wordcount is checked. 0 = DISABLE: Wordcount Check is disabled 1 = ENABLE: Wordcount Check is enabled
7	X	CSI_PPB_CRC_CHECK: CSI Pixel Parser B Data CRC Check. This parameter specifies whether the last 2 bytes of packet should be treated as CRC checksum and used to perform CRC check on the payload data. Note that in case there are 2 bytes of data CRC at the end of the packet, the packet word count does not include the CRC bytes. 0 = DISABLE: Data CRC Check is disabled regardless of whether there are CRC checksum at the end of the packet. 1 = ENABLE: Data CRC Check is enabled.
6	X	CSI_PPB_WORD_COUNT_SELECT: CSI Pixel Parser B Word Count Select. This parameter is effective only if packet header is sent as part of the stream. 0 = REGISTER: Word Count in packet header is ignored and the number of bytes per line/ packet is specified by CSI_PPB_WORD_COUNT. Payload CRC check will not be valid if the word count in CSI_PPB_WORD_COUNT is different than the count in the packet header. Interlaced support relies on frame number and will not work in REGISTER mode. 1 = HEADER: The number of bytes per line is to be extracted from Word Count field in the packet header. Note that if the serial link is not error free, programming this bit to HEADER may be dangerous because the word count information in the header may be corrupted. It is recommended to always program this bit to HEADER.
5	X	CSI_PPB_DATA_IDENTIFIER: CSI Pixel Parser B Data Identifier (DI) byte processing. This parameter is effective only if packet header is sent as part of the stream. 0 = DISABLED: Disabled - Data Identifier byte in packet header should be ignored (not checked against CSI_PPB_DATA_TYPE and against CSI_PPB_VIRTUAL_CHANNEL_ID). In this case, CSI_PPB_DATA_TYPE specifies the stream data format. 1 = ENABLED: Enabled - Data Identifier byte in packet header should be compared against the CSI_PPB_DATA_TYPE and the CSI_PPB_VIRTUAL_CHANNEL_ID.
4	X	CSI_PPB_PACKET_HEADER: CSI Pixel Parser B Packet Header processing. This specifies whether packet header is sent in the beginning of packet or not. 0 = NOT_SENT: Packet header is not sent. This setting should not be used if the stream source is CSI Interface A or B. Unless CSI-A, or CSI-B, is operating in a stream capture debug mode. In this case, CSI_PPB_DATA_TYPE specifies the stream data format and the number of bytes per line/packet is specified by CSI_PPB_WORD_COUNT. This implies that a packet footer is also not sent. In this case, no packet footer CRC check should be performed. 1 = SENT: Packet header is sent. This setting should be used if the stream source is CSI Interface A or B.
2:0	0x0	CSI_PPB_STREAM_SOURCE: CSI Pixel Parser B Stream Source 0 = CSI_A: CSI Interface A 1 = CSI_B: CSI Interface B

29.16.12 CSI_PIXEL_STREAM_B_CONTROL1_0

CSI Pixel Stream B Control 1

Offset: 0x21d | Byte Offset: 0x874 | Read/Write: R/W | Reset: 0x00000000 (0bxxxxxxxxxxxxxxxxxxxxxxxxx00000000)

Bit	Reset	Description
7:4	0x0	CSI_PPB_TOP_FIELD_FRAME_MASK: CSI Pixel Parser B Top Field Frame Mask
3:0	0x0	CSI_PPB_TOP_FIELD_FRAME: CSI Pixel Parser B Top Field Frame. This parameter specifies the frame number for top field detection for interlaced input video stream. Top Field is indicated when each of the least significant four bits of the frame number that has a one in its mask bit matches the corresponding bit in this parameter. In other words, Top Field is detected when the bitwise OR of ~(CSI_PPB_TOP_FIELD_FRAME ^ <frame number>) & CSI_PPB_TOP_FIELD_FRAME_MASK is one. Frame Number is taken from the WC field of the Frame Start short packet. Due to the reliance on WC field in packet header, interlaced support will not work if WC is selected from REGISTER mode.

29.16.13 CSI_PIXEL_STREAM_B_GAP_0

CSI Pixel Stream B Gap

Offset: 0x21e | Byte Offset: 0x878 | Read/Write: R/W | Reset: 0x00000000 (0b00000000000000000000000000000000)

Bit	Reset	Description
31:16	0x0	PPB_FRAME_MIN_GAP: Minimum number of viclk cycles from end of frame (Video_control = EF) to start of next frame (Video_control = SF). This parameter ensures that the minimum V-blank time requirement of VI/ISP is satisfied. This field takes effect only when the frame gap of the input stream is less than the specified value.
15:0	0x0	PPB_LINE_MIN_GAP: Minimum number of viclk cycles from end of previous line (Video_control = EL_DATA) to start of next line (Video_control = SL). This parameter ensures that the minimum H-blank time requirement of VI/ISP is satisfied. This field takes effect only when the line gap of the input stream is less than the specified value.

29.16.14 CSI_PIXEL_STREAM_PPB_COMMAND_0

CSI Pixel Parser B Command

Offset: 0x21f | Byte Offset: 0x87c | Read/Write: R/W | Reset: 0x0000XXX4 (0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx100)

Bit	Reset	Description
15:12	X	CSI_PPB_START_MARKER_FRAME_MAX: CSI Pixel Parser B Start Marker Maximum. Start Frame is indicated when the Minimum condition above is met and the least significant four bits of the frame number are less than or equal to this value.
11:8	X	CSI_PPB_START_MARKER_FRAME_MIN: CSI Pixel Parser B Start Marker Minimum. Start Frame is indicated when the Maximum condition below is met and the least significant four bits of the frame number are greater than or equal to this value.
4	X	CSI_PPB_VSYNC_START_MARKER: CSI Pixel Parser B VSYNC Start Marker. 0 = FSPKT: Start of frame is indicated when a Frame Start short packet is received with a frame number whose least significant four bits are greater than or equal to CSI_PPB_START_MARKER_FRAME_MIN and less than or equal to CSI_PPB_START_MARKER_FRAME_MAX. When the input stream is from a CSI port, or from the host path, or from the VIP path and the data mode is PAYLOAD_ONLY, then this field may be programmed to FSPKT. 1 = VSYNC: Start of frame is indicated when VSYNC signal is received. When the input stream is from the VIP path and the data mode is PACKET, then this field may be programmed to VSYNC.
2	0x1	CSI_PPB_SINGLE_SHOT: CSI Pixel Parser B Single Shot Mode. Software should clear it along with disabling CSI_PPB_ENABLE, once a frame is captured 0 = DISABLE 1 = ENABLE
1:0	0x0	CSI_PPB_ENABLE: CSI Pixel Parser B Enable. This parameter controls CSI Pixel Parser B to start or stop receiving data. 0 = NOP: no operation 1 = ENABLE: enable at the next frame start as specified by the CSI Start Marker 2 = DISABLE: disable after current frame end and before next frame start. 3 = RST: reset (disable immediately). Enabling the pixel parser does not enable the corresponding input source to receive data. If the pixel parser is enabled later than the corresponding input source, the CSI will keep rejecting the incoming stream, until it encounters a valid SF.

29.16.15 CSI_PIXEL_STREAM_B_EXPECTED_FRAME_0

CSI Pixel Stream B Expected Frame

Offset: 0x220 | Byte Offset: 0x880 | Read/Write: R/W | Reset: 0x0000XXX0 (0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx0)

Bit	Reset	Description
15:4	X	PPB_MAX_CLOCKS: Maximum Number of viclk clock cycles between line start requests. The value in this field is in terms of 256 viclk clock cycles.

Bit	Reset	Description
0	0x0	PPB_ENABLE_LINE_TIMEOUT: When set to one, enables checking of the time between start line requests from the Header Parser to CSI-PPB. A fake EF will be output by CSI-PPB if this time between line starts exceeds the value in MAX_CLOCKS_BETWEEN_LINES. Padding lines can be inserted before the fake EF, if the number of lines output, when the fake EF is generated is less than the expected frame height. The type of padding is specified using CSI_PPB_PAD_FRAME.

29.16.16 CSI_CSI_PIXEL_PARSER_B_INTERRUPT_MASK_0

CSI Pixel Parser B Interrupt Mask

Offset: 0x221 | Byte Offset: 0x884 | Read/Write: R/W | Reset: 0x00000000 (0bxxxxxxxxxxxxxxxxxx0xx000000000000)

Bit	Reset	Description
14	0x0	HPB_UNC_HDR_ERR_INT_MASK: Interrupt Mask for HPB_UNC_HDR_ERR. 0 = DISABLED: Do not generate an interrupt when HPB_UNC_HDR_ERR is set. 1 = ENABLED: Generate an interrupt when HPB_UNC_HDR_ERR is set.
10	0x0	PPB_SPARE_STATUS_1_INT_MASK: Interrupt Mask for PPB_SPARE_STATUS_1. 0 = DISABLED: Do not generate an interrupt when PPB_SPARE_STATUS_1 is set. 1 = ENABLED: Generate an interrupt when PPB_SPARE_STATUS_1 is set.
9	0x0	PPB_INTERFRAME_LINE_INT_MASK: Interrupt Mask for PPB_INTERFRAME_LINE. 0 = DISABLED: Do not generate an interrupt when PPB_INTERFRAME_LINE is set. 1 = ENABLED: Generate an interrupt when PPB_INTERFRAME_LINE is set.
8	0x0	PPB_EXTRA_SF_INT_MASK: Interrupt Mask for PPB_EXTRA_SF. 0 = DISABLED: Do not generate an interrupt when PPB_EXTRA_SF is set. 1 = ENABLED: Generate an interrupt when PPB_EXTRA_SF is set.
7	0x0	PPB_SHORT_FRAME_INT_MASK: Interrupt Mask for PPB_SHORT_FRAME. 0 = DISABLED: Do not generate an interrupt when PPB_SHORT_FRAME is set. 1 = ENABLED: Generate an interrupt when PPB_SHORT_FRAME is set.
6	0x0	PPB_STMERR_INT_MASK: Interrupt Mask for PPB_STMERR. 0 = DISABLED: Do not generate an interrupt when PPB_STMERR is set. 1 = ENABLED: Generate an interrupt when PPB_STMERR is set.
5	0x0	PPB_FIFO_OVRF_INT_MASK: Interrupt Mask for PPB_FIFO_OVRF. 0 = DISABLED: Do not generate an interrupt when PPB_FIFO_OVRF is set. 1 = ENABLED: Generate an interrupt when PPB_FIFO_OVRF is set.
4	0x0	PPB_PL_CRC_ERR_INT_MASK: Interrupt Mask for PPB_PL_CRC_ERR. 0 = DISABLED: Do not generate an interrupt when PPB_PL_CRC_ERR is set. 1 = ENABLED: Generate an interrupt when PPB_PL_CRC_ERR is set.
3	0x0	PPB_SL_PKT_DROPPED_INT_MASK: Interrupt Mask for PPB_SL_PKT_DROPPED. 0 = DISABLED: Do not generate an interrupt when PPB_SL_PKT_DROPPED is set. 1 = ENABLED: Generate an interrupt when PPB_SL_PKT_DROPPED is set.
2	0x0	PPB_SL_PROCESSED_INT_MASK: Interrupt Mask for PPB_SL_PROCESSED. 0 = DISABLED: Do not generate an interrupt when PPB_SL_PROCESSED is set. 1 = ENABLED: Generate an interrupt when PPB_SL_PROCESSED is set.
1	0x0	PPB_ILL_WD_CNT_INT_MASK: Interrupt Mask for PPB_ILL_WD_CNT. 0 = DISABLED: Do not generate an interrupt when PPB_ILL_WD_CNT is set. 1 = ENABLED: Generate an interrupt when PPB_ILL_WD_CNT is set.
0	0x0	PPB_HDR_ERR_COR_INT_MASK: Interrupt Mask for PPB_HDR_ERR_COR. 0 = DISABLED: Do not generate an interrupt when PPB_HDR_ERR_COR is set. 1 = ENABLED: Generate an interrupt when PPB_HDR_ERR_COR is set.

29.16.17 CSI_CSI_PIXEL_PARSER_B_STATUS_0

Pixel Parser B Status

Offset: 0x222 | Byte Offset: 0x888 | Read/Write: RO | Reset: 0x0000XXXX (0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx)

Bit	Reset	Description
14	X	HPB_UNC_HDR_ERR: Uncorrectable Header Error. Set when header parser B parses a header with a multi bit error. This error will be detected by the headers ECC, but can't be corrected.

Bit	Reset	Description
10	X	PPB_SPARE_STATUS_1: PPB Spare Status bit. This bit will get set when Pixel Parser B has a line timeout. Line timeout needs to be enabled by setting PPB_ENABLE_LINE_TIMEOUT and programming PPB_MAX_CLOCKS for the MAX clocks between lines.
9	X	PPB_INTERFRAME_LINE: Set when CSI-PPB receives a request to output a line that is not in the active part of the frame output. That is after EF and before SF, or before start marker is found. The interframe line will not be outputted by the Pixel Parser.
8	X	PPB_EXTRA_SF: Set when CSI-PPB receives a SF when it is expecting an EF. This happens when EF of the frame gets corrupted before arriving CSI. CSI-PPB will insert a fake EF and the drop the current frame with Correct SF.
7	X	PPB_SHORT_FRAME: Set when CSI-PPB receives a short frame. This bit gets set even if CSI_PPB_PAD_FRAME specifies that short frames are to be padded to the correct line length.
6	X	PPB_STMERR: Stream Error, set when the control output of PPB doesn't follow the correct sequence. The correct sequence for CSI is: SF -> (SL_DATA or EF), SL_DATA -> (DATA or EL_DATA), DATA -> EL_DATA, EL_DATA -> (SL_DATA or EF), EF -> SF. Stream Errors can be caused by receiving a corrupted stream.
5	X	PPB_FIFO_OVRF: FIFO Overflow, set when the FIFO that is feeding packets to PPB overflows.
4	X	PPB_PL_CRC_ERR: PayLoad CRC Error. Set when a packet that was processed by PPB had a payload CRC error.
3	X	PPB_SL_PKT_DROPPED: Short Line Packet Dropped. Set when an incoming packet gets dropped because the input FIFO level reaches CSI_B_SKIP_PACKET_THRESHOLD when padding a short line.
2	X	PPB_SL_PROCESSED: Short Line Processed, Set when a line with a payload that is shorter than its packet header word count is processed by PPB.
1	X	PPB_ILL_WD_CNT: Illegal Word Count, set when a line with a word count that doesn't generate an integer number of pixels (Unused bytes at the end of payload) is processed by PPB.
0	X	PPB_HDR_ERR_COR: Header Error Corrected, set when a packet that was processed by PPB has a single bit header error. This error will be detected by the headers ECC, and corrected by it if header error correction is enabled (CSI_B_HEADER_EC_ENABLE = 0). This flag will be set and the packet will be processed even if the error is not corrected.

29.16.18 CSI_CSI_SW_SENSOR_B_RESET_0

Offset: 0x223 | Byte Offset: 0x88c | Read/Write: R/W | Reset: 0x00000000 (0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx0)

Bit	Reset	Description
0	0x0	CSI_SENSOR_B_RESET: Reset CSI sensor B

29.16.19 CSI_PHY_CIL_COMMAND_0

CSI PHY and CIL Command

Offset: 0x242 | Byte Offset: 0x908 | Read/Write: R/W | Reset: 0x00000000 (0bxxxxxxxxxxxxxxxxxxxxxx00xxxxxx00)

Bit	Reset	Description
9:8	0x0	CSI_B_PHY_CIL_ENABLE: CSI B PHY and CIL Enable. This parameter controls CSI B PHY and CIL receiver to start or stop receiving data. disable (reset) 0 = NOP: no operation 1 = ENABLE: enable 2 = DISABLE
1:0	0x0	CSI_A_PHY_CIL_ENABLE: CSI A PHY and CIL Enable. This parameter controls CSI A PHY and CIL receiver to start or stop receiving data. disable (reset) 0 = NOP: no operation 1 = ENABLE: enable 2 = DISABLE

29.16.20 CSI_CIL_PAD_CONFIG0_0

CIL Pad Configuration 0

Offset: 0x243 | Read/Write: R/W | Reset: 0x00000000 (0bxxxxxxxxxxxxxxxx00000000xxxxxxxx)

Bit	Reset	Description
15:8	0x0	PAD_CIL_SPARE: Spare bit for CIL BIAS Config. PAD_CIL_SPARE[7] is used is being used to flush VI's Y-FIFO when it is being use as a stream source for one of the Pixel Parsers. Setting PAD_CIL_SPARE[7] to 1 will hold vi2csi_host_stall low. This will force VI's Y-FIFO to be purged. PAD_CIL_SPARE[7] must be low for the pixel parser to receive source data from VI's Y-FIFO.

29.16.21 CSI_CILA_PAD_CONFIG0_0

CIL-A Pad Configuration 0

Offset: 0x24b | Byte Offset: 0x92c | Read/Write: R/W | Reset: 0x00010007 (0b0000x000000000010000x000x0000111)

Bit	Reset	Description
31	0x0	PAD_CILA_E_TXBW: 0 = default to enable VCLAMP regulator 1 = turn off regulator and short vclamp to VDDP. will cause stress and need waiver to use
30:28	0x0	PAD_CILA_SLEWDNADJ: Pull down slew rate adjust, default 000. From 000 -> 011, slew rate increases. 100 is the same as 000. From 100->111, skew rate decreases. This control is unused for CSI MIPI pads, which are receive only
26:24	0x0	PAD_CILA_SLEWUPADJ: Pull up slew rate adjust, default 000. From 000 -> 011, slew rate increases. 100 is the same as 000. From 100->111, skew rate decreases. This control is unused for CSI MIPI pads, which are receive only
23:21	0x0	PAD_CILA_LPDNADJ: Driver pull down impedance control. 00 -> 130ohm, default 01 -> 110ohm 10 -> 130ohm, same as 00 11 -> 150ohm This control is unused for CSI MIPI pads, which are receive only
20:18	0x0	PAD_CILA_LPUPADJ: Driver pull up impedance control. 00 -> 130ohm, default 01 -> 110ohm 10 -> 130ohm, same as 00 11 -> 150ohm This control is unused for CSI MIPI pads, which are receive only
17:16	0x1	PAD_AB_BK_MODE: 00: two independent 2x bricks 01: one 4x brick, received clock from partition A is used. Clock from partition B is not used 10: one 4x brick, received clock from partition B is used. Clock from partition A is not used 11: illegal
15	0x0	PAD_CILA_BANDWD_IN: Increase bandwidth of differential receiver
14:12	0x0	PAD_CILA_INADJ1: bit 1 input delay trimmer, each tap delays 20ps
10:8	0x0	PAD_CILA_INADJ0: bit 0 input delay trimmer, each tap delays 20ps
6:4	0x0	PAD_CILA_INADJCLK: Clock bit input delay trimmer, each tap delays 20ps
3	0x0	PAD_CILA_PDVCLAMP: Power down regulator which supplies current to serializer/deserializer logic
2	0x1	PAD_CILA_PDIO_CLK: Power down for clock bit, including drivers, receivers and contention detectors
1:0	0x3	PAD_CILA_PDIO: Power down for each data bit, including drivers, receivers and contention detectors

29.16.22 CSI_CILA_PAD_CONFIG1_0

CIL-A Pad Configuration 4

Offset: 0x24c | Byte Offset: 0x930 | Read/Write: R/W | Reset: 0xXXXX0000 (0bxxxxxxxxxxxxxxxx0000000000000000)

Bit	R/W	Reset	Description
31:16	RO	X	PAD_CILA_SPARE_RO: Spare Read only bits for CILA Config
15:8	RW	0x0	PAD_CILA_SPARE: Spare bits for CILA Config. PAD_CILA_SPARE[15] is being used to disable the CSI-A RTL code that blocks FIFO pushes that are past the end of the line packet. 0: disabled 1: push blocking enabled
7:6	RW	0x0	PAD_CILA_PEMPD_CLK: Enable data bit HS driver pull down pre-emphasis. 00=no pre-emphasis, 11=max This control is unused for CSI MIPI pads, which are receive only

3:2	RW	0x0	PAD_CILA_PEMPD: Enable data bit HS driver pull down pre-emphasis. 00=no pre-emphasis, 11=max This control is unused for CSI MIPI pads, which are receive only
1:0	RW	0x0	PAD_CILA_PEMPU: Enable data bit HS driver pull up pre-emphasis. 00=no pre-emphasis, 11=max This control is unused for CSI MIPI pads, which are receive only

29.16.23 CSI_PHY_CILA_CONTROL0_0

CSI-A PHY and CIL Control

Offset: 0x24d | Byte Offset: 0x934 | Read/Write: R/W | Reset: 0x00000002 (0bxxxxxxxxxxxxxxxxxx000000x0000010)

Bit	Reset	Description
13:8	0x0	CILA_CLK_SETTLE: Settle time for clock lane when moving from LP to HS (LP11->LP01->LP00), this setting determines how many CSICIL clock cycles (72 MHz LP clock cycles) to wait after LP00. Hardware uses an internal delay of ~15 csicil cycles for the default value. So the programming value (0 to 15) of this field works like this: 0 = 15 cilclk cycles (default internal delay) 1 = 15 - 7 (8 cilclk cycles) 2 = 15 - 6 (9 cilclk cycles) … 7 = 15 - 1 (14 cilclk cycles) 8 = 15 - 0 (default internal delay) 9 = 15 + 1 (16 cilclk cycles) … 57 = 15 + 49 (64 cilclk cycles)
6	0x0	CILA_BYPASS_LP_SEQ: The LP signals should sequence through LP11->LP01->LP00 state, to indicate to CLOCK CIL about the mode switching to HS Rx mode. In case the Camera is enabled earlier than CIL, it is highly likely that the camera sends this control sequence sooner than CIL can detect it. Enabling this bit allows the CLOCK CIL to overlook the LP control sequence and step in HS Rx mode directly looking at LP00 only.
5:0	0x2	CILA_THS_SETTLE: Settle time for data lane when moving from LP to HS (LP11->LP01->LP00), this setting determines how many CSICIL clock cycles (102 MHz LP clock cycles) to wait, after LP00, before starting to look at the data. 0xF is an illegal value for this field. 85ns + 6 * UI < (Ths-settle-programmed + 5) * csicil_clk_period < 145ns + 10 * UI

29.16.24 CSI_CSI_CIL_A_INTERRUPT_MASK_0

CSI Control and Interface Logic A Interrupt Mask

Offset: 0x24e | Byte Offset: 0x938 | Read/Write: R/W | Reset: 0x00000000 (0bxxxxxxxxxxxxxxxxxxxxxxx0x0000x000)

Bit	Reset	Description
9	0x0	CILA_CLK_LANE_CTRL_ERR_INT_MASK: Interrupt Mask for CILA_CLK_CTRL_ERR. 0 = DISABLED: Do not generate an interrupt when CILA_CLK_CTRL_ERR is set. 1 = ENABLED: Generate an interrupt when CILA_CLK_CTRL_ERR is set.
6	0x0	CILA_ESC_DATA_REC_INT_MASK: Interrupt Mask for CILA_ESC_DATA_REC. 0 = DISABLED: Do not generate an interrupt when CILA_ESC_DATA_REC is set. 1 = ENABLED: Generate an interrupt when CILA_ESC_DATA_REC is set.
5	0x0	CILA_ESC_CMD_REC_INT_MASK: Interrupt Mask for CILA_ESC_CMD_REC. 0 = DISABLED: Do not generate an interrupt when CILA_ESC_CMD_REC is set. 1 = ENABLED: Generate an interrupt when CILA_ESC_CMD_REC is set.
4	0x0	CILA_CTRL_ERR_INT_MASK: Interrupt Mask for CILA_CTRL_ERR. 0 = DISABLED: Do not generate an interrupt when CILA_CTRL_ERR is set. 1 = ENABLED: Generate an interrupt when CILA_CTRL_ERR is set.
2	0x0	CILA_SYNC_ESC_ERR_INT_MASK: Interrupt Mask for CILA_SYNC_ESC_ERR. 0 = DISABLED: Do not generate an interrupt when CILA_SYNC_ESC_ERR is set. 1 = ENABLED: Generate an interrupt when CILA_SYNC_ESC_ERR is set.
1	0x0	CILA_SOT_MB_ERR_INT_MASK: Interrupt Mask for CILA_SOT_MB_ERR. 0 = DISABLED: Do not generate an interrupt when CILA_SOT_MB_ERR is set. 1 = ENABLED: Generate an interrupt when CILA_SOT_MB_ERR is set.
0	0x0	CILA_SOT_SB_ERR_INT_MASK: Interrupt Mask for CILA_SOT_SB_ERR. 0 = DISABLED: Do not generate an interrupt when CILA_SOT_SB_ERR is set. 1 = ENABLED: Generate an interrupt when CILA_SOT_SB_ERR is set.

29.16.25 CSI_CSI_CIL_A_STATUS_0

CSI Control and Interface Logic A Status

Each status bit is cleared to zero when its bit position is written with one. For example writing 0x2 to CSI_CIL_A_STATUS will clear only CILA_SOT_MB_ERR.

Offset: 0x24f | Byte Offset: 0x93c | Read/Write: RO | Reset: 0x000000XX (0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx)

Bit	Reset	Description
6	X	CILA_ESC_DATA_REC: Escape Mode Data Received. Set when CIL-A receives an Escape Mode Data byte. The Data Byte can be read from bits 7-0 of ESCAPE_MODE_DATA. This status bit will also be cleared when CILA_ESC_CMD_REC is set.
5	X	CILA_ESC_CMD_REC: Escape Mode Command Received. Set when CIL-A receives an Escape Mode Command byte. The Command Byte can be read from bits 7-0 of ESCAPE_MODE_COMMAND.
4	X	CILA_CTRL_ERR: Control Error. Set when CIL-A detects LP state 01 or 10 followed by a stop state (LP11) instead of transitioning into the Escape mode or Turn Around mode (LP00).
2	X	CILA_SYNC_ESC_ERR: Sync Escape Error, set when CIL-A detects that the wrong (non-multiple of 8) number of bits have been received for an Escape Command or Data Byte.
1	X	CILA_SOT_MB_ERR: Start of Transmission Multi Bit Error. Set when CIL-A detects a multi bit start of transmission byte error in one of the packet's SOT bytes. The packet will be discarded.
0	X	CILA_SOT_SB_ERR: Start of Transmission Single Bit Error. Set when CIL-A detects a single bit error in one of the packet's Start of Transmission bytes. The packet will be sent to the CSI-A for processing.

29.16.26 CSI_CSI_CILA_STATUS_0

CSI-CILA Control and Interface Logic Status

Each status bit is cleared to zero when its bit position is written with one. For example writing 0x2 to CSI_CIL_STATUS will clear only SOT_MB_ERR.

Offset: 0x250 | Byte Offset: 0x940 | Read/Write: RO | Reset: 0x000X00XX (0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx)

Bit	Reset	Description
18	X	CILA_DATA_LANE1_CTRL_ERR: Control Error. Set when CIL-A detects LP state 01 or 10 followed by a stop state (LP11) instead of transitioning
17	X	CILA_DATA_LANE1_SOT_MB_ERR: Start of Transmission Multi Bit Error. Set when CIL-A detects a multi bit start of transmission byte error in one of the packet's SOT bytes on data lane-1. The packet will be discarded.
16	X	CILA_DATA_LANE1_SOT_SB_ERR: Start of Transmission Single Bit Error. Set when CIL-A detects a single bit error in one of the packet's Start of Transmission bytes on data lane-1. The packet will be sent to the CSI-A for processing.
6	X	CILA_DATA_LANE0_CTRL_ERR: Control Error. Set when CIL-A detects LP state 01 or 10 followed by a stop state (LP11) instead of transitioning
5	X	CILA_DATA_LANE0_SOT_MB_ERR: Start of Transmission Multi Bit Error. Set when CIL-A detects a multi bit start of transmission byte error in one of the packet's SOT bytes on data lane-0. The packet will be discarded.
4	X	CILA_DATA_LANE0_SOT_SB_ERR: Start of Transmission Single Bit Error. Set when CIL-A detects a single bit error in one of the packet's Start of Transmission bytes on data lane-0. The packet will be sent to the CSI-A for processing.
0	X	CILA_CLK_LANE_CTRL_ERR: Control Error. Set when CIL-A detects incorrect line state sequence on clk lane

29.16.27 CSI_CIL_A_ESCAPE_MODE_COMMAND_0

Escape Mode Command

This register is used to receive escape mode command bytes from CIL-A.

Offset: 0x251 | Byte Offset: 0x944 | Read/Write: RO | Reset: 0x000000XX (0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx)

Bit	Reset	Description
7:0	X	CILA_ESC_CMD_BYTE: CIL-A Escape Mode Command Byte. This is the 8 bit entry command that was received, by CIL-A, during the last escape Mode sequence. CIL-A monitors Byte Lane 0, only, for escape mode sequences. This command byte can only be assumed to be valid when CILA_ESC_CMD_REC status bit is set.

29.16.28 CSI_CIL_A_ESCAPE_MODE_DATA_0

Escape Mode Data

This register is used to receive escape mode data bytes from CIL-A.

Offset: 0x252 | Byte Offset: 0x948 | Read/Write: RO | Reset: 0x000000XX (0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx)

Bit	Reset	Description
7:0	X	CILA_ESC_DATA_BYTE: CIL-A Escape Mode Data Byte. When read this field returns the last Escape Mode Data byte that was received by CIL-A. Escape Mode Data bytes are the bytes that are received in Escape Mode after receiving the Escape Mode Command. These bytes can be used to implement MIPI's CSI Specs Low Power Data Transmission. This field is only valid when the status bit, CILA_ESC_DATA_REC, is set, and will be overwritten by the next Escape Mode data byte if not read before the next byte comes in.

29.16.29 CSI_CSICIL_SW_SENSOR_A_RESET_0

Offset: 0x253 | Byte Offset: 0x94c | Read/Write: R/W | Reset: 0x00000000 (0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx0)

Bit	Reset	Description
0	0x0	CSICIL_SENSOR_A_RESET: Reset CSICIL sensor A

29.16.30 CSI_CILB_PAD_CONFIG0_0

CIL-B Pad Configuration 0

Offset: 0x258 | Byte Offset: 0x960 | Read/Write: R/W | Reset: 0x00000007 (0b0000x000000000xx0000x000x0000111)

Bit	Reset	Description
31	0x0	PAD_CILB_E_TXBW: 0 = default to enable VCLAMP regulator 1 = turn off regulator and short vclamp to VDDP. will cause stress and need waiver to use
30:28	0x0	PAD_CILB_SLEWDNADJ: Pull down slew rate adjust, default 000. From 000 -> 011, slew rate increases. 100 is the same as 000. From 100->111, skew rate decreases. This control is unused for CSI MIPI pads, which are receive only
26:24	0x0	PAD_CILB_SLEWUPADJ: Pull up slew rate adjust, default 000. From 000 -> 011, slew rate increases. 100 is the same as 000. From 100->111, skew rate decreases. This control is unused for CSI MIPI pads, which are receive only
23:21	0x0	PAD_CILB_LPDNADJ: Driver pull down impedance control. 00 -> 130ohm, default. 01 -> 110ohm. 10 -> 130ohm, same as 00. 11 -> 150ohm This control is unused for CSI MIPI pads, which are receive only
20:18	0x0	PAD_CILB_LPUPADJ: Driver pull up impedance control. 00 -> 130ohm, default. 01 -> 110ohm. 10 -> 130ohm, same as 00. 11 -> 150ohm This control is unused for CSI MIPI pads, which are receive only
15	0x0	PAD_CILB_BANDWD_IN: Increase bandwidth of differential receiver

3:2	RW	0x0	PAD_CILB_PEMPD: Enable data bit HS driver pull down pre-emphasis. 00=no pre-emphasis, 11=max This control is unused for CSI MIPI pads, which are receive only
1:0	RW	0x0	PAD_CILB_PEMPU: Enable data bit HS driver pull up pre-emphasis. 00=no pre-emphasis, 11=max This control is unused for CSI MIPI pads, which are receive only

29.16.32 CSI_PHY_CILB_CONTROL0_0

CSI-B PHY and CIL Control

Offset: 0x25a | Byte Offset: 0x968 | Read/Write: R/W | Reset: 0x00000002 (0bxxxxxxxxxxxxxxxxxx000000x0000010)

Bit	Reset	Description
13:8	0x0	CILB_CLK_SETTLE: Settle time for clock lane when moving from LP to HS (LP11->LP01->LP00), this setting determines how many CSICIL clock cycles (72 MHz LP clock cycles) to wait after LP00. Hardware uses an internal delay of ~15 CSICIL cycles for default value. So the programming value (0 to 15) of this field works like this: 0 = 15 cilclk cycles (default internal delay) 1 = 15 - 7 (8 cilclk cycles) 2 = 15 - 6 (9 cilclk cycles) … 7 = 15 - 1 (14 cilclk cycles) 8 = 15 - 0 (default internal delay) 9 = 15 + 1 (16 cilclk cycles) … 57 = 15 + 49 (64 cilclk cycles)
6	0x0	CILB_BYPASS_LP_SEQ: see CILA_BYPASS_LP_SEQ above
5:0	0x2	CILB_THS_SETTLE: Settle time for data lane when moving from LP to HS (LP11->LP01->LP00), this setting determines how many CSICIL clock cycles (102 MHz LP clock cycles) to wait, after LP00, before starting to look at the data. 0xF is an illegal value for this field. 85ns + 6 * UI < (Ths-settle-programmed + 5) * csicil_clk_period < 145ns + 10 * UI

29.16.33 CSI_CSI_CIL_B_INTERRUPT_MASK_0

CSI Control and Interface Logic B Interrupt Mask

Offset: 0x25b | Byte Offset: 0x96c | Read/Write: R/W | Reset: 0x00000000 (0bxxxxxxxxxxxxxxxxxxxxxxxx0x0000x000)

Bit	Reset	Description
6	0x0	CILB_ESC_DATA_REC_INT_MASK: Interrupt Mask for CILB_ESC_DATA_REC. 0 = DISABLED: Do not generate an interrupt when CILB_ESC_DATA_REC is set. 1 = ENABLED: Generate an interrupt when CILB_ESC_DATA_REC is set.
5	0x0	CILB_ESC_CMD_REC_INT_MASK: Interrupt Mask for CILB_ESC_CMD_REC. 0 = DISABLED: Do not generate an interrupt when CILB_ESC_CMD_REC is set. 1 = ENABLED: Generate an interrupt when CILB_ESC_CMD_REC is set.
4	0x0	CILB_CTRL_ERR_INT_MASK: Interrupt Mask for CILB_CTRL_ERR. 0 = DISABLED: Do not generate an interrupt when CILB_CTRL_ERR is set. 1 = ENABLED: Generate an interrupt when CILB_CTRL_ERR is set.
2	0x0	CILB_SYNC_ESC_ERR_INT_MASK: Interrupt Mask for CILB_SYNC_ESC_ERR. 0 = DISABLED: Do not generate an interrupt when CILB_SYNC_ESC_ERR is set. 1 = ENABLED: Generate an interrupt when CILB_SYNC_ESC_ERR is set.
1	0x0	CILB_SOT_MB_ERR_INT_MASK: Interrupt Mask for CILB_SOT_MB_ERR. 0 = DISABLED: Do not generate an interrupt when CILB_SOT_MB_ERR is set. 1 = ENABLED: Generate an interrupt when CILB_SOT_MB_ERR is set.
0	0x0	CILB_SOT_SB_ERR_INT_MASK: Interrupt Mask for CILB_SOT_SB_ERR. 0 = DISABLED: Do not generate an interrupt when CILB_SOT_SB_ERR is set. 1 = ENABLED: Generate an interrupt when CILB_SOT_SB_ERR is set.

29.16.34 CSI_CSI_CIL_B_STATUS_0

CSI Control and Interface Logic B Status

Each status bit is cleared to zero when its bit position is written with one. For example writing 0x2 to CSI_CIL_B_STATUS will clear only CILB_SOT_MB_ERR.

Offset: 0x25c | Byte Offset: 0x970 | Read/Write: RO | Reset: 0x000000XX (0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx)

Bit	Reset	Description
6	X	CILB_ESC_DATA_REC: Escape Mode Data Received. Set when CIL-B receives an Escape Mode Data byte. The Data Byte can be read from bits 23-16 of ESCAPE_MODE_DATA. This status bit will also be cleared when CILB_ESC_CMD_REC is set.
5	X	CILB_ESC_CMD_REC: Escape Mode Command Received. Set when CIL-B receives an Escape Mode Command byte. The Command Byte can be read from bits 23-16 of ESCAPE_MODE_COMMAND.
4	X	CILB_CTRL_ERR: Control Error. Set when CIL-B detects LP state 01 or 10 followed by a stop state (LP11) instead of transitioning into the Escape mode or Turn Around mode (LP00).
2	X	CILB_SYNC_ESC_ERR: Sync Escape Error, set when CIL-B detects that the wrong (non-multiple of 8) number of bits have been received for an Escape Command or Data Byte.
1	X	CILB_SOT_MB_ERR: Start of Transmission Multi Bit Error. Set when CIL-B detects a multi bit start of transmission byte error in one of the packet's SOT bytes. The packet will be discarded.
0	X	CILB_SOT_SB_ERR: Start of Transmission Single Bit Error. Set when CIL-B detects a single bit error in one of the packets start of transmission bytes. The packet will be sent to CSI-B for processing.

29.16.35 CSI_CSI_CILB_STATUS_0

CSI-CILB Control and Interface Logic Status

Each status bit is cleared to zero when its bit position is written with one. For example writing 0x2 to CSI_CIL_STATUS will clear only SOT_MB_ERR.

Offset: 0x25d | Byte Offset: 0x974 | Read/Write: RO | Reset: 0x000X00XX (0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx)

Bit	Reset	Description
18	X	CILB_DATA_LANE1_CTRL_ERR: Control Error. Set when CIL-B detects LP state 01 or 10 followed by a stop state (LP11) instead of transitioning
17	X	CILB_DATA_LANE1_SOT_MB_ERR: Start of Transmission Multi Bit Error. Set when CIL-B detects a multi bit start of transmission byte error in one of the packet's SOT bytes on data lane-1. The packet will be discarded.
16	X	CILB_DATA_LANE1_SOT_SB_ERR: Start of Transmission Single Bit Error. Set when CIL-A detects a single bit error in one of the packet's Start of Transmission bytes on data lane-1. The packet will be sent to the CSI-B for processing.
6	X	CILB_DATA_LANE0_CTRL_ERR: Control Error. Set when CIL-B detects LP state 01 or 10 followed by a stop state (LP11) instead of transitioning
5	X	CILB_DATA_LANE0_SOT_MB_ERR: Start of Transmission Multi Bit Error. Set when CIL-B detects a multi bit start of transmission byte error in one of the packet's SOT bytes on data lane-0. The packet will be discarded.
4	X	CILB_DATA_LANE0_SOT_SB_ERR: Start of Transmission Single Bit Error. Set when CIL-B detects a single bit error in one of the packet's Start of Transmission bytes on data lane-0. The packet will be sent to the CSI-B for processing.
0	X	CILB_CLK_LANE_CTRL_ERR: Control Error. Set when CIL-B detects incorrect line state sequence on clk lane

29.16.36 CSI_CIL_B_ESCAPE_MODE_COMMAND_0

Escape Mode Command

This register is used to receive escape mode command bytes from CIL-B.

Offset: 0x25e | Byte Offset: 0x978 | Read/Write: RO | Reset: 0x000000XX (0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx)

Bit	Reset	Description
7:0	X	CILB_ESC_CMD_BYTE: CIL-B Escape Mode Command Byte. This is the 8-bit entry command that was received, by CIL-B, during the last escape Mode sequence. CIL-B monitors Byte Lane 0, only, for escape mode sequences. This command byte can only be assumed to be valid when CILB_ESC_CMD_REC status bit is set.

29.16.37 CSI_CIL_B_ESCAPE_MODE_DATA_0

Escape Mode Data

This register is used to receive escape mode data bytes from CIL-B.

Offset: 0x25f | Byte Offset: 0x97c | Read/Write: RO | Reset: 0x000000XX (0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx)

Bit	Reset	Description
7:0	X	CILB_ESC_DATA_BYTE: CIL-A Escape Mode Data Byte. When read this field returns the last Escape Mode Data byte that was received by CIL-B. Escape Mode Data bytes are the bytes that are received in Escape Mode after receiving the Escape Mode Command. These bytes can be used to implement MIPI's CSI Specs Low Power Data Transmission. This field is only valid when the status bit, CILB_ESC_DATA_REC, is set, and will be overwritten by the next Escape Mode data byte if not read before the next byte comes in.

7	RO	X	CLR_DBG_CNT_2: Clear Debug Counter 2, write a one to this bit to clear debug counter 2 and dbg_cnt_rolled_2.
6	RO	X	CLR_DBG_CNT_1: Clear Debug Counter 1, write a one to this bit to clear debug counter 1 and dbg_cnt_rolled_1.
5	RO	X	CLR_DBG_CNT_0: Clear Debug Counter 0, write a one to this bit to clear debug counter 0 and dbg_cnt_rolled_0.

Bit	R/W	Reset	Description
2	RO	X	CSIB_DBG_SF: When CSI-B is operating in a "Header Not Sent mode", writing a 1 to this bit indicates start frame (SF) or end frame (EF) control code. After the pixel parser is enabled, writing a 1 to this bit will start frame capture and send start frame (SF) control code. Writing a 1 to this bit again will stop frame capture and send end frame (EF) control code. "Header Not Sent mode" can be used as a debug mode to capture what the sensor is sending without interpreting the packets. Writing a 1 to this bit continually will generate SF and EF control codes. Note that a wait for MISC_CSI_PPB_FRAME_END syncpt is needed between an EF trigger for the current frame and an SF trigger for the next frame.
1	RO	X	CSIA_DBG_SF: When CSI-A is operating in a "Header Not Sent mode", writing a 1 to this bit indicates start frame (SF) or end frame (EF) control code. After the pixel parser is enabled, writing a 1 to this bit will start frame capture and send start frame (SF) control code. Writing a 1 to this bit again will stop frame capture and send end frame (EF) control code. "Header Not Sent mode" can be used as a debug mode to capture what the sensor is sending without interpreting the packets. Writing a 1 to this bit continually will generate SF and EF control codes. Note that a wait for MISC_CSI_PPA_FRAME_END syncpt is needed between an EF trigger for the current frame and an SF trigger for the next frame.
0	RW	0x0	DEBUG_EN: Debug Enable Second level CSI Debug clock is enabled. Debug counters 2, 1 & 0 are powered up. 0 = DISABLED : Debug counters 2, 1, and 0 are powered down. Second level CSI Debug clock is disabled. 1 = ENABLED

29.16.66 CSI_DEBUG_COUNTER_0_0

Debug Counter 0

This register can be used to count error conditions or packets processed.

Offset: 0x296 | Byte Offset: 0xa58 | Read/Write: RO | Reset: 0xXXXXXXXX (0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx)

Bit	Reset	Description
31:0	X	DBG_CNT_0: When read returns the value of debug counter 0.

29.16.67 CSI_DEBUG_COUNTER_1_0

Debug Counter 1

This register can be used to count error conditions or packets processed.

Offset: 0x297 | Byte Offset: 0xa5c | Read/Write: RO | Reset: 0xXXXXXXXX (0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx)

Bit	Reset	Description
31:0	X	DBG_CNT_1: When read returns the value of debug counter 1.

29.16.68 CSI_DEBUG_COUNTER_2_0

Debug Counter 2

This register can be used to count error conditions or packets processed.

Offset: 0x298 | Byte Offset: 0xa60 | Read/Write: RO | Reset: 0xXXXXXXXX (0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx)

Bit	Reset	Description
31:0	X	DBG_CNT_2: When read returns the value of debug counter 2

29.16.69 CSI1_CSI_CAP_CIL_0

CIL Capability

Interface packets

Offset: 0x402 | Read/Write: RO | Reset: 0x000000XX (0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx)

Bit	Reset	Description
6:4	X	CIL_B_NUMLANES: CIL-B logic exists only if the returned value is other than _NONE. Returned value indicates how many lanes that CSI has. 0 = NONE 1 = ONE 2 = TWO
2:0	X	CIL_A_NUMLANES: CIL-A logic exists only if the returned value is other than _NONE. Returned value indicates how many lanes that CSI has. 0 = NONE 1 = ONE 2 = TWO

29.16.70 CSI1_CSI_CAP_CSI_0

CSI Capability

Offset: 0x406 | Read/Write: RO | Reset: 0x000000XX (0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx)

Bit	Reset	Description
7:4	X	CSIB_EXISTS: CSIB logic exists only if the returned value is other than _NO. 0 = NO 1 = YES
3:0	X	CSIA_EXISTS: CSIA logic exists only if the returned value is other than _NO. 0 = NO 1 = YES

29.16.71 CSI1_CSI_CAP_PP_0

PP Capabilities

Offset: 0x40a | Read/Write: RO | Reset: 0x000000XX (0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx)

Bit	Reset	Description
7:4	X	PPB_EXISTS: PPB logic exists only if the returned value is other than _NO. 0 = NO 1 = YES
3:0	X	PPA_EXISTS: PPA logic exists only if the returned value is other than _NO. 0 = NO 1 = YES

29.16.72 CSI1_INPUT_STREAM_A_CONTROL_0

CSI Input Stream A Control

CSI PPA group

Offset: 0x40e | Byte Offset: 0x1038 | Read/Write: R/W | Reset: 0x00ff0004 (0bxxxxxxx011111111xxxxxxxxxx0x100)

Bit	Reset	Description
24:16	0xff	CSI_A_SKIP_PACKET_THRESHOLD: CSI-A Skip Packet Threshold. This value is compared against the internal FIFO that buffers the input streams. A packet will be skipped (discarded) if the pixel stream processor is busy (probably due to padding process of a short line) and the number of entries in the internal FIFO exceeds this threshold value. Note that each entry in the internal FIFO buffer is four bytes. To turn off this feature, set the value to its maximum value (all ones).
4	0x0	CSI_A_SKIP_PACKET_THRESHOLD_ENABLE: Enables skip packet threshold feature. 0 = DISABLE: Skip packet feature is disabled. 1 = ENABLE: Skip packet feature is enabled.
2	0x1	CSI_A_BYPASS_ALIGN: Bypass aligning CSIA and CSIB lanes if valids for the lanes are out of sync by a cycle.

Bit	Reset	Description
1:0	0x0	CSI_A_DATA_LANE: CSI-A Data Lane 0= 1 data lane 1= 2 data lanes 2= 3 data lanes 3= 4 data lanes Note: 3 data lanes is not supported in Test Pattern Generation mode

29.16.73 CSI1_PIXEL_STREAM_A_CONTROL0_0

CSI Pixel Stream A Control 0

Offset: 0x40f | Byte Offset: 0x103c | Read/Write: R/W | Reset: 0xXXXX01X0 (0bxxxxxxxxxxxxxxxxxxxxxxxx1xxxxx000)

Bit	Reset	Description
29:28	X	CSI_PPA_PAD_FRAME: CSI Pixel Parser A Pad Frame. This specifies how to deal with frames that are shorter (fewer lines) than expected. Short frames are usually caused by line packets being dropped because of packet errors. Expected frame height is specified in PPA_EXP_FRAME_HEIGHT. To do padding, the value in CSI_PPA_WORD_COUNT needs to be set to the number of input bytes in each line's payload. 0 = PAD0S: Lines of all zeros will be used to pad out frames that are shorter than expected height. PPA_EXP_FRAME_HEIGHT must be programmed to an appropriate value if this field is set to PAD0S. 1 = PAD1S: Lines of all ones will be used to pad out frames that are shorter than expected height. PPA_EXP_FRAME_HEIGHT must be programmed to an appropriate value if this field is set to PAD1S. 2 = NOPAD: Short frames will not be padded out.
27	X	CSI_PPA_HEADER_EC_ENABLE: CSI Pixel Parser A Packet Header Error Correction Enable. This parameter specifies whether single bit errors in the packet header will be automatically corrected or not. 0 = ENABLE: Single bit errors in the header will be automatically corrected. 1 = DISABLE: Single bit errors in the header will not be corrected. Header ECC check will still set header ECC status bits and the packet will be processed by Pixel Parser A. DISABLE should not be used when processing interleaved streams (Same stream going to both PPA and PPB).
25:24	X	CSI_PPA_PAD_SHORT_LINE: CSI Pixel Parser A Pad Short Line. This specifies how to deal with shorter than expected line (the number of bytes received is less than the specified word count). 0 = PAD0S: short line is padded by pixel of zeros such that the expected number of output pixels is correct. Due to the time required to do the padding, subsequent line packet maybe discarded and therefore may cause a short frame (total number of lines per frame is less than expected). 1 = PAD1S: short line is padded by pixel of ones such that the expected number of output pixels is correct. Due to the time required to do the padding, subsequent line packet maybe discarded and therefore may cause a short frame (total number of lines per frame is less than expected). 2 = NOPAD: short line is not padded (will output less pixels than expected). This option is not recommended and may cause other modules that receive CSI output stream to hang up.
21:20	X	CSI_PPA_EMBEDDED_DATA_OPTIONS: CSI Pixel Parser A Embedded Data Options. This specifies how to deal with embedded data within the specified input stream assuming that the CSI_PPA_DATA_TYPE is not embedded data and assuming that embedded data is not already processed by other CSI pixel stream processor. 0 = DISCARD: discard (throw away) embedded data 1 = EMBEDDED: output embedded data as 8-bpp arbitrary data stream.
19:16	X	CSI_PPA_OUTPUT_FORMAT_OPTIONS: CSI Pixel Parser A Output Format Options. This parameter specifies options for output data format. 0 = ARBITRARY: Output as 8-bit arbitrary data stream. This may be used for compressed JPEG stream 1 = PIXEL: Output the normal 1 pixel/clock. Undefined LS color bits for RGB_666, RGB_565, RGB_555, and RGB_444, will be zeroed. 2 = PIXEL_REP: Same as PIXEL except MS color bits, for RGB_666, RGB_565, RGB_555, and RGB_444, will be replicated to their undefined LS bits. 3 = STORE: Output for storing RAW data to memory through ISP. Undefined LS color bits for RGB_666, RGB_565, RGB_555, and RGB_444, will be zeroed.
8	0x1	CSI_PPA_WC_CHECK: CSI Pixel Parser A Data WC Check. This parameter specifies whether the wordcount is checked. 0 = DISABLE: Word count Check is disabled 1 = ENABLE: Word count Check is enabled.
7	X	CSI_PPA_CRC_CHECK: CSI Pixel Parser A Data CRC Check. This parameter specifies whether the last 2 bytes of packet should be treated as CRC checksum and used to perform CRC check on the payload data. Note that in case there are 2 bytes of data CRC at the end of the packet, the packet word count does not include the CRC bytes. 0 = DISABLE: Data CRC Check is disabled regardless of whether there are CRC checksum at the end of the packet. 1 = ENABLE: Data CRC Check is enabled.

Bit	Reset	Description
6	X	CSI_PPA_WORD_COUNT_SELECT: CSI Pixel Parser A Word Count Select. This parameter is effective only if the packet header is sent as part of the stream. 0 = REGISTER: Word Count in packet header is ignored and the number of bytes per line/packet is specified by CSI_PPA_WORD_COUNT. Payload CRC check will not be valid if the word count in CSI_PPA_WORD_COUNT is different than the count in the packet header. Interlaced support relies on frame number and will not work in REGISTER mode. 1 = HEADER: The number of bytes per line is to be extracted from Word Count field in the packet header. Note that if the serial link is not error free, programming this bit to HEADER may be dangerous because the word count information in the header may be corrupted. It is recommended to always program this bit to HEADER.
5	X	CSI_PPA_DATA_IDENTIFIER: CSI Pixel Parser A Data Identifier (DI) byte processing. This parameter is effective only if packet header is sent as part of the stream. 0 = DISABLED: Disabled - Data Identifier byte in packet header should be ignored (not checked against CSI_PPA_DATA_TYPE and against CSI_PPA_VIRTUAL_CHANNEL_ID). In this case, CSI_PPA_DATA_TYPE specifies the stream data format. 1 = ENABLED: Enabled - Data Identifier byte in packet header should be compared against the CSI_PPA_DATA_TYPE and the CSI_PPA_VIRTUAL_CHANNEL_ID.
4	X	CSI_PPA_PACKET_HEADER: CSI Pixel Parser A Packet Header processing. This specifies whether packet header is sent in the beginning of the packet or not. 0 = NOT_SENT: Packet header is not sent. This setting should not be used if the stream source is CSI Interface A or B. Unless CSI-A, or CSI-B, is operating in a stream capture debug mode. In this case, CSI_PPA_DATA_TYPE specifies the stream data format and the number of bytes per line/packet is specified by CSI_PPA_WORD_COUNT. This implies that a packet footer is also not sent. In this case, no packet footer CRC check should be performed. 1 = SENT: Packet header is sent. This setting should be used if the stream source is CSI Interface A or B.
2:0	0x0	CSI_PPA_STREAM_SOURCE: CSI Pixel Parser A Stream Source 0 = CSI_A: CSI Interface A 1 = CSI_B: CSI Interface B

29.16.74 CSI1_PIXEL_STREAM_A_CONTROL1_0

CSI Pixel Stream A Control 1

Offset: 0x410 | Byte Offset: 0x1040 | Read/Write: R/W | Reset: 0x00000000 (0bxxxxxxxxxxxxxxxxxxxxxxxxx00000000)

Bit	Reset	Description
7:4	0x0	CSI_PPA_TOP_FIELD_FRAME_MASK: CSI Pixel Parser A Top Field Frame Mask
3:0	0x0	CSI_PPA_TOP_FIELD_FRAME: CSI Pixel Parser A Top Field Frame. This parameter specifies the frame number for top field detection for interlaced input video stream. Top Field is indicated when each of the least significant four bits of the frame number that has a one in its mask bit matches the corresponding bit in this parameter. In other words, Top Field is detected when the bitwise OR of ~(CSI_PPA_TOP_FIELD_FRAME ^ <frame number>) & CSI_PPA_TOP_FIELD_FRAME_MASK is one. Frame Number is taken from the WC field of the Frame Start short packet. Due to the reliance on WC field in packet header, interlaced support will not work if WC is selected from REGISTER mode.

29.16.75 CSI1_PIXEL_STREAM_A_GAP_0

CSI Pixel Stream A Gap

Offset: 0x411 | Byte Offset: 0x1044 | Read/Write: R/W | Reset: 0x00000000 (0b00000000000000000000000000000000)

Bit	Reset	Description
31:16	0x0	PPA_FRAME_MIN_GAP: Minimum number of viclk cycles from end of frame (Video_control = EF) to start of next frame (Video_control = SF). This parameter ensures that minimum V-blank time requirement of VI/ISP is satisfied. This field takes effect only when the frame gap of the input stream is less than the specified value.
15:0	0x0	PPA_LINE_MIN_GAP: Minimum number of viclk cycles from end of previous line (Video_control = EL_DATA) to start of next line (Video_control = SL). This parameter ensures that minimum H-blank time requirement of VI/ISP is satisfied. This field takes effect only when the line gap of the input stream is less than the specified value.

29.16.76 CSI1_PIXEL_STREAM_PPA_COMMAND_0

CSI Pixel Parser A Command

Offset: 0x412 | Byte Offset: 0x1048 | Read/Write: R/W | Reset: 0x0000XXX4 (0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx100)

Bit	Reset	Description
15:12	X	CSI_PPA_START_MARKER_FRAME_MAX: CSI Pixel Parser A Start Marker Maximum. Start Frame is indicated when Minimum condition above is met and the least significant four bits of the frame number are less than or equal to this value.
11:8	X	CSI_PPA_START_MARKER_FRAME_MIN: CSI Pixel Parser A Start Marker Minimum. Start Frame is indicated when Maximum condition below is met and the least significant four bits of the frame number are greater than or equal to this value.
4	X	CSI_PPA_VSYNC_START_MARKER: CSI Pixel Parser A VSYNC Start Marker 0 = FSPKT: Start of frame is indicated when a Frame Start short packet is received with a frame number whose least significant four bits are greater than or equal to CSI_PPA_START_MARKER_FRAME_MIN and less than or equal to CSI_PPA_START_MARKER_FRAME_MAX. When the input stream is from a CSI port, or from the host path, or from the VIP path and the data mode is PAYLOAD_ONLY, then this field may be programmed to FSPKT. 1 = VSYNC: Start of frame is indicated when VSYNC signal is received. When the input stream is from the VIP path and the data mode is PACKET, then this field may be programmed to VSYNC.
2	0x1	CSI_PPA_SINGLE_SHOT: CSI Pixel Parser A Single Shot Mode. SW should clear this bit along with disabling the CSI_PPA_ENABLE, once a frame is captured. 0 = DISABLE 1 = ENABLE
1:0	0x0	CSI_PPA_ENABLE: CSI Pixel Parser A Enable. This parameter controls CSI Pixel Parser A to start or stop receiving data. 0 = NOP: no operation 1 = ENABLE: enable at the next frame start as specified by the CSI Start Marker 2 = DISABLE: disable after current frame end and before next frame start. 3 = RST: reset (disable immediately). Enabling the pixel parser does not enable the corresponding input source to receive data. If pixel parser is enabled later than the corresponding input source, the CSI will keep on rejecting incoming stream, until it encounters a valid SF.

29.16.77 CSI1_PIXEL_STREAM_A_EXPECTED_FRAME_0

CSI Pixel Stream A Expected Frame

Offset: 0x413 | Byte Offset: 0x104c | Read/Write: R/W | Reset: 0x0000XXX0 (0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx0)

Bit	Reset	Description
15:4	X	PPA_MAX_CLOCKS: Maximum Number of viclk clock cycles between line start requests. The value in this field is in terms of 256 viclk clock cycles.
0	0x0	PPA_ENABLE_LINE_TIMEOUT: When set to one enables checking of the time between start line requests from the Header Parser to CSI-PPA. A fake EF will be outputted by CSI-PPA if this time between line starts exceeds the value in MAX_CLOCKS_BETWEEN_LINES. Padding lines can be inserted before the fake EF, if the number of lines outputted, when the fake EF is generated is less than the expected frame height. The type of padding is specified using CSI_PPA_PAD_FRAME.

29.16.78 CSI1_CSI_PIXEL_PARSER_A_INTERRUPT_MASK_0

CSI Pixel Parser A Interrupt Mask

Offset: 0x414 | Byte Offset: 0x1050 | Read/Write: R/W | Reset: 0x00000000 (0bxxxxxxxxxxxxxxxxxx0xx000000000000)

Bit	Reset	Description
14	0x0	HPA_UNC_HDR_ERR_INT_MASK: Interrupt Mask for HPA_UNC_HDR_ERR. 0 = DISABLED: Don't generate an interrupt when HPA_UNC_HDR_ERR is set. 1 = ENABLED: Generate an interrupt when HPA_UNC_HDR_ERR is set.
10	0x0	PPA_SPARE_STATUS_1_INT_MASK: Interrupt Mask for PPA_SPARE_STATUS_1. 0 = DISABLED: Don't generate an interrupt when PPA_SPARE_STATUS_1 is set. 1 = ENABLED: Generate an interrupt when PPA_SPARE_STATUS_1 is set.
9	0x0	PPA_INTERFRAME_LINE_INT_MASK: Interrupt Mask for PPA_INTERFRAME_LINE. 0 = DISABLED: Don't generate an interrupt when PPA_INTERFRAME_LINE is set. 1 = ENABLED: Generate an interrupt when PPA_INTERFRAME_LINE is set.

Bit	Reset	Description
8	0x0	PPA_EXTRA_SF_INT_MASK: Interrupt Mask for PPA_EXTRA_SF. 0 = DISABLED: Don't generate an interrupt when PPA_EXTRA_SF is set. 1 = ENABLED: Generate an interrupt when PPA_EXTRA_SF is set.
7	0x0	PPA_SHORT_FRAME_INT_MASK: Interrupt Mask for PPA_SHORT_FRAME. 0 = DISABLED: Don't generate an interrupt when PPA_SHORT_FRAME is set. 1 = ENABLED: Generate an interrupt when PPA_SHORT_FRAME is set.
6	0x0	PPA_STMERR_INT_MASK: Interrupt Mask for PPA_STMERR. 0 = DISABLED: Don't generate an interrupt when PPA_STMERR is set. 1 = ENABLED: Generate an interrupt when PPA_STMERR is set.
5	0x0	PPA_FIFO_OVRF_INT_MASK: Interrupt Mask for PPA_FIFO_OVRF. 0 = DISABLED: Don't generate an interrupt when PPA_FIFO_OVRF is set. 1 = ENABLED: Generate an interrupt when PPA_FIFO_OVRF is set.
4	0x0	PPA_PL_CRC_ERR_INT_MASK: Interrupt Mask for PPA_PL_CRC_ERR. 0 = DISABLED: Don't generate an interrupt when PPA_PL_CRC_ERR is set. 1 = ENABLED: Generate an interrupt when PPA_PL_CRC_ERR is set.
3	0x0	PPA_SL_PKT_DROPPED_INT_MASK: Interrupt Mask for PPA_SL_PKT_DROPPED. 0 = DISABLED: Don't generate an interrupt when PPA_SL_PKT_DROPPED is set. 1 = ENABLED: Generate an interrupt when PPA_SL_PKT_DROPPED is set.
2	0x0	PPA_SL_PROCESSED_INT_MASK: Interrupt Mask for PPA_SL_PROCESSED. 0 = DISABLED: Don't generate an interrupt when PPA_SL_PROCESSED is set. 1 = ENABLED: Generate an interrupt when PPA_SL_PROCESSED is set.
1	0x0	PPA_ILL_WD_CNT_INT_MASK: Interrupt Mask for PPA_ILL_WD_CNT. 0 = DISABLED: Don't generate an interrupt when PPA_ILL_WD_CNT is set. 1 = ENABLED: Generate an interrupt when PPA_ILL_WD_CNT is set.
0	0x0	PPA_HDR_ERR_COR_INT_MASK: Interrupt Mask for PPA_HDR_ERR_COR. 0 = DISABLED: Don't generate an interrupt when PPA_HDR_ERR_COR is set. 1 = ENABLED: Generate an interrupt when PPA_HDR_ERR_COR is set.

29.16.79 CSI1_CSI_PIXEL_PARSER_A_STATUS_0

Pixel Parser A Status

Each status bit is cleared to zero when its bit position is written with one. For example, write 0x2 to CSI_PIXEL_PARSER_STATUS will clear only PPA_ILL_WD_CNT.

Offset: 0x415 | Byte Offset: 0x1054 | Read/Write: RO | Reset: 0x0000XXXX (0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx)

Bit	Reset	Description
14	X	HPA_UNC_HDR_ERR: Uncorrectable Header Error. Set when header parser A parses a header with a multi-bit error. This error will be detected by the headers ECC, but cannot be corrected. The packet will be discarded.
10	X	PPA_SPARE_STATUS_1: PPA Spare Status bit. This bit will get set when Pixel Parser A has a line timeout. Line timeout needs to be enabled by setting PPA_ENABLE_LINE_TIMEOUT and programming PPA_MAX_CLOCKS for the MAX clocks between lines.
9	X	PPA_INTERFRAME_LINE: Set when CSI-PPA receives a request to output a line that is not in the active part of the frame output. That is after EF and before SF, or before start marker is found. The interframe line will not be outputted by the Pixel Parser.
8	X	PPA_EXTRA_SF: Set when CSI-PPA receives a SF when it is expecting an EF. This happens when EF of the frame gets corrupted before arriving CSI. CSI-PPA will insert a fake EF and the drop the current frame with the Correct SF.
7	X	PPA_SHORT_FRAME: Set when CSI-PPA receives a short frame. This bit gets set even if CSI_PPA_PAD_FRAME specifies that short frames are to be padded to the correct line length.
6	X	PPA_STMERR: Stream Error, set when the control output of PPA does not follow the correct sequence. The correct sequence for CSI is: SF -> (SL_DATA or EF), SL_DATA -> (DATA or EL_DATA), DATA -> EL_DATA, EL_DATA -> (SL_DATA or EF), EF -> SF. Stream Errors can be caused by receiving a corrupted stream.
5	X	PPA_FIFO_OVRF: FIFO Overflow. Set when the FIFO that is feeding packets to PPA overflows.
4	X	PPA_PL_CRC_ERR: PayLoad CRC Error. Set when a packet that was processed by PPA had a payload CRC error.
3	X	PPA_SL_PKT_DROPPED: Short Line Packet Dropped. Set when an incoming packet gets dropped because the input FIFO level reaches CSI_A_SKIP_PACKET_THRESHOLD when padding a short line.

Bit	Reset	Description
2	X	PPA_SL_PROCESSED: Short Line Processed. Set when a line with a payload that is shorter than its packet header word count processed by PPA.
1	X	PPA_ILL_WD_CNT: Illegal Word Count. Set when a line with a word count that does not generate an integer number of pixels (unused bytes at the end of payload) is processed by PPA.
0	X	PPA_HDR_ERR_COR: Header Error Corrected. Set when a packet that was processed by PPA has a single bit header error. This error will be detected by the headers ECC, and corrected by it if header error correction is enabled (CSI_A_HEADER_EC_ENABLE = 0). This flag will be set and the packet will be processed even if the error is not corrected.

29.16.80 CSI1_CSI_SW_SENSOR_A_RESET_0

Offset: 0x416 | Byte Offset: 0x1058 | Read/Write: R/W | Reset: 0x00000000 (0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx0)

Bit	Reset	Description
0	0x0	CSI_SENSOR_A_RESET: Reset CSI sensor A

29.16.81 CSI1_INPUT_STREAM_B_CONTROL_0

CSI Input Stream B Control

CSI PPB group

Offset: 0x41b | Byte Offset: 0x106c | Read/Write: R/W | Reset: 0x00ff0004 (0bxxxxxxx011111111xxxxxxxxxx0x100)

Bit	Reset	Description
24:16	0xff	CSI_B_SKIP_PACKET_THRESHOLD: CSI-B Skip Packet Threshold. This value is compared against the internal FIFO that buffers the input streams. A packet will be skipped (discarded) if the pixel stream processor is busy (probably due to padding process of a short line) and the number of entries in the internal FIFO exceeds this threshold value. Note that each entry in the internal FIFO buffer is four bytes. To turn off this feature, set the value to its maximum value (all ones).
4	0x0	CSI_B_SKIP_PACKET_THRESHOLD_ENABLE: 0 = DISABLE: Skip packet feature is disabled. 1 = ENABLE: Enables skip packet threshold feature. Skip packet feature is enabled.
2	0x1	CSI_B_BYPASS_ALIGN: Bypass aligning CSIB lanes if valids for the lanes are out of sync by a cycle
1:0	0x0	CSI_B_DATA_LANE: CSI-B Data Lane 0= 1 data lane 1= 2 data lanes 2= 3 data lanes (not supported) 3= 4 data lanes (not supported) Note: 3 data lanes is not supported in Test Pattern Generation mode

29.16.82 CSI1_PIXEL_STREAM_B_CONTROL0_0

CSI Pixel Stream A Control 0

Offset: 0x41c | Byte Offset: 0x1070 | Read/Write: R/W | Reset: 0xXXXX01X0 (0bxxxxxxxxxxxxxxxxxxxxxxxx1xxxxx000)

Bit	Reset	Description
29:28	X	CSI_PPB_PAD_FRAME: CSI Pixel Parser B Pad Frame. This specifies how to deal with frames that are shorter (fewer lines) than expected. Short frames are usually caused by line packets being dropped because of packet errors. Expected frame height is specified in PPB_EXP_FRAME_HEIGHT. To do padding the value in CSI_PPB_WORD_COUNT needs to be set to the number of input bytes in each lines payload. 0 = PAD0S: Lines of all zeros will be used to pad out frames that are shorter than expected height. PPB_EXP_FRAME_HEIGHT must be programmed to an appropriate value if this field is set to PAD0S. 1 = PAD1S: Lines of all ones will be used to pad out frames that are shorter than expected height. PPB_EXP_FRAME_HEIGHT must be programmed to an appropriate value if this field is set to PAD1S. 2 = NOPAD: Short frames will not be padded out.

Bit	Reset	Description
27	X	CSI_PPB_HEADER_EC_ENABLE: CSI Pixel Parser B Packet Header Error Correction Enable. This parameter specifies whether single bit errors in the packet header will be automatically corrected, or not. 0 = ENABLE: Single bit errors in the header will be automatically corrected. 1 = DISABLE: Single bit errors in the header will not be corrected. Header ECC check will still set header ECC status bits and the packet will be processed by Pixel Parser B. DISABLE should not be used when processing interleaved streams (Same stream going to both PPA and PPB).
25:24	X	CSI_PPB_PAD_SHORT_LINE: CSI Pixel Parser B Pad Short Line. This specifies how to deal with shorter than expected line (the number of bytes received is less than the specified word count) 0 = PAD0S: short line is padded by pixel of zeros such that the expected number of output pixels is correct. Due to the time required to do the padding, subsequent line packet maybe discarded and therefore may cause a short frame (total number of lines per frame is less than expected). 1 = PAD1S: short line is padded by pixel of ones such that the expected number of output pixels is correct. Due to the time required to do the padding, subsequent line packet maybe discarded and therefore may cause a short frame (total number of lines per frame is less than expected). 2 = NOPAD: short line is not padded (will output less pixels than expected). This option is not recommended and may cause other modules that receive CSI output stream to hang up.
21:20	X	CSI_PPB_EMBEDDED_DATA_OPTIONS: CSI Pixel Parser B Embedded Data Options. This specifies how to deal with embedded data within the specified input stream assuming that the CSI_PPB_DATA_TYPE is not embedded data and assuming that embedded data is not already processed by another CSI pixel stream processor. 0 = DISCARD: discard (throw away) embedded data 1 = EMBEDDED: output embedded data as 8-bpp arbitrary data stream
19:16	X	CSI_PPB_OUTPUT_FORMAT_OPTIONS: CSI Pixel Parser B Output Format Options. This parameter specifies output data format. 0 = ARBITRARY: Output as 8-bit arbitrary data stream This may be used for compressed JPEG stream 1 = PIXEL: Output the normal 1 pixel/clock. Undefined LS color bits for RGB_666, RGB_565, RGB_555, and RGB_444, will be zeroed. 2 = PIXEL_REP: Same as PIXEL except MS color bits, for RGB_666, RGB_565, RGB_555, and RGB_444, will be replicated to their undefined LS bits. 3 = STORE: Output for storing RAW data to memory through ISP. Undefined LS color bits for RGB_666, RGB_565, RGB_555, and RGB_444, will be zeroed.
8	0x1	CSI_PPB_WC_CHECK: CSI Pixel Parser B Data WC Check. This parameter specifies whether the wordcount is checked. 0 = DISABLE: Word count Check is disabled 1 = ENABLE: Word count Check is enabled.
7	X	CSI_PPB_CRC_CHECK: CSI Pixel Parser B Data CRC Check. This parameter specifies whether the last 2 bytes of packet should be treated as CRC checksum and used to perform CRC check on the payload data. Note that in case there are 2 bytes of data CRC at the end of the packet, the packet word count does not include the CRC bytes. 0 = DISABLE: Data CRC Check is disabled regardless of whether there are CRC checksum at the end of the packet. 1 = ENABLE: Data CRC Check is enabled.
6	X	CSI_PPB_WORD_COUNT_SELECT: CSI Pixel Parser B Word Count Select. This parameter is effective only if the packet header is sent as part of the stream. 0 = REGISTER: Word Count in packet header is ignored and the number of bytes per line/packet is specified by CSI_PPB_WORD_COUNT. Payload CRC check will not be valid if the word count in CSI_PPB_WORD_COUNT is different than the count in the packet header. Interlaced support relies on frame number and will not work in REGISTER mode. 1 = HEADER: The number of bytes per line is to be extracted from Word Count field in the packet header. Note that if the serial link is not error free, programming this bit to HEADER may be dangerous because the word count information in the header may be corrupted. It is recommended to always program this bit to HEADER.
5	X	CSI_PPB_DATA_IDENTIFIER: CSI Pixel Parser B Data Identifier (DI) byte processing. This parameter is effective only if packet header is sent as part of the stream. 0 = DISABLED: Disabled - Data Identifier byte in packet header should be ignored (not checked against CSI_PPB_DATA_TYPE and against CSI_PPB_VIRTUAL_CHANNEL_ID). In this case, CSI_PPB_DATA_TYPE specifies the stream data format. 1 = ENABLED: Enabled - Data Identifier byte in packet header should be compared against the CSI_PPB_DATA_TYPE and the CSI_PPB_VIRTUAL_CHANNEL_ID.
4	X	CSI_PPB_PACKET_HEADER: CSI Pixel Parser B Packet Header processing. This specifies whether packet header is sent in the beginning of packet or not. 0 = NOT_SENT: Packet header is not sent. This setting should not be used if the stream source is CSI Interface A or B. Unless CSI-A, or CSI-B, is operating in a stream capture debug mode. In this case, CSI_PPB_DATA_TYPE specifies the stream data format and the number of bytes per line/packet is specified by CSI_PPB_WORD_COUNT. This implies that a packet footer is also not sent. In this case, no packet footer CRC check should be performed. 1 = SENT: Packet header is sent. This setting should be used if the stream source is CSI Interface A or B.

Bit	Reset	Description
2:0	0x0	CSI_PPB_STREAM_SOURCE: CSI Pixel Parser B Stream Source CSI Interface B 0 = CSI_A: CSI Interface A 1 = CSI_B

29.16.83 CSI1_PIXEL_STREAM_B_CONTROL1_0

CSI Pixel Stream B Control 1

Offset: 0x41d | Byte Offset: 0x1074 | Read/Write: R/W | Reset: 0x00000000 (0bxxxxxxxxxxxxxxxxxxxxxxxxx00000000)

Bit	Reset	Description
7:4	0x0	CSI_PPB_TOP_FIELD_FRAME_MASK: CSI Pixel Parser B Top Field Frame Mask
3:0	0x0	CSI_PPB_TOP_FIELD_FRAME: CSI Pixel Parser B Top Field Frame. This parameter specifies the frame number for top field detection for interlaced input video stream. Top Field is indicated when each of the least significant four bits of the frame number that has a one in its mask bit matches the corresponding bit in this parameter. In other words, Top Field is detected when the bitwise OR of ~(CSI_PPB_TOP_FIELD_FRAME ^ <frame number>) & CSI_PPB_TOP_FIELD_FRAME_MASK is one. Frame Number is taken from the WC field of the Frame Start short packet. Due to the reliance on WC field in packet header, interlaced support will not work if WC is selected from REGISTER mode.

29.16.84 CSI1_PIXEL_STREAM_B_GAP_0

CSI Pixel Stream B Gap

Offset: 0x41e | Byte Offset: 0x1078 | Read/Write: R/W | Reset: 0x00000000 (0b00000000000000000000000000000000)

Bit	Reset	Description
31:16	0x0	PPB_FRAME_MIN_GAP: Minimum number of viclk cycles from end of frame (Video_control = EF) to start of next frame (Video_control = SF). This parameter ensures that minimum V-blank time requirement of VI/ISP is satisfied. This field takes effect only when the frame gap of the input stream is less than the specified value.
15:0	0x0	PPB_LINE_MIN_GAP: Minimum number of viclk cycles from end of previous line (Video_control = EL_DATA) to start of next line (Video_control = SL). This parameter ensures that minimum H-blank time requirement of VI/ISP is satisfied. This field takes effect only when the line gap of the input stream is less than the specified value.

29.16.85 CSI1_PIXEL_STREAM_PPB_COMMAND_0

CSI Pixel Parser B Command

Offset: 0x41f | Byte Offset: 0x107c | Read/Write: R/W | Reset: 0x0000XXX4 (0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxx100)

Bit	Reset	Description
15:12	X	CSI_PPB_START_MARKER_FRAME_MAX: CSI Pixel Parser B Start Marker Maximum. Start Frame is indicated when Minimum condition above is met and the least significant four bits of the frame number are less than or equal to this value.
11:8	X	CSI_PPB_START_MARKER_FRAME_MIN: CSI Pixel Parser B Start Marker Minimum. Start Frame is indicated when Maximum condition below is met and the least significant four bits of the frame number are greater than or equal to this value.
4	X	CSI_PPB_VSYNC_START_MARKER: CSI Pixel Parser B VSYNC Start Marker. 0 = FSPKT: Start of frame is indicated when a Frame Start short packet is received with a frame number whose least significant four bits are greater than or equal to CSI_PPB_START_MARKER_FRAME_MIN and less than or equal to CSI_PPB_START_MARKER_FRAME_MAX. When the input stream is from a CSI port, or from the host path, or from the VIP path and the data mode is PAYLOAD_ONLY, then this field may be programmed to FSPKT. 1 = VSYNC: Start of frame is indicated when VSYNC signal is received. When the input stream is from the VIP path and the data mode is PACKET, then this field may be programmed to VSYNC.
2	0x1	CSI_PPB_SINGLE_SHOT: CSI Pixel Parser B Single Shot Mode. Software should clear it along with disabling the CSI_PPB_ENABLE, once a frame is captured 0 = DISABLE 1 = ENABLE

Bit	Reset	Description
1:0	0x0	CSI_PPB_ENABLE: CSI Pixel Parser B Enable. This parameter controls CSI Pixel Parser B to start or stop receiving data. 0 = NOP: no operation 1 = ENABLE: enable at the next frame start as specified by the CSI Start Marker 2 = DISABLE: disable after current frame end and before next frame start. 3 = RST: reset (disable immediately). Enabling the pixel parser does not enable the corresponding input source to receive data. If pixel parser is enabled later than the corresponding input source, the CSI will keep on rejecting incoming stream, until it encounters a valid SF.

29.16.86 CSI1_PIXEL_STREAM_B_EXPECTED_FRAME_0

CSI Pixel Stream B Expected Frame

Offset: 0x420 | Byte Offset: 0x1080 | Read/Write: R/W | Reset: 0x0000XXX0 (0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx0)

Bit	Reset	Description
15:4	X	PPB_MAX_CLOCKS: Maximum Number of viclk clock cycles between line start requests. The value in this field is in terms of 256 viclk clock cycles.
0	0x0	PPB_ENABLE_LINE_TIMEOUT: When set to one enables checking of the time between start line requests from the Header Parser to CSI-PPB. A fake EF will be outputted by CSI-PPB if this time between line starts exceeds the value in MAX_CLOCKS_BETWEEN_LINES. Padding lines can be inserted before the fake EF, if the number of lines outputted, when the fake EF is generated is less than the expected frame height. The type of padding is specified using CSI_PPB_PAD_FRAME.

29.16.87 CSI1_CSI_PIXEL_PARSER_B_INTERRUPT_MASK_0

CSI Pixel Parser B Interrupt Mask

Offset: 0x421 | Byte Offset: 0x1084 | Read/Write: R/W | Reset: 0x00000000 (0bxxxxxxxxxxxxxxxxx0xx000000000000)

Bit	Reset	Description
14	0x0	HPB_UNC_HDR_ERR_INT_MASK: Interrupt Mask for HPB_UNC_HDR_ERR. 0 = DISABLED: Don't generate an interrupt when HPB_UNC_HDR_ERR is set. 1 = ENABLED: Generate an interrupt when HPB_UNC_HDR_ERR is set.
10	0x0	PPB_SPARE_STATUS_1_INT_MASK: Interrupt Mask for PPB_SPARE_STATUS_1. 0 = DISABLED: Don't generate an interrupt when PPB_SPARE_STATUS_1 is set. 1 = ENABLED: Generate an interrupt when PPB_SPARE_STATUS_1 is set.
9	0x0	PPB_INTERFRAME_LINE_INT_MASK: Interrupt Mask for PPB_INTERFRAME_LINE. 0 = DISABLED: Don't generate an interrupt when PPB_INTERFRAME_LINE is set. 1 = ENABLED: Generate an interrupt when PPB_INTERFRAME_LINE is set.
8	0x0	PPB_EXTRA_SF_INT_MASK: Interrupt Mask for PPB_EXTRA_SF. 0 = DISABLED: Don't generate an interrupt when PPB_EXTRA_SF is set. 1 = ENABLED: Generate an interrupt when PPB_EXTRA_SF is set.
7	0x0	PPB_SHORT_FRAME_INT_MASK: Interrupt Mask for PPB_SHORT_FRAME. 0 = DISABLED: Don't generate an interrupt when PPB_SHORT_FRAME is set. 1 = ENABLED: Generate an interrupt when PPB_SHORT_FRAME is set.
6	0x0	PPB_STMERR_INT_MASK: Interrupt Mask for PPB_STMERR. 0 = DISABLED: Don't generate an interrupt when PPB_STMERR is set. 1 = ENABLED: Generate an interrupt when PPB_STMERR is set.
5	0x0	PPB_FIFO_OVRF_INT_MASK: Interrupt Mask for PPB_FIFO_OVRF. 0 = DISABLED: Don't generate an interrupt when PPB_FIFO_OVRF is set. 1 = ENABLED: Generate an interrupt when PPB_FIFO_OVRF is set.
4	0x0	PPB_PL_CRC_ERR_INT_MASK: Interrupt Mask for PPB_PL_CRC_ERR. 0 = DISABLED: Don't generate an interrupt when PPB_PL_CRC_ERR is set. 1 = ENABLED: Generate an interrupt when PPB_PL_CRC_ERR is set.
3	0x0	PPB_SL_PKT_DROPPED_INT_MASK: Interrupt Mask for PPB_SL_PKT_DROPPED. 0 = DISABLED: Don't generate an interrupt when PPB_SL_PKT_DROPPED is set. 1 = ENABLED: Generate an interrupt when PPB_SL_PKT_DROPPED is set.
2	0x0	PPB_SL_PROCESSED_INT_MASK: Interrupt Mask for PPB_SL_PROCESSED. 0 = DISABLED: Don't generate an interrupt when PPB_SL_PROCESSED is set. 1 = ENABLED: Generate an interrupt when PPB_SL_PROCESSED is set.

Bit	Reset	Description
1	0x0	PPB_ILL_WD_CNT_INT_MASK: Interrupt Mask for PPB_ILL_WD_CNT. 0 = DISABLED: Don't generate an interrupt when PPB_ILL_WD_CNT is set. 1 = ENABLED: Generate an interrupt when PPB_ILL_WD_CNT is set.
0	0x0	PPB_HDR_ERR_COR_INT_MASK: Interrupt Mask for PPB_HDR_ERR_COR. 0 = DISABLED: Don't generate an interrupt when PPB_HDR_ERR_COR is set. 1 = ENABLED: Generate an interrupt when PPB_HDR_ERR_COR is set.

29.16.88 CSI1_CSI_PIXEL_PARSER_B_STATUS_0

Pixel Parser B Status

Offset: 0x422 | Byte Offset: 0x1088 | Read/Write: RO | Reset: 0x0000XXXX (0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx)

Bit	Reset	Description
14	X	HPB_UNC_HDR_ERR: Uncorrectable Header Error. Set when header parser B parses a header with a multi bit error. This error will be detected by the headers ECC, but can't be corrected.
10	X	PPB_SPARE_STATUS_1: PPB Spare Status bit. This bit will get set when Pixel Parser B has a line timeout. Line timeout needs to be enabled by setting PPB_ENABLE_LINE_TIMEOUT and programming PPB_MAX_CLOCKS for the MAX clocks between lines.
9	X	PPB_INTERFRAME_LINE: Set when CSI-PPB receives a request to output a line that is not in the active part of the frame output. That is after EF and before SF, or before start marker is found. The interframe line will not be outputted by the Pixel Parser.
8	X	PPB_EXTRA_SF: Set when CSI-PPB receives a SF when it is expecting an EF. This happens when the EF of the frame gets corrupted before arriving to the CSI. CSI-PPB will insert a fake EF and drop the current frame with the Correct SF.
7	X	PPB_SHORT_FRAME: Set when CSI-PPB receives a short frame. This bit gets set even if CSI_PPB_PAD_FRAME specifies that short frames are to be padded to the correct line length.
6	X	PPB_STMERR: Stream Error. Set when the control output of PPB doesn't follow the correct sequence. The correct sequence for CSI is: SF -> (SL_DATA or EF), SL_DATA -> (DATA or EL_DATA), DATA -> EL_DATA, EL_DATA -> (SL_DATA or EF), EF -> SF. Stream Errors can be caused by receiving a corrupted stream.
5	X	PPB_FIFO_OVRF: FIFO Overflow. Set when the FIFO that is feeding packets to PPB overflows.
4	X	PPB_PL_CRC_ERR: PayLoad CRC Error. Set when a packet that was processed by PPB had a payload CRC error.
3	X	PPB_SL_PKT_DROPPED: Short Line Packet Dropped. Set when an incoming packet gets dropped because the input FIFO level reaches CSI_B_SKIP_PACKET_THRESHOLD when padding a short line.
2	X	PPB_SL_PROCESSED: Short Line Processed. Set when a line with a payload that is shorter than its packet header word count is processed by PPB.
1	X	PPB_ILL_WD_CNT: Illegal Word Count. Set when a line with a word count that doesn't generate an integer number of pixels (unused bytes at the end of payload) is processed by PPB.
0	X	PPB_HDR_ERR_COR: Header Error Corrected. Set when a packet that was processed by PPB has a single bit header error. This error will be detected by the headers ECC, and corrected by it if header error correction is enabled (CSI_B_HEADER_EC_ENABLE = 0). This flag will be set and the packet will be processed even if the error is not corrected.

29.16.89 CSI1_CSI_SW_SENSOR_B_RESET_0

Offset: 0x423 | Byte Offset: 0x108c | Read/Write: R/W | Reset: 0x00000000 (0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx0)

Bit	Reset	Description
0	0x0	CSI_SENSOR_B_RESET: Reset CSI sensor B

29.16.90 CSI1_PHY_CIL_COMMAND_0

CSI Phy and CIL Command

CSI CIL group

Offset: 0x442 | Byte Offset: 0x1108 | Read/Write: R/W | Reset: 0x00000000 (0bxxxxxxxxxxxxxxxxxxxxxxxx00xxxxxx00)

Bit	Reset	Description
9:8	0x0	CSI_B_PHY_CIL_ENABLE: CSI B Phy and CIL Enable. This parameter controls CSI B Phy and CIL receiver to start or stop receiving data. 0 = NOP: no operation 1 = ENABLE: enable 2 = DISABLE: disable (reset)
1:0	0x0	CSI_A_PHY_CIL_ENABLE: CSI A Phy and CIL Enable. This parameter controls CSI A Phy and CIL receiver to start or stop receiving data. 0 = NOP: no operation 1 = ENABLE: enable 2 = DISABLE: disable (reset)

29.16.91 CSI1_CIL_PAD_CONFIG0_0

CIL Pad Configuration 0

Offset: 0x443 | Read/Write: R/W | Reset: 0x00000000 (0bxxxxxxxxxxxxxxxx00000000xxxxxxxx)

Bit	Reset	Description
15:8	0x0	PAD_CIL_SPARE: Spare bit for CIL BIAS Config. PAD_CIL_SPARE[7] is used to flush VI's Y-FIFO when it is being used as a stream source for one of the Pixel Parsers. Setting PAD_CIL_SPARE[7] to 1 will hold vi2csi_host_stall low, which will force VI's Y-FIFO to be purged. PAD_CIL_SPARE[7] must be low for the pixel parser to receive source data from VI's Y-FIFO.

29.16.92 CSI1_CILA_PAD_CONFIG0_0

CIL-A Pad Configuration 0

CSI CILA group

Offset: 0x44b | Byte Offset: 0x112c | Read/Write: R/W | Reset: 0x00010007 (0b0000x000000000010000x000x0000111)

Bit	Reset	Description
31	0x0	PAD_CILA_E_TXBW: 0 = default to enable VCLAMP regulator 1 = turn off regulator and short vclamp to VDDP. Will cause stress and need waiver to use.
30:28	0x0	PAD_CILA_SLEWDNADJ: Pull down slew rate adjust, default 000. From 000 -> 011, slew rate increases. 100 is the same as 000. From 100->111, skew rate decreases. This control is unused for CSI MIPI pads, which are receive only.
26:24	0x0	PAD_CILA_SLEWUPADJ: Pull up slew rate adjust, default 000. From 000 -> 011, slew rate increases. 100 is the same as 000. From 100->111, skew rate decreases. This control is unused for CSI MIPI pads, which are receive only.
23:21	0x0	PAD_CILA_LPDNADJ: Driver pull down impedance control. 00 -> 130ohm, default. 01 -> 110ohm. 10 -> 130ohm, same as 00. 11 -> 150ohm. This control is unused for CSI MIPI pads, which are receive only.
20:18	0x0	PAD_CILA_LPUPADJ: Driver pull up impedance control. 00 -> 130ohm, default. 01 -> 110ohm. 10 -> 130ohm, same as 00. 11 -> 150ohm. This control is unused for CSI MIPI pads, which are receive only
17:16	0x1	PAD_AB_BK_MODE: 00: Two independent 2x bricks. 01: one 4x brick, received clock from partition A is used. Clock from partition B is not used. 10: one 4x brick, received clock from partition B is used. Clock from partition A is not used. 11: illegal
15	0x0	PAD_CILA_BANDWD_IN: Increase bandwidth of differential receiver

29.16.94 CSI1_PHY_CILA_CONTROL0_0

CSI-A PHY and CIL Control

Offset: 0x44d | Byte Offset: 0x1134 | Read/Write: R/W | Reset: 0x00000002 (0bxxxxxxxxxxxxxxxxxx000000x0000010)

Bit	Reset	Description
13:8	0x0	CILA_CLK_SETTLE: settle time for clk lane when moving from LP to HS (LP11->LP01->LP00), this setting determines how many csicil clock cycles (72 MHz lp clock cycles) to wait after LP00. Hardware uses an internal delay of ~15 csicil cycles for the default value. So the programming value (0 to 15) of this field works like this: 0 = 15 cilclk cycles (default internal delay) 1 = 15 - 7 (8 cilclk cycles) 2 = 15 - 6 (9 cilclk cycles) . . 7 = 15 - 1 (14 cilclk cycles) 8 = 15 - 0 (default internal delay) 9 = 15 + 1 (16 cilclk cycles) . 57 = 15 + 49 (64 cilclk cycles)
6	0x0	CILA_BYPASS_LP_SEQ: The LP signals should sequence through LP11->LP01->LP00 states, to indicate to CLOCK CIL about the mode switching to HS Rx mode. In case the camera is enabled earlier than CIL , it is highly likely that the camera sends this control sequence sooner than CIL can detect it. Enabling this bit allows the CLOCK CIL to overlook the LP control sequence and step in HS Rx mode directly looking at LP00 only.
5:0	0x2	CILA_THS_SETTLE: settle time for data lane when moving from LP to HS (LP11->LP01->LP00), this setting determines how many CSICIL clock cycles (102 MHz LP clock cycles) to wait, after LP00, before starting to look at the data. 0xF is an illegal value for this field. 85ns + 6 * UI < (Ths-settle-programmed + 5) * csicil_clk_period < 145ns + 10 * UI

29.16.96 CSI1_CSI_CIL_A_STATUS_0

CSI Control and Interface Logic A Status

Each status bit is cleared to zero when its bit position is written with one. For example writing 0x2 to CSI_CIL_A_STATUS will clear only CILA_SOT_MB_ERR.

Offset: 0x44f | Byte Offset: 0x113c | Read/Write: RO | Reset: 0x000000XX (0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx)

Bit	Reset	Description
6	X	CILA_ESC_DATA_REC: Escape Mode Data Received. Set when CIL-A receives an Escape Mode Data byte. The Data Byte can be read from bits 7-0 of ESCAPE_MODE_DATA. This status bit will also be cleared when CILA_ESC_CMD_REC is set.
5	X	CILA_ESC_CMD_REC: Escape Mode Command Received. Set when CIL-A receives an Escape Mode Command byte. The Command Byte can be read from bits 7-0 of ESCAPE_MODE_COMMAND.
4	X	CILA_CTRL_ERR: Control Error. Set when CIL-A detects LP state 01 or 10 followed by a stop state (LP11) instead of transitioning into the Escape mode or Turn Around mode (LP00).
2	X	CILA_SYNC_ESC_ERR: Sync Escape Error. Set when CIL-A detects that the wrong (non-multiple of 8) number of bits have been received for an Escape Command or Data Byte.
1	X	CILA_SOT_MB_ERR: Start of Transmission Multi Bit Error. Set when CIL-A detects a multi bit start of transmission byte error in one of the packets SOT bytes. The packet will be discarded.
0	X	CILA_SOT_SB_ERR: Start of Transmission Single Bit Error. Set when CIL-A detects a single bit error in one of the packet’s Start of Transmission bytes. The packet will be sent to the CSI-A for processing.

29.16.97 CSI1_CSI_CILA_STATUS_0

CSI-CILA Control and Interface Logic Status

Each status bit is cleared to zero when its bit position is written with one. For example, writing 0x2 to CSI_CIL_STATUS will clear only SOT_MB_ERR.

Offset: 0x450 | Byte Offset: 0x1140 | Read/Write: RO | Reset: 0x000X00XX (0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx)

Bit	Reset	Description
18	X	CILA_DATA_LANE1_CTRL_ERR: Control Error. Set when CIL-A detects LP state 01 or 10 followed by a stop state (LP11) instead of transitioning
17	X	CILA_DATA_LANE1_SOT_MB_ERR: Start of Transmission Multi Bit Error. Set when CIL-A detects a multi bit start of transmission byte error in one of the packets SOT bytes on data lane-1. The packet will be discarded.
16	X	CILA_DATA_LANE1_SOT_SB_ERR: Start of Transmission Single Bit Error. Set when CIL-A detects a single bit error in one of the packets Start of Transmission bytes on data lane-1. The packet will be sent to the CSI-A for processing.
6	X	CILA_DATA_LANE0_CTRL_ERR: Control Error. Set when CIL-A detects LP state 01 or 10 followed by a stop state (LP11) instead of transitioning

Bit	Reset	Description
5	X	CILA_DATA_LANE0_SOT_MB_ERR: Start of Transmission Multi Bit Error. Set when CIL-A detects a multi bit start of transmission byte error in one of the packets SOT bytes on data lane-0. The packet will be discarded.
4	X	CILA_DATA_LANE0_SOT_SB_ERR: Start of Transmission Single Bit Error. Set when CIL-A detects a single bit error in one of the packets Start of Transmission bytes on data lane-0. The packet will be sent to the CSI-A for processing.
0	X	CILA_CLK_LANE_CTRL_ERR: Control Error. Set when CIL-A detects incorrect line state sequence on clk lane

29.16.98 CSI1_CIL_A_ESCAPE_MODE_COMMAND_0

Escape Mode Command

This register is used to receive escape mode command bytes from CIL-A.

Offset: 0x451 | Byte Offset: 0x1144 | Read/Write: RO | Reset: 0x000000XX (0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx)

Bit	Reset	Description
7:0	X	CILA_ESC_CMD_BYTE: CIL-A Escape Mode Command Byte. This is the 8 bit entry command that was received, by CIL-A, during the last escape Mode sequence. CIL-A monitors Byte Lane 0, only, for escape mode sequences. This command byte can only be assumed to be valid when CILA_ESC_CMD_REC status bit is set.

29.16.99 CSI1_CIL_A_ESCAPE_MODE_DATA_0

Escape Mode Data

This register is used to receive escape mode data bytes from CIL-A.

Offset: 0x452 | Byte Offset: 0x1148 | Read/Write: RO | Reset: 0x000000XX (0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx)

Bit	Reset	Description
7:0	X	CILA_ESC_DATA_BYTE: CIL-A Escape Mode Data Byte. When read this field returns the last Escape Mode Data byte that was received by CIL-A. Escape Mode Data bytes are the bytes that are received in Escape Mode after receiving the Escape Mode Command. These bytes can be used to implement MIPI's CSI Specs Low Power Data Transmission. This field is only valid when the status bit, CILA_ESC_DATA_REC, is set, and will be overwritten by the next Escape Mode data byte if not read before the next byte comes in.

29.16.100 CSI1_CSICIL_SW_SENSOR_A_RESET_0

29.16.105 CSI1_CSI_CIL_B_STATUS_0

CSI Control and Interface Logic B Status

Each status bit is cleared to zero when its bit position is written with one. For example, writing 0x2 to CSI_CIL_B_STATUS will clear only CILB_SOT_MB_ERR.

Offset: 0x45c | Byte Offset: 0x1170 | Read/Write: RO | Reset: 0x000000XX (0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx)

Bit	Reset	Description
6	X	CILB_ESC_DATA_REC: Escape Mode Data Received. Set when CIL-B receives an Escape Mode Data byte. The Data Byte can be read from bits 23-16 of ESCAPE_MODE_DATA. This status bit will also be cleared when CILB_ESC_CMD_REC is set.
5	X	CILB_ESC_CMD_REC: Escape Mode Command Received. Set when CIL-B receives an Escape Mode Command byte. The Command Byte can be read from bits 23-16 of ESCAPE_MODE_COMMAND.
4	X	CILB_CTRL_ERR: Control Error. Set when CIL-B detects LP state 01 or 10 followed by a stop state (LP11) instead of transitioning into the Escape mode or Turn Around mode (LP00).
2	X	CILB_SYNC_ESC_ERR: Sync Escape Error. Set when CIL-B detects that the wrong (non-multiple of 8) number of bits have been received for an Escape Command or Data Byte.
1	X	CILB_SOT_MB_ERR: Start of Transmission Multi Bit Error. Set when CIL-B detects a multi bit start of transmission byte error in one of the packets SOT bytes. The packet will be discarded.
0	X	CILB_SOT_SB_ERR: Start of Transmission Single Bit Error. Set when CIL-B detects a single bit error in one of the packets start of transmission bytes. The packet will be sent to CSI-B for processing.

29.16.106 CSI1_CSI_CILB_STATUS_0

CSI-CILB Control and Interface Logic Status

Each status bit is cleared to zero when its bit position is written with one. For example, writing 0x2 to CSI_CIL_STATUS will clear only SOT_MB_ERR.

Offset: 0x45d | Byte Offset: 0x1174 | Read/Write: RO | Reset: 0x000X00XX (0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx)

Bit	Reset	Description
18	X	CILB_DATA_LANE1_CTRL_ERR: Control Error. Set when CIL-B detects LP state 01 or 10 followed by a stop state (LP11) instead of transitioning

Bit	Reset	Description
17	X	CILB_DATA_LANE1_SOT_MB_ERR: Start of Transmission Multi Bit Error. Set when CIL-B detects a multi bit start of transmission byte error in one of the packets SOT bytes on data lane-1. The packet will be discarded.
16	X	CILB_DATA_LANE1_SOT_SB_ERR: Start of Transmission Single Bit Error. Set when CIL-A detects a single bit error in one of the packets Start of Transmission bytes on data lane-1. The packet will be sent to the CSI-B for processing.
6	X	CILB_DATA_LANE0_CTRL_ERR: Control Error. Set when CIL-B detects LP state 01 or 10 followed by a stop state (LP11) instead of transitioning
5	X	CILB_DATA_LANE0_SOT_MB_ERR: Start of Transmission Multi Bit Error. Set when CIL-B detects a multi bit start of transmission byte error in one of the packets SOT bytes on data lane-0. The packet will be discarded.
4	X	CILB_DATA_LANE0_SOT_SB_ERR: Start of Transmission Single Bit Error. Set when CIL-B detects a single bit error in one of the packets Start of Transmission bytes on data lane-0. The packet will be sent to the CSI-B for processing.
0	X	CILB_CLK_LANE_CTRL_ERR: Control Error. Set when CIL-B detects incorrect line state sequence on clk lane

29.16.107 CSI1_CIL_B_ESCAPE_MODE_COMMAND_0

Escape Mode Command

This register is used to receive escape mode command bytes from CIL-B.

Offset: 0x45e | Byte Offset: 0x1178 | Read/Write: RO | Reset: 0x000000XX (0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx)

Bit	Reset	Description
7:0	X	CILB_ESC_CMD_BYTE: CIL-B Escape Mode Command Byte. This is the 8 bit entry command that was received, by CIL-B, during the last escape Mode sequence. CIL-B monitors Byte Lane 0, only, for escape mode sequences. This command byte can only be assumed to be valid when CILB_ESC_CMD_REC status bit is set.

29.16.108 CSI1_CIL_B_ESCAPE_MODE_DATA_0

Escape Mode Data

This register is used to receive escape mode data bytes from CIL-B.

Offset: 0x45f | Byte Offset: 0x117c | Read/Write: RO | Reset: 0x000000XX (0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx)

Bit	Reset	Description
7:0	X	CILB_ESC_DATA_BYTE: CIL-A Escape Mode Data Byte. When read, this field returns the last Escape Mode Data byte that was received by CIL-B. Escape Mode Data bytes are the bytes that are received in Escape Mode after receiving the Escape Mode Command. These bytes can be used to implement MIPI's CSI Specs Low Power Data Transmission. This field is only valid when the status bit, CILB_ESC_DATA_REC, is set, and will be overwritten by the next Escape Mode data byte if not read before the next byte comes in.

29.16.138 CSI2_INPUT_STREAM_A_CONTROL_0

CSI Input Stream A Control

CSI PPA group

Offset: 0x60e | Byte Offset: 0x1838 | Read/Write: R/W | Reset: 0x00ff0004 (0bxxxxxxx011111111xxxxxxxxxx0x100)

Bit	Reset	Description
24:16	0xff	CSI_A_SKIP_PACKET_THRESHOLD: CSI-A Skip Packet Threshold. This value is compared against the internal FIFO that buffers the input streams. A packet will be skipped (discarded) if the pixel stream processor is busy (probably due to padding process of a short line) and the number of entries in the internal FIFO exceeds this threshold value. Note that each entry in the internal FIFO buffer is four bytes. To turn off this feature, set the value to its maximum value (all ones).
4	0x0	CSI_A_SKIP_PACKET_THRESHOLD_ENABLE: Enables skip packet threshold feature. 0 = DISABLE: Skip packet feature is disabled. 1 = ENABLE: Skip packet feature is enabled.

Bit	Reset	Description
2	0x1	CSI_A_BYPASS_ALIGN: Bypass aligning CSIA and CSIB lanes if valids for the lanes are out of sync by a cycle
1:0	0x0	CSI_A_DATA_LANE: CSI-A Data Lane 0= 1 data lane 1= 2 data lanes 2= 3 data lanes 3= 4 data lanes Note: 3 data lanes is not supported in Test Pattern Generation mode

29.16.139 CSI2_PIXEL_STREAM_A_CONTROL0_0

CSI Pixel Stream A Control 0

Offset: 0x60f | Byte Offset: 0x183c | Read/Write: R/W | Reset: 0xXXXX01X0 (0bxxxxxxxxxxxxxxxxxxxxxxxx1xxxxx000)

Bit	Reset	Description
29:28	X	CSI_PPA_PAD_FRAME: CSI Pixel Parser A Pad Frame. This specifies how to deal with frames that are shorter (fewer lines) than expected. Short frames are usually caused by line packets being dropped because of packet errors. Expected frame height is specified in PPA_EXP_FRAME_HEIGHT. To do padding, the value in CSI_PPA_WORD_COUNT needs to be set to the number of input bytes in each line's payload. 0 = PAD0S: Lines of all zeros will be used to pad out frames that are shorter than expected height. PPA_EXP_FRAME_HEIGHT must be programmed to an appropriate value if this field is set to PAD0S. 1 = PAD1S: Lines of all ones will be used to pad out frames that are shorter than expected height. PPA_EXP_FRAME_HEIGHT must be programmed to an appropriate value if this field is set to PAD1S. 2 = NOPAD: Short frames will not be padded out.
27	X	CSI_PPA_HEADER_EC_ENABLE: CSI Pixel Parser A Packet Header Error Correction Enable. This parameter specifies whether single bit errors in the packet header will be automatically corrected, or not. 0 = ENABLE: Single bit errors in the header will be automatically corrected. 1 = DISABLE: Single bit errors in the header will not be corrected. Header ECC check will still set header ECC status bits and the packet will be processed by Pixel Parser A. DISABLE should not be used when processing interleaved streams (Same stream going to both PPA and PPB).
25:24	X	CSI_PPA_PAD_SHORT_LINE: CSI Pixel Parser A Pad Short Line. This specifies how to deal with shorter than expected line (the number of bytes received is less than the specified word count) 0 = PAD0S: short line is padded by pixel of zeros such that the expected number of output pixels is correct. Due to the time required to do the padding, subsequent line packet maybe discarded and therefore may cause a short frame (total number of lines per frame is less than expected). 1 = PAD1S: short line is padded by pixel of ones such that the expected number of output pixels is correct. Due to the time required to do the padding, subsequent line packet maybe discarded and therefore may cause a short frame (total number of lines per frame is less than expected). 2 = NOPAD: short line is not padded (will output less pixels than expected). This option is not recommended and may cause other modules that receives CSI output stream to hang up.
21:20	X	CSI_PPA_EMBEDDED_DATA_OPTIONS: CSI Pixel Parser A Embedded Data Options. This specifies how to deal with embedded data within the specified input stream assuming that the CSI_PPA_DATA_TYPE is not embedded data and assuming that embedded data is not already processed by other CSI pixel stream processor. 1 = EMBEDDED: output embedded data as 8-bpp arbitrary data stream. 0 = DISCARD: discard (throw away) embedded data
19:16	X	CSI_PPA_OUTPUT_FORMAT_OPTIONS: CSI Pixel Parser A Output Format Options. This parameter specifies options for output data format. 0 = ARBITRARY: Output as 8-bit arbitrary data stream This may be used for compressed JPEG stream 1 = PIXEL: Output the normal 1 pixel/clock. Undefined LS color bits for RGB_666, RGB_565, RGB_555, and RGB_444, will be zeroed. 2 = PIXEL_REP: Same as PIXEL except MS color bits, for RGB_666, RGB_565, RGB_555, and RGB_444, will be replicated to their undefined LS bits. 3 = STORE: Output for storing RAW data to memory through ISP. Undefined LS color bits for RGB_666, RGB_565, RGB_555, and RGB_444, will be zeroed.
8	0x1	CSI_PPA_WC_CHECK: CSI Pixel Parser A Data WC Check. This parameter specifies whether the wordcount is checked. 0 = DISABLE: Word count Check is disabled 1 = ENABLE: Word count Check is enabled.

Bit	Reset	Description
7	X	CSI_PPA_CRC_CHECK: CSI Pixel Parser A Data CRC Check. This parameter specifies whether the last 2 bytes of the packet should be treated as CRC checksum and used to perform CRC check on the payload data. Note that in case there are 2 bytes of data CRC at the end of the packet, the packet word count does not include the CRC bytes. 0 = DISABLE: Data CRC Check is disabled regardless of whether there are CRC checksum at the end of the packet. 1 = ENABLE: Data CRC Check is enabled.
6	X	CSI_PPA_WORD_COUNT_SELECT: CSI Pixel Parser A Word Count Select. This parameter is effective only if packet header is sent as part of the stream. 0 = REGISTER: Word Count in packet header is ignored and the number of bytes per line/packet is specified by CSI_PPA_WORD_COUNT. Payload CRC check will not be valid if the word count in CSI_PPA_WORD_COUNT is different than the count in the packet header. Interlaced support relies on frame number and will not work in REGISTER mode. 1 = HEADER: The number of bytes per line is to be extracted from Word Count field in the packet header. Note that if the serial link is not error free, programming this bit to HEADER may be dangerous because the word count information in the header may be corrupted. It is recommended to always program this bit to HEADER.
5	X	CSI_PPA_DATA_IDENTIFIER: CSI Pixel Parser A Data Identifier (DI) byte processing. This parameter is effective only if packet header is sent as part of the stream. 0 = DISABLED: Disabled - Data Identifier byte in packet header should be ignored (not checked against CSI_PPA_DATA_TYPE and against CSI_PPA_VIRTUAL_CHANNEL_ID). In this case, CSI_PPA_DATA_TYPE specifies the stream data format. 1 = ENABLED: Enabled - Data Identifier byte in packet header should be compared against the CSI_PPA_DATA_TYPE and the CSI_PPA_VIRTUAL_CHANNEL_ID.
4	X	CSI_PPA_PACKET_HEADER: CSI Pixel Parser A Packet Header processing. This specifies whether packet header is sent in the beginning of packet or not. 0 = NOT_SENT: Packet header is not sent. This setting should not be used if the stream source is CSI Interface A or B. Unless CSI-A, or CSI-B, is operating in a stream capture debug mode. In this case, CSI_PPA_DATA_TYPE specifies the stream data format and the number of bytes per line/packet is specified by CSI_PPA_WORD_COUNT. This implies that a packet footer is also not sent. In this case, no packet footer CRC check should be performed. 1 = SENT: Packet header is sent. This setting should be used if the stream source is CSI Interface A or B.
2:0	0x0	CSI_PPA_STREAM_SOURCE: CSI Pixel Parser A Stream Source 0 = CSI_A: CSI Interface A 1 = CSI_B: CSI Interface B

29.16.140 CSI2_PIXEL_STREAM_A_CONTROL1_0

CSI Pixel Stream A Control 1

Offset: 0x610 | Byte Offset: 0x1840 | Read/Write: R/W | Reset: 0x00000000 (0bxxxxxxxxxxxxxxxxxxxxxxxx00000000)

Bit	Reset	Description
7:4	0x0	CSI_PPA_TOP_FIELD_FRAME_MASK: CSI Pixel Parser A Top Field Frame Mask
3:0	0x0	CSI_PPA_TOP_FIELD_FRAME: CSI Pixel Parser A Top Field Frame. This parameter specifies the frame number for top field detection for interlaced input video stream. Top Field is indicated when each of the least significant four bits of the frame number that has a one in its mask bit matches the corresponding bit in this parameter. In other words, Top Field is detected when the bitwise OR of ~(CSI_PPA_TOP_FIELD_FRAME ^ <frame number>) & CSI_PPA_TOP_FIELD_FRAME_MASK is one. Frame Number is taken from the WC field of the Frame Start short packet. Due to the reliance on WC field in packet header, interlaced support will not work if WC is selected from REGISTER mode.

29.16.141 CSI2_PIXEL_STREAM_A_GAP_0

CSI Pixel Stream A Gap

Offset: 0x611 | Byte Offset: 0x1844 | Read/Write: R/W | Reset: 0x00000000 (0b00000000000000000000000000000000)

Bit	Reset	Description
31:16	0x0	PPA_FRAME_MIN_GAP: Minimum number of viclk cycles from end of frame (Video_control = EF) to start of next frame (Video_control = SF). This parameter ensures that minimum V-blank time requirement of VI/ISP is satisfied. This field takes effect only when the frame gap of the input stream is less than the specified value.

Bit	Reset	Description
15:0	0x0	PPA_LINE_MIN_GAP: Minimum number of viclk cycles from end of previous line (Video_control = EL_DATA) to start of next line (Video_control = SL). This parameter ensures that minimum H-blank time requirement of VI/ISP is satisfied. This field takes effect only when the line gap of the input stream is less than the specified value.

29.16.142 CSI2_PIXEL_STREAM_PPA_COMMAND_0

CSI Pixel Parser A Command

Offset: 0x612 | Byte Offset: 0x1848 | Read/Write: R/W | Reset: 0x0000XXX4 (0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx100)

Bit	Reset	Description
15:12	X	CSI_PPA_START_MARKER_FRAME_MAX: CSI Pixel Parser A Start Marker Maximum. Start Frame is indicated when Minimum condition above is met and the least significant four bits of the frame number are less than or equal to this value.
11:8	X	CSI_PPA_START_MARKER_FRAME_MIN: CSI Pixel Parser A Start Marker Minimum. Start Frame is indicated when Maximum condition below is met and the least significant four bits of the frame number are greater than or equal to this value.
4	X	CSI_PPA_VSYNC_START_MARKER: CSI Pixel Parser A 0 = FSPKT: Start of frame is indicated when a Frame Start short packet is received with a frame number whose least significant four bits are greater than or equal to CSI_PPA_START_MARKER_FRAME_MIN and less than or equal to CSI_PPA_START_MARKER_FRAME_MAX. When the input stream is from a CSI port, or from the host path, or from the VIP path and the data mode is PAYLOAD_ONLY, then this field may be programmed to FSPKT. 1 = VSYNC: VSYNC Start Marker start of frame is indicated when VSYNC signal is received. When the input stream is from the VIP path and the data mode is PACKET, then this field may be programmed to VSYNC.
2	0x1	CSI_PPA_SINGLE_SHOT: CSI Pixel Parser A Single Shot Mode. Software should clear it along with disabling the CSI_PPA_ENABLE, once a frame is captured 0 = DISABLE 1 = ENABLE
1:0	0x0	CSI_PPA_ENABLE: CSI Pixel Parser A Enable. This parameter controls CSI Pixel Parser A to start or stop receiving data. 0 = NOP: no operation 1 = ENABLE: enable at the next frame start as specified by the CSI Start Marker 2 = DISABLE: disable after current frame end and before next frame start. 3 = RST: reset (disable immediately). Enabling the pixel parser does not enable the corresponding input source to receive data. If pixel parser is enabled later than the corresponding input source, the CSI will keep on rejecting incoming streams, until it encounters a valid SF.

29.16.143 CSI2_PIXEL_STREAM_A_EXPECTED_FRAME_0

CSI Pixel Stream A Expected Frame

Offset: 0x613 | Byte Offset: 0x184c | Read/Write: R/W | Reset: 0x0000XXX0 (0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx0)

Bit	Reset	Description
15:4	X	PPA_MAX_CLOCKS: Maximum Number of viclk clock cycles between line start requests. The value in this field is in terms of 256 viclk clock cycles.
0	0x0	PPA_ENABLE_LINE_TIMEOUT: When set to one enables checking of the time between start line requests from the Header Parser to CSI-PPA. A fake EF will be outputted by CSI-PPA if this time between line starts exceeds the value in MAX_CLOCKS_BETWEEN_LINES. Padding lines can be inserted before the fake EF, if the number of lines outputted, when the fake EF is generated is less than the expected frame height. The type of padding is specified using CSI_PPA_PAD_FRAME.

29.16.144 CSI2_CSI_PIXEL_PARSER_A_INTERRUPT_MASK_0

CSI Pixel Parser A Interrupt Mask

Offset: 0x614 | Byte Offset: 0x1850 | Read/Write: R/W | Reset: 0x00000000 (0bxxxxxxxxxxxxxxxxxx0xx000000000000)

Bit	Reset	Description
14	0x0	HPA_UNC_HDR_ERR_INT_MASK: Interrupt Mask for HPA_UNC_HDR_ERR. 0 = DISABLED: Don't generate an interrupt when HPA_UNC_HDR_ERR is set. 1 = ENABLED: Generate an interrupt when HPA_UNC_HDR_ERR is set.
10	0x0	PPA_SPARE_STATUS_1_INT_MASK: Interrupt Mask for PPA_SPARE_STATUS_1. 0 = DISABLED: Don't generate an interrupt when PPA_SPARE_STATUS_1 is set. 1 = ENABLED: Generate an interrupt when PPA_SPARE_STATUS_1 is set.
9	0x0	PPA_INTERFRAME_LINE_INT_MASK: Interrupt Mask for PPA_INTERFRAME_LINE. 0 = DISABLED: Don't generate an interrupt when PPA_INTERFRAME_LINE is set. 1 = ENABLED: Generate an interrupt when PPA_INTERFRAME_LINE is set.
8	0x0	PPA_EXTRA_SF_INT_MASK: Interrupt Mask for PPA_EXTRA_SF. 0 = DISABLED: Don't generate an interrupt when PPA_EXTRA_SF is set. 1 = ENABLED: Generate an interrupt when PPA_EXTRA_SF is set.
7	0x0	PPA_SHORT_FRAME_INT_MASK: Interrupt Mask for PPA_SHORT_FRAME. 0 = DISABLED: Don't generate an interrupt when PPA_SHORT_FRAME is set. 1 = ENABLED: Generate an interrupt when PPA_SHORT_FRAME is set.
6	0x0	PPA_STMERR_INT_MASK: Interrupt Mask for PPA_STMERR. 0 = DISABLED: Don't generate an interrupt when PPA_STMERR is set. 1 = ENABLED: Generate an interrupt when PPA_STMERR is set.
5	0x0	PPA_FIFO_OVRF_INT_MASK: Interrupt Mask for PPA_FIFO_OVRF. 0 = DISABLED: Don't generate an interrupt when PPA_FIFO_OVRF is set. 1 = ENABLED: Generate an interrupt when PPA_FIFO_OVRF is set.
4	0x0	PPA_PL_CRC_ERR_INT_MASK: Interrupt Mask for PPA_PL_CRC_ERR. 0 = DISABLED: Don't generate an interrupt when PPA_PL_CRC_ERR is set. 1 = ENABLED: Generate an interrupt when PPA_PL_CRC_ERR is set.
3	0x0	PPA_SL_PKT_DROPPED_INT_MASK: Interrupt Mask for PPA_SL_PKT_DROPPED. 0 = DISABLED: Don't generate an interrupt when PPA_SL_PKT_DROPPED is set. 1 = ENABLED: Generate an interrupt when PPA_SL_PKT_DROPPED is set.
2	0x0	PPA_SL_PROCESSED_INT_MASK: Interrupt Mask for PPA_SL_PROCESSED. 0 = DISABLED: Don't generate an interrupt when PPA_SL_PROCESSED is set. 1 = ENABLED: Generate an interrupt when PPA_SL_PROCESSED is set.
1	0x0	PPA_ILL_WD_CNT_INT_MASK: Interrupt Mask for PPA_ILL_WD_CNT. 0 = DISABLED: Don't generate an interrupt when PPA_ILL_WD_CNT is set. 1 = ENABLED: Generate an interrupt when PPA_ILL_WD_CNT is set.
0	0x0	PPA_HDR_ERR_COR_INT_MASK: Interrupt Mask for PPA_HDR_ERR_COR. 0 = DISABLED: Don't generate an interrupt when PPA_HDR_ERR_COR is set. 1 = ENABLED: Generate an interrupt when PPA_HDR_ERR_COR is set.

29.16.145 CSI2_CSI_PIXEL_PARSER_A_STATUS_0

Pixel Parser A Status

Each status bit is cleared to zero when its bit position is written with one. For example, writing 0x2 to CSI_PIXEL_PARSER_STATUS will clear only PPA_ILL_WD_CNT.

Offset: 0x615 | Byte Offset: 0x1854 | Read/Write: RO | Reset: 0x0000XXXX (0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx)

Bit	Reset	Description
14	X	HPA_UNC_HDR_ERR: Uncorrectable Header Error. Set when header parser A parses a header with a multi bit error. This error will be detected by the headers ECC, but can't be corrected. The packet will be discarded.
10	X	PPA_SPARE_STATUS_1: PPA Spare Status bit. This bit will get set when Pixel Parser A has a line timeout. Line timeout needs to be enabled by setting PPA_ENABLE_LINE_TIMEOUT and programming PPA_MAX_CLOCKS for the MAX clocks between lines.
9	X	PPA_INTERFRAME_LINE: Set when CSI-PPA receives a request to output a line that is not in the active part of the frame output. That is after EF and before SF, or before start marker is found. The interframe line will not be outputted by the Pixel Parser.

Bit	Reset	Description
8	X	PPA_EXTRA_SF: Set when CSI-PPA receives a SF when it is expecting an EF. This happens when EF of the frame gets corrupted before arriving CSI. CSI-PPA will insert a fake EF and the drop the current frame with Correct SF.
7	X	PPA_SHORT_FRAME: Set when CSI-PPA receives a short frame. This bit gets set even if CSI_PPA_PAD_FRAME specifies that short frames are to be padded to the correct line length.
6	X	PPA_STMERR: Stream Error. Set when the control output of PPA doesn't follow the correct sequence. The correct sequence for CSI is: SF -> (SL_DATA or EF), SL_DATA -> (DATA or EL_DATA), DATA -> EL_DATA, EL_DATA -> (SL_DATA or EF), EF -> SF. Stream Errors can be caused by receiving a corrupted stream.
5	X	PPA_FIFO_OVRF: FIFO Overflow. Set when the FIFO that is feeding packets to PPA overflows.
4	X	PPA_PL_CRC_ERR: PayLoad CRC Error. Set when a packet that was processed by PPA had a payload CRC error.
3	X	PPA_SL_PKT_DROPPED: Short Line Packet Dropped. Set when an incoming packet gets dropped because the input FIFO level reaches CSI_A_SKIP_PACKET_THRESHOLD when padding a short line.
2	X	PPA_SL_PROCESSED: Short Line Processed, Set when a line with a payload that is shorter than its packet header word count is processed by PPA.
1	X	PPA_ILL_WD_CNT: Illegal Word Count, set when a line with a word count that doesn't generate an integer number of pixels (Unused bytes at the end of payload) is processed by PPA.
0	X	PPA_HDR_ERR_COR: Header Error Corrected, Set when a packet that was processed by PPA has a single bit header error. This error will be detected by the headers ECC, and corrected by it if header error correction is enabled (CSI_A_HEADER_EC_ENABLE = 0). This flag will be set and the packet will be processed even if the error is not corrected.

29.16.146 CSI2_CSI_SW_SENSOR_A_RESET_0

Offset: 0x616 | Byte Offset: 0x1858 | Read/Write: R/W | Reset: 0x00000000 (0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx0)

Bit	Reset	Description
0	0x0	CSI_SENSOR_A_RESET: Reset CSI sensor A

29.16.147 CSI2_INPUT_STREAM_B_CONTROL_0

CSI Input Stream B Control

CSI PPB group

Offset: 0x61b | Byte Offset: 0x186c | Read/Write: R/W | Reset: 0x00ff0004 (0bxxxxxxx011111111xxxxxxxxxx0x100)

Bit	Reset	Description
24:16	0xff	CSI_B_SKIP_PACKET_THRESHOLD: CSI-B Skip Packet Threshold. This value is compared against the internal FIFO that buffers the input streams. A packet will be skipped (discarded) if the pixel stream processor is busy (probably due to padding process of a short line) and the number of entries in the internal FIFO exceeds this threshold value. Note that each entry in the internal FIFO buffer is four bytes. To turn off this feature, set the value to its maximum value (all ones).
4	0x0	CSI_B_SKIP_PACKET_THRESHOLD_ENABLE: Enables skip packet threshold feature. Skip packet feature is enabled. 0 = DISABLE: Skip packet feature is disabled. 1 = ENABLE
2	0x1	CSI_B_BYPASS_ALIGN: Bypass aligning CSIB lanes if valids for the lanes are out of sync by a cycle
1:0	0x0	CSI_B_DATA_LANE: CSI-B Data Lane 0= 1 data lane 1= 2 data lanes 2= 3 data lanes (not supported) 3= 4 data lanes (not supported) Note: 3 data lanes is not supported in Test Pattern Generation mode

29.16.148 CSI2_PIXEL_STREAM_B_CONTROL0_0

CSI Pixel Stream A Control 0

Offset: 0x61c | Byte Offset: 0x1870 | Read/Write: R/W | Reset: 0xXXXX01X0 (0bxxxxxxxxxxxxxxxxxxxxxxxx1xxxxx000)

Bit	Reset	Description
29:28	X	CSI_PPB_PAD_FRAME: CSI Pixel Parser B Pad Frame. This specifies how to deal with frames that are shorter (fewer lines) than expected. Short frames are usually caused by line packets being dropped because of packet errors. Expected frame height is specified in PPB_EXP_FRAME_HEIGHT. To do padding the value in CSI_PPB_WORD_COUNT needs to be set to the number of input bytes in each lines payload. 0 = PAD0S: Lines of all zeros will be used to pad out frames that are shorter than expected height. PPB_EXP_FRAME_HEIGHT must be programmed to an appropriate value if this field is set to PAD0S. 1 = PAD1S: Lines of all ones will be used to pad out frames that are shorter than expected height. PPB_EXP_FRAME_HEIGHT must be programmed to an appropriate value if this field is set to PAD1S. 2 = NOPAD: Short frames will not be padded out.
27	X	CSI_PPB_HEADER_EC_ENABLE: CSI Pixel Parser B Packet Header Error Correction Enable. This parameter specifies whether single bit errors in the packet header will be automatically corrected, or not. 0 = ENABLE: Single bit errors in the header will be automatically corrected. 1 = DISABLE: Single bit errors in the header will not be corrected. Header ECC check will still set header ECC status bits and the packet will be processed by Pixel Parser B. DISABLE should not be used when processing interleaved streams (Same stream going to both PPA and PPB).
25:24	X	CSI_PPB_PAD_SHORT_LINE: CSI Pixel Parser B Pad Short Line. This specifies how to deal with shorter than expected line (the number of bytes received is less than the specified word count) 0 = PAD0S: short line is padded by pixel of zeros such that the expected number of output pixels is correct. Due to the time required to do the padding, subsequent line packet maybe discarded and therefore may cause a short frame (total number of lines per frame is less than expected). 1 = PAD1S: short line is padded by pixel of ones such that the expected number of output pixels is correct. Due to the time required to do the padding, subsequent line packet maybe discarded and therefore may cause a short frame (total number of lines per frame is less than expected). 2 = NOPAD: short line is not padded (will output less pixels than expected). This option is not recommended and may cause other modules that receives CSI output stream to hang up.
21:20	X	CSI_PPB_EMBEDDED_DATA_OPTIONS: CSI Pixel Parser B Embedded Data Options. This specifies how to deal with embedded data within the specified input stream assuming that the CSI_PPB_DATA_TYPE is not embedded data and assuming that embedded data is not already processed by other CSI pixel stream processor. 0 = DISCARD: discard (throw away) embedded data 1 = EMBEDDED: output embedded data as 8-bpp arbitrary data stream.
19:16	X	CSI_PPB_OUTPUT_FORMAT_OPTIONS: CSI Pixel Parser B Output Format Options. This parameter specifies output data format. 0 = ARBITRARY: Output as 8-bit arbitrary data stream This may be used for compressed JPEG stream 1 = PIXEL: Output the normal 1 pixel/clock. Undefined LS color bits for RGB_666, RGB_565, RGB_555, and RGB_444, will be zeroed. 2 = PIXEL_REP: Same as PIXEL except MS color bits, for RGB_666, RGB_565, RGB_555, and RGB_444, will be replicated to their undefined LS bits. 3 = STORE: Output for storing RAW data to memory through ISP. Undefined LS color bits for RGB_666, RGB_565, RGB_555, and RGB_444, will be zeroed.
8	0x1	CSI_PPB_WC_CHECK: CSI Pixel Parser B Data WC Check. This parameter specifies whether the word-count is checked. 0 = DISABLE: Word count Check is disabled 1 = ENABLE: Word count Check is enabled
7	X	CSI_PPB_CRC_CHECK: CSI Pixel Parser B Data CRC Check. This parameter specifies whether the last 2 bytes of packet should be treated as CRC checksum and used to perform CRC check on the payload data. Note that in case there are 2 bytes of data CRC at the end of the packet, the packet word count does not include the CRC bytes. 0 = DISABLE: Data CRC Check is disabled regardless of whether there are CRC checksum at the end of the packet. 1 = ENABLE: Data CRC Check is enabled.
6	X	CSI_PPB_WORD_COUNT_SELECT: CSI Pixel Parser B Word Count Select. This parameter is effective only if packet header is sent as part of the stream. 0 = REGISTER: Word Count in packet header is ignored and the number of bytes per line/packet is specified by CSI_PPB_WORD_COUNT. Payload CRC check will not be valid if the word count in CSI_PPB_WORD_COUNT is different than the count in the packet header. Interlaced support relies on frame number and will not work in REGISTER mode. 1 = HEADER: The number of bytes per line is to be extracted from Word Count field in the packet header. Note that if the serial link is not error free, programming this bit to HEADER may be dangerous because the word count information in the header may be corrupted. It is recommended to always program this bit to HEADER.

Bit	Reset	Description
5	X	CSI_PPB_DATA_IDENTIFIER: CSI Pixel Parser B Data Identifier (DI) byte processing. This parameter is effective only if packet header is sent as part of the stream. 0 = DISABLED: Disabled - Data Identifier byte in packet header should be ignored (not checked against CSI_PPB_DATA_TYPE and against CSI_PPB_VIRTUAL_CHANNEL_ID). In this case, CSI_PPB_DATA_TYPE specifies the stream data format. 1 = ENABLED: Enabled - Data Identifier byte in packet header should be compared against the CSI_PPB_DATA_TYPE and the CSI_PPB_VIRTUAL_CHANNEL_ID.
4	X	CSI_PPB_PACKET_HEADER: CSI Pixel Parser B Packet Header processing. This specifies whether packet header is sent in the beginning of packet or not. 0 = NOT_SENT: Packet header is not sent. This setting should not be used if the stream source is CSI Interface A or B. Unless CSI-A, or CSI-B, is operating in a stream capture debug mode. In this case, CSI_PPB_DATA_TYPE specifies the stream data format and the number of bytes per line/packet is specified by CSI_PPB_WORD_COUNT. This implies that a packet footer is also not sent. In this case, no packet footer CRC check should be performed. 1 = SENT: Packet header is sent. This setting should be used if the stream source is CSI Interface A or B.
2:0	0x0	CSI_PPB_STREAM_SOURCE: CSI Pixel Parser B Stream Source 0 = CSI_A: CSI Interface A 1 = CSI_B: CSI Interface B

29.16.149 CSI2_PIXEL_STREAM_B_CONTROL1_0

CSI Pixel Stream B Control 1

Offset: 0x61d | Byte Offset: 0x1874 | Read/Write: R/W | Reset: 0x00000000 (0bxxxxxxxxxxxxxxxxxxxxxxxxx00000000)

Bit	Reset	Description
7:4	0x0	CSI_PPB_TOP_FIELD_FRAME_MASK: CSI Pixel Parser B Top Field Frame Mask
3:0	0x0	CSI_PPB_TOP_FIELD_FRAME: CSI Pixel Parser B Top Field Frame. This parameter specifies the frame number for top field detection for interlaced input video stream. Top Field is indicated when each of the least significant four bits of the frame number that has a one in its mask bit matches the corresponding bit in this parameter. In other words, Top Field is detected when the bitwise OR of ~(CSI_PPB_TOP_FIELD_FRAME ^ <frame number>) & CSI_PPB_TOP_FIELD_FRAME_MASK is one. Frame Number is taken from the WC field of the Frame Start short packet. Due to the reliance on WC field in packet header, interlaced support won't work if WC is selected from REGISTER mode.

29.16.150 CSI2_PIXEL_STREAM_B_GAP_0

CSI Pixel Stream B Gap

Offset: 0x61e | Byte Offset: 0x1878 | Read/Write: R/W | Reset: 0x00000000 (0b00000000000000000000000000000000)

Bit	Reset	Description
31:16	0x0	PPB_FRAME_MIN_GAP: Minimum number of viclk cycles from end of frame (Video_control = EF) to start of next frame (Video_control = SF). This parameter ensures that minimum V-blank time requirement of VI/ISP is satisfied. This field takes effect only when the frame gap of the input stream is less than the specified value.
15:0	0x0	PPB_LINE_MIN_GAP: Minimum number of viclk cycles from end of previous line (Video_control = EL_DATA) to start of next line (Video_control = SL). This parameter ensures that minimum H-blank time requirement of VI/ISP is satisfied. This field takes effect only when the line gap of the input stream is less than the specified value.

29.16.151 CSI2_PIXEL_STREAM_PPB_COMMAND_0

CSI Pixel Parser B Command

Offset: 0x61f | Byte Offset: 0x187c | Read/Write: R/W | Reset: 0x0000XXX4 (0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxx100)

Bit	Reset	Description
15:12	X	CSI_PPB_START_MARKER_FRAME_MAX: CSI Pixel Parser B Start Marker Maximum. Start Frame is indicated when Minimum condition above is met and the least significant four bits of the frame number are less than or equal to this value.

Bit	Reset	Description
11:8	X	CSI_PPB_START_MARKER_FRAME_MIN: CSI Pixel Parser B Start Marker Minimum. Start Frame is indicated when Maximum condition below is met and the least significant four bits of the frame number are greater than or equal to this value.
4	X	CSI_PPB_VSYNC_START_MARKER: CSI Pixel Parser B VSYNC Start Marker 0 = FSPKT: Start of frame is indicated when a Frame Start short packet is received with a frame number whose least significant four bits are greater than or equal to CSI_PPB_START_MARKER_FRAME_MIN and less than or equal to CSI_PPB_START_MARKER_FRAME_MAX. When the input stream is from a CSI port, or from the host path, or from the VIP path and the data mode is PAYLOAD_ONLY, then this field may be programmed to FSPKT. 1 = VSYNC: Start of frame is indicated when VSYNC signal is received. When the input stream is from the VIP path and the data mode is PACKET, then this field may be programmed to VSYNC.
2	0x1	CSI_PPB_SINGLE_SHOT: CSI Pixel Parser B Single Shot Mode. Software should clear it along with disabling the CSI_PPB_ENABLE, once a frame is captured 0 = DISABLE 1 = ENABLE
1:0	0x0	CSI_PPB_ENABLE: CSI Pixel Parser B Enable. This parameter controls CSI Pixel Parser B to start or stop receiving data. 0 = NOP: no operation 1 = ENABLE: enable at the next frame start as specified by the CSI Start Marker 2 = DISABLE: disable after current frame end and before next frame start. 3 = RST: reset (disable immediately). Enabling the pixel parser does not enable the corresponding input source to receive data. If Pixel parser is enabled later than the corresponding input source, the CSI will keep on rejecting incoming streams, until it encounters a valid SF.

29.16.152 CSI2_PIXEL_STREAM_B_EXPECTED_FRAME_0

CSI Pixel Stream B Expected Frame

Offset: 0x620 | Byte Offset: 0x1880 | Read/Write: R/W | Reset: 0x0000XXX0 (0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx0)

Bit	Reset	Description
15:4	X	PPB_MAX_CLOCKS: Maximum Number of viclk clock cycles between line start requests. The value in this field is in terms of 256 viclk clock cycles.
0	0x0	PPB_ENABLE_LINE_TIMEOUT: When set to one enables checking of the time between start line requests from the Header Parser to CSI-PPB. A fake EF will be outputted by CSI-PPB if this time between line starts exceeds the value in MAX_CLOCKS_BETWEEN_LINES. Padding lines can be inserted before the fake EF, if the number of lines outputted, when the fake EF is generated is less than the expected frame height. The type of padding is specified using CSI_PPB_PAD_FRAME.

29.16.153 CSI2_CSI_PIXEL_PARSER_B_INTERRUPT_MASK_0

CSI Pixel Parser B Interrupt Mask

Offset: 0x621 | Byte Offset: 0x1884 | Read/Write: R/W | Reset: 0x00000000 (0bxxxxxxxxxxxxxxxxxx0xx000000000000)

Bit	Reset	Description
14	0x0	HPB_UNC_HDR_ERR_INT_MASK: Interrupt Mask for HPB_UNC_HDR_ERR. 0 = DISABLED: Don't generate an interrupt when HPB_UNC_HDR_ERR is set. 1 = ENABLED: Generate an interrupt when HPB_UNC_HDR_ERR is set.
10	0x0	PPB_SPARE_STATUS_1_INT_MASK: Interrupt Mask for PPB_SPARE_STATUS_1. 0 = DISABLED: Don't generate an interrupt when PPB_SPARE_STATUS_1 is set. 1 = ENABLED: Generate an interrupt when PPB_SPARE_STATUS_1 is set.
9	0x0	PPB_INTERFRAME_LINE_INT_MASK: Interrupt Mask for PPB_INTERFRAME_LINE. 0 = DISABLED: Don't generate an interrupt when PPB_INTERFRAME_LINE is set. 1 = ENABLED: Generate an interrupt when PPB_INTERFRAME_LINE is set.
8	0x0	PPB_EXTRA_SF_INT_MASK: Interrupt Mask for PPB_EXTRA_SF. 0 = DISABLED: Don't generate an interrupt when PPB_EXTRA_SF is set. 1 = ENABLED: Generate an interrupt when PPB_EXTRA_SF is set.
7	0x0	PPB_SHORT_FRAME_INT_MASK: Interrupt Mask for PPB_SHORT_FRAME. 0 = DISABLED: Don't generate an interrupt when PPB_SHORT_FRAME is set. 1 = ENABLED: Generate an interrupt when PPB_SHORT_FRAME is set.
6	0x0	PPB_STMERR_INT_MASK: Interrupt Mask for PPB_STMERR. 0 = DISABLED: Don't generate an interrupt when PPB_STMERR is set. 1 = ENABLED: Generate an interrupt when PPB_STMERR is set.

Bit	Reset	Description
5	0x0	PPB_FIFO_OVRF_INT_MASK: Interrupt Mask for PPB_FIFO_OVRF. 0 = DISABLED: Don't generate an interrupt when PPB_FIFO_OVRF is set. 1 = ENABLED: Generate an interrupt when PPB_FIFO_OVRF is set.
4	0x0	PPB_PL_CRC_ERR_INT_MASK: Interrupt Mask for PPB_PL_CRC_ERR. 0 = DISABLED: Don't generate an interrupt when PPB_PL_CRC_ERR is set. 1 = ENABLED: Generate an interrupt when PPB_PL_CRC_ERR is set.
3	0x0	PPB_SL_PKT_DROPPED_INT_MASK: Interrupt Mask for PPB_SL_PKT_DROPPED. 0 = DISABLED: Don't generate an interrupt when PPB_SL_PKT_DROPPED is set. 1 = ENABLED: Generate an interrupt when PPB_SL_PKT_DROPPED is set.
2	0x0	PPB_SL_PROCESSED_INT_MASK: Interrupt Mask for PPB_SL_PROCESSED. 0 = DISABLED: Don't generate an interrupt when PPB_SL_PROCESSED is set. 1 = ENABLED: Generate an interrupt when PPB_SL_PROCESSED is set.
1	0x0	PPB_ILL_WD_CNT_INT_MASK: Interrupt Mask for PPB_ILL_WD_CNT. 0 = DISABLED: Don't generate an interrupt when PPB_ILL_WD_CNT is set. 1 = ENABLED: Generate an interrupt when PPB_ILL_WD_CNT is set.
0	0x0	PPB_HDR_ERR_COR_INT_MASK: Interrupt Mask for PPB_HDR_ERR_COR. 0 = DISABLED: Don't generate an interrupt when PPB_HDR_ERR_COR is set. 1 = ENABLED: Generate an interrupt when PPB_HDR_ERR_COR is set.

29.16.154 CSI2_CSI_PIXEL_PARSER_B_STATUS_0

Pixel Parser B Status

Offset: 0x622 | Byte Offset: 0x1888 | Read/Write: RO | Reset: 0x0000XXXX (0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx)

Bit	Reset	Description
14	X	HPB_UNC_HDR_ERR: Uncorrectable Header Error. Set when header parser B parses a header with a multi bit error. This error will be detected by the headers ECC, but can't be corrected.
10	X	PPB_SPARE_STATUS_1: PPB Spare Status bit. This bit will get set when Pixel Parser B has a line timeout. Line timeout needs to be enabled by setting PPB_ENABLE_LINE_TIMEOUT and programming PPB_MAX_CLOCKS for the MAX clocks between lines.
9	X	PPB_INTERFRAME_LINE: Set when CSI-PPB receives a request to output a line that is not in the active part of the frame output. That is after EF and before SF, or before start marker is found. The interframe line will not be outputted by the Pixel Parser.
8	X	PPB_EXTRA_SF: Set when CSI-PPB receives a SF when it is expecting an EF. This happens when EF of the frame gets corrupted before arriving CSI. CSI-PPB will insert a fake EF and the drop the current frame with Correct SF.
7	X	PPB_SHORT_FRAME: Set when CSI-PPB receives a short frame. This bit gets set even if CSI_PPB_PAD_FRAME specifies that short frames are to be padded to the correct line length.
6	X	PPB_STMERR: Stream Error. Set when the control output of PPB doesn't follow the correct sequence. The correct sequence for CSI is: SF -> (SL_DATA or EF), SL_DATA -> (DATA or EL_DATA), DATA -> EL_DATA, EL_DATA -> (SL_DATA or EF), EF -> SF. Stream Errors can be caused by receiving a corrupted stream.
5	X	PPB_FIFO_OVRF: FIFO Overflow. Set when the FIFO that is feeding packets to PPB overflows.
4	X	PPB_PL_CRC_ERR: PayLoad CRC Error. Set when a packet that was processed by PPB had a payload CRC error.
3	X	PPB_SL_PKT_DROPPED: Short Line Packet Dropped. Set when an incoming packet gets dropped because the input FIFO level reaches CSI_B_SKIP_PACKET_THRESHOLD when padding a short line.
2	X	PPB_SL_PROCESSED: Short Line Processed, Set when a line with a payload that is shorter than its packet header word count is processed by PPB.
1	X	PPB_ILL_WD_CNT: Illegal Word Count, set when a line with a word count that doesn't generate an integer number of pixels (Unused bytes at the end of payload) is processed by PPB.
0	X	PPB_HDR_ERR_COR: Header Error Corrected, set when a packet that was processed by PPB has a single bit header error. This error will be detected by the headers ECC, and corrected by it if header error correction is enabled (CSI_B_HEADER_EC_ENABLE = 0). This flag will be set and the packet will be processed even if the error is not corrected.

29.16.155 CSI2_CSI_SW_SENSOR_B_RESET_0

Offset: 0x623 | Byte Offset: 0x188c | Read/Write: R/W | Reset: 0x00000000 (0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx0)

Bit	Reset	Description
0	0x0	CSI_SENSOR_B_RESET: Reset CSI sensor B

29.16.156 CSI2_PHY_CIL_COMMAND_0

CSI Phy and CIL Command

CSI CIL group

Offset: 0x642 | Byte Offset: 0x1908 | Read/Write: R/W | Reset: 0x00000000 (0bxxxxxxxxxxxxxxxxxxxxxx00xxxxxx00)

Bit	Reset	Description
9:8	0x0	CSI_B_PHY_CIL_ENABLE: CSI B Phy and CIL Enable. This parameter controls CSI B Phy and CIL receiver to start or stop receiving data. 0 = NOP: no operation 1 = ENABLE: enable 2 = DISABLE: disable (reset)
1:0	0x0	CSI_A_PHY_CIL_ENABLE: CSI A Phy and CIL Enable. This parameter controls CSI A Phy and CIL receiver to start or stop receiving data. 0 = NOP: no operation 1 = ENABLE: enable 2 = DISABLE: disable (reset)

29.16.157 CSI2_CIL_PAD_CONFIG0_0

CIL Pad Configuration 0

Offset: 0x643 | Read/Write: R/W | Reset: 0x00000000 (0bxxxxxxxxxxxxxxxx00000000xxxxxxxx)

Bit	Reset	Description
15:8	0x0	PAD_CIL_SPARE: Spare bit for CIL BIAS Config. PAD_CIL_SPARE[7] is used is being used to flush VI's Y-FIFO when it is being use as a stream source for one of the Pixel Parsers. Setting PAD_CIL_SPARE[7] to 1 will hold vi2csi_host_stall low. Which will force VI's Y-FIFO to be purged. PAD_CIL_SPARE[7] must be low for the pixel parser to receive source data from VI's Y-FIFO.

29.16.158 CSI2_CILA_PAD_CONFIG0_0

CIL-A Pad Configuration 0

CSI CILA group

Offset: 0x64b | Byte Offset: 0x192c | Read/Write: R/W | Reset: 0x00010007 (0b0000x000000000010000x000x0000111)

Bit	Reset	Description
31	0x0	PAD_CILA_E_TXBW: 0 = default to enable VCLAMP regulator 1 = turn off regulator and short vclamp to VDDP. will cause stress and need waiver to use
30:28	0x0	PAD_CILA_SLEWDNADJ: Pull down slew rate adjust, default 000. From 000 -> 011, slew rate increases. 100 is the same as 000. From 100->111, skew rate decreases. This control is unused for CSI MIPI pads, which are receive only
26:24	0x0	PAD_CILA_SLEWUPADJ: Pull up slew rate adjust, default 000. From 000 -> 011, slew rate increases. 100 is the same as 000. From 100->111, skew rate decreases. This control is unused for CSI MIPI pads, which are receive only
23:21	0x0	PAD_CILA_LPDNADJ: Driver pull down impedance control. 00 -> 130ohm, default. 01 -> 110ohm. 10 -> 130ohm, same as 00. 11 -> 150ohm. This control is unused for CSI MIPI pads, which are receive only

29.16.160 CSI2_PHY_CILA_CONTROL0_0

CSI-A Phy and CIL Control

Offset: 0x64d | Byte Offset: 0x1934 | Read/Write: R/W | Reset: 0x00000002 (0bxxxxxxxxxxxxxxxxxx000000x0000010)

Bit	Reset	Description
13:8	0x0	CILA_CLK_SETTLE: settle time for clk lane when moving from LP to HS (LP11->LP01->LP00), this setting determines how many csicil clock cycles (72 MHz lp clock cycles) to wait after LP00. Hardware uses an internal delay of ~15 csicil cycles for default value. So the programming value (0 to 15) of this field works like this 0 = 15 cilclk cycles (default internal delay), 1 = 15 - 7 (8 cilclk cycles), 2 = 15 - 6 (9 cilclk cycles), . . 7 = 15 - 1 (14 cilclk cycles), 8 = 15 - 0 (default internal delay), 9 = 15 + 1 (16 cilclk cycles), . 57 = 15 + 49 (64 cilclk cycles)
6	0x0	CILA_BYPASS_LP_SEQ: The LP signals should sequence through LP11->LP01->LP00 state, to indicate to CLOCK CIL about the mode switching to HS Rx mode. In case the camera is enabled earlier than CIL, it is highly likely that camera sends this control sequence sooner than CIL can detect it. Enabling this bit allows the CLOCK CIL to overlook the LP control sequence and step in HS Rx mode directly looking at LP00 only.
5:0	0x2	CILA_THS_SETTLE: settle time for data lane when moving from LP to HS (LP11->LP01->LP00), this setting determines how many csicil clock cycles (102 MHz LP clock cycles) to wait, after LP00, before starting to look at the data. 0xF is an illegal value for this field 85ns + 6 * UI < (Ths-settle-programmed + 5) * csicil_clk_period < 145ns + 10 * UI

29.16.161 CSI2_CSI_CIL_A_INTERRUPT_MASK_0

29.16.162 CSI2_CSI_CIL_A_STATUS_0

CSI Control and Interface Logic A Status

Each status bit is cleared to zero when its bit position is written with one. For example, writing 0x2 to CSI_CIL_A_STATUS will clear only CILA_SOT_MB_ERR.

Offset: 0x64f | Byte Offset: 0x193c | Read/Write: RO | Reset: 0x000000XX (0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx)

Bit	Reset	Description
6	X	CILA_ESC_DATA_REC: Escape Mode Data Received. Set when CIL-A receives an Escape Mode Data byte. The Data Byte can be read from bits 7-0 of ESCAPE_MODE_DATA. This status bit will also be cleared when CILA_ESC_CMD_REC is set.
5	X	CILA_ESC_CMD_REC: Escape Mode Command Received. Set when CIL-A receives an Escape Mode Command byte. The Command Byte can be read from bits 7-0 of ESCAPE_MODE_COMMAND.
4	X	CILA_CTRL_ERR: Control Error. Set when CIL-A detects LP state 01 or 10 followed by a stop state (LP11) instead of transitioning into the Escape mode or Turn Around mode (LP00).
2	X	CILA_SYNC_ESC_ERR: Sync Escape Error. Set when CIL-A detects that the wrong (non-multiple of 8) number of bits have been received for an Escape Command or Data Byte.
1	X	CILA_SOT_MB_ERR: Start of Transmission Multi Bit Error. Set when CIL-A detects a multi bit start of transmission byte error in one of the packets SOT bytes. The packet will be discarded.
0	X	CILA_SOT_SB_ERR: Start of Transmission Single Bit Error. Set when CIL-A detects a single bit error in one of the packets Start of Transmission bytes. The packet will be sent to the CSI-A for processing.

29.16.163 CSI2_CSI_CILA_STATUS_0

CSI-CILA Control and Interface Logic Status

Each status bit is cleared to zero when its bit position is written with one. For example, writing 0x2 to CSI_CIL_STATUS will clear only SOT_MB_ERR.

Offset: 0x650 | Byte Offset: 0x1940 | Read/Write: RO | Reset: 0x000X00XX (0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx)

Bit	Reset	Description
18	X	CILA_DATA_LANE1_CTRL_ERR: Control Error. Set when CIL-A detects LP state 01 or 10 followed by a stop state (LP11) instead of transitioning
17	X	CILA_DATA_LANE1_SOT_MB_ERR: Start of Transmission Multi Bit Error. Set when CIL-A detects a multi bit start of transmission byte error in one of the packets SOT bytes on data lane-1. The packet will be discarded.
16	X	CILA_DATA_LANE1_SOT_SB_ERR: Start of Transmission Single Bit Error. Set when CIL-A detects a single bit error in one of the packets Start of Transmission bytes on data lane-1. The packet will be sent to the CSI-A for processing.
6	X	CILA_DATA_LANE0_CTRL_ERR: Control Error. Set when CIL-A detects LP state 01 or 10 followed by a stop state (LP11) instead of transitioning
5	X	CILA_DATA_LANE0_SOT_MB_ERR: Start of Transmission Multi Bit Error. Set when CIL-A detects a multi bit start of transmission byte error in one of the packets SOT bytes on data lane-0. The packet will be discarded.
4	X	CILA_DATA_LANE0_SOT_SB_ERR: Start of Transmission Single Bit Error. Set when CIL-A detects a single bit error in one of the packets Start of Transmission bytes on data lane-0. The packet will be sent to the CSI-A for processing.
0	X	CILA_CLK_LANE_CTRL_ERR: Control Error. Set when CIL-A detects incorrect line state sequence on clk lane

29.16.164 CSI2_CIL_A_ESCAPE_MODE_COMMAND_0

Escape Mode Command

This register is used to receive escape mode command bytes from CIL-A.

Offset: 0x651 | Byte Offset: 0x1944 | Read/Write: RO | Reset: 0x000000XX (0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx)

Bit	Reset	Description
7:0	X	CILA_ESC_CMD_BYTE: CIL-A Escape Mode Command Byte. This is the 8 bit entry command that was received, by CIL-A, during the last escape Mode sequence. CIL-A monitors Byte Lane 0, only, for escape mode sequences. This command byte can only be assumed to be valid when CILA_ESC_CMD_REC status bit is set.

29.16.165 CSI2_CIL_A_ESCAPE_MODE_DATA_0

Escape Mode Data

This register is used to receive escape mode data bytes from CIL-A.

Offset: 0x652 | Byte Offset: 0x1948 | Read/Write: RO | Reset: 0x000000XX (0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx)

Bit	Reset	Description
7:0	X	CILA_ESC_DATA_BYTE: CIL-A Escape Mode Data Byte. When read this field returns the last Escape Mode Data byte that was received by CIL-A. Escape Mode Data bytes are the bytes that are received in Escape Mode after receiving the Escape Mode Command. These bytes can be used to implement MIPI's CSI Specs Low Power Data Transmission. This field is only valid when the status bit, CILA_ESC_DATA_REC, is set, and will be overwritten by the next Escape Mode data byte if not read before the next byte comes in.

29.16.171 CSI2_CSI_CIL_B_STATUS_0

CSI Control and Interface Logic B Status

Each status bit is cleared to zero when its bit position is written with one. For example, writing 0x2 to CSI_CIL_B_STATUS will clear only CILB_SOT_MB_ERR.

Offset: 0x65c | Byte Offset: 0x1970 | Read/Write: RO | Reset: 0x000000XX (0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx)

Bit	Reset	Description
6	X	CILB_ESC_DATA_REC: Escape Mode Data Received. Set when CIL-B receives an Escape Mode Data byte. The Data Byte can be read from bits 23-16 of ESCAPE_MODE_DATA. This status bit will also be cleared when CILB_ESC_CMD_REC is set.
5	X	CILB_ESC_CMD_REC: Escape Mode Command Received. Set when CIL-B receives an Escape Mode Command byte. The Command Byte can be read from bits 23-16 of ESCAPE_MODE_COMMAND.
4	X	CILB_CTRL_ERR: Control Error. Set when CIL-B detects LP state 01 or 10 followed by a stop state (LP11) instead of transitioning into the Escape mode or Turn Around mode (LP00).

Bit	Reset	Description
2	X	CILB_SYNC_ESC_ERR: Sync Escape Error. Set when CIL-B detects that the wrong (non-multiple of 8) number of bits have been received for an Escape Command or Data Byte.
1	X	CILB_SOT_MB_ERR: Start of Transmission Multi Bit Error. Set when CIL-B detects a multi bit start of transmission byte error in one of the packets SOT bytes. The packet will be discarded.
0	X	CILB_SOT_SB_ERR: Start of Transmission Single Bit Error. Set when CIL-B detects a single bit error in one of the packets start of transmission bytes. The packet will be sent to CSI-B for processing.

29.16.172 CSI2_CSI_CILB_STATUS_0

CSI-CILB Control and Interface Logic Status

Each status bit is cleared to zero when its bit position is written with one. For example, writing 0x2 to CSI_CIL_STATUS will clear only SOT_MB_ERR.

Offset: 0x65d | Byte Offset: 0x1974 | Read/Write: RO | Reset: 0x000X00XX (0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx)

Bit	Reset	Description
18	X	CILB_DATA_LANE1_CTRL_ERR: Control Error. Set when CIL-B detects LP state 01 or 10 followed by a stop state (LP11) instead of transitioning
17	X	CILB_DATA_LANE1_SOT_MB_ERR: Start of Transmission Multi Bit Error. Set when CIL-B detects a multi bit start of transmission byte error in one of the packets SOT bytes on data lane-1. The packet will be discarded.
16	X	CILB_DATA_LANE1_SOT_SB_ERR: Start of Transmission Single Bit Error. Set when CIL-A detects a single bit error in one of the packets Start of Transmission bytes on data lane-1. The packet will be sent to the CSI-B for processing.
6	X	CILB_DATA_LANE0_CTRL_ERR: Control Error. Set when CIL-B detects LP state 01 or 10 followed by a stop state (LP11) instead of transitioning
5	X	CILB_DATA_LANE0_SOT_MB_ERR: Start of Transmission Multi Bit Error. Set when CIL-B detects a multi bit start of transmission byte error in one of the packets SOT bytes on data lane-0. The packet will be discarded.
4	X	CILB_DATA_LANE0_SOT_SB_ERR: Start of Transmission Single Bit Error. Set when CIL-B detects a single bit error in one of the packets Start of Transmission bytes on data lane-0. The packet will be sent to the CSI-B for processing.
0	X	CILB_CLK_LANE_CTRL_ERR: Control Error. Set when CIL-B detects incorrect line state sequence on clk lane

29.16.173 CSI2_CIL_B_ESCAPE_MODE_COMMAND_0

Escape Mode Command

This register is used to receive escape mode command bytes from CIL-B.

Offset: 0x65e | Byte Offset: 0x1978 | Read/Write: RO | Reset: 0x000000XX (0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx)

Bit	Reset	Description
7:0	X	CILB_ESC_CMD_BYTE: CIL-B Escape Mode Command Byte. This is the 8 bit entry command that was received, by CIL-B, during the last escape Mode sequence. CIL-B monitors Byte Lane 0, only, for escape mode sequences. This command byte can only be assumed to be valid when CILB_ESC_CMD_REC status bit is set.

29.16.174 CSI2_CIL_B_ESCAPE_MODE_DATA_0

Escape Mode Data

This register is used to receive escape mode data bytes from CIL-B.

Offset: 0x65f | Byte Offset: 0x197c | Read/Write: RO | Reset: 0x000000XX (0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx)

Bit	Reset	Description
7:0	X	CILB_ESC_DATA_BYTE: CIL-A Escape Mode Data Byte. When read, this field returns the last Escape Mode Data byte that was received by CIL-B. Escape Mode Data bytes are the bytes that are received in Escape Mode after receiving the Escape Mode Command. These bytes can be used to implement MIPI's CSI Specs Low Power Data Transmission. This field is only valid when the status bit, CILB_ESC_DATA_REC, is set, and will be overwritten by the next Escape Mode data byte if not read before the next byte comes in.

0	0x0	CSI_STATUS_RESET: Reset CSI status and dbgcnt registers

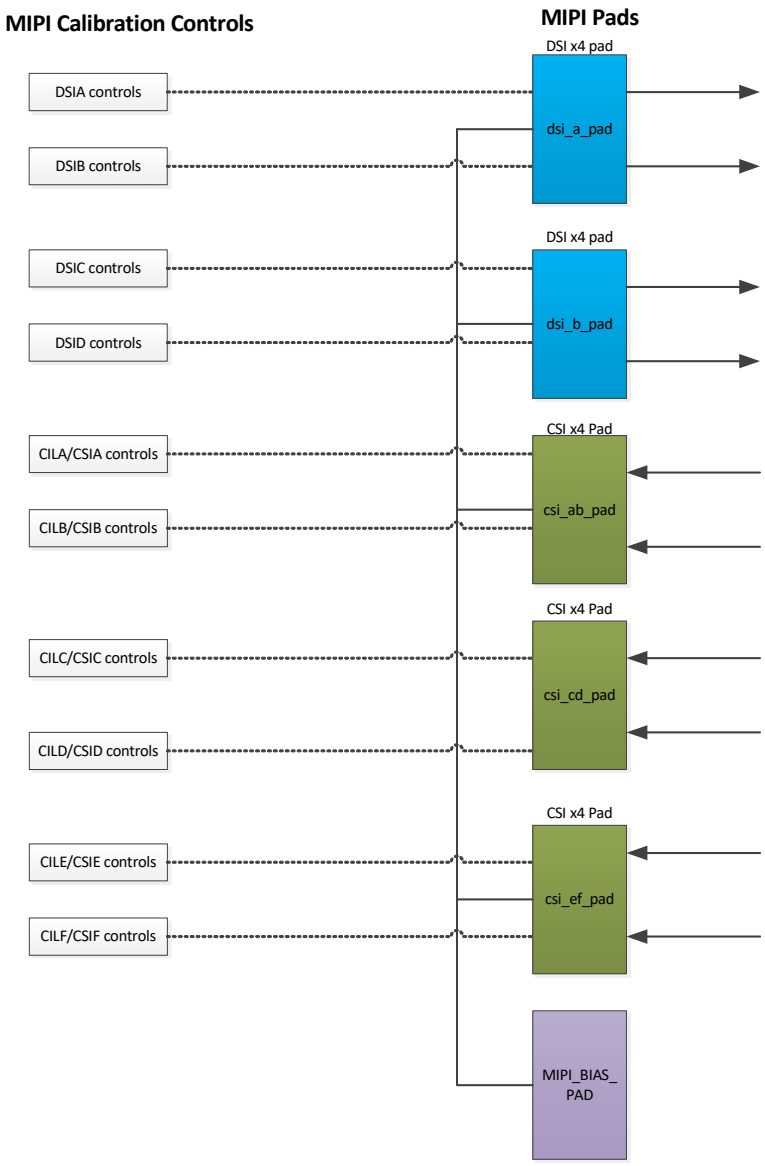
CHAPTER 30: MIPI D-PHY CALIBRATION FOR CSI AND DSI

This chapter describes the MIPI D-PHY Calibration registers. This information is provided to aid in system debug and diagnostics. It is expected that NVIDIA® supplied drivers will normally be used to program these.

MIPI D-PHY blocks are used for both the DSI display interface and the CSI camera interface. The calibration for both interfaces is controlled by these registers.

The MIPI pad calibration block controls a voltage regulator that must be powered up whenever any of the DSI pads are used. The regulator is controlled by the PAD_PDVREG bit in the MIPI_CAL_MIPI_BIAS_PAD_CFG2_0 register. Clearing this bit powers up the regulator while setting the bit powers it down.

Figure 124: Mapping of MIPI Calibration Control Registers to MIPI Pads



The figure above shows the channel assignments of the MIPI D-PHYs in Tegra® X1.

30.1 Implementation of DSI MIPI Calibration

30.1.1 Pre MIPI_CAL

1. Set MIPI_CAL_MIPI_BIAS_PAD_CFG0_0 and MIPI_CAL_MIPI_BIAS_PAD_CFG2_0

   MIPI_CAL_MIPI_BIAS_PAD_CFG0_0[0]: MIPI_BIAS_PAD_E_VCLAMP_REF = 1

   MIPI_CAL_MIPI_BIAS_PAD_CFG2_0 = 0
2. Reset MIPI_CAL and enable MIPI_CAL Clock

   ///SW reset MIPI_CAL

   REG(CLK_RST_CONTROLLER_RST_DEVICES_H_0,SWR_MIPI_CAL_RST,1)

   waitmsec(100)

   REG(CLK_RST_CONTROLLER_RST_DEVICES_H_0,SWR_MIPI_CAL_RST,0)

   //enable MIPI_CAL clock

   REG(CLK_RST_CONTROLLER_PLLP_OUTB_0, PLLP_OUT3_RATIO, 4)

   //If PLLP=216 MHz, PLLP_OUT3=72 MHz. If PLLP=408 MHz, set Ratio to 10 to have

   PLLP_OUT3=68 MHz

   REG(CLK_RST_CONTROLLER_PLLP_OUTB_0, PLLP_OUT3_CLKEN, 1)

   waitmsec(1)

   REG(CLK_RST_CONTROLLER_CLK_OUT_ENB_H_0, CLK_ENB_MIPI_CAL, 1) //MIPI_CLK

   source PLLP_OUT3

30.1.2 MIPI_CAL Settings

MIPI_CAL shall be done with DSI_A, DSI_B and DSI_A + DSI_B (dual channel) based on the applications.

1. Use of DSI_A
   a. Select the lanes to be used

      reg(MIPI_CAL_DSIA_MIPI_CAL_CONFIG_0,MIPI_CAL_SELDSIA, 1) // first 2 lanes in DSI_A

      REG(MIPI_CAL_DSIB_MIPI_CAL_CONFIG_0,MIPI_CAL_SELDSIB,1) // 2nd 2 lanes in DSI_A

      REG(MIPI_CAL_DSIA_MIPI_CAL_CONFIG_2_0,MIPI_CAL_CLKSELDSIA,1) //SEL_DSIA_CLK

      REG(MIPI_CAL_DSIB_MIPI_CAL_CONFIG_2_0,MIPI_CAL_CLKSELDSIB,1) //SEL_DSIB_CLK

   b. De-select non-used MIPI lanes

      reg(MIPI_CAL_CILA_MIPI_CAL_CONFIG_0,MIPI_CAL_SELA, 0) //CILA

      reg(MIPI_CAL_CILB_MIPI_CAL_CONFIG_0,MIPI_CAL_SELB, 0) //CILB

      reg(MIPI_CAL_CILC_MIPI_CAL_CONFIG_0,MIPI_CAL_SELC, 0) //CILC

      reg(MIPI_CAL_CILD_MIPI_CAL_CONFIG_0,MIPI_CAL_SELD, 0) //CILD

      reg(MIPI_CAL_CILE_MIPI_CAL_CONFIG_0,MIPI_CAL_SELE, 0) //CILE

      reg(MIPI_CAL_CILC_MIPI_CAL_CONFIG_2_0,MIPI_CAL_CLKSELC, 0) //CLKSELC

      reg(MIPI_CAL_CILD_MIPI_CAL_CONFIG_2_0,MIPI_CAL_CLKSELD, 0) //CLKSELD

      reg(MIPI_CAL_CSIE_MIPI_CAL_CONFIG_2_0,MIPI_CAL_CLKSELE, 0) //CLKSELE

   c. Set MIPI_CAL parameters

      MIPI_CAL_MIPI_BIAS_PAD_CFG1_0[10:8] = 3 // PAD_DRIV_UP_REF

      MIPI_CAL_MIPI_BIAS_PAD_CFG1_0[18:16] = 0 // PAD_DRIV_DN_REF

MIPI_CAL_DSIA_MIPI_CAL_CONFIG_2_0[4:0] = 2 // MIPI_CAL_HSCLKPUOSDSIA

MIPI_CAL_DSIA_MIPI_CAL_CONFIG_2_0[12:8] = 0 // MIPI_CAL_HSCLKPDOSDSIA

MIPI_CAL_DSIB_MIPI_CAL_CONFIG_2_0[4:0] = 2 // MIPI_CAL_HSCLKPUOSDSIB

MIPI_CAL_DSIB_MIPI_CAL_CONFIG_2_0[12:8] = 0 // MIPI_CAL_HSCLKPDOSDSIB

Other non-mentioned parameters keep with the default values.

d. DSI settings

DSI_PAD_CONTROL_3_0[1:0] = 3 //DSI_PAD_PREEMP_PU

DSI_PAD_CONTROL_3_0[5:4] = 3 //DSI_PAD_PREEMP_PD

DSI_PAD_CONTROL_3_0[9:8] = 3 //DSI_PAD_PREEMP_PU_CLK

e. Adjustment based on PCB trace and layout

Since individual customer PCB boards have different trace length and characterizations, it may need to adjust the clock and data delays in individual lanes with the following registers.

DSI_PAD_CONTROL_2_0[2:0] =>DSI_PAD_OUTADJCLK

DSI_PAD_CONTROL_1_0[2:0] => DSI_PAD_OUTADJ0

DSI_PAD_CONTROL_1_0[6:4] => DSI_PAD_OUTADJ1

DSI_PAD_CONTROL_1_0[10:8] => DSI_PAD_OUTADJ2

DSI_PAD_CONTROL_1_0[14:12] => DSI_PAD_OUTADJ3

Since it is PCB specific, it does not provide a definite value for the setting for the delay here. If there is noise with unclear border lines in the display image, it requires this adjustment.

2. Use of DSI_B

a. Switch the bus from CSI to DSI

REG(APB_MISC_GP_MIPI_PAD_CTRL_0, DSIB_MODE, 1) //0=CSI, 1 =DSIB

b. Reset DSIB

REG(CLK_RST_CONTROLLER_RST_DEVICES_U_0, SWR_DSIB_RST, 1)

waitmsec(20)

REG(CLK_RST_CONTROLLER_RST_DEVICES_U_0, SWR_DSIB_RST, 0)

REG(CLK_RST_CONTROLLER_RST_DEV_U_SET_0, SET_DSIB_RST, 1)

waitmsec(20)

REG(CLK_RST_CONTROLLER_RST_DEV_U_CLR_0, CLR_DSIB_RST, 1)

REG(CLK_RST_CONTROLLER_CLK_OUT_ENB_U_0, CLK_ENB_DSIB, 1)

REG(CLK_RST_CONTROLLER_CLK_ENB_U_SET_0, SET_CLK_ENB_DSIB, 1)

c. Select the lanes to be used

reg(MIPI_CAL_CILC_MIPI_CAL_CONFIG_0,MIPI_CAL_SELC, 1) //CILC

reg(MIPI_CAL_CILD_MIPI_CAL_CONFIG_0,MIPI_CAL_SELD, 1) //CILD

reg(MIPI_CAL_CILC_MIPI_CAL_CONFIG_2_0,MIPI_CAL_CLKSELC, 1) //CLKSELC

reg(MIPI_CAL_CILD_MIPI_CAL_CONFIG_2_0,MIPI_CAL_CLKSELD, 1) //CLKSELD

d. De-select non-used MIPI lanes

reg(MIPI_CAL_CILA_MIPI_CAL_CONFIG_0,MIPI_CAL_SELA, 0) //CILA

reg(MIPI_CAL_CILB_MIPI_CAL_CONFIG_0,MIPI_CAL_SELB, 0) //CILB

reg(MIPI_CAL_CILE_MIPI_CAL_CONFIG_0,MIPI_CAL_SELE, 0) //CILE

reg(MIPI_CAL_CSIE_MIPI_CAL_CONFIG_2_0,MIPI_CAL_CLKSELE, 0) //CLKSELE

reg(MIPI_CAL_DSIA_MIPI_CAL_CONFIG_0,MIPI_CAL_SELDSIA, 0)

REG(MIPI_CAL_DSIA_MIPI_CAL_CONFIG_2_0,MIPI_CAL_CLKSELDSIA,0)

REG(MIPI_CAL_DSIB_MIPI_CAL_CONFIG_0,MIPI_CAL_SELDSIB,0)

REG(MIPI_CAL_DSIB_MIPI_CAL_CONFIG_2_0,MIPI_CAL_CLKSELDSIB,0)

e. Set MIPI_CAL parameters

MIPI_CAL_MIPI_BIAS_PAD_CFG1_0[10:8] = 3 // PAD_DRIV_UP_REF

MIPI_CAL_MIPI_BIAS_PAD_CFG1_0[18:16] = 0 // PAD_DRIV_DN_REF

MIPI_CAL_CILC_MIPI_CAL_CONFIG_2_0 [4:0] = 2 // MIPI_CAL_HSCLKPUOSCILC

MIPI_CAL_CILC_MIPI_CAL_CONFIG_2_0 [12:8] = 3 // MIPI_CAL_HSCLKPDOSCILC

MIPI_CAL_CILD_MIPI_CAL_CONFIG_2_0 [4:0] = 2 // MIPI_CAL_HSCLKPUOSCILD

MIPI_CAL_CILD_MIPI_CAL_CONFIG_2_0 [12:8] = 3 // MIPI_CAL_HSCLKPDOSCILD

Other non-mentioned parameters keep with the default values.

f. DSI settings

DSI_PAD_CONTROL_3_1[1:0] = 3 //DSI_PAD_PREEMP_PU

DSI_PAD_CONTROL_3_1[5:4] = 3 //DSI_PAD_PREEMP_PD

DSI_PAD_CONTROL_3_1[9:8] = 3 //DSI_PAD_PREEMP_PU_CLK

g. Adjustment based on PCB trace and layout

Since individual customer PCB boards have different trace length and characterizations, it may need to adjust the clock and data delays in individual lanes with the following registers.

DSI_PAD_CONTROL_2_1[2:0] =>DSI_PAD_OUTADJCLK

DSI_PAD_CONTROL_1_1[2:0] => DSI_PAD_OUTADJ0

DSI_PAD_CONTROL_1_1[6:4] => DSI_PAD_OUTADJ1

DSI_PAD_CONTROL_1_1[10:8] => DSI_PAD_OUTADJ2

DSI_PAD_CONTROL_1_1[14:12] => DSI_PAD_OUTADJ3

Since it is PCB specific, it does not provide a definite value for the setting for the delay here. If there is noise with unclear border lines in the display image, it requires this adjustment.

3. Use of DSI_A + DSI_B for dual channel

Do both steps for Use of DSI_A and DSI_B listed above in addition to ganged mode settings.

30.1.3 MIPI_CAL Enable

1. Enable MIPI_CAL

reg 0x700e3008 0xffffffff //clear status

REG(MIPI_CAL_MIPI_CAL_CTRL_0,MIPI_CAL_NOISE_FLT,0xa) //Filter

REG(MIPI_CAL_MIPI_CAL_CTRL_0,MIPI_CAL_PRESCALE,0x2) //pre-scale

REG(MIPI_CAL_MIPI_CAL_CTRL_0,MIPI_CAL_CLKEN_OVR,0x1) //clk_always_on

reg(MIPI_CAL_MIPI_CAL_CTRL_0,MIPI_CAL_AUTOCAL_EN, %autocal_en) ///if need keeping

MIPI_CAL, %autocal_en = 1 and %startcal = 0

reg(MIPI_CAL_MIPI_CAL_AUTOCAL_CTRL0_0,MIPI_CAL_AUTOCAL_PERIOD, 0xFFFFFFF) //

reg(MIPI_CAL_MIPI_CAL_CTRL_0,MIPI_CAL_STARTCAL, %startcal) //start autocal

2. Status Verification

   After MIPI_CAL enabled, it may need to check the status of MIPI_CAL by calling

   reg list MIPI_CAL_CIL_MIPI_CAL_STATUS_0* *

   reg list MIPI_CAL_CIL_MIPI_CAL_STATUS_2_0* *

30.2 MIPI-CAL Registers

Refer to Section 1.4: Reading Register Tables in the Introduction chapter for the register table protocol as well as recommendations for accessing registers.

30.2.1 MIPI_CAL_MIPI_CAL_CTRL_0

Calibration Control Register

Offset: 0x0 | Read/Write: R/W | Reset: 0x2a000000 (0bxx101010xxxxxxxxxxxxxxxxxxxx0xx00)

Bit	R/W	Reset	Description
29:26	RW	0xa	MIPI_CAL_NOISE_FLT: The DRIVRY and TERMRY signals coming from MIPI pads are utilized by the Calibration state machine for pad calibration. The drivry/termry comes from a noisy analog source, which might have some glitches. The filter in the Calibration state machine is sensitive to these noises. If the calibration done status does not show up, the sensitivity of the filter can be changed through these bits. Ideally, this has to be programmed in a range from 10 to 15. When MIPI_CAL_PRESCALE = 2'b00, this needs to be programmed between 2 to 5.
25:24	RW	0x2	MIPI_CAL_PRESCALE: Auto-Cal calibration step prescale: 00: when calibration step is 0.1 µs 01: when calibration step is 0.5 µs 10: when calibration step is 1.0 µs (default) 11: when calibration step is 1.5 µs This keeps the MIPI bias calibration step between 0.1-1.5 µs.
4	RW	CLK_GATED	MIPI_CAL_CLKEN_OVR: 0 = CLK_GATED 1 = CLK_ALWAYS_ON
1	RW	0x0	MIPI_CAL_AUTOCAL_EN: When set, calibration is triggered periodically. The Period is set using MIPI_CAL_AUTOCAL_CTRL0 register
0	RO	0x0	MIPI_CAL_STARTCAL: Writing a one to this bit starts the Calibration State machine. This bit must be set even if the TERM/HSPU/HSPD values need to be overridden using the TERMOS/HSPUOS/HSPDOS register fields.

30.2.2 MIPI_CAL_MIPI_CAL_AUTOCAL_CTRL0_0

Offset: 0x4 | Read/Write: R/W | Reset: 0xffffffff (0b11111111111111111111111111111111)

Bit	Reset	Description
31:0	-1	MIPI_CAL_AUTOCAL_PERIOD: Auto-calibration period in number of APB system clock cycles.

30.2.3 MIPI_CAL_CIL_MIPI_CAL_STATUS_0

CIL MIPI Calibration Status

Offset: 0x8 | Read/Write: RO | Reset: 0xXXXXXXXX (0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx)

Bit	Reset	Description
31	X	MIPI_AUTO_CAL_DONE_DSID: Debug bit. MIPI Auto Calibration done for DSID, set when the auto calibration sequence for DSID pad brick is done. Write 1-to-clear.
30	X	MIPI_AUTO_CAL_DONE_DSIC: Debug bit. MIPI Auto Calibration done for DSIC, set when the auto calibration sequence for DSIC pad brick is done. Write 1-to-clear.
29	X	MIPI_AUTO_CAL_DONE_DSIB: Debug bit. MIPI Auto Calibration done for DSIB. Set when the auto calibration sequence for DSIA (upper two data lanes) pad brick is done. Write 1-to-clear.

Bit	Reset	Description
28	X	MIPI_AUTO_CAL_DONE_DSIA: Debug bit. MIPI Auto Calibration done for DSI. Set when the auto calibration sequence for DSIA (upper two data lanes) pad brick is done. Write 1-to-clear.
25	X	MIPI_AUTO_CAL_DONE_CSIF: Debug bit. MIPI Auto Calibration done for CSI, set when the auto calibration sequence for CSIF pad brick is done. Write 1-to-clear.
24	X	MIPI_AUTO_CAL_DONE_CSIE: Debug bit. MIPI Auto Calibration done for CSI, set when the auto calibration sequence for CSIE pad brick is done. Write 1-to-clear.
23	X	MIPI_AUTO_CAL_DONE_CSID: Debug bit. MIPI Auto Calibration done for CSI. Set when the auto calibration sequence for shared CSID/DSIB (upper two data lanes) pad brick is done. Write 1-to-clear.
22	X	MIPI_AUTO_CAL_DONE_CSIC: Debug bit. MIPI Auto Calibration done for CSI. Set when the auto calibration sequence for shared CSIC/DSIB (lower two data lanes) pad brick is done. Write 1-to-clear.
21	X	MIPI_AUTO_CAL_DONE_CSIB: Debug bit. MIPI Auto Calibration done for CSI. Set when the auto calibration sequence for CSIB pad brick is done. Write 1-to-clear.
20	X	MIPI_AUTO_CAL_DONE_CSIA: Debug bit. MIPI Auto Calibration done for CSI. Set when the auto calibration sequence for CSIA pad brick is done. Write 1-to-clear.
16	X	MIPI_AUTO_CAL_DONE: Debug bit. MIPI Auto Calibration done. Set when the auto-calibration sequence for all the selected CSI/DSI MIPI pad bricks is done. Write 1-to-clear.
15:12	X	MIPI_CAL_DRIV_DN_ADJ: Debug bit. Driver Pull-down calibration code generated by MIPI auto calibration. Valid only after the auto-calibration sequence has completed (MIPI_CAL_ACTIVE == 0).
11:8	X	MIPI_CAL_DRIV_UP_ADJ: Debug bit. Driver Pull up calibration code generated by MIPI auto calibration. Valid only after auto calibration sequence has completed (MIPI_CAL_ACTIVE == 0).
7:4	X	MIPI_CAL_TERMADJ: Debug bit. Termination code generated by MIPI auto calibration. Valid only after the auto-calibration sequence has completed (MIPI_CAL_ACTIVE == 0).
0	X	MIPI_CAL_ACTIVE: Debug bit. One when auto calibration is active.

30.2.4 MIPI_CAL_CIL_MIPI_CAL_STATUS_2_0

MIPI CLK Calibration Status 2

Offset: 0xc | Read/Write: RO | Reset: 0x000000XX (0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx)

Bit	Reset	Description
6	X	MIPI_CLK_AUTO_CAL_DONE_DSID: MIPI CLK Auto Calibration done for DSID, set when the auto calibration sequence for DSIB pad's CLK (upper) lane is done. Write 1-to-clear.
5	X	MIPI_CLK_AUTO_CAL_DONE_DSIC: MIPI CLK Auto Calibration done for DSIC, set when the auto calibration sequence for DSIB pad's CLK (lower) lane is done. Write 1-to-clear.
4	X	MIPI_CLK_AUTO_CAL_DONE_DSIB: MIPI CLK Auto Calibration done for DSIB, set when the auto calibration sequence for DSIA pad's CLK (upper) lane is done. Write 1-to-clear.
3	X	MIPI_CLK_AUTO_CAL_DONE_DSIA: MIPI CLK Auto Calibration done for DSIA, set when the auto calibration sequence for DSIA pad's CLK (lower) lane is done. Write 1-to-clear.

30.2.5 MIPI_CAL_CILA_MIPI_CAL_CONFIG_0

Calibration Settings for CSI-ABMIPI Pad’s Channel A (lower two data lanes)

Offset: 0x14 | Read/Write: R/W | Reset: 0x00200000 (0bx0xxxxxxx1xxxxxxxxxxxxxxxx00000)

Bit	Reset	Description
30	0x0	MIPI_CAL_OVERIDEA: When 0 (normal operation), use the value in the TERMOS/HSPUOS/HSPDOS register fields as an offset to the Calibration State machine setting for channel A TERMADJ/HSPUADJ/ HSPDADJ values to the MIPI pads. When 1, use the register values in TERMOS/HSPUOS/HSPDOS as the actual value going to channel A TERMADJ/HSPUADJ/HSPDADJ on the MIPI pads.
21	0x1	MIPI_CAL_SELA: Select the CSI-AB Pad's channel A data lanes for auto calibration.
4:0	0x0	MIPI_CAL_TERMOSA: 2's complement offset for TERMADJ going to channel A (currently negative offsets are not supported)

30.2.6 MIPI_CAL_CILB_MIPI_CAL_CONFIG_0

Calibration Settings for CSI-ABMIPI Pad’s Channel B (upper two data lanes)

Offset: 0x18 | Read/Write: R/W | Reset: 0x00200000 (0bx0xxxxxxxx1xxxxxxxxxxxxxxxx00000)

Bit	Reset	Description
30	0x0	MIPI_CAL_OVERIDEB: When 0 (normal operation), use the value in the TERMOS/HSPUOS/HSPDOS register fields as an offset to the Calibration State machine setting for channel B TERMADJ/HSPUADJ/ HSPDADJ values to the MIPI pads. When 1, use the register values in TERMOS/HSPUOS/HSPDOS as the actual value going to channel B TERMADJ/HSPUADJ/HSPDADJ on the MIPI pads. Writing a one to MIPI_CAL_STARTCAL starts the Calibration State machine.
21	0x1	MIPI_CAL_SELB: Select the CSI-AB Pad's channel A data lanes for auto calibration.
4:0	0x0	MIPI_CAL_TERMOSB: 2's complement offset for TERMADJ going to channel B (currently negative offsets are not supported)

30.2.7 MIPI_CAL_CILC_MIPI_CAL_CONFIG_0

Calibration Settings for CSI-ABMIPI Pad’s Channel B (upper two data lanes)

Offset: 0x1c | Read/Write: R/W | Reset: 0x00200000 (0bx0xxxxxxxx1xxxxxxxxxxxxxxxx00000)

Bit	Reset	Description
30	0x0	MIPI_CAL_OVERIDEC: When 0 (normal operation), use the value in the TERMOS/HSPUOS/HSPDOS register fields as an offset to the Calibration State machine setting for channel C TERMADJ/HSPUADJ/ HSPDADJ values to the MIPI pads. When 1, use the register values in TERMOS/HSPUOS/HSPDOS as the actual value going to channel C TERMADJ/HSPUADJ/HSPDADJ on the MIPI pads.
21	0x1	MIPI_CAL_SELC: Select the CSI-AB Pad's channel B data lanes for auto calibration.
4:0	0x0	MIPI_CAL_TERMOSC: 2's complement offset for TERMADJ going to channel C (currently negative offsets are not supported)

30.2.8 MIPI_CAL_CILD_MIPI_CAL_CONFIG_0

Calibration Settings for Shared CSI-CD MIPI Pad’s channel B (upper two data lanes)

Offset: 0x20 | Read/Write: R/W | Reset: 0x00200000 (0bx0xxxxxxxx1xxxxxxxxxxxxxxxx00000)

Bit	Reset	Description
30	0x0	MIPI_CAL_OVERIDED: When 0 (normal operation), use the value in the TERMOS/HSPUOS/HSPDOS register fields as an offset to the Calibration State machine setting for channel B TERMADJ/HSPUADJ/ HSPDADJ values to the MIPI pads. When 1, use the register values in TERMOS/HSPUOS/HSPDOS as the actual value going to channel B TERMADJ/HSPUADJ/HSPDADJ on the MIPI pads.
21	0x1	MIPI_CAL_SELD: Select the CSI-CD Pad's channel B data lanes for auto calibration.
4:0	0x0	MIPI_CAL_TERMOSD: 2's complement offset for TERMADJ going to channel B (currently negative offsets are not supported)

30.2.9 MIPI_CAL_CILE_MIPI_CAL_CONFIG_0

Calibration Settings for CSI-EF MIPI Pad’s Channel A (lower two data lanes

Offset: 0x24 | Read/Write: R/W | Reset: 0x00200000 (0bx0xxxxxxxx1xxxxxxxxxxxxxxxx00000)

Bit	Reset	Description
30	0x0	MIPI_CAL_OVERIDEE: When 0 (normal operation), use the value in the TERMOS/HSPUOS/HSPDOS register fields as an offset to the Calibration State machine setting for channel A TERMADJ/HSPUADJ/ HSPDADJ values to the MIPI pads. When 1, use the register values in TERMOS/HSPUOS/HSPDOS as the actual value going to channel A TERMADJ/HSPUADJ/HSPDADJ on the MIPI pads.
21	0x1	MIPI_CAL_SELE: Select the CSIEF pad’s channel A data lanes for auto calibration.
4:0	0x0	MIPI_CAL_TERMOSE: 2's complement offset for TERMADJ going to channel E (currently negative offsets are not supported)

30.2.10 MIPI_CAL_CILF_MIPI_CAL_CONFIG_0

Calibration Settings for CSI-EF MIPI pad's channel B (upper two data lanes)

Offset: 0x28 | Read/Write: R/W | Reset: 0x00200000 (0bx0xxxxxxxx1xxxxxxxxxxxxxxxx00000)

Bit	Reset	Description
30	0x0	MIPI_CAL_OVERIDEF: When 0 (normal operation), use the value in TERMOS/HSPUOS/HSPDOS register fields as an offset to the Calibration State machine setting for channel E TERMADJ/HSPUADJ/HSPDADJ values to the MIPI pad. When 1, use the register values in TERMOS/HSPUOS/HSPDOS as the actual value going to channel E TERMADJ/HSPUADJ/HSPDADJ on the MIPI pad.
21	0x1	MIPI_CAL_SELF: Select the CSIEF pad's channel B data lanes for auto calibration.
4:0	0x0	MIPI_CAL_TERMOSF: 2's complement offset for TERMADJ going to channel B (Currently negative offsets are not supported)

30.2.11 MIPI_CAL_DSIA_MIPI_CAL_CONFIG_0

Calibration Settings for DSIA MIPI Pad's Channel A (lower two data lanes)

Offset: 0x38 | Read/Write: R/W | Reset: 0x00200000 (0bx0xxxxxxxx100000xxx00000xxx00000)

Bit	Reset	Description
30	0x0	MIPI_CAL_OVERIDEDSIA: When 0 (normal operation), use the value in the TERMOS/HSPUOS/ HSPDOS register fields as an offset to the Calibration State machine setting for TERMADJ/HSPUADJ/ HSPDADJ values to the MIPI pads. When 1, use the register values in TERMOS/HSPUOS/HSPDOS as the actual value going to TERMADJ/HSPUADJ/HSPDADJ on the MIPI pads.
21	0x1	MIPI_CAL_SELDSIA: Select the DSIA pad's Channel A data lanes for auto calibration.
20:16	0x0	MIPI_CAL_HSPDOSDSIA: 2's complement offset for HSPDADJ going to channel A (currently negative offsets are not supported)
12:8	0x0	MIPI_CAL_HSPUOSDSIA: 2's complement offset for HSPUADJ going to channel A (currently negative offsets are not supported)
4:0	0x0	MIPI_CAL_TERMOSDSIA: 2's complement offset for TERMADJ going to channel A (currently negative offsets are not supported)

30.2.12 MIPI_CAL_DSIB_MIPI_CAL_CONFIG_0

Calibration Settings for DSIA MIPI Pad’s Channel B (upper two data lanes)

Offset: 0x3c | Read/Write: R/W | Reset: 0x00200000 (0bx0xxxxxxxx100000xxx00000xxx00000)

Bit	Reset	Description
30	0x0	MIPI_CAL_OVERIDEDSIB: When 0 (normal operation), use the value in the TERMOS/HSPUOS/ HSPDOS register fields as an offset to the Calibration State machine setting for TERMADJ/HSPUADJ/ HSPDADJ values to the MIPI pads. When 1, use the register values in TERMOS/HSPUOS/HSPDOS as the actual value going to TERMADJ/HSPUADJ/HSPDADJ on the MIPI pads.
21	0x1	MIPI_CAL_SELDSIB: Select the DSIA pad's Channel B data lanes for auto calibration.
20:16	0x0	MIPI_CAL_HSPDOSDSIB: 2's complement offset for HSPDADJ going to channel B (currently negative offsets are not supported)
12:8	0x0	MIPI_CAL_HSPUOSDSIB: 2's complement offset for HSPUADJ going to channel B (currently negative offsets are not supported)
4:0	0x0	MIPI_CAL_TERMOSDSIB: 2's complement offset for TERMADJ going to channel B (currently negative offsets are not supported)

30.2.13 MIPI_CAL_DSIC_MIPI_CAL_CONFIG_0

Calibration settings for DSIB MIPI pad's Channel A (lower two data lanes)

Offset: 0x40 | Read/Write: R/W | Reset: 0x00200000 (0bx0xxxxxxx100000xxx00000xxx00000)

Bit	Reset	Description
30	0x0	MIPI_CAL_OVERIDEDSIC: When 0 (normal operation), use the value in TERMOS/HSPUOS/HSPDOS register fields as an offset to the Calibration State machine setting for TERMADJ/HSPUADJ/HSPDADJ values to the MIPI pad. When 1, use the register values in TERMOS/HSPUOS/HSPDOS as the actual value going to TERMADJ/HSPUADJ/HSPDADJ on the MIPI pad.
21	0x1	MIPI_CAL_SELDSIC: Select the DSIB pad's Channel A data lanes for auto calibration.
20:16	0x0	MIPI_CAL_HSPDOSDSIC: 2's complement offset for HSPDADJ going to channel A (Currently negative offsets are not supported)
12:8	0x0	MIPI_CAL_HSPUOSDSIC: 2's complement offset for HSPUADJ going to channel A (Currently negative offsets are not supported)
4:0	0x0	MIPI_CAL_TERMOSDSIC: 2's complement offset for TERMADJ going to channel A (Currently negative offsets are not supported)

30.2.14 MIPI_CAL_DSID_MIPI_CAL_CONFIG_0

Calibration settings for DSIB MIPI pad's Channel B (upper two data lanes)

Offset: 0x44 | Read/Write: R/W | Reset: 0x00200000 (0bx0xxxxxxx100000xxx00000xxx00000)

Bit	Reset	Description
30	0x0	MIPI_CAL_OVERIDEDSID: When 0 (normal operation), use the value in TERMOS/HSPUOS/HSPDOS register fields as an offset to the Calibration State machine setting for TERMADJ/HSPUADJ/HSPDADJ values to the MIPI pad. When 1, use the value in TERMOS/HSPUOS/HSPDOS as the actual value going to TERMADJ/HSPUADJ/HSPDADJ on the MIPI pad.
21	0x1	MIPI_CAL_SELDSID: Select the DSIB pad's Channel B data lanes for auto calibration.
20:16	0x0	MIPI_CAL_HSPDOSDSID: 2's complement offset for HSPDADJ going to channel B (Currently negative offsets are not supported)
12:8	0x0	MIPI_CAL_HSPUOSDSID: 2's complement offset for HSPUADJ going to channel B (Currently negative offsets are not supported)
4:0	0x0	MIPI_CAL_TERMOSDSID: 2's complement offset for TERMADJ going to channel B (Currently negative offsets are not supported)

30.2.15 MIPI_CAL_MIPI_BIAS_PAD_CFG0_0

MIPI Bias Pad Configuration Register

Offset: 0x58 | Read/Write: R/W | Reset: 0x00000000 (0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx00)

Bit	Reset	Description
1	0x0	MIPI_BIAS_PAD_PDVCLAMP: 1=Power down regulator which supplies current to pre-driver logic.
0	0x0	MIPI_BIAS_PAD_E_VCLAMP_REF: 0=The reference voltage internal regulator is merged with Bandgap voltage generator (preferred setting) 1=Generates reference voltage for internal regulator from resistor divider.

30.2.16 MIPI_CAL_MIPI_BIAS_PAD_CFG1_0

MIPI Bias Pad Configuration Register

Offset: 0x5c | Read/Write: R/W | Reset: 0x00000000 (0bxxxxx000xxxxx000xxxxx000xxxxx000)

Bit	Reset	Description
26:24	0x0	PAD_TEST_SEL: Controls which signal to be routed to TEST_OUT 000=VAUXP 001=RUP 010=RDN 011=VREG 1xx=TBD
18:16	0x0	PAD_DRIV_DN_REF: Adjust internal reference level for drive pull-down calibration
10:8	0x0	PAD_DRIV_UP_REF: Adjust internal reference level for drive pull-up calibration
2:0	0x0	PAD_TERM_REF: Adjust internal reference level for termination calibration

30.2.17 MIPI_CAL_MIPI_BIAS_PAD_CFG2_0

MIPI Bias Pad Configuration Register 2

Offset: 0x60 | Read/Write: R/W | Reset: 0x00000002 (0bxxxxxxxxxxxxx00000000000x000x010)

Bit	Reset	Description
18:16	0x0	PAD_VCLAMP_LEVEL: VCLAMP level adjustment
15:8	0x0	PAD_SPARE: Spare bit for MIPI Bias Config
6:4	0x0	PAD_VAUXP_LEVEL: VAUXP level adjustment 00 = no adjustment, default 01 = 105% 10 = 110% 11 = 115% 100 = no adjustment 101 = 95% 110 = 90% 111 = 85%
2	0x0	PAD_E_TXBW: This bit should not be used. Set it to 0.
1	0x1	PAD_PDVREG: Power down the MIPI DSI and CSI pad supply voltage regulator. 0: power up supply voltage regulator 1: power down supply voltage regulator
0	0x0	PAD_VBYPASS: Bypass bang gap voltage reference

30.2.18 MIPI_CAL_DSIA_MIPI_CAL_CONFIG_2_0

Calibration Settings for DSIA pad Channel A CLK (lower CLK lane)

Offset: 0x64 | Read/Write: R/W | Reset: 0x00200000 (0bx0xxxxxxxx1xxxxxxxx00000xxx00000)

Bit	Reset	Description
30	0x0	MIPI_CAL_CLKOVERIDEDSIA: When 0 (normal operation), use the value in HSPUOS/HSPDOS register fields as an offset to the Calibration State machine setting for channel A HSCLKPUADJ/HSCLKPDADJ values to the MIPI Pads. When 1, use the register values in HSPUOS/HSPDOS as the actual values going to channel A HSCLKPUADJ/HSCLKPDADJ on the MIPI Pads.
21	0x1	MIPI_CAL_CLKSELDSIA: Select the DSIA PAD Channel A clock lane for auto calibration.
12:8	0x0	MIPI_CAL_HSCLKPDOSDSIA: 2's complement offset for HSCLKPDADJ going to Channel A CLK lane (currently negative offsets are not supported)
4:0	0x0	MIPI_CAL_HSCLKPUOSDSIA: 2's complement offset for HSCLKPUADJ going to Channel A CLK lane (Currently negative offsets are not supported)

30.2.19 MIPI_CAL_DSIB_MIPI_CAL_CONFIG_2_0

Calibration Settings for DSIA pad's Channel B CLK (upper CLK lane)

Offset: 0x68 | Read/Write: R/W | Reset: 0x00200000 (0bx0xxxxxxxx1xxxxxxxx00000xxx00000)

Bit	Reset	Description
30	0x0	MIPI_CAL_CLKOVERIDEDSIB: When 0 (normal operation), use the value in HSPUOS/HSPDOS register fields as an offset to the Calibration State machine setting for channel B HSCLKPUADJ/HSCLKPDADJ values to the MIPI Pads. When 1, use the register values in HSPUOS/HSPDOS as the actual values going to channel B HSCLKPUADJ/HSCLKPDADJ on the MIPI Pads.
21	0x1	MIPI_CAL_CLKSELDSIB: Select the DSIA PAD Channel B clock lane for auto calibration.
12:8	0x0	MIPI_CAL_HSCLKPDOSDSIB: 2's complement offset for HSCLKPDADJ going to Channel B CLK lane (Currently negative offsets are not supported)
4:0	0x0	MIPI_CAL_HSCLKPUOSDSIB: 2's complement offset for HSCLKPUADJ going to Channel B CLK lane (Currently negative offsets are not supported)

30.2.20 MIPI_CAL_DSIC_MIPI_CAL_CONFIG_2_0

Calibration Settings for DSIB pad's Channel A CLK (lower CLK lane)

Offset: 0x70 | Read/Write: R/W | Reset: 0x00200000 (0bx0xxxxxxxx1xxxxxxxx00000xxx00000)

Bit	Reset	Description
30	0x0	MIPI_CAL_CLKOVERIDEDSIC: When 0 (normal operation), use the above registers as an offset to the Calibration State machine setting for channel A HSCLKPUADJ/HSCLKPDADJ values to the MIPI Pads. When 1, use the register values above as the actual values going to channel A HSCLKPUADJ/ HSCLKPDADJ on the MIPI Pads.
21	0x1	MIPI_CAL_CLKSELDSIC: Select the DSIB PAD Channel A clock lane for auto calibration.
12:8	0x0	MIPI_CAL_HSCLKPDOSDSIC: 2's complement offset for HSCLKPDADJ going to Channel A CLK lane (Currently negative offsets are not supported)
4:0	0x0	MIPI_CAL_HSCLKPUOSDSIC: 2's complement offset for HSCLKPUADJ going to Channel A CLK lane (Currently negative offsets are not supported)

30.2.21 MIPI_CAL_DSID_MIPI_CAL_CONFIG_2_0

Calibration Settings for DSIB pad's Channel B CLK (upper CLK lane)

Offset: 0x74 | Read/Write: R/W | Reset: 0x00200000 (0bx0xxxxxxxx1xxxxxxxx00000xxx00000)

Bit	Reset	Description
30	0x0	MIPI_CAL_CLKOVERIDEDSID: When 0 (normal operation), use the value in the HSPUOS/HSPDOS register field as an offset to the Calibration State machine setting for channel B HSCLKPUADJ/ HSCLKPDADJ values to the MIPI Pads. When 1, use the register values above as the actual values going to channel B HSCLKPUADJ/HSCLKPDADJ on the MIPI Pads.
21	0x1	MIPI_CAL_CLKSELDSID: Select the DSIB PAD Channel B clock lane for auto calibration.
12:8	0x0	MIPI_CAL_HSCLKPDOSDSID: 2's complement offset for HSCLKPDADJ going to Channel B CLK lane (Currently negative offsets are not supported)
4:0	0x0	MIPI_CAL_HSCLKPUOSDSID: 2's complement offset for HSCLKPUADJ going to Channel B CLK lane (Currently negative offsets are not supported)

CHAPTER 31: VIDEO INPUT (VI)

The Video Input unit (VI3) receives data from the CSI unit and prepares it for presentation to system memory or the dedicated ISP execution resources. The Video Input unit provides formatting for RGB, YCbCr, and raw Bayer data in support of a number of camera user models. These models include single and multi-camera systems, which may have up to six active streams. The input streams are obtained from MIPI compliant CMOS sensor camera modules.

In addition to packing of image data, several advanced use cases are supported with processing of the raw Bayer data. These user modes involve the capture of high-resolution still images while simultaneously maintaining a lower resolution preview or video capture through the ISP2 in addition to the capture of stereo video and still images. In order to provide for improved synchronization of camera sensor control and the rest of the camera capture logic, a second physical interface to the Host1x is provided along with a dedicated I^2C interface as a major feature upgrade for the VI3 unit.

This chapter also describes the VI registers; however, it is not intended to be a programming guide to VI, as it is expected that NVIDIA supplied drivers will always be used with it. However, the register interface is documented to aid with understanding those drivers.

31.1 VI Glossary

Term	Definition
Bayer	A type of image sampling pattern invented by Dr. Bryce E. Bayer of Eastman Kodak. The pattern consists of quads of pixels with two green samples, one red sample and one blue sample: EOF	End of Frame
RGB	Name given to pixels with Red Green and Blue color components. This is the pixel format typically found in most display technologies since each color component corresponds to the colors of the filters or phosphors used in the display device.
SOF	Start of Frame
YCbCr	An alternative pixel representation that takes advantage of the properties of the human psycho-perceptual vision system. It consists of a luminance channel Y and two color difference signals Cb and Cr.
YUV	See YCbCr. U and V are equivalent to Cb and Cr, respectively.
ZSL	Zero Shutter Lag

31.2 Functionality

31.2.1 Camera Subsystem

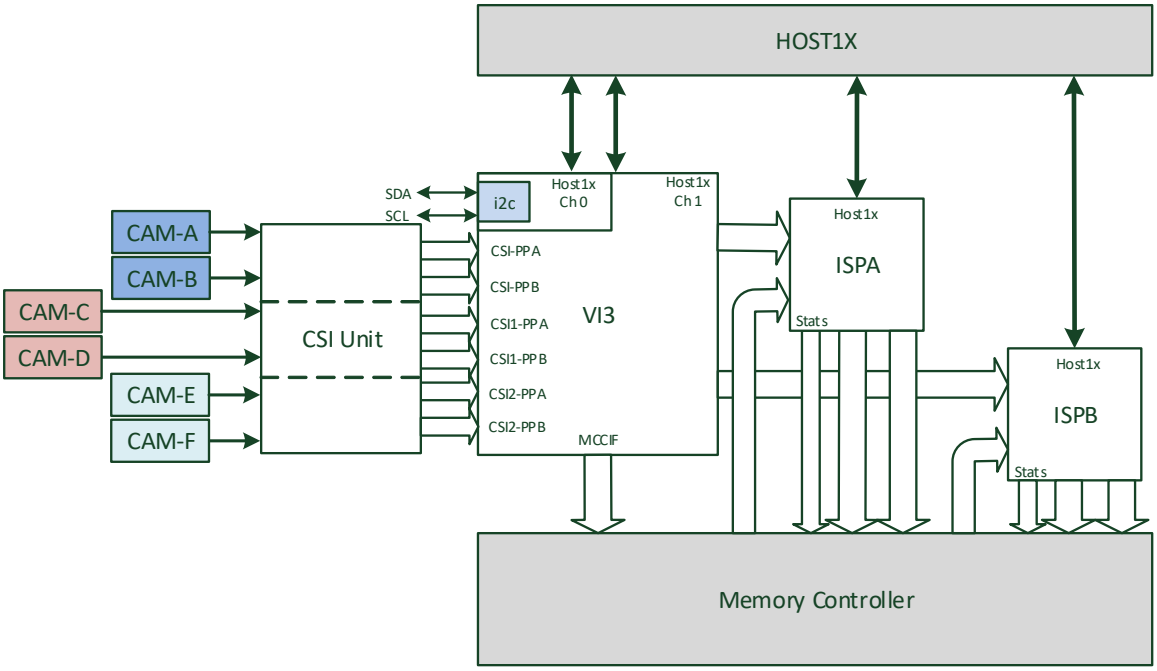
The VI3 unit interfaces with four major functional units within the Tegra® X1 camera subsystem in addition to the Host1x, which is used for control programming:

- Camera Serial Interface (CSI) – Provides for the interface to up to six MIPI compliant CMOS sensors through the CSI, CSI1 and CSI2 instances and formats the pixel data for presentation to the VI3 unit.
- Image Signal Processors A and B (ISPA and ISPB) – Execution resource providing image processing in support of various camera use cases and raw Bayer processing.
- Memory Controller (MC) – Interface between the VI3 unit and ISP and memory resources.

The main paths for the flow of image data for the VI3 unit are from the CSI → VI3 → ISPA/ISPB and from the CSI → VI3 → Memory Controller. There are also several additional paths for data flow within the camera's subsystem, which includes paths from the VI3 unit to Memory Controller and the Memory Controller to the ISP. The ability to present data to system memory

allows customer-specific algorithms, such as blur reduction, chromatic aberration correction, and high ISO noise processing, to be inserted into the ISP3.1 pipeline. An added benefit is the ability to divide input data into more manageable widths when processing high-resolution still images. The high-level block diagram for the Tegra X1 camera subsystem is illustrated in the following figure.

Figure 125: Tegra X1 Camera Subsystem



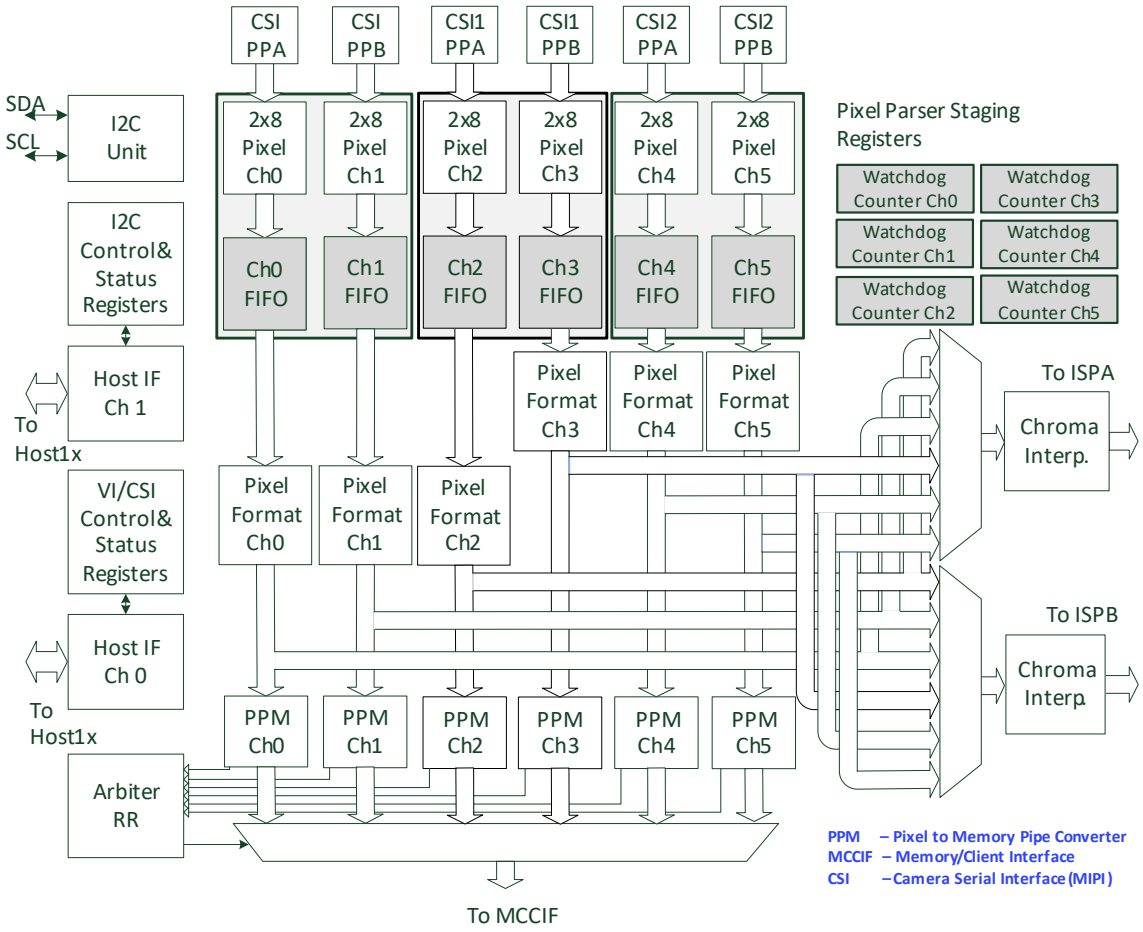
The support for multiple paths to and from memory within the camera subsystem is useful for very wide surfaces, such as still capture, where the alternative would be to have very large on-chip line stores. Because there are two ISP resources, two data streams from separate sensors or camera modules can be provided for immediate processing in support of dual and stereo camera capture models. In addition to the basic multi-camera user modes, the output path from the VI3 unit to memory allows the maintenance of a Zero Shutter Lag (ZSL) circular buffer for high-resolution capture while the ISP is processing the preview stream for display.

Two Host1x interfaces are provided within the VI3 unit. The first Host1x interface handles the flow of the programmed control state for the VI3 unit. The second Host1x interface provides a dedicated low latency control for camera support hardware through the I2C. The I2C module is embedded within the VI3 unit and may be programmed with either the Host1x or through Memory Mapped I/O. The CSI registers are physically located in the VI3 unit and are accessed through the Host interface of the VI3 unit. The I2C registers and interrupts are accessed through the dedicated Host1x. Refer to Chapter 29: MIPI-CSI (Camera Serial Interface) in this document for more information.

31.2.2 Block Diagram

The VI3 unit accepts pixel data from an external source, packages the received data, and presents the data to either system memory or the ISP resources directly. The pixel data received can be in a variety of formats including Raw, RGB, and YCbCr. The high-level block diagram for the VI3 unit is shown in the following figure.

Figure 126: VI3 High-Level Block Diagram



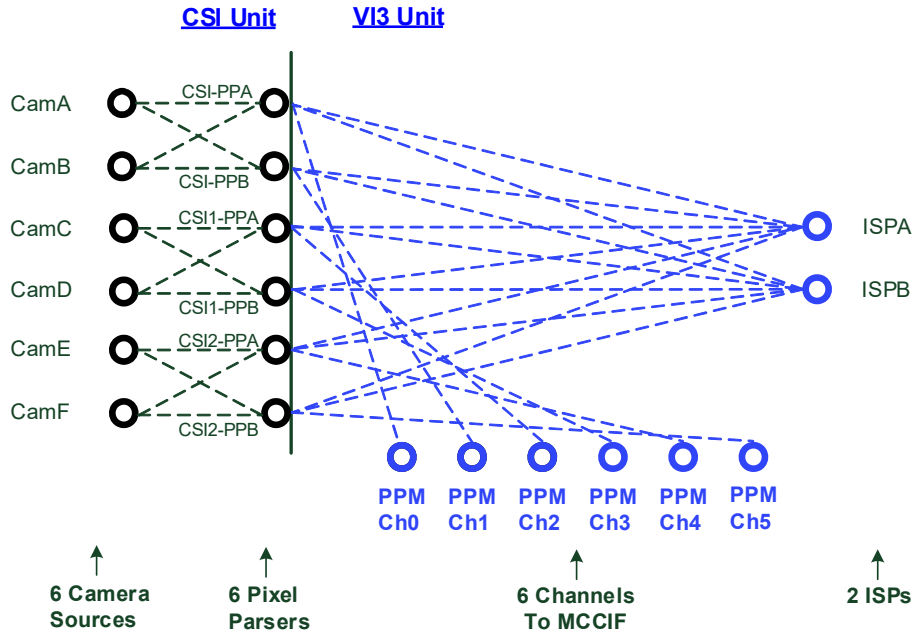
The VI3 unit offers these features not present in earlier Tegra devices:

- Four additional channels to allow up to six simultaneous streams to be managed
- An I^2C interface with a dedicated Host1x channel for control

31.2.3 Single and Multiple Stream Datapaths

The Tegra X1 camera subsystem provides considerable flexibility in the support of various single and dual camera user models as in previous implementations. In addition, to the single and dual camera support an expanded capability is introduced to manage multiple camera models with support for data capture from up to six camera sources. In all of the use cases, either one or two of the streams may be presented directly to the ISP resources in addition to system memory. As a result of having two ISP execution resources in the system, any capture scenario involving more than two camera sources will require management of at least one through presentation to system memory. The support for up to six camera streams introduces a flexibility that is manifested as a number of programmable configurations that allow the image data to be directed to system memory and ISP execution resources. The datapaths for the camera subsystem are illustrated in the following figure.

Figure 127: Multi-Stream Datapaths through the CSI and VI3



The CSI unit provides for connection of up to six cameras in the system and is organized as three identical instances of two MIPI support blocks, each with a separate 4-lane interface that can be configured as a single camera with 4 lanes or as a dual camera with 2 lanes available for each camera. Each of the two camera interfaces has two pixel parsers which provide the data feed to the VI3 unit. The VI3 unit can be programmed to route the data streams to system memory, the ISP resources, or both the ISP and system memory using the various configurations options available. In addition to supporting a dual stream capture from two sources, the CSI unit supports a broadcast mode in which a single camera data stream can be broadcast to both pixel parsers simultaneously for each of the instances (CSI-PPA and CSI-PPB, CSI1-PPA and CSI1-PPB, and CSI2-PPA and CSI2-PPB). In the broadcast mode the same data stream can be presented to the ISP or memory resources in a number of different ways.

There are many configurations possible for the single, dual, and three to six camera user models with the primary constraint that at most only two streams may be presented to the ISPA and/or ISPB with all other streams being routed to system memory. As with the previous VI implementations, a support for broadcast to both ISPs and/or system memory is supported. The following table provides the configuration options for a single camera source.

Table 176: Datapath Options through VI3 for Single Camera User Models

Datapath Active for Single Camera Source	Comments
ISPA	Single stream capture through either CSI-PPA, CSI-PPB, CSI1-PPA, CSI1-PPB, CSI2-PPA, or CSI2-PPB
ISPB	Single stream capture through either CSI-PPA, CSI-PPB, CSI1-PPA, CSI1-PPB, CSI2-PPA, or CSI2-PPB
ISPA & ISPB	Single stream broadcast through either (CSI-PPA and CSI-PPB), or (CSI1-PPA and CSI1-PPB), or (CSI2-PPA and CSI2-PPB),
ISPA & ISPB & [(PPM0 or PPM1)or (PPM2 or PPM3) or (PPM4 or PPM5)]	Single stream broadcast through either (CSI-PPA and CSI-PPB), or (CSI1-PPA and CS1I-PPB), or (CSI2-PPA and CSI2-PPB) ; single stream to MEM through either (PPM0 or PPM1) or (PPM2 or PPM3) or (PPM4 or PPM5)].
ISPA & ISPB & [(PPM0 & PPM1)or (PPM2 & PPM3) or (PPM4 & PPM5)]	Single stream broadcast through either (CSI-PPA and CSI-PPB), or (CSI1-PPA and CSI1-PPB), or (CSI2-PPA and CSI2-PPB); both ISPA and ISPB and either (PPM0 and PPM1) or (PPM2 and PPM3) or (PPM4 and PPM5) active.
ISPA & [(PPM0 or PPM1)or (PPM2 or PPM3) or (PPM4 or PPM5)]	Single stream capture through either (CSI-PPA or CSI-PPB), or (CSI1-PPA or CSI1-PPB), or (CSI2-PPA or CSI2-PPB); single stream to ISPA and MEM through either (PPM0 or PPM1) or (PPM2 or PPM3) or (PPM4 or PPM5).
ISPA & [(PPM0 & PPM1)or (PPM2 & PPM3) or (PPM4 & PPM5)]	Single stream capture through both either (CSI-PPA and CSI-PPB), or (CSI1-PPA and CSI1-PPB), or (CSI2-PPA and CSI2-PPB), single stream to ISPA and MEM through either (PPM0 and PPM1) or (PPM2 and PPM3) or (PPM4 and PPM5)

Table 176: Datapath Options through VI3 for Single Camera User Models

Datapath Active for Single Camera Source	Comments
ISPB & [(PPM0 or PPM1)or (PPM2 or PPM3) or (PPM4 or PPM5)]	Single stream capture through either (CSI-PPA and CSI-PPB), or (CSI1-PPA and CSI1-PPB), or (CSI2-PPA and CSI2-PPB), single stream to ISPB and MEM through either (PPM0 and PPM1) or (PPM2 and PPM3) or (PPM4 and PPM5)
(PPM0 or PPM1)or (PPM2 or PPM3) or (PPM4 or PPM5)	Single stream capture through either (CSI-PPA or CSI-PPB), or (CSI1-PPA or CSI1-PPB), or (CSI2-PPA or CSI2-PPB); single stream to MEM through either (PPM0 or PPM1) or (PPM2 or PPM3) or (PPM4 or PPM5).
(PPM0 & PPM1)or (PPM2 & PPM3) or (PPM4 & PPM5)	Single stream capture through either (CSI-PPA or CSI-PPB), or (CSI1-PPA or CSI1-PPB), or (CSI2-PPA or CSI2-PPB); single stream to MEM through either (PPM0 and PPM1) or (PPM2 and PPM3) or (PPM4 and PPM5)

The multiple camera use cases follow a similar set of configuration options as seen with the single camera. The system limitation of two ISP resources and the separate instances for the CSI unit introduce some constraints. The constraints are primarily that only two streams can be presented directly to the ISPA and ISPB simultaneously, and the broadcast capability is constrained to the grouping associated with CSI-PPA and CSI-PPB, CSI1-PPA and CSI1-PPB, and CSI2-PPA and CSI2-PPB.

31.2.4 Host1x Interfaces

The Host1x interface is the primary method for communicating control state from the CPU to the VI3 unit. It is responsible for the register write and read requests. Two Host1x interfaces are available. The first is used to configure the registers for to manage the camera data streaming from the CSI, CSI1, and CSI2 instances within the CSI unit to memory or the ISPA/B, and the second Host1x interface is provided to manage the I^2C transactions provided with the VI_I2C block.

The Tegra X1 camera subsystem targets single and multiple image sources for still and video capture as in previous Tegra devices. The VI3 unit has increased the number of camera streams which can be managed simultaneously to a maximum of six and added the VI_I2C as a means of issuing I^2C transactions. As a result of the increase in camera streams and the inclusion of the I^2C Controller within the VI3 unit, the number of host channels has also been increased to four.

31.2.4.1 Primary Host1x Interface

The Host1x interface of the VI3 unit is used to configure the registers for the VI3 unit and the CSI, CSI1, and CSI2 instances within the CSI unit. The rest of the section also describes some of the CSI related logic.

The registers can be categorized in two categories: configuration registers and operational registers. The configuration registers should remain constant for the life of the camera operation (until the camera unit is re-enabled between application switching). The operational registers are required to process a given frame of image.

The registers can be divided into two categories: configuration registers and operational registers. The configuration registers remain constant for the life of the camera operation (until the camera unit is re-enabled between application switching). The operational registers are required to process a given frame of image.

In order to process the images with minimum V-blank, the operational registers need to be double-buffered to speed up the transition between the operational parameters between the two frames.

VI State Updates

The operation registers are initially assembled in the assembly state. The registers are copied to the active state when the pipe is idle or immediately after startup. In all other cases, they are copied to the active state when the update command is received and when the next EOF is received. The following table describes the VI state update trigger.

Table 177: Single Shot Register Definition

Register	Field	Bits	Reset	Description
VI_CSI_[0..5]_SINGLE_SHOT	CAPTURE	0	0	Software sets this bit to request transition of the previously assembled assembly state to the active state and schedule single shot capture. The actual update of the operational register is gated by the next EOF. Register read back returns the current capture status 0: No capture pending. 1: Capture pending
VI_CSI_[0..5]_SINGLE_SHOT_UPDATE	CAPTURE_GOOD_FRAME	0	1	This bit controls when the update command should be processed. 1'b0: Transition to update when the next EOF is received, irrespective of the state of previous frame. **Note1:** Useful for debugging and/or bring up when the sensor/VI configuration could be incorrect. 1'b1: Transition to next operational state when the next EOF is received AND the previous frame was the correct frame based on the current operational state. **Note2:** Any mismatch will result in the frame getting dropped and the CSI rearming with unchanged configuration. **Note3**: After exiting the reset state, the previous frame with the correct state should be set.

In the normal functional mode of operation, the EOF updates the pending assembly state to the active state only if the previous frame was successfully captured (or this is the first frame out of reset). If for any reason the previous frame was detected to be an errored frame, on the next SOF, the VI3 and CSI units continue to work on the previous operational state configuration and do not update to the next set of operational parameters. An additional configuration register controls the behavior of VI3 unit.

VI Sync Points

Sync points (syncpts) are a means of synchronizing software programmed control state and hardware operations, without the need for register polling or interrupt service routines. Host1x contains a number of counters. These counters are referenced through an ***index***. Software can issue two kinds of syncpt-related methods:

- INCR_SYNCPT ***<condition> <index>***
- WAIT_SYNCPT ***<index> <threshold>***

INCR_SYNCPT tells the hardware that when ***<condition>*** is met, the hardware should send the value of ***<index>*** to the Host1x on the RtnIndx bus. On receiving the index return, Host1x will increment the counter pointed to by ***<index>***.

WAIT_SYNCPT is a Host1x method which tells Host1x to cease processing commands and register writes for that unit until the value of the counter pointed to by ***<index>*** reaches or exceeds the value of ***<threshold>***.

Since software can be made to wait for the counter to reach a certain value and hardware controls the incrementing of the counter, the two can be kept synchronized, ensuring that control state is metered out at the appropriate times by Host1x. In order to support the single shot and shadow register behaviors, sync point conditions 0x03 through 0x1F are buffered, allowing up to two sync points for each of these conditions to be programmed. The following table describes the VI3 sync point conditions.

Table 178: Sync Point Conditions

Condition	Value	FIFO Depth	Description
IMMEDIATE	0x00	1	Predefined Immediate condition. The VI3 returns this syncpt immediately.
OP_DONE	0x01	1	Predefined Operation Done Condition
RD_DONE	0x02	1	Predefined Read Done condition. The VI3 treats this as IMMEDIATE because CSI/VI do not have any read ports.
REG_WR_SAFE	0x03	2	Predefined Register Write Safe condition. Technically software should know when it is safe to write to the functional registers because it knows when CSI/VI is idle. The VI3 instead generates this syncpt when there are no pending captures and pending OP*_DONE syncpts have been sent to Host1x.
VI_CSI_PPA_LINE_START	0x04	2	Received a SOL indication on camera (CSI PPA) input stream. This SOL is detected at the VI3 input.
VI_CSI_PPA_FRAME_START	0x05	2	Valid SOF has been received by the camera (CSI PPA) input. This SOF is detected at the VI3 input.
VI_MWA_REQ_DONE	0x06	2	Predefined Operation Done for All Reqs for a Frame condition. VI3 generates this syncpt when all requests for a captured frame from camera (CSI PPA) to memory are completed.
VI_MWA_ACK_DONE	0x07	2	Predefined Operation Done for all WrAck's for a Frame condition. VI3 generates this syncpt when all WrAck for a captured frame from camera (CSI PPA) to memory are received.
VI_CSI_PPB_LINE_START	0x08	2	Received a SOL indication on camera (CSI PPB) input stream. This SOL is detected at the VI3 input.
VI_CSI_PPB_FRAME_START	0x09	2	Valid SOF has been received by the camera (CSI PPB) input. This SOF is detected at the VI3 input.
VI_MWB_REQ_DONE	0x0A	2	Predefined Operation Done for All Reqs for a Frame condition. VI3 generates this syncpt when all requests for a captured frame from camera (CSI PPB) to memory are completed.
VI_MWB_ACK_DONE	0x0B	2	Predefined Operation Done for all WrAck's for a Frame condition. VI3 generates this syncpt when all WrAck for a captured frame from camera (CSI PPB) to memory are received.
VI_CSI_PPC_LINE_START	0x0C	2	Received a SOL indication on camera (CSI1 PPA) input stream. This SOL is detected at the VI3 input.
VI_CSI_PPC_FRAME_START	0x0D	2	Valid SOF has been received by the camera (CSI1 PPA) input. This SOF is detected at the VI3 input.
VI_MWC_REQ_DONE	0x0E	2	Predefined Operation Done for All Reqs for a Frame condition. VI3 generates this syncpt when all requests for a captured frame from camera (CSI1 PPA) to memory are completed.
VI_MWC_ACK_DONE	0x0F	2	Predefined Operation Done for all WrAck's for a Frame condition. VI3 generates this syncpt when all WrAck for a captured frame from camera (CSI1 PPA) to memory are received.
VI_CSI_PPD_LINE_START	0x10	2	Received a SOL indication on camera (CSI1 PPB) input stream. This SOL is detected at the VI3 input.
VI_CSI_PPD_FRAME_START	0x11	2	Valid SOF has been received by the camera (CSI1 PPB) input. This SOF is detected at the VI3 input.
VI_MWD_REQ_DONE	0x12	2	Predefined Operation Done for All Reqs for a Frame condition. VI3 generates this syncpt when all requests for a captured frame from camera (CSI1 PPB) to memory are completed.
VI_MWD_ACK_DONE	0x13	2	Predefined Operation Done for all WrAck's for a Frame condition. VI3 generates this syncpt when all WrAck for a captured frame from camera (CSI1 PPB) to memory are received.
VI_CSI_PPE_LINE_START	0x14	2	Received a SOL indication on camera (CSI2 PPA) input stream. This SOL is detected at the VI3 input.
VI_CSI_PPE_FRAME_START	0x15	2	Valid SOF has been received by the camera (CSI2 PPA) input. This SOF is detected at the VI3 input.

Table 178: Sync Point Conditions

Condition	Value	FIFO Depth	Description
VI_MWE_REQ_DONE	0x16	2	Predefined Operation Done for All Reqs for a Frame condition. VI3 generates this syncpt when all requests for a captured frame from camera (CSI2 PPA) to memory are completed.
VI_MWE_ACK_DONE	0x17	2	Predefined Operation Done for all WrAck's for a Frame condition. VI3 generates this syncpt when all WrAck for a captured frame from camera (CSI2 PPA) to memory are received.
VI_CSI_PPF_LINE_START	0x18	2	Received a SOL indication on camera (CSI2 PPB) input stream. This SOL is detected at the VI3 input.
VI_CSI_PPF_FRAME_START	0x19	2	Valid SOF has been received by the camera (CSI2 PPB) input. This SOF is detected at the VI3 input.
VI_MWF_REQ_DONE	0x1A	2	Predefined Operation Done for All Reqs for a Frame condition. VI3 generates this syncpt when all requests for a captured frame from camera (CSI2 PPB) to memory are completed.
VI_MWF_ACK_DONE	0x1B	2	Predefined Operation Done for all WrAck's for a Frame condition. VI3 generates this syncpt when all WrAck for a captured frame from camera (CSI2 PPB)to memory are received.
VI_ISPA_DONE	0x1C	2	Predefined Operation Done condition. VI3 generates this syncpt when it finishes sending frame from the configured camera to ISPA
VI_ISPB_DONE	0x1D	2	Predefined Operation Done condition. VI3 generates this syncpt when it finishes sending frame from the configured camera to ISPB
VI_VGP0_RECD	0x1E	2	Rising edge detection on VGPx (VGPx being selected by a configuration register)
VI_VGP1_RECD	0x1F	2	Rising edge detection on VGPy (VGPy being selected by a configuration register)

VI Configuration Register Details

When the Host1x writes to any of the functional mode registers, the configuration value is immediately visible. So the software should write to such registers when the CSI/VI3 pipeline is idle. Software has visibility when the CSI/VI3 units are idle because it is not waiting for any syncpts.

When the VI3 unit receives the SOF from the CSI unit, it raises the syncpt corresponding to SOF_RECD on the appropriate syncpt index. This indicates to the software that the CSI and VI3 units are currently capturing a frame. At this time, software sends out the operational parameters for the next frame. These register writes are written to the shadow register. After the shadow register writes are complete, software indicates that the shadow registers update is done by writing to the VI_CSI_[0..5]_SINGLE_SHOT_CAPTURE register. After the single shot capture trigger is set, all shadow copies are now programmed and the VI3 unit will wait for the next EOF for transferring the active copy. When it receives the EOF and the previous frame is error free and correct, it updates the active registers from the shadow copy.

The VI3 unit marks all writes to memory as writes with ACK required. It also maintains a counter to keep track of number of writes outstanding. When the EOF is received from the CSI and there are no WrAcks pending, the VI3 unit generates MW[A..F]_REQ_DONE to Host1x. Software uses this syncpt to pass this memory buffer to the next unit which will process the frame. In case the VI3 unit is configured to send the frame to ISP, it raises the ISPA_DONE or ISPB_DONE syncpt when the EOF packet is sent to the ISP. Depending on the configuration of HOST1X_UPDATE register configuration, these syncpts are either raised when the frame is known to be good or when any frame is sent to memory/ISP.

31.2.4.2 VI-I2C Dedicated Host1x Interface

The Host1x interface is the primary method of communicating the control state from the CPU to the VI_I2C. It is responsible for the register write and register read requests. The VI_I2C shares the 4 channels allocated to the VI3 unit and for the Host1x interface. The use of two channels from the available four allows the VI_ I2C block to the software to simultaneously capture images from 2 cameras or devices asynchronous to each other.

VI-I2C Sync Points

The VI_I2C provides a similar set of sync points as seen with the VI for managing transactions based on frame events. Since the VI_I2C does not require shadowing, there is no need to provide for a FIFO to buffer the sync point. The SOF, SOL, and EOF sync points are available to enable the ability to manage the direct transaction and to provide general program control. The following table describes the sync points for the VI_I2C block.

Table 179: VI_I2C Sync Point Conditions

Condition	Value	Description
IMMEDIATE	0x00	Predefined Immediate condition. The VI3 unit returns this syncpt immediately.
OP_DONE	0x01	Predefined Operation Done Condition
RD_DONE	0x02	Predefined Read Done condition. The VI3 unit treats this as IMMEDIATE because CSI/VI do not have any read ports.
REG_WR_SAFE	0x03	Predefined Register Write Safe condition. Technically, software should know when it is safe to write to the functional registers as it knows when CSI/VI is idle. The VI3 unit instead generates this syncpt when there are no pending captures and pending OP*_DONE syncpt have been sent to Host1x
VI_I2C_ERECOVERY_TX_DONE	0x04	An Error Recovery path Direct packet TX has completed.
VI_I2C_DIRECT_TX_DONE	0x05	A Direct mode packet TX transaction has completed
VI_I2C_DIRECT_RX_DONE	0x08	A Direct mode packet RX transaction has completed
VI_I2C_CSI_PPA_FS	0x09	Valid SOF has been received by the camera (CSI PPA) input. This SOF is detected at the VI3 input.
VI_I2C_CSI_PPB_FS	0x0A	Valid SOF has been received by the camera (CSI PPB) input. This SOF is detected at the VI3 input.
VI_I2C_CSI_PPA_FE	0x0B	Valid EOF has been received by the camera (CSI PPA). This is detected at the VI3 input.
VI_I2C_CSI_PPB_FE	0x0C	Valid EOF has been received by the camera (CSI PPB). This is detected at the VI3 input.
VI_I2C_CSI_PPA_LS	0x0D	Received an SOL indication on the camera (CSI PPA) input stream. This SOL is detected at the VI3 input.
VI_I2C_CSI_PPB_LS	0x0E	Received an SOL indication on the camera (CSI PPB) input stream. This SOL is detected at the VI3 input.
VI_I2C_CSI1_PPA_FS	0x0F	Valid SOF has been received by the camera (CSI1 PPA) input. This SOF is detected at the VI3 input.
VI_I2C_CSI1_PPB_FS	0x10	Valid SOF has been received by the camera (CSI1 PPB) input. This SOF is detected at the VI3 input.
VI_I2C_CSI1_PPA_FE	0x11	Valid EOF has been received by the camera (CSI1 PPA). This is detected at the VI3 input.
VI_I2C_CSI1_PPB_FE	0x12	Valid EOF has been received by the camera (CSI1 PPB). This is detected at the VI3 input.
VI_I2C_CSI1_PPA_LS	0x13	Received an SOL indication on the camera (CSI1 PPA) input stream. This SOL is detected at the VI3 input.
VI_I2C_CSI1_PPB_LS	0x14	Received an SOL indication on the camera (CSI1 PPB) input stream. This SOL is detected at the VI3 input.
VI_I2C_CSI2_PPA_FS	0x15	Valid SOF has been received by the camera (CSI2 PPA) input. This SOF is detected at the VI3 input.
VI_I2C_CSI2_PPB_FS	0x16	Valid SOF has been received by the camera (CSI2 PPB) input. This SOF is detected at the VI3 input.
VI_I2C_CSI2_PPA_FE	0x17	Valid EOF has been received by the camera (CSI2 PPA). This is detected at the VI3 input.
VI_I2C_CSI2_PPB_FE	0x18	Valid EOF has been received by the camera (CSI2 PPB). This is detected at the VI3 input.
VI_I2C_CSI2_PPA_LS	0x19	Received a SOL indication on the camera (CSI2 PPA) input stream. This SOL is detected at the VI3 input.
VI_I2C_CSI2_PPB_LS	0x1A	Received a SOL indication on the camera (CSI2 PPB) input stream. This SOL is detected at the VI3 input.

VI I2C Configuration Register Details

When the VI_I2C Host1x writes to any of the functional mode registers, the configuration value are immediately visible.

31.2.5 VI I2C Clocking and Reset

The VI_I2C block in the VI3 unit is clocked independent of the VI3. In order to enable the VI_I2C along with its embedded I2C controller, the clocks to both must be enabled. The VI_I2C clock is enabled by setting the CLK_ENB_VI_I2C bit in the CLK_RST_CONTROLLER_CLK_OUT_ENB_Y_0 register and the clock for the embedded I2C controller by setting the CLK_ENB_I2C_SLOW bit in the CLK_RST_CONTROLLER_CLK_OUT_ENB_L_0 in the CAR block. In order to program the VI_I2C, the Host1x must also be enabled.

The VI_I2C block and the VI_I2C dedicated Host1x interface have independent resets from the VI3. The VI_I2C portion of the VI3 is reset by setting the SWR_VI_I2C_RST in the CLK_RST_CONTROLLER_RST_DEVICES_Y_0 register in the CAR block. This resets everything associated with the VI_I2C block including the I2C Host1x slave interface, the I2C IP block, and all VI_I2C control logic.

31.2.6 Error Status and Interrupts

This section discusses the reporting of various error conditions that can occur with the VI3 unit during the operation of the camera subsystem. The VI and the VI_I2C have different requirements for reporting various error conditions.

31.2.6.1 VI Error Status and Interrupts

The VI_CSI_[0..5]_ERROR_STATUS and VI_CSI_[0..5]_ERROR_INT_MASK functional registers are expected to be active for the camera use session. The remaining VI3 functional registers are described in the following table.

The VI_CSI_[0..5]_ERROR STATUS is a read-only register that indicates whether an error has occurred. All of the conditions defined in this register can be programmed to generate an interrupt using the VI_CSI_[0..5]_ERROR_INT_MASK as described in the following table.

Table 180: VI Error Status and Interrupt Mask Registers Functional Register Definitions

Register	Field	Bits	Reset Value	Description
VI_CSI_[0..5]_ERROR_STATUS	LINE_WIDTH_SHORT_ERROR:	0	X	Flagged if the frame line width is smaller than WIDTH. Write 1 to clear.
	LINE_WIDTH_LONG_ERROR:	1	X	Flagged if the frame line width is larger than WIDTH. Write 1 to clear
	FRAME_HEIGHT_SHORT_ERROR	2	X	Flagged if the frame height is smaller than HEIGHT. Write 1 to clear
	FRAME_HEIGHT_LONG_ERROR	3	X	Flagged if the frame height is larger than HEIGHT. Write 1 to clear
	CSI_FRAME_ERROR	4	X	Flagged if the EOF field from the CSI has FRAME_ERROR bit set
	WATCHDOG_INT	5	X	This event occurs when Watchdog timer expires and the EOF is not received on the CSI2VI interface
VI_CSI_[0..5]_ERROR_INT_MASK	LINE_WIDTH_SHORT_INT_MASK	0	0x0	Line width short error interrupt mask
	LINE_WIDTH_LONG_INT_MASK	1	0x0	Line width long error interrupt mask
	FRAME_HEIGHT_SHORT_INT_MASK	2	0x0	Frame height short error interrupt mask
	FRAME_HEIGHT_LONG_INT_MASK	3	0x0	Frame height long error interrupt mask
	CSI_FRAME_ERROR_INT_MASK	4	0x0	CSI error interrupt mask
	WATCHDOG_INT_MASK:	5		Watchdog Timer 0 Interrupt Mask. This controls interrupts when a Watchdog trigger event occurs for the CSI stream. 0 = Disabled 1 = Enabled

Watchdog Counter

To detect catastrophic error conditions in which the CSI or VI3 unit has ceased operating, there are six Watchdog timers provided with the VI3 unit. The WD timers are associated with the image data streams being presented to the VI3 through the CSI, CSI1, and CSI2 PPA and PPB ports. Once the WD timer is configured for an image data stream, the timer must be prevented from expiring by the hardware. If the hardware does not disable the timer before the count expires, an interrupt is generated.

The WD timer counter is initialized to the value in the PERIOD register on the arrival of the SOF packet at the CSI to the VI3 interface for the active stream. The counter then proceeds to count down one count for every pixel clock. If the count reaches zero, with the WATCHDOG_INT_MASK bit set in the VI_CSI_[0..1]_ERROR_INT_MASK register, an interrupt is generated.

If an EOF packet is received at the CSI port, the countdown is stopped. In normal operation, this prevents the counter from reaching zero and generating an interrupt.

The ISP also provides a WD timer system.

31.2.6.2 VI_I2C Status and Interrupts

This section discusses the reporting of various status and error conditions that can occur with the VI_I2C during the operation of the I^2C controller. Refer to Chapter 35: I2C Controller in this TRM for details on the I^2C registers. The corresponding VI3 I^2C registers and I^2C reference registers are defined at the end of this chapter and summarized in the table below.

Table 181: I^2C Status and Interrupt Mask Registers Fields Used for Master Transactions

VI_I2C Virtual Status and Interrupt Reference Registers	I2C Controller Mapped Register
VI_ I2C_STREAM_DIRECT_I2C_INTERRUPT_MASK_REGISTER_0 VI_ I2C_STREAM_ERECOVERY_I2C_INTERRUPT_MASK_REGISTER_0	I2C_INTERRUPT_MASK_REGISTER_0
VI_ I2C_ STREAM_DIRECT_I2C_INTERRUPT_SET_REGISTER_0 VI_ I2C_ STREAM_ERECOVERY_I2C_INTERRUPT_SET_REGISTER_0	I2C_INTERRUPT_SET_REGISTER_0
VI_ I2C_ STREAM_DIRECT_I2C_INTERRUPT_STATUS_REGISTER_0 VI_ I2C_ STREAM_ERECOVERY_I2C_INTERRUPT_STATUS_REGISTER_0	I2C_INTERRUPT_STATUS_REGISTER_0
VI_ I2C_ STREAM_DIRECT_I2C_INTERRUPT_SOURCE_REGISTER_0 VI_ I2C_ STREAM_ERECOVERY_I2C_INTERRUPT_SOURCE_REGISTER_0	I2C_INTERRUPT_SOURCE_REGISTER_0
VI_I2C_ STREAM_DIRECT_I2C_PACKET_TRANSFER_STATUS_0 VI_I2C_ STREAM_ERECOVERY_I2C_PACKET_TRANSFER_STATUS_0	I2C_PACKET_TRANSFER_STATUS_0
VI_I2C_ STREAM_DIRECT_I2C_ BUS_CLEAR _STATUS_0 VI_I2C_ STREAM_ERECOVERY_I2C_BUS_CLEAR _STATUS_0	I2C_BUS_CLEAR_STATUS
VI_I2C_ STREAM_DIRECT_I2C_FIFO_STATUS_0 VI_I2C_ STREAM_ERECOVERY_I2C_FIFO_STATUS_0	I2C_FIFO_STATUS_0

The interrupt registers are set up to generate interrupts based on various error conditions or to indicate a packet transfer has completed. Since the VI_I2C is only supporting master packet transactions and provides sync points for indicating successful completion of a packet transaction, only the following subset of the available interrupts is needed:

- BUS_CLEAR_DONE
- TLOW_MEXT_TIMEOUT_EN
- TLOW_SEXT_TIMEOUT_EN
- TIMEOUT_INT_EN
- TFIFO_OVF_INT_EN
- RFIFO_UNF_INT_EN
- NOACK_INT_EN
- ARB_LOST_INT_EN

The status and interrupt registers are accessible by software and can be read at any time to get the status of the current transaction. In the case of an interrupt, software can access the status registers and identify the packet ID which was in process when an error occurred. All I^2C interrupt registers are accessed through ERECOVERY or DIRECT FIFO.

The VI_I2C hardware has access to the interrupt status registers signals during normal operation and uses the packet transaction complete into an increment for a particular transaction complete sync point and to manage the data flow to the TX_FIFO by using the DMA REQ signal. In order to facilitate the VI_I2C management of the TX_FIFO and sync points, the I^2C Controller provides the interrupt signals as the interface to the VI_I2C.

In addition to the interrupts managed within the I^2C controller, it is necessary to provide some additional indication to software if the DIRECT FIFO has overflowed. The combined I^2C and VI_I2C interrupt status is provided in the VII2C_INT_STATUS register as described in the VI I^2C Registers section.

Although the slave interrupts are provided in the VII2C_INT_STATUS register, these signals are not used in the VI_I2C.

In addition to the interrupt status and mask registers, the VII2C_EROVERY_MASK register is provided to manage the passing of the arbitration to the Error Recovery path when an interrupt is generated. This register should be programmed with the applicable bits set, which are used to generate an interrupt only. The Error Recovery path will gain immediate access to the APB bus when any of the programmed error conditions occur.

31.2.7 VI3 Programming Guidelines

The programming of the VI3 unit to initiate data capture involves setting up the image sensor, the CSI unit, the VI unit, and the ISP unit if the data is targeted for processing by the ISP. There are several different modes of image capture supported by the camera subsystem including progressive frame capture, interlaced frame capture, and interleaved frame capture. The capture modes may be set up as either single or dual stream to support the various user models, with the exception of the interleaved still capture. In the interleaved capture mode, both streams are assumed to be active.

31.2.7.1 Basic Progressive Frame Capture Sequence

The basic progressive frame capture programming sequence supports a number of user models involving both single and dual stream image captures. The basic sequence for the progressive capture is as follows:

1. Program the sensor or sensors in the dual stream use case.
2. Program the CSI and VI with parameters that do not change every frame.
3. Program Frame #1 specific parameters for the CSI and VI.
4. Enable CSI pixel parsers after completing PPA and/or PPB setup.
5. Arm the syncpt.
6. Trigger single shot by setting CAPTURE in the VI_CSI_[0..1]_SINGLE_SHOT register

   If (Outstanding capture requests == 1)

   Wait for SOF

   Else if (Outstanding capture requests > 1)

   Wait for MW_REQ_DONE
7. Program Frame #2 specific parameters for CSI and VI.
8. Repeat from step 5 for the next frames.

31.2.7.2 Basic Interlaced Frame Capture Sequence

The interlaced capture programming sequence is similar to the basic progressive capture sequence. However, since the interlaced capture results in the capture of a top and bottom field pair for each frame, there are some differences in how the hardware manages the syncpt generation and the single shot generation. Because the frame capture consists of a frame pair, both the syncpt and single shot are also managed based on frame pairs. The basic sequence for the interlaced capture is as follows:

1. Program the sensor or sensors in dual stream use case
2. Program the CSI and VI with parameters that do not change every frame.
3. Program Frame #1 Top/Bottom Field specific parameters for the CSI and VI.
4. Program the CSI TOP_FIELD_FRAME and TOP_FIELD_FRAME_MASK
5. Enable CSI Pixel Parser after completing the PPA and/or PPB setup
6. Arm syncpts for the field pair capture
7. Trigger single shot by setting CAPTURE in the VI_CSI_[0..5]_SINGLE_SHOT register

   If (Outstanding capture requests == 1)

   Wait for PP[A..B]_ FRAME_START

   Else if (Outstanding capture requests > 1)

   Wait for MW_REQ_DONE
8. Program Frame #2 specific parameters for CSI and VI.
9. Repeat from step 6 for next frames.

Step 4 is unique to the interlaced capture and is necessary for generating the top/bottom field signaling for the VI3. This signaling manages the data flow to memory and handling of field drop error conditions. The SOF syncpt is generated only when a top field is signaled on the CSI to VI interface, and the MW_REQ_DONE syncpt is generated only after a top and bottom field are paired and written to memory. The VI3 unit generates a single shot trigger for the top and bottom field when the interlaced mode is enabled. In addition, the VI3 unit provides for a frame-dropping mechanism which automatically re-issues a single shot to capture another field if a frame is dropped.

31.2.8 VI-I^{2}C Programming Guidelines

This section describes the programming sequences for the VI-I^{2}C block when initializing and controlling multiple devices within the camera subsystem. In the following sections, several scenarios are approached.

31.2.8.1 Register Programming Overview

This subsection describes some of the registers associated with setting up and programming the various modes supported with the VI-I^{2}C.

I^{2}C Frequency Divisor and Interface Timing Register

The frequency divisor and interface timing registers are used to set up the Standard/HS mode clock frequency and for tuning the I^{2}C interface bus timing, if needed. Separate bit fields are provided for non-HS (STD/FM/FM+) and HS modes timing:

- VI_I2C_STREAM_[DIRECT,ERECOVERY]_I2C_CLK_DIVISOR_REGISTER_0
- VI_I2C_STREAM_[DIRECT,ERECOVERY]_I2C_INTERFACE_TIMING_0_0
- VI_I2C_STREAM_[DIRECT,ERECOVERY]_I2C_INTERFACE_TIMING_1_0
- VI_I2C_STREAM_[DIRECT,ERECOVERY]_I2C_HS_INTERFACE_TIMING_0_0
- VI_I2C_STREAM_[DIRECT,ERECOVERY]_I2C_HS_INTERFACE_TIMING_1_0

These functional registers are not expected to be updated during a camera use session. During the initialization of the VI_I2C controller, the timing is configured prior to initiating any command transactions to external devices. Refer to Chapter 35: I2C Controller in this TRM for detailed information on programming these bit fields.

I^{2}C Configuration and Configuration Load Register

The I^{2}C configuration and configuration load registers are used to set up the I^{2}C master configurations and to initiate transfer of the software programmed configuration in the I^{2}C registers to hardware registers that are used by the actual logic.

DIRECT MODE:

- VI_I2C_STREAM_DIRECT_I2C_CNFG_0
- VI_I2C_STREAM_DIRECT_I2C_CONFIG_LOAD_0
- VI_I2C_STREAM_ERECOVERY_I2C_CNFG_0
- VI_I2C_STREAM_ERECOVERY_I2C_CONFIG_LOAD_0

The VI_I2C_CONFIG register is used to both configure the I^2C master and to initiate transactions on the bus. It contains a number of fields which allow software to program the number of bytes, single or two slave transaction, and whether to send a start byte or not. The bit VI_I2C_CNGF [9] is used to issue a “Begin-Transaction” command to the VI-I^2C Master Controller when in normal mode and VI_I2C_CNFG[10] is used to initiate transfer in packet mode. This bit is reset by hardware and other bits of the register are masked for writes when this bit is programmed to one. Hence, the firmware should first configure all other registers and the bits [8:0] of I2C_CNFG register before the bit I2C_CNFG [9] is programmed to one when in direct mode. Similarly in the synchronized mode all of the registers should be first presented to the VI-I^2C controller with these bit fields zero, and HW will re-write the register with the “GO’ bit set to one to initiate transactions.

This CONFIG load register is used to transfer the software programmed configuration in I^2C registers to hardware internal registers that are used in the actual logic. The CONFIG load register has three bit fields:

- MSTR_CONFIG_LOAD for regular master and Bus Clear master logic
- SLV_CONFIG_LOAD bit field for slave controller logic
- TIMEOUT_CONFIG_LOAD bit field for SMBUS timeout logic

From the programming side, software has to set them to 1 for the actual register configuration to take effect. It is as if software is programming only shadow registers through regular configuration. When these load_config bit fields are set to 1, the regular/ shadows registers configuration is transferred to the hardware internal active registers. So software has to set these bit fields at the end of all regular registers configuration. But in normal or non-packet mode, these should be set to 1 before the I2C_I2C_CNFG_0[SEND] bit is set to 1. The I2C_I2C_CNFG_0[SEND] bit triggers a transfer on the I^2C bus and should be programmed at the end of entire configuration (these config_load bits are hardware auto-clear bits). Hardware clears these bit fields once the register configuration is moved to hardware internal active registers. So software has to wait until these bits are auto-cleared before there is any further programming.

Because the VI_I2C supports the master mode of operation only, the master and timeout bit fields must be programmed. For the MSTR_CONFIG_LOAD and TIMEOUT_CONFIG_LOAD, the following VI-I^2C Master Configuration Load registers are loaded:

DIRECT MODE:

- VI_I2C_STREAM_DIRECT_I2C_CNFG_0
- VI_I2C_STREAM_ERECOVERY_I2C_CNFG_0
- VI_I2C_STREAM_[DIRECT,ERECOVERY]_I2C_CLK_DIVISOR_REGISTER_0
- VI_I2C_STREAM_[DIRECT,ERECOVERY]_I2C_BUS_CLEAR_CONFIG_0
- VI_I2C_STREAM_[DIRECT,ERECOVERY]_I2C_INTERFACE_TIMING_0_0
- VI_I2C_STREAM_[DIRECT,ERECOVERY]_I2C_INTERFACE_TIMING_1_0
- VI_I2C_STREAM_[DIRECT,ERECOVERY]_I2C_HS_INTERFACE_TIMING_0_0
- VI_I2C_STREAM_[DIRECT,ERECOVERY]_I2C_HS_INTERFACE_TIMING_1_0
- VI_I2C_STREAM_[DIRECT,ERECOVERY]_I2C_TLOW_SEXT_0

31.2.8.2 VI_I2C Direct Mode Programming

The direct mode programming provides for either device initialization or provides a means to issue transactions during frame capture.

1. Program the functional registers:
   - VI_I2C_STREAM_DIRECT_I2C_CLKEN_OVERRIDE_0
   - VI_I2C_STREAM_DIRECT_I2C_CLK_DIVISOR_REGISTER_0
   - VI_I2C_STREAM_DIRECT_I2C_INTERFACE_TIMING_0_0
   - VI_I2C_STREAM_DIRECT_I2C_INTERFACE_TIMING_1_0
   - VI_I2C_STREAM_DIRECT_I2C_HS_INTERFACE_TIMING_0_0
   - VI_I2C_STREAM_DIRECT_I2C_HS_INTERFACE_TIMING_1_0
   - VI_I2C_STREAM_DIRECT_I2C_BUS_CLEAR_CONFIG_0
   - VI_I2C_STREAM_DIRECT_I2C_TLOW_SEXT_0
2. Set up Interrupt MASK and STATUS registers
3. Arm DIRECT_PCKT_DONE syncpt
4. Program VI_I2C_STREAM_DIRECT_I2C_CONFIG_0, bit 10, PACKET_MODE_EN = 1
5. Program VI_I2C_STREAM_DIRECT_I2C_FIFO_CONTROL trigger level
6. Program VI_I2C_ STREAM_DIRECT_I2C_CONFIG_LOAD
7. Write VI_I2C_ STREAM_DIRECT_I2C_TX_PACKET_FIFO[0..2] with generic header, payload size, and I2C specific header
8. Write VI_I2C_ STREAM_DIRECT_I2C_TX_PACKET_FIFO[2..N] with payload or additional headers plus payload.
9. Write VI_I2C_STREAM_DIRECT_STREAM_DIRECT_FENCE with frame number.

   Wait for VI_I2C: PCKT DONE syncpt
10. Read VI_I2C_ STREAM_DIRECT_I2C_RX_FIFO if read transaction.
11. Repeat steps 2 through 12 for next transaction.

31.2.8.3 VI_I2C MMIO Direct Mode Programming

The programming of the VI_I2C may also be done using the MMIO approach as an alternative to the standard Host1x programming model. In this case, the register writes are done using the Linux kernel APIs. A basic pseudo-code example using writel, readl and nvhost_syncpt_* are Linux kernel APIs is illustrated below.

```
writel(val, reg-address);
writel(val, reg-address);
writel(val, reg-address);
writel(val, reg-address);
writel(val, 0x0);
SyncPt-val = nvhost_syncpt_incr_max();
nvhost_syncpt_wait(SyncPt-val);
```

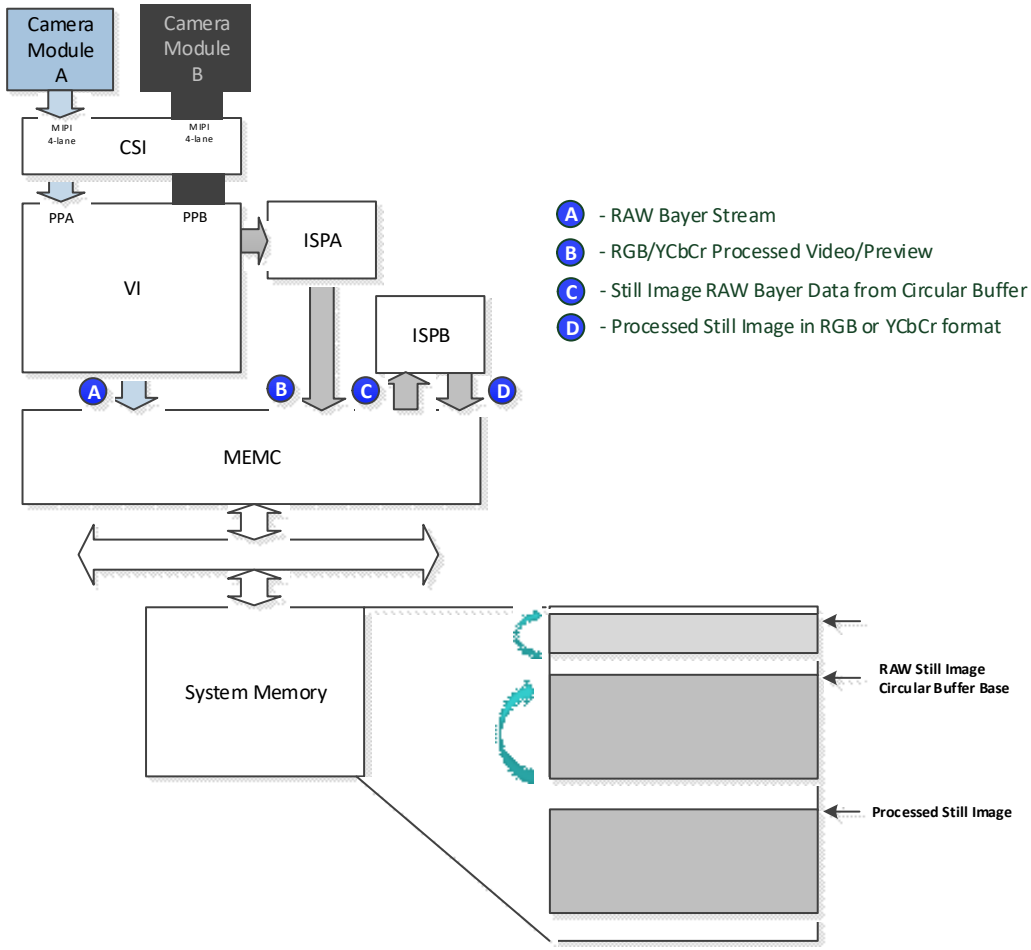
31.2.9 Frame Capture Modes

There are several frame capture scenarios available within the camera subsystem, which utilize various resources within the VI3 unit. The modes include scene preview or simple progressive video capture, multi camera progressive or interlaced video capture, high-resolution still capture, high-resolution zero shutter lag still capture, and an 8-lane interleaved capture.

31.2.9.1 High Resolution and ZSL Still Image Capture

The high resolution and ZSL still capture models utilize the VI3 resources for providing a path to system memory for Raw Bayer image data while simultaneously maintaining an image data stream to the ISP(s) for preview. The following figure shows the active data paths during mono ZSL capture mode.

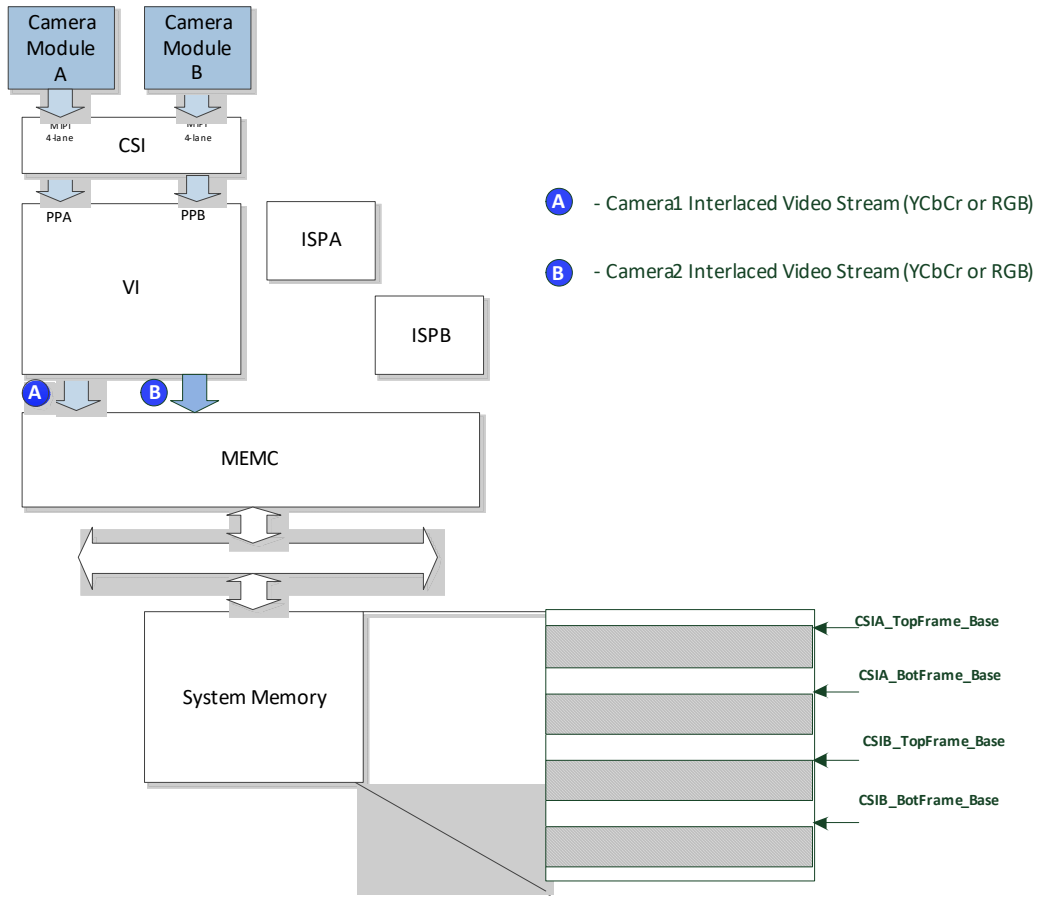
Figure 128: Zero Shutter Lag Mode



31.2.9.2 Interlaced Video Capture

The interlaced capture model provides for the management of interlaced video from an external camera module. The interleaved image data is presented to the CSI unit in a sequence of odd and even frames which represent the top and bottom fields in the interleaved composite frame. Since the interleaved image frames are not targeting raw Bayer processing by the ISP, the data formats are limited to either be RGB or YCbCr. The VI3 capture of interlaced video allows up to two camera pixel streams and associated channel pointers frame pointers to be managed simultaneously. The interlaced video capture mode is shown in the following figure.

Figure 129: Interlaced Capture Mode



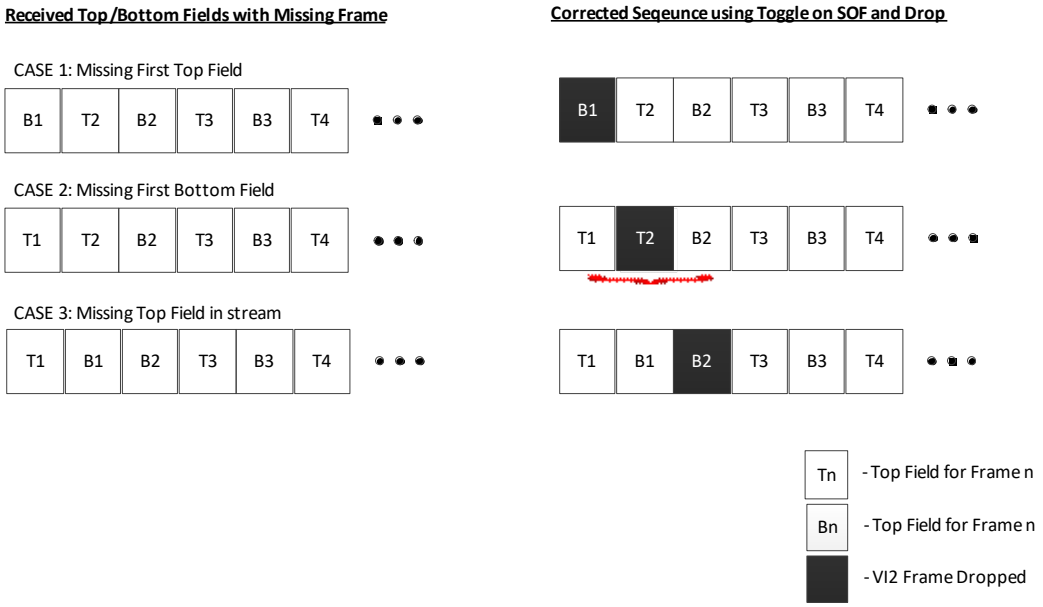
Twelve (12) pointers are available for managing the interleaved image streams. Three are available for the top field and three are available for the bottom fields for each of the two streams. All three pointers are used for each stream when the data is YCbCr422 and the target is planar, otherwise either two or only one are needed for semi-planar and non-planar formats, respectively.

The CSI unit signals the VI3 unit when a frame is either the top or bottom field by setting or clearing the LSB on the CSI[A,B]2VI_DATA, CSI1[A,B]2VI_DATA, or CSI2[A,B]2VI_DATA bus when the SOF is being sent. The VI3 unit uses the signaling to provide for switching between the top and bottom field source and stride registers setting used for the address calculations. The signals are managed through the CSI by programming the appropriate CSI, CSI1, or CSI2 instance's CSI_PPA_TOP_FIELD_FRAME_MASK and CSI_PPA_TOP_FIELD_FRAME parameters. The actual frame number used in the associated calculation is taken from the WC field of the Frame Start short packet.

Interlaced Capture Error Handling

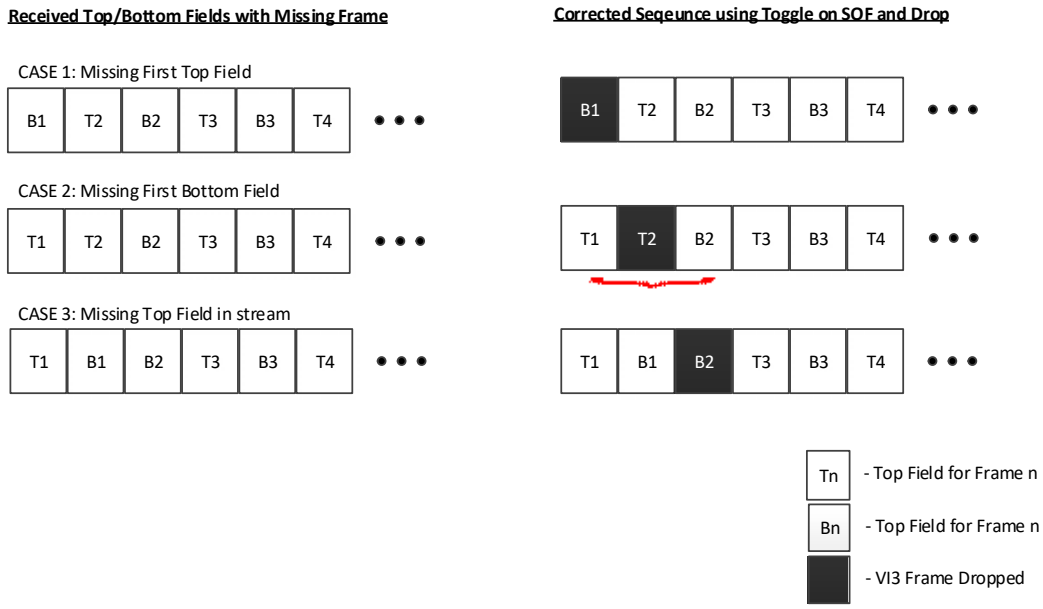
The interlaced capture generates two frames of data, one for the top field and one for the bottom field. It is important that the pairing of the frames in the top and bottom field buffers is accurate since any mismatch could result in artifacts that could propagate as errors in future frames captured in the video sequence. The issue is manifested with the occurrence of dropped frames either at the camera module or in the CSI unit. If a frame is lost, several pairing errors are possible.

Figure 130: Interleaved Field Pairing Errors due to Dropped Frames



In order to manage the dropped frame event, a flag is maintained in hardware that toggles on every SOF received from the CSI while in interlaced video mode. This indicates whether the frame is even or odd. The VI3 unit also compares the state of the TOP field bit during the SOF. If the flag is odd and the top field bit is not set, the received field is then dropped. In a similar fashion, a missing bottom field results in a top field being dropped. The toggle and drop correction are illustrated in the following figure.

Figure 131: Error Correction for Interlaced Capture



The loss of a bottom field results in a single pairing error but is not propagated into the following field pair. It is considered to be an acceptable error tradeoff.

Interlaced Single Shot and Sync Points

The programming sequence for the interlaced capture is basically the same as for the progressive capture. The primary difference between the two modes is that the interlaced mode operates on the concept of top and field pairs. The VI3 unit manages the frame single shot trigger and EOF events based on the successful pairing of top and bottom fields.

The VI_CSI_[0..5]_SINGLE_SHOT is programmed once for each top and bottom field pair in the interlaced mode of frame capture and hardware manages the generation of a single shot trigger for both the top and bottom field capture. In the event that a top field is not signaled by the CSI following the issue of the single shot capture, the frame is dropped and the single shot is re-issued until a top field is indicated. Once a top field has been successfully captured and an EOF received, the VI3 unit then issues a single shot capture for the bottom field. In a similar fashion with a missing top field first, the single shot is re-issued if a bottom filed is not signaled after the top field was successfully captured.

Sync points are also managed in a field pair fashion making it necessary to arm a sync point once for the frame event. For example, the VI_CSI_PP[A..F]_FRAME_START sync points are only returned on a successful start of a top field capture and similarly the VI_MW[A..F]_REQ_DONE sync points are only returned after the successful completion of a bottom field capture in a top/bottom field pair.

31.2.9.3 Stereo Still and Video Capture

The stereo still and video capture modes can utilize ISPA and ISPB to process the left and right camera streams simultaneously in support of preview, video capture, and the combination of preview and high-resolution still processing. The stereo capture models should be managed carefully to achieve maximum throughput and minimize system loading. The stereo capture modes are listed in the following table.

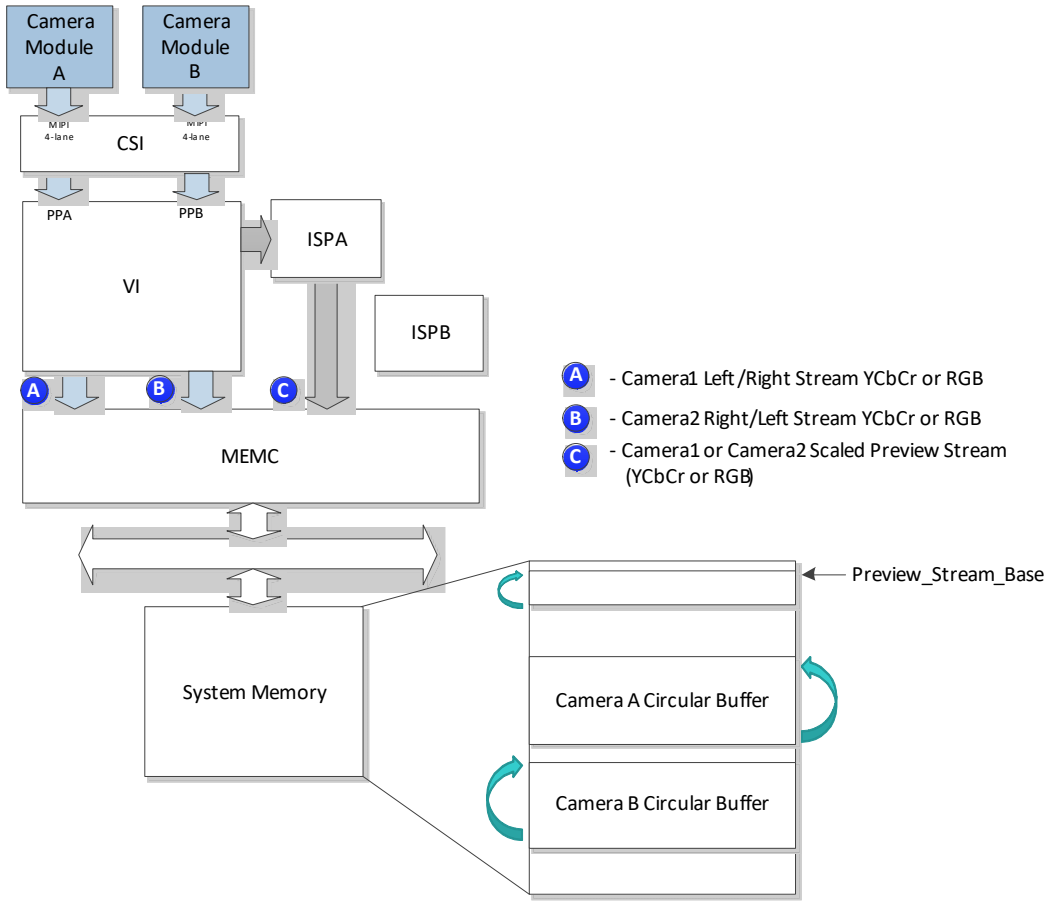
Table 182: Stereo Image/Video Capture Modes

Stereo Mode	Data Type	
Stereo Preview	YUV/RGB/RAW	Both Streams Active; ISPA or ISPB may be used for preview management; Should provide L/R preview switching; Raw data can be processed through the ISP or YUV. RGB data may be enhanced or delivered to memory through the MCCIF.
Stereo Preview for ZSL Still	YUV/RGB	Both Streams Active; ISPA or ISPB may be used for preview management; Should provide L/R preview switching; High resolution stills are delivered to the circular buffer in system memory through the MCCIF
	RAW	Both Streams Active; ISPA or ISPB used for Raw processing of one stream. Should provide L/R preview switching. High resolution Raw stills are delivered to the circular buffer in system memory through the MCCIF. During capture, the idle ISP may be used for processing so that preview can be continuous using the other ISP.
Stereo Preview + Video Capture	YUV/RGB/RAW	Both Streams Active; ISPA or ISPB may be used for preview management. Should provide L/R preview switching. Raw data may be processed through the ISP or YUV. RGB data may be enhanced or delivered to memory through the MCCIF.

There are three basic modes of operation when engaging the stereo capture user model: the preview of the image data for scene composition, the capture of a high resolution stereo pairs, and the capture of stereo video.

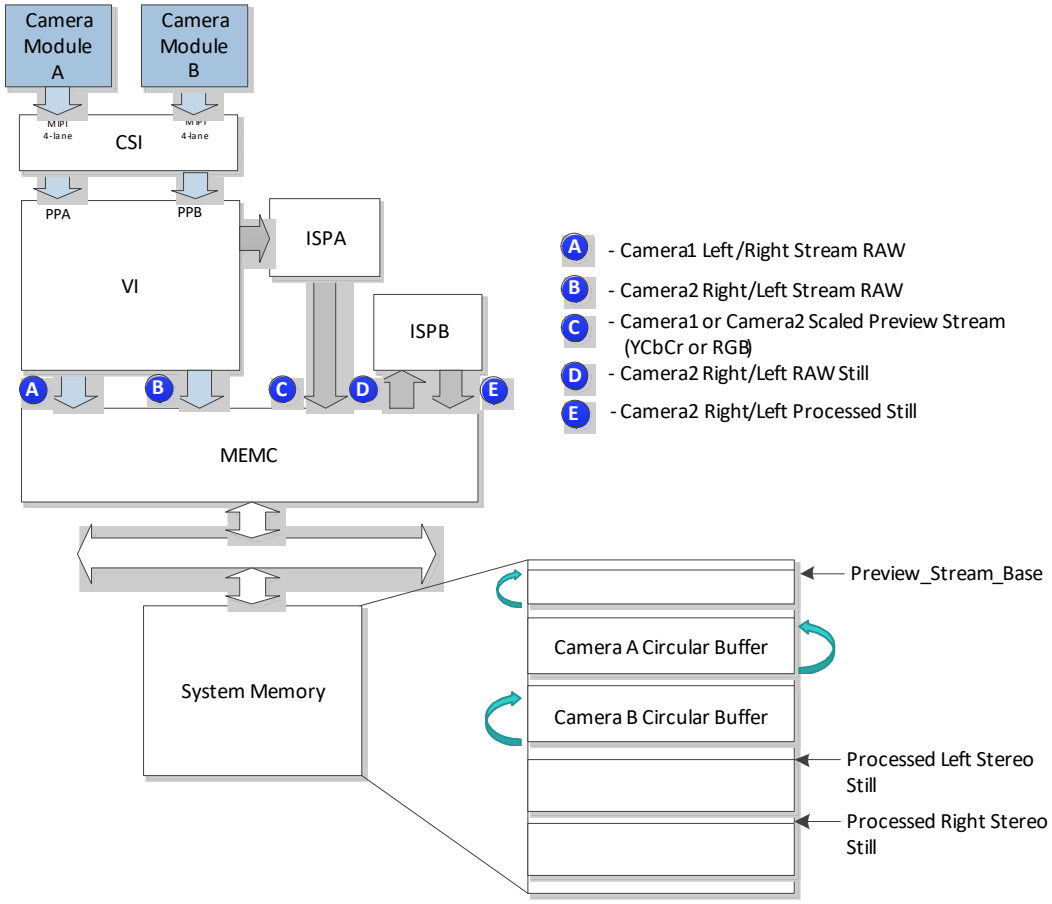
The still and video capture models for YUV or RGB processed data from the camera module may utilize the ISPA or ISPB resource as a scaling and image enhancement engine by providing the image data from either the left or right camera directly to the ISP. In most cases, the capture of processed data in a YUV or RGB format will be written directed to memory where it can be accessed by various resources in the system. The requirement for different resolutions for LCD display and the frame capture makes this option attractive since it can help to minimize memory traffic. A ZSL stereo capture sequence where both high-resolution streams are being stored in separate circular buffers for the left and right channels is illustrated in the following figure.

Figure 132: Zero Shutter Stereo Capture for YUV or RGB Image Data



The still and video capture models for Raw data utilize both ISPA and ISPB simultaneously under most conditions. During the stereo video capture, the image streams being captured by the left and right camera modules can each be assigned to either ISPA or ISPB, allowing a preview to be extracted from either processed stream with the stereo video being available to the compression resources. The ZSL stereo capture model also utilizes both ISPA and ISPB, however, only one ISP is used for managing the preview, and the second is idle until a still capture is initiated. Both high-resolution Raw streams are provided to system memory through the MCCIF to maintain the circular buffer for the left and right channels. Once the ZSL still capture is initiated, the idle ISP can be utilized to process the still images while the other is available to maintain a preview and allow a new ZSL sequence to be initiated with little delay. The basic sequence for the Raw stereo capture is shown in the following figure.

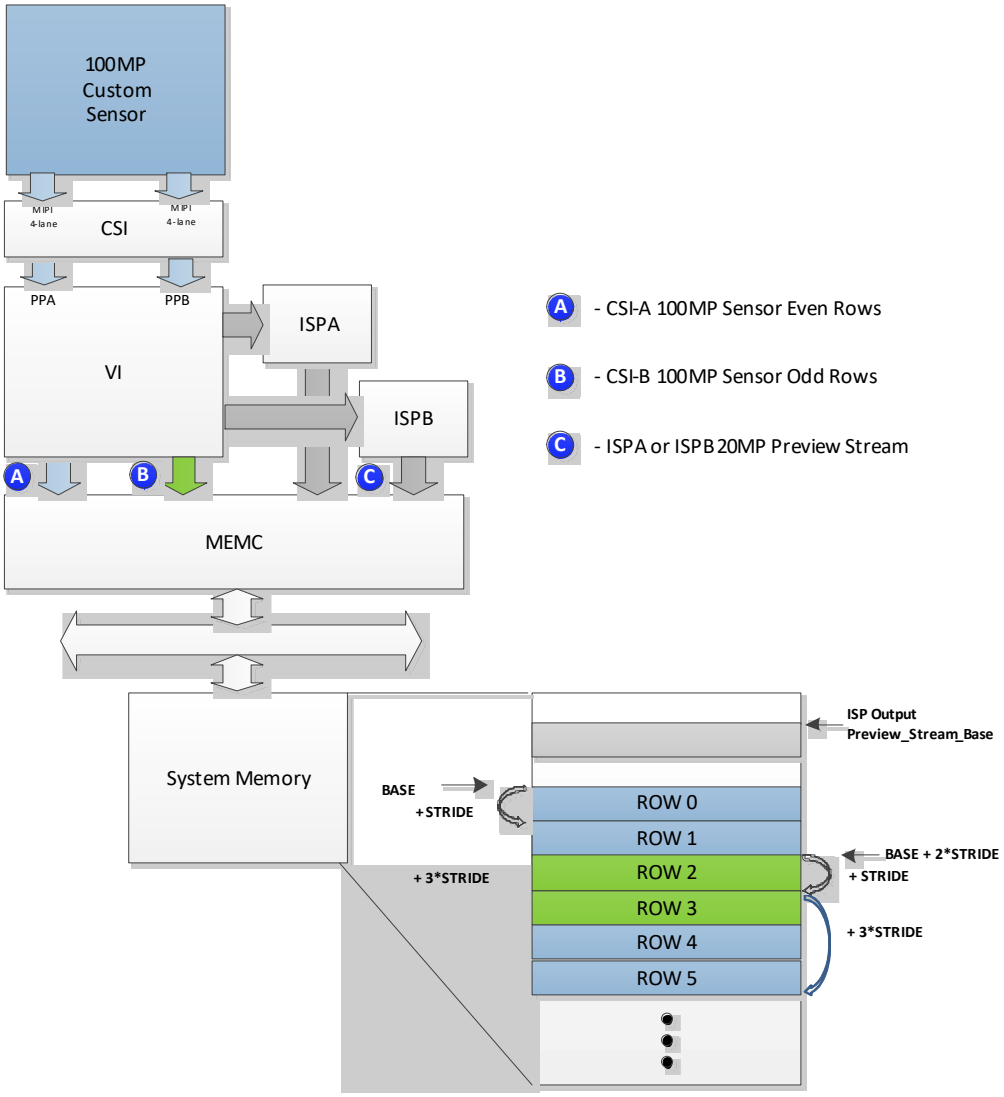
Figure 133: Zero Shutter Stereo Capture for Raw Image Data



31.2.9.4 Interleaved Capture

The interleaved capture mode supports management of pixel data delivered using all 8 available MIPI lanes. In this mode of operation, image data is delivered across all 8 lanes with two rows being provided simultaneously to two of the CSI 4-lane MIPI ports. In this mode, the VI3 unit manages the interleaving of the even and odd rows when writing the data to system memory. The sensor interfaces to the CSI unit through two of the 4-lane MIPI bricks using all four lanes for each interface. The following figure illustrates the interleaved capture model.

Figure 134: Interleaved Capture Model

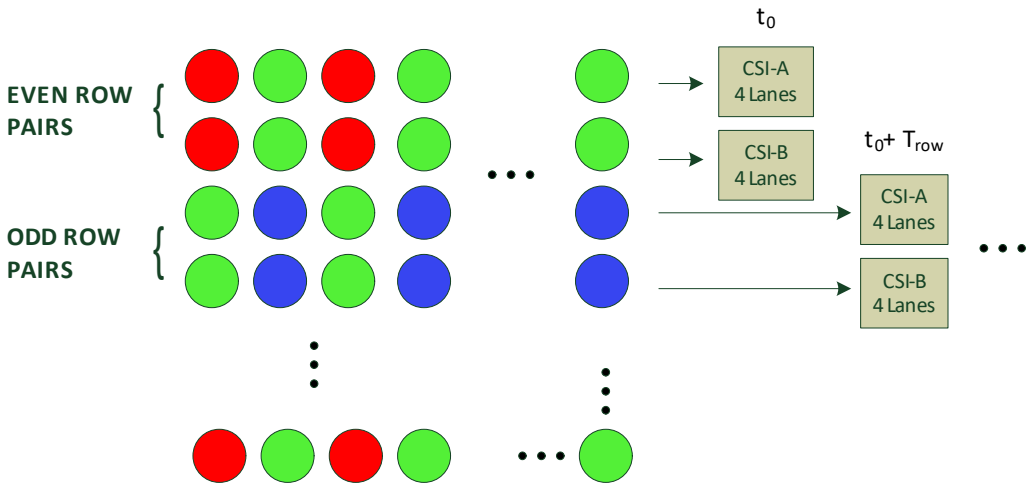


Interleaved Capture Model

The interleaved capture model supports image data that is presented as a standard RGGB Bayer pattern with either the even or odd rows available through one of the CSI ports and the odd or even rows through another of the CSI ports. The VI3 unit provides the RAW10 image data to system memory.

Utilizing two of the CSI 4-lane MIPI interfaces allows an effective still capture data rate to be doubled since all 8 MIPI lanes are active simultaneously. In this mode, the data is presented to the CSI interface in a unique fashion with even row pairs, both consisting of Red/Green pixels presented to one of the three CSI instance MIPI 4-lane interfaces, and one of the two remaining CSI instance, MIPI 4-lane interfaces, followed by the odd row pairs consisting of Green/Blue pixels.To provide a standard RGGB Bayer pattern in memory, an interleaving mechanism is provided as the data is written to memory. The following figure illustrates the even and odd row pair's presentation to the CSI with the first and second 4-lane interfaces referred to as CSI-A and CSI-B, respectively.

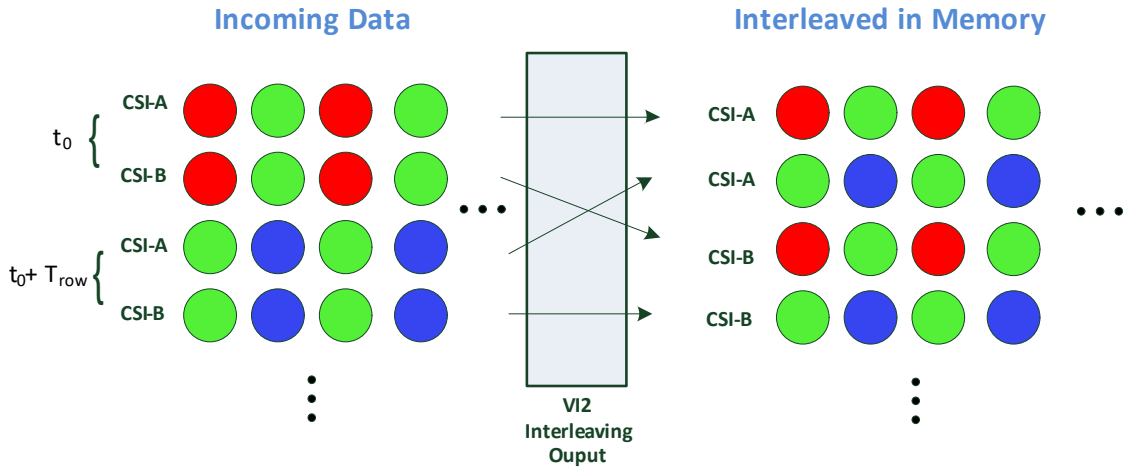
Figure 135: Interleaved Capture Data Presentation



Dual-Channel Interleaving

The interleaved still image is delivered in even and odd row pairs resulting in two Red/Green or two Blue/Green rows being presented to memory at the same time. The preparation of the data for processing involves interleaving the rows so that a Bayer pattern organization of the row data is available in system memory. To accomplish this, the VI3 unit provides a special interleaved mode in which the line counters for the two streams are incremented in a predetermined sequence. The following figure illustrates the interleaving of the incoming data stream in system memory.

Figure 136: Dual-Channel Interleaving During Write to Memory



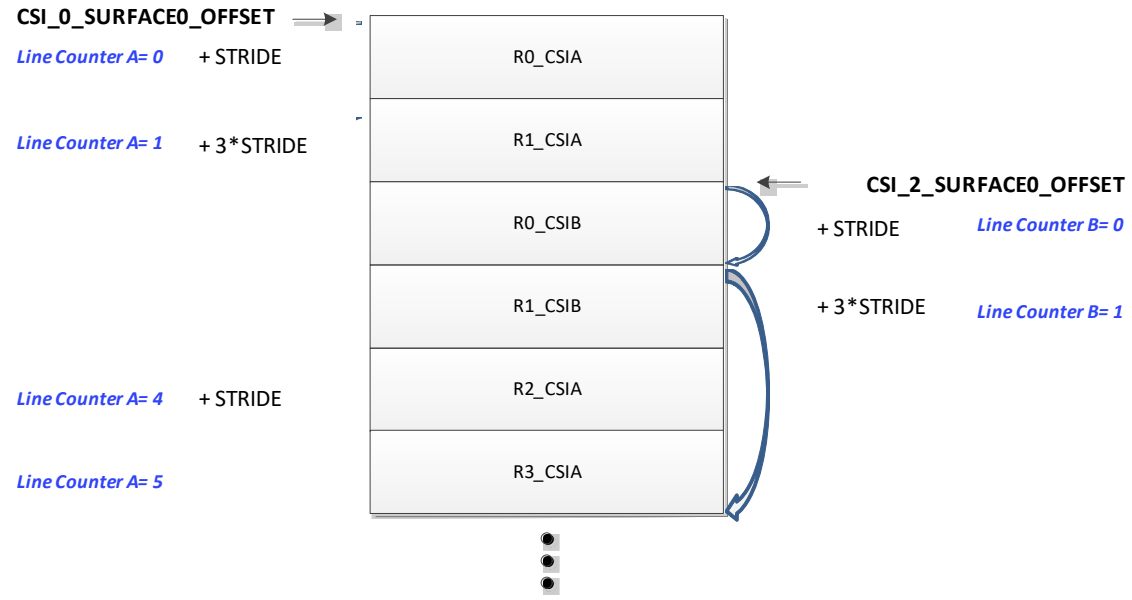
The interleaved mode is enabled by setting the INTERLEAVING_MODE bit in the appropriate VI_CSI_[0..5]_IMAGE_DEF registers. The mode setting changes the normal operation of the line counters used to calculate the memory address after a line is written to increment in a line pair skipping fashion as opposed to the normal mode of single increments.

Figure 137: Line Counter Sequence (Normal and Interleaved Modes)

Captured Row delivered by CSIA or CSIB	NORMAL MODE LINE COUNTER SEQUENCE	INTERLEAVED MODE LINE COUNTER SEQUENCE
Row 0	0	0
Row 1	1	1
Row 2	2	4
Row 3	3	5
Row 4	4	8
Row 5	5	9
.	.	.
.	.	.
.	.	.
Row (Height-1)	HEIGHT-1	HEIGHT-1

The base address and stride for each of the channels are programmed prior to initiating the image capture. Once the image capture is initiated, the line counters for the two channels will sequence in a row pair fashion as illustrated in the following figure.

Figure 138: Dual Channel Interleaving in Memory for T_R16_



The RAW10 format is used for the interleaving capture and may be stored in either the T_R16_I or the T_L10_L10_L10_X2 formats. In addition to the INTERLEAVING_MODE selection, six registers must be programmed to manage the writing of the data to memory.

Table 183: Dual-Channel Interleaving Mode Address and Stride Programming

Register	Data Format	Comment
VI_CSI_0_SURFACE0_OFFSET_LSB VI_CSI_0_SURFACE0_OFFSET_MSB	T_L16_I or T_L10_L10_L10_X2	Base Address for the first even row pair still image in system memory. Only atom aligned (64 Bytes) address is supported
VI_CSI_2_SURFACE0_OFFSET_LSB VI_CSI_2_SURFACE0_OFFSET_MSB	T_L16_I or T_L10_L10_L10_X2	Base Address for the odd even row pair still image in system memory Only atom aligned (64 Bytes) address is supported. VI_CSI_0_SURFACE0_OFFSET_LSB + 2 * STRIDE.
VI_CSI_0_SURFACE0_STRIDE0 VI_CSI_2_SURFACE0_STRIDE0	T_L16_I	STRIDE = 2 * IMAGE_WIDTH Only atom aligned (64 Bytes) strides are supported
	T_L10_L10_L10_X2	STRIDE = (4/3) * IMAGE_WIDTH Only atom aligned (64 Bytes) strides are supported

31.2.9.5 Multi-Camera Still and Video Capture

The multi-camera capture model is defined for automotive applications in which there are up to six camera streams that are provided to system memory.

31.2.10 TrustZone Support

The VI3 unit allows management of several CSI registers associated with memory transactions and resets as either freely programmable in the system or only programmable by secure world functions. The registers supporting the secure programming feature include the reset and base, stride, and image definition registers for CSI[0..5]. These TrustZone® support registers are listed below.

- VI_CSI_[0,5]_ SW_RESET
- VI_CSI_[0,5]_ IMAGE_DEF
- VI_CSI_[0,5]_SURFACE0_OFFSET_MSB
- VI_CSI_[0,5]_SURFACE0_OFFSET_LSB
- VI_CSI_[0,5]_SURFACE1_OFFSET_MSB
- VI_CSI_[0,5]_SURFACE1_OFFSET_LSB
- VI_CSI_[0,5]_SURFACE2_OFFSET_MSB
- VI_CSI_[0,5]_SURFACE2_OFFSET_LSB
- VI_CSI_[0,5]_SURFACE0_BF_OFFSET_MSB
- VI_CSI_[0,5]_SURFACE0_BF_OFFSET_LSB
- VI_CSI_[0,5]_SURFACE1_BF_OFFSET_MSB
- VI_CSI_[0,5]_SURFACE1_BF_OFFSET_LSB
- VI_CSI_[0,5]_SURFACE2_BF_OFFSET_MSB
- VI_CSI_[0,5]_SURFACE3_BF_OFFSET_LSB
- VI_CSI_[0,5]_SURFACE0_STRIDE
- VI_CSI_[0,5]_SURFACE1_STRIDE
- VI_CSI_[0,5]_SURFACE2_STRIDE
- VI_CSI_[0,5]_SURFACE_HEIGHT0

Programming control of the secure CSI registers is based on the programmed output security PMC's APBDEV_PMC_STICKY_BITS_0 field: CSI_SECURE_ENABLE and the TrustZone secure mode being active or inactive. Once the CPU is context switched from the normal operation “non-secure world” to the “secure world” (indicated to the rest of the system by the TrustZone_NS (non-secure bit) being deasserted, for example, there is a Host1x trustzone_nonsecure signal), the VI allows for writes to the CSI registers when the sticky bit register is asserted. If the sticky bit is asserted, but the _NS signal is asserted (that is, the CPU is operating in the non-secure world), then the VI’s CSI registers are not writable. If the sticky bit is not asserted at all, then the VI’s CSI registers can be written to normally.

31.3 Data Formatting

The following subsections describe the CSI pixel formats, ISP2 pixel formatting, and the various formats and packing options for delivering data to system memory.

31.3.1 CSI Input Data Formats

The CSI provides data to the VI3 unit in one of several possible formats. The following table describes the different formats presented to the VI3 unit through the CSI interfaces.

Table 184: CSI to VI3 Pixel Formats

Format Name		23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

The formats include various flavors of RAW, RGB, and YCbCr in addition to 8-bit arbitrary or embedded data. The bits marked ‘0’ are actually don’t-care for VI3 and are ignored by the VI3 unit and the odd line in the above table refers to the first line from the CSI unit.

31.3.2 Raw Pixel Data Formatting

The Raw pixel data may be delivered to the ISP, system memory, or both the ISP and system memory simultaneously. In order to interface to the ISP efficiently, pixels are prepared for the ISP pipeline by converting to the unsigned offset binary representation of the form:

I.F

Where:

I is the number of integer bits.

F is the number of fractional bits.

The zero offset shall have a value of $2^{(F + I - 2)}$. For the ISP, it is suggested that the values of I and F should be:

I = 1, F = 13, offset = 4096_{10}

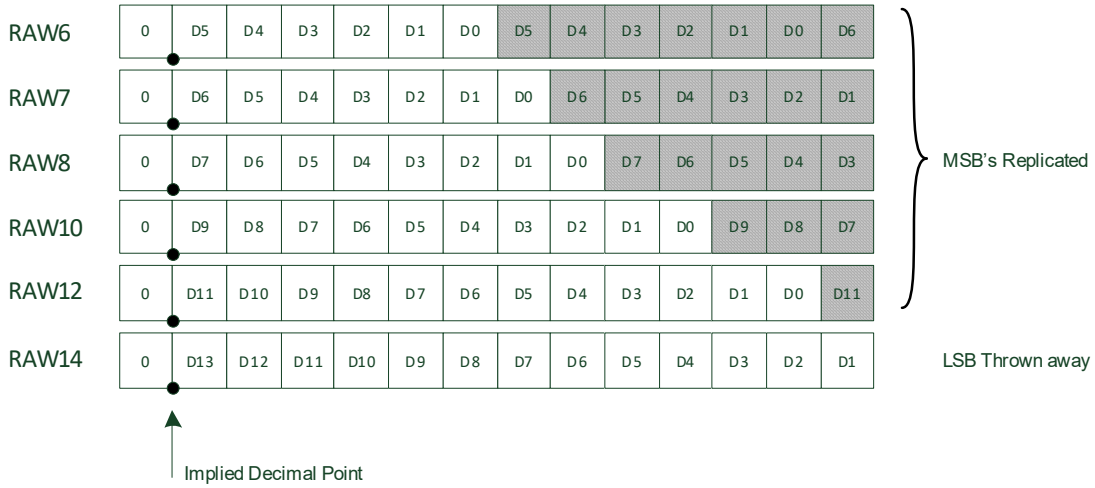
The formatting of the captured RAW data to the 14-bit I.F format requires several steps to be performed. Data may also be stored to memory either simultaneous with the ISP presentation or alone. When storing data to memory, either the formatted data or the original data may be stored to memory. Since the VI3 RAW data streams are all targeted for processing by the ISP, the storing of data which has formatting provided within the VI3 pipeline is the default behavior. Optionally the formatting may be bypassed by setting the BYPASS_PXL_TRANSFORM in the VI_CSI_[0..5]_IMAGE_DEF register.

The formatting steps for preparation of RAW pixel data for the ISP pipeline and/or memory are described in the following sections.

31.3.2.1 Raw Pixel Formatting to VI Pipeline

The Raw data received from the CSI unit is formatted as a 14-bit unsigned operand, U1.13. The data is scaled to provide align the MSB with the implied decimal point. When converting from a source data size that is smaller than the destination data size, the MSBs of the source are replicated to fill the missing LSBs in the destination. The bit replication is shown in the following figure.

Figure 139: VI3 Pipeline Formatting for U1.13 Raw Pixel Data

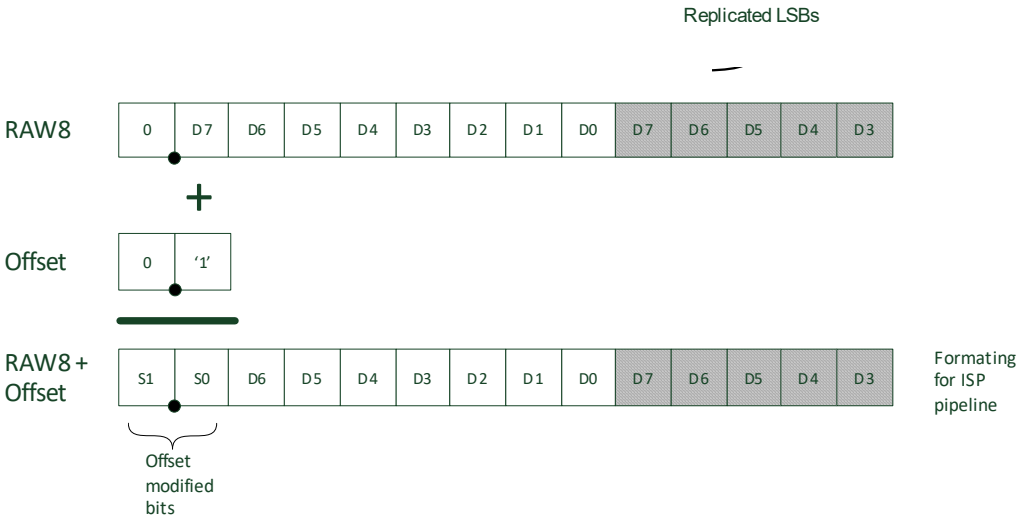


Since the RAW14 data would be wider than the ISP pipe when converting to the unsigned U1.13 format, the LSB is truncated.

31.3.2.2 RAW Pixel Formatting to ISP Pipeline

If the destination format is the pixel bus format, the data must be aligned with the implied decimal point position and the offset must be added. For example the formatting of RAW8 pixel data for the ISP pipeline is illustrated in the following figure.

Figure 140: RAW8 to ISP Pipeline Formatting Example



31.3.2.3 Raw Pixel Formatting to Memory

The raw pixel data may be presented to system memory in three possible formats specific to the input bit precision. The TL_8 formatting operation provides source to destination bit precision increase and decrease. All of the TL_8 formats are packed four per 32-bit word when stored to memory. The T_R16_I employs MSB replication based off of the RAW data previously formatted for the VI pipeline and a new format is introduced for packing three 10-bit raw pixels into a 32-bit word. The different options are summarized in the following table.

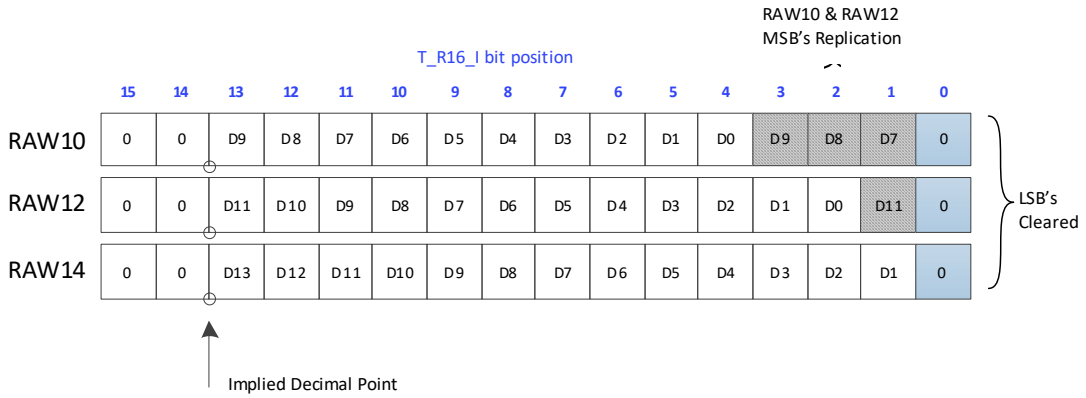
Table 185: Raw Supported Memory Formats

CSI Format Name	Pixel Format in Memory	bpp	Notes
RAW6	T_L8	8	
RAW7	T_L8	8	
RAW8	T_L8	8	
RAW10	T_L8	8	Drop 2 LSBs
	T_R16_I	16	
	T_L10__L10__L10_X2	32	3 RAW10 Pixels Packed
RAW12	T_L8	8	Drop 4 LSBs
	T_R16_I	16	
RAW14	T_L8	8	Drop 6 LSBs
	T_R16_I	16	

T_R16_I Formatting for RAW10 RAW12 and RAW14

The formatting of the raw data from the VI3 pipeline for bit precisions above eight involves an additional MSB bit replication as illustrated in the following figure.

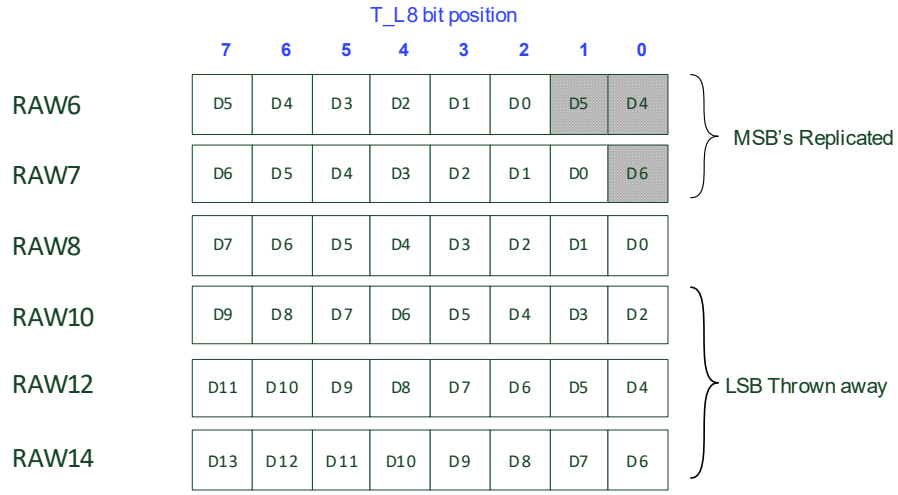
Figure 141: RAW10, RAW12, and RAW14 Formatting to Memory



T_L8_F Formatting for all Raw Pixel Precisions

The formatting for the 8-bit data is a straightforward mapping with either truncation or MSB replication being employed. The formatting for 8-bit data is illustrated in the following figure.

Figure 142: Raw Formatting to T_L8 Memory Format



T_L10__L10__L10_X2 Formatting for RAW10

The T_L10_L10_L10_X2 packed format is introduced to help reduce the burden on the system memory resources during high bandwidth camera user models. In this format, three RAW10 pixels are packed per 32-bit word allowing an improvement in utilization to be realized. The memory efficiency is 93.75% compared to the T_R16_I format with 62.5%.

31.3.3 RGB Pixel Data Formatting

The VI3 unit receives RGB data from the CSI in one of several possible formats and provides for formatting and presentation to system memory. The RGB formats are represented through variation in the number of bits used to represent the red, green, and blue channels. The RGB memory formats and options for source to destination formatting are described in the following table.

Table 186: RGB Supported Memory Formats

CSI Format Name	Pixel Formats in Memory	bpp	Notes
RGB565	T_L8	8	(C1*R+C2*G+C3*B)/16
	T_A1B5G5R5; T_A1R5G5B5; T_B5G5R5A1; T_R5G5B5A1	16	
	T_B5G6R5; T_R5G6B5	16	

Table 186: RGB Supported Memory Formats

CSI Format Name	Pixel Formats in Memory	bpp	Notes
RGB555	T_L8	8	(C1*R+C2*G+C3*B)/16
	T_A1B5G5R5; T_A1R5G5B5; T_B5G5R5A1; T_R5G5B5A1	16	
	T_B5G6R5; T_R5G6B5	16	
RGB888	T_L8	8	(C1*R+C2*G+C3*B)/16
	T_A1B5G5R5; T_A1R5G5B5; T_B5G5R5A1; T_R5G5B5A1	16	
	T_A4B4G4R4; T_A4R4G4B4; T_B4G4R4A4; T_R4G4B4A4	16	
	T_B5G6R5; T_R5G6B5	16	
	T_A8B8G8R8; T_A8R8G8B8; T_B8G8R8A8; T_R8G8B8A8	32	
	T_A2B10G10R10; T_A2R10G10B10; T_B10G10R10A2; T_R10G10B10A2	32	
RGB444	T_L8	8	(C1*R+C2*G+C3*B)/16
	T_A1B5G5R5; T_A1R5G5B5; T_B5G5R5A1; T_R5G5B5A1;	16	
	T_A4B4G4R4; T_A4R4G4B4; T_B4G4R4A4; T_R4G4B4A4	16	
	T_B5G6R5; T_R5G6B5	16	
RGB666	T_L8	8	(C1*R+C2*G+C3*B)/16
	T_A1B5G5R5; T_A1R5G5B5; T_B5G5R5A1; T_R5G5B5A1	16	
	T_B5G6R5; T_R5G6B5	16	
	T_A8B8G8R8; T_A8R8G8B8; T_B8G8R8A8; T_R8G8B8A8	32	

Each of the capture RGB formats can be formatted by adjusting the precision of the channels, ordering the channels differently, or extracting a luminance approximation into a packed T_L8 format.

31.3.3.1 RGB Pixel Data Size Conversions

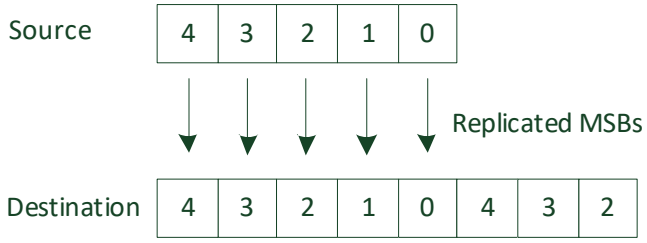
The VI3 unit supports the conversion of the received RGB data into other formats by either increasing or decreasing the precision of the data representing each of the channels. The following table describes the possible conversions.

Table 187: RGB Data Precision Adjustments Options

RGB Format Received	RGB Format Conversion (Precision Increase)	RGB Format Conversion (Precision Decrease)
RGB444	RGB555, RGB565	None
RGB555	RGB565	None
RGB565	None	RGB555
RGB666	RGB888	RGB555, RGB565
RGB888	RGB101010	RGB444,RGB555, RGB565, RGB666

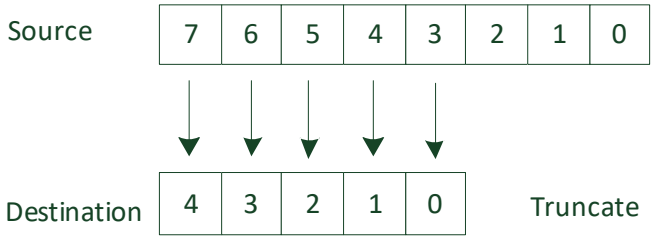
The RGB pixel data is converted to higher bit precision through replication of the MSBs in the source to fill in the missing LSBs in the destination in a similar fashion as the Raw data formatting for the ISP pipe. For example:

Figure 143: 5-bit to 8-bit Precision Increase



When converting from a source data size that is larger than the destination size, the destination is a truncated version of the source data. For example:

Figure 144: 8-bit to 5-bit Precision Decrease



31.3.3.2 RGB to Luma Data Formatting

In addition to providing format conversions, the RGB data may also be stored as luma data by approximating a luminance calculation. This is useful for applications that would otherwise have to compute the luminance channel from the RGB data in a separate step. The luma calculation is performed by multiplying each of the red, green, and blue channel components by a U0.6 coefficient as shown in the following pseudo code.

```
#define SHIFT      5
#define COEFF_BITS 6
    Y = ( (PIXEL.RED_CR * MW_R2Y_COEFF)
        + (PIXEL.GRN_Y * MW_G2Y_COEFF)
        + (PIXEL.BLU_CB * MW_B2Y_COEFF) ) >> (SHIFT + COEFF_BITS);
if (Y < 0)   Y =   0;
if (Y > 255) Y = 255;
```

31.3.3.3 RGB Pixel Formatting to ISP Pipeline

If the destination format is the pixel bus format, the data must be aligned with the implied decimal point position and the offset must be added. For example, the formatting of RGB565 pixel data for the ISP pipeline will involve formatting each of the color components into the 14-bit I.F format.

31.3.4 YUV Pixel Data Formatting

The VI3 unit provides for formatting and packing of YCbCr data received from the CSI and is responsible for its presentation to system memory or to the ISP for scaling or image enhancement. There are two formats captured: YUV422 and YUV420. The formatting provided for YUV capture data is shown in the following table.

Table 188: YUV Supported Memory Formats

CSI Format Name	Pixel Formats in Memory	bpp (per plane)	Notes
YUV422 8-bit	T_L8	8	Y component only
	T_Y8_U8__Y8_V8 [a] ; T_Y8_V8__Y8_U8 [a] ; T_U8_Y8__V8_Y8 [a] ; T_V8_Y8__U8_Y8 [a]	32	
	T_Y8___U8V8_N422	8	Semi-planar; Y+UV
	T_Y8___V8U8_N422	8	Semi-planar; Y+VU
	T_Y8___U8___V8_N422 [b]	8	Planar
YUV420 8-bit legacy	T_L8	8	Y component only
YUV420 8-bit / 8-bit (CSPS)	T_L8	8	Y Component only.

The 8-bit YUV422 format is designated a primary format in the MIPI CSI specification and all others are considered as secondary formats. The supported pixel layout will be Pitch Linear or planar pitch-linear. YUV420 is always stored as T_L8 with even and odd lines stored to memory as they are received from the CSI interface.

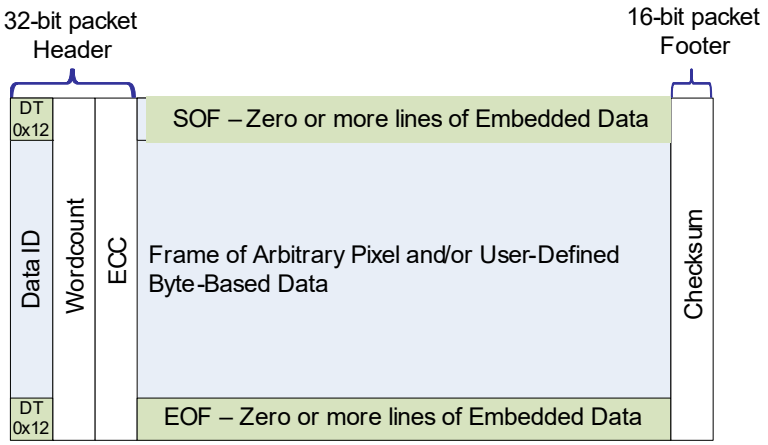
31.3.4.1 YUV Pixel Formatting to ISP Pipeline

The formatting of YUV422 data for presentation to the ISP follows a similar formatting as is done with the raw and RGB formats to convert the data to the unsigned offset binary representation with the exception that an offset of 8192 is used for the chroma channels and an offset of 4096 is used for the luma. The LSB replication follows the same approach as with the RGB and RAW formats. Following the conversion of the luma and chroma to the 14-bit representation for the ISP pipe, the data is then converted from 422 to 444 sampling through interpolation.

31.3.5 Embedded Data Formats

A number of sensor and camera modules utilize embedded data to communicate meta data or calibration data associated with an image capture to the host application. The inclusion of embedded data in the data stream is defined in the MIPI CSI2 specification and has a specific data type of 0x12 assigned. If the embedded data exists, it is identified by the embedded data type at the beginning of a long packet resulting in extra lines added to the beginning or end of a frame. An illustration of embedded and fare data is shown in the following figure.

Figure 145: CSI-2 Incoming Frame Structure with Embedded Data



The CSI and VI3 units work together to manage the capture and handling of the embedded data during a frame capture. Three basic modes of operation associated with the embedded data capture model are supported. The embedded data capture modes are described in the following section.

31.3.5.1 Embedded Data Capture Modes

The CSI[,1,2] can discard embedded data in the CSI[,1,2], to pass embedded data through one pixel parser with the image data being presented to the other pixel parser, or to combine the embedded data with the frame data when presented to a single pixel parser.

Embedded data is discarded by setting CSI[,1,2]_PP[A..B]_EMBEDDED_DATA_OPTION to DISCARD in the CSI[,1,2]_PIXEL_STREAM_[A..B]_CONTROL_0 register. If it is desired to keep the embedded data, this field should be set. Depending on the mode of operation and the data format the embedded data, the frame data, or the combined embedded and frame data may be delivered to system memory or the ISP execution resources. The options for embedded data capture are described in the following table.

Table 189: Embedded Data Capture Modes

EMBEDDED	Pixel Format in Memory	Notes
DISCARD	Either PP will deliver frame data only.	MEM or ISPA/ISPB
Embedded Capture with One PP	Embedded Data and Frame Data using Same PP	MEM only
Embedded Capture with Two PPs	One PP used for streaming Embedded Data.	MEM only
	One PP used for streaming Frame data.	MEM or ISPA/ISPB

If the mode is set to discard, the embedded data is discarded in the CSI instance and only image data is presented to the VI3 unit resulting in the normal data processing with the frame data formatting and presentation to memory and/or the ISP. If the mode is set to capture embedded data using one pixel parser, the embedded data is streamed with the image data using the same pixel parser. In this mode the embedded data is combined with the frame data and presented to system memory. The third mode uses both pixel parsers with one pixel parser managing the embedded data and the other managing the frame data.

The discard embedded capture is relatively straightforward and only requires the CSI[,1,2]_PP[A..B]_EMBEDDED_DATA_OPTION to be set to discard with all other programming settings the same as during non-embedded frame capture. The other two modes have some complexity associated with the programming and how the data is organized in memory. The following sections describe the single and dual Pixel Parser (PP) modes in more detail.

Embedded Capture using One PP

The embedded capture using one pixel parser will result in embedded data being stored with the frame data in system memory. Since the line width for the 8-bit embedded data may be longer or shorter than the line with for the pixel data, the line width short/long errors are ignored. In addition, the CSI[,1,2] will signal to the VI3 unit that an incoming line is embedded by setting the CSI[,1,2][A,B]2VI_FRAME_ERROR during the start of a line. In this fashion, the VI3 will know that the line is embedded and provide for managing the capture and providing the specialized formatting depending on the VI3 memory format setting. The register programming is similar to non-embedded cases except that:

1. VI_CSI_[0..5]_CSI_IMAGE_SIZE register HEIGHT should be programmed with the SOF Embedded Lines+EOF Embedded lines +Normal Lines
2. The CSI_PP[A..B]_EMBEDDED_DATA_OPTION should be set to EMBEDDED in the CSI[,1,2]_PIXEL_STREAM_[A..B]_CONTROL_0 register

In the single PP embedded capture mode, the only destination supported is to MEM since the ISP does not support embedded data with the pixel stream. There are several additional constraints on the supported data formats when using this embedded capture option:

1. RGB Embedded Data capture is not supported.
2. Several Raw variations with various output options are not supported.
3. YUV embedded capture will combine the embedded data with the Luma plane, and insert zeros into the Chroma planes for some formatting options.

Embedded Capture using Two PPs

The embedded capture using two pixel parsers results in one of the pixel parsers delivering only embedded data to the VI3 unit and the other delivering only image data. In order to accomplish this, one PP would be programed to parse pixel data and discard embedded data, and the other PP would be programmed to parse only embedded data. The embedded data would then be sent to memory for the VI3 and the pixel data could either be presented to system memory or the ISP.

For example, if an embedded image stream is being captured from CILA, the pixel path could be set up to be CILA → PPA →VI and the embedded data path could be set up to be CILA→PPB→VI→ MEM. The PPA stream programming is similar to normal cases and the stream B programming would be as follows:

1. Route CILA to PPB by setting the CSI_PPB_STREAM_SOURCE to CSI_A
2. Program VI_CSI_1_CSI_IMAGE_SIZE register HEIGHT to be the sum of SOF Embedded Lines+EOF Embedded lines.
3. Program VI_CSI_1_CSI_IMAGE_SIZE register WIDTH to be based on the pixel data line width/data format.
4. Set the DATA_TYPE to EMBED in the VI_CSI_1_CSI_IMAGE_DT register.
5. Set the CSI_PP[A..B]_EMBEDDED_DATA_OPTION to EMBEDDED in the CSI_PIXEL_STREAM_[A..B]_CONTROL_0 register

The programming of the image width in step three is sometimes different than the image width of the normal frame data since the embedded data lines have the same length in bytes as the image data. For example, for a RAW6 64x64 image, there are 48 bytes in each long packet payload resulting in a line width of 48 bytes for the embedded data. Embedded data is always stored as T_L8 in this mode.

31.3.5.2 Frame Data Type with Embedded Data Limitations

The embedded data when using the two pixel parser option is straightforward as long as the frame height and width are programmed appropriate to the data type and the number of embedded lines. The single PP mode of embedded capture is more complex and software will be required to parse the embedded data from the stored embedded data plus image data frame.

The Raw embedded data capture options supported with a single pixel parsers are summarized in the following table.

Table 190: Raw and DPCM Embedded Data Formatting

CSI Format	VI Pixel Format in Memory	1 PP Embed Mode Support	Embedded Data Layout in 32-bit DWORD
RAW6	T_L8	No	NA
RAW7	T_L8	No	NA
RAW8	T_L8	Yes	[emdat3, emdat2, emdat1, emdat0]
RAW10 or DPCM 10-8-10	T_L8	No	NA
	T_R16_I	Yes	{4'h0,embed_data1,4'hX,4'h0,embed_data0,4'hX}
	T_X2Lc10Lb10La10	Yes	{2'b00,embed_data2,2'b00,embed_data1,2'b00,embed_data0}
RAW12 or DPCM 12-8-12	T_L8	No	NA
	T_R16_I	Yes	{6'h0,embed_data1,2'hX,6'h0,embed_data0,2'hX}

Table 190: Raw and DPCM Embedded Data Formatting

CSI Format	VI Pixel Format in Memory	1 PP Embed Mode Support	Embedded Data Layout in 32-bit DWORD
RAW14 or DPCM 14-8-14	T_L8	No	NA
	T_R16_I	No	NA

The YUV420 format is straightforward since only the Luma plane capture is supported. In this capture mode, embedded data is formatted to look like extra rows of equal length as the Luma data since both are packed T_L8. The YUV422 formatting is significantly more complex and some care is necessary to properly parse the data. The YUV embedded data formatting using a single PP is summarized in the following table.

Table 191: YUV Embedded Data Formatting

CSI Format	VI Pixel Format in Memory	1 PP Embed Mode Support	Embedded Data Layout in 32-bit DWORD
YUV420	T_L8	Yes	[emdat3, emdat2, emdat1, emdat0]
YUV422_8	T_L8	Yes	[emdat3, emdat2, emdat1, emdat0]
	T_Y8_U8__Y8_V8	Yes	{8'h0, embed_data1, 8'h0, embed_data0}
	T_U8_Y8__V8_Y8	Yes	{embed_data1, 8'h0, embed_data0, 8'h0}
	T_Y8_V8__Y8_U8	Yes	{8'h0, embed_data1, 8'h0, embed_data0}
	T_V8_Y8__U8_Y8	Yes	{embed_data1, 8'h0, embed_data0, 8'h0}
	T_Y8__U8V8_N422	Yes	{embed_data3,embed_data2,embed_data1,embed_data0} in Y buffer, The Embedded lines in U/V buffer will be zeroes
	T_Y8__U8V8_N422	Yes	{embed_data3,embed_data2,embed_data1,embed_data0} in Y buffer, The Embedded lines in U/V buffer will be zeroes
	T_Y8__U8__V8_N422	Yes	{embed_data3,embed_data2,embed_data1,embed_data0} in Y buffer, The Embedded lines in U/V buffer will be zeroes

31.3.6 Pixel Formats Memory Layout

31.3.6.1 Non-Planar Formats

The bit arrangements of the color components within a pixel for all the supported non-planar color formats are shown in the table below.

Table 192: Pixel Bit Assignments for Non-Planar Formats

Format	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

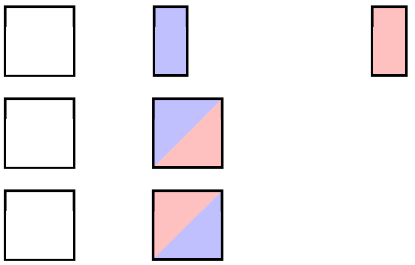
31.3.6.2 Pixel Formats (Planar and Semi-Planar)

Some pixel formats require that the individual color components are separated out into distinct buffers in memory. These formats are defined below:

Table 193: Planar and Semi-Planar Format Definitions

Name	FOURCC	Organization	Sample structure
T_Y8___U8___V8_N422	YV16	Planar	4:2:2
T_Y8___U8V8_N422	NV16	Semi-planar	4:2:2, U followed by V
T_Y8___V8U8_N422	NV61	Semi-planar	4:2:2, V followed by U

Figure 146: Planar and Semi-Planar Buffer Layout Diagram



31.4 VGP (GPIO) Interface

The VI3 unit provides for six programmable GPIOs to control various aspects of the camera system. All may be configured as either I/O or PWM and two may also be configured for I^2C camera control.

Table 194: VGP1-VGP6 Functions

GPIO	Functions		
	A	B	C
VGP1	I/O	PWM	I2C_SCK
VGP2	I/O	PWM	I2C_SDA
VGP3	I/O	PWM	-
VGP4	I/O	PWM	-
VGP5	I/O	PWM	-
VGP6	I/O	PWM	-

The Pulse Width Modulation (PWM) unit generates a series of 128 identical pulses. The unit can use any of the (VGP1-6) pins as an output, provided that the unit is enabled and the pin is configured to carry PWM data. A pulse's length (in clock cycles), duty cycle, and starting polarity are programmable. A single pulse can take between 2 and 32 clock cycles, where a high or low level is no more than 16 cycles long. A series' length is always 128 times the length of a single pulse. Once the unit is enabled, a series can be either generated once, a set number of times, or repeatedly until the unit is disabled.

31.5 Error Handling

The errors can be broadly classified in the categories provided in the following table.

Table 195: VI Error Categories

Error Categories	Description
CSI Error Indication	D-PHY Level Errors
	Packet Level Errors
	Protocol Decoding Errors
Bad Frame Size	Pixel Per Line Error
	Lines Per Frame Error
Overflow Conditions	Back pressure from ISP3.1
	Backpressure from MCCIF
	Backpressure from ISP in ZSL and SZSL Modes
	Backpressure from MCCIF in ZSL and SZSL Modes
Control Flag Error from CSI	Error in control flag sequence

The rest of this section describes details of various errors and their handling by the VI.

31.5.1 SOF Followed by EOF

This is not really an error condition. When the CSI is trying to capture a frame while in single shot mode, if it instead comes across a different frame (not matching the expected parameters of VC/DT/WC), it still sends the SOF indication for the 'bad' frame it dropped and then follows it up with the EOF. This results in the VI receiving an EOF marker without any pixel data or other control flags in between. On receiving this, the VI (depending on the HOSTIF_UPDATE.CAPTURE_GOOD_FRAME configuration) either updates the pending assembly state to active state or overwrites the SOF control flag in the input staging registers.

31.5.2 Missing Control Flags

The missing control flag error occurs when an SOF-SOL-EOL-SOL-EOL-..EOF-SOF sequence occurs. Since the VI does not check for SOL, any error in the sequence concerning SOL is ignored.

31.5.3 Pixels per Line Errors

Pixels Per Line Greater than Image Width

This error is for the case where the first line of the frame was correct and one or more intermediate lines were too long. The CSI will drop any line that does not have the matching WC in the header. This dropping of lines by the CSI might result in a frame-too-short scenario and should be handled as such. The CSI should indicate to the VI when it drops any line via the error flag along with the EOF for that frame. The VI checks for line width and, in case of any error, ignores the rest of the frame.

Pixels Per Line Greater than Image Width

This error is for the case where the first line of the frame was correct and one or more intermediate lines were shorter than expected. This dropping of lines by the CSI might result in a frame-too-short scenario and should be handled as such. The CSI should indicate to VI when it drops any line via the error flag along with the EOF for that frame. The VI checks for line width and, in case of any error, ignores the rest of the frame.

31.5.4 Lines per Frame Errors

Line per Frame Greater than Image Height

In this condition, the input logic should drop the lines beyond the expected frame height and indicate the error to the gatekeeper. On the output side, this error indication is used by output logic to mark the EOF with 'frame too long' error logic to ISP. When sending the frame to memory, the VI should drop the additional lines (beyond the expected height) and not corrupt the memory buffer.

Line per Frame Less than Image Height

In this condition, the input logic does not do any special handling. It may mark the EOF with the error flag (not necessarily required as the read logic can identify the frame too short condition too). The input logic still needs to indicate the error to the gatekeeper module for appropriate handling of next set of assembly registers based on CAPTURE_GOOD_FRAME configuration. On the output side of the line-store buffer, the EOF to ISP is marked with frame-too-short error flag.

31.5.5 CSI Error Indication

In this condition, the error flag is used by the gatekeeper module for appropriate handling (update from assembly state or not as defined by the CAPTURE_GOOD_FRAME configuration). The rest of the frame handling follows normal handling or as defined by other defined error-handling scenarios.

31.5.6 Line Buffer Overflow

In case the backpressure from ISP/MC causes the line buffer to overflow, the incoming pixel data from the CSI is dropped until the EOF. On the read side of line-store buffer, if a premature SOF is detected (since the rest of the frame was dropped at the input), the OP*_DONE syncpt is generated as programmed by the CAPTURE_GOOD_FRAME configuration.

31.6 VI Registers

Refer to Section 1.4: Reading Register Tables in the Introduction chapter for the register table protocol as well as recommendations for accessing registers.

31.6.1 VI_CFG_VI_INCR_SYNCPT_0

Offset: 0x0 | Byte Offset: 0x0 | Read/Write: R/W | Reset: 0x00000000 (0bxxxxxxxxxxxxxxxx0000000000000000)

Bit	Reset	Description
15:8	0x0	VI_COND: Condition mapped from raise/wait 0 = IMMEDIATE 1 = OP_DONE 2 = RD_DONE 3 = REG_WR_SAFE 4 = VI_CSI_PPA_LINE_START 5 = VI_CSI_PPA_FRAME_START 6 = VI_MWA_REQ_DONE 7 = VI_MWA_ACK_DONE 8 = VI_CSI_PPB_LINE_START 9 = VI_CSI_PPB_FRAME_START 10 = VI_MWB_REQ_DONE 11 = VI_MWB_ACK_DONE 12 = VI_CSI_PPC_LINE_START 13 = VI_CSI_PPC_FRAME_START 14 = VI_MWC_REQ_DONE 15 = VI_MWC_ACK_DONE 16 = VI_CSI_PPD_LINE_START 17 = VI_CSI_PPD_FRAME_START 18 = VI_MWD_REQ_DONE 19 = VI_MWD_ACK_DONE 20 = VI_CSI_PPE_LINE_START 21 = VI_CSI_PPE_FRAME_START 22 = VI_MWE_REQ_DONE 23 = VI_MWE_ACK_DONE 24 = VI_CSI_PPF_LINE_START 25 = VI_CSI_PPF_FRAME_START 26 = VI_MWF_REQ_DONE 27 = VI_MWF_ACK_DONE 28 = VI_ISPA_DONE 29 = VI_ISPB_DONE 30 = VI_VGP0_RCVD 31 = VI_VGP1_RCVD 32 = COND_32
7:0	0x0	VI_INDX: syncpt index value

31.6.2 VI_CFG_VI_INCR_SYNCPT_CNTRL_0

Offset: 0x1 | Byte Offset: 0x4 | Read/Write: R/W | Reset: 0x00000000 (0bxxxxxxxxxxxxxxxxxxxxxxxx0xxxxxx0)

Bit	Reset	Description
8	0x0	VI_INCR_SYNCPT_NO_STALL: If NO_STALL is 1, then when FIFOs are full, INCR_SYNCPT methods will be dropped and the INCR_SYNCPT_ERROR[COND] bit will be set. If NO_STALL is 0, then when FIFOs are full, the client host interface will be stalled.
0	0x0	VI_INCR_SYNCPT_SOFT_RESET: If SOFT_RESET is set, then all internal state of the client syncpt block will be reset. To do soft reset, first set SOFT_RESET of all Host1x clients affected, then clear all SOFT_RESETs.

31.6.3 VI_CFG_VI_INCR_SYNCPT_ERROR_0

Offset: 0x2 | Byte Offset: 0x8 | Read/Write: R/W | Reset: 0xXXXXXXXX (0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx)

Bit	Reset	Description
31:0	X	VI_COND_STATUS: COND_STATUS[COND] is set if the FIFO for COND overflows. This bit is sticky and will remain set until cleared. Cleared by writing 1.

31.6.4 VI_CFG_CTXSW_0

Context Switch Register

Should be common to all modules. Includes the current channel/class (which is writable by software) and the next channel/class (which the hardware sets when it receives a context switch).

The context switch works like this:

Any context switch request triggers an interrupt to the host and causes the new channel/class to be stored in NEXT_CHANNEL/NEXT_CLASS. Software sees that there is a context switch interrupt and does the necessary operations to make the module ready to receive traffic from the new context. It clears the context switch interrupt and writes CURR_CHANNEL/CLASS to the same value as NEXT_CHANNEL/CLASS, which causes a context switch acknowledge packet to be sent to the host. This completes the context switch and allows the host to continue sending data to the module.

Context switches can also be preloaded. If CURR_CLASS/CHANNEL are written and updated to the next CLASS/CHANNEL before the context switch request occurs, an acknowledge will be generated by the module, and no interrupt will be triggered. This is one way for software to avoid dealing with context switch interrupts.

Another way to avoid context switch interrupts is to set the AUTO_ACK bit. This bit tells the module to automatically acknowledge any incoming context switch requests without triggering an interrupt. CURR_* and NEXT_* will be updated by the module so they will always be current.

Offset: 0x8 | Byte Offset: 0x20 | Read/Write: R/W | Reset: 0xXXXXf800 (0bxxxxxxxxxxxxxxxx11111x0000000000)

Bit	R/W	Reset	Description
31:28	RO	X	NEXT_CHANNEL: Next requested channel
25:16	RO	X	NEXT_CLASS: Next requested class
15:12	RW	0xf	CURR_CHANNEL: Current working channel, reset to 'invalid'
11	RW	0x1	AUTO_ACK: Automatically acknowledge any incoming context switch requests 0 = MANUAL 1 = AUTOACK
9:0	RW	0x0	CURR_CLASS: Current working class

31.6.5 VI_CFG_INTSTATUS_0

Offset: 0x9 | Byte Offset: 0x24 | Read/Write: RO | Reset: 0x00000000 (0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx0)

Bit	Reset	Description
0	0x0	CTXSW_INT: Context switch interrupt status (clear on write)

31.6.6 VI_PWM_CONTROL_0

VI Pulse Width Modulation Control

PWM signal generation logic can generate up to 128 pulses per line internally and the PWM pulse select registers determine which of the 128 pulses will be output. Any of the 128 internally generated pulse can be independently selected as output if they occur within one line time.

The PWM signal can be output on the VGP6 pin if VGP6 output is enabled and the output select is set to PWM.

The PWM is triggered by the first VSYNC after the PWM_ENABLE bit has been set.

Offset: 0xe | Byte Offset: 0x38 | Read/Write: R/W | Reset: 0x00000000 (0b00000000xx00xxxxxxxxxxxxxxx0xxx0)

Bit	Reset	Description
31:24	0x0	PWM_COUNTER: 8-bit PWM Counter value used when PWM_MODE is set to COUNTER to determine how many times the PWM will cycle through the 128 cycles before stopping.
21:20	0x0	PWM_MODE: PWM Mode Continuous: After the PWM is turned on, continue through the PWM's 128 cycles repeatedly until the PWM is turned off. Single: After the PWM is turned on, cycle once through the 128 cycles and stop. Counter: After the PWM is turned on, cycle through the 128 cycles PWM_COUNTER number of times then stop. 0 = CONTINUOUS 1 = SINGLE 2 = COUNTER
4	0x0	PWM_DIRECTION: PWM Direction 0= Incrementing 1= Decrementing 0 = INCR 1 = DECR
0	0x0	PWM_ENABLE: PWM Enable 0 = DISABLED 1 = ENABLED

31.6.7 VI_CFG_PWM_HIGH_PULSE_0

PWM High Pulse Period

Offset: 0xf | Byte Offset: 0x3c | Read/Write: R/W | Reset: 0x00000000 (0b00000000000000000000000000000000)

Bit	Reset	Description
31:0	0x0	PWM_HIGH_PULSE: PWM High Pulse

31.6.8 VI_CFG_PWM_LOW_PULSE_0

PWM Low Pulse Period

Offset: 0x10 | Byte Offset: 0x40 | Read/Write: R/W | Reset: 0x00000000 (0b00000000000000000000000000000000)

Bit	Reset	Description
31:0	0x0	PWM_LOW_PULSE: PWM Low Pulse

31.6.9 VI_CFG_PWM_SELECT_PULSE_A_0

PWM Pulse Select A

The next 4 registers select which of the internal 128 pulses to output. Each bit in the four registers corresponds to one internal pulse.

Offset: 0x11 | Byte Offset: 0x44 | Read/Write: R/W | Reset: 0xXXXXXXXX (0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx)

Bit	Reset	Description
31:0	X	PWM_SELECT_A: PWM Select bits 31 to 0

31.6.10 VI_CFG_PWM_SELECT_PULSE_B_0

PWM Pulse Select B

Offset: 0x12 | Byte Offset: 0x48 | Read/Write: R/W | Reset: 0xXXXXXXXX (0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx)

Bit	Reset	Description
31:0	X	PWM_SELECT_B: PWM Select bits 63 to 32

31.6.11 VI_CFG_PWM_SELECT_PULSE_C_0

PWM Pulse Select C

Offset: 0x13 | Byte Offset: 0x4c | Read/Write: R/W | Reset: 0xXXXXXXXX (0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx)

Bit	Reset	Description
31:0	X	PWM_SELECT_C: PWM Select bits 95 to 64

31.6.12 VI_CFG_PWM_SELECT_PULSE_D_0

PWM Pulse Select D

Offset: 0x14 | Byte Offset: 0x50 | Read/Write: R/W | Reset: 0xXXXXXXXX (0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx)

Bit	Reset	Description
31:0	X	PWM_SELECT_D: PWM Select bits 127 to 96

31.6.13 VI_CFG_VGP*n*_0

VI VGP*n* Input/Output Config/Data

There are six VI VGP*n* Config registers, where *n* = 1 through 6.

Offset: 0x19 + (*n* – 1) | Byte Offset: 0x64 + (*n* – 1)*0x4 | Read/Write: R/W | Reset: 0x00000X0X (0bxxxxxxxx0xxxxxx00xxxxxxxxxxxxxxx)

Bit	R/W	Reset	Description
24	RW	0x0	VGP*n*_INPUT_ENABLE: Reserved
17	RW	0x0	PIN_OUTPUT_SELECT_VGP*n*: Pin Output Select VGP*n* 0 = VG*Pn*_OUTPUT_DATA 1 = 1'b0
16	RW	0x0	VGP*n*_OUTPUT_ENABLE: VGP*n* pin Output Enable. This bit controls the VGP*n* pin output. 0 = DISABLED 1 = ENABLED
8	RO	X	VGP*n*_INPUT_DATA: VGP*n* pin Input Data (effective if VGP*n*_INPUT_ENABLE is ENABLED) 0= VGP*n* input low 1= VGP*n* input high
0	RW	X	VGP*n*_OUTPUT_DATA: VGP*n* pin Output Data (effective if VGP*n*_OUTPUT_ENABLE is ENABLED and VGP*n*_OUTPUT_SELECT is DATA)

31.6.14 VI_CFG_INTERRUPT_MASK_0

Interrupt Mask

Offset: 0x23 | Byte Offset: 0x8c | Read/Write: R/W | Reset: 0x00000000 (0bxxxxxxxxxxxxxxxxxxxxxxxxxx000000x)

Bit	Reset	Description
6	0x0	VGP6_INT_MASK: VGP6 pin Interrupt Mask. This bit controls interrupting when a VGP6 rising/falling edge is detected. 0 = DISABLED 1 = ENABLED
5	0x0	VGP5_INT_MASK: VGP5 pin Interrupt Mask. This bit controls interrupting when a VGP5 rising/falling edge is detected. 0 = DISABLED 1 = ENABLED
4	0x0	VGP4_INT_MASK: VGP4 pin Interrupt Mask. This bit controls interrupting when a VGP4 rising/falling edge is detected. 0 = DISABLED 1 = ENABLED

Bit	Reset	Description
3	0x0	VGP3_INT_MASK: VGP3 pin Interrupt Mask. This bit controls interrupting when a VGP3 rising/falling edge is detected. 0 = DISABLED 1 = ENABLED
2	0x0	VGP2_INT_MASK: VGP2 pin Interrupt Mask. This bit controls interrupting when a VGP2 rising/falling edge is detected. 0 = DISABLED 1 = ENABLED
1	0x0	VGP1_INT_MASK: VGP1 pin Interrupt Mask. This bit controls interrupting when a VGP1 rising/falling edge is detected. 0 = DISABLED 1 = ENABLED

31.6.15 VI_CFG_INTERRUPT_TYPE_SELECT_0

Interrupt Type Select

Offset: 0x24 | Byte Offset: 0x90 | Read/Write: R/W | Reset: 0x00000000 (0bxxxxxxxxxxxxxxxxxxxxxxxxxxx000000x)

Bit	Reset	Description
6	0x0	VGP6_INT_TYPE: VGP6 pin Interrupt Type. This bit controls interrupt VGP6 0= Edge type 1= Level type 0 = EDGE 1 = LEVEL
5	0x0	VGP5_INT_TYPE: VGP5 pin Interrupt Type. This bit controls interrupt VGP5 0= Edge type 1= Level type 0 = EDGE 1 = LEVEL
4	0x0	VGP4_INT_TYPE: VGP4 pin Interrupt Type. This bit controls interrupt VGP4 0= Edge type 1= Level type 0 = EDGE 1 = LEVEL
3	0x0	VGP3_INT_TYPE: VGP3 pin Interrupt Type. This bit controls interrupt VGP3 0= Edge type 1= Level type 0 = EDGE 1 = LEVEL
2	0x0	VGP2_INT_TYPE: VGP2 pin Interrupt Type. This bit controls interrupt VGP2 0= Edge type 1= Level type 0 = EDGE 1 = LEVEL
1	0x0	VGP1_INT_TYPE: VGP1 pin Interrupt Type. This bit controls interrupt VGP1 0= Edge type 1= Level type 0 = EDGE 1 = LEVEL

31.6.16 VI_CFG_INTERRUPT_POLARITY_SELECT_0

Interrupt Polarity Select

Offset: 0x25 | Byte Offset: 0x94 | Read/Write: R/W | Reset: 0x00000000 (0bxxxxxxxxxxxxxxxxxxxxxxxxxxx000000x)

Bit	Reset	Description
6	0x0	VGP6_INT_POLARITY: VGP6 pin Interrupt Type. This bit controls interrupt VGP6. 0= falling edge or low level 1= rising edge or high level 0 = LOW 1 = HIGH

Bit	Reset	Description
5	0x0	VGP5_INT_POLARITY: VGP5 pin Interrupt Type. This bit controls interrupt VGP5. 0= falling edge or low level 1= rising edge or high level 0 = LOW 1 = HIGH
4	0x0	VGP4_INT_POLARITY: VGP4 pin Interrupt Type. This bit controls interrupt VGP4. 0= falling edge or low level 1= rising edge or high level 0 = LOW 1 = HIGH
3	0x0	VGP3_INT_POLARITY: VGP3 pin Interrupt Type. This bit controls interrupt VGP3. 0= falling edge or low level 1= rising edge or high level 0 = LOW 1 = HIGH
2	0x0	VGP2_INT_POLARITY: VGP2 pin Interrupt Type. This bit controls interrupt VGP2. 0= falling edge or low level 1= rising edge or high level 0 = LOW 1 = HIGH
1	0x0	VGP1_INT_POLARITY: VGP1 pin Interrupt Type. This bit controls interrupt VGP1. 0= falling edge or low level 1= rising edge or high level 0 = LOW 1 = HIGH

31.6.17 VI_CFG_INTERRUPT_STATUS_0

Interrupt Enable

This register returns interrupt status when read. When this register is written, the interrupt status corresponding to the bits written with 1 is reset. Interrupt status corresponding to the bits written with 0 will be left unchanged.

Note that interrupt status bits can be set even when their corresponding interrupt enable bits, in the VI_CFG_INTERRUPT_MASK_0 register, are cleared. When these bits are set and their corresponding interrupt enable bits are set, an interrupt is generated. The interrupt can be cleared or left unchanged by writing 1 or 0, respectively, to the corresponding bits in this register.

Clearing the interrupt status bits does not affect the interrupt enable bits.

Offset: 0x26 | Byte Offset: 0x98 | Read/Write: RO | Reset: 0x000000XX (0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx)

Bit	Reset	Description
6	X	VGP6_INT_STATUS: VGP6 pin Interrupt Status. This bit controls interrupt when a VGP6 rising/falling edge is detected. 0= Interrupt not detected 1= Interrupt detected 0 = NOINTR 1 = INTR
5	X	VGP5_INT_STATUS: VGP5 pin Interrupt Status. This bit controls interrupt when a VGP5 rising/falling edge is detected. 0= Interrupt not detected 1= Interrupt detected 0 = NOINTR 1 = INTR
4	X	VGP4_INT_STATUS: VGP4 pin Interrupt Status. This bit controls interrupt when a VGP4 rising/falling edge is detected. 0= Interrupt not detected 1= Interrupt detected 0 = NOINTR 1 = INTR

Bit	Reset	Description
3	X	VGP3_INT_STATUS: VGP3 pin Interrupt Status. This bit controls interrupt when a VGP3 rising/falling edge is detected. 0= Interrupt not detected 1= Interrupt detected 0 = NOINTR 1 = INTR
2	X	VGP2_INT_STATUS: VGP2 pin Interrupt Status. This bit controls interrupt when a VGP2 rising/falling edge is detected. 0= Interrupt not detected 1= Interrupt detected 0 = NOINTR 1 = INTR
1	X	VGP1_INT_STATUS: VGP1 pin Interrupt Status. This bit controls interrupt when a VGP1 rising/falling edge is detected. 0= Interrupt not detected 1= Interrupt detected 0 = NOINTR 1 = INTR

31.6.18 VI_CFG_VGP_SYNCPT_CONFIG_0

Offset: 0x2b | Byte Offset: 0xac | Read/Write: R/W | Reset: 0x00000000 (0bxxxxxxxxxxxxxxxxxxxxxxxxxxx000x000)

Bit	Reset	Description
6:4	0x0	SYNCPT_VGPY_SELECT: Selects the VGP (1-6) for SYNCPT condition VGP_1_RECD
2:0	0x0	SYNCPT_VGPX_SELECT: Selects the VGP (1-6) for SYNCPT condition VGP_0_RECD

31.6.19 VI_CFG_VI_SW_RESET_0

Offset: 0x2d | Byte Offset: 0xb4 | Read/Write: R/W | Reset: 0x00000000 (0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx0)

Bit	Reset	Description
0	0x0	MCCIF_RESET: Resets the MCCIF interface

31.6.20 VI_CFG_CG_CTRL_0

Offset: 0x2e | Byte Offset: 0xb8 | Read/Write: R/W | Reset: 0x00000001 (0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx1)

Bit	Reset	Description
0	0x1	CG_2ND_LEVEL_EN: Second-level clock gating control 0: Disables any second-level clock gating (MCCIF clocks should be controlled from CAR registers) 1: Enables second-level clock gating 0 = DISABLE 1 = ENABLE

31.6.21 VI_CFG_VI_MCCIF_FIFOCTRL_0

Memory Client Interface FIFO Control Register (where applicable) and Clock Gating Control

Note: *The FIFO timing aspects of this register are not supported but are retained for software compatibility.*

The clock override/ovr_mode fields of this register control the 2nd-level clock gating for the client and MC side of the MCCIF. All clock gating is enabled by default.

A '1' written to the rclk/wclk override field will result in one of the following:

- With wclk/rclk override mode = LEGACY, the clock reverts to the legacy mode of operation where the clock is on whenever the client clock is enabled.
- With wclk/rclk override mode = ON, the clock is always on inside the MCCIF and PC.

A '1' written to the cclk override field keeps the client's clock always on inside the MCCIF.

Offset: 0x37 | Byte Offset: 0xdc | Read/Write: R/W | Reset: 0x00000000 (0bxxxxxxxxxxxxxx00000xxxxxxxxxxxxxx00)

Bit	Reset	Description
20	LEGACY	VI_RCLK_OVR_MODE: 0 = LEGACY 1 = ON
19	LEGACY	VI_WCLK_OVR_MODE: 0 = LEGACY 1 = ON
18	0x0	VI_CCLK_OVERRIDE
17	0x0	VI_RCLK_OVERRIDE
16	0x0	VI_WCLK_OVERRIDE
1	DISABLE	VI_MCCIF_RDMC_RDFAST: 0 = DISABLE 1 = ENABLE
0	DISABLE	VI_MCCIF_WRCL_MCLE2X: 0 = DISABLE 1 = ENABLE

31.6.22 VI_CFG_TIMEOUT_WCOAL_VI_0

Write Coalescing Time-Out Register

Note: *Write coalescing is not supported by the MCCIF clients. Registers are retained for backwards compatibility but are not used by the hardware.*

Offset: 0x38 | Byte Offset: 0xe0 | Read/Write: R/W | Reset: 0x00000032 (0bxxxxxxxxxxxxxxxxxxxxxxxxxx00110010)

Bit	Reset	Description
7:0	0x32	VIWSB_WCOAL_TMVAL

31.6.23 VI_CFG_DVFS_0

Dynamic Voltage Frequency Shift Register

Offset: 0x3a | Byte Offset: 0xe8 | Read/Write: R/W | Reset: 0x404001ff (0bx1000000x1000000xxxxxxx111111111)

Bit	Reset	Description
30:24	0x40	SENSORB_LB_THRESHOLD: This field defines the DVFS threshold for the VI Line buffer for Sensor B, which is compared against the buffer utilization in order to assert the ready_for_latency event signal to the MC. The final ready_for_latency_signal is ANDed with the one generated from the MCCIF_THRESHOLD comparison.
22:16	0x40	SENSORA_LB_THRESHOLD: This field defines the DVFS threshold for the VI Line buffer for Sensor A, which is compared against the buffer utilization in order to assert the ready_for_latency event signal to the MC. The final ready_for_latency_signal is ANDed with the one generated from the MCCIF_THRESHOLD comparison.
8:0	0xff	MCCIF_THRESHOLD: This field defines the DVFS threshold for the MCCIF FIFO, which is compared against the write request buffer utilization in order to assert the ready_for_latency_event signal to the MC.

31.6.24 VI_CFG_DVFS_1_0

Dynamic Voltage Frequency Shift Register

Offset: 0x3c | Byte Offset: 0xf0 | Read/Write: R/W | Reset: 0x40404040 (0bx1000000x1000000x1000000x1000000)

Bit	Reset	Description
30:24	0x40	SENSORF_LB_THRESHOLD: This register defines the DVFS threshold for VI Line buffer for Sensor B, which is compared against the buffer utilization in order to assert ready_for_latency event signal to the Memory Controller. The final ready_for_latency_signal is AND'd with the one generated from MCCIF_THRESHOLD comparison.
22:16	0x40	SENSORE_LB_THRESHOLD: This register defines the DVFS threshold for VI Line buffer for Sensor B, which is compared against the buffer utilization in order to assert ready_for_latency event signal to the Memory Controller. The final ready_for_latency_signal is AND'd with the one generated from MCCIF_THRESHOLD comparison.
14:8	0x40	SENSORD_LB_THRESHOLD: This register defines the DVFS threshold for VI Line buffer for Sensor B, which is compared against the buffer utilization in order to assert ready_for_latency event signal to the Memory Controller. The final ready_for_latency_signal is AND'd with the one generated from MCCIF_THRESHOLD comparison.
6:0	0x40	SENSORC_LB_THRESHOLD: This register defines the DVFS threshold for VI Line buffer for Sensor A, which is compared against the buffer utilization in order to assert ready_for_latency event signal to the Memory Controller. The final ready_for_latency_signal is AND'd with the one generated from MCCIF_THRESHOLD comparison.

31.6.25 VI_CFG_DVFSFIFO_CNTRL_0

Offset: 0x3d | Byte Offset: 0xf4 | Read/Write: R/W | Reset: 0x00000000 (0bxxxxxxxxxxxxxxxxxxxxxxxx000000000)

Bit	Reset	Description
8:0	0x0	DVFS_WR_LIMIT_VAL

31.6.26 VI_CFG_RESERVE_0_0

Reserved register

Offset: 0x3e | Byte Offset: 0xf8 | Read/Write: R/W | Reset: 0x0000XXXX (0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx)

3:0	X	nc_RESERVE_1_0

31.7 VI Input CSI Interface Registers

CSI Channel Registers

31.7.1 VI_CSI_0_SW_RESET_0

Offset: 0x40 | Byte Offset: 0x100 | Read/Write: R/W | Secure: Trust Zone Protected | Reset: 0x00000000 (0bxxxxxxxxxxxxxxxxxxxxxxxxxxxx00000)

Bit	Reset	Description
4	0x0	ISPINTF_RESET: Reset ISP interface
3	0x0	MCINTF_RESET: Reset Memory Client i/f logic
2	0x0	PF_RESET: Reset Pixel format logic
1	0x0	SENSORCTL_RESET: Reset Sensor control logic
0	0x0	SHADOW_RESET: Reset Shadow copy logic

31.7.2 VI_CSI_0_SINGLE_SHOT_0

Offset: 0x41 | Byte Offset: 0x104 | Read/Write: RO | Reset: 0x00000000 (0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx0)

Bit	Reset	Description
0	0x0	CAPTURE: request update of the previously assembled 'assembly state' to 'active state' and schedule single shot capture for the VI channel. The actual update of operational register is gated by the next EOF Register read back returns pending capture status (at input of VI)

31.7.3 VI_CSI_0_SINGLE_SHOT_STATE_UPDATE_0

Offset: 0x42 | Byte Offset: 0x108 | Read/Write: R/W | Reset: 0x00000001 (0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx1)

Bit	Reset	Description
0	0x1	CAPTURE_GOOD_FRAME: 1'b0: update state when the next SOF is received, irrespective of the state of previous frame. 1'b1: update state when the next SOF is received AND the previous frame was the correct frame based on current operational state.

31.7.4 VI_CSI_0_IMAGE_DEF_0

Offset: 0x43 | Byte Offset: 0x10c | Read/Write: R/W | Secure: Trust Zone Protected | Reset: 0x00000000 (0bxxxxxxx000000000xxxxxx0xxxxx000)

Bit	Reset	Description
24	0x0	BYPASS_PXL_TRANSFORM: Bypass pixel transformation VI unit does convert the pixels into I.F format while interfacing with Memory packer. This bit can be used to bypass this conversion and will useful in writing compressed image format into memory.

Bit	Reset	Description
23:16	0x0	FORMAT: Pixel memory format for the VI channel The following are not supported: T_A2Y10U10V10, T_V10U10Y10A2 T_Y8__U8__V8_N444, T_Y8__U8V8_N444, T_Y8__V8U8_N444 16 = T_L8 32 = T_R16_I 33 = T_B5G6R5 34 = T_R5G6B5 35 = T_A1B5G5R5 36 = T_A1R5G5B5 37 = T_B5G5R5A1 38 = T_R5G5B5A1 39 = T_A4B4G4R4 40 = T_A4R4G4B4 41 = T_B4G4R4A4 42 = T_R4G4B4A4 64 = T_A8B8G8R8 65 = T_A8R8G8B8 66 = T_B8G8R8A8 67 = T_R8G8B8A8 68 = T_A2B10G10R10 69 = T_A2R10G10B10 70 = T_B10G10R10A2 71 = T_R10G10B10A2 193 = T_A8Y8U8V8 194 = T_V8U8Y8A8 197 = T_A2Y10U10V10 198 = T_V10U10Y10A2 200 = T_Y8_U8__Y8_V8 201 = T_Y8_V8__Y8_U8 202 = T_U8_Y8__V8_Y8 203 = T_V8_Y8__U8_Y8 224 = T_Y8__U8__V8_N444 225 = T_Y8__U8V8_N444 226 = T_Y8__V8U8_N444 227 = T_Y8__U8__V8_N422 228 = T_Y8__U8V8_N422 229 = T_Y8__V8U8_N422 230 = T_Y8__U8__V8_N420 231 = T_Y8__U8V8_N420 232 = T_Y8__V8U8_N420 233 = T_X2Lc10Lb10La10 234 = T_A2R6R6R6R6R6
8	0x0	INTERLEAVING_MODE: 1= Enable interleaving mode for writing image into memory
2	0x0	DEST_ISPB: 1= send VI channel data to ISPB
1	0x0	DEST_ISPA: 1= send VI channel data to ISPA
0	0x0	DEST_MEM: 1= send VI channel data to MEM

31.7.5 VI_CSI_0_RGB2Y_CTRL_0

Offset: 0x44 | Byte Offset: 0x110 | Read/Write: R/W | Reset: 0x00XXXXX (0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx)

Bit	Reset	Description
23:18	X	B2Y_COEFF: Blue coefficient used to convert RGB pixel data to Y for writing to Memory (in U0.6 format)
15:10	X	G2Y_COEFF: Green coefficient used to convert RGB pixel data to Y for writing to Memory (in U0.6 format)
7:2	X	R2Y_COEFF: Red coefficient used to convert RGB pixel data to Y for writing to Memory (in U0.6 format)

31.7.6 VI_CSI_0_MEM_TILING_0

Offset: 0x45 | Byte Offset: 0x114 | Read/Write: R/W | Reset: 0x00000000 (0bxxxxxxxxxxxxxxxxxxxxxxxx00000000)

Bit	Reset	Description
7:0	0x0	TILING_FORMAT: VI channel memory surface tiling format 254 = BLOCK_LINEAR 0 = PITCH_LINEAR

31.7.7 VI_CSI_0_CSI_IMAGE_SIZE_0

Offset: 0x46 | Byte Offset: 0x118 | Read/Write: R/W | Reset: 0xXXXXXXXX (0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx)

Bit	Reset	Description
31:16	X	HEIGHT: Height of VI channel frame in Lines. This Register field is double buffered. Image size is constrained by HEIGHT >= 32 lines and WIDTH*HEIGHT <= 128 MegaPixels
15:0	X	WIDTH: Width of VI channel frame in Pixels. This Register field is double buffered. Image size is constrained by WIDTH > = 32 pixels and WIDTH*HEIGHT < 128 MegaPixels.

31.7.8 VI_CSI_0_CSI_IMAGE_SIZE_WC_0

Offset: 0x47 | Byte Offset: 0x11c | Read/Write: R/W | Reset: 0x0000XXXX (0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx)

Bit	Reset	Description
15:0	X	WORDCOUNT: VI channel word count for the Image to be captured This parameter specifies the number of bytes per line/packet. This is matched against the Word Count field in packet header if enabled. This count does not include the additional 2 bytes of CRC checksum if data CRC check is enabled. When the input stream comes from a CSI camera port, this parameter must be programmed when CSI_PPA_PAD_SHORT_LINE is set to either PAD0S or PAD1S, no matter whether CSI_PPA_WORD_COUNT_SELECT is set to REGISTER or HEADER. When the input stream comes from the host path or from the VIP path, and the data mode is PAYLOAD_ONLY, this count must be programmed. Given a line width of N pixels, the programming value of this parameters is as follows ---------- data format value ---------- YUV420_8 N bytes YUV420_10 N/4*5 bytes LEG_YUV420_8 N/2*3 bytes YUV422_8 N*2 bytes YUV422_10 N/2*5 bytes RGB888 N*3 bytes RGB666 N/4*9 bytes RGB565 N*2 bytes RGB555 N*2 bytes RGB444 N*2 bytes RAW6 N/4*3 bytes RAW7 N/8*7 bytes RAW8 N bytes RAW10 N/4*5 bytes RAW12 N/2*3 bytes RAW14 N/4*7 bytes This register is used in to set the wordcount in Test Pattern Generation mode. The wordcount size needed to be set in 16-pixel boundary depended on data type selection (RAW10 or RGB888) This Register field is double buffered.

31.7.9 VI_CSI_0_CSI_IMAGE_DT_0

Offset: 0x48 | Byte Offset: 0x120 | Read/Write: R/W | Reset: 0x00000XXX (0bxxxxxxxxxxxxxxxxxxxx0xxxxxxxxxxx)

Bit	Reset	Description
12	0x0	INTERLACED_VIDEO: VI channel interlaced video format enable
9:8	X	VC: VI channel virtual channel ID. This Register field is double buffered.

Bit	Reset	Description
5:0	X	DATA_TYPE: VI channel input data type. This Register field is double buffered. 18 = EMBED 24 = YUV420_8 25 = YUV420_10 26 = LEG_YUV420_8 28 = YUV420CSPS_8 29 = YUV420CSPS_10 30 = YUV422_8 31 = YUV422_10 32 = RGB444 33 = RGB555 34 = RGB565 35 = RGB666 36 = RGB888 40 = RAW6 41 = RAW7 42 = RAW8 43 = RAW10 44 = RAW12 45 = RAW14 48 = ARB_DT1 49 = ARB_DT2 50 = ARB_DT3 51 = ARB_DT4

31.7.10 VI_CSI_0_SURFACE0_OFFSET_MSB_0

Offset: 0x49 | Byte Offset: 0x124 | Read/Write: R/W | Secure: Trust Zone Protected | Reset: 0x0000000X (0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx)

Bit	Reset	Description
1:0	X	OFFSET_MSB_0: Base address MSB for Surface 0 in Memory (or Top Frame for Interlaced Video). This Register field is double buffered. Only atom aligned (64Bytes) address is supported.

31.7.11 VI_CSI_0_SURFACE0_OFFSET_LSB_0

Offset: 0x4a | Byte Offset: 0x128 | Read/Write: R/W | Secure: Trust Zone Protected | Reset: 0xXXXXXXXX (0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx)

Bit	Reset	Description
31:0	X	OFFSET_LSB_0: Base address LSB for Surface 0 in Memory (or Top Frame for Interlaced Video). This Register field is double buffered. Only atom aligned (64Bytes) address is supported.

31.7.12 VI_CSI_0_SURFACE1_OFFSET_MSB_0

Offset: 0x4b | Byte Offset: 0x12c | Read/Write: R/W | Secure: Trust Zone Protected | Reset: 0x0000000X (0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx)

Bit	Reset	Description
1:0	X	OFFSET_MSB_1: Base address MSB for Surface 1 in Memory (or Top Frame for Interlaced Video). This Register field is double buffered. Only atom aligned (64Bytes) address is supported.

31.7.13 VI_CSI_0_SURFACE1_OFFSET_LSB_0

Offset: 0x4c | Byte Offset: 0x130 | Read/Write: R/W | Secure: Trust Zone Protected | Reset: 0xXXXXXXXX (0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx)

Bit	Reset	Description
31:0	X	OFFSET_LSB_1: Base address LSB for Surface 1 in Memory (or Top Frame for Interlaced Video). This Register field is double buffered.Only atom aligned (64Bytes) address is supported.

31.7.14 VI_CSI_0_SURFACE2_OFFSET_MSB_0

Offset: 0x4d | Byte Offset: 0x134 | Read/Write: R/W | Secure: Trust Zone Protected | Reset: 0x0000000X (0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx)

Bit	Reset	Description
31:16	X	HEIGHT: Height of VI channel frame in Lines. This Register field is double buffered. Image size is constrained by HEIGHT >= 32 lines and WIDTH*HEIGHT <= 128 MegaPixels
15:0	X	WIDTH: Width of VI channel frame in Pixels. This Register field is double buffered. Image size is constrained by WIDTH > = 32 pixels and WIDTH*HEIGHT < 128 MegaPixels.

31.7.38 VI_CSI_1_CSI_IMAGE_SIZE_WC_0

Offset: 0x87 | Byte Offset: 0x21c | Read/Write: R/W | Reset: 0x0000XXXX (0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx)

Bit	Reset	Description
15:0	X	WORDCOUNT: VI channel word count for the Image to be captured This parameter specifies the number of bytes per line/packet. This is matched against the Word Count field in packet header if enabled. This count does not include the additional 2 bytes of CRC checksum if data CRC check is enabled. When the input stream comes from a CSI camera port, this parameter must be programmed when CSI_PPA_PAD_SHORT_LINE is set to either PAD0S or PAD1S, no matter whether CSI_PPA_WORD_COUNT_SELECT is set to REGISTER or HEADER. When the input stream comes from the host path or from the VIP path, and the data mode is PAYLOAD_ONLY, this count must be programmed. Given a line width of N pixels, the programming value of this parameters is as follows ---------- data format value ---------- YUV420_8 N bytes YUV420_10 N/4*5 bytes LEG_YUV420_8 N/2*3 bytes YUV422_8 N*2 bytes YUV422_10 N/2*5 bytes RGB888 N*3 bytes RGB666 N/4*9 bytes RGB565 N*2 bytes RGB555 N*2 bytes RGB444 N*2 bytes RAW6 N/4*3 bytes RAW7 N/8*7 bytes RAW8 N bytes RAW10 N/4*5 bytes RAW12 N/2*3 bytes RAW14 N/4*7 bytes This register is used in to set the word count in Test Pattern Generation mode. The wordcount size needed to be set in 16-pixel boundary depended on data type selection (RAW10 or RGB888) This Register field is double buffered.

31:0	X	VI_I2C_COND_STATUS: COND_STATUS[COND] is set if the FIFO for COND overflows. This bit is sticky and will remain set until cleared. Cleared by writing 1.

31.8.4 VII2C_CTXSW_0

Context switch register. Should be common to all modules. Includes the current channel/class (which is writable by software) and the next channel/class (which the hardware sets when it receives a context switch).

Context switching works like this:

Any context switch request triggers an interrupt to the host and causes the new channel/class to be stored in NEXT_CHANNEL/NEXT_CLASS. Software sees that there is a context switch interrupt and does the necessary operations to make the module ready to receive traffic from the new context. It clears the context switch interrupt and writes CURR_CHANNEL/CLASS to the same value as NEXT_CHANNEL/CLASS, which causes a context switch acknowledge packet to be sent to the host. This completes the context switch and allows the host to continue sending data to the module.

Context switches can also be pre-loaded. If CURR_CLASS/CHANNEL are written and updated to the next CLASS/CHANNEL before the context switch request occurs, an acknowledge will be generated by the module and no interrupt will be triggered. This is one way for software to avoid dealing with context switch interrupts.

Another way to avoid context switch interrupts is to set the AUTO_ACK bit. This bit tells the module to automatically acknowledge any incoming context switch requests without triggering an interrupt. CURR_* and NEXT_* will be updated by the module so they will always be current.

31.8.15 VII2C_I2C_STREAM_DIRECT_I2C_CNFG_0

IC Controller Configuration Register (Master)

The I2C_CNFG register is used to configure:

- the number of bytes to be transmitted or received
- the slave device type, either a 7-bit device or a 10-bit device
- Enable mode to send Start Byte or not
- select either a single slave transaction or two slave transaction
- Enable mode to handle devices that do not generate ACK.

Offset: 0x300 | Read/Write: R/W | Reset: 0x00020800 (0bxxxxxxxxxxxxxxx100000100000000000)

Bit	Reset	Description
17	ENABLE	MULTI_MASTER_MODE:used to select single or multi master mode 0=single master; 1=multi_master in single_master mode, no Arbitration checks would happen 0 = DISABLE 1 = ENABLE
15	0x0	MSTR_CLR_BUS_ON_TIMEOUT: When this bit is set, the I2C master will force the clock low for an extended period of time(>TIMEOUT) to force all SMB slaves to release the bus 0 = Do not clear the bus on TLow:SEXT/TIMEOUT timeout 1 = clear the bus on TLow:SEXT/TIMEOUT timeout
14:12	0x0	DEBOUNCE_CNT: Debounce period for sda and scl lines 0 = No debounce, 1 = 2T, 2 = 4T, 3 = 6T, etc., where T is the period of the fix PLL clk source coming to I2C. Maximum debounce period programmable is 14T.A debounce period of >50ns is desirable
11	0x1	NEW_MASTER_FSM: Maintained for compatibility purposes. 0 = DISABLE 1 = ENABLE
10	0x0	PACKET_MODE_EN: Write 1 to initiate transfer in packet mode. 0 = NOP 1 = GO
9	0x0	SEND: Writing a 1 causes the master to initiate the transaction in normal mode. Values of other bits are not affected when this bit is 1,Cleared by hardware. Other bits of the register are masked for writes when this bit is programmed to one.hence,firmware should first configure all other registers and bits [8:0] of I2C_CNFG register before the bit I2C_CNFG[9] is programmed to zero. 0 = NOP 1 = GO
8	0x0	NOACK: Enable mode to handle devices that do not generate ACK. 1 - Do not look for an ack at the end of the Enable 0 = DISABLE 1 = ENABLE
7	0x0	CMD2: Read/Write Command for Slave 2: 1 - Read Transaction; 0 - write Transaction. For a 7-bit slave address,this bit must match with the LSB of address byte for slave 2. Valid only when bit 4 of this register is set 0 = DISABLE 1 = ENABLE
6	0x0	CMD1: Read/Write Command for Slave 1: 1 - Read Transaction; 0 - write Transaction. Command for Slave 1: For a 7-bit slave address this bit must match with the LSB of address byte for slave1. 0 = DISABLE 1 = ENABLE
5	0x0	START: 1 = Yes, a Start byte needs to be sent. 0 = DISABLE 1 = ENABLE
4	0x0	SLV2: 1 - Enables a two slave transaction ; 0 = No command for Slave 2 present. 0 = DISABLE 1 = ENABLE
3:1	0x0	LENGTH: The number of bytes to be transmitted per transaction 000= 1 byte ... 111 = 8 bytes. In a two slave transaction number of bytes should be programmed less than 011.
0	0x0	A_MOD: Address mode defines whether a 7-bit or a 10-bit slave address is programmed. 1 = 10-bit device address, 0 = 7-bit device address 0 = SEVEN_BIT_DEVICE_ADDRESS 1 = TEN_BIT_DEVICE_ADDRESS

31.8.16 VII2C_I2C_STREAM_DIRECT_I2C_CMD_ADDR0_0

I2C Slave-1 Address

I2C_CMD_ADDR0 is programmed the 7 Bit or 10 Bit address of slave 1 with which the transaction is intended;

Offset: 0x304 | Read/Write: R/W | Reset: 0x00000000 (0bxxxxxxxxxxxxxxxxxxxxxxx0000000000)

Bit	Reset	Description
9:0	0x0	ADDR0: In case of 7-Bit mode address is written in the I2C_CMD_ADDR0[7:1] and I2C_CMD_ADDR0[0] indicates the read/write transaction.I2C_CMD_ADDR0[0] bit must match with the I2C_CNFG[6]. In case of 10-Bit mode address is written in I2C_CMD_ADDR0[9:0] and I2C_CNFG[6] indicates the read/write transaction.

31.8.17 VII2C_I2C_STREAM_DIRECT_I2C_CMD_ADDR1_0

I2C Slave-2 Address

I2C_CMD_ADDR1 is programmed the 7 Bit or 10 Bit address of slave 2 with which the transaction is intended;

Offset: 0x308 | Read/Write: R/W | Reset: 0x00000000 (0bxxxxxxxxxxxxxxxxxxxxxxx0000000000)

Bit	Reset	Description
9:0	0x0	ADDR1: In case of 7-Bit mode address is written in the I2C_CMD_ADDR0[7:1] and I2C_CMD_ADDR0[0] indicates the read/write transaction.I2C_CMD_ADDR0[0] bit must match with the I2C_CNFG[7]. In case of 10-Bit mode address is written in I2C_CMD_ADDR0[9:0] and I2C_CNFG[7] indicates the read/write transaction.

31.8.18 VII2C_I2C_STREAM_DIRECT_I2C_CMD_DATA1_0

IC Controller Data 1: Transmit/Receive

The four Least Significant Bytes of Data to be Transmitted is loaded into the register when I2c Master is in Write Mode; the four Least Significant Bytes of Data are Read through this register when I2c Master is in Read mode.

Offset: 0x30c | Read/Write: R/W | Reset: 0x00000000 (0b00000000000000000000000000000000)

Note: *Program the field PACKET_MODE_EN of I2C_CNFG register while working in packet mode.*

The set of registers below describe the interface for packet mode only. These registers describe the interface for normal mode. When the packet mode interface changes, normal mode registers and the operation are not affected. The transition from normal mode to packet mode is suggested because packet mode allows

1. There is no restriction on the number of bytes before and the after the repeated start
2. The number of bytes that can be transferred with a single cmd is not limited to 8.
   Though a packet can contain 4k bytes,because any number of packets can be pushed into the FIFO,there is no limit on the number of bytes that can be transferred.
3. The transactions to different slaves can be chained together with repeat start and there is no limit on the number of slaves it can address.

31.8.31 VII2C_I2C_STREAM_DIRECT_I2C_TX_PACKET_FIFO_0

A packet contains header and payload. The header size is variable and could vary from 2 to 5 words. For I2C, it is 3 words. The first two words of the header contain generic information. The third word contains I2C transaction specific information. Payload contains actual data to be written to the slave. In case of read operation, Payload is nil,hence the packet contains header only .

Offset: 0x350 | Read/Write: R/W | Reset: 0x00000000 (0b00000000000000000000000000000000)

31.8.37 VII2C_I2C_STREAM_DIRECT_INTERRUPT_STATUS_REGISTER_0

This register indicates the status bit for which the interrupt is set. If set,Write 1 to clear it However TFIFO_DATA_REQ,RFIFO_DATA_REQ fields depend on the FIFO trigger levels and cannot be cleared.

Slv_rd2wr indicates there is a switch from rd to wr by repeat start and the current rd transaction needs to be closed and start with wr transaction.Similarly slv_wr2rd indicates switch from wr to rd.

31.8.52 VII2C_I2C_STREAM_ERECOVERY_I2C_CNFG_0

IC Controller Configuration Register (Master)

The I2C_CNFG register is used to configure:

- the number of bytes to be transmitted or received
- the slave device type, either a 7-bit device or a 10-bit device
- Enable mode to send Start Byte or not
- select either a single slave transaction or two slave transaction
- Enable mode to handle devices that do not generate ACK.

Offset: 0x400 | Read/Write: R/W | Reset: 0x00020800 (0bxxxxxxxxxxxxxxx100000100000000000)

Bit	Reset	Description
17	ENABLE	MULTI_MASTER_MODE:used to select single or multi master mode 0=single master; 1=multi_master in single_master mode, no Arbitration checks would happen 0 = DISABLE 1 = ENABLE
15	0x0	MSTR_CLR_BUS_ON_TIMEOUT: When this bit is set, the I2C master will force the clock low for an extended period of time(>TIMEOUT) to force all SMB slaves to release the bus 0 = Do not clear the bus on TLow:SEXT/TIMEOUT timeout 1 = clear the bus on TLow:SEXT/TIMEOUT timeout

Bit	Reset	Description
14:12	0x0	DEBOUNCE_CNT: Debounce period for sda and scl lines 0 = No debounce, 1 = 2T, 2 = 4T, 3 = 6T, etc., where T is the period of the fix PLL clk source coming to I2C. Maximum debounce period programmable is 14T.A debounce period of >50ns is desirable
11	0x1	NEW_MASTER_FSM: Maintained for compatibility purposes. 0 = DISABLE 1 = ENABLE
10	0x0	PACKET_MODE_EN: Write 1 to initiate transfer in packet mode. 0 = NOP 1 = GO
9	0x0	SEND: Writing a 1 causes the master to initiate the transaction in normal mode. Values of other bits are not affected when this bit is 1,Cleared by hardware. Other bits of the register are masked for writes when this bit is programmed to one.hence,firmware should first configure all other registers and bits [8:0] of I2C_CNFG register before the bit I2C_CNFG[9] is programmed to zero. 0 = NOP 1 = GO
8	0x0	NOACK: Enable mode to handle devices that do not generate ACK. 1 - do not look for an ack at the end of the Enable 0 = DISABLE 1 = ENABLE
7	0x0	CMD2: Read/Write Command for Slave 2: 1 - Read Transaction; 0 - write Transaction. For a 7-bit slave address,this bit must match with the LSB of address byte for slave 2. Valid only when bit 4 of this register is set 0 = DISABLE 1 = ENABLE
6	0x0	CMD1: Read/Write Command for Slave 1: 1 - Read Transaction; 0 - write Transaction. Command for Slave 1: For a 7-bit slave address this bit must match with the LSB of address byte for slave1. 0 = DISABLE 1 = ENABLE
5	0x0	START: 1 = Yes, a Start byte needs to be sent. 0 = DISABLE 1 = ENABLE
4	0x0	SLV2: 1 - Enables a two slave transaction ; 0 = No command for Slave 2 present. 0 = DISABLE 1 = ENABLE
3:1	0x0	LENGTH: The Number of bytes to be transmitted per transaction 000= 1 byte ... 111 = 8 bytes. In a two slave transaction number of bytes should be programmed less than 011.
0	0x0	A_MOD: Address mode defines whether a 7-bit or a 10-bit slave address is programmed. 1 = 10-bit device address, 0 = 7-bit device address 0 = SEVEN_BIT_DEVICE_ADDRESS 1 = TEN_BIT_DEVICE_ADDRESS

31.8.53 VII2C_I2C_STREAM_ERECOVERY_I2C_CMD_ADDR0_0

I2C Slave-1 Address

I2C_CMD_ADDR0 is programmed the 7 Bit or 10 Bit address of slave 1 with which the transaction is intended;

Offset: 0x404 | Read/Write: R/W | Reset: 0x00000000 (0bxxxxxxxxxxxxxxxxxxxxxxxx0000000000)

Bit	Reset	Description
9:0	0x0	ADDR0: In case of 7-Bit mode address is written in the I2C_CMD_ADDR0[7:1] and I2C_CMD_ADDR0[0] indicates the read/write transaction.I2C_CMD_ADDR0[0] bit must match with the I2C_CNFG[6]. In case of 10-Bit mode address is written in I2C_CMD_ADDR0[9:0] and I2C_CNFG[6] indicates the read/write transaction.

31.8.54 VII2C_I2C_STREAM_ERECOVERY_I2C_CMD_ADDR1_0

I2C Slave-2 Address

I2C_CMD_ADDR1 is programmed the 7 Bit or 10 Bit address of slave 2 with which the transaction is intended;

Offset: 0x408 | Read/Write: R/W | Reset: 0x00000000 (0bxxxxxxxxxxxxxxxxxxxxxxxx0000000000)

Bit	Reset	Description
9:0	0x0	ADDR1: In case of 7-Bit mode address is written in the I2C_CMD_ADDR0[7:1] and I2C_CMD_ADDR0[0] indicates the read/write transaction.I2C_CMD_ADDR0[0] bit must match with the I2C_CNFG[7]. In case of 10-Bit mode address is written in I2C_CMD_ADDR0[9:0] and I2C_CNFG[7] indicates the read/write transaction.

31.8.55 VII2C_I2C_STREAM_ERECOVERY_I2C_CMD_DATA1_0

IC Controller Data 1: Transmit/Receive

The four Least Significant Bytes of Data to be Transmitted is loaded into the register when I2c Master is in Write Mode;

The four Least Significant Bytes of Data are Read through this register when I2c Master is in Read mode.

Offset: 0x40c | Read/Write: R/W | Reset: 0x00000000 (0b00000000000000000000000000000000)

Bit	Reset	Description
31:24	0x0	DATA4: Fourth data byte to be sent/received

Note: *Program the field PACKET_MODE_EN of I2C_CNFG register while working in packet mode.*

The set of registers below describe the interface for packet mode only. These registers describe the interface for normal mode. When the packet mode interface changes, normal mode registers and the operation are not affected. The transition from normal mode to packet mode is suggested because packet mode allows

1. There is no restriction on the number of bytes before and the after the repeated start
2. The number of bytes that can be transferred with a single cmd is not limited to 8.
   Though a packet can contain 4kbytes because any number of packets can be pushed into the FIFO, there is no limit on the number of bytes that can be transferred.
3. The transactions to different slaves can be chained together with repeat start and there is no limit on the number of slaves it can address.

31.8.68 VII2C_I2C_STREAM_ERECOVERY_I2C_TX_PACKET_FIFO_0

A packet contains header and payload. The header size is variable and could vary from 2 to 5 words. For I2C, it is 3 words. The first two words of the header contain generic information. The third word contains I2C transaction specific information.payload contains actual data to be written to the slave. In case of read operation, payload is nil,hence the packet contains header only .

Offset: 0x450 | Read/Write: R/W | Reset: 0x00000000 (0b00000000000000000000000000000000)

31.8.74 VII2C_I2C_STREAM_ERECOVERY_INTERRUPT_STATUS_REGISTER_0

This register indicates the status bit for which the interrupt is set.If set, write 1 to clear it; however, TFIFO_DATA_REQ,RFIFO_DATA_REQ fields depend on the FIFO trigger levels and cannot be cleared.

Slv_rd2wr indicates there is a switch from rd to wr by repeat start and the current rd transaction needs to be closed and start with wr transaction. Similarly slv_wr2rd indicates switch from wr to rd.

Bit	Reset	Description
25	X	ACK_WITHHELD:Indicates that ack is withheld for last byte and slave is waiting for the host to explicitly command slave to ACK the last byte 0 = Bus is released 1 = ACK is withheld
24	X	TRANSFER_COMPLETE:ALL the packets have been transferred successfully
23:16	X	TRANSFER_PKT_ID: The current packet ID for which the transaction is happening on the bus
15:4	X	TRANSFER_BYTENUM:The number of bytes transferred in the current packet

31.8.81 VII2C_I2C_STREAM_ERECOVERY_I2C_BUS_CLEAR_CONFIG_0

Offset: 0x484 | Read/Write: R/W | Reset: 0x00090004 (0bxxxxxxxx00001001xxxxxxxxxxxx100)

Bit	Reset	Description
23:16	0x9	BC_SCLK_THRESHOLD:send the clock pulses until this threshold is met
2	0x1	BC_STOP_COND: 0 = NO_STOP : do not send stop condition at the end of bus clear operation 1 = STOP : send stop condition at the end of the bus clear operation
1	0x0	BC_TERMINATE: 0 = THRESHOLD : irrespective of SDA release status during BC, terminate the BC only after threshold is reached. 1 = IMMEDIATE : terminate the bus clear operation immediately when SDA is released or threshold count is reached whichever is earlier
0	0x0	BC_ENABLE: starts bus clear operation, HW auto-clears this bit upon bus clear transaction completion

31.8.82 VII2C_I2C_STREAM_ERECOVERY_I2C_BUS_CLEAR_STATUS_0

Offset: 0x488 | Read/Write: RO | Reset: 0x0000000X (0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx)

Bit	Reset	Description
0	X	BC_STATUS: 0 = NOT_CLEARED : indicates SDA is not released by slave, its status is still low. 1 = CLEARED : SDA is released

31.8.83 VII2C_I2C_STREAM_ERECOVERY_I2C_CONFIG_LOAD_0

Offset: 0x48c | Read/Write: R/W | Reset: 0x00000000 (0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxx000)

Bit	Reset	Description
2	0x0	TIMEOUT_CONFIG_LOAD: This bit loads the timeout configuration from pclk domain to the receive (i2c_slow_clk)domain. Software has to set this bit finally after doing the required registers configuration for the logic to take the updates. Once the internal update is done, hardware auto-clears this bit.Since the hardware would be busy with internal updating, software should not write again until this bit is cleared by hardware. 0 = DISABLE 1 = ENABLE
1	0x0	SLV_CONFIG_LOAD: This bit loads the slave configuration from pclk domain to the receive (i2c_clk) domain. Software has to set this bit finally after doing the required registers configuration for the slave controller to take updates. Once the internal update is done, hardware auto-clears this bit. Since the hardware would be busy with internal updating, software should not write again until this bit is cleared by hardware. 0 = DISABLE 1 = ENABLE
0	0x0	MSTR_CONFIG_LOAD: This bit loads the master configuration from pclk domain to the receive (i2c_clk) domain. Software has to set this bit finally after doing the required registers configuration like I2C_I2C_CNFG_0 bit fields etc. Once the internal update is done, hardware auto-clears this bit. Since the hardware would be busy with internal updating, software should not write again until this bit is cleared by hardware. 0 = DISABLE 1 = ENABLE

31.8.84 VII2C_I2C_STREAM_ERECOVERY_I2C_CLKEN_OVERRIDE_0

Offset: 0x490 | Read/Write: R/W | Reset: 0x00000000 (0bxxxxxxxxxxxxxxxxxxxxxxxxxxxx000x0)

Bit	Reset	Description
4	CLK_GATED	I2C_BUS_CLEAR_CLKEN_OVR: override for 2nd-level clock enable for I2C bus clear logic 0 = CLK_GATED 1 = CLK_ALWAYS_ON
3	CLK_GATED	I2C_SLV_HIF_CLKEN_OVR: override for 2nd-level clock enable for I2C slave to host interface logic 0 = CLK_GATED 1 = CLK_ALWAYS_ON
2	CLK_GATED	I2C_SLV_CORE_CLKEN_OVR: override for 2nd-level clock enable for I2C slave core logic 0 = CLK_GATED 1 = CLK_ALWAYS_ON
0	CLK_GATED	I2C_MST_CORE_CLKEN_OVR: override for 2nd-level clock enable for I2C master core logic 0 = CLK_GATED 1 = CLK_ALWAYS_ON

31.8.85 VII2C_I2C_STREAM_ERECOVERY_I2C_INTERFACE_TIMING_0_0

register for Standard/Fast/Fm+ mode timing

Offset: 0x494 | Read/Write: R/W | Reset: 0x00000204 (0bxxxxxxxxxxxxxxxxxx000010xx000100)

Bit	Reset	Description
13:8	0x2	THIGH:High period of the SCL clock
5:0	0x4	TLOW:Low period of the SCL clock

31.8.86 VII2C_I2C_STREAM_ERECOVERY_I2C_INTERFACE_TIMING_1_0

register for Standard/Fast/Fm+ mode timing

Offset: 0x498 | Read/Write: R/W | Reset: 0x04070404 (0bxx000100xx000111xx000100xx000100)

Bit	Reset	Description
29:24	0x4	TBUF:Bus free time between STOP and START conditions
21:16	0x7	TSU_STO:Setup time for STOP condition
13:8	0x4	THD_STA: Hold time for a (repeated) START condition
5:0	0x4	TSU_STA:Setup time for a Repeated START condition

31.8.87 VII2C_I2C_STREAM_ERECOVERY_I2C_HS_INTERFACE_TIMING_0_0

I2C interface timing register for HS mode transfers. Since HS master code is sent in Std/Fm/FMm+ modes, standard/fast/fm+ timing registers need to be programmed too along with HS timing registers

Offset: 0x49c | Read/Write: R/W | Reset: 0x00000308 (0bxxxxxxxxxxxxxxxxxxx000011xx001000)

Bit	Reset	Description
13:8	0x3	HS_THIGH:High period of the SCL clock
5:0	0x8	HS_TLOW:Low period of the SCL clock

31.8.88 VII2C_I2C_STREAM_ERECOVERY_I2C_HS_INTERFACE_TIMING_1_0

I2C interface timing register for HS mode transfers. Since HS master code is sent in Std/Fm/FMm+ modes, standard/fast/fm+ timing registers need to be programmed too along with HS timing registers

Offset: 0x4a0 | Read/Write: R/W | Reset: 0x000b0b0b (0bxxxxxxxxxx001011xx001011xx001011)

Bit	Reset	Description
21:16	0xb	HS_TSU_STO:Setup time for STOP condition
13:8	0xb	HS_THD_STA: Hold time for a (repeated) START condition
5:0	0xb	HS_TSU_STA:Setup time for a Repeated START condition

31.9 MIPI-CSI Registers

Refer to Chapter 29: MIPI-CSI (Camera Serial Interface) in this document for descriptions of these registers.

CHAPTER 32: SD/MMC CONTROLLER

The Tegra® X1 SD/MMC Controller can interface with SD Cards or eSD, SDIO or eMMC devices. It supports both non-removable devices and plug-in cards. It has a direct MCCIF2 interface and can initiate data transfers between memory and the external card. It has an APB Slave interface to access its configuration registers. To access the iRAM for Micro Boot, the SD/MMC controller relies on the AHB Redirection Controller (ARC) in the Memory Controller.

The SD/MMC controller supports two different bus protocols: SD/SDIO bus protocol and eMMC bus protocol for eMMC devices.

The Tegra X1 device supports 4 SDMMC controllers with 4 pin-muxing options. Each SD/MMC controller is required to talk to one type of device. Each SDMMC controller is capable of all protocols. The combination of SD/MMC controller together with the type of pads it connects to defines the use case for that SD/MMC controller. The use cases for SD/MMC controllers are:

- SDMMC1/SDMMC3: WiFi on SDIO, removable mass storage memory, or removable SD card with 3.3V/1.8V I/O support (Note: This is for primary use case. In general, one can use any slot for SDIO as all slots support interrupt on DAT1 line.)
- SDMMC2: eMMC5.0 device or SDIO with 1.8V I/O support
- SDMMC4: eMMC5.0 device (embedded flash memory) for Booting and Non-volatile storage

32.1 Supported Specifications and Standards

The SD/MMC controller supports the specifications from the SD Card Association and JEDEC (MMC) at the versions listed in the following table.

Table 196: Protocol Versions

Protocol	Version
SD	4.0 (UHS-I only)
SDIO	4.0 (UHS-I only)
eSD	2.1
eMMC	5.0
SDHOST	4.0 (UHS-I only)

The specifications are as follows:

- “SD Specifications, Part E1, SDIO Specification”, Technical Committee SD Card Association, Version 4.00, February 20, 2012
- “SD Specifications, Part 1, Physical Layer Specification”, Technical Committee SD Card Association, Version 4.00, May 30, 2011.
- “SD Specification, Part 1, eSD (Embedded SD) Addendum”, Technical Committee SD Card Association, Version 2.10, November 25, 2008.
- “SD Specifications, Part A2, SD Host Controller Standard Specification”, Technical Committee SD Card Association, Version 4.00, February 20, 2012.
- “JEDEC Standard, Embedded Multi-Media Card (eMMC) Electrical Standard (5.0)”, JEDEC Solid State Technology Association, September 2013.
- “JEDEC standard, Embedded Multi-Media Card (eMMC) Electrical Standard (5.1)”, JEDEC Solid State Technology Association, DRAFT version partly. It is possible to deploy the software version CQE operation, Enhanced Strobe Scheme to avoid tuning mechanism.

32.2 Supported Speeds

These tables show the maximum data rates available over the physical interface. The speeds achievable in actual use will be less than these rates, depending on the performance of the device itself, protocol limitations, and the software driver.

For SD 3.0 data transfer modes, these are the maximum data transfer speeds:

Table 197: Maximum Data Transfer Speeds (SD)

Speed Mode	Signal Voltage	I/O Frequency (MHz)	Bus Width	Maximum Throughput (MBytes/s)	UHS Protocol
Default Speed	3.3	25	1,4	12.5	UHS-I, 50 (SD3.0) UHS-I, 104 (SD3.0)
HIGH SPEED	3.3	50	1,4	25	UHS-I, 50 (SD3.0) UHS-I, 104 (SD3.0)
SDR12	1.8	25	1,4	12.5	UHS-I, 50 (SD3.0) UHS-I, 104 (SD3.0)
SDR25	1.8	50	1,4	25	UHS-I, 50 (SD3.0) UHS-I, 104 (SD3.0)
SDR50	1.8	100	1,4	50	UHS-I, 50 (SD3.0) UHS-I, 104 (SD3.0)
SDR104 UHS-I	1.8	208	1,4	104	UHS-I, 104 (SD3.0)

For eSD 2.1 data transfer modes, these are the maximum data transfer speeds:

Table 198: Maximum Data Transfer Speeds (eSD 2.1)

Speed Mode	Signal Voltage	I/O Frequency (MHz)	Bus Width	Maximum Throughput (MBytes/s)	eSD Protocol
Default Speed	3.3	25	1,4,8	12.5	eSD 2.1
High Speed	3.3	50	1,4,8	25	eSD 2.1

For SDIO data transfer modes, these are the maximum data transfer speeds:

Table 199: Maximum Data Transfer Speeds (SDIO)

Speed Mode	I/O Frequency (MHz)	Bus Width	Maximum Throughput (MBytes/s)	Protocol Version/UHS Version
Default Speed	25	1,4	12.5	SDIO2.0 /UHS-I, 50/ UHS-I, 104
High Speed	50	1,4	25	SDIO2.0 /UHS-I, 50/ UHS-I, 104
SDR12	25	1,4	12.5	UHS-I, 50 (SDIO3.0) UHS-I, 104 (SDIO3.0)
SDR25	50	1,4	25	UHS-I, 50 (SDIO3.0) UHS-I, 104 (SDIO3.0)
SDR50	100	1,4	50	UHS-I, 50 (SDIO3.0) UHS-I, 104 (SDIO3.0)
SDR104 UHS-I	208	1,4	104	UHS-I, 104 (SDIO3.0)

For eMMC data transfer modes, these are the maximum data transfer speeds:

Table 200: Maximum Data Transfer Speeds (eMMC)

Speed Mode	I/O Frequency (MHz)	Bus Width	Maximum Throughput (MBytes/s)	MMC Revision
LEGACY SPEED	26	1,4,8	26	MMC 4.3
HIGH SPEED SDR	52	1,4,8	52	MMC 4.3
HIGH SPEED DDR	52	4,8	104	MMC 4.4
HS200 (SDR)	200	4,8	200	MMC 4.51
HS400 (DDR)	200	8	400	eMMC5.0

Table 200: Maximum Data Transfer Speeds (eMMC)

Speed Mode	I/O Frequency (MHz)	Bus Width	Maximum Throughput (MBytes/s)	MMC Revision
HS533 (DDR)	266	8	533	Overclocked HS400 mode (Nvidia proprietary)

32.3 Operation

32.3.1 Hardware/Software Partitioning

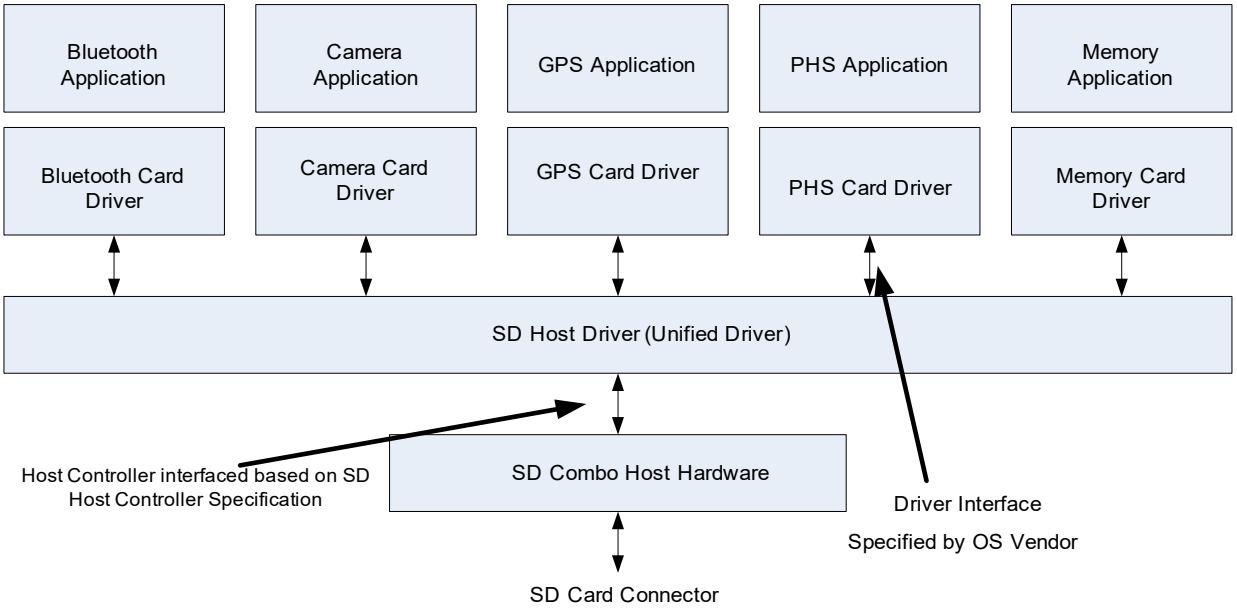
Hardware

The role of the hardware controller is to send out the programmed command, store the response, and make it visible to software. It updates the status registers and generates interrupts when attention is required. Software may also configure it for DMA operation.

Software

The software driver determines which type of card is inserted in the slot by sending the initialization commands and observing the responses received from the card. After identifying the card that is inserted, it should only program the corresponding set of commands that are applicable. It can enable interrupts for which notification is desired.

Figure 147: Host Hardware and Driver Architecture



32.4 Caveats and Assumptions

- A single SD/MMC controller handles only one device at a time.
- The software should configure SDMMC_VENDOR_CLOCK_CNTRL_0_SDMMC_CLK to DISABLE before turning off the SD/MMC clock (and configure back to ENABLE after turning on the SD/MMC clock). This is required in order to support asynchronous card interrupts when no clock is supplied to the card.
  - SDMMC_VENDOR_CLOCK_CNTRL_0_SDMMC_CLK can be left as the Reset Value (ENABLE) if Asynchronous Interrupt is not used.
- PMC can be configured to wake the Tegra X1 device from the LP0 power state based on either:
  - Card Detection pin.
  - Asynchronous interrupt on the DAT1 line.
- Write protect and card detect logic is implemented in Tegra only for SDMMC1 and SDMMC3.

- Off-card ECC, described in the MMC specification, is not supported.

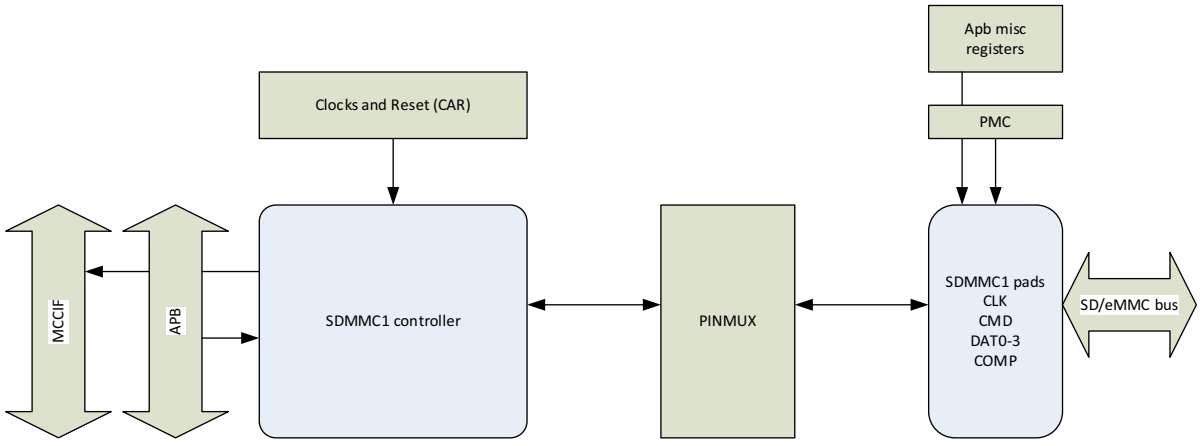
32.5 SD/MMC Interfaces

Table 201: SD Interfaces on Tegra X1

Controller	Number of Pinmuxings		Data Bus width	Pads Used	I/O Voltage (V)	Max. I/O Clock supported (MHz)	Speed modes Supported			Typical Use Case	Max. BW (MBps)
SDMMC1	1	SDMMC1	4	BDSDMEM_B	3.3/1.8	208	DS, HS, SDR12, SDR25, SDR50 and SDR104	DS, HS, SDR12, SDR25, SDR50 and SDR104	LEGACY SPEED, HIGH SPEED SDR, HIGH SPEED DDR and HS200 in 4-bit mode	SDIO for WiFi or removable SD card	104
SDMMC2	1	SDMMC2	8	BDEMMC _IOBRICK_BFC	1.8	208 Or 333	Removable SD card not supported	DS, HS, SDR12, SDR25, SDR50 and SDR104	LEGACY SPEED, HIGH SPEED SDR, HIGH SPEED DDR, HS200, HS400 and HS533	SDIO for secondary Modem Or eMMC5.0 device	667
SDMMC3	1	SDMMC3	4	BDSDMEM_B	3.3/1.8	208	DS, HS, SDR12, SDR25, SDR50 and SDR104	DS, HS, SDR12, SDR25, SDR50 and SDR104	LEGACY SPEED, HIGH SPEED SDR, HIGH SPEED DDR and HS200 in 4-bit mode	Removable SD card or SDIO device	104
SDMMC4	1	SDMMC4	8	BDEMMC _IOBRICK_BFC	1.8	333	Removable SD card not supported	DS, HS, SDR12, SDR25, SDR50 and SDR104	LEGACY SPEED, HIGH SPEED SDR, HIGH SPEED DDR, HS200, HS400 and HS533	Bootable eMMC	667

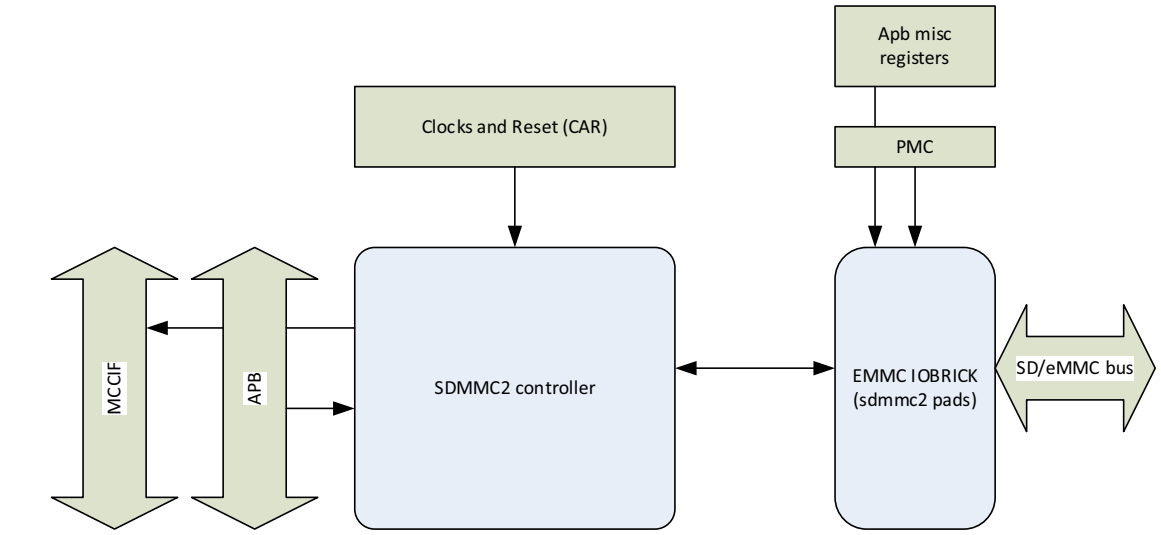
The diagrams below show how the SDMMC controller is hooked up in the SoC.

Figure 148: SDMMC 1 Interface



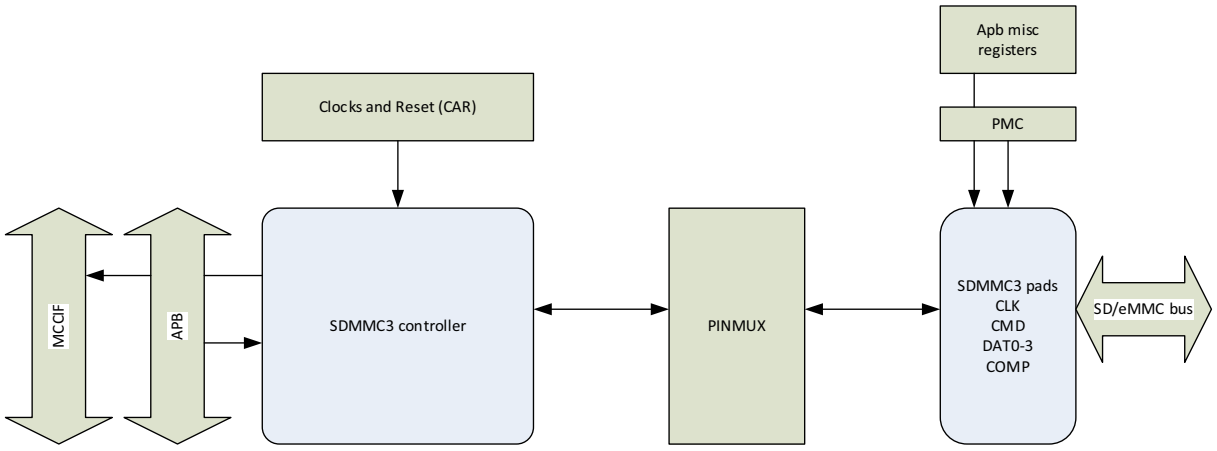
*COMP is compensation pad used for pad drive strength calibration.

Figure 149: SDMMC 2 Interface



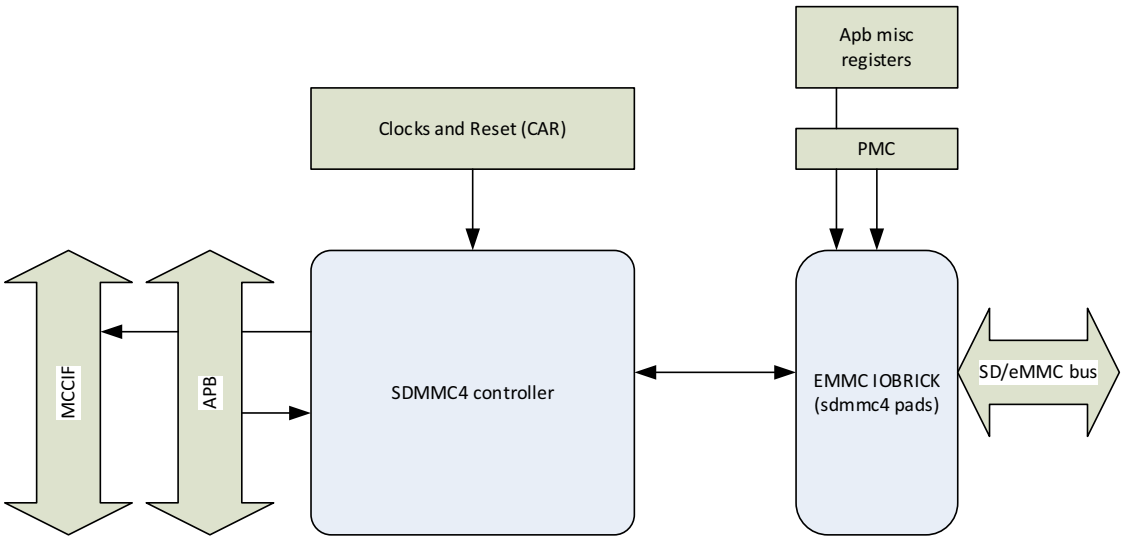
*COMP is compensation pad used for pad drive strength calibration.

Figure 150: SDMMC 3 Interface



*COMP is compensation pad used for pad drive strength calibration.

Figure 151: SDMMC 4 Interface



*COMP is compensation pad used for pad drive strength calibration.

32.6 Pinmux Options

The table below provides an overview of the Pinmux configuration for SDMMC controllers. Software should use the Pinmux spreadsheet provided along with the TRM to get full details.

Table 202: SD/MMC Pinmux Options

Controller	Config	Signal	Ball Name	PINGROUP
SDMMC1	sdmmc1_cmd_cfg	SDMMC1_CMD	SDMMC1_CMD	sdmmc1_cmd_pm
	sdmmc1_clk_cfg	SDMMC1_CLK	SDMMC1_CLK	sdmmc1_clk_pm
	sdmmc1_dat0_cfg	SDMMC1_DAT0	SDMMC1_DAT0	sdmmc1_dat0_pm
	sdmmc1_dat1_cfg	SDMMC1_DAT1	SDMMC1_DAT1	sdmmc1_dat1_pm
	sdmmc1_dat2_cfg	SDMMC1_DAT2	SDMMC1_DAT2	sdmmc1_dat2_pm
	sdmmc1_dat3_cfg	SDMMC1_DAT3	SDMMC1_DAT3	sdmmc1_dat3_pm
	gpio_pz4_cfg	SDMMC1_WP	GPIO_PZ4	gpio_pz4_pm
	gpio_pz1_cfg	SDMMC1_CD	GPIO_PZ1	gpio_pz1_pm
SDMMC2	emmccfg2	SDMMC2_CMD	SDMMC2_CMD	IOBRICK
	emmccfg2	SDMMC2_CLK	SDMMC2_CLK	IOBRICK
	emmccfg2	SDMMC2_CLKB	SDMMC2_CLKB	IOBRICK
	emmccfg2	SDMMC2_DAT0	SDMMC2_DAT0	IOBRICK
	emmccfg2	SDMMC2_DAT1	SDMMC2_DAT1	IOBRICK
	emmccfg2	SDMMC2_DAT2	SDMMC2_DAT2	IOBRICK
	emmccfg2	SDMMC2_DAT3	SDMMC2_DAT3	IOBRICK
	emmccfg2	SDMMC2_DAT4	SDMMC2_DAT4	IOBRICK

	emmccfg4	SDMMC4_DQSB	SDMMC4_DQSB	IOBRICK

32.6.1 SD CD# and SDWP# Pins

The removable SD cards' Card Detect and Write protect pins apply to SDMMC1 and SDMMC3 only.

32.7 Programming Guidelines

32.7.1 Introduction

This section assumes a SD Host driver complying with the SD Specifications' Part A2, SD Host Control Standard Specification 4.0, is already available. The following subsections detail the necessary changes required for fully-featured SD (and eMMC boot mode) operation.

32.7.2 Initialization

As a part of initialization, software would be enabling pads, pinmux, SDMMC controller clocks by programming PLLs and CLK dividers, programming Host controller vendor registers, device initialization and tuning. Once initialization is done, SDMMC controller will be ready for executing data transfers.

Each SDMMC controller is functionally the same but differ in data bus supported and speed modes supported. And also each controller has separate register set for programming CLK sources, pad controls and PINMUX settings. Full details of each and every step involved in this initialization process per controller is given in the following sections.

32.7.2.1 SDMMC1 Initialization Sequence

This section provides SDMMC1 controller initialization sequence which should be followed by software driver before doing any CMD/DAT transfers to external SD/SDIO device.

Power ON

1. Make sure SDMMC1 controller is powered up by programming external PMU/PMIC (platform specific) to set VDD_CORE voltage.
2. Refer to the PMU/PMIC datasheet and power up sequence section in this TRM for programming details.

Program Clocks and Reset

Refer to Chapter 5: Clock and Reset Controller for full details of PLL programming used for SDMMC1 clocking.

3. Set SDMMC1 Reset:
   a. Keep SDMMC1 in reset by writing

      CLK_RST_CONTROLLER_RST_DEV_L_SET_0_ SET_SDMMC1_RST with ENABLE (0x1).
4. Program CLK divider and source
   a. Program SDMMC1 host clock divider

      (CLK_RST_CONTROLLER_CLK_SOURCE_SDMMC1_0_ SDMMC1_CLK_DIVISOR) and PLL source (CLK_RST_CONTROLLER_CLK_SOURCE_SDMMC1_0_ SDMMC1_CLK_SRC) as per below guidelines.
   b. PLLP and PLLC4 are the main CLK sources for SDMMC1 controller.
      - PLLP: VCO running at fixed 408 MHz
      - PLLC4: VCO running at fixed ~1GHz (998.4MHz +/-18ppm quality) - Dedicated PLL for eMMC5.0 HS400 and HS667 clocking. This can also be used for clocking other lower speed modes for SD/SDIO.
      - For SD/SDIO interfaces, it is preferable to source from PLLP for power saving.
      - PLLC4 clock jitter and DCD (Duty Cycle Distortion) are optimized for HS400/533 usage. PLLP can't be used for HS400/533. In other modes, software can use PLLP always.
   c. Software driver should program SDCLK Frequency Select in the Clock Control Register to get the desired SD/SDIO device clock which is derived from SDMMC host clock. Follow SD clock supply sequence mentioned in SD Host specification 4.0.

d. Maximum operating host clock frequency for SDMMC1 controller is 208 MHz.

e. Software may choose to run SDMMC1 controller host clock at a lower speed also.

f. The initializing frequency up to 400 KHz is provided to SD/SDIO card using SDCLK Frequency Select (current maximum divisor 2046 as per SD host specification). This is completely software dependent.

g. In HIGH SPEED DDR/DDR50 modes, SDMMC1 host clock should be run at 2X frequency than device clock. This requires SDMMC internal clock divider should be set to '2' [Standard Host Register SDMMCA_SW_RESET_TIMEOUT_CTRL_CLOCK_CONTROL_0_ SDCLK_FREQUENCYSELECT value would be '1']. This is mandatory to make DDR50/52 mode work.

h. Note there is no SDCLK Frequency Select restriction in SDR modes (DS, HS, SDR12, SDR25, SDR50, SDR104 and HS200).

The following table summarizes the CLK divider options for the PLLP clock source.

Table 203: PLL CLK Divider Options for PLLP

Speed Mode	Target I/O Max Frequency (MHz)	Clock Source Name[1]	Clock Source Frequency (MHz)	CAR Divider[2]	SDMMC Host Clock Frequency (MHz)	SDMMC Divider[3]	Actual I/O Frequency (MHz)
Identification	400 (kHz)	PLLP_OUT0	408	16.5	24.72727273	62	398.83 (kHz)
Default Speed	25	PLLP_OUT0	408	16.5	24.72727273	1	24.72727273
High Speed	50	PLLP_OUT0	408	8.5	48	1	48
SDR12	25	PLLP_OUT0	408	16.5	24.72727273	1	24.72727273
SDR25	50	PLLP_OUT0	408	8.5	48	1	48
SDR50	100	PLLP_OUT0	408	4.5	90.66666667	1	90.66666667
DDR50	50	PLLP_OUT0	408	5	81.6	2	40.8
SDR104	208	PLLP_OUT0	408	2	204	1	204

1. It is set by SDMMC1_CLK_SRC in CLK_RST_CONTROLLER_CLK_SOURCE_SDMMC1_0.
2. It is set by SDMMC1_CLK_DIVISOR in CLK_RST_CONTROLLER_CLK_SOURCE_SDMMC1_0.
3. It is set by SDCLK Frequency Select in Clock Control Register.

5. Program SDMMC1 timeout clock source and divider

   a. SDMMC1 uses 12MHz TMCLK which is advertised in Host capabilities register -SDMMCA_CAPABILITIES_0_ TIMEOUT_CLOCK_FREQUENCY.

   b. Software should program below registers to provide TMCLK to SDMMC1.

      - CLK_RST_CONTROLLER_CLK_SOURCE_SDMMC_LEGACY_TM_0_ SDMMC_LEGACY_TM_CLK_SRC
      - CLK_RST_CONTROLLER_CLK_SOURCE_SDMMC_LEGACY_TM_0_ SDMMC_LEGACY_TM_CLK_DIVISOR

   c. PLLP_OUT0 is the recommended TMCLK source for SDMMC1.

6. Enable SDMMC1 host clock and TMCLK by setting below registers.

   a. Enable Host clock for SDMMC1 by writing 1 into SET_CLK_ENB_SDMMC1 field of register CLK_RST_CONTROLLER_CLK_ENB_L_SET_0.

   b. Enable TMCLK for SDMMC1 by writing 1 into CLK_ENB_SDMMC_LEGACY_TM_ENABLE field of register CLK_RST_CONTROLLER_CLK_OUT_ENB_Y_0.

7. Wait for at least 100 sdmmc1 host clock cycles time to get reset propagated down the pipe and also to get internal clocks stabilized.

8. Clear SDMMC1 reset by writing CLK_RST_CONTROLLER_RST_DEV_L_CLR_0_ CLR_SDMMC1_RST with ENABLE. Enable takes effect immediately.

Card Detection and Write Protect Status

9. Tegra X1 supports GPIO based card detection mechanism. Refer to Chapter 9: Multi-Purpose I/O Pins and Pin Multiplexing (Pinmuxing) in this TRM for full details about GPIO implementation.
    a. Software should program SDMMC1_CD and SDMMC1_WP pinmux registers as per customer pinmux datasheet.
10. SDMMC1 controller gets SDCD and SDWP status from GPIO pins (SDMMC1_CD and SDMMC1_WP). Software has to program CD/WP source appropriately in below register to get SDMMC1 correct status.
    a. APB_MISC_GP_VGPIO_GPIO_MUX_SEL_0_ SDMMC1_WP_SOURCE = GPIO
    b. APB_MISC_GP_VGPIO_GPIO_MUX_SEL_0_ SDMMC1_CD_SOURCE = GPIO

Power ON SD card or SDIO device

11. If removable card is detected using GPIO, power ON SD card (3.3V to start with). No need to wait for card detection in case of SDIO.
12. To avoid high leakage and pad damage, set

    SDMMCA_SDMEMCOMPPADCTRL_0_ PAD_E_INPUT_OR_E_PWRD to 0x1 before turning ON SD card power.
13. Program PWR_DET for SDMMC1 pads before turning ON SD/SDIO card power:
    a. SDMMC1 pads are capable of supporting both 3.3V and 1.8V I/O. But software needs to notify pads about the operating I/O voltage whether it is either 3.3V or 1.8V. This is needed as SDMMC1 pads don't have PWR_DET cells to detect voltage level automatically. Incorrect programming could lead to pad damage.
    b. Set APBDEV_PMC_PWR_DET_VAL_0_SDMMC1 = 1 before switching I/O voltage to 3.3V
    c. Set APBDEV_PMC_PWR_DET_VAL_0_SDMMC1 = 0 after switching I/O voltage to 1.8V

PINMUX and Pad Control Programming

SDMMC1 pads are pinmuxed. Software has to program PINMUX registers to select SDMMC1 and also to program pad controls.

14. Program CLK pad pinmux and control settings:
    a. Select 33 Ohm driver - PINMUX_AUX_SDMMC1_CLK_0_ DRV_TYPE_ DRIVE_2X. Ensure that the SDMMC1_COMP pad is connected to GND via 66 Ohm resistor on board.
    b. DRV_TYPE_DRIVE2X and 66 Ohm calibration resistor are used to get drive strength codes for 33 ohm driver. This is Tegra specific implementation.
    c. Schmitt trigger selection
    - PINMUX_AUX_SDMMC1_CLK_0_ E_SCHMT_ENABLE for 1.8V I/O - provides better duty cycle - low jitter clock
    - PINMUX_AUX_SDMMC1_CLK_0_ E_SCHMT_DISABLE for 3.3V I/O
    d. Both E_INPUT and E_LPBK of SDMMC1 CLK pad should be enabled to provide loopback CLK for SDMMC1 Receiver. If disabled, reads from SD/eMMC device won't work.
    - APB_MISC_GP_SDMMC1_CLK_LPBK_CONTROL_0_SDMMC1_CLK_PAD_E_LPBK = 1'b1
    - PINMUX_AUX_SDMMC1_CLK_0_E_INPUT = ENABLE
    e. Remove tri-state to enable pad output driver - PINMUX_AUX_SDMMC1_CLK_0_TRISTATE_ PASSTHROUGH
    f. Select SDMMC1 in pinmux - PINMUX_AUX_SDMMC1_CLK_0_PM_SDMMC1
    g. Other pad control settings in PINMUX_AUX_SDMMC1_CLK_0 register should be left as default values. No need to modify.
15. Program CMD pad pinmux and control settings:
    a. Select 33 Ohm driver - PINMUX_AUX_SDMMC1_CMD_0_ DRV_TYPE_ DRIVE_2X
    b. Schmidt trigger selection
    - PINMUX_AUX_SDMMC1_CMD_0_ E_SCHMT_ENABLE for 1.8V I/O - provides better duty cycle - low jitter clock

- PINMUX_AUX_SDMMC1_CMD_0_ E_SCHMT_DISABLE for 3.3V I/O

c. E_INPUT of SDMMC1 CMD pad should be enabled to activate receiver in CMD pad. If disabled, response sent by SD/SDIO will be lost.

- PINMUX_AUX_SDMMC1_CMD_0_E_INPUT_ENABLE

d. Remove tri-state to enable pad output driver - PINMUX_AUX_SDMMC1_CMD_0_TRISTATE_ PASSTHROUGH

e. Select SDMMC1 in pinmux - PINMUX_AUX_SDMMC1_CMD_0_PM_SDMMC1

f. Other pad control settings in PINMUX_AUX_SDMMC1_CMD_0 register should be left as default values. No need to modify.

16. Program DAT0/1/2/3 pad pinmux and control settings:

a. Select 33 Ohm driver - PINMUX_AUX_SDMMC1_DATx_0_ DRV_TYPE_ DRIVE_2X

b. Schmitt trigger selection

- PINMUX_AUX_SDMMC1_DATx_0_ E_SCHMT_ENABLE for 1.8V I/O - provides better duty cycle - low jitter clock

- PINMUX_AUX_SDMMC1_DATx_0_ E_SCHMT_DISABLE for 3.3V I/O

c. E_INPUT of SDMMC1 DATx pad should be enabled to activate receiver in DATx pad. If disabled, data sent by SD/SDIO will be lost.

- PINMUX_AUX_SDMMC1_DATx_0_E_INPUT_ENABLE

d. Remove tri-state to enable pad output driver - PINMUX_AUX_SDMMC1_DATx_0_TRISTATE_ PASSTHROUGH

e. Select SDMMC1 in pinmux - PINMUX_AUX_SDMMC1_DATx_0_PM_SDMMC1

f. Other pad control settings in PINMUX_AUX_SDMMC1_DATx_0 register should be left as default values. No need to modify.

Note: *x = 0, 1, 2 or 3 – DAT lane number*

Program Pad Control and Vendor Registers

17. Program below registers before running auto-calibration to prevent CRC errors during data transfers.

a. Write 0x1 into bit 19 (SPARE_OUT[3]) of register SDMMCA_IO_SPARE_0.

b. Write 0x0 into bit 2 (SEL_VREG) of register SDMMCA_VENDOR_IO_TRIM_CNTRL_0.

Refer to Section 32.8.3: DLL Calibration for software sequence to be followed to program this register field.

18. Set outbound clock trimmer tap value (works in all speed modes - up to 208 MHz) before doing any cmd/data transfers to device. This is needed to meet interface timing specification.

a. SDMMCA_VENDOR_CLOCK_CNTRL_0_ TRIM_VAL = 0x2

19. Set inbound clock trimmer tap value (works up to 50MHz – in non-tunable modes such as DS, HS, SDR12, SDR25 and DDR50) before doing any cmd/data transfers to device. Tuning procedure needs to be run in other modes – SDR50 and SDR104.

a. SDMMCA_VENDOR_CLOCK_CNTRL_0_ TAP_VAL = 0x4

20. Set CLK pad slew codes to 0x0 to get good quality clock.

a. APB_MISC_GP_SDMMC1_PAD_CFGPADCTRL_0_ CFG2TMC_SDMMC1_CLK_CFG_CAL_DRVUP_SLWF = 0x1

b. APB_MISC_GP_SDMMC1_PAD_CFGPADCTRL_0_ CFG2TMC_SDMMC1_CLK_CFG_CAL_DRVDN_SLWR = 0x1

21. Set Calibration pad VSEL:

a. SDMMCA_SDMEMCOMPPADCTRL_0_SDMMC2TMC_CFG_SDMEMCOMP_VREF_SEL = 0x7

Run Auto-Calibration

Run auto-calibration procedure to set proper drive strength codes in SDMMC1 pads. This is needed to use 33 Ohm driver for driving SD/SDIO interface. This procedure should be run before doing device initialization when SD card I/O is using 3.3V and SDIO is using 1.8V.

Software also needs to re-run auto-calibration immediately after switching to 1.8V I/O from 3.3V I/O and before doing any transfers to SD device.

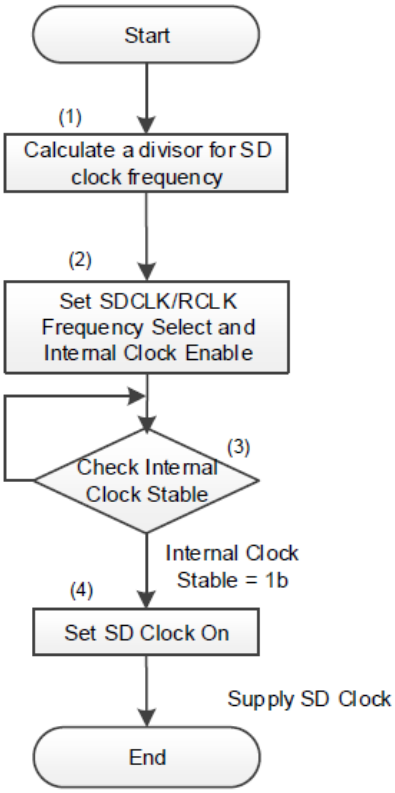
22. Program drive code offsets when for 3.3V operation before running auto-calibration:
    a. SDMMCA_AUTO_CAL_CONFIG_0_AUTO_CAL_PD_OFFSET = 8'd125
    b. SDMMCA_AUTO_CAL_CONFIG_0_AUTO_CAL_PU_OFFSET = 8'd0
23. Program drive code offsets for 1.8V operation before running auto-calibration:
    a. SDMMCA_AUTO_CAL_CONFIG_0_AUTO_CAL_PD_OFFSET = 8'd123
    b. SDMMCA_AUTO_CAL_CONFIG_0_AUTO_CAL_PU_OFFSET = 8'd123
24. Run auto-calibration procedure. Ensure that the SD/eMMC device clock is off during the calibration procedure.
    a. Set E_INPUT_OR_E_PWRD = 1 in SDMMCA_SDMEMCOMPPADCTRL_0 register, if not set.
    b. Wait for 1 us after E_INPUT_OR_E_PWRD is enabled.
    c. Set AUTO_CAL_START and AUTO_CAL_ENABLE to 1 in SDMMCA_AUTO_CAL_CONFIG_0 register.
    d. Wait for 1 us
    e. Wait for up to 10 ms for AUTO_CAL_ACTIVE in SDMMCA_AUTO_CAL_STATUS_0 register to become 0. If it is not 0 after 10 ms, software can assume auto-calibration has timed out. If it becomes zero within 10ms, it is assumed that calibration has completed.
    f. Clear E_INPUT_OR_E_PWRD to save power.
    g. Software should not clear AUTO_CAL_ENABLE in SDMMCA_AUTO_CAL_CONFIG_0 register after calibration. It should be set to 1 always to use calibration codes generated by calibration controller.
    h. If timeout occurs in auto-calibration process, Software should program the drive strength code values below. Software should clear AUTO_CAL_ENABLE in SDMMCA_AUTO_CAL_CONFIG_0 register to use calibration codes programmed in below registers and bypass calibration controller.
    i. For 3.3V I/O:
        - APB_MISC_GP_SDMMC1_PAD_CFGPADCTRL_0_CFG2TMC_SDMMC1_PAD_CAL_DRVUP = 0xC
        - APB_MISC_GP_SDMMC1_PAD_CFGPADCTRL_0_CFG2TMC_SDMMC1_PAD_CAL_DRVDN = 0xC
    j. For 1.8V I/O:
        - APB_MISC_GP_SDMMC1_PAD_CFGPADCTRL_0_CFG2TMC_SDMMC1_PAD_CAL_DRVUP = 0xB
        - APB_MISC_GP_SDMMC1_PAD_CFGPADCTRL_0_CFG2TMC_SDMMC1_PAD_CAL_DRVDN = 0xF
    k. Enable periodic calibration to compensate for drift in driver strength due to temperature variation.
        - Re-run calibration for every 100 ms.
        - Start 100 ms timer after completing calibration iteration.
        - Once 100 ms timer expires, software has to re-initiate calibration as per above sequence but software needs to check if there are any ongoing transfers or not.

          If there are no transfers, calibration can be triggered immediately or before a new data transfer starts. If a new data transfer request comes from upper OS layers during calibration, software should stall that request till calibration is completed.

          If there are ongoing transfers, software should wait for transfers to complete and re-initiate calibration.

25. Enable SD device clock by writing into SD Host registers (should follow SD bus power and Clock supply sequence described in section 3.2 of SD Host 4.0 specification). The SD bus power field in Power Control register should be set to 1 before enabling SDCLK. A flowchart of the SD clock supply sequence is given for quick reference below.

Figure 152: SD Clock Supply Sequence



26. Do SD/SDIO device initialization as per the sequence mentioned in Section 3.6 of SD Host 4.0 specification published by SD Card Association.
27. Points to remember while doing device initialization:
    a. During device initialization, when I/O power is switched to 1.8V from 3.3V, software needs to run auto-calibration again to set proper drive strengths before accessing external device.
    b. During voltage switching, follow the guidelines below to avoid pad damage.
        - Make sure APBDEV_PMC_PWR_DET_VAL_0_SDMMC1 = 1 when I/O voltage is 3.3V.
        - Program PMIC to switch I/O voltage to 1.8V from 3.3V.
        - Wait for 1 ms to cover LDO ramp time from 3.3V to 1.8V (5 mV/us)
        - Set APBDEV_PMC_PWR_DET_VAL_0_SDMMC1 = 0 since I/O voltage is switched to 1.8V.
        - Note I/O power switching can be done by programming PMU/PMIC along with programming the SD Host Power Control register, 1.8V signaling enable in Host Control2 register.
        - Program vendor registers and pad controls for 1.8V I/O as mentioned in previous sections, if needed.
28. Software driver needs to set inbound clock trimmer tap value as per below guidelines to fix sampling point for data coming from device.
    a. In non-tunable modes (DS, HS, SDR12, SDR25 and DDR50 – up to 50 MHz), Software needs to program inbound trimmer tap value as mentioned in Inbound Tap Values (SDMMC_VENDOR_CLOCK_CNTRL_0_TAP_VAL).
    b. To do data transfers in tunable modes (SDR50 and SDR104), the tuning procedure needs to be run to fix sampling point first. For Tuning procedure details, refer to Section 32.8.9: SDR50/SDR104/HS200 Tuning Procedure.
29. Now, Host and device are ready for doing a data transfers.

30. Follow software programming sequences mentioned in Chapter 3 of SD Host 4.0 specification published by SD Card Association for doing data/cmd transfers.

32.7.2.2 SDMMC2 Initialization Sequence

This section provides SDMMC2 controller initialization sequence which should be followed by the software driver before doing any CMD/DAT transfers to external eMMC device.

Power ON

1. Make sure SDMMC2 controller is powered up by programming external PMU/PMIC (platform specific) to set VDD_CORE voltage.
2. Refer to the PMU/PMIC datasheet and power up sequence section in this TRM for programming details.

Program Clocks and Reset

Refer to Chapter 5: Clock and Reset Controller for full details of PLLs programming which are used for SDMMC2 clocking.

3. Set SDMMC2 reset:
   a. Keep SDMMC2 in reset by writing CLK_RST_CONTROLLER_RST_DEV_L_SET_0_ SET_SDMMC2_RST with ENABLE (0x1).
4. Program CLK divider and source
   a. Program SDMMC2 host clock divider

      (CLK_RST_CONTROLLER_CLK_SOURCE_SDMMC2_0_ SDMMC2_CLK_DIVISOR) and PLL source

      (CLK_RST_CONTROLLER_CLK_SOURCE_SDMMC2_0_ SDMMC2_CLK_SRC) as per below guidelines.
   b. PLLP and PLLC4 are the main CLK sources for SDMMC2 controller.
      - PLLP: VCO running at fixed 408 MHz
      - PLLC2: VCO running at fixed ~1GHz (998.4 MHz +-18ppm quality) - Dedicated PLL for eMMC5.0 HS400 and HS667 clocking.
      - For eMMC HS400/HS533 modes, software should use PLLC4 only since PLLC4 clock path is optimized to meet HS400 duty cycle distortion specification requirements.
   c. Software driver should program SDCLK Frequency Select to get desired SD/SDIO device clock which is derived from SDMMC host clock. Follow the SD clock supply sequence mentioned in the SD Host specification 4.0.
   d. Maximum operating host clock frequency for SDMMC2 controller is 333 MHz.
   e. The initializing frequency up to 400 kHz is provided to eMMC using the SDCLK Frequency Select of SDMMC2 (current maximum divisor 2046 as per SD host specification). This is completely software dependent.
   f. In HIGH SPEED DDR mode, SDMMC2 host should be run at 2X frequency than I/O. This requires SDMMC internal clock divider should be set to ‘2’ [Standard Host Register SDMMCAA_SW_RESET_TIMEOUT_CTRL_CLOCK_CONTROL_0_ SDCLK_FREQUENCYSELECT value would be ‘1’].This is mandatory to make DDR50/52 mode work.
   g. Note there is no SDCLK Frequency Select restriction in SDR modes (DS, HS, SDR12, SDR25, SDR50, SDR104 and HS200).
   h. HS400/HS533 mode: This is DDR mode only but has different timing and protocol compared to DDR50/52 mode. In this mode, host clock frequency should match I/O clock frequency. This is a Tegra design requirement. There is no specification compliance issue due to this as this mode is specific to eMMC devices and not defined in SD host specification.

The following table summarizes CLK divider options for PLLP, PLLC4 clock sources.

Table 204: PLL CLK Divider Options for PLLP and PLLC4

Speed Mode	Target I/O Max Frequency (MHz)	Clock Source[1]	Clock Source Frequency (MHz)	CAR Divider[2]	SDMMC host Clock Frequency (MHz)	SDMMC Divider[3]	Actual I/O Frequency (MHz)
Identification	400 (kHz)	PLLP_OUT0	408	16.5	24.72727273	62	398.83 (kHz)
LEGACY SPEED	26	PLLP_OUT0	408	16	25.5	1	25.5
HIGH SPEED SDR	52	PLLP_OUT0	408	8	51	1	51
HIGH SPEED DDR	52	PLLP_OUT0	408	4	102	2	51
HS200 (SDR)	200	PLLC4_OUT2_LJ	199.68	1	199.68	1	199.68
HS400 (DDR)	200	PLLC4_OUT2_LJ	199.68	1	199.68	1	199.68
HS533 (DDR)	266	PLLC4_OUT0_LJ (DIVP=4)	249.6	1	249.6	1	249.6

1. It is set by SDMMC2_CLK_SRC in CLK_RST_CONTROLLER_CLK_SOURCE_SDMMC2_0.
2. It is set by SDMMC2_CLK_DIVISOR in CLK_RST_CONTROLLER_CLK_SOURCE_SDMMC2_0.
3. It is set by SDCLK Frequency Select in Clock Control Register.

5. Program SDMMC2 timeout clock source and divider
   a. SDMMC2 uses 12 MHz TMCLK which is advertised in Host capabilities register -SDMMCAA_CAPABILITIES_0_ TIMEOUT_CLOCK_FREQUENCY.
   b. Software should program below registers to provide TMCLK to SDMMC2.
   - CLK_RST_CONTROLLER_CLK_SOURCE_SDMMC_LEGACY_TM_0_ SDMMC_LEGACY_TM_CLK_SRC
   - CLK_RST_CONTROLLER_CLK_SOURCE_SDMMC_LEGACY_TM_0_SDMMC_LEGACY_TM_CLK_DIVISOR
   c. PLLP_OUT0 is the recommended TMCLK source for SDMMC2.
6. Enable SDMMC2 host clock and TMCLK by setting below registers.
   a. Enable SET_CLK_ENB_SDMMC2 in CLK_RST_CONTROLLER_CLK_ENB_L_SET_0.
   b. Enable CLK_ENB_SDMMC_LEGACY_TM in CLK_RST_CONTROLLER_CLK_OUT_ENB_Y_0.
7. Wait for at least 100 SDMMC2 host clock cycles time to get reset propagated down the pipe and also to get internal clocks stabilized.
8. Clear SDMMC2 reset by writing CLK_RST_CONTROLLER_RST_DEV_L_CLR_0_ CLR_SDMMC2_RST with ENABLE. Enable takes effect immediately.

Power ON eMMC or SDIO Device

9. Power ON eMMC (1.8V I/O). No need to wait for card detection as it is an embedded device.

PINMUX and eMMC IOBRICK Control Programming

10. SDMMC2 uses IOBRICK which is not pinmuxed. No PINMUX programming is needed.
11. E_INPUT and E_LPBK for SDMMC2 CLK pin should be enabled to provide loopback CLK for SDMMC2 Rx. If disabled, reads from eMMC device will not work.
    a. APB_MISC_GP_EMMC2_PAD_CFG_CONTROL_0_EMMC2_PAD_E_DEEP_LPBK_CLK = 1’b1
    b. APB_MISC_GP_EMMC2_PAD_CFG_CONTROL_0_ EMMC2_PAD_E_INPUT_CLK = 1’b1
12. Program below register fields in APB_MISC_GP_EMMC2_PAD_CFGPADCTRL_0 register.
    a. APB_MISC_GP_EMMC2_PAD_CFGPADCTRL_0 _CFG2TMC_EMMC2_PAD_DRVUP_COMP = 0x10
    b. APB_MISC_GP_EMMC2_PAD_CFGPADCTRL_0 _CFG2TMC_EMMC2_PAD_DRVDN_COMP = 0x10
    c. The other bits in register APB_MISC_GP_EMMC2_PAD_CFGPADCTRL_0 must not be touched by software. Default values should be used.
13. Select 50 Ohm driver:

a. Ensure SDMMC2_COMP pad is connected to GND via 50 Ohm resistor on board.

b. Make sure all DRV_TYPE fields in APB_MISC_GP_EMMC2_PAD_DRV_TYPE_CFGPADCTRL_0 are not updated by software. Software should use default values (DRV_TYPE_2X) only.

14. Pull Up/Pull Down values in APB_MISC_GP_EMMC2_PAD_PUPD_CFGPADCTRL_0 should match with default values. No updates are needed.

Program Host Vendor Registers

15. Program below registers before running auto-calibration to prevent CRC errors during data transfers done later.

    a. Write 0x1 into bit 19 (SPARE_OUT[3]) of register SDMMCAA_IO_SPARE_0.

    b. Write 0x0 into bit 2 (SEL_VREG) of register SDMMCAA_VENDOR_IO_TRIM_CNTRL_0. Refer to Section 32.8.5: DLL and Inbound Clock Trimmer Power Supply (VREG) Programming for the software sequence to be followed to program this register field.

16. Set outbound clock trimmer tap value (works in all speed modes - up to 200 MHz) before doing any cmd/data transfers to device. This is needed to meet interface timing specification.

    a. SDMMCAA_VENDOR_CLOCK_CNTRL_0_ TRIM_VAL = 0x8

17. Set internal DQS trimmer tap value before doing any cmd/data transfers to device in HS400/533 mode. This is needed to meet interface timing specification.

    a. For device clock frequency <=200 MHz:

       SDMMCAA_VENDOR_CAP_OVERRIDES_0_ DQS_TRIM_VAL = 40 (decimal)

    b. For device clock frequency > 200MHz and <=333 MHz:

       SDMMCAA_VENDOR_CAP_OVERRIDES_0_ DQS_TRIM_VAL = 24 (decimal)

18. Set inbound clock trimmer tap value (works up to 50 MHz – in non-tunable modes such as SDR@26, SDR@52 and HIGH SPEED DDR) before doing any cmd/data transfers to device. Tuning procedure needs to be run in other modes – HS200 and HS400/533.

    a. SDMMCAA_VENDOR_CLOCK_CNTRL_0_ TAP_VAL = 0x0

19. Set Calibration pad VSEL:
    SDMMCAA_SDMEMCOMPPADCTRL_0_SDMMC2TMC_CFG_SDMEMCOMP_VREF_SEL = 0x7

Run Auto-Calibration

Run auto-calibration procedure to set proper drive strength codes for SDMMC2 IOBRICK. This is needed to use 50 Ohm driver for driving eMMC interface. This procedure should be run before doing device initialization.

20. Program drive code offsets for 1.8V operation before running auto-calibration:

    a. SDMMCAA_AUTO_CAL_CONFIG_0_AUTO_CAL_PD_OFFSET = 8’d5

    b. SDMMCAA_AUTO_CAL_CONFIG_0_AUTO_CAL_PU_OFFSET = 8’d5

21. Run auto-calibration procedure. Ensure that the SD/eMMC device clock is off during calibration procedure.

    a. Set E_INPUT_OR_E_PWRD = 1 in SDMMCAA_SDMEMCOMPPADCTRL_0 register, if not set.

    b. Wait for 1us after E_INPUT_OR_E_PWRD is enabled.

    c. Set AUTO_CAL_START and AUTO_CAL_ENABLE to 1 in SDMMCAA_AUTO_CAL_CONFIG_0 register.

    d. Wait for 1 us.

    e. Wait for up to 10 ms for AUTO_CAL_ACTIVE in SDMMCAA_AUTO_CAL_STATUS_0 register to become 0. If it is not 0 after 10 ms, software can assume auto-calibration has timed out. If it becomes zero within 10 ms, it is assumed that calibration has completed.

    f. Clear E_INPUT_OR_E_PWRD to save power.

    g. Software should not clear AUTO_CAL_ENABLE in SDMMCAA_AUTO_CAL_CONFIG_0 register after calibration. It should be set to 1 always to use calibration codes generated by calibration controller.

h. If timeout occurs in auto-calibration process, software should program below drive strength code values. Software should clear AUTO_CAL_ENABLE in SDMMCAA_AUTO_CAL_CONFIG_0 register to use calibration codes programmed in below registers and bypass calibration controller.

i. For 1.8V I/O:

- APB_MISC_GP_EMMC2_PAD_CFGPADCTRL_0 _CFG2TMC_EMMC2_PAD_DRVUP_COMP = 0x10
- APB_MISC_GP_EMMC2_PAD_CFGPADCTRL_0 _CFG2TMC_EMMC2_PAD_DRVDN_COMP = 0x10

22. Enable eMMC device clock by writing into SD Host registers (should follow SD bus power and SD Clock supply sequence described in section 3.2 of SD Host 4.0 specification). See the SD clock supply sequence flowchart in Figure 152. SD bus power field in Power Control register should be set to 1 before enabling SD clock.
23. Do eMMC device initialization as per the sequence mentioned in eMMC5.0 specification published by JEDEC.
24. Run DLL calibration first, if software wants to use HS400/HS533 mode for doing data transfers to/from eMMC. For HS400 mode switching details, refer to Section 32.8.1: HS400 and HS667 Mode Selection.
25. Software driver needs to set inbound clock trimmer tap value as per below guidelines to fix sampling point for data coming from device.
    a. In non-tunable modes (LEGACY SPEED, HIGH SPEED SDR, and HIGH SPEED DDR – up to 52 MHz), software needs to program inbound trimmer tap value as mentioned in Inbound Tap Values (SDMMC_VENDOR_CLOCK_CNTRL_0_TAP_VAL).
    b. To do data transfers in tunable modes (HS200 and HS400), Tuning procedure needs to be run to fix sampling point first. For Tuning procedure details, refer to Section 32.8.9: SDR50/SDR104/HS200 Tuning Procedure.
26. Now, Host and device are ready for doing a data transfers.
27. Follow software programming sequences mentioned in Chapter 3 of SD Host 4.0 specification published by SDA for doing data/cmd transfers.

32.7.2.3 SDMMC3 Initialization Sequence

This section provides SDMMC3 controller initialization sequence which should be followed by software driver before doing any CMD/DAT transfers to external SD/SDIO device.

Power ON

1. Make sure SDMMC3 controller is powered up by programming external PMU/PMIC (platform specific) to set VDD_CORE voltage.
2. Refer to the PMU/PMIC datasheet and power up sequence section in this TRM for programming details.

Program Clocks and Reset

Refer to Chapter 5: Clock and Reset Controller for full details of PLLs programming which are used for SDMMC3 clocking.

3. Set SDMMC3 reset:
    a. Keep SDMMC3 in reset by writing CLK_RST_CONTROLLER_RST_DEV_U_SET_0_ SET_SDMMC3_RST with ENABLE (0x1).
4. Program CLK divider and source
    a. Program SDMMC3 host clock divider (CLK_RST_CONTROLLER_CLK_SOURCE_SDMMC3_0_ SDMMC3_CLK_DIVISOR) and PLL source (CLK_RST_CONTROLLER_CLK_SOURCE_SDMMC3_0_ SDMMC3_CLK_SRC) as per below guidelines.
    b. PLLP and PLLC4 are the main CLK sources for SDMMC3 controller.
        - PLLP: VCO running at fixed 408 MHz
        - PLLC4: VCO running at fixed ~1GHz (998.4 MHz +-18ppm quality) - Dedicated PLL for eMMC5.0 HS400 and HS667 clocking. This can also be used for clocking other lower speed modes for SD/SDIO.
        - For SD/SDIO interfaces, it is preferable to source from PLLP for power saving.

c. Software driver should program SDCLK Frequency Select in SD Host Clock control register to get desired SD/SDIO device clock which is derived from SDMMC host clock. Follow SD clock supply sequence mentioned in SD Host specification 4.0.

d. Maximum operating host clock frequency for SDMMC3 controller is 208 MHz.

e. The initializing frequency up to 400 kHz is provided to SD/SDIO card using the internal divider (SDCLK Frequency Select) of SDMMC3 (current maximum divisor 2046 as per SD host specification). This is completely software dependent.

f. In HIGH SPEED DDR/DDR50 modes, SDMMC3 host should be run at 2X frequency than I/O. This requires SDMMC internal clock divider should be set to '2' [Standard Host Register SDMMC_SW_RESET_TIMEOUT_CTRL_CLOCK_CONTROL_0_ SDCLK_FREQUENCYSELECT value would be '1'].This is mandatory to make DDR50/52 mode work.

g. Note there is no SDCLK Frequency Select restriction in SDR modes (DS, HS, SDR12, SDR25, SDR50, SDR104 and HS200).

The following table summarizes the CLK divider options for the PLLP clock source.

Table 205: PLL CLK Divider Options for PLLP Clock Source

Speed Mode	Target I/O Max Frequency (MHz)	Clock Source Name(1)	Clock Source Frequency (MHz)	CAR Divider(2)	SDMMC host Clock Frequency (MHz)	SDMMC divider(3)	Actual I/O Frequency (MHz)
Identification	400 (kHz)	PLLP_OUT0	408	16.5	24.72727273	62	398.83 (kHz)
Default Speed	25	PLLP_OUT0	408	16.5	24.72727273	1	24.72727273
High Speed	50	PLLP_OUT0	408	8.5	48	1	48
SDR12	25	PLLP_OUT0	408	16.5	24.72727273	1	24.72727273
SDR25	50	PLLP_OUT0	408	8.5	48	1	48
SDR50	100	PLLP_OUT0	408	4.5	90.66666667	1	90.66666667
DDR50	50	PLLP_OUT0	408	5	81.6	2	40.8
SDR104	208	PLLP_OUT0	408	2	204	1	204

1. It is set by SDMMC3_CLK_SRC in CLK_RST_CONTROLLER_CLK_SOURCE_SDMMC3_0.
2. It is set by SDMMC3_CLK_DIVISOR in CLK_RST_CONTROLLER_CLK_SOURCE_SDMMC3_0.
3. It is set by SDCLK Frequency Select in Clock Control Register.

5. Program SDMMC3 timeout clock source and divider

   a. SDMMC3 uses 12 MHz TMCLK which is advertised in Host capabilities register - SDMMC_CAPABILITIES_0_TIMEOUT_CLOCK_FREQUENCY.

   b. Software should program below registers to provide TMCLK to SDMMC3.

      - CLK_RST_CONTROLLER_CLK_SOURCE_SDMMC_LEGACY_TM_0_ SDMMC_LEGACY_TM_CLK_SRC
      - CLK_RST_CONTROLLER_CLK_SOURCE_SDMMC_LEGACY_TM_0_SDMMC_LEGACY_TM_CLK_DIVISOR

   c. PLLP_OUT0 is the recommended TMCLK source for SDMMC3.

6. Enable SDMMC3 host clock and TMCLK by setting below registers.

   a. Enable SET_CLK_ENB_SDMMC3 in CLK_RST_CONTROLLER_CLK_ENB_U_SET_0.

   b. Enable CLK_ENB_SDMMC_LEGACY_TM in CLK_RST_CONTROLLER_CLK_OUT_ENB_Y_0.

7. Wait for at least 100 SDMMC3 host clock cycles time to get reset propagated down the pipe and also to get internal clocks stabilized.

8. Clear SDMMC3 reset by writing CLK_RST_CONTROLLER_RST_DEV_U_CLR_0_ CLR_SDMMC3_RST with ENABLE. Enable takes effect immediately.

Card Detection and Write Protect Status

9. Tegra X1 supports GPIO based card detection mechanism. Refer to the GPIO section in TRM for full details about GPIO programming.
    a. Software needs to program SDMMC3_CD and SDMMC3_WP pinmux registers as per customer pinmux datasheet.
10. SDMMC3 controller gets SDCD and SDWP status from GPIO pins (SDMMC3_CD and SDMMC3_WP). Software has to program CD/WP source appropriately in below register to get SDMMC3 correct status.
    a. APB_MISC_GP_VGPIO_GPIO_MUX_SEL_0_ SDMMC3_WP_SOURCE = GPIO
    b. APB_MISC_GP_VGPIO_GPIO_MUX_SEL_0_ SDMMC3_CD_SOURCE = GPIO

Power ON SD Card or SDIO Device

11. If removable card is detected using GPIO, power ON SD card (3.3V to start with). No need to wait for card detection in case of SDIO.
12. To avoid high leakage and pad damage, set SDMMC_SDMEMCOMPPADCTRL_0_PAD_E_INPUT_OR_E_PWRD to 0x1 before turning ON SD card power.
13. Program PWR_DET for SDMMC3 pads before turning ON SD/SDIO card power:
    a. SDMMC3 pads are capable of supporting both 3.3V and 1.8V I/O. Software should notify pads about the operating I/O voltage whether it is either 3.3V or 1.8V. This is needed as SDMMC3 pads don't have PWR_DET cells to detect voltage level automatically. Incorrect programming could lead to pad damage.
    b. Set APBDEV_PMC_PWR_DET_VAL_0_SDMMC3 = 1 before switching I/O voltage to 3.3V
    c. Set APBDEV_PMC_PWR_DET_VAL_0_SDMMC3 = 0 after switching I/O voltage to 1.8V

PINMUX and Pad Control Programming

SDMMC3 pads are pinmuxed. Software has to program PINMUX registers to select SDMMC3 and also to program pad controls.

14. Program CLK pad pinmux and control settings:
    a. Select 33 Ohm driver - PINMUX_AUX_SDMMC3_CLK_0_ DRV_TYPE_ DRIVE_2X. Ensure that the SDMMC3_COMP pad is connected to GND via 66 Ohm resistor on board.
    b. DRV_TYPE_DRIVE2X and 66 Ohm calibration resistor are used to get drive strength codes for 33 Ohm driver. This is a Tegra specific implementation.
    c. Schmitt trigger selection
        - PINMUX_AUX_SDMMC3_CLK_0_ E_SCHMT_ENABLE for 1.8V I/O - provides better duty cycle - low jitter clock
        - PINMUX_AUX_SDMMC3_CLK_0_ E_SCHMT_DISABLE for 3.3V I/O
    d. Both E_INPUT and E_LPBK of SDMMC3 CLK pad should be enabled to provide loopback CLK for SDMMC3 Receiver. If disabled, reads from SD/eMMC device won't work.
        - APB_MISC_GP_SDMMC3_CLK_LPBK_CONTROL_0_SDMMC3_CLK_PAD_E_LPBK = 1'b1
        - PINMUX_AUX_SDMMC3_CLK_0_E_INPUT_ENABLE
    e. Remove tri-state to enable pad output driver - PINMUX_AUX_SDMMC3_CLK_0_TRISTATE_PASSTHROUGH
    f. Select SDMMC3 in pinmux - PINMUX_AUX_SDMMC3_CLK_0_PM_SDMMC3
    g. Other pad control settings in PINMUX_AUX_SDMMC3_CLK_0 register should be left as default values. No need to modify.
15. Program CMD pad pinmux and control settings:
    a. Select 33 Ohm driver - PINMUX_AUX_SDMMC3_CMD_0_ DRV_TYPE_ DRIVE_2X
    b. Schmidt trigger selection

- PINMUX_AUX_SDMMC3_CMD_0_ E_SCHMT_ENABLE for 1.8V I/O - provides better duty cycle - low jitter clock
- PINMUX_AUX_SDMMC3_CMD_0_ E_SCHMT_DISABLE for 3.3V I/O

c. E_INPUT of SDMMC3 CMD pad should be enabled to activate receiver in CMD pad. If disabled, response sent by SD/SDIO will be lost.

- PINMUX_AUX_SDMMC3_CMD_0_E_INPUT_ENABLE

d. Remove tri-state to enable pad output driver - PINMUX_AUX_SDMMC3_CMD_0_TRISTATE_ PASSTHROUGH

e. Select SDMMC3 in pinmux - PINMUX_AUX_SDMMC3_CMD_0_PM_SDMMC3

f. Other pad control settings in PINMUX_AUX_SDMMC3_CMD_0 register should be left as default values. No need to modify.

16. Program DAT0/1/2/3 pad pinmux and control settings:

a. Select 33 Ohm driver - PINMUX_AUX_SDMMC3_DATx_0_ DRV_TYPE_ DRIVE_2X

b. Schmitt trigger selection

- PINMUX_AUX_SDMMC3_DATx_0_ E_SCHMT_ENABLE for 1.8V I/O - provides better duty cycle - low jitter clock
- PINMUX_AUX_SDMMC3_DATx_0_ E_SCHMT_DISABLE for 3.3V I/O

c. E_INPUT of SDMMC3 DATx pad should be enabled to activate receiver in DATx pad. If disabled, data sent by SD/SDIO will be lost.

d. PINMUX_AUX_SDMMC3_DATx_0_E_INPUT_ENABLE

e. Remove tri-state to enable pad output driver - PINMUX_AUX_SDMMC3_DATx_0_TRISTATE_ PASSTHROUGH

f. Select SDMMC3 in pinmux - PINMUX_AUX_SDMMC3_DATx_0_PM_SDMMC3

g. Other pad control settings in PINMUX_AUX_SDMMC3_DATx_0 register should be left as default values. No need to modify.

Note: *x = 0, 1, 2 or 3 – DAT lane number.*

Program Pad Control and Vendor Registers

17. Program below registers before running auto-calibration to prevent CRC errors during data transfers done later.

a. Write 0x1 into bit 19 (SPARE_OUT[3]) of register SDMMC_IO_SPARE_0.

b. Write 0x0 into bit 2 (SEL_VREG) of register SDMMC_VENDOR_IO_TRIM_CNTRL_0. Refer to Section 32.8.5: DLL and Inbound Clock Trimmer Power Supply (VREG) Programming for software sequence to be followed to program this register field.

18. Set outbound clock trimmer tap value (works in all speed modes - up to 208 MHz) before doing any cmd/data transfers to device. This is needed to meet the interface timing specification.

a. SDMMC_VENDOR_CLOCK_CNTRL_0_ TRIM_VAL = 0x3

19. Set inbound clock trimmer tap value (works up to 50MHz – in non-tunable modes such as DS, HS, SDR12, SDR25 and DDR50) before doing any cmd/data transfers to device. Tuning procedure needs to be run in other modes – SDR50 and SDR104.

a. SDMMC_VENDOR_CLOCK_CNTRL_0_ TAP_VAL = 0x3

20. Set CLK pad slew codes to 0x0 to get good quality clock.

a. APB_MISC_GP_SDMMC3_PAD_CFGPADCTRL_0_ CFG2TMC_SDMMC3_CLK_CFG_CAL_DRVUP_SLWF = 0x1

b. APB_MISC_GP_SDMMC3_PAD_CFGPADCTRL_0_ CFG2TMC_SDMMC3_CLK_CFG_CAL_DRVDN_SLWR = 0x1

21. Set Calibration pad VSEL: SDMMC_SDMEMCOMPPADCTRL_0_SDMMC2TMC_CFG_SDMEMCOMP_VREF_SEL = 0x7

Run Auto-Calibration

Run auto-calibration procedure to set proper drive strength codes in SDMMC3 pads. This is needed to use 33 Ohm driver for driving SD/SDIO interface. This procedure should be run before doing device initialization when SD card I/O is using 3.3V and SDIO is using 1.8V.

Software also needs to re-run auto-calibration immediately after switching to 1.8V I/O from 3.3V I/O and before doing any transfers to SD device.

22. Program drive code offsets when for 3.3V operation before running auto-calibration:
    a. SDMMC_AUTO_CAL_CONFIG_0_AUTO_CAL_PD_OFFSET = 8'd125
    b. SDMMC_AUTO_CAL_CONFIG_0_AUTO_CAL_PU_OFFSET = 8'd0
23. Program drive code offsets for 1.8V operation before running auto-calibration:
    a. SDMMC_AUTO_CAL_CONFIG_0_AUTO_CAL_PD_OFFSET = 8'd123
    b. SDMMC_AUTO_CAL_CONFIG_0_AUTO_CAL_PU_OFFSET = 8'd123
24. Run auto-calibration procedure. Ensure that the SD/eMMC device clock is off during calibration procedure.
    a. Set E_INPUT_OR_E_PWRD = 1 in SDMMC_SDMEMCOMPPADCTRL_0 register, if not set.
    b. Wait for 1us after E_INPUT_OR_E_PWRD is enabled.
    c. Set AUTO_CAL_START and AUTO_CAL_ENABLE to 1 in SDMMC_AUTO_CAL_CONFIG_0 register.
    d. Wait for 1 us.
    e. Wait for up to 10 ms for AUTO_CAL_ACTIVE in SDMMC_AUTO_CAL_STATUS_0 register to become 0. If it is not 0 after 10 ms, software can assume auto-calibration has timed out. If it becomes zero within 10 ms, it is assumed that calibration has completed.
    f. Clear E_INPUT_OR_E_PWRD to save power.
    g. Software should not clear AUTO_CAL_ENABLE in SDMMC_AUTO_CAL_CONFIG_0 register after calibration. It should be set to 1 always to use calibration codes generated by calibration controller.
    h. If timeout occurs in auto-calibration process, software should program below drive strength code values. Software should clear AUTO_CAL_ENABLE in SDMMC_AUTO_CAL_CONFIG_0 register to use calibration codes programmed in below registers and bypass calibration controller.
    i. For 3.3V I/O:
        • APB_MISC_GP_SDMMC3_PAD_CFGPADCTRL_0_CFG2TMC_SDMMC3_PAD_CAL_DRVUP = 0xC
        • APB_MISC_GP_SDMMC3_PAD_CFGPADCTRL_0_CFG2TMC_SDMMC3_PAD_CAL_DRVDN = 0xC
    j. For 1.8V I/O:
        • APB_MISC_GP_SDMMC3_PAD_CFGPADCTRL_0_CFG2TMC_SDMMC3_PAD_CAL_DRVUP = 0xB
        • APB_MISC_GP_SDMMC3_PAD_CFGPADCTRL_0_CFG2TMC_SDMMC3_PAD_CAL_DRVDN = 0xF
    k. Enable periodic calibration to compensate for drift in driver strength due to temperature variation.
        • Re-run calibration for every 100 ms.
        • Start 100 ms timer after completing calibration iteration.
    - Once 100 ms timer expires, software has to re-initiate calibration as per above sequence but software needs to check if there are any ongoing transfers or not.
        • If there are no transfers, calibration can be triggered immediately or before a new data transfer starts. If a new data transfer request comes from upper OS layers during calibration, software should stall that request till calibration is completed.
        • If there are ongoing transfers, software should wait for transfers to complete and re-initiate calibration

25. Enable SD device clock by writing into SD Host registers (should follow SD bus power and Clock supply sequence described in section 3.2 of SD Host 4.0 specification). SD bus power field in Power Control register should be set to 1 before enabling SDCLK. See the SD clock supply sequence flowchart in Figure 152.
26. Do SD/SDIO device initialization as per the sequence mentioned in section 3.6 of SD Host 4.0 specification published by SDA. (SD Card Association).
27. Points to note:
    a. During device initialization, when I/O power is switched to 1.8V from 3.3V, software need to run auto-calibration again to set proper drive strengths before accessing external device.
    b. During voltage switching, follow the guidelines below to avoid pad damage.
        - Make sure APBDEV_PMC_PWR_DET_VAL_0_SDMMC3 = 1 when I/O voltage is 3.3V.
        - Program PMIC to switch I/O voltage to 1.8V from 3.3V.
        - Wait for 1 ms to cover LDO ramp time from 3.3V to 1.8V (5 mV/us)
        - Set APBDEV_PMC_PWR_DET_VAL_0_SDMMC3 = 0 since I/O voltage is switched to 1.8V.
        - Note I/O power switching can be done by programming PMU/PMIC along with programming SD Host Power Control register, 1.8V signaling enable in Host Control2 register.
        - Program vendor registers and pad controls for 1.8V I/O as mentioned in previous sections, if needed.
28. Software driver needs to set inbound clock trimmer tap value as per below guidelines to fix sampling point for data coming from device.
    a. In non-tunable modes (DS, HS, SDR12, SDR25 and DDR50 – up to 50 MHz), software needs to program inbound trimmer tap value as mentioned in Inbound Tap Values (SDMMC_VENDOR_CLOCK_CNTRL_0_TAP_VAL).
    b. To do data transfers in tunable modes (SDR50 and SDR104), Tuning procedure needs to be run to fix sampling point first. For Tuning procedure details, refer to Section 32.8.9: SDR50/SDR104/HS200 Tuning Procedure.
29. Now, Host and device are ready for doing a data transfers.
30. Follow software programming sequences mentioned in Chapter 3 of SD Host 4.0 specification published by SDA for doing data/cmd transfers.

32.7.2.4 SDMMC4 Initialization Sequence

This section provides SDMMC4 controller initialization sequence which should be followed by software driver before doing any CMD/DAT transfers to external eMMC device.

Power ON

1. Make sure SDMMC4 controller is powered up by programming external PMU/PMIC (platform specific) to set VDD_CORE voltage.
2. Refer to the PMU/PMIC datasheet and power up sequence section in TRM for programming details.

Program Clocks and Reset

Refer to Chapter 5: Clock and Reset Controller for full details of PLLs programming which are used for SDMMC4 clocking.

3. Set SDMMC4 reset:
    a. Keep SDMMC4 in reset by writing

    CLK_RST_CONTROLLER_RST_DEV_L_SET_0_ SET_SDMMC4_RST with ENABLE (0x1).
4. Program CLK divider and source
    a. Program SDMMC4 host clock divider
        - (CLK_RST_CONTROLLER_CLK_SOURCE_SDMMC4_0_ SDMMC4_CLK_DIVISOR) and PLL source
        - (CLK_RST_CONTROLLER_CLK_SOURCE_SDMMC4_0_ SDMMC4_CLK_SRC) as per below guidelines.
    b. PLLP and PLLC4 are the main CLK sources for SDMMC4 controller.

- PLLP: VCO running at fixed 408 MHz
- PLLC4: VCO running at fixed ~1GHz (998.4 MHz +-18ppm quality) - Dedicated PLL for eMMC5.0 HS400 and HS667 clocking.
- For eMMC HS400/HS533 modes, software should use PLLC4 only since PLLC4 clock path is optimized to meet HS400 duty cycle distortion specification.

c. Software driver should program SDCLK Frequency select in SD host clock control register to get desired eMMC device clock which is derived from SDMMC4 host clock. Follow SD clock supply sequence mentioned in SD Host specification 4.0.

d. Maximum operating host clock frequency for SDMMC4 controller is 333 MHz.

e. The initializing frequency up to 400 kHz is provided to SD/SDIO card using the SDCLK Frequency select in SD host clock control register of SDMMC4 (current maximum divisor 2046 as per SD host specification). This is completely software dependent.

f. In HIGH SPEED DDR mode, SDMMC4 host should be run at 2X frequency than I/O. This requires SDMMC internal clock divider should be set to '2' [Standard Host Register SDMMCAB_SW_RESET_TIMEOUT_CTRL_CLOCK_CONTROL_0_ SDCLK_FREQUENCYSELECT value would be '1'].This is mandatory to make DDR50/52 mode work.

g. Note there is no SDCLK Frequency select restriction in SDR modes (DS, HS, SDR12, SDR25, SDR50, SDR104 and HS200).

h. HS400/HS533 mode: This is DDR mode only but has different timing and protocol compared to DDR50/52 mode. In this mode, host clock frequency should match device clock frequency. This is a Tegra design requirement. There is no specification compliance issue due to this as this mode is specific to eMMC devices and not defined in SD host specification.

The following table summarizes CLK divider options for PLLP and PLLC4 clock sources.

Table 206: PLL Clock Divider Options for PLLP and PLLC4

Speed Mode	Target I/O Max Frequency (MHz)	Clock Source[1]	Clock Source Frequency (MHz)	CAR divider[2]	SDMMC Host Clock Frequency (MHz)	SDMMC divider[3]	Actual I/O Frequency (MHz)
Identification	400 (kHz)	PLLP_OUT0	408	16.5	24.72727273	62	398.83 (kHz)
LEGACY SPEED	26	PLLP_OUT0	408	16	25.5	1	25.5
HIGH SPEED SDR	52	PLLP_OUT0	408	8	51	1	51
HIGH SPEED DDR	52	PLLP_OUT0	408	4	102	2	51
HS200 (SDR)	200	PLLC4_OUT2_LJ	199.68	1	199.68	1	199.68
HS400 (DDR)	200	PLLC4_OUT2_LJ	199.68	1	199.68	1	199.68
HS533 (DDR)	266	PLLC4_OUT0_LJ (DIVP=4)	249.6	1	249.6	1	249.6

1. It is set by SDMMC4_CLK_SRC in CLK_RST_CONTROLLER_CLK_SOURCE_SDMMC4_0.
2. It is set by SDMMC4_CLK_DIVISOR in CLK_RST_CONTROLLER_CLK_SOURCE_SDMMC4_0.
3. It is set by SDCLK Frequency Select in Clock Control Register

5. Program SDMMC4 timeout clock source and divider

a. SDMMC4 uses 12 MHz TMCLK which is advertised in Host capabilities register -SDMMCAB_CAPABILITIES_0_ TIMEOUT_CLOCK_FREQUENCY.

b. Software should program below registers to provide TMCLK to SDMMC4.

- CLK_RST_CONTROLLER_CLK_SOURCE_SDMMC_LEGACY_TM_0_ SDMMC_LEGACY_TM_CLK_SRC
- CLK_RST_CONTROLLER_CLK_SOURCE_SDMMC_LEGACY_TM_0_ SDMMC_LEGACY_TM_CLK_DIVISOR

c. PLLP_OUT0 is the recommended TMCLK source for SDMMC4.

6. Enable SDMMC4 host clock and TMCLK by setting below registers.
   a. Enable SET_CLK_ENB_SDMMC4 in CLK_RST_CONTROLLER_CLK_ENB_L_SET_0.
   b. Enable CLK_ENB_SDMMC_LEGACY_TM in CLK_RST_CONTROLLER_CLK_OUT_ENB_Y_0.
7. Wait for at least 100 SDMMC4 host clock cycles time to get reset propagated down the pipe and also to get internal clocks stabilized.
8. Clear SDMMC4 reset by writing CLK_RST_CONTROLLER_RST_DEV_L_CLR_0_ CLR_SDMMC4_RST with ENABLE. Enable takes effect immediately.

Power ON eMMC or SDIO Device

9. Power ON eMMC (1.8V I/O). No need to wait for card detection as it is an embedded device.

PINMUX and eMMC IOBRICK Control Programming

10. SDMMC4 uses IOBRICK which is not pinmuxed. No PINMUX programming is needed.
11. E_INPUT and E_LPBK for SDMMC4 CLK pin should be enabled to provide loopback CLK for SDMMC4 Rx. If disabled, reads from SD/eMMC device won't work.
    a. APB_MISC_GP_EMMC4_PAD_CFG_CONTROL_0_EMMC4_PAD_E_DEEP_LPBK_CLK = 1'b1
    b. APB_MISC_GP_EMMC4_PAD_CFG_CONTROL_0_ EMMC4_PAD_E_INPUT_CLK = 1'b1
12. Program below register fields in APB_MISC_GP_EMMC4_PAD_CFGPADCTRL_0 register.
    a. APB_MISC_GP_EMMC4_PAD_CFGPADCTRL_0 _CFG2TMC_EMMC4_PAD_DRVUP_COMP = 0x10
    b. APB_MISC_GP_EMMC4_PAD_CFGPADCTRL_0 _CFG2TMC_EMMC4_PAD_DRVDN_COMP = 0x10
    c. Ensure that other bits in register APB_MISC_GP_EMMC4_PAD_CFGPADCTRL_0 are not touched by software. Default values should be used.
13. Select 50 Ohm driver:
    a. Ensure that the SDMMC4_COMP pad is connected to GND via 50 Ohm resistor on board.
    b. Make sure all DRV_TYPE fields in APB_MISC_GP_EMMC4_PAD_DRV_TYPE_CFGPADCTRL_0 are not updated by software. Software should use default values (DRV_TYPE_2X) only.
14. Pull Up/Pull Down values in APB_MISC_GP_EMMC4_PAD_PUPD_CFGPADCTRL_0 should match with default values. No updates are needed.

Program Host Vendor Registers

15. Program below registers before running auto-calibration to prevent CRC errors during data transfers done later.
    a. Write 0x1 into bit 19 (SPARE_OUT[3]) of register SDMMCAB_IO_SPARE_0.
    b. Write 0x0 into bit 2 (SEL_VREG) of register SDMMCAB_VENDOR_IO_TRIM_CNTRL_0. Refer to Section 32.8.5: DLL and Inbound Clock Trimmer Power Supply (VREG) Programming for software sequence to be followed to program this register field.
16. Set outbound clock trimmer tap value (works in all speed modes - up to 200 MHz) before doing any cmd/data transfers to device. This is needed to meet interface timing specification.
    a. SDMMCAB_VENDOR_CLOCK_CNTRL_0_ TRIM_VAL = 0x8
17. Set internal DQS trimmer tap value before doing any cmd/data transfers to device in HS400/533 mode. This is needed to meet interface timing specification.
    a. For device clock frequency <=200 MHz:

       SDMMCAB_VENDOR_CAP_OVERRIDES_0_ DQS_TRIM_VAL = 40 (decimal)
    b. For device clock frequency > 200MHz and <=333 MHz:

       SDMMCAB_VENDOR_CAP_OVERRIDES_0_ DQS_TRIM_VAL = 24 (decimal)

18. Set inbound clock trimmer tap value (works up to 50 MHz – in non-tunable modes such as SDR@26, SDR@52 and HIGH SPEED DDR) before doing any cmd/data transfers to device. Tuning procedure needs to be run in other modes – HS200 and HS400/533.
    a. SDMMCAB_VENDOR_CLOCK_CNTRL_0_ TAP_VAL = 0x0
19. Set Calibration pad VSEL:

    SDMMCAB_SDMEMCOMPPADCTRL_0_SDMMC2TMC_CFG_SDMEMCOMP_VREF_SEL = 0x7

Run Auto-Calibration

Run auto-calibration procedure to set proper drive strength codes for SDMMC4 IOBRICK. This is needed to use 50 Ohm driver for driving eMMC interface. This procedure should be run before doing device initialization.

20. Program drive code offsets for 1.8V operation before running auto-calibration:
    a. SDMMCAB_AUTO_CAL_CONFIG_0_AUTO_CAL_PD_OFFSET = 8'd5
    b. SDMMCAB_AUTO_CAL_CONFIG_0_AUTO_CAL_PU_OFFSET = 8'd5
21. Run auto-calibration procedure. Ensure that the SD/eMMC device clock is off during calibration procedure.
    a. Set E_INPUT_OR_E_PWRD = 1 in SDMMCAB_SDMEMCOMPPADCTRL_0 register, if not set.
    b. Wait for 1us after E_INPUT_OR_E_PWRD is enabled.
    c. Set AUTO_CAL_START and AUTO_CAL_ENABLE to 1 in SDMMCAB_AUTO_CAL_CONFIG_0 register.
    d. Wait for 1us.
    e. Wait for up to 10 ms for AUTO_CAL_ACTIVE in SDMMCAB_AUTO_CAL_STATUS_0 register to become 0. If it is not 0 after 10 ms, software can assume auto-calibration has timed out. If it becomes zero within 10 ms, it is assumed that calibration has completed.
    f. Clear E_INPUT_OR_E_PWRD to save power.
    g. Software should not clear AUTO_CAL_ENABLE in SDMMCAB_AUTO_CAL_CONFIG_0 register after calibration. It should be set to 1 always to use calibration codes generated by calibration controller.
    h. If timeout occurs in auto-calibration process, software should program the drive strength code values below. Software should clear AUTO_CAL_ENABLE in SDMMCAB_AUTO_CAL_CONFIG_0 register to use calibration codes programmed in below registers and bypass calibration controller.
    i. For 1.8V I/O:
        - APB_MISC_GP_EMMC4_PAD_CFGPADCTRL_0 _CFG2TMC_EMMC4_PAD_DRVUP_COMP = 0x10
        - APB_MISC_GP_EMMC4_PAD_CFGPADCTRL_0 _CFG2TMC_EMMC4_PAD_DRVDN_COMP = 0x10
22. Enable eMMC device clock by writing into SD Host registers (should follow SD bus power and Clock supply sequence described in section 3.2 of SD Host 4.0 specification). See the SD clock supply sequence flowchart in Figure 152. SD Bus Power register field in Power Control register should be set to 1 to enable SDCLK.
23. Do eMMC device initialization as per the sequence mentioned in eMMC5.0 specification published by JEDEC.
24. Run DLL calibration first, if software wants to use HS400/HS533 mode for doing data transfers to/from eMMC. For HS400 mode switching details, refer to Section 32.8.1: HS400 and HS667 Mode Selection.
25. Software driver needs to set inbound clock trimmer tap value as per below guidelines to fix sampling point for data coming from device.
    a. In non-tunable modes (LEGACY SPEED, HIGH SPEED SDR, and HIGH SPEED DDR – up to 52 MHz), software needs to program inbound trimmer tap value as mentioned in Inbound Tap Values (SDMMC_VENDOR_CLOCK_CNTRL_0_TAP_VAL).
    b. To do data transfers in tunable modes (HS200 and HS400), Tuning procedure needs to be run to fix sampling point first. For Tuning procedure details, refer to Section 32.8.9: SDR50/SDR104/HS200 Tuning Procedure.
26. Now, Host and device are ready for doing a data transfers.

27. Follow software programming sequences mentioned in Chapter 3 of SD Host 4.0 specification published by SDA for doing data/cmd transfers.

32.7.3 General Guidelines

These settings are applicable for all SD/MMC controllers in use:

- Enable SDR50 mode tuning support in SDMMC controller by setting SDMMCxx_VENDOR_CLOCK_CNTRL_0_SDR50_TUNING_OVERRIDE. This enables SDR50 mode tuning circuit in Host controller.
- Enable HS200 mode by setting UHS_MODE_SEL to SDR104 in HOST_CONTROL_2 (offset 03Eh) register. This field is used for SDR104 by standard Host register specification. Reusing the same for HS200 mode as there is no standard specification for eMMC Host.
- Enable HS400 (HS400 or HS667 or HS533 for eMMC5.0) support by setting UHS_MODE_SEL to HS400 in HOST_CONTROL_2 (offset 03Eh) register. This field is reserved as per standard Host register specification. But using the same as HS400 mode enable as there is no standard specification for eMMC Host.
- Set SDMMCxx_VENDOR_CLOCK_CNTRL_0_PADPIPE_CLKEN_OVERRIDE with OVERRIDE in all SD/eMMC speed modes.
- Write ‘1’ into bit 19 (SPARE_OUT[3]) of register SDMMCxx_IO_SPARE_0.
- Write ‘0’ into bit 2 (SEL_VREG) of register SDMMCxx_VENDOR_IO_TRIM_CNTRL_0.

32.7.3.1 SDCLK Divider (SDCLK Frequency select) Restriction

- In an SDR modes (DS, HS, SDR12/eMMC LEGACY SPEED, SDR25/eMMC HIGH SPEED SDR, SDR50, SDR104 and HS200), there is no restriction on SDCLK divider. Software can select any SDCLK divider to get desired device clock from Host clock. But Host clock should be less than the frequency that we support. Maximum Host clock frequency is 208 MHz for all controllers except in HS533 mode. In HS533 mode, they can use host clock of 267 MHz.
- In DDR50/52 mode, we have clock divider restriction. Host clock should be running at 2X speed than I/O clock. This is a design limitation. That's why we unadvertised DDR50 support (by default) in SD Host capabilities not to run into specification compliance issues. In this case software should use SDR50 instead DDR50 as both give same throughput. But it is not a specification compliance issue for eMMC as there is no eMMC host specification. In either case, software can always use DDR50/52 mode with the given SDCLK divider restriction.
- HS400/HS533 mode: This is DDR mode only but has different timing and protocol compared to DDR50/52 mode. In this mode, host clock frequency should match I/O clock frequency. This is our design requirement. There is no specification compliance issue due to this as this mode is specific to eMMC devices and not defined in SD host specification.

32.7.3.2 Card Insertion Interrupt

If software resets the SD/eMMC controller, it should not try to clear the Card Inserted interrupt within 300 us after asserting the SD/e.MMC reset. Trying to clear the Card Inserted interrupt before that time will not successfully clear the Card Inserted interrupt, causing an interrupt storm that may last for up to 300 us.

32.7.3.3 SDMMC1

These settings are specific to the SDMMC1 controller:

- Software should run auto-calibration procedure to setup proper driver for SD/eMMC interface before doing any transfers. Auto-calibration procedure determines and programs drive codes of pads, if it passes.
- If auto-calibration procedure fails due to some unknown reason, the following drive strength codes need to be programmed for the pads. Software should clear AUTO_CAL_ENABLE in SDMMCA_AUTO_CAL_CONFIG_0 register to use calibration codes programmed in below registers and bypass calibration controller.

Supply	33 Ohm	50 Ohm
	Up DN	Up DN

Supply	33 Ohm		50 Ohm	
3.3V	12	12	8	8
1.8V	11	15	3	4

DRV UP code - APB_MISC_GP_SDMMC1_PAD_CFGPADCTRL_0_CFG2TMC_SDMMC1_PAD_CAL_DRVUP

DRV DN code - APB_MISC_GP_SDMMC1_PAD_CFGPADCTRL_0_CFG2TMC_SDMMC1_PAD_CAL_DRVDN

- APB_MISC_GP_SDMMC1_PAD_CFGPADCTRL_0_ CFG2TMC_SDMMC1_CLK_CFG_CAL_DRVUP_SLWF = 0x1
- APB_MISC_GP_SDMMC1_PAD_CFGPADCTRL_0_ CFG2TMC_SDMMC1_CLK_CFG_CAL_DRVDN_SLWR = 0x1
- SDMMC_SDMEMCOMPPADCTRL_0_SDMMC2TMC_CFG_SDMEMCOMP_VREF_SEL = 0x7
- SDMMC_AUTO_CAL_CONFIG_0_AUTO_CAL_ENABLE_ENABLED
- For 3.3V operation:
  - SDMMC_AUTO_CAL_CONFIG_0_AUTO_CAL_PD_OFFSET = 8’d125
  - SDMMC_AUTO_CAL_CONFIG_0_AUTO_CAL_PU_OFFSET = 8’d0
- For 1.8V operation:
  - SDMMC_AUTO_CAL_CONFIG_0_AUTO_CAL_PD_OFFSET = 8’d123
  - SDMMC_AUTO_CAL_CONFIG_0_AUTO_CAL_PU_OFFSET = 8’d123
- E_INPUT and E_LPBK for SDMMC1 CLK pin should be enabled to provide loopback CLK for SDMMC1 Rx. If disabled, reads to SD/eMMC device won’t work.
  - APB_MISC_GP_SDMMC1_CLK_LPBK_CONTROL_0_SDMMC1_CLK_PAD_E_LPBK = 1’b1
  - PINMUX_AUX_SDMMC1_CLK_0_ E_INPUT_ ENABLE
- If using the SDMMC1 interface, correctly enable the integrated pullup/down resistors there:
  - PINMUX_AUX_SDMMC1_CLK_0_PULL_UP_NORMAL
  - If using eMMC (a stronger external 4.7 kOhm pull-up is used on the CMD line):
  - PINMUX_AUX_SDMMC1_CMD_0_PULL_UP_NORMAL
- If using SD or SDIO:
  - PINMUX_AUX_SDMMC1_CMD_0_PULL_UP_PULL_UP
  - PINMUX_AUX_SDMMC1_DAT3_0_PUPD_PULL_UP
  - PINMUX_AUX_SDMMC1_DAT2_0_PUPD_PULL_UP
  - PINMUX_AUX_SDMMC1_DAT1_0_PUPD_PULL_UP
  - PINMUX_AUX_SDMMC1_DAT0_0_PUPD_PULL_UP
- Select 33 ohm driver for SDMMC1 interface.
  - PINMUX_AUX_SDMMC1_CLK_0_ DRV_TYPE_DRIVE_2X
  - PINMUX_AUX_SDMMC1_CMD_0_ DRV_TYPE_DRIVE_2X.
  - PINMUX_AUX_SDMMC1_DAT0_0_ DRV_TYPE_DRIVE_2X.
  - PINMUX_AUX_SDMMC1_DAT1_0_ DRV_TYPE_DRIVE_2X.
  - PINMUX_AUX_SDMMC1_DAT2_0_ DRV_TYPE_DRIVE_2X.
  - PINMUX_AUX_SDMMC1_DAT3_0_ DRV_TYPE_DRIVE_2X.
- Make sure SDMMC1_COMP pad is connected to GND via 66 ohm resistor on board.
- DRV_TYPE_DRIVE2X and 66 Ohm calibration resistor are used to get drive strength codes for 33 ohm driver. This is Tegra specific implementation.

- Schmitt trigger selection for CLK/CMD/DAT pads
  - PINMUX_AUX_SDMMC1_xxxx_0_ E_SCHMT_ENABLE for 1.8V I/O - provides better duty cycle - low jitter clock
  - PINMUX_AUX_SDMMC1_xxxx_0_ E_SCHMT_DISABLE for 3.3V I/O
  - [xxxx = CLK, CMD, DAT0, DAT1, DAT2 or DAT3].
- E_HSM selection for CLK/CMD/DAT pads
  - PINMUX_AUX_SDMMC1_xxxx_0_ E_HSM_DISABLE for both 3.3V and 1.8V I/O

    [xxxx = CLK, CMD, DAT0, DAT1, DAT2 or DAT3].

32.7.3.4 SDMMC2

These settings are specific to the SDMMC2 controller:

- Software should run auto-calibration procedure to setup proper driver for SD/eMMC interface before doing any transfers. Auto-calibration procedure determines and programs drive codes of pads, if it passes.
- If auto-calibration procedure fails due to some unknown reason, the following drive strength codes need to be programmed for the pads. Software should clear AUTO_CAL_ENABLE in SDMMCAA_AUTO_CAL_CONFIG_0 register to use calibration codes programmed in below registers and bypass calibration controller.

  UP - APB_MISC_GP_EMMC2_PAD_CFGPADCTRL_0_ CFG2TMC_EMMC2_PAD_DRVUP_COMP = 0x10

  DN - APB_MISC_GP_EMMC2_PAD_CFGPADCTRL_0_ CFG2TMC_EMMC2_PAD_DRVDN_COMP = 0x10
- SDMMC_SDMEMCOMPPADCTRL_0_SDMMC2TMC_CFG_SDMEMCOMP_VREF_SEL = 0x7
- SDMMC_AUTO_CAL_CONFIG_0_AUTO_CAL_ENABLE_ENABLED
- SDMMC_AUTO_CAL_CONFIG_0_AUTO_CAL_PD_OFFSET = 8’h5
- SDMMC_AUTO_CAL_CONFIG_0_AUTO_CAL_PU_OFFSET = 8’h5
- Ensure that the SDMMC2_COMP pad is connected to GND via 50 ohm resistor on board.
- DRV_TYPE_DRIVE2X and 50 Ohm calibration resistor are used to get drive strength codes for 50 ohm driver. This is Tegra specific implementation.
- SDMMC2 controller uses EMMC IOBRICK which is not shared with any other controller. If using the SDMMC2 controller’s external interface with eMMC or SDIO, correctly enable the integrated pullup/down resistors.
- E_INPUT and E_LPBK for SDMMC2 CLK pin should be enabled to provide loopback CLK for SDMMC2 Rx. If disabled, reads to SD/eMMC device won’t work.

  APB_MISC_GP_EMMC2_PAD_CFG_CONTROL_0_EMMC2_PAD_E_DEEP_LPBK_CLK = 1’b1

  APB_MISC_GP_EMMC2_PAD_CFG_CONTROL_0_ EMMC2_PAD_E_INPUT_CLK = 1’b1

32.7.3.5 SDMMC3

These settings are specific to the SDMMC3 controller:

- Software should run auto-calibration procedure to setup proper driver for SD/eMMC interface before doing any transfers. Auto-calibration procedure determines and programs drive codes of pads, if it passes.
- If auto-calibration procedure fails due to some unknown reason, the following drive strength codes need to be programmed for the pads. Software should clear AUTO_CAL_ENABLE in SDMMC_AUTO_CAL_CONFIG_0 register to use calibration codes programmed in below registers and bypass calibration controller.

Supply	33 Ohm	50 Ohm
	Up DN	Up DN
3.3V	12 12	8 8
1.8V	11 15	3 4

DRV UP code - APB_MISC_GP_SDMMC3_PAD_CFGPADCTRL_0_CFG2TMC_SDMMC3_PAD_CAL_DRVUP

DRV DN code - APB_MISC_GP_SDMMC3_PAD_CFGPADCTRL_0_CFG2TMC_SDMMC3_PAD_CAL_DRVDN

- APB_MISC_GP_SDMMC3_PAD_CFGPADCTRL_0_CFG2TMC_SDMMC3_CLK_CFG_CAL_DRVUP_SLWF = 0x1

- SDMMC_SDMEMCOMPPADCTRL_0_SDMMC2TMC_CFG_SDMEMCOMP_VREF_SEL = 0x7
- SDMMC_AUTO_CAL_CONFIG_0_AUTO_CAL_ENABLE_ENABLED
- For 3.3V operation:
  - SDMMC_AUTO_CAL_CONFIG_0_AUTO_CAL_PD_OFFSET = 8’d125
  - SDMMC_AUTO_CAL_CONFIG_0_AUTO_CAL_PU_OFFSET = 8’d0
- For 1.8V operation:
  - SDMMC_AUTO_CAL_CONFIG_0_AUTO_CAL_PD_OFFSET = 8’d123
  - SDMMC_AUTO_CAL_CONFIG_0_AUTO_CAL_PU_OFFSET = 8’d123
- E_INPUT and E_LPBK for SDMMC3 CLK pin should be enabled to provide loopback CLK for SDMMC3 Rx. If disabled, reads to SD/eMMC device won’t work.
  - APB_MISC_GP_SDMMC3_CLK_LPBK_CONTROL_0_SDMMC3_CLK_PAD_E_LPBK = 1’b1
  - PINMUX_AUX_SDMMC3_CLK_0_ E_INPUT_ ENABLE
- If using the SDMMC3 interface, correctly enable the integrated pullup/down resistors there:
  - PINMUX_AUX_SDMMC3_CLK_0_PULL_UP_NORMAL
- If using eMMC (a stronger external 4.7 kOhm pull-up is used on the CMD line):
  - PINMUX_AUX_SDMMC3_CMD_0_PULL_UP_NORMAL
- If using SD or SDIO:
  - PINMUX_AUX_SDMMC3_CMD_0_PULL_UP_PULL_UP
  - PINMUX_AUX_SDMMC3_DAT3_0_PUPD_PULL_UP
  - PINMUX_AUX_SDMMC3_DAT2_0_PUPD_PULL_UP
  - PINMUX_AUX_SDMMC3_DAT1_0_PUPD_PULL_UP
  - PINMUX_AUX_SDMMC3_DAT0_0_PUPD_PULL_UP
- Select 33 ohm driver for SDMMC3 interface.
  - PINMUX_AUX_SDMMC3_CLK_0_ DRV_TYPE_ DRIVE_2X
  - PINMUX_AUX_SDMMC3_CMD_0_ DRV_TYPE_ DRIVE_2X.
  - PINMUX_AUX_SDMMC3_DAT0_0_ DRV_TYPE_ DRIVE_2X.
  - PINMUX_AUX_SDMMC3_DAT1_0_ DRV_TYPE_ DRIVE_2X.
  - PINMUX_AUX_SDMMC3_DAT2_0_ DRV_TYPE_ DRIVE_2X.
  - PINMUX_AUX_SDMMC3_DAT3_0_ DRV_TYPE_ DRIVE_2X.
- Ensure that the SDMMC3_COMP pad is connected to GND via 66 Ohm resistor on board.
- DRV_TYPE_DRIVE2X and 66 ohm calibration resistor are used to get drive strength codes for 33 ohm driver. This is Tegra specific implementation.
- Schmitt trigger selection for CLK/CMD/DAT pads
  - PINMUX_AUX_SDMMC3_xxxx_0_ E_SCHMT_ENABLE for 1.8V I/O - provides better duty cycle - low jitter clock
  - PINMUX_AUX_SDMMC3_xxxx_0_ E_SCHMT_DISABLE for 3.3V I/O

[xxxx = CLK, CMD, DAT0, DAT1, DAT2 or DAT3].

- E_HSM selection for CLK/CMD/DAT pads
  - PINMUX_AUX_SDMMC3_xxxx_0_ E_HSM_DISABLE for both 3.3V and 1.8V I/O

    [xxxx = CLK, CMD, DAT0, DAT1, DAT2 or DAT3].

32.7.3.6 SDMMC4

These settings are specific to the SDMMC4 controller:

- Software should run auto-calibration procedure to setup proper driver for SD/eMMC interface before doing any transfers. Auto-calibration procedure determines and programs drive codes of pads, if it passes.
- If auto-calibration procedure fails due to some unknown reason, the following drive strength codes need to be programmed for the pads. Software should clear AUTO_CAL_ENABLE in SDMMCAB_AUTO_CAL_CONFIG_0 register to use calibration codes programmed in below registers and bypass calibration controller.
  - UP - APB_MISC_GP_EMMC4_PAD_CFGPADCTRL_0_CFG2TMC_EMMC4_PAD_DRVUP_COMP = 0x10
  - DN - APB_MISC_GP_EMMC4_PAD_CFGPADCTRL_0_CFG2TMC_EMMC4_PAD_DRVDN_COMP = 0x10
- SDMMC_SDMEMCOMPPADCTRL_0_SDMMC2TMC_CFG_SDMEMCOMP_VREF_SEL = 0x7
- SDMMC_AUTO_CAL_CONFIG_0_AUTO_CAL_ENABLE_ENABLED
- SDMMC_AUTO_CAL_CONFIG_0_AUTO_CAL_PD_OFFSET = 8’h5
- SDMMC_AUTO_CAL_CONFIG_0_AUTO_CAL_PU_OFFSET = 8’h5
- Ensure that the SDMMC4_COMP pad is connected to GND via 50 ohm resistor on board.
- DRV_TYPE_DRIVE2X and 50 ohm calibration resistor are used to get drive strength codes for 50 ohm driver. This is Tegra specific implementation.
- SDMMC4 controller uses EMMC IOBRICK which is not shared with any other controller. If using the SDMMC4 controller’s external interface with eMMC or SDIO, correctly enable the integrated pullup/down resistors.
- E_INPUT and E_LPBK for SDMMC4 CLK pin should be enabled to provide loopback CLK for SDMMC4 Rx. If disabled, reads to SD/eMMC device won’t work.
- APB_MISC_GP_EMMC4_PAD_CFG_CONTROL_0_EMMC4_PAD_E_DEEP_LPBK_CLK = 1’b1
- APB_MISC_GP_EMMC4_PAD_CFG_CONTROL_0_ EMMC4_PAD_E_INPUT_CLK = 1’b1

32.7.4 SDR50 Mode Workaround for Avoiding Read CRC Errors

The SDMMC controller DMA buffer may become full during read data transfer and trigger an SD card clock stopping during block transfer (clock stopping is the flow control mechanism defined on SD interface). In SDR50 mode, this intra-block SD card clock stopping may cause the SDMMC controller to misalign the received data and result in a read CRC error.

The failure occurs only if:

1. Intra-block SD clock stopping occurs AND
2. The trimmer tap value selected for SDR50 read data receiver clock is more than one UI (one SD clock cycle). This issue is present only in SDR50 mode. Only SD/SDIO devices are affected with this issue. eMMC is not affected.

32.7.4.1 Software Workaround

Set UHS_MODEL_SEL to SDR104 in the SDMMC controller even though the SD/SDIO card is in SDR50 mode. This enables inter-block clock stopping in the SDR50 mode which prevents CRC errors.

32.8 Programming Guidelines for eMMC HS400/HS667 Mode

This section provides HS400/HS533/HS667 mode programming guidelines. This mode is eMMC specific mode and supported by only SDMMC2 and SDMMC4 controllers.

32.8.1 HS400 and HS667 Mode Selection

The software driver community is using SD host specification for developing eMMC driver. Tegra X1 SDMMC supports HS400 and HS667 speed modes for devices which support eMMC5.0 specification and beyond. But the SD host specification does not have support for these modes. Our SD/eMMC host controller uses RSVD fields of UHS_MODE_SEL to enable HS400 and HS667 modes which adheres to SD specification compliance.

Software driver should program UHS_MODE_SEL as per below to select appropriate speed modes.

32.8.1.1 Host Control2 Register / Auto CMD Error Status Register

UHS_MODE_SEL - UHS Mode Select

- 000b SDR12/eMMC LEGACY SPEED
- 001b SDR25/eMMC HIGH SPEED SDR
- 010b SDR50
- 011b SDR104 (SD/SDIO)/HS200(eMMC)
- 100b DDR50 (SD/SDIO)/HIGH SPEED DDR (eMMC)
- 101b HS400(eMMC)/HS667(eMMC)
- 111b UHS2
- 111b Reserved

32.8.2 Clock Divider Programming in HS400/667 Modes

SDCLK Frequency Select should be set to ‘0’ in HS400/HS667 modes. No other divisors are supported.

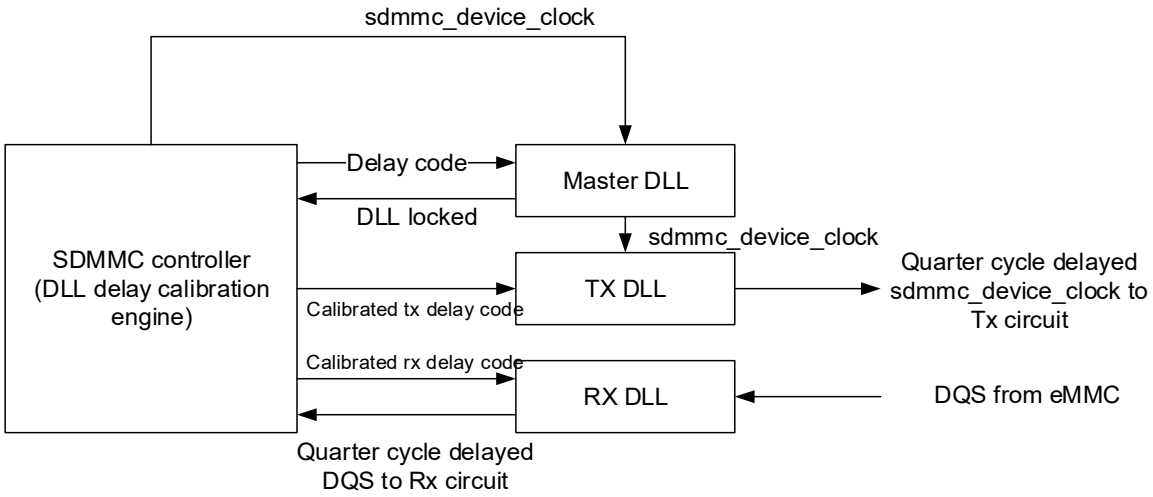
For example, to get 333 I/O clock frequency, sdmmc_clk should be running at 333 MHz only. That means both I/O and controller should be running at same clock frequency in HS400/HS667 modes.

32.8.3 DLL Calibration

HS400/533 transmitter and receiver circuit uses a pair of DLLs (Tx DLL and Rx DLL) to delay tx/rx clock by quarter cycle. Quarter cycle delay is needed as per our HS400 implementation. DLL is a mixed signal circuit whose delay code should be programmed to get quarter cycle delay. DLL delay code varies based on Si process and frequency of clock used. So, we use a Master DLL for calibration to get delay code required for getting quarter cycle delay at given frequency of operation. SD/MMC controller has DLL calibration controller which sends delay code in iterative fashion to Master DLL and gets feedback from it. As per the feedback received from Master DLL per applied delay code, DLL calibration controller determines the delay code needed to get quarter cycle delay. Hardware applies the determined code to both Tx and Rx DLLs and turns off Master DLL. This ends DLL calibration process.

Below diagram shows DLLs present in SD/MMC subsystem.

Figure 153: DLLs in SD/MMC Subsystem



Software needs to calibrate DLL before using eMMC5.0 HS400/HS667 mode (before tuning process). Re-calibration is required whenever eMMC I/O clock frequency is changed. This can be done as a part of standard clock frequency change sequence.

Points to note:

- DLL calibration should work at when target I/O CLK is running at ~200 (180 to 200) MHz and above.
- For Target I/O CLK frequency is below 180 MHz, software should calculate delay code as per below equation and program delay code:
  - Delay Code = (Delay Code at 200 MHz) * 200 MHz / Target I/O Frequency
  - Delay code at ~200 MHz is determined by running DLL calibration and the same is available for software in below RO registers.
    - Tx DLL: SDMMCxx_VENDOR_DLLCAL_CFG_STA_0_ TX_DLY_CODE_ADJ
    - Rx DLL: SDMMCxx_VENDOR_DLLCAL_CFG_STA_0_ RX_DLY_CODE_ADJ
- Under 85 MHz, DLL delay code may reach its maximum code (128 taps) for FF corner chips. In this case, software should use 128 taps.
- Software can run DLL calibration at 200 MHz once at boot time, save those values, scale and use them whenever frequency is changed. This is needed if software wants to do DFS (Dynamic Frequency Scaling).
- Program calculated delay code by writing into below registers:
  - Set SDMMCAB_VENDOR_DLL_CTRL0_0_ DLLCAL_BYPASS with 0x1 to bypass DLL calibration.
  - Set SDMMCAB_VENDOR_DLL_CTRL0_0_ TX_SLV_DLL_DLY_CODE with delay code calculated in above step.
  - SDMMCAB_VENDOR_DLL_CTRL0_0_ RX_SLV_DLL_DLY_CODE with delay code calculated in above step.
- PROD setting:
  - *ONLY* for HS533 mode at 266 MHz the following setting should be used to improve setup/hold time margins:

    TX_DLL_OFFSET = -4 (decimal negative four) = 0x7C

    (HS400 mode at 200 MHz or lower doesn't need the above setting)
  - Register field SDMMCxx_VENDOR_DLL_CTRL0_0_TX_DLY_CODE_OFFSET should be programmed with above value in two’s complement format.

32.8.4 Software Programming Sequence for Executing DLL Calibration

- Set SDMMCxx_VENDOR_IO_TRIM_CNTRL_0_SEL_VREG to 0x0 to select Band Gap VREG to supply DLL. If it is 0x1, set it to 0x0 and follow guidelines mentioned in Section 32.8.3: DLL Calibration before triggering DLL calibration process.

- Write DLL CAL CFG registers -
  - SDMMCAB_VENDOR_DLLCAL_CFG_0,
  - SDMMCAB_VENDOR_DLL_CTRL0_0,
  - SDMMCAB_VENDOR_DLL_CTRL1_0 and SDMMCAB_VENDOR_DLLCAL_CFG_STA_0 to update various control parameters, if software wants to override default values. It is strongly recommended to use default values for DLL calibration.
- Software can choose either using software timer (5 ms) or END_COUNT for stopping calibration.
- Program END_COUNT field in register SDMMCAB_VENDOR_DLLCAL_CFG_STA0_0 or maintain software timer for DLL lock time (5 ms). Default value of END_COUNT is sufficient.
- Set CALIBRATE bit in register SDMMCAB_VENDOR_DLLCAL_CFG_STA0_0 to trigger calibration process.
- If END_COUNT is set to zero, software should stop calibration by clearing CALIBRATE bit once software timer expires. Else poll for CALIBRATE = 0 (hardware clears it once it sees end of calibration condition.)
- Poll for CAL_ACTIVE=0 to see if calibrated delay code is applied to slave DLLs. DLL calibration process may take up to 10 ms.
- Software can exit DLL calibration loop after this and can start tuning process.

32.8.5 DLL and Inbound Clock Trimmer Power Supply (VREG) Programming

- Inbound clock trimmer is used to delay loopback clock to sample incoming data and command response in SDR50, SDR104, and HS200. Inbound clock trimmer is also used in HS400 without enhanced strobe mode for command response).
- DLL is used in HS400 receiver to latch incoming data and command response when enhanced strobe mode is enabled.
- Delay chain in trimmer and DLL have two power supplies.
  - Regulated power supply (VREG) from Band gap (BG) reference circuit which is a constant power supply has almost zero variation with VDD_CORE changes. This is the recommended power supply for both trimmer and DLL.
  - VDD_CORE/VAUXC is another option. This one is used when BG circuit is turned off in idle state to save power. Software should not use this during transfers as it causes drift in trimmer and DLL delay with VDD_CORE/VAUXC change.
- Software should use BG power supply to power both trimmer and DLL to make delay produced by internal delay chain invariant to Vcore changes.
  - By default, VDD_CORE/VAUXC (core power supply) is used as trimmer/DLL power supply which saves power by turning off Band gap regulator supply (BG). Software should set SDMMCxx_VENDOR_IO_TRIM_CNTRL_0_SEL_VREG to 0x0 in all speed modes to select VREG as trimmer power supply which makes trimmer delay independent of VDD_CORE.
- Software should follow below sequence for switching power supply from VDD_CORE/VAUXC to BG.
  - Make sure SDMMC is idle – no activity on SD/eMMC interface.
  - Turn off SD interface clock.
  - Program SDMMCxx_VENDOR_IO_TRIM_CNTRL_0_SEL_VREG with 0x0 to turn ON BG supply.
  - BG circuit power up time is ~3 us. Wait for 3 us to make sure BG supply is stabilized.
  - Both DLL and inbound clock trimmer are powered using BG supply and their output could glitch with this power supply switching to/from BG from/to VAUXC/VDD_CORE. This glitch can happen irrespective of input clock/DQS state which would cause disturbance in downstream Rx logic which in turn affects data transfers later on.
  - To prevent errors on interface due to DLL/trimmer output glitch, software driver should reset host controller by issuing both SW_RESET_DAT and SW_RESET_CMD (sequence should be followed as per SD host specification) before starting any new transfers.

- Software can choose to switch back to VAUXC from BG to turn OFF Band gap regulator to save power when eMMC/SD interface is idle. But software should switch back to BG before starting new transfers and follow above sequence for VAUXC to BG switching.

NOTE (informative):

DLL output glitch (not trimmer glitch) can be avoided by following below steps:

- Program below register fields first before switching power supply from/to BG to/from VAUXC.
  - SDMMCAB_VENDOR_DLLCAL_CFG_STA_0SLV_DLL_CLK_OUT_DIS_OVERRIDE_EN = 0x1
  - SDMMCAB_VENDOR_DLLCAL_CFG_STA_0SLV_DLL_CLK_OUT_DIS = 0x1
- Wait for 32 SDMMC clock cycles after power supply switching (above sequence).
- Clear override SLV_DLL_CLK_OUT_DIS_OVERRIDE_EN to give control to DLL calibration engine.
- This sequence can be used to clamp DLL output to zero whenever there is change in DLL controls.

- This sequence can help avoiding DLL glitch but not trimmer glitch. Software has to issue SW_RESET to recover from bad state due to trimmer glitch. To make fix simple and reduce software overhead, we suggest software to issue SW_RESET only to recover from DLL and trimmer glitch issues whenever there is a change in DLL and trimmer power supply.

32.8.6 HS400 Mode Guidelines

32.8.6.1 Software Programming Sequence for Entering into HS400 Mode

Refer to the eMMC5.1 specification for HS400 mode selection.

32.8.6.2 Software Programming Sequence for Changing the Frequency in HS400 Mode

- Follow the clock stop sequence defined in SD host software sequence chapter.
- Change the SDMMC Clk Frequency.
- SDCLK turn ON sequence.
- Perform DLL calibration.
- Configure device in HS400 mode.
- Set HS400 mode in the controller.

32.8.7 Clock Trimmer Settings

32.8.7.1 IB and OB Trimmer Tap Value Setting

Software should select proper tap values for:

- Outbound clock trimmer - SDMMC_VENDOR_CLOCK_CNTRL_0_TRIM_VAL and
- Inbound clock trimmer - SDMMC_VENDOR_CLOCK_CNTRL_0_TAP_VAL to prevent data/cmd CRC errors.

Note: *Trimmer settings depend on speed mode used. Program as per the tables below.*

Inbound Tap Values (SDMMC_VENDOR_CLOCK_CNTRL_0_TAP_VAL)

The tap values below can be used up to SDR25/DDR50 and HIGH SPEED DDR (eMMC) speeds (Frequency <= 52 MHz).

(Trace length = 0.45 ns for SDMMC2 and SDMMC4 and 0.75 ns for SDMMC1 and SDMMC3.)

Controller	Tap Value for I/O trimmer (default)	Tap Value for Core Trimmer (If SDMMC_VENDOR_SYS_SW_CNTRL_0_IO_TRIM_BYPASS is set to 1)
SDMMC1	4	3
SDMMC2	0	3
SDMMC3	3	3
SDMMC4	0	3

Notes:

- *These tap values work only up to 48 MHz in DDR50 mode for SDMMC1 and SDMMC3. Software should use SDR50, if it needs to run I/O at 50 MHz for SDMMC1 and SDMMC3.*
- *Tunable modes: Software should use tuning procedure to determine the tap value in SDR50 and SDR104/HS200 modes.*

Outbound Tap Values (SDMMC_VENDOR_CLOCK_CNTRL_0_TRIM_VAL)

Below settings are valid in all speed modes.

Controller	Tap Value
SDMMC1	2
SDMMC2	8
SDMMC3	3
SDMMC4	8

DQS Trimmer Tap Values (SDMMC_VENDOR_CAP_OVERRIDES_0_ DQS_TRIM_VAL)

HS400 (<=200 MHz):.

Controller	Tap Value
SDMMC1	N/A
SDMMC2	40
SDMMC3	N/A
SDMMC4	40

HS533/667 (>200 MHz and <=333 MHz):

Controller	Tap Value
SDMMC1	N/A
SDMMC2	24
SDMMC3	N/A
SDMMC4	24

32.8.8 Pad Control Programming for SDMMC1/SDMMC3 to Avoid Pad Damage

- In Tegra X1, PWT_DET cells are removed for non-bootable interfaces. software should set PWR_DET value appropriately by programming PMC register whenever Vio is changed from 3.3V to 1.8V and vice versa.
- SDMMC1 and SDMMC3 use BDSDMEM pads which are capable of supporting both 3.3V and 1.8V I/O. 3.3V would be selected on PWR_ON.

- Before ramping up to 3.3V on VDDIO_SDMMC1/SDMMC3 rails, pad voltage must be set correctly. Set PWR_DET_VAL_0 = 1 and SDMMCx_SDMEMCOMPPADCTRL_0_PAD_E_INPUT_OR_E_PWRD = 1. Not doing so can damage the I/O PADS and result in higher leakage.
  - PWR_DET_VAL=1 => Enable E_33V for 3.3V I/O voltage
  - PWR_DET_VAL=0 => Disable E_33V for 1.8V I/O voltage
  - Pad damage may occur if PWR_DET_VAL = 0 when VDDIO_SDMMC = 3.3V.
  - PMC register:
    - APBDEV_PMC_PWR_DET_VAL_0_SDMMC3 for SDMMC3
    - APBDEV_PMC_PWR_DET_VAL_0_SDMMC1 for SDMMC1

32.8.8.1 Software Sequence for SD Card

On Cold boot / Card Insertion (via GPIO interrupt) / LP0 resume:

- VDDIO_SDMMC1 or VDDIO_SDMMC3 is tuned OFF.
- Set PAD_E_INPUT_OR_E_PWRD = 1 of SDMMCx_SDMEMCOMPPADCTRL_0[31] to avoid leakage power and pad damage.
- Set PWR_DET_VAL = 1 (Enable E_33 V)
- Turn on 3.3V slot power at SD Card Slot
- Turn on VDDIO_SDMMC 3.3V I/O at Tegra
- Leave PAD_E_INPUT_OR_E_PWRD =1 until auto_calibration is completed for 3.3 V level.
- Clear PAD_E_INPUT_OR_E_PWRD =0 when auto_calibration is completed
- Initialization sequence
- If card support UHS-1 modes issue voltage switch command
- Change I/O Voltage from 3.3V to 1.8V
- Set PWR_DET_VAL = 0 (Disable E_33 V)

On Card removal (via GPIO interrupt):

- Enable GPIO mode and output "1" on the entire SDMMC bus (CLK, CMD, DAT3, DAT2, DAT1, and DAT0).
- Shutdown the VDDIO_SDMMC rail
- Shutdown the SDMMC slot power (3.3V supply)
- Set SDMMCx in APBDEV_PMC_NO_IOPOWER_0 as SDMMCx interface is shutdown
- Set E_33V = 0 via PWR_DET_VAL = 0
- Set E_33V = 1 (default POR) via PWR_DET_VAL = 1
- Disable GPIO mode and set pinmux to POR values

32.8.8.2 Software Sequence for SDIO

For 1.8V SDIO: Set PWR_DET_VAL = 0 (Disable E_33V) always.

32.8.9 SDR50/SDR104/HS200 Tuning Procedure

32.8.9.1 Vendor Registers Programming Before Executing Tuning Procedure

- SDMMC_VENDOR_IO_TRIM_CNTRL_0_SEL_VREG should be set to 0x0 to select VREG as trimmer power supply which makes trimmer delay independent of VDD_CORE. By default, VDD_CORE is used as trimmer power supply

which saves power by turning off BG+REG. For switching power supply, software should guidelines mentioned in Section 32.8.5: DLL and Inbound Clock Trimmer Power Supply (VREG) Programming.

- SDMMC_VENDOR_SYS_SW_CNTRL_0_ IO_TRIM_BYPASS should be set to 0x0 (default value).
- Set SDMMC_VENDOR_TUNING_CNTRL0_0_ NUM_TUNING_ITERATIONS based on speed mode selected.
  - TRIES_256 for SDR50 mode
  - TRIES_128 for SDR104 mode
  - TRIES_128 for HS200 and HS400 modes
  - TRIES_64 for HS533 and HS667 modes
- Set SDMMC_VENDOR_TUNING_CNTRL1_0_ STEP_SIZE_SDR104_HS200 with 0x0
- Set SDMMC_VENDOR_TUNING_CNTRL1_0_ STEP_SIZE_SDR50 with 0x0

32.8.9.2 Tuning Procedure

1. Make sure SDCLK is running at desired frequency as per speed mode selected for future data transfers.
2. Set HostControl2.ExecuteTuning = 1
3. Set ClockControl.SDClockEnable = 0 to stop SDCLK
4. Issue Tuning command (CMD19 for SD/SDIO or CMD21 for eMMC) as per CMD issuing sequence defined in SD host specification.
5. Wait for 1 us
6. Issue SW_RESET_FOR_DAT_LINE && SW_RESET_FOR_CMD_LINE by programming SDMMC_SW_RESET_TIMEOUT_CTRL_CLOCK_CONTROL_0 register.
7. Wait for SW_RESET for both CMD and DAT lines to complete.
8. Set ClockControl.SDClockEnable = 1 to enable SDCLK
9. Wait until BufferReadReady is 1
10. Check ExecuteTuning:

    if 0: Go to STEP 11
    if 1: Go back to STEP 3
11. Check SamplingClockSelect:

    if 0: Tuning Failure
    if 1: Tuning Success
12. Now Host is ready for data transfers.

Note: *In tunable modes, hardware tuning engine sets trimmer tap value but in non-tunable modes (during speed mode change or LP0 exit or DFS), software driver has to update trimmer tap value manually. In that case also, SW_RESET should be issued to host to reset internal logic.*

32.8.9.3 Post Tuning Procedure

When connected to devices that drive fast edges, the SOC SDMMC controller may not be able to detect a failing tap between two valid windows during tuning. This causes the SDMMC controller to set a marginal inbound tap delay which is at the middle of two merged valid windows. This can result in data or command CRC during SDMMC transactions. This affects all the tunable SDMMC speed modes (SDR50, SDR104, HS200, and HS400 without enhanced strobe mode). As an issue workaround, it is recommended that software implement a post-tuning function after tuning is completed and to apply the correct tap value when a merge window is detected. Refer to the “SDMMC Tuning Update” application note for details.

32.8.9.4 Tuning Bug Workaround

As a part of a workaround, the trimmer input clock is stopped during tap value change which would avoid output to glitch in most cases. In some Vreg and Vcore combinations and at high frequencies, the trimmer may glitch even though the input clock is not running when the tap value is changed.

To nullify the effect of a glitch on downstream logic which uses the trimmer output clock, issue a SW_RESET to clear the data pipeline after the tap value is changed.

Workaround Sequence for Tuning

STEP_SIZE used for the tuning process should be set to 0x1 (register value is 0x0) for this workaround.

- Stop SD/eMMC device clk which would gate input clk to trimmer.
- Issue Tuning Command to Host controller (this would trigger trimmer tap value update)
- Wait for 1 us - trimmer output uncertainty period – trimmer output could glitch and corrupt downstream logic.
- Recover from bad state caused by trimmer glitch by issuing SW_RESET for both CMD and DAT circuits.
  - Issue software reset for DAT Line and software reset for CMD line in Software Reset register to 1.
  - Wait for SW_RESET for both CMD and DAT lines to complete.
- Start SD/eMMC (SDCLK) device clk
- Wait for buffer_read_ready=1 (Tuning command completion interrupt)
- Go back to step 1 if tuning process is not done.

Workaround for Other Scenarios

SW_RESET should be issued whenever software changes trimmer tap value during speed mode change or LP0 exit or DFS.

Number of Tuning Iterations

As per the software workaround, software should use 256 tuning iterations for scanning all 256 taps of trimmer. But it is not needed for every I/O speed mode. Software can use fewer iterations based on speed mode selected (I/O clock frequency) to reduce tuning time. Below register field should be written with appropriate value per speed mode.

SDMMC_VENDOR_TUNING_CNTRL0_0 (Vendor Tuning Control0 register), Offset: 0x1c0

15:13	TRIES_40	NUM_TUNING_ITERATIONS:The number of tuning iterations to be used by tuning circuit; Preferred value is 40 iterations as per Host specification. 0 = TRIES_40 1 = TRIES_64 (for HS533 and HS667 modes) 2 = TRIES_128 (for SDR104, HS200, and HS400 modes) 3 = TRIES_192 4 = TRIES_256 (for SDR50 mode)

32.8.10 Pad Drive Strength Calibration Sequence

SDMMC controller pads need calibration to set proper drive strength for 33 ohm (SDMMC1/3) / 50 ohm (SDMMC2/4) driver. Calibration process uses a dedicated calibration pad which is connected to a 66 ohm (SDMMC1/3) / 50 ohm (SDMMC2/4) resistor to ground. Pad control DRV_TYPE is should select DRIVE2X to get 33 ohm/ 50 ohm driver codes using 66 ohm / 50 ohm calibration resistor. This is a Tegra specific implementation. Programming details are given in initialization sequence.

32.8.10.1 Drive Strength Calibration Process

In order to maintain a constant drive strength of 33/50 ohms for SD or eMMC interface, Tegra X1 uses an additional calibration pad (SDMMCxx_COMP_PD), which have the same driver as the other pads, to account for

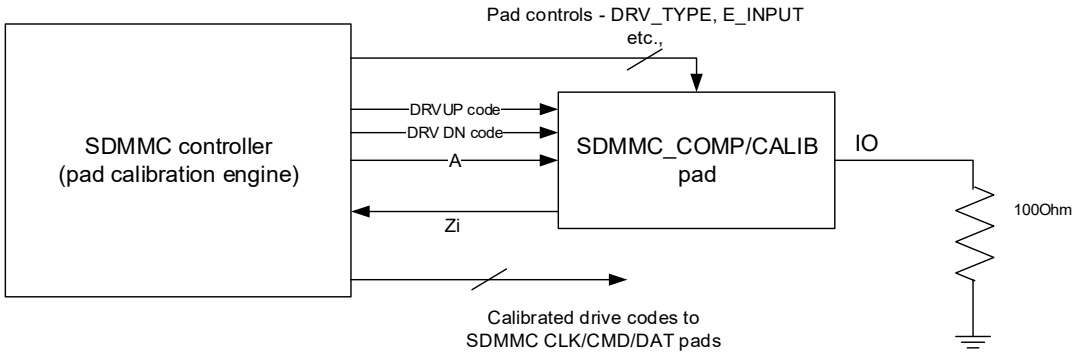
1. Process, Voltage and Temperature (PVT) variations - resistor calibration is done once during boot.
2. Temperature Drifts, resistor calibration needs to be done when pads are idle and dynamically

For this, SDMMC implements resistor calibration registers. The calibration can either be done manually by the Host Driver or SDMMC can do Auto Calibration. The basic idea is to keep increasing the voltage and identifying the correct level for driving a 1 and a 0 since PVT/Temperature will vary the drive impedance. This is done with the help of an external precise calibration resistor which is connected to the COMP_PD pad and ground.

Within the calibration pads, the drive codes are incremented in steps which, in turn, increase the voltage level on the COMP_PU and decreases the voltage levels on COMP_PD. An internal comparator compares the voltage with a reference voltage and drives a 1 on a match. At this point, the values on the DRVUP/DN values of the comp pads are sampled and programmed into the other pads.

Below diagram shows calibration circuit.

Figure 154: Calibration Circuit



32.8.10.2 Calibration Software Sequence

This section provides drive strength calibration sequence details. This sequence is required during initialization or switching frequencies or periodic intervals depending on the platform usage scenario. Ensure that the SD/eMMC device clock (SDCLK) is off during calibration procedure.

- Set up proper reference voltage as per the SDMMC port as described in Section 32.8.7: Clock Trimmer Settings.
- Set E_INPUT_OR_E_PWRD = 1 in SDMMCxx_SDMEMCOMPPADCTRL_0 register.
- Wait for 1us after E_INPUT_OR_E_PWRD is enabled.
- Set AUTO_CAL_START and AUTO_CAL_ENABLE to 1 in SDMMCxx_AUTO_CAL_CONFIG_0 register.
- Wait for 1 us.
- Wait for up to 10 ms for AUTO_CAL_ACTIVE in SDMMCxx_AUTO_CAL_STATUS_0 register to become 0. If it is not 0 after 10 ms, software can assume auto-calibration has timed out. If it becomes zero within 10 ms, it is assumed that calibration has completed.
- Clear E_INPUT_OR_E_PWRD to save power.
- Software should not clear AUTO_CAL_ENABLE in SDMMCxx_AUTO_CAL_CONFIG_0 register after calibration. It should be set to 1 always to use calibration codes generated by calibration controller.
- If software timeout occurs during calibration process, software should program drive strength up/down static values as described in the Run Auto-Calibration section. Software should clear AUTO_CAL_ENABLE in SDMMCxx_AUTO_CAL_CONFIG_0 register to use calibration codes programmed in APB_MISC_GP* registers and bypass calibration controller.

32.8.10.3 Pseudo Code for Calibration

1. auto_calibration() {
2. e_input = (*SD_SDMEMCOMPPADCTRL >> SDMMC_SDMEMCOMPPADCTRL_0_PAD_E_INPUT_OR_E_PWRD_FIELD)&1 ; // read e_input value

3. if(e_input == 0) { // enable e_input if not enabled yet
4. *SD_SDMEMCOMPPADCTRL |= 1 << SDMMC_SDMEMCOMPPADCTRL_0_PAD_E_INPUT_OR_E_PWRD_FIELD; // enable e_input
5. uSecDelay(1) ; } // Wait 1 us after e_input is enabled
6. *SD_AUTO_CAL_CONFIG |= (1<<31) | (1<<29); // enable auto_calibratoin and start it.
7. uSecDelay(1) ; } // Wait 1 us before polling CAL_ACTIVE status
8. while(*SD_AUTO_CAL_STATUS & (1<<31)) {} // wait for auto_calibration completed status
9. if(DISABLE_E_INPUT_AFTER_CALIB)
10. *SD_SDMEMCOMPPADCTRL &= ~(1 << SDMMC_SDMEMCOMPPADCTRL_0_PAD_E_INPUT_OR_E_PWRD_FIELD); }
11. Re-run calibration as per the conditions mentioned in the previous section.

32.8.11 eMMC Boot Modes

The section of this document on the boot process describes the boot process in more detail. Note that only the SDMMC4 controller can be used as the eMMC boot device.

32.8.12 Boot Option1

1. The clock to the card needs to be configured to 26 MHz.
2. Program the number of blocks. Configuring block length has no effect; it is always fixed to 512 bytes.
3. Configuring the data transfer direction has no impact, since it taken as CARD to HOST for boot mode.
4. Select either SDMA or PIO mode.
5. Configure SDMMC_VENDOR_BOOT_ACK_TIMEOUT_0 – The maximum timeout value that needs to be programmed is 50ms.The value programmed should exclude the 74 cycles that are required to enter boot mode.
6. Configure SDMMC_VENDOR_BOOT_DAT_TIMEOUT_0 – The maximum timeout value that needs to be programmed is 1 second. The value programmed should exclude the 74 cycles that are required to enter boot mode.
7. Configure SDMMC_VENDOR_BOOT_CNTRL_0[1] to 1 to ask the engine to look for boot_ack.
8. Configure SDMMC_VENDOR_BOOT_CNTRL_0[0] to trigger the engine.
9. If SDMMC_INTERRUPT_STATUS_0[31] = 1,the BOOT_ACK is not equal to 00101.The engine just informs the software and continues to fetch data from the card.
10. If SDMMC_INTERRUPT_STATUS_0[30] = 1, the BOOT_ACK timeout has occurred. The engine just informs the software and continues to fetch data from the card.
11. The software should look for transfer complete interrupt. If “data_time_out” error has occurred, then the data transfer is not successful.
12. After successful data transfer from card, the software should look for “sdma_engine_busy” bit of SDMMC_OBS_SDMMC_DBG0_0[0]. Software shouldn’t program commands until this bit is zero.

32.8.13 Boot Option2

Boot option2 is treated like any normal read command. The BOOT_ACK should be enabled if the card supports boot acknowledgment. SDMMC_VENDOR_BOOT_ACK_TIMEOUT_0 and SDMMC_VENDOR_BOOT_DAT_TIMEOUT_0 should be programmed based on the frequency of operation.

32.8.14 Card Detect and Write Protect

Only SDMMC1 and SDMMC3 support removable SD cards. The standard SD Host, SDCD# pin act as card detect pin and CDWP# pin act as Write protect pin. The SD Card State registers can be ignored for embedded on-board devices.

PIN MUX detail for CD and WP pins for SDMMC1 and SDMMC3.

PINMUX_AUX_SDMMC1_WP_N_0_PUPD_PULL_UP

PINMUX_AUX_KB_COL4_0_PUPD_PULL_UP - This is the Pinmux option for SDMMC1 CD

PINMUX_AUX_KB_COL4_0_PUPD_PULL_UP - This is the Pinmux option for SDMMC3 WP

PINMUX_AUX_SDMMC3_CD_N_0_PUPD_PULL_UP

Additionally, an abort command should be issued if a card is removed during an SD transfer.

32.8.15 SD3.0 Signal Voltage Switching

Note: *This section is applicable only to the removable-card-capable SDMMC1 and SDMMC3 controllers. The SDMMC2 and SDMMC4 controllers do not require these settings.*

32.8.16 SD Bus Power

When the standard SD driver changes the Power Control Register's SD Bus Power field, the hardware needs assistance from platform software to implement the change via the PMIC.

32.8.16.1 Initialization

Before the standard SD drive begins running:

1. Route the SD/MMC controller's system interrupt to the appropriate driver.
2. Write 1 to SDMMC_VENDOR_SYS_SW_CNTRL_0_SD_BUS_POWER_ON_OFF_INT_STATUS to clear any latent interrupts.
3. Set SDMMC_VENDOR_SYS_SW_CNTRL_0_SD_BUS_POWER_ON_OFF_INT_ENABLE to enable the system interrupt on an SD3.0 UHS-I Bus Power change event.

32.8.16.2 Entry

Once an SD/MMC system interrupt is received:

1. Confirm the SDMMC System interrupt was from a Bus Power change event by reading SDMMC_VENDOR_SYS_SW_CNTRL_0_SD_BUS_POWER_ON_OFF_INT_STATUS.
2. Write 1 to SDMMC_VENDOR_SYS_SW_CNTRL_0_SD_BUS_POWER_ON_OFF_INT_STATUS to clear the interrupt condition.
3. Read SD BUS POWER for VDD1 in POWER CONTROL register to determine the power state change request.

If Bus Power is cleared, power off the SD power supply via the PMIC. Otherwise, if Bus Power is set, power on the SD power supply via the PMIC.

32.8.16.3 Exit

No actions required.

32.9 SD/MMC Registers

Refer to Section 1.4: Reading Register Tables in the Introduction chapter for the register table protocol as well as recommendations for accessing registers.

32.9.1 Standard Registers

Note: *For standard registers' usage, refer to the SD Host Controller Specification version 4.00.*

There are a few vendor-specific register fields within the standard register offset range (0x00 through 0xff). These fields are described below:

32.9.1.1 Interrupt Status Register

Offset: 0x30 | Read/Write: R/W | Reset: 0x00000000 (0b0000000000000000xxxxxxxx00000000)

Bit	Reset	Description
31:30	0	VEND_SPEC_ERR Bit 1: BOOT_ACK_ERR: Occurs when Boot Ack Status is not equal to '010' Bit 0: BOOT_ACK_TIMEOUT_ERR: Occurs when Boot Ack is not received within the programmed number of cycles.

32.9.1.2 Interrupt Status Enable Register

Offset: 0x34 | Read/Write: R/W | Reset: 0x00000000 (0b0000000000000000xxx0xxx000000000)

Bit	Reset	Description
31:30	0	VENDOR_SPECIFIC_ERR 0 = Enable neither BOOT_ACK_ERR nor BOOT_ACK_TIMEOUT_ERR statuses. 1 = Enable only BOOT_ACK_TIMEOUT_ERR status. 2 = Enable only BOOT_ACK_ERR status. 3 = Enable both BOOT_ACK_ERR and BOOT_ACK_TIMEOUT_ERR statuses.

32.9.1.3 Interrupt Signal Enable Register

Offset: 0x38 | Read/Write: R/W | Reset: 0x00000000 (0b0000000000000000xxx0xxx000000000)

Bit	Reset	Description
31:30	0	VENDOR_SPECIFIC_ERR 0 = Enable neither BOOT_ACK_ERR nor BOOT_ACK_TIMEOUT_ERR interrupts to CPU. 1 = Enable only BOOT_ACK_TIMEOUT_ERR interrupt to CPU. 2 = Enable only BOOT_ACK_ERR interrupt to CPU. 3 = Enable both BOOT_ACK_ERR and BOOT_ACK_TIMEOUT_ERR interrupts to CPU.

32.9.1.4 SDMMC_AUTO_CMD12_ERR_STATUS_0

Offset: 0x3c I Read/Write: R/W I Reset: 0x000000XX (0b0000xxx000000000xxxxxxxxxxxxxxxx)

Bit	R/W	Reset	Description
18:16	RW	0x0	UHS_MODE_SEL: UHS Mode Select This field is used to select one of UHS-I modes and effective when 1.8V Signaling Enable is set to 1. If Preset Value Enable in the Host Control 2 register is set to 1, Host Controller sets SDCLK Frequency Select, Clock Generator Select in the Clock Control register and Driver Strength Select according to Preset Value registers. In this case, one of preset value registers is selected by this field. Host Driver needs to reset SD Clock Enable before changing this field to avoid generating clock glitch. After setting this field, Host Driver sets SD Clock Enable again. 000b: SDR12/eMMC LEGACY SPEED 001b: SDR25/eMMC HIGH SPEED SDR 010b: SDR50 011b: SDR104 (SD/SDIO)/HS200 (eMMC) 100b: DDR50 (SD/SDIO)/HIGH SPEED DDR (eMMC) 101b: HS400 (eMMC) When SDR50, SDR104 or DDR50 is selected for SDIO card, interrupt detection at the block gap shall not be used. Read Wait timing is changed for these modes. Refer to the SDIO Specification Version 3.00 for more detail. HS667 is overclocked HS400 mode; Note that tuning should be done in HS200 (reg value=SDR104) mode before entering HS400 or HS667 modes. For HS400 mode: tuning should be in HS200 - SDR at 200 MHz For HS667 mode: tuning should be in HS200 - SDR at 333 MHz - overclocking.

32.9.1.5 Force Event Register

Offset: 0x50 | Read/Write: R/W | Reset: 0x00000000 (0b00000000000000000xxxxxxx0x000000)

Bit	Reset	Description
31:30	0	VENDOR_SPECIFIC_ERR_STATUS 0 = No effect 1 = Force a BOOT_ACK_TIMEOUT_ERR event 2 = Force a BOOT_ACK_ERR event. 3 = Force both BOOT_ACK_ERR and BOOT_ACK_TIMEOUT_ERR events.

32.9.2 SDMMC1 Vendor Registers

32.9.2.1 SDMMCA_VENDOR_CLOCK_CNTRL_0

The following registers are Vendor Specific Registers and are mapped to Vendor Specific Address Space (0x100 - 0x1FF)

Vendor Clock Control Register

Offset: 0x100 I Read/Write: R/W I Reset: 0x0000d02d (0bxx00000000000000011010000x0101101)

Bit	Reset	Description
29	0x0	DIFF_CLK_SEL: If set, selects differential CLK and DQS; Used by eMMC IOBRICK only. Software should set this appropriately based on eMMC part used. E_INPUT_* (CMD/DAT/CLK) of eMMC IOBRICK should be set to 0 when differential signaling is used. default is '0' - selects single ended signaling for clk/dqs
28:24	0x0	TRIM_VAL: Tap value for output data path trimmer This determines the trimmer value needed to drive the output data correctly. The tap for outbound trimmer is single MUX. The trim settings required are within very small (0-3) with absolute delay requirement of ~400 ps. Minimal change with PVT variations. Following values are recommended. These are common for all speed modes of SD/eMMC. These are the initial values to start with. SDMMC1 - 2 SDMMC2 - 8 SDMMC3 - 3 SDMMC4 - 8
23:16	0x0	TAP_VAL: Tap value for input data path trimmer This determines the tap value needed to sample the input data correctly. Delay per each tap can range from 70 ps (hv_ff) to 505 ps (lv_ss). Following values are recommended. These are the initial values to start with. 1> SDR12/SDR25/HIGH SPEED DDR modes: If I/O pad trimmer is used (default): SDMMC1 - 4 SDMMC2 - 0 SDMMC3 - 3 SDMMC4 - 0 If core legacy trimmer is used (not recommended): SDMMC1 - 3 SDMMC2 - 3 SDMMC3 - 3 SDMMC4 - 3 2> SDR50 and SDR104/HS200/HS400/HS667 should use tuning procedure to determine the tap value
15:8	0xd0	BASE_CLK_FREQ: System software programs the base SD/MMC clock frequency into this register before loading the SD/MMC driver.This should not be touched when software wants to use SD card in uhs-II mode. This value is readable in the standard, but not writable, SDMMC_CAPABILITIES_0_BASE_CLOCK_FREQUENCY register field. Software should program the actual clock frequency programmed in CAR registers CLK_RST_CONTROLLER_CLK_SOURCE_SDMMC*_0 for each SDMMC controller. This should be done after every time SDMMC is reset and after every soft reset. This is important as all SDMMC controllers follow the same register map, but could be programmed with different frequencies depending on the use case.

Bit	Reset	Description
6	0x0	LEGACY_CLKEN_OVERRIDE: Override for sdmmc_legacy_g_clk clken; Set this to 0 when in UHS-II mode to save power 0 = NORMAL: 0 -> sdmmc_legacy_g_clk is gated 1 = OVERRIDE: 1 -> sdmmc_legacy_g_clk is not gated
5	0x1	SDR50_TUNING_OVERRIDE: override the SDR50_TUNING capabilities bit. Software should only set this bit if it is required to use Tuning for SDR50. (only supported for SDMMC1 and SDMMC3) 0 = NORMAL: 0 -> No Tuning support advertised for SDR50 mode. 1 = OVERRIDE: 1 -> Tuning support is enabled for SDR50 mode.
4	0x0	UHS2_CAPABILITY_OVERRIDE: override the UHS-II capabilities bit. 0 = NORMAL: 0 -> UHS-II support is unadvertised 1 = OVERRIDE: 1 -> UHS-II support is advertised
3	0x1	PADPIPE_CLKEN_OVERRIDE: Override for padmacro and pipemacro clken. 0 = NORMAL: 0 -> CLKEN is de-asserted when internal CLKEN is de-asserted. 1 = OVERRIDE: 1 -> CLKEN is kept asserted even when internal CLKEN is de-asserted. Software should always program this to 0x1 (OVERRIDE).
2	0x1	SPI_MODE_CLKEN_OVERRIDE: Override for CLKEN during SPI_MODE during sw_reset. 0 = NORMAL: 0 -> CLKEN is de-asserted while doing sw_reset. 1 = OVERRIDE: 1 -> CLKEN is kept asserted while doing sw_reset. Software should always program this to 0 (NORMAL).
1	0x0	INPUT_IO_CLK: Feedback clock is selected by default. Software should not change this. Disabling Feedback clock will select Internal Clock that requires different tap value programming. 0 = FEEDBACK 1 = INTERNAL
0	0x1	SDMMC_CLK: This is set when sdmmc_clk is supplied by the CAR module.Prior to sdmmc_clk switch OFF.This bit should be written '0'. By writing zero, the asynchronous card interrupt is routed to the Interrupt controller. 0 = DISABLE 1 = ENABLE

32.9.2.2 SDMMCA_VENDOR_SYS_SW_CNTRL_0

Vendor System Software Control Register

Offset: 0x104 I Read/Write: R/W I Reset: 0x38600002 (0b00111000011xxxxxx0000000x0000010)

Bit	Reset	Description
31	0x0	ENHANCED_STROBE_MODE: Enables enhanced strobe mode in HS400/HS667 mode for eMMC5.x devices 0 - cmd_in(Resp) is sampled by loopback clock which requires tuning 1 - cmd_in(Resp) is sampled by DQS_in which requires no tuning software has to set this bit appropriately based on device capability since this is an optional feature for eMMC5.x devices. If device supports this feature, software should set this bit to avoid tuning.
30	0x0	USE_TMCLK_FOR_WR_CRC_STATUS_TIMEOUT: When set, uses TMCLK data timeout counter for generating wr_crc_status data-timeout When cleared, uses sdmmc_clk for maintaining wr_crc_status data timeout counter
29	0x1	USE_NCRC_FOR_WR_CRC_STATUS_TIMEOUT_VAL:This field is valid only when USE_TMCLK_FOR_WR_CRC_STATUS_TIMEOUT is set to 0. When cleared, uses data timeout value as wr CRC status timeout value (specification defined one) When set, uses Ncrc cycles as timeout value
28	0x1	USE_TMCLK_FOR_DATA_TIMEOUT: When set, uses TMCLK data timeout counter for generating legacy data timeout error (except wr_crc_status timeout) When cleared, uses sdmmc_clk for maintaining data timeout counter
27:24	0x8	DEVICE_BUSY_WAIT_CYCLES:In HS400/667 mode, busy should be sampled using clock instead DQS.So, Dat0 from card is passed to two different async FIFOs (one is running in sdmmc_clk and other is in sdmmc_dqs).CRC status is taken from dat0 sampled in DQS and busy should be checked after CRC status end bit reception using dat0 sampled in clk.Both clk and DQS dat0 paths don't have same propagation delay due to sync-ers used in async FIFOs and also due to phase difference between clk and dqs.Due to this delay difference between the paths, we may sample wrong busy status if we sample busy immediately after receiving END bit of CRC status. To avoid incorrect sampling of busy, a wait state before busy polling is added. This register field is used to load wait_cycles counter. Note that this counter is used only in HS400/667 mode.
23	0x0	ALLOW_CARD_CLK_STALLS_IN_WR: When set, allows card clock stopping during transfer of data within a block in HIGH SPEED DDR/HS400 writes.
22	0x1	EMMC_IOBRICK_CLK_DATA:Used to drive AP_CLK and AN_CLK input of iobrick.0x1 - clk_out will be same as iobrick_clk_in0x0 - clk_out will be inverted iobrick_clk_in
21	0x1	QUALIFY_WITH_RD_DATA_VLD:We have async FIFOs in both cmd_in and dat_in paths in padmacro which are used in tunable modes.When this bit set, rdata from FIFO is treated as valid data only when rd_req is high. This is needed to handle bubbles on 'rd_req' when MTBF is high.
14	0x0	SD_BUS_POWER_ON_OFF_INT_STATUS: SD_BUS_POWER was changed. System software can use this interrupt to implement power switch.

Bit	Reset	Description
13	0x0	VOLT_SWITCH_INT_STATUS: VOLT_18_EN was changed. System software can use this interrupt to implement a UHS-I voltage switch procedure for a standard SD Host driver 0 = NO_INT 1 = GEN_INT
12	0x0	TUNING_SYS_INT_STATUS: CMD19 was issued while EXECUTE_TUNING was set. System software can use this interrupt to implement a UHS-I tuning procedure for a standard SD Host driver. 0 = NO_INT 1 = GEN_INT
11:8	0x0	TUNING_ASYNC_FIFO_ADDNL_DELAY:In tunable modes, data/cmd IB path uses async FIFO which contributes additional delay to cmd/resp and wdata/CRC token round trip delay.Controller waits for this round trip delay before waiting for Ncr or Ncrc. This is required not to latch previous data/cmd driven by host itself as start bits of resp or CRC.Round trip delay is calculated for async FIFO with sync-2d.This register field holds the additional delay in cycles which should be added to round trip delay. This additional delay is caused by increasing sync-er depth (more than 2) or addition of output flop stage in async FIFO. Default value is zero. NOTE: Software should not update this field unless a new PROD setting is given.
6	0x0	SD_BUS_POWER_ON_OFF_INT_ENABLE: Enables a separate system interrupt (i.e., not the standard SDHCI interrupt) when SD_BUS_POWER is changed. 0 = DISABLE 1 = ENABLE
5	0x0	VOLT_SWITCH_INT_ENABLE: Enables a separate system interrupt (i.e., not the standard SDHCI interrupt) when VOLT_18_EN is changed. 0 = DISABLE 1 = ENABLE
4	0x0	TUNING_SYS_INT_ENABLE: Enables a separate system interrupt (i.e., not the standard SDHCI interrupt) when CMD19 is issued while EXECUTE_TUNING is set. 0 = DISABLE 1 = ENABLE
3	0x0	ASSERT_BUFF_RD_RDY_INT: Write a 1 to this field to assert sdmmc_interrupt_status_0_buffer_read_ready. Used by the system software that implements the tuning procedure to signal to the standard SD driver that the tuning process has completed 0 = DISABLE 1 = ENABLE
2	0x0	IO_TRIM_BYPASS:Override bit for selecting between core trimmer (Vcore dependent) and I/O trimmer (custom trimmer) in IB clock path. Default option is I/O trimmer; software should not set this field.
1	0x1	INT_MASK_WHILE_TUNING: As per specification, Host should not generate any interrupts (including cmd_complete and data_xfer_complete) except buffer_read_ready interrupt during tuning sequence is being performed software can override this behavior by clearing this bit - but this leads to a specification violation 0 = DISABLE 1 = ENABLE
0	0x0	SPI_MODE: This is a mirror bit.The SPI mode is set if this bit is set or CMD_XFER_MODE[7] is set Writing 1 will drive the CS Low and writing zero will de-assert the CS Signal 0 = DISABLE : 0 -> SPI mode is disabled. 1 = ENABLE : 1 -> SPI mode is enabled.

32.9.2.3 SDMMCA_VENDOR_ERR_INTR_STATUS_0

Legacy Interrupt Status Register

The fields are valid when an error interrupt has occurred.

Offset: 0x108 I Read/Write: RO I Reset: 0x000XXXXX (0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx)

Bit	Reset	Description
18	X	SDMMC_LEGACY_CTLR_IDLE: indicates legacy SD interface controller is idle - no active data transfers on legacy SD interface
17	X	READ_DATA_TIMEOUT: valid when a data timeout error occurs
16	X	WRITE_CRC_STATUS_TIMEOUT: valid when a data timeout error occurs
15	X	WRITE_BUSY_TIMEOUT: valid when a data timeout error occurs
14	X	RESP_BUSY_TIMEOUT: valid when a data timeout error occurs
13	X	SPI_WRITE_BUSY_TIMEOUT
12	X	SPI_RX_START_TOKEN_TIMEOUT
8:5	X	SPI_DAT_ERR_TOKEN: Data Error Token,while read from card.

Bit	Reset	Description
4:0	X	SPI_DAT_RESPONSE: Data Response while write to card 5 = DATA_ACCEPTED 11 = CRC_ERR 13 = WRITE_ERR

32.9.2.4 SDMMCA_VENDOR_CAP_OVERRIDES_0

Capabilities Override Bits

Offset: 0x10c I Read/Write: R/W I Reset: 0x00000007 (0bxxx0xxxxxxxxxxxxx000000xxxx0111)

Bit	Reset	Description
28	0x0	CMD_QUEUING_MODE_EN: useful for eMMC5.x devices which support CMD queuing. Software should enable this when it wants to use cmd queuing of eMMC5.x devices in HS400 mode.
13:8	0x0	DQS_TRIM_VAL: PROD_VAL=0x11 - Tap value for incoming DQS path trimmer - used in HS400/HS667 modes
3	0x0	DRV_LPBK_CLK_ON_CMD_LINE: Loopback trimmed clock will be driven onto cmd line, if this bit set to 1. Should be set to zero during normal data transfers.Useful in debug.
2	0x1	VOLTAGE_3_3_V_SUPPORT_OVERRIDE: Voltage support 3_3_V override
1	0x1	VOLTAGE_3_0_V_SUPPORT_OVERRIDE: Voltage support 3_0_V override
0	0x1	VOLTAGE_1_8_V_SUPPORT_OVERRIDE: Voltage support 1_8_V override

32.9.2.5 SDMMCA_VENDOR_BOOT_CNTRL_0

Vendor Boot Control Register

This register is used to configure Boot Mode to support MMC v4.3 cards.

Offset: 0x110 I Read/Write: R/W I Reset: 0x00000000 (0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx00)

Bit	Reset	Description
1	0x0	BOOT_ACK: This bit is used to support Boot Option in MMC 4.3 version cards. If set Boot acknowledgment is given by card else not given by card 0 = DISABLE 1 = ENABLE
0	0x0	BOOT: This bit enables/disable BootOption1.If set BootOption1 is enabled, hardware auto clears it when boot data is done. Writing 0 terminates the BootOption1 0 = DISABLE 1 = ENABLE

32.9.2.6 SDMMCA_VENDOR_BOOT_ACK_TIMEOUT_0

Vendor Boot Acknowledgment Timeout Register

Offset: 0x114 I Read/Write: R/W I Reset: 0x00000000 (0bxxxxxxxxxxxx00000000000000000000)

Bit	Reset	Description
19:0	0x0	VALUE: If Boot Acknowledgment is not received within the programmed number of cycles. Boot Acknowledgment Timeout error occurs (VENDOR_SPECIFIC_ERR[0])

32.9.2.7 SDMMCA_VENDOR_BOOT_DAT_TIMEOUT_0

Boot Data Timeout Register

Offset: 0x118 I Read/Write: R/W I Reset: 0x00000000 (0bxxxxxxx00000000000000000000000)

Bit	Reset	Description
24:0	0x0	VALUE: If Boot Data is not received within the programmed number of cycles. Then Data Timeout error occurs.

32.9.2.8 SDMMCA_VENDOR_DEBOUNCE_COUNT_0

Debounce Counter Value Register

The Debounce Counter runs on 32KHz clock. Keeping the default value to 100 ms = (100 * 32cycles/1 ms) = 3200 cycles for 100 ms = 0xC80

Offset: 0x11c I Read/Write: R/W I Reset: 0x00000c80 (0bxxxxxxxx00000000000110010000000)

Bit	Reset	Description
23:0	0xc80	VALUE: The number of 32KHz clock cycles is programmed to meet Debounce period of the card slot.

32.9.2.9 SDMMCA_VENDOR_MISC_CNTRL_0

Miscellaneous Vendor Control Register

SDMMC_SPARE0: Spare register bits with reset value of 0

SDMMC_SPARE0[0]: SW_RESET_CLKEN_OVERRIDE, override the sdmmc_clken when doing SW_RESET if set to 1.

SDMMC_SPARE0[1]: When set, allows SD clock to be stopped in the middle of a read data block while in SDR104/ HS400/HS667 modes(allow_sdr104_intrablock_stalls).

Unsafe for at least some SD/eMMC cards, but may improve SDR104 DMA read performance in some cases.

SDMMC_SPARE0[2]: When set, SDR104 support is advertised in SDMMC_CAPABILITIES_HIGHER_0_SDR104

SDMMC_SPARE0[3]: When set, SDR50 support is advertised in SDMMC_CAPABILITIES_HIGHER_0_SDR50

SDMMC_SPARE0[5]: When 0, masks the pad macro's "high speed" enable to 0, causing the pad macro to always launch data on the falling edge of the clock. This prevents the SD Host driver's setting of SDMMC_POWER_CONTROL_HOST_x_HIGH_SPEED_EN from undesirably affecting the output timing.

SDMMC_SPARE0[7:6]: Number of pipe stages.

SDMMC_SPARE0[8]: When set, DDR50 support is advertised in SDMMC_CAPABILITIES_HIGHER_0_DDR50

SDMMC_SPARE1: Spare register bits with reset value of 1

SDMMC_SPARE1[0]: CMD_CONFLICT_DISABLE, disable command line conflict if set to 1.

SDMMC_SPARE1[1]: Control bit to select between internal and external loop back clock. 1-external 0-internal

Tegra X1 does not support external loopback for any SDMMC controller.

Offset: 0x120 I Read/Write: R/W I Reset: 0xffff0098 (0b11111111111111110000000010011000)

Bit	Reset	Description
31:16	0xffff	SDMMC_SPARE1: Spare register bits with reset value of 1
15:1	0x4c	SDMMC_SPARE0: Spare register bits with reset value of 0x40
0	0x0	ERASE_TIMEOUT_LIMIT: Erase timeout value. 0 = FINITE: Finite, It is limited to the programmed value in the DATA_TIMEOUT_VALUE 1 = INFINITE: Infinite,Controller would be monitoring until the card is busy.

32.9.2.10 SDMMCA_MAX_CURRENT_OVERRIDE_0

Offset: 0x124 I Read/Write: R/W I Reset: 0x00000000 (0bxxxxxxxx00000000000000000000000)

Bit	Reset	Description
23:16	0x0	OVERRIDE_FOR_1_8V: Maximum override for 1.8V VDD1
15:8	0x0	OVERRIDE_FOR_3_0V: Maximum override for 3.0V VDD1
7:0	0x0	OVERRIDE_FOR_3_3V: Maximum override for 3.3V VDD1

32.9.2.11 SDMMCA_MAX_CURRENT_OVERRIDE_HI_0

Offset: 0x128 I Read/Write: R/W I Reset: 0x00000000 (0bxxxxxxxxxxxxxxxxxxxxxxxxx00000000)

Bit	Reset	Description
7:0	0x0	OVERRIDE_FOR_1_8V_VDD2: Maximum override for 1.8V VDD2

32.9.2.12 SDMMCA_VENDOR_IO_TRIM_CNTRL_0

Vendor I/O trimmer control register

Used to configure I/O trimmer

Table 207: Truth Table

Input Pins			Output	Comments
E_DPD	SEL_VREG	SEL_VREF	CLKOUT	
1	x[1]	x	0	The cell is in deep power down mode.
0	1	x	based on ip_clk_select selected clock input	Trimmer is powered by VAUXC.
0	0	x	based on ip_clk_select selected clock input	Trimmer is powered by regulated voltage.

1. 'x' indicates don't care.

Offset: 0x1ac I Read/Write: R/W I Reset: 0x00000015 (0bxxxxxxxxxxxxxxxxxxxxxxxxxxx010101)

Bit	Reset	Description
5	ENABLE	TRIM_PWRSAVE: Enables power saving mode by clock gating the unused taps in delay chain Active low signal, 0 - power saving mode enabled - clock gating is enabled for unused trimmer taps - may affect tap delay 1 - no power saving - all the trimmer taps are not clock gated 0 = ENABLE 1 = DISABLE
4:3	VREF_925_MV	SEL_VREF_LEVEL: Selects Vref voltage level 0 = VREF_875_MV 1 = VREF_900_MV 2 = VREF_925_MV 3 = VREF_950_MV
2	0x1	SEL_VREG: Select voltage supply for delay chain present in both Trimmer and DLLPROD value: 0x0 ***Software should set this to 0x0 before accessing SD/eMMC. This setting makes IB trimmer delay independent of VDD_CORE*** 0 - selects regulated reference voltage for trimmer and DLL supply - default (recommended option for tunable SD/eMMC modes) 1 - selects VAUXC for trimmer and DLL supply and shut down BG+REG circuit (can be used in non-tunable modes for power saving) Power up time for BG+REG is ~3us(worst case). Power down time for BG+REG is ~1 us (worst case). If software wants to turn on/off BG+REG when SDMMC is idle, it has to take hit of 3 us power on time. When SEL_VREG is toggled, both DLL and rx clock trimmer output could glitch irrespective of input clock state which could cause corresponding rx CMD and DATA FIFOs to go into bad state. Software should issue SW_RESET_DAT and SW_RESET_CMD to reset host FIFOs after BG <-> VAUXC switching. This would ensure error free data transfers from there on. Powering down BG would need 3 us turn ON time which may cause IOPS reduction, if software shuts down BG after every transfer and enables it on seeing new transfer request; it may not be possible to do dynamic shut down of BG without stalling new requests.
1	0x0	SEL_VREF: Select reference voltage for voltage regulator 0 - selects Bandgap Voltage Reference (recommended option for SD/eMMC tunable modes) 1 - selects resistor divider voltage reference and power down bandgap Switching time between the supplies is 1 us. When switching from one supply to other supply, we need to wait for at least 1 us before doing any data transfers.
0	0x1	PD_BGREG: Not used - Dummy control Power down Band Gap voltage reference, voltage regulator and resistor chain voltage ref (BG+REG) present in custom I/O trimmer used for SD/eMMC bus tuning. Active High signal, PD_BGREG=1 => Power down BG+REG; PD_BGREG=0 => power up Power down and up time for BG+REG is 1 us. If software wants to turn on/off BG+REG when SDMMC is idle, it has to follow 1us power on/off time. Back-up option for powering down BG. Software should clear this bit when it wants to turn ON BG by setting SEL_VREG=0. The original idea to have PD_BGREG pin is to provide power saving feature when the eMMC/SDMMC is in IDLE state, but not in DPD mode. This pin function is actually merged into SEL_VREG function -BG+REG circuit is shut-down when SEL_VREG=1 (trimmer powered by VAUXC)

32.9.2.13 SDMMCA_VENDOR_TUNING_CNTRL0_0

Vendor Tuning Control0 Register

Offset: 0x1c0 I Read/Write: R/W I Reset: 0x74020090 (0bx111010000000001x0000000010010000) I Default: 0x00000040

Bit	Reset	SW Default	Description
30	0x1	_NONE_	RD_DATA_CRC_ERR_EN: If cleared, Re-tuning request/tuning error is not generated on read data CRC error
29	0x1	_NONE_	WR_DATA_CRC_ERR_EN: If cleared, Re-tuning request/tuning error is not generated on write CRC error
28	0x1	_NONE_	CMD_CRC_ERR_EN: If cleared, Re-tuning request/tuning error is not generated on cmd CRC error
27	0x0	_NONE_	RETUNING_REQ_EN_ON_CRC_ERR_DETECTION: Re-tuning request is generated when set to initiate re-tuning by software to compensate for temperature drift when any data or cmd CRC errors are detected in SDR50/SDR104/HS200 modes
26	0x1	_NONE_	TUNING_ERR_EN_ON_CRC_ERR_DETECTION: Tuning error is generated to initiate re-tuning by software to compensate for temperature drift when any data or cmd CRC errors are detected in SDR50/SDR104/HS200 modes
25:18	0x0	_NONE_	START_TAP_VAL:start tap value to be used by tuning; start_tap should be multiple of step_size chosen and its valid range is 0-255; Not valid when TAP_VAL_UPDATED_BY_HW is set to zero. Tuning algorithm uses this as the start tap value for scanning through trimmer taps.
17	0x1	_NONE_	TAP_VAL_UPDATED_BY_HW: This bit is functional only in tunable modes (SDR50, SDR104 and HS200). Software can choose to update the tap value by itself by clearing this bit; Preferred value is 1 - tap value is updated by hardware. If this bit is cleared, hardware does not update tap_val per every tuning iteration. Software can update it as desired. Tuning pattern match is indicated by sampling_clock_select per every tuning iteration. Software has to maintain the status of each tuning iteration and determine the best PASS window to fix the final sampling point. Software can program NUM_TUNING_ITERATIONS as desired. Once the number of tuning commands issued reaches number of tuning iterations programmed, execute_tuning bit will be cleared to indicate the completion of tuning procedure. Note that using this option violates Host specification but provided for legacy reasons. It helps us in using legacy software tuning solution in case hardware solution does not work.
15:13	TRIES_40	_NONE_	NUM_TUNING_ITERATIONS: The number of tuning iterations to be used by tuning circuit; Preferred value is 40 iterations as per Host specification. Using other values violates the specification but provided for trimmer characterization purpose. 0 = TRIES_40 1 = TRIES_64 2 = TRIES_128 3 = TRIES_192 4 = TRIES_256
12:6	0x2	0x1	MUL_M: implements a multiplier - M+1 Final tap value is derived from best passing window and calculated as follows. Final tap value = first_pass + ((last_pass - first_pass)*Q); where Q = percentage of pass window;default-75% Q = M+1/(2^N); N:1...7 M:should be in range [0:2^N-1];
5:3	0x2	_NONE_	DIV_N: implements a divider - 2^N; maximum div is 2^7 =>128
2:0	0x0	_NONE_	TUNING_WORD_SEL: Selects desired word from 256-bit tuning status bitmap status_word[31:0] = status[255:0] >> (tuning_word_sel * 32)

32.9.2.14 SDMMCA_VENDOR_TUNING_CNTRL1_0

Vendor Tuning Control1 register

Different step size is required in SDR50 mode to cover two UI (100 MHz => 2*10 ns)

With 70 ps/tap trimmer resolution, we can cover almost 2 UI using step_size=8 in SDR50 and step_size=4 in SDR104.

Tuning will be done in HS200 - SDR mode only.

HS200 - tuning at 200 MHz - UHS_SEL should be SDR104 for executing tuning

Before initiating data transfers in HS400 mode, tuning procedure should be executed in HS200 mode with I/O clock running at 200 MHz

For overclocked modes: Before initiating data transfers in HS667 mode, tuning procedure should be executed in HS200 mode with I/O clock running at 333 MHz

Note: *eMMC bus tuning will always be run in HS200 mode only.*

Use step_size = 1 to scan through all taps due to hardware issue.

Offset: 0x1c4 I Read/Write: R/W I Reset: 0x00000023 (0bxxxxxxxxxxxxxxxxxxxxxxxxxxx010x011) I Default: 0x00000000

Bit	Reset	SW Default	Description
6:4	0x2	0x0	STEP_SIZE_SDR104_HS200: tap_val is incremented by step_size for every tuning iteration - used in SDR104/ HS200/HS400 mode increment = 2^step_size; step_size should be in range 0-4. Others are RSVD For overclocking modes, set this field to 0x1
2:0	0x3	0x0	STEP_SIZE_SDR50: tap_val is incremented by step_size for every tuning iteration - used in SDR50 mode increment = 2^step_size; step_size should be in range 0-4. Others are RSVD

32.9.2.15 SDMMCA_VENDOR_TUNING_STATUS0_0

Vendor Tuning Status0 register

Offset: 0x1c8 I Read/Write: RO I Reset: 0xXXXXXXXX (0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx)

Bit	Reset	Description
31:0	X	STATUS_WORD: Each bit indicates the status of each tuning iteration, when tap value is updated by hardware (TAP_VAL_UPDATED_BY_HW=1); 0-Tuning pattern not matched 1-tuning pattern matched We have a total of 256 tap values. Software can issue a maximum.of 256 tuning commands for debug. Software needs to read this register eight times to get status of all 256 iterations by changing tuning_word_sel status[255:0] is left shifted and loaded into this register every time when tuning_word_sel is changed status_word[31:0] = status[255:0] >> (tuning_word_sel * 32)

23:16	X	PASS_WINDOW_START_BEFORE_FINE_TUNING: Start tap value of best PASS window found by scan FSM
15:8	X	PASS_WINDOW_END_AFTER_FINE_TUNING: End tap value of best PASS window after fine tuning
7:0	X	PASS_WINDOW_START_AFTER_FINE_TUNING: Start tap value of best PASS window after fine tuning

32.9.2.17 SDMMCA_VENDOR_CLK_GATE_HYSTERESIS_COUNT_0

Vendor Clk gating Hysteresis Counter initial value

Offset: 0x1d0 I Read/Write: R/W I Reset: 0x0000000f (0bxxxxxxxxxxxxxxxxxxxxxxxxxxx001111)

Bit	Reset	Description
5:0	0xf	CLK_COUNT: Before gating second level clocks controller will wait for these many cycles. we can recover if any idle windows are missed in clken equation

32.9.2.18 SDMMCA_VENDOR_PRESET_VAL0_0

Vendor Preset Value Registers

SD host specification defines one preset value register for each bus speed mode which should be set by host by some unique method.

Preset values vary based on the base frequency used which is in software (Tegra system driver) control.

Tegra System driver supposed to set BASE_CLK_FREQ in VENDOR_CLOCK_CNTRL register before handling over the control to SD host standard driver.

In the similar way, system driver should set below vendor preset values based on the base clock frequency and the desired card clock frequency in each bus speed mode

This should be done after every time SDMMC is reset and after every soft reset.

This is important as all SDMMC controllers follow the same register map, but could be programmed with different frequencies depending on the use case.

Default values are set assuming base clock frequency=208 MHz.

Offset: 0x1d4 I Read/Write: R/W I Reset: 0x00201000 (0bxx00000000100000000100000000000)

Bit	Reset	Description
29:20	0x2	SDCLK_FREQ_SEL_HIGH_SPEED: System software programs 10-bit divider value to generate SDCLK in default speed mode (<50 MHz, 3.3V signaling) This value is readable in the standard via PRESET_SDR12_AND_HIGH_0_SDCLK_FREQ_VAL_LOW register field. Default value is 0x2 assuming 208 MHz base clock
19:10	0x4	SDCLK_FREQ_SEL_DEFAULT: System software programs 10-bit divider value to generate SDCLK in default speed mode (<25 MHz, 3.3V signaling). This value is readable in the standard via PRESET_DEFAULT_AND_INIT_0_SDCLK_FREQ_VAL_HIGH register field. Default value is 0x4 assuming 208 MHz base clock
9:0	0x0	SDCLK_FREQ_SEL_INIT: System software programs 10-bit divider value to generate desired SDCLK frequency during initialization. This value is readable in the standard via PRESET_DEFAULT_AND_INIT_0_SDCLK_FREQ_VAL_LOW register field. For example, if 400 kHz SDCLK is desired at base clk freq=48 MHz, this register should be programmed with 0x3C

32.9.2.19 SDMMCA_VENDOR_PRESET_VAL1_0

Offset: 0x1d8 I Read/Write: R/W I Reset: 0x00100804 (0bxx00000000100000000100000000100)

Bit	Reset	Description
29:20	0x1	SDCLK_FREQ_SEL_SDR50: System software programs 10-bit divider value to generate SDCLK in SDR50 mode (<100 MHz, 1.8V signaling) This value is readable in the standard via PRESET_SDR50_AND_SDR25_0_SDCLK_FREQ_VAL_HIGH register field. Default value is 0x1 (gives 2N divider) assuming 208 MHz base clock
19:10	0x2	SDCLK_FREQ_SEL_SDR25: System software programs 10-bit divider value to generate SDCLK in SDR25 mode (<50 MHz, 1.8V signaling). This value is readable in the standard via PRESET_SDR50_AND_SDR25_0_SDCLK_FREQ_VAL_LOW register field. Default value is 0x2 assuming 208 MHz base clock
9:0	0x4	SDCLK_FREQ_SEL_SDR12: System software programs 10-bit divider value to generate SDCLK in SDR12 mode (<25 MHz, 1.8V signaling). This value is readable in the standard via PRESET_SDR12_AND_HIGH_0_SDCLK_FREQ_VAL_HIGH register field

Bit	Reset	Description
19:10	0x2	SDCLK_FREQ_SEL_DDR50: System software programs 10-bit divider value to generate SDCLK in DDR50 mode (<50MHz,1.8V signaling). This value is readable in the standard via PRESET_DDR50_AND_SDR104_0_SDCLK_FREQ_VAL_HIGH register field. Default value is 0x2 assuming 208MHz base clock
9:0	0x0	SDCLK_FREQ_SEL_SDR104: System software programs 10-bit divider value to generate SDCLK in SDR104 mode (<208MHz,1.8V signaling). This value is readable in the standard via PRESET_DDR50_AND_SDR104_0_SDCLK_FREQ_VAL_LOW register field

32.9.2.21 SDMMCA_SDMEMCOMPPADCTRL_0

SDMEMCOMP Pad control register

This register is used to control COMP pad inputs.

Offset: 0x1e0 I Read/Write: R/W I Reset: 0x88000001 (0b10x01xxxxxxxxxxxxxxxx0xxx0000001) I Default: 0x00000000

Bit	Reset	SW Default	Description
31	0x1	0x0	PAD_E_INPUT_OR_E_PWRD: used to control E_INPUT (for SDMMC1/3) and E_PWRD (for SDMMC2/4) input of pu/pd comp pad should be set before starting auto-cal and cleared once auto-calibration is done (for power saving) NOTE: E_PWRD = !PAD_E_INPUT_OR_E_PWRD and E_INPUT = PAD_E_INPUT_OR_E_PWRD
30	0x0	_NONE_	COMP_PAD_REG_ON: If set, turns ON regulator in comp pad. Software should not set this bit.
28:27	0x1	_NONE_	COMP_PAD_DRV_TYPE: used to control drv_type input of BDSDMEMLVCOMP_C pad
10	0x0	_NONE_	COMP_PAD_E_TEST_OUT: used to control e_test_out input of COMP pad
6:4	0x0	_NONE_	COMP_PAD_TEST_SEL: used to control test_sel input of COMP pad
3:0	0x1	_NONE_	SDMMC2TMC_CFG_SDMEMCOMP_VREF_SEL: used to control vref_sel input of COMP pad. Software should set this to 0x7.

32.9.2.22 SDMMCA_AUTO_CAL_CONFIG_0

SDMEMCOMP pad auto-calibration settings

AUTO_CAL_SLW_OVERRIDE

0 (Normal operation) pad DRVDN/UP_SLWR/F tied to AUTO_CAL output

DRDVDN/UP_SLWR/F[1:0] = AUTO_CAL_PULLDOWN/UP[4:3]

1 (override) use CFG2TMC_SDIO[1|3]*_DRVDN/UP_SLWR/F pins to control pad slew inputs

AUTO_CAL_OVERRIDE

0 (normal operation): use AUTO_CAL_PU/PD_OFFSET as an offset to the calibration state machine setting

1 (override): use AUTO_CAL_PU/PD_OFFSET register values directly

Offset: 0x1e4 I Read/Write: R/W I Reset: 0x00010000 (0b0000xxxxxxxxx001x0000000x0000000) I Default: 0x20000000

Bit	Reset	SW Default	Description
31	0x0	_NONE_	AUTO_CAL_START: Writing a one to this bit starts the calibration state machine. This bit must be set even if the override is set in order to latch in the override value.
30	0x0	_NONE_	AUTO_CAL_OVERRIDE: AUTOCAL override. 0 = NORMAL: 0 (normal operation): use AUTO_CAL_PU/PD_OFFSET as an offset to the calibration state machine setting 1 = OVERRIDE: 1 (override): use AUTO_CAL_PU/PD_OFFSET register values directly
29	DISABLED	0x1	AUTO_CAL_ENABLE: AUTOCAL enable. 0 = DISABLED: 0 (disabled): use sdmmc2tmc_cfg* register settings for pullup/dn 1 = ENABLED: 1 (normal operation): use SDMMC generated pullup/dn (override or AUTOCAL)
28	0x0	_NONE_	AUTO_CAL_SLW_OVERRIDE: AUTOCAL slew rate override 0 = NORMAL: 0 (Normal operation) pad DRVDN/UP_SLWR/F tied to AUTO_CAL output DRDVDN/UP_SLWR/F[1:0] = AUTO_CAL_PULLDOWN/UP[4:3] 1 = OVERRIDE: 1 (override) use CFG2TMC_SDIO[1|3]*_DRVDN/UP_SLWR/F pins to control pad slew inputs
18:16	0x1	_NONE_	AUTO_CAL_STEP: calibration step interval (in microseconds)
14:8	0x0	_NONE_	AUTO_CAL_PD_OFFSET: 2's complement offset for pull-down value
6:0	0x0	_NONE_	AUTO_CAL_PU_OFFSET: 2's complement offset for pull-up value

32.9.2.23 SDMMCA_AUTO_CAL_INTERVAL_0

SDMEMCOMP pad calibration interval - Valid for SDMMC1/SDMMC3 Instances

Offset: 0x1e8 I Read/Write: R/W I Reset: 0x00000000 (0b00000000000000000000000000000000)

Bit	Reset	Description
31:0	0x0	AUTO_CAL_INTERVAL: 0: do calibration once Otherwise, auto-calibration occurs at intervals equivalent to the programmed number of microseconds.This feature is not supported from Tegra X1 due to movement of level shifters to COMP pad. Software should trigger calibration at regular intervals, if needed.

32.9.2.24 SDMMCA_AUTO_CAL_STATUS_0

SDMEMCOMP pad calibration status - Valid for SDMMC1/SDMMC3 Instances

Offset: 0x1ec I Read/Write: RO I Reset: 0xXXXXXXXX (0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx)

Bit	Reset	Description
31	X	AUTO_CAL_ACTIVE: One when auto calibrate is active - valid only after auto calibrate sequence has completed (AUTO_CAL_ACTIVE == 0)
30:24	X	AUTO_CAL_PULLDOWN_ADJ: Pulldown code sent to pads
22:16	X	AUTO_CAL_PULLUP_ADJ: Pullup code sent to pads
14:8	X	AUTO_CAL_PULLDOWN: Pulldown code generated by auto-calibration
6:0	X	AUTO_CAL_PULLUP: Pullup code generated by auto-calibration

32.9.2.25 SDMMCA_IO_SPARE_0

SPARE bits. These SPARE_OUT bits go to pipe -> pad and then come back as SPARE_IN

SPARE_OUT[3]: IO_SPARE[19] - used as MUX select which selects between one cycle delay and two cycle delay versions of cmd_oen to mask wdata of IB capture flop.

0x0: selects two cycle delayed version

0x1: selects one cycle delayed version - recommended

SPARE_OUT[2]: IO_SPARE[18] - used as active low enable for gating both CMD_IN and DAT_IN async FIFOs wdata when we are driving CMD/DAT lines.

0x0: write 1 when OEN is active and Zi value when OEN is not active into FIFO (default)

0x1: write Zi value into FIFO irrespective of OEN state.

Offset: 0x1f0 I Read/Write: R/W I Reset: 0xXXXXXXXX (0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx) I Default: 0x00080008

Bit	R/W	Reset	SW Default	Description
31:16	RW	X	0x8	SPARE_OUT:PROD value: Software should set SPARE_OUT[3]: IO_SPARE[19] to 1 before accessing SD/eMMC.
15:0	RO	X	0x8	SPARE_IN

32.9.2.26 SDMMCA_SDMMCA_MCCIF_FIFOCTRL_0

Memory Client Interface FIFO Control (where applicable) and Clock Gating Control Register.

> ***Note:*** *The FIFO timing aspects of this register are no longer supported, but retained for software compatibility*

The clock override/ovr_mode fields of this register control the 2nd-level clock gating for the client and MC side of the MCCIF. All clock gating is enabled by default.

A '1' written to the rclk/wclk override field will result in one of the following:

With wclk/rclk override mode = LEGACY, the clock reverts to legacy mode of operation where the clock is on whenever the client clk is enabled.

With wclk/rclk override mode = ON, the clock is always on inside MCCIF and PC.

A '1' written to the CCLK override field keeps client's clk always on inside MCCIF.

Offset: 0x1f4 I Read/Write: R/W I Reset: 0x00000000 (0bxxxxxxxxxxxx00000xxxxxxxxxxxxxxxx)

Bit	Reset	Description
20	0x0	SDMMCA_RCLK_OVR_MODE
19	0x0	SDMMCA_WCLK_OVR_MODE
18	0x0	SDMMCA_CCLK_OVERRIDE
17	0x0	SDMMCA_RCLK_OVERRIDE
16	0x0	SDMMCA_WCLK_OVERRIDE

32.9.2.27 SDMMCA_TIMEOUT_WCOAL_SDMMCA_0

Write Coalescing Time-Out Register

> ***Note:*** *Write coalescing is no longer supported by the MCCIF clients.*

Registers are retained for software compatibility but are not used by the hardware.

Offset: 0x1f8 I Read/Write: R/W I Reset: 0x00000032 (0bxxxxxxxxxxxxxxxxxxxxxxxxxx00110010)

Bit	Reset	Description
7:0	0x32	SDMMCWA_WCOAL_TMVAL

32.9.3 SDMMC2 Vendor Registers

32.9.3.1 SDMMCAA_VENDOR_CLOCK_CNTRL_0

The following registers are Vendor Specific Registers and are mapped to Vendor Specific Address Space (0x100 - 0x1FF)

Vendor Clock Control Register

Offset: 0x100 I Read/Write: R/W I Reset: 0x0000d02d (0bxx00000000000011010000x0101101)

Bit	Reset	Description
29	0x0	DIFF_CLK_SEL: If set, selects differential CLK and DQS; Used by eMMC IOBRICK only. Software should set this appropriately based on eMMC part used. E_INPUT_* (CMD/DAT/CLK) of EMMC IOBRICK should be set to 0 when differential signaling is used. default is '0' - selects single ended signaling for clk/dqs
28:24	0x0	TRIM_VAL: Tap value for output data path trimmer This determines the trimmer value needed to drive the output data correctly. The tap for outbound trimmer is single MUX. The trim settings required are within very small (0-3) with absolute delay requirement of ~400 ps. Minimal change with PVT variations. Following values are recommended. These are common for all speed modes of SD/eMMC. These are the initial values to start with. SDMMC1 - 2 SDMMC2 - 8 SDMMC3 - 3 SDMMC4 - 8

Bit	Reset	Description
23:16	0x0	TAP_VAL: Tap value for input data path trimmer This determines the tap value needed to sample the input data correctly. Delay per each tap can range from 70ps (hv_ff) to 505ps (lv_ss). Following values are recommended. These are the initial values to start with. 1> SDR12/SDR25/High Speed DDR modes: If I/O pad trimmer is used (default): SDMMC1 - 4 SDMMC2 - 0 SDMMC3 - 3 SDMMC4 - 0 If core legacy trimmer is used: SDMMC1 - 3 SDMMC2 - 3 SDMMC3 - 3 SDMMC4 - 3 2> SDR50 and SDR104/HS200/HS400/HS667 should use tuning procedure to determine the tap value
15:8	0xd0	BASE_CLK_FREQ: System software programs the base SD/MMC clock frequency into this register before loading the SD/MMC driver.This should not be touched when software wants to use SD card in uhs-II mode. This value is readable in the standard, but not writeable, SDMMC_CAPABILITIES_0_BASE_CLOCK_FREQUENCY register field. Software should program the actual clock frequency programmed in CAR registers CLK_RST_CONTROLLER_CLK_SOURCE_SDMMC*_0 for each SDMMC controller. This should be done after every time SDMMC is reset and after every soft reset. This is important as all SDMMC controllers follow the same register map, but could be programmed with different frequencies depending on the use case.
6	0x0	LEGACY_CLKEN_OVERRIDE: Override for sdmmc_legacy_g_clk clken; Set this to 0 when in UHS-II mode to save power 0 = NORMAL: 0 -> sdmmc_legacy_g_clk is gated 1 = OVERRIDE: 1 -> sdmmc_legacy_g_clk is not gated
5	0x1	SDR50_TUNING_OVERRIDE: override the SDR50_TUNING capabilities bit. Software should only set this bit if it is required to use Tuning for SDR50. (only supported for SDMMC1 and SDMMC3) 0 = NORMAL: 0 -> No Tuning support advertised for SDR50 mode. 1 = OVERRIDE: 1 -> Tuning support is enabled for SDR50 mode.
4	0x0	UHS2_CAPABILITY_OVERRIDE: override the UHS-II capabilities bit. 0 = NORMAL: 0 -> UHS-II support is unadvertised 1 = OVERRIDE: 1 -> UHS-II support is advertised
3	0x1	PADPIPE_CLKEN_OVERRIDE: Override for padmacro and pipemacro clken. 0 = NORMAL: 0 -> CLKEN is de-asserted when internal CLKEN is de-asserted. 1 = OVERRIDE: 1 -> CLKEN is kept asserted even when internal CLKEN is de-asserted. Software should always program this to 0x1 (OVERRIDE).
2	0x1	SPI_MODE_CLKEN_OVERRIDE: Override for CLKEN during SPI_MODE during sw_reset. 0 = NORMAL: 0 -> CLKEN is de-asserted while doing sw_reset. 1 = OVERRIDE: 1 -> CLKEN is kept asserted while doing sw_reset. Software should always program this to 0 (NORMAL).
1	0x0	INPUT_IO_CLK: Feedback clock is selected by default. Software should not change this. Disabling Feedback clock will select Internal Clock that requires different TAP Value Programming. 0 = FEEDBACK 1 = INTERNAL
0	0x1	SDMMC_CLK: This is set when sdmmc_clk is supplied by the CAR module.Prior to sdmmc_clk switch OFF.This bit should be written '0'. By writing zero,the asynchronous card interrupt is routed to the Interrupt controller. 0 = DISABLE 1 = ENABLE

32.9.3.2 SDMMCAA_VENDOR_SYS_SW_CNTRL_0

Vendor System Software Control Register

Offset: 0x104 I Read/Write: R/W I Reset: 0x38600002 (0b00111000011xxxxxx0000000x0000010)

Bit	Reset	Description
31	0x0	ENHANCED_STROBE_MODE: Enables enhanced strobe mode in HS400/HS667 mode for eMMC5.x devices 0 - cmd_in(Resp) is sampled by loopback clock which requires tuning 1 - cmd_in(Resp) is sampled by DQS_in which requires no tuning software has to set this bit appropriately based on device capability since this is an optional feature for eMMC5.x devices. If device supports this feature, software should set this bit to avoid tuning.
30	0x0	USE_TMCLK_FOR_WR_CRC_STATUS_TIMEOUT: When set, uses TMCLK data timeout counter for generating wr_crc_status data-timeout When cleared, uses sdmmc_clk for maintaining wr_crc_status data timeout counter
29	0x1	USE_NCRC_FOR_WR_CRC_STATUS_TIMEOUT_VAL: This field is valid only when USE_TMCLK_FOR_WR_CRC_STATUS_TIMEOUT is set to 0. When cleared, uses data timeout value as wr CRC status timeout value (specification defined one) When set, uses Ncrc cycles as timeout value
28	0x1	USE_TMCLK_FOR_DATA_TIMEOUT: When set, uses TMCLK data timeout counter for generating legacy data timeout error (except wr_crc_status timeout) When cleared, uses sdmmc_clk for maintaining data timeout counter
27:24	0x8	DEVICE_BUSY_WAIT_CYCLES: In HS400/667 mode, busy should be sampled using clock instead DQS.So, Dat0 from card is passed to two different async FIFOs (one is running in sdmmc_clk and other is in sdmmc_dqs).CRC status is taken from dat0 sampled in DQS and busy should be checked after CRC status end bit reception using dat0 sampled in clk.Both clk and DQS dat0 paths don't have same prop delay due to sync-ers used in async FIFOs and also due to phase difference between clk and dqs.Due to this delay difference between the paths, we may sample wrong busy status if we sample busy immediately after receiving END bit of CRC status. To avoid incorrect sampling of busy, a wait state before busy polling is added. This register field is used to load wait_cycles counter. Note that this counter is used only in HS400/667 mode.
23	0x0	ALLOW_CARD_CLK_STALLS_IN_WR: When set, allows card clock stopping during transfer of data within a block in HIGH SPEED DDR/HS400 writes.
22	0x1	EMMC_IOBRICK_CLK_DATA: Used to drive AP_CLK and AN_CLK input of iobrick.0x1 - clk_out will be same as iobrick_clk_in0x0 - clk_out will be inverted iobrick_clk_in
21	0x1	QUALIFY_WITH_RD_DATA_VLD: We have async FIFOs in both cmd_in and dat_in paths in padmacro which are used in tunable modes.When this bit set, rdata from FIFO is treated as valid data only when rd_req is high. This is needed to handle bubbles on 'rd_req' when MTBF is high.
14	0x0	SD_BUS_POWER_ON_OFF_INT_STATUS: SD_BUS_POWER was changed. System software can use this interrupt to implement power switch.
13	0x0	VOLT_SWITCH_INT_STATUS: VOLT_18_EN was changed. System software can use this interrupt to implement a UHS-I voltage switch procedure for a standard SD Host driver 0 = NO_INT 1 = GEN_INT
12	0x0	TUNING_SYS_INT_STATUS: CMD19 was issued while EXECUTE_TUNING was set. System software can use this interrupt to implement a UHS-I tuning procedure for a standard SD Host driver. 0 = NO_INT 1 = GEN_INT
11:8	0x0	TUNING_ASYNC_FIFO_ADDNL_DELAY: In tunable modes, data/cmd IB path uses async FIFO which contributes additional delay to cmd/resp and wdata/CRC token round trip delay.Controller waits for this round trip delay before waiting for Ncr or Ncrc. This is required not to latch previous data/cmd driven by host itself as start bits of resp or CRC.Round trip delay is calculated for async FIFO with sync-2d.This register field holds the additional delay in cycles which should be added to round trip delay. This additional delay is caused by increasing sync-er depth (more than 2) or addition of output flop stage in async FIFO. Default value is zero. NOTE: Software should not update this field unless a new PROD setting is given.
6	0x0	SD_BUS_POWER_ON_OFF_INT_ENABLE: Enables a separate system interrupt (i.e., not the standard SDHCI interrupt) when SD_BUS_POWER is changed. 0 = DISABLE 1 = ENABLE
5	0x0	VOLT_SWITCH_INT_ENABLE: Enables a separate system interrupt (i.e., not the standard SDHCI interrupt) when VOLT_18_EN is changed. 0 = DISABLE 1 = ENABLE
4	0x0	TUNING_SYS_INT_ENABLE: Enables a separate system interrupt (i.e., not the standard SDHCI interrupt) when CMD19 is issued while EXECUTE_TUNING is set. 0 = DISABLE 1 = ENABLE
3	0x0	ASSERT_BUFF_RD_RDY_INT: Write a 1 to this field to assert sdmmc_interrupt_status_0_buffer_read_ready. Used by the system software that implements the tuning procedure to signal to the standard SD driver that the tuning process has completed 0 = DISABLE 1 = ENABLE

Bit	Reset	Description
2	0x0	IO_TRIM_BYPASS: Override bit for selecting between core trimmer (Vcore dependent) and I/O trimmer (custom trimmer) in IB clock path. Default option is I/O trimmer; software should not set this field.
1	0x1	INT_MASK_WHILE_TUNING: As per specification, Host should not generate any interrupts (including cmd_complete and data_xfer_complete) except buffer_read_ready interrupt during tuning sequence is being performed. Software can override this behavior by clearing this bit - but this leads to a specification violation 0 = DISABLE 1 = ENABLE
0	0x0	SPI_MODE: This is a mirror bit.The SPI mode is set if this bit is set or CMD_XFER_MODE[7] is set Writing 1 will drive the CS Low and writing zero will de-assert the CS Signal 0 = DISABLE: 0 -> SPI mode is disabled. 1 = ENABLE: 1 -> SPI mode is enabled.

32.9.3.3 SDMMCAA_VENDOR_ERR_INTR_STATUS_0

Legacy Interrupt Status Register

The fields are valid when an error interrupt has occurred.

Offset: 0x108 I Read/Write: RO I Reset: 0x000XXXXX (0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx)

Bit	Reset	Description
18	X	SDMMC_LEGACY_CTLR_IDLE: indicates legacy SD interface controller is idle - no active data transfers on legacy SD interface
17	X	READ_DATA_TIMEOUT: valid when a data timeout error occurs
16	X	WRITE_CRC_STATUS_TIMEOUT: valid when a data timeout error occurs
15	X	WRITE_BUSY_TIMEOUT: valid when a data timeout error occurs
14	X	RESP_BUSY_TIMEOUT: valid when a data timeout error occurs
13	X	SPI_WRITE_BUSY_TIMEOUT
12	X	SPI_RX_START_TOKEN_TIMEOUT
8:5	X	SPI_DAT_ERR_TOKEN: Data Error Token, while read from card.
4:0	X	SPI_DAT_RESPONSE: Data Response while write to card 5 = DATA_ACCEPTED 11 = CRC_ERR 13 = WRITE_ERR

32.9.3.4 SDMMCAA_VENDOR_CAP_OVERRIDES_0

Capabilities override bits

Offset: 0x10c I Read/Write: R/W I Reset: 0x00000007 (0bxxx0xxxxxxxxxxxxxx000000xxxx0111)

Bit	Reset	Description
28	0x0	CMD_QUEUING_MODE_EN: useful for eMMC5.x devices which support CMD queuing. Software should enable this when it wants to use cmd queuing of eMMC5.x devices in HS400 mode.
13:8	0x0	DQS_TRIM_VAL:PROD_VAL=0x11 - Tap value for incoming DQS path trimmer - used in HS400/HS667 modes
3	0x0	DRV_LPBK_CLK_ON_CMD_LINE: Loopback trimmed clock will be driven onto cmd line, if this bit set to 1. Should be set to zero during normal data transfers.Useful in debug.
2	0x1	VOLTAGE_3_3_V_SUPPORT_OVERRIDE: Voltage support 3_3_V override
1	0x1	VOLTAGE_3_0_V_SUPPORT_OVERRIDE: Voltage support 3_0_V override
0	0x1	VOLTAGE_1_8_V_SUPPORT_OVERRIDE: Voltage support 1_8_V override

32.9.3.5 SDMMCAA_VENDOR_BOOT_CNTRL_0

Vendor Boot Control Register

This register is used to configure Boot Mode to support MMC v4.3 cards.

Offset: 0x110 I Read/Write: R/W I Reset: 0x00000000 (0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx00)

Bit	Reset	Description
1	0x0	BOOT_ACK: This bit is used to support Boot Option in MMC 4.3 version cards. If set Boot acknowledgment is given by card else not given by card 0 = DISABLE 1 = ENABLE
0	0x0	BOOT: This bit enables/disable BootOption1.If set BootOption1 is enabled, hardware auto clears it when boot data is done. Writing 0 terminates the BootOption1 0 = DISABLE 1 = ENABLE

32.9.3.6 SDMMCAA_VENDOR_BOOT_ACK_TIMEOUT_0

Vendor Boot Acknowledgment Timeout Register

Offset: 0x114 I Read/Write: R/W I Reset: 0x00000000 (0bxxxxxxxxxxxx00000000000000000000)

Bit	Reset	Description
19:0	0x0	VALUE: If Boot Acknowledgment is not received within the programmed number of cycles. Boot Acknowledgment Timeout error occurs(VENDOR_SPECIFIC_ERR[0])

32.9.3.7 SDMMCAA_VENDOR_BOOT_DAT_TIMEOUT_0

Boot Data Timeout Register

Offset: 0x118 I Read/Write: R/W I Reset: 0x00000000 (0bxxxxxxxx00000000000000000000000)

Bit	Reset	Description
24:0	0x0	VALUE: If Boot Data is not received within the programmed number of cycles. Then Data Timeout error occurs.

32.9.3.8 SDMMCAA_VENDOR_DEBOUNCE_COUNT_0

Debounce Counter Value Register

The Debounce Counter runs on 32 kHz clock. Keeping the default value to 100 ms = (100 * 32 cycles/1 ms) = 3200 cycles for 100 ms = 0xC80

Offset: 0x11c I Read/Write: R/W I Reset: 0x00000c80 (0bxxxxxxxx00000000000110010000000)

Bit	Reset	Description
23:0	0xc80	VALUE: The number of 32 kHz clock cycles is programmed to meet Debounce period of the card slot.

32.9.3.9 SDMMCAA_VENDOR_MISC_CNTRL_0

Miscellaneous Vendor Control Register

SDMMC_SPARE0: Spare register bits with reset value of 0

SDMMC_SPARE0[0]: SW_RESET_CLKEN_OVERRIDE, override the sdmmc_clken when doing SW_RESET if set to 1.

SDMMC_SPARE0[1]: When set, allows SD clock to be stopped in the middle of a read data block while in SDR104/ HS400/HS667 modes (allow_sdr104_intrablock_stalls).

Unsafe for at least some SD/eMMC cards, but may improve SDR104 DMA read performance in some cases.

SDMMC_SPARE0[2]: When set, SDR104 support is advertised in SDMMC_CAPABILITIES_HIGHER_0_SDR104

SDMMC_SPARE0[3]: When set, SDR50 support is advertised in SDMMC_CAPABILITIES_HIGHER_0_SDR50

SDMMC_SPARE0[5]: When 0, masks the pad macro's "high speed" enable to 0, causing the pad macro to always launch data on the falling edge of the clock. This prevents the SD Host driver's setting of SDMMC_POWER_CONTROL_HOST_x_HIGH_SPEED_EN from undesirably affecting the output timing.

SDMMC_SPARE0[7:6]: Number of pipe stages.

SDMMC_SPARE0[8]: When set, DDR50 support is advertised in SDMMC_CAPABILITIES_HIGHER_0_DDR50

SDMMC_SPARE1: Spare register bits with reset value of 1

SDMMC_SPARE1[0]: CMD_CONFLICT_DISABLE, disable command line conflict if set to 1.

SDMMC_SPARE1[1]: Control bit to select between internal and external loop back clock. 1-external 0-internal

Tegra X1 does not support external loopback for any SDMMC controller.

Offset: 0x120 I Read/Write: R/W I Reset: 0xffff0098 (0b11111111111111110000000010011000)

Bit	Reset	Description
31:16	0xffff	SDMMC_SPARE1: Spare register bits with reset value of 1
15:1	0x4c	SDMMC_SPARE0: Spare register bits with reset value of 0x40
0	0x0	ERASE_TIMEOUT_LIMIT: Erase timeout value. 0 = FINITE: Finite, It is limited to the programmed value in the DATA_TIMEOUT_VALUE 1 = INFINITE: Infinite, Controller would be monitoring until the card is busy.

32.9.3.10 SDMMCAA_MAX_CURRENT_OVERRIDE_0

Offset: 0x124 I Read/Write: R/W I Reset: 0x00000000 (0bxxxxxxxx00000000000000000000000)

Bit	Reset	Description
23:16	0x0	OVERRIDE_FOR_1_8V: Maximum override for 1.8V VDD1
15:8	0x0	OVERRIDE_FOR_3_0V: Maximum override for 3.0V VDD1
7:0	0x0	OVERRIDE_FOR_3_3V: Maximum override for 3.3V VDD1

32.9.3.11 SDMMCAA_MAX_CURRENT_OVERRIDE_HI_0

Offset: 0x128 I Read/Write: R/W I Reset: 0x00000000 (0bxxxxxxxxxxxxxxxxxxxxxxxxxx00000000)

Bit	Reset	Description
7:0	0x0	OVERRIDE_FOR_1_8V_VDD2: Maximum override for 1.8V VDD2

32.9.3.12 SDMMCAA_VENDOR_IO_TRIM_CNTRL_0

Vendor I/O trimmer control register

Used to configure I/O trimmer

Table 208: Truth Table

Input Pins			Output	Comments
E_DPD	SEL_VREG	SEL_VREF	CLKOUT	
1	x[1]	x	0	The cell is in deep power down mode.
0	1	x	based on ip_clk_select selected clock input	Trimmer is powered by VAUXC.
0	0	x	based on ip_clk_select selected clock input	Trimmer is powered by regulated voltage.

1. 'x' indicates don't care.

* 'x' indicates don't care

Offset: 0x1ac I Read/Write: R/W I Reset: 0x00000015 (0bxxxxxxxxxxxxxxxxxxxxxxxxxxxx010101)

Bit	Reset	Description
5	ENABLE	TRIM_PWRSAVE: Enables power saving mode by clock gating the unused taps in delay chain Active low signal, 0 - power saving mode enabled - clock gating is enabled for unused trimmer taps - may affect tap delay 1 - no power saving - all the trimmer taps are not clock gated 0 = ENABLE 1 = DISABLE
4:3	VREF_925_MV	SEL_VREF_LEVEL: Selects Vref voltage level 0 = VREF_875_MV 1 = VREF_900_MV 2 = VREF_925_MV 3 = VREF_950_MV
2	0x1	SEL_VREG: Select voltage supply for delay chain present in both Trimmer and DLLPROD value: 0x0 ***Software should set this to 0x0 before accessing SD/eMMC. This setting makes IB trimmer delay independent of VDD_CORE*** 0 - selects regulated reference voltage for trimmer and DLL supply - default (recommended option for tunable SD/eMMC modes) 1 - selects VAUXC for trimmer and DLL supply and shut down BG+REG circuit (can be used in non-tunable modes for power saving) Power up time for BG+REG is ~3us(worst case). Power down time for BG+REG is ~1us(worst case). If software wants to turn on/off BG+REG when SDMMC is idle, it has to take hit of 3us power on time. When SEL_VREG is toggled, both DLL and rx clock trimmer output could glitch irrespective of input clock state which could cause corresponding rx CMD and DATA FIFOs to go into bad state. Software should issue SW_RESET_DAT and SW_RESET_CMD to reset host FIFOs after BG <-> VAUXC switching. This would ensure error free data transfers from there on. Powering down BG would need 3 us turn ON time which may cause IOPS reduction, if software shuts down BG after every transfer and enables it on seeing new transfer request; it may not be possible to do dynamic shut down of BG without stalling new requests.
1	0x0	SEL_VREF: Select reference voltage for voltage regulator 0 - selects Bandgap Voltage Reference (recommended option for SD/eMMC tunable modes) 1 - selects resistor divider voltage reference and power down bandgap Switching time between the supplies is 1us. When switching from one supply to other supply, we need to wait for at least 1us before doing any data transfers.
0	0x1	PD_BGREG: Not used - Dummy control Power down Band Gap voltage reference, voltage regulator and resistor chain voltage ref (BG+REG) present in custom I/O trimmer used for SD/eMMC bus tuning. Active High signal, PD_BGREG=1 => Power down BG+REG; PD_BGREG=0 => power up Power down and up time for BG+REG is 1us. If software wants to turn on/off BG+REG when SDMMC is idle, it has to follow 1us power on/off time. Back-up option for powering down BG. Software should clear this bit when it wants to turn ON BG by setting SEL_VREG=0. The original idea to have PD_BGREG pin is to provide power saving feature when the eMMC/SDMMC is in IDLE state, but not in DPD mode. This pin function is actually merged into SEL_VREG function -BG+REG circuit is shut-down when SEL_VREG=1 (trimmer powered by VAUXC)

32.9.3.13 SDMMCAA_VENDOR_DLLCAL_CFG_0

Vendor DLL calibration configuration register

This register is used to setup the DLL Calibration settings. Software has to run DLL calibration first before initiating data transfers in HS400 or HS667 modes and re-calibration is required whenever there is a change in eMMC device clock frequency in HS400/HS667 modes.

Offset: 0x1b0 I Read/Write: R/W I Reset: 0x16083504 (0b0x01011000001000001101010000010 0)

Bit	Reset	Description
31	0x0	CALIBRATE: CALIBRATE is used to start a DLL calibration process. Software should set this bit to trigger calibration and should not clear this bit. This bit will be cleared once the calibration process is completed.
29:25	0xb	END_COUNT: END_COUNT determines the end condition of the calibration. If USE_STATIC_CYCLES is not set, a usec timer is loaded with (2^END_COUNT) and calibration will be stopped once the timer expires. Recommended timer value is 1msec. If USE_STATIC_CYCLES is set and if the trimmer tap value being calibrated has not changed for this number of loops, the calibration ends. The number iterations is (2 ^ END_COUNT), if END_COUNT != 0
24	0x0	USE_STATIC_CYCLES: When set, calibration will be stopped when num static cycles reaches END_COUNT else usec timer is used. Recommended option is use usec timer.
23	0x0	IGNORE_START_TRIM: IGNORE_START is used to ignore the START_TRM value. Instead the calibration starts at the current programmed DDLLCAL value. This is intended to be used if we ever support periodic DDLL calibration.
22:16	0x8	START_TRIM: START_TRM specifies the starting trimmer value to calibrate the with.
15:12	0x3	FILTER_BITS: FILTER_BITS is the LSB of the counter to use for updating the trimmer value. The new trimmer value is trim_old + (count >> FILTER_BITS) - (trim_old >> FILTER_BITS) FILTER_BITS chosen < bits used for SAMPLE_COUNT
11:8	0x5	SAMPLE_COUNT: SAMPLE_COUNT is the number of times the phase detector is sampled before going onto the next set of trimmer values. The number of samples is (2 ^ SAMPLE_COUNT)

Bit	Reset	Description
7:0	0x4	SAMPLE_DELAY: SAMPLE_DELAY is the number of SDMMC host clks from changing the trimmer value to when the phase detector is sampled.

32.9.3.16 SDMMCAA_VENDOR_DLLCAL_CFG_STA_0

Vendor DLL calibration configuration register

This register is used to setup the DLL Calibration settings.

Software has to run DLL calibration first before initiating data transfers in HS400 or HS667 modes and re-calibration is required whenever there is a change in eMMC device clock frequency in HS400/HS667 modes. DLL calibration process is an open loop process in which DLL calibration controller can’t decide the final tap value on its own by looking at PD output from DLL.

Summary of DLL calibration process implemented:

1. Software programs SAMPLE_COUNT (number of samples to be taken per every tap value) and STOP_TIMER_VALUE in microseconds.
2. These two values decide the stop condition of calibration.
3. DLL calibration is triggered on writing '1' into CALIBRATE register field by software. The controller sets CAL_ACTIVE bit to indicate calibration running status.
4. DLL controller starts calibration by applying a tap value (may use START_TAP programmed) to MST DLL and loads usec timer with STOP_TIMER_VALUE.
    a. After SAMPLE_DELAY (4 cycles of DLL in clock), it starts taking SAMPLE_COUNT number of PD samples. A phase counter is updated based on PD value per every cycle.
    b. Based on phase counter value, 'Filter' decides whether to increment or decrement current tap value to get next tap value to be applied in next iteration.
    c. FILTER_BITS decides the accuracy of the decision made. FILTER_BITS < bits used for SAMPLE_COUNT.
5. Repeat step 3 till STOP_TIMER expires.
6. The controller stops calibration (updating tap value) and latches the tap value used in last calibration iteration. CALIBRATE bit will be cleared at this step.
7. The controller adds offsets programmed to calibrated tap value and applies the final codes to SLAVE DLLs.
8. The controller waits for slave DLL settle time and clears CAL_ACTIVE register bit.
9. Software polls for CAL_ACTIVE=0 and can start data transfers.

DLL lock time is represented as:

Each tap test time = (SAMPLE_DELAY + SAMPLE_COUNT) * DLL_CAL_CLK_PERIOD

Worst case DLL locking time = STOP_TIMER_VALUE = (NUM_CAL_ITERATIONS * (SAMPLE_DELAY + SAMPLE_COUNT) * DLL_CAL_CLK_PERIOD)

Default values chosen:

Worst case DLL locking time=1 ms = 1000 us = STOP_TIMER_VALUE.

SAMPLE_COUNT=32 samples per one tap;

SAMPLE_DELAY=4 cycles

Tap value is decided by PD and filter logic.

Notes:

- *Software needs to calibrate DLL before using eMMC5.0 HS400/HS667 mode (before tuning process). Re-calibration is required whenever eMMC I/O clock frequency is changed. This can be done as a part of standard clock frequency change sequence.*
- *DLL calibration would work at when I/O CLK is running at 200 MHz and above.*
- *For I/O CLK frequency is below 200 MHz, software should calculate delay code as per below equation:*
- *Delay Code = (Delay Code at 200 MHz) * 200 MHz / Target Frequency*
- *Under 85 MHz, DLL delay code may reach its maximum code (128 taps) for FF chips. In this case, software should use 128 taps.*
- *Software can run DLL calibration at 200 MHz once at boot time, save those values, scale and use them whenever frequency is changed. This is needed if software wants to do DFS.*

12:6	0x2	0x1	MUL_M: implements a multiplier - M+1 Final tap value is derived from best passing window and calculated as follows. Final tap value = first_pass + ((last_pass - first_pass)*Q); where Q = percentage of pass window;default-75% Q = M+1/(2^N); N:1...7 M:should be in range [0:2^N-1];
5:3	0x2	_NONE_	DIV_N: implements a divider - 2^N; maximum div is 2^7 =>128
2:0	0x0	_NONE_	TUNING_WORD_SEL: Selects desired word from 256-bit tuning status bitmap status_word[31:0] = status[255:0] >> (tuning_word_sel * 32)

32.9.3.18 SDMMCAA_VENDOR_TUNING_CNTRL1_0

Vendor Tuning Control1 register

Different step size is required in SDR50 mode to cover two UI (100 MHz => 2*10ns)

With 70ps/tap trimmer resolution, we can cover almost 2UI using step_size=8 in SDR50 and step_size=4 in SDR104.

Tuning will be done in HS200 - SDR mode only.

HS200 - tuning at 200 MHz - UHS_SEL should be SDR104 for executing tuning

Before initiating data transfers in HS400 mode, tuning procedure should be executed in HS200 mode with I/O clock running at 200 MHz

For overclocked modes: Before initiating data transfers in HS667 mode, tuning procedure should be executed in HS200 mode with I/O clock running at 333 MHz

---

Note: *eMMC bus tuning will always be run in HS200 mode only.*

Use step_size = 1 to scan through all taps.

32.9.3.22 SDMMCAA_VENDOR_PRESET_VAL0_0

Vendor Preset Value Registers

SD host specification defines one preset value register for each bus speed mode which should be set by host by some unique method.

Preset values vary based on the base frequency used which is in software (Tegra system driver) control.

Tegra System driver supposed to set BASE_CLK_FREQ in VENDOR_CLOCK_CNTRL register before handling over the control to SD host standard driver.

In the similar way, system driver should set below vendor preset values based on the base clock frequency and the desired card clock frequency in each bus speed mode

This should be done after every time SDMMC is reset and after every soft reset.

This is important as all SDMMC controllers follow the same register map, but could be programmed with different frequencies depending on the use case.

Default values are set assuming base clock frequency=208MHz.

Offset: 0x1d4 I Read/Write: R/W I Reset: 0x00201000 (0bxx00000001000000001000000000000)

31	0x0	_NONE_	AUTO_CAL_START: Writing a one to this bit starts the calibration state machine. This bit must be set even if the override is set in order to latch in the override value.
30	0x0	_NONE_	AUTO_CAL_OVERRIDE: AUTOCAL override. 0 = NORMAL: 0 (normal operation): use AUTO_CAL_PU/PD_OFFSET as an offset to the calibration state machine setting 1 = OVERRIDE: 1 (override): use AUTO_CAL_PU/PD_OFFSET register values directly
29	DISABLED	0x1	AUTO_CAL_ENABLE: AUTOCAL enable. 0 = DISABLED: 0 (disabled): use sdmmc2tmc_cfg* register settings for pullup/dn 1 = ENABLED: 1 (normal operation): use SDMMC generated pullup/dn (override or AUTOCAL)
28	0x0	_NONE_	AUTO_CAL_SLW_OVERRIDE: AUTOCAL slew rate override 0 = NORMAL: 0 (Normal operation) pad DRVDN/UP_SLWR/F tied to AUTO_CAL output DRDVDN/ UP_SLWR/F[1:0] = AUTO_CAL_PULLDOWN/UP[4:3] 1 = OVERRIDE: 1 (override) use CFG2TMC_SDIO[1|3]*_DRVDN/UP_SLWR/F pins to control pad slew inputs
18:16	0x1	_NONE_	AUTO_CAL_STEP: calibration step interval (in microseconds)
14:8	0x0	_NONE_	AUTO_CAL_PD_OFFSET: 2's complement offset for pull-down value
6:0	0x0	_NONE_	AUTO_CAL_PU_OFFSET: 2's complement offset for pull-up value

32.9.3.27 SDMMCAA_AUTO_CAL_INTERVAL_0

SDMEMCOMP pad calibration interval - Valid for SDMMC1/SDMMC3 Instances

Offset: 0x1e8 I Read/Write: R/W I Reset: 0x00000000 (0b00000000000000000000000000000000)

Bit	Reset	Description
31:0	0x0	AUTO_CAL_INTERVAL: 0: do calibration once Otherwise, auto-calibration occurs at intervals equivalent to the programmed number of microseconds.This feature is not supported from Tegra X1 due to movement of level shifters to COMP pad.Software should trigger calibration at regular intervals, if needed.

32.9.3.28 SDMMCAA_AUTO_CAL_STATUS_0

SDMEMCOMP pad calibration status - Valid for SDMMC1/SDMMC3 Instances

Offset: 0x1ec I Read/Write: RO I Reset: 0xXXXXXXXX (0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx)

Bit	Reset	Description
31	X	AUTO_CAL_ACTIVE: One when auto calibrate is active - valid only after auto calibrate sequence has completed (AUTO_CAL_ACTIVE == 0)
30:24	X	AUTO_CAL_PULLDOWN_ADJ: Pulldown code sent to pads
22:16	X	AUTO_CAL_PULLUP_ADJ: Pullup code sent to pads
14:8	X	AUTO_CAL_PULLDOWN: Pulldown code generated by auto-calibration
6:0	X	AUTO_CAL_PULLUP: Pullup code generated by auto-calibration

32.9.3.29 SDMMCAA_IO_SPARE_0

SPARE bits. These SPARE_OUT bits go to pipe -> pad and then come back as SPARE_IN

SPARE_OUT[3]: IO_SPARE[19] - used as MUX select which selects between one cycle delay and two cycle delay versions of cmd_oen to mask wdata of IB capture flop.

0x0: selects two cycle delayed version

0x1: selects one cycle delayed version - recommended

SPARE_OUT[2]: IO_SPARE[18] - used as active low enable for gating both CMD_IN and DAT_IN async FIFOs wdata when we are driving CMD/DAT lines.

0x0: write 1 when OEN is active and Zi value when OEN is not active into FIFO (default)

0x1: write Zi value into FIFO irrespective of OEN state.

Offset: 0x1f0 I Read/Write: R/W I Reset: 0xXXXXXXXX (0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx) I Default: 0x00080008

Bit	R/W	Reset	SW Default	Description
31:16	RW	X	0x8	SPARE_OUT:PROD value: Software should set SPARE_OUT[3]: IO_SPARE[19] to 1 before accessing SD/eMMC.
15:0	RO	X	0x8	SPARE_IN

32.9.3.30 SDMMCAA_SDMMCAA_MCCIF_FIFOCTRL_0

Memory Client Interface FIFO Control (where applicable) and Clock Gating Control Register.

Note: *The FIFO timing aspects of this register are no longer supported, but retained for software compatibility*

The clock override/ovr_mode fields of this register control the 2nd-level clock gating for the client and mc side of the mccif. All clock gating is enabled by default.

A '1' written to the rclk/wclk override field will result in one of the following:

With wclk/rclk override mode = LEGACY, the clock reverts to legacy mode of operation where the clock is on whenever the client clk is enabled.

With wclk/rclk override mode = ON, the clock is always on inside mccif and PC.

A '1' written to the cclk override field keeps client's clk always on inside mccif.

Offset: 0x1f4 I Read/Write: R/W I Reset: 0x00000000 (0bxxxxxxxxxxxx00000xxxxxxxxxxxxxxxx)

Bit	Reset	Description
20	0x0	SDMMCA_RCLK_OVR_MODE
19	0x0	SDMMCA_WCLK_OVR_MODE
18	0x0	SDMMCA_CCLK_OVERRIDE
17	0x0	SDMMCA_RCLK_OVERRIDE
16	0x0	SDMMCA_WCLK_OVERRIDE

32.9.3.31 SDMMCAA_TIMEOUT_WCOAL_SDMMCAA_0

Write Coalescing Time-Out Register

Note: *Write coalescing is no longer supported by the MCCIF clients.*

Registers are retained for software compatibility but are not used by the hardware.

Offset: 0x1f8 I Read/Write: R/W I Reset: 0x00000032 (0bxxxxxxxxxxxxxxxxxxxxxxxxx00110010)

Bit	Reset	Description
7:0	0x32	SDMMCWA_WCOAL_TMVAL

32.9.4 SDMMC3 Vendor Registers

32.9.4.1 SDMMC_VENDOR_CLOCK_CNTRL_0

The following registers are Vendor Specific Registers and are mapped to Vendor Specific Address Space (0x100 - 0x1FF)

Vendor Clock Control Register

Offset: 0x100 I Read/Write: R/W I Reset: 0x0000d02d (0bxx00000000000000011010000x0101101)

Bit	Reset	Description
29	0x0	DIFF_CLK_SEL: If set, selects differential CLK and DQS; Used by eMMC IOBRICK only. Software should set this appropriately based on eMMC part used. E_INPUT_* (CMD/DAT/CLK) of emmc IOBRICK should be set to 0 when differential signaling is used. default is '0' - selects single ended signaling for clk/dqs
28:24	0x0	TRIM_VAL: Tap value for output data path trimmer This determines the trimmer value needed to drive the output data correctly. The tap for outbound trimmer is single MUX. The trim settings required are within very small (0-3) with absolute delay requirement of ~400ps. Minimal change with PVT variations. Following values are recommended. These are common for all speed modes of SD/eMMC. These are the initial values to start with. SDMMC1 - 2 SDMMC2 - 8 SDMMC3 - 3 SDMMC4 - 8
23:16	0x0	TAP_VAL: Tap value for input data path trimmer This determines the tap value needed to sample the input data correctly. Delay per each tap can range from 70ps (hv_ff) to 505ps (lv_ss). Following values are recommended. These are the initial values to start with. 1> SDR12/SDR25/High Speed DDRmodes: If I/O pad trimmer is used (default): SDMMC1 - 4 SDMMC2 - 0 SDMMC3 - 3 SDMMC4 - 0 If core legacy trimmer is used: SDMMC1 - 3 SDMMC2 - 3 SDMMC3 - 3 SDMMC4 - 3 2> SDR50 and SDR104/HS200/HS400/HS667 should use tuning procedure to determine the tap value
15:8	0xd0	BASE_CLK_FREQ: System software programs the base SD/MMC clock frequency into this register before loading the SD/MMC driver.This should not be touched when software wants to use SD card in uhs-II mode. This value is readable in the standard, but not writeable, SDMMC_CAPABILITIES_0_BASE_CLOCK_FREQUENCY register field. Software should program the actual clock frequency programmed in CAR registers CLK_RST_CONTROLLER_CLK_SOURCE_SDMMC*_0 for each SDMMC controller. This should be done after every time SDMMC is reset and after every soft reset. This is important as all SDMMC controllers follow the same register map, but could be programmed with different frequencies depending on the use case.
6	0x0	LEGACY_CLKEN_OVERRIDE: Override for sdmmc_legacy_g_clk clken; Set this to 0 when in UHS-II mode to save power 0 = NORMAL: 0 -> sdmmc_legacy_g_clk is gated 1 = OVERRIDE: 1 -> sdmmc_legacy_g_clk is not gated
5	0x1	SDR50_TUNING_OVERRIDE: override the SDR50_TUNING capabilities bit. Software should only set this bit if it is required to use Tuning for SDR50. (only supported for SDMMC1 and SDMMC3) 0 = NORMAL: 0 -> No Tuning support advertised for SDR50 mode. 1 = OVERRIDE : 1 -> Tuning support is enabled for SDR50 mode.
4	0x0	UHS2_CAPABILITY_OVERRIDE: override the UHS-II capabilities bit. 0 = NORMAL: 0 -> UHS-II support is unadvertised 1 = OVERRIDE: 1 -> UHS-II support is advertised
3	0x1	PADPIPE_CLKEN_OVERRIDE: Override for padmacro and pipemacro clken. 0 = NORMAL: 0 -> CLKEN is de-asserted when internal CLKEN is de-asserted. 1 = OVERRIDE : 1 -> CLKEN is kept asserted even when internal CLKEN is de-asserted. Software should always program this to 0x1 (OVERRIDE).

Bit	Reset	Description
2	0x1	SPI_MODE_CLKEN_OVERRIDE: Override for CLKEN during SPI_MODE during resettle. 0 = NORMAL: 0 -> CLKEN is de-asserted while doing sw_reset. 1 = OVERRIDE: 1 -> CLKEN is kept asserted while doing sw_reset. Software should always program this to 0 (NORMAL).
1	0x0	INPUT_IO_CLK: Feedback clock is selected by default. Software should not change this. Disabling Feedback clock will select Internal Clock that requires different TAP Value Programming. 0 = FEEDBACK 1 = INTERNAL
0	0x1	SDMMC_CLK: This is set when sdmmc_clk is supplied by the CAR module.Prior to sdmmc_clk switch OFF.This bit should be written '0'. By writing zero,the asynchronous card interrupt is routed to the Interrupt controller. 0 = DISABLE 1 = ENABLE

32.9.4.2 SDMMC_VENDOR_SYS_SW_CNTRL_0

Vendor System Software Control Register

Offset: 0x104 I Read/Write: R/W I Reset: 0x38600002 (0b00111000011xxxxxx0000000x0000010)

Bit	Reset	Description
31	0x0	ENHANCED_STROBE_MODE: Enables enhanced strobe mode in HS400/HS667 mode for eMMC5.x devices 0 - cmd_in(Resp) is sampled by loopback clock which requires tuning 1 - cmd_in(Resp) is sampled by DQS_in which requires no tuning software has to set this bit appropriately based on device capability since this is an optional feature for eMMC5.x devices. If device supports this feature, software should set this bit to avoid tuning.
30	0x0	USE_TMCLK_FOR_WR_CRC_STATUS_TIMEOUT: When set, uses TMCLK data timeout counter for generating wr_crc_status data-timeout When cleared, uses sdmmc_clk for maintaining wr_crc_status data timeout counter
29	0x1	USE_NCRC_FOR_WR_CRC_STATUS_TIMEOUT_VAL: This field is valid only when USE_TMCLK_FOR_WR_CRC_STATUS_TIMEOUT is set to 0. When cleared, uses data timeout value as wr CRC status timeout value (specification defined one) When set, uses Ncrc cycles as timeout value
28	0x1	USE_TMCLK_FOR_DATA_TIMEOUT: When set, uses TMCLK data timeout counter for generating legacy data timeout error (except wr_crc_status timeout) When cleared, uses sdmmc_clk for maintaining data timeout counter
27:24	0x8	DEVICE_BUSY_WAIT_CYCLES: In HS400/667 mode, busy should be sampled using clock instead DQS.So, Dat0 from card is passed to two different async FIFOs (one is running in sdmmc_clk and other is in sdmmc_dqs).CRC status is taken from dat0 sampled in DQS and busy should be checked after CRC status end bit reception using dat0 sampled in clk.Both clk and DQS dat0 paths don't have same prop delay due to sync-ers used in async FIFOs and also due to phase difference between clk and dqs.Due to this delay difference between the paths, we may sample wrong busy status if we sample busy immediately after receiving END bit of CRC status. To avoid incorrect sampling of busy, a wait state before busy polling is added. This register field is used to load wait_cycles counter. Note that this counter is used only in HS400/667 mode.
23	0x0	ALLOW_CARD_CLK_STALLS_IN_WR: When set, allows card clock stopping during transfer of data within a block in HIGH SPEED DDR/HS400 writes.
22	0x1	EMMC_IOBRICK_CLK_DATA: Used to drive AP_CLK and AN_CLK input of iobrick.0x1 - clk_out will be same as iobrick_clk_in0x0 - clk_out will be inverted iobrick_clk_in
21	0x1	QUALIFY_WITH_RD_DATA_VLD: We have async FIFOs in both cmd_in and dat_in paths in padmacro which are used in tunable modes.When this bit set, rdata from FIFO is treated as valid data only when rd_req is high. This is needed to handle bubbles on 'rd_req' when MTBF is high.
14	0x0	SD_BUS_POWER_ON_OFF_INT_STATUS: SD_BUS_POWER was changed. System software can use this interrupt to implement power switch.
13	0x0	VOLT_SWITCH_INT_STATUS: VOLT_18_EN was changed. System software can use this interrupt to implement a UHS-I voltage switch procedure for a standard SD Host driver 0 = NO_INT 1 = GEN_INT
12	0x0	TUNING_SYS_INT_STATUS: CMD19 was issued while EXECUTE_TUNING was set. System software can use this interrupt to implement a UHS-I tuning procedure for a standard SD Host driver. 0 = NO_INT 1 = GEN_INT
11:8	0x0	TUNING_ASYNC_FIFO_ADDNL_DELAY: In tunable modes, data/cmd IB path uses async FIFO which contributes additional delay to cmd/resp and wdata/CRC token round trip delay.Controller waits for this round trip delay before waiting for Ncr or Ncrc. This is required not to latch previous data/cmd driven by host itself as start bits of resp or CRC.Round trip delay is calculated for async FIFO with sync-2d.This register field holds the additional delay in cycles which should be added to round trip delay. This additional delay is caused by increasing sync-er depth (more than 2) or addition of output flop stage in async FIFO. Default value is zero. NOTE: Software should not update this field unless a new PROD setting is given.

Bit	Reset	Description
6	0x0	SD_BUS_POWER_ON_OFF_INT_ENABLE: Enables a separate system interrupt (i.e., not the standard SDHCI interrupt) when SD_BUS_POWER is changed. 0 = DISABLE 1 = ENABLE
5	0x0	VOLT_SWITCH_INT_ENABLE: Enables a separate system interrupt (i.e., not the standard SDHCI interrupt) when VOLT_18_EN is changed. 0 = DISABLE 1 = ENABLE
4	0x0	TUNING_SYS_INT_ENABLE: Enables a separate system interrupt (i.e., not the standard SDHCI interrupt) when CMD19 is issued while EXECUTE_TUNING is set. 0 = DISABLE 1 = ENABLE
3	0x0	ASSERT_BUFF_RD_RDY_INT: Write a 1 to this field to assert sdmmc_interrupt_status_0_buffer_read_ready. Used by the system software that implements the tuning procedure to signal to the standard SD driver that the tuning process has completed 0 = DISABLE 1 = ENABLE
2	0x0	IO_TRIM_BYPASS: Override bit for selecting between core trimmer (Vcore dependent) and I/O trimmer (custom trimmer) in IB clock path. Default option is I/O trimmer; software should not set this field.
1	0x1	INT_MASK_WHILE_TUNING: As per specification, Host should not generate any interrupts (including cmd_complete and data_xfer_complete) except buffer_read_ready interrupt during tuning sequence is being performed software can override this behavior by clearing this bit - but this leads to a specification violation 0 = DISABLE 1 = ENABLE
0	0x0	SPI_MODE: This is a mirror bit.The SPI mode is set if this bit is set or CMD_XFER_MODE[7] is set Writing 1 will drive the CS Low and writing zero will de-assert the CS Signal 0 = DISABLE: 0 -> SPI mode is disabled. 1 = ENABLE: 1 -> SPI mode is enabled.

32.9.4.3 SDMMC_VENDOR_ERR_INTR_STATUS_0

Legacy Interrupt Status Register

The fields are valid when an error interrupt has occurred.

Offset: 0x108 I Read/Write: RO I Reset: 0x000XXXXX (0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx)

Bit	Reset	Description
18	X	SDMMC_LEGACY_CTLR_IDLE: indicates legacy SD interface controller is idle - no active data transfers on legacy SD interface
17	X	READ_DATA_TIMEOUT: valid when a data timeout error occurs
16	X	WRITE_CRC_STATUS_TIMEOUT: valid when a data timeout error occurs
15	X	WRITE_BUSY_TIMEOUT: valid when a data timeout error occurs
14	X	RESP_BUSY_TIMEOUT: valid when a data timeout error occurs
13	X	SPI_WRITE_BUSY_TIMEOUT
12	X	SPI_RX_START_TOKEN_TIMEOUT
8:5	X	SPI_DAT_ERR_TOKEN: Data Error Token, while read from card.
4:0	X	SPI_DAT_RESPONSE: Data Response while write to card 5 = DATA_ACCEPTED 11 = CRC_ERR 13 = WRITE_ERR

32.9.4.4 SDMMC_VENDOR_CAP_OVERRIDES_0

Capabilities override bits

Offset: 0x10c I Read/Write: R/W I Reset: 0x00000007 (0bxxx0xxxxxxxxxxxxx000000xxxx0111)

Bit	Reset	Description
28	0x0	CMD_QUEUING_MODE_EN: useful for eMMC5.x devices which support CMD queuing. Software should enable this when it wants to use cmd queuing of eMMC5.x devices in HS400 mode.
13:8	0x0	DQS_TRIM_VAL:PROD_VAL=0x11 - Tap value for incoming DQS path trimmer - used in HS400/HS667 modes
3	0x0	DRV_LPBK_CLK_ON_CMD_LINE:Loopback trimmed clock will be driven onto cmd line, if this bit set to 1. Should be set to zero during normal data transfers.Useful in debug.
2	0x1	VOLTAGE_3_3_V_SUPPORT_OVERRIDE: Voltage support 3_3_V override
1	0x1	VOLTAGE_3_0_V_SUPPORT_OVERRIDE: Voltage support 3_0_V override
0	0x1	VOLTAGE_1_8_V_SUPPORT_OVERRIDE: Voltage support 1_8_V override

32.9.4.5 SDMMC_VENDOR_BOOT_CNTRL_0

Vendor Boot Control Register

This register is used to configure Boot Mode to support MMC v4.3 cards.

Offset: 0x110 I Read/Write: R/W I Reset: 0x00000000 (0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx00)

Bit	Reset	Description
1	0x0	BOOT_ACK: This bit is used to support Boot Option in MMC 4.3 version cards. If set Boot acknowledgment is given by card else not given by card 0 = DISABLE 1 = ENABLE
0	0x0	BOOT: This bit enables/disable BootOption1.If set BootOption1 is enable, hardware auto clears it when boot data is done. Writing 0 terminates the BootOption1 0 = DISABLE 1 = ENABLE

32.9.4.6 SDMMC_VENDOR_BOOT_ACK_TIMEOUT_0

Vendor Boot Acknowledgment Timeout Register

Offset: 0x114 I Read/Write: R/W I Reset: 0x00000000 (0bxxxxxxxxxxxx00000000000000000000)

Bit	Reset	Description
19:0	0x0	VALUE: If Boot Acknowledgment is not received within the programmed number of cycles. Boot Acknowledgment Timeout error occurs(VENDOR_SPECIFIC_ERR[0])

32.9.4.7 SDMMC_VENDOR_BOOT_DAT_TIMEOUT_0

Boot Data Timeout Register

Offset: 0x118 I Read/Write: R/W I Reset: 0x00000000 (0bxxxxxxxx00000000000000000000000)

Bit	Reset	Description
24:0	0x0	VALUE: If Boot Data is not received within the programmed number of cycles. Then Data Timeout error occurs.

32.9.4.8 SDMMC_VENDOR_DEBOUNCE_COUNT_0

Debounce Counter Value Register

The Debounce Counter runs on 32 kHz clock. Keeping the default value to 100 ms = (100 * 32 cycles/1ms) = 3200 cycles for 100 ms = 0xC80

Offset: 0x11c I Read/Write: R/W I Reset: 0x00000c80 (0bxxxxxxxx00000000000110010000000)

Bit	Reset	Description
23:0	0xc80	VALUE: The number of 32KHz clock cycles is programmed to meet Debounce period of the card slot.

32.9.4.9 SDMMC_VENDOR_MISC_CNTRL_0

Miscellaneous Vendor Control Register

SDMMC_SPARE0: Spare register bits with reset value of 0

SDMMC_SPARE0[0]: SW_RESET_CLKEN_OVERRIDE, override the sdmmc_clken when doing SW_RESET if set to 1.

SDMMC_SPARE0[1]: When set, allows SD clock to be stopped in the middle of a read data block while in SDR104/ HS400/HS667 modes(allow_sdr104_intrablock_stalls).

Unsafe for at least some SD/eMMC cards, but may improve SDR104 DMA read performance in some cases.

SDMMC_SPARE0[2]: When set, SDR104 support is advertised in SDMMC_CAPABILITIES_HIGHER_0_SDR104

SDMMC_SPARE0[3]: When set, SDR50 support is advertised in SDMMC_CAPABILITIES_HIGHER_0_SDR50

SDMMC_SPARE0[5]: When 0, masks the pad macro's "high speed" enable to 0, causing the pad macro to always launch data on the falling edge of the clock. This prevents the SD Host driver's setting of SDMMC_POWER_CONTROL_HOST_x_HIGH_SPEED_EN from undesirably affecting the output timing.

SDMMC_SPARE0[7:6]: Number of pipe stages.

SDMMC_SPARE0[8]: When set, DDR50 support is advertised in SDMMC_CAPABILITIES_HIGHER_0_DDR50

SDMMC_SPARE1: Spare register bits with reset value of 1

SDMMC_SPARE1[0]: CMD_CONFLICT_DISABLE, disable command line conflict if set to 1.

SDMMC_SPARE1[1]: Control bit to select between internal and external loopback clock. 1-external 0-internal

Tegra X1 does not support external loopback for any SDMMC controller.

Offset: 0x120 I Read/Write: R/W I Reset: 0xffff0098 (0b11111111111111111000000010011000)

Bit	Reset	Description
31:16	0xffff	SDMMC_SPARE1: Spare register bits with reset value of 1
15:1	0x4c	SDMMC_SPARE0: Spare register bits with reset value of 0x40
0	0x0	ERASE_TIMEOUT_LIMIT: Erase timeout value. 0 = FINITE: Finite, It is limited to the programmed value in the DATA_TIMEOUT_VALUE 1 = INFINITE: Infinite,Controller would be monitoring until the card is busy.

32.9.4.10 SDMMC_MAX_CURRENT_OVERRIDE_0

Offset: 0x124 I Read/Write: R/W I Reset: 0x00000000 (0bxxxxxxxx00000000000000000000000)

Bit	Reset	Description
23:16	0x0	OVERRIDE_FOR_1_8V: Maximum override for 1.8V VDD1
15:8	0x0	OVERRIDE_FOR_3_0V: Maximum override for 3.0V VDD1
7:0	0x0	OVERRIDE_FOR_3_3V: Maximum override for 3.3V VDD1

32.9.4.11 SDMMC_MAX_CURRENT_OVERRIDE_HI_0

Offset: 0x128 I Read/Write: R/W I Reset: 0x00000000 (0bxxxxxxxxxxxxxxxxxxxxxxxxxx00000000)

Bit	Reset	Description
7:0	0x0	OVERRIDE_FOR_1_8V_VDD2: Maximum override for 1.8V VDD2

32.9.4.12 SDMMC_VENDOR_IO_TRIM_CNTRL_0

Vendor I/O trimmer control register

Used to configure I/O trimmer

Table 209: Truth Table

Input Pins			Output	Comments
E_DPD	SEL_VREG	SEL_VREF	CLKOUT	
1	x[1]	x	0	The cell is in deep power down mode.
0	1	x	based on ip_clk_select selected clock input	Trimmer is powered by VAUXC.
0	0	x	based on ip_clk_select selected clock input	Trimmer is powered by regulated voltage.

1. 'x' indicates don't care.

Offset: 0x1ac I Read/Write: R/W I Reset: 0x00000015 (0bxxxxxxxxxxxxxxxxxxxxxxxxxxxx010101)

Bit	Reset	Description
5	ENABLE	TRIM_PWRSAVE: Enables power saving mode by clock gating the unused taps in delay chain Active low signal, 0 - power saving mode enabled - clock gating is enabled for unused trimmer taps - may affect tap delay 1 - no power saving - all the trimmer taps are not clock gated 0 = ENABLE 1 = DISABLE
4:3	VREF_925_MV	SEL_VREF_LEVEL: Selects Vref voltage level 0 = VREF_875_MV 1 = VREF_900_MV 2 = VREF_925_MV 3 = VREF_950_MV
2	0x1	SEL_VREG: Select voltage supply for delay chain present in both Trimmer and DLLPROD value: 0x0 ***Software should set this to 0x0 before accessing SD/eMMC. This setting makes IB trimmer delay independent of VDD_CORE*** 0 - selects regulated reference voltage for trimmer and DLL supply - default (recommended option for tunable SD/eMMC modes) 1 - selects VAUXC for trimmer and DLL supply and shut down BG+REG circuit (can be used in non-tunable modes for power saving) Power up time for BG+REG is ~3 us (worst case). Power down time for BG+REG is ~1us(worst case). If software wants to turn on/off BG+REG when SDMMC is idle, it has to take hit of 3us power on time. When SEL_VREG is toggled, both DLL and rx clock trimmer output could glitch irrespective of input clock state which could cause corresponding rx CMD and DATA FIFOs to go into bad state. Software should issue SW_RESET_DAT and SW_RESET_CMD to reset host FIFOs after BG <-> VAUXC switching. This would ensure error free data transfers from there on. Powering down BG would need 3 us turn ON time which may cause IOPS reduction, if software shuts down BG after every transfer and enables it on seeing new transfer request; it may not be possible to do dynamic shut down of BG without stalling new requests.
1	0x0	SEL_VREF: Select reference voltage for voltage regulator 0 - selects Bandgap Voltage Reference (recommended option for SD/eMMC tunable modes) 1 - selects resistor divider voltage reference and power down bandgap Switching time between the supplies is 1us. When switching from one supply to other supply, we need to wait for at least 1us before doing any data transfers.
0	0x1	PD_BGREG: Not used - Dummy control Power down Band Gap voltage reference, voltage regulator and resistor chain voltage ref (BG+REG) present in custom I/O trimmer used for SD/eMMC bus tuning. Active High signal, PD_BGREG=1 => Power down BG+REG; PD_BGREG=0 => power up Power down and up time for BG+REG is 1us. If software wants to turn on/off BG+REG when SDMMC is idle, it has to follow 1us power on/off time. Back-up option for powering down BG. Software should clear this bit when it wants to turn ON BG by setting SEL_VREG=0. The original idea to have PD_BGREG pin is to provide power saving feature when the eMMC/SDMMC is in IDLE state, but not in DPD mode. This pin function is actually merged into SEL_VREG function -BG+REG circuit is shut-down when SEL_VREG=1 (trimmer powered by VAUXC)

32.9.4.13 SDMMC_VENDOR_TUNING_CNTRL0_0

Vendor Tuning Control0 Register

Offset: 0x1c0 I Read/Write: R/W I Reset: 0x74020090 (0bx11101000000001x0000000010010000) I Default: 0x00000040

Bit	Reset	SW Default	Description
29	0x1	_NONE_	WR_DATA_CRC_ERR_EN: If cleared, Re-tuning request/tuning error is not generated on write CRC error
28	0x1	_NONE_	CMD_CRC_ERR_EN: If cleared, Re-tuning request/tuning error is not generated on cmd CRC error
27	0x0	_NONE_	RETUNING_REQ_EN_ON_CRC_ERR_DETECTION: Re-tuning request is generated when set to initiate re-tuning by software to compensate for temperature drift when any data or cmd CRC errors are detected in SDR50/SDR104/HS200 modes
26	0x1	_NONE_	TUNING_ERR_EN_ON_CRC_ERR_DETECTION: Tuning error is generated to initiate re-tuning by software to compensate for temperature drift when any data or cmd CRC errors are detected in SDR50/SDR104/HS200 modes
25:18	0x0	_NONE_	START_TAP_VAL: start tap value to be used by tuning; start_tap should be multiple of step_size chosen and its valid range is 0-255; Not valid when TAP_VAL_UPDATED_BY_HW is set to zero. Tuning algorithm uses this as the start tap value for scanning through trimmer taps.
17	0x1	_NONE_	TAP_VAL_UPDATED_BY_HW: This bit is functional only in tunable modes (SDR50, SDR104 and HS200) software can choose to update the tap value by itself by clearing this bit; Preferred value is 1 - tap value is updated by hardware. If this bit is cleared, hardware does not update tap_val per every tuning iteration. Software can update it as desired. Tuning pattern match is indicated by sampling_clock_select per every tuning iteration. Software has to maintain the status of each tuning iteration and determine the best PASS window to fix the final sampling point. Software can program NUM_TUNING_ITERATIONS as desired. Once the number of tuning commands issued reaches number of tuning iterations programmed, execute_tuning bit will be cleared to indicate the completion of tuning procedure. Note that using this option violates Host specification but provided for legacy reasons. It helps us in using legacy software tuning solution in case hardware solution does not work.
15:13	TRIES_40	_NONE_	NUM_TUNING_ITERATIONS: The number of tuning iterations to be used by tuning circuit; Preferred value is 40 iterations as per Host specification. Using other values violates the specification but provided for trimmer characterization purpose. 0 = TRIES_40 1 = TRIES_64 2 = TRIES_128 3 = TRIES_192 4 = TRIES_256
12:6	0x2	0x1	MUL_M: implements a multiplier - M+1 Final tap value is derived from best passing window and calculated as follows. Final tap value = first_pass + ((last_pass - first_pass)*Q); where Q = percentage of pass window;default-75% Q = M+1/(2^N); N:1...7 M: should be in range [0:2^N-1];
5:3	0x2	_NONE_	DIV_N: implements a divider - 2^N; maximum div is 2^7 =>128
2:0	0x0	_NONE_	TUNING_WORD_SEL: Selects desired word from 256-bit tuning status bitmap status_word[31:0] = status[255:0] >> (tuning_word_sel * 32)

32.9.4.14 SDMMC_VENDOR_TUNING_CNTRL1_0

Vendor Tuning Control1 register

Different step size is required in SDR50 mode to cover two UI (100MHz => 2*10ns)

With 70ps/tap trimmer resolution, we can cover almost 2UI using step_size=8 in SDR50 and step_size=4 in SDR104.

Tuning will be done in HS200 - SDR mode only.

HS200 - tuning at 200 MHz - UHS_SEL should be SDR104 for executing tuning

Before initiating data transfers in HS400 mode, tuning procedure should be executed in HS200 mode with I/O clock running at 200 MHz

For overclocked modes: Before initiating data transfers in HS667 mode, tuning procedure should be executed in HS200 mode with I/O clock running at 333MHz

> ***Note:*** *eMMC bus tuning will always be run in HS200 mode only.*

Use step_size = 1 to scan through all taps due to hardware issue.

Offset: 0x1c4 I Read/Write: R/W I Reset: 0x00000023 (0bxxxxxxxxxxxxxxxxxxxxxxxxxxx010x011) I Default: 0x00000000

5:0	0xf	CLK_COUNT: Before gating second level clocks controller will wait for these many cycles. we can recover if any idle windows are missed in clken equation

32.9.4.18 SDMMC_VENDOR_PRESET_VAL0_0

Vendor Preset Value Registers

SD host specification defines one preset value register for each bus speed mode which should be set by host by some unique method.

Preset values vary based on the base frequency used which is in software (Tegra system driver) control.

Tegra System driver supposed to set BASE_CLK_FREQ in VENDOR_CLOCK_CNTRL register before handling over the control to SD host standard driver.

In the similar way, system driver should set below vendor preset values based on the base clock frequency and the desired card clock frequency in each bus speed mode

This should be done after every time SDMMC is reset and after every soft reset.

This is important as all SDMMC controllers follow the same register map, but could be programmed with different frequencies depending on the use case.

Default values are set assuming base clock frequency=208MHz.

Offset: 0x1d4 I Read/Write: R/W I Reset: 0x00201000 (0bxx00000000100000000010000000000000)

Bit	Reset	Description
29:20	0x2	SDCLK_FREQ_SEL_HIGH_SPEED: System software programs 10-bit divider value to generate SDCLK in default speed mode (<50 MHz,3.3V signaling). This value is readable in the standard via PRESET_SDR12_AND_HIGH_0_SDCLK_FREQ_VAL_LOW register field. Default value is 0x2 assuming 208 MHz base clock
19:10	0x4	SDCLK_FREQ_SEL_DEFAULT: System software programs 10-bit divider value to generate SDCLK in default speed mode (<25MHz,3.3V signaling). This value is readable in the standard via PRESET_DEFAULT_AND_INIT_0_SDCLK_FREQ_VAL_HIGH register field. Default value is 0x4 assuming 208 MHz base clock
9:0	0x0	SDCLK_FREQ_SEL_INIT: System software programs 10-bit divider value to generate desired SDCLK frequency during initialization. This value is readable in the standard via PRESET_DEFAULT_AND_INIT_0_SDCLK_FREQ_VAL_LOW register field. For example, if 400 kHz SDCLK is desired at base clk freq=48 MHz, this register should be programmed with 0x3C

32.9.4.19 SDMMC_VENDOR_PRESET_VAL1_0

Offset: 0x1d8 I Read/Write: R/W I Reset: 0x00100804 (0bxx00000000100000000100000000100)

6:0	0x0	_NONE_	AUTO_CAL_PU_OFFSET: 2's complement offset for pull-up value

32.9.4.23 SDMMC_AUTO_CAL_INTERVAL_0

SDMEMCOMP pad calibration interval - Valid for SDMMC1/SDMMC3 Instances

Offset: 0x1e8 I Read/Write: R/W I Reset: 0x00000000 (0b00000000000000000000000000000000)

Bit	Reset	Description
31:0	0x0	AUTO_CAL_INTERVAL: 0: do calibration once Otherwise, auto-calibration occurs at intervals equivalent to the programmed number of microseconds.This feature is not supported from Tegra X1 due to movement of level shifters to COMP pad.Software should trigger calibration at regular intervals, if needed.

32.9.4.24 SDMMC_AUTO_CAL_STATUS_0

SDMEMCOMP pad calibration status - Valid for SDMMC1/SDMMC3 Instances

Offset: 0x1ec I Read/Write: RO I Reset: 0xXXXXXXXX (0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx)

Bit	Reset	Description
31	X	AUTO_CAL_ACTIVE: One when auto calibrate is active - valid only after auto calibrate sequence has completed (AUTO_CAL_ACTIVE == 0)
30:24	X	AUTO_CAL_PULLDOWN_ADJ: Pulldown code sent to pads
22:16	X	AUTO_CAL_PULLUP_ADJ: Pullup code sent to pads
14:8	X	AUTO_CAL_PULLDOWN: Pulldown code generated by auto-calibration
6:0	X	AUTO_CAL_PULLUP: Pullup code generated by auto-calibration

32.9.4.25 SDMMC_IO_SPARE_0

SPARE bits. These SPARE_OUT bits go to pipe -> pad and then come back as SPARE_IN

SPARE_OUT[3]: IO_SPARE[19] - used as MUX select which selects between one cycle delay and two cycle delay versions of cmd_oen to mask wdata of IB capture flop.

0x0: selects two cycle delayed version

0x1: selects one cycle delayed version - recommended

SPARE_OUT[2]: IO_SPARE[18] - used as active low enable for gating both CMD_IN and DAT_IN async FIFOs wdata when we are driving CMD/DAT lines.

0x0: write 1 when OEN is active and Zi value when OEN is not active into FIFO (default)

0x1: write Zi value into FIFO irrespective of OEN state.

Offset: 0x1f0 I Read/Write: R/W I Reset: 0xXXXXXXXX (0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx) I Default: 0x00080008

Bit	R/W	Reset	SW Default	Description
31:16	RW	X	0x8	SPARE_OUT:PROD value: Software should set SPARE_OUT[3]: IO_SPARE[19] to 1 before accessing SD/eMMC.
15:0	RO	X	0x8	SPARE_IN

32.9.4.26 SDMMC_SDMMC_MCCIF_FIFOCTRL_0

Memory Client Interface FIFO Control (where applicable) and Clock Gating Control Register.

> ***Note:*** *The FIFO timing aspects of this register are no longer supported, but retained for software compatibility*

The clock override/ovr_mode fields of this register control the 2nd-level clock gating for the client and mc side of the mccif. All clock gating is enabled by default.

A '1' written to the rclk/wclk override field will result in one of the following:

With wclk/rclk override mode = LEGACY, the clock reverts to legacy mode of operation where the clock is on whenever the client clk is enabled.

With wclk/rclk override mode = ON, the clock is always on inside mccif and PC.

A '1' written to the cclk override field keeps client's clk always on inside mccif.

Offset: 0x1f4 I Read/Write: R/W I Reset: 0x00000000 (0bxxxxxxxxxxxx00000xxxxxxxxxxxxxxxx)

Bit	Reset	Description
20	0x0	SDMMCA_RCLK_OVR_MODE

16	0x0	SDMMCA_WCLK_OVERRIDE

32.9.4.27 SDMMC_TIMEOUT_WCOAL_SDMMC_0

Write Coalescing Time-Out Register

Note: *Write coalescing is no longer supported by the MCCIF clients.*

Registers are retained for software compatibility but are not used by the hardware.

Offset: 0x1f8 I Read/Write: R/W I Reset: 0x00000032 (0bxxxxxxxxxxxxxxxxxxxxxxxxxx00110010)

Bit	Reset	Description
7:0	0x32	SDMMCWA_WCOAL_TMVAL

32.9.5 SDMMC4 Vendor Registers

32.9.5.1 SDMMCAB_VENDOR_CLOCK_CNTRL_0

The following registers are Vendor Specific Registers and are mapped to Vendor Specific Address Space (0x100 - 0x1FF)

Vendor Clock Control Register

Offset: 0x100 I Read/Write: R/W I Reset: 0x0000d02d (0bxx00000000000011010000x0101101)

Bit	Reset	Description
29	0x0	DIFF_CLK_SEL: If set, selects differential CLK and DQS; Used by eMMC IOBRICK only. Software should set this appropriately based on eMMC part used. E_INPUT_* (CMD/DAT/CLK) of emmc IOBRICK should be set to 0 when differential signaling is used. default is '0' - selects single ended signaling for clk/dqs
28:24	0x0	TRIM_VAL: Tap value for output data path trimmer This determines the trimmer value needed to drive the output data correctly. The tap for outbound trimmer is single MUX. The trim settings required are within very small (0-3) with absolute delay requirement of ~400ps. Minimal change with PVT variations. Following values are recommended. These are common for all speed modes of SD/eMMC. These are the initial values to start with. SDMMC1 - 2 SDMMC2 - 8 SDMMC3 - 3 SDMMC4 - 8

Bit	Reset	Description
23:16	0x0	TAP_VAL: Tap value for input data path trimmer This determines the tap value needed to sample the input data correctly. Delay per each tap can range from 70ps (hv_ff) to 505ps (lv_ss). Following values are recommended. These are the initial values to start with. 1> SDR12/SDR25/High Speed DDR modes: If I/O pad trimmer is used (default): SDMMC1 - 4 SDMMC2 - 0 SDMMC3 - 3 SDMMC4 - 0 If core legacy trimmer is used: SDMMC1 - 3 SDMMC2 - 3 SDMMC3 - 3 SDMMC4 - 3 2> SDR50 and SDR104/HS200/HS400/HS667 should use tuning procedure to determine the tap value
15:8	0xd0	BASE_CLK_FREQ: System software programs the base SD/MMC clock frequency into this register before loading the SD/MMC driver.This should not be touched when software wants to use SD card in uhs-II mode. This value is readable in the standard, but not writeable, SDMMC_CAPABILITIES_0_BASE_CLOCK_FREQUENCY register field. Software should program the actual clock frequency programmed in CAR registers CLK_RST_CONTROLLER_CLK_SOURCE_SDMMC*_0 for each SDMMC controller. This should be done after every time SDMMC is reset and after every soft reset. This is important as all SDMMC controllers follow the same register map, but could be programmed with different frequencies depending on the use case.
6	0x0	LEGACY_CLKEN_OVERRIDE: Override for sdmmc_legacy_g_clk clken; Set this to 0 when in UHS-II mode to save power 0 = NORMAL: 0 -> sdmmc_legacy_g_clk is gated 1 = OVERRIDE: 1 -> sdmmc_legacy_g_clk is not gated
5	0x1	SDR50_TUNING_OVERRIDE: override the SDR50_TUNING capabilities bit. Software should only set this bit if it is required to use Tuning for SDR50. (only supported for SDMMC1 and SDMMC3) 0 = NORMAL: 0 -> No Tuning support advertised for SDR50 mode. 1 = OVERRIDE: 1 -> Tuning support is enabled for SDR50 mode.
4	0x0	UHS2_CAPABILITY_OVERRIDE: override the UHS-II capabilities bit. 0 = NORMAL: 0 -> UHS-II support is unadvertised 1 = OVERRIDE: 1 -> UHS-II support is advertised
3	0x1	PADPIPE_CLKEN_OVERRIDE: Override for padmacro and pipemacro clken. 0 = NORMAL: 0 -> CLKEN is de-asserted when internal CLKEN is de-asserted. 1 = OVERRIDE: 1 -> CLKEN is kept asserted even when internal CLKEN is de-asserted. Software should always program this to 0x1 (OVERRIDE).
2	0x1	SPI_MODE_CLKEN_OVERRIDE: Override for CLKEN during SPI_MODE during sw_reset. 0 = NORMAL: 0 -> CLKEN is de-asserted while doing sw_reset. 1 = OVERRIDE: 1 -> CLKEN is kept asserted while doing sw_reset. Software should always program this to 0 (NORMAL).
1	0x0	INPUT_IO_CLK: Feedback clock is selected by default. Software should not change this. Disabling Feedback clock will select Internal Clock that requires different TAP Value Programming. 0 = FEEDBACK 1 = INTERNAL
0	0x1	SDMMC_CLK: This is set when sdmmc_clk is supplied by the CAR module.Prior to sdmmc_clk switch OFF.This bit should be written '0'. By writing zero,the asynchronous card interrupt is routed to the Interrupt controller. 0 = DISABLE 1 = ENABLE

32.9.5.2 SDMMCAB_VENDOR_SYS_SW_CNTRL_0

Vendor System Software Control Register

Offset: 0x104 I Read/Write: R/W I Reset: 0x38600002 (0b00111000011xxxxxx0000000x0000010)

Bit	Reset	Description
31	0x0	ENHANCED_STROBE_MODE: Enables enhanced strobe mode in HS400/HS667 mode for eMMC5.x devices 0 - cmd_in(Resp) is sampled by loopback clock which requires tuning 1 - cmd_in(Resp) is sampled by DQS_in which requires no tuning software has to set this bit appropriately based on device capability since this is an optional feature for eMMC5.x devices. If device supports this feature, software should set this bit to avoid tuning.
30	0x0	USE_TMCLK_FOR_WR_CRC_STATUS_TIMEOUT: When set, uses TMCLK data timeout counter for generating wr_crc_status data-timeout When cleared, uses sdmmc_clk for maintaining wr_crc_status data timeout counter
29	0x1	USE_NCRC_FOR_WR_CRC_STATUS_TIMEOUT_VAL:This field is valid only when USE_TMCLK_FOR_WR_CRC_STATUS_TIMEOUT is set to 0. When cleared, uses data timeout value as wr CRC status timeout value (specification defined one) When set, uses Ncrc cycles as timeout value
28	0x1	USE_TMCLK_FOR_DATA_TIMEOUT: When set, uses TMCLK data timeout counter for generating legacy data timeout error (except wr_crc_status timeout) When cleared, uses sdmmc_clk for maintaining data timeout counter
27:24	0x8	DEVICE_BUSY_WAIT_CYCLES:In HS400/667 mode, busy should be sampled using clock instead DQS.So, Dat0 from card is passed to two different async FIFOs (one is running in sdmmc_clk and other is in sdmmc_dqs).CRC status is taken from dat0 sampled in DQS and busy should be checked after CRC status end bit reception using dat0 sampled in clk.Both clk and DQS dat0 paths don't have same prop delay due to sync-ers used in async FIFOs and also due to phase difference between clk and dqs.Due to this delay difference between the paths, we may sample wrong busy status if we sample busy immediately after receiving END bit of CRC status. To avoid incorrect sampling of busy, a wait state before busy polling is added. This register field is used to load wait_cycles counter. Note that this counter is used only in HS400/667 mode.
23	0x0	ALLOW_CARD_CLK_STALLS_IN_WR: When set, allows card clock stopping during transfer of data within a block in HIGH SPEED DDR/HS400 writes.
22	0x1	EMMC_IOBRICK_CLK_DATA:Used to drive AP_CLK and AN_CLK input of iobrick.0x1 - clk_out will be same as iobrick_clk_in0x0 - clk_out will be inverted iobrick_clk_in
21	0x1	QUALIFY_WITH_RD_DATA_VLD: There is async FIFOs in both cmd_in and dat_in paths in padmacro which are used in tunable modes. When this bit set, rdata from FIFO is treated as valid data only when rd_req is high. This is needed to handle bubbles on 'rd_req' when MTBF is high.
14	0x0	SD_BUS_POWER_ON_OFF_INT_STATUS: SD_BUS_POWER was changed. System software can use this interrupt to implement power switch.
13	0x0	VOLT_SWITCH_INT_STATUS: VOLT_18_EN was changed. System software can use this interrupt to implement a UHS-I voltage switch procedure for a standard SD Host driver 0 = NO_INT 1 = GEN_INT
12	0x0	TUNING_SYS_INT_STATUS: CMD19 was issued while EXECUTE_TUNING was set. System software can use this interrupt to implement a UHS-I tuning procedure for a standard SD Host driver. 0 = NO_INT 1 = GEN_INT
11:8	0x0	TUNING_ASYNC_FIFO_ADDNL_DELAY: In tunable modes, data/cmd IB path uses async FIFO which contributes additional delay to cmd/resp and wdata/CRC token round trip delay. Controller waits for this round trip delay before waiting for Ncr or Ncrc. This is required not to latch previous data/cmd driven by host itself as start bits of resp or CRC.Round trip delay is calculated for async FIFO with sync-2d. This register field holds the additional delay in cycles which should be added to round trip delay. This additional delay is caused by increasing sync-er depth (more than 2) or addition of output flop stage in async FIFO. Default value is zero. NOTE: Software should not update this field unless a new PROD setting is given.
6	0x0	SD_BUS_POWER_ON_OFF_INT_ENABLE: Enables a separate system interrupt (i.e., not the standard SDHCI interrupt) when SD_BUS_POWER is changed. 0 = DISABLE 1 = ENABLE
5	0x0	VOLT_SWITCH_INT_ENABLE: Enables a separate system interrupt (i.e., not the standard SDHCI interrupt) when VOLT_18_EN is changed. 0 = DISABLE 1 = ENABLE
4	0x0	TUNING_SYS_INT_ENABLE: Enables a separate system interrupt (i.e., not the standard SDHCI interrupt) when CMD19 is issued while EXECUTE_TUNING is set. 0 = DISABLE 1 = ENABLE

Bit	Reset	Description
3	0x0	ASSERT_BUFF_RD_RDY_INT: Write a 1 to this field to assert sdmmc_interrupt_status_0_buffer_read_ready. Used by the system software that implements the tuning procedure to signal to the standard SD driver that the tuning process has completed 0 = DISABLE 1 = ENABLE
2	0x0	IO_TRIM_BYPASS: Override bit for selecting between core trimmer (Vcore dependent) and I/O trimmer (custom trimmer) in IB clock path. Default option is I/O trimmer; software should not set this field.
1	0x1	INT_MASK_WHILE_TUNING: As per specification, Host should not generate any interrupts (including cmd_complete and data_xfer_complete) except buffer_read_ready interrupt during tuning sequence is being performed. Software can override this behavior by clearing this bit - but this leads to a specification violation 0 = DISABLE 1 = ENABLE
0	0x0	SPI_MODE: This is a mirror bit.The SPI mode is set if this bit is set or CMD_XFER_MODE[7] is set Writing 1 will drive the CS Low and writing zero will de-assert the CS Signal 0 = DISABLE: 0 -> SPI mode is disabled. 1 = ENABLE: 1 -> SPI mode is enabled.

32.9.5.3 SDMMCAB_VENDOR_ERR_INTR_STATUS_0

Legacy Interrupt Status Register

The fields are valid when an error interrupt has occurred.

Offset: 0x108 I Read/Write: RO I Reset: 0x000XXXXX (0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx)

Bit	Reset	Description
18	X	SDMMC_LEGACY_CTLR_IDLE: indicates legacy SD interface controller is idle - no active data transfers on legacy SD interface
17	X	READ_DATA_TIMEOUT: valid when a data timeout error occurs
16	X	WRITE_CRC_STATUS_TIMEOUT: valid when a data timeout error occurs
15	X	WRITE_BUSY_TIMEOUT: valid when a data timeout error occurs
14	X	RESP_BUSY_TIMEOUT: valid when a data timeout error occurs
13	X	SPI_WRITE_BUSY_TIMEOUT
12	X	SPI_RX_START_TOKEN_TIMEOUT
8:5	X	SPI_DAT_ERR_TOKEN: Data Error Token, while read from card.
4:0	X	SPI_DAT_RESPONSE: Data Response while write to card 5 = DATA_ACCEPTED 11 = CRC_ERR 13 = WRITE_ERR

Bit	Reset	Description
24:0	0x0	VALUE: If Boot Data is not received within the programmed number of cycles. Then Data Timeout error occurs.

32.9.5.8 SDMMCAB_VENDOR_DEBOUNCE_COUNT_0

Debounce Counter Value Register

The Debounce Counter runs on 32 kHz clock. Keeping the default value to 100 ms = (100 * 32 cycles/1 ms) = 3200 cycles for 100 ms = 0xC80

Offset: 0x11c I Read/Write: R/W I Reset: 0x00000c80 (0bxxxxxxxx000000000000110010000000)

Bit	Reset	Description
23:0	0xc80	VALUE: The number of 32KHz clock cycles is programmed to meet Debounce period of the card slot.

32.9.5.9 SDMMCAB_VENDOR_MISC_CNTRL_0

Miscellaneous Vendor Control Register

SDMMC_SPARE0: Spare register bits with reset value of 0

SDMMC_SPARE0[0]: SW_RESET_CLKEN_OVERRIDE, override the sdmmc_clken when doing SW_RESET if set to 1.

SDMMC_SPARE0[1]: When set, allows SD clock to be stopped in the middle of a read data block while in SDR104/ HS400/HS667 modes (allow_sdr104_intrablock_stalls).

Unsafe for at least some SD/eMMC cards, but may improve SDR104 DMA read performance in some cases.

SDMMC_SPARE0[2]: When set, SDR104 support is advertised in SDMMC_CAPABILITIES_HIGHER_0_SDR104

SDMMC_SPARE0[3]: When set, SDR50 support is advertised in SDMMC_CAPABILITIES_HIGHER_0_SDR50

SDMMC_SPARE0[5]: When 0, masks the pad macro's "high speed" enable to 0, causing the pad macro to always launch data on the falling edge of the clock. This prevents the SD Host driver's setting of

SDMMC_POWER_CONTROL_HOST_x_HIGH_SPEED_EN from undesirably affecting the output timing.

SDMMC_SPARE0[7:6]: Number of pipe stages.

SDMMC_SPARE0[8]: When set, DDR50 support is advertised in SDMMC_CAPABILITIES_HIGHER_0_DDR50

SDMMC_SPARE1: Spare register bits with reset value of 1

SDMMC_SPARE1[0]: CMD_CONFLICT_DISABLE, disable command line conflict if set to 1.

SDMMC_SPARE1[1]: Control bit to select between internal and external loop back clock. 1-external 0-internal

Tegra X1 does not support external loopback for any SDMMC controller.

Vendor I/O trimmer control register

Used to configure I/O trimmer

Table 210: Truth Table

Input Pins			Output	Comments
E_DPD	SEL_VREG	SEL_VREF	CLKOUT	
1	x[1]	x	0	The cell is in deep power down mode.
0	1	x	based on ip_clk_select selected clock input	Trimmer is powered by VAUXC.
0	0	x	based on ip_clk_select selected clock input	Trimmer is powered by regulated voltage.

1. 'x' indicates don't care.

Offset: 0x1ac I Read/Write: R/W I Reset: 0x00000015 (0bxxxxxxxxxxxxxxxxxxxxxxxxxxxx010101)

Bit	Reset	Description
5	ENABLE	TRIM_PWRSAVE: Enables power saving mode by clock gating the unused taps in delay chain Active low signal, 0 - power saving mode enabled - clock gating is enabled for unused trimmer taps - may affect tap delay 1 - no power saving - all the trimmer taps are not clock gated 0 = ENABLE 1 = DISABLE
4:3	VREF_925_MV	SEL_VREF_LEVEL: Selects Vref voltage level 0 = VREF_875_MV 1 = VREF_900_MV 2 = VREF_925_MV 3 = VREF_950_MV
2	0x1	SEL_VREG: Select voltage supply for delay chain present in both Trimmer and DLLPROD value: 0x0 ***Software should set this to 0x0 before accessing SD/eMMC. This setting makes IB trimmer delay independent of VDD_CORE*** 0 - selects regulated reference voltage for trimmer and DLL supply - default (recommended option for tunable SD/eMMC modes) 1 - selects VAUXC for trimmer and DLL supply and shut down BG+REG circuit (can be used in non-tunable modes for power saving) Power up time for BG+REG is ~3us(worst case). Power down time for BG+REG is ~1us(worst case). If software wants to turn on/off BG+REG when SDMMC is idle, it has to take hit of 3us power on time. When SEL_VREG is toggled, both DLL and rx clock trimmer output could glitch irrespective of input clock state which could cause corresponding rx CMD and DATA FIFOs to go into bad state. Software should issue SW_RESET_DAT and SW_RESET_CMD to reset host FIFOs after BG <-> VAUXC switching. This would ensure error free data transfers from there on. Powering down BG would need 3 us turn ON time which may cause IOPS reduction, if software shuts down BG after every transfer and enables it on seeing new transfer request; it may not be possible to do dynamic shut down of BG without stalling new requests.
1	0x0	SEL_VREF: Select reference voltage for voltage regulator 0 - selects Bandgap Voltage Reference (recommended option for SD/eMMC tunable modes) 1 - selects resistor divider voltage reference and power down bandgap Switching time between the supplies is 1 us. When switching from one supply to other supply, we need to wait for at least 1us before doing any data transfers.
0	0x1	PD_BGREG: Not used - Dummy control Power down Band Gap voltage reference, voltage regulator and resistor chain voltage ref (BG+REG) present in custom I/O trimmer used for SD/eMMC bus tuning. Active High signal, PD_BGREG=1 => Power down BG+REG; PD_BGREG=0 => power up Power down and up time for BG+REG is 1us. If software wants to turn on/off BG+REG when SDMMC is idle, it has to follow 1 us power on/off time. Back-up option for powering down BG. Software should clear this bit when it wants to turn ON BG by setting SEL_VREG=0. The original idea to have PD_BGREG pin is to provide power saving feature when the eMMC/SDMMC is in IDLE state, but not in DPD mode. This pin function is actually merged into SEL_VREG function -BG+REG circuit is shut-down when SEL_VREG=1 (trimmer powered by VAUXC)

32.9.5.13 SDMMCAB_VENDOR_DLLCAL_CFG_0

Vendor DLL calibration configuration register

This register is used to setup the DLL Calibration settings. Software has to run DLL calibration first before initiating data transfers in HS400 or HS667 modes and re-calibration is required whenever there is a change in eMMC device clock frequency in HS400/HS667 modes.

Offset: 0x1b0 I Read/Write: R/W I Reset: 0x16083504 (0b0x01011000001000001101010000010 0)

Bit	Reset	Description
31	0x0	CALIBRATE: CALIBRATE is used to start a DLL calibration process. Software should set this bit to trigger calibration and should not clear this bit. This bit will be cleared once the calibration process is completed.
29:25	0xb	END_COUNT: END_COUNT determines the end condition of the calibration. If USE_STATIC_CYCLES is not set, a usec timer is loaded with (2^END_COUNT) and calibration will be stopped once the timer expires. Recommended timer value is 1 ms. If USE_STATIC_CYCLES is set and if the trimmer tap value being calibrated has not changed for this number of loops, the calibration ends. The number iterations is (2 ^ END_COUNT), if END_COUNT != 0
24	0x0	USE_STATIC_CYCLES: When set, calibration will be stopped when num static cycles reaches END_COUNT else usec timer is used. Recommended option is use usec timer.
23	0x0	IGNORE_START_TRIM: IGNORE_START is used to ignore the START_TRM value. Instead the calibration starts at the current programmed DDLLCAL value. This is intended to be used if we ever support periodic DDLL calibration.
22:16	0x8	START_TRIM: START_TRM specifies the starting trimmer value to calibrate the with.
15:12	0x3	FILTER_BITS: FILTER_BITS is the LSB of the counter to use for updating the trimmer value. The new trimmer value is trim_old + (count >> FILTER_BITS) - (trim_old >> FILTER_BITS) FILTER_BITS chosen < bits used for SAMPLE_COUNT

Bit	Reset	Description
11:8	0x5	SAMPLE_COUNT: SAMPLE_COUNT is the number of times the phase detector is sampled before going onto the next set of trimmer values. The number of samples is (2 ^ SAMPLE_COUNT)
7:0	0x4	SAMPLE_DELAY: SAMPLE_DELAY is the number of sdmmc host clks from changing the trimmer value to when the phase detector is sampled.

10:7	0xf	SLV_DLL_SETTLE_TIME: Slave DLL requires 4 cycles settle time when dly code is changed for providing stable output
6:0	0x0	MST_DLL_DLY_CODE: 7-bit delay code (128 taps) to be applied to master DLL when DLLCAL_BYPASS is enabled

32.9.5.16 SDMMCAB_VENDOR_DLLCAL_CFG_STA_0

Vendor DLL calibration configuration register

This register is used to setup the DLL Calibration settings.

Software has to run DLL calibration first before initiating data transfers in HS400 or HS667 modes and re-calibration is required whenever there is a change in eMMC device clock frequency in HS400/HS667 modes. DLL calibration process is an open loop process in which DLL calibration controller can't decide the final tap value on its own by looking at PD output from DLL.

Summary of DLL calibration process implemented:

1. Software programs SAMPLE_COUNT (number of samples to be taken per every tap value) and STOP_TIMER_VALUE in microseconds.
2. These two values decide the stop condition of calibration.
3. DLL calibration is triggered on writing '1' into CALIBRATE register field by software. The controller sets CAL_ACTIVE bit to indicate calibration running status.
4. DLL controller starts calibration by applying a tap value (may use START_TAP programmed) to MST DLL and loads usec timer with STOP_TIMER_VALUE.
    a. After SAMPLE_DELAY (4 cycles of DLL in clock), it starts taking SAMPLE_COUNT number of PD samples. A phase counter is updated based on PD value per every cycle.
    b. Based on phase counter value, 'Filter' decides whether to increment or decrement current tap value to get next tap value to be applied in next iteration.
    c. FILTER_BITS decides the accuracy of the decision made. FILTER_BITS < bits used for SAMPLE_COUNT.
5. Repeat step 3 till STOP_TIMER expires.
6. The controller stops calibration (updating tap value) and latches the tap value used in last calibration iteration. CALIBRATE bit will be cleared at this step.
7. The controller adds offsets programmed to calibrated tap value and applies the final codes to SLAVE DLLs.
8. The controller waits for slave DLL settle time and clears CAL_ACTIVE register bit.
9. Software polls for CAL_ACTIVE=0 and can start data transfers.

DLL lock time is represented as:

Each tap test time = (SAMPLE_DELAY + SAMPLE_COUNT) * DLL_CAL_CLK_PERIOD

Worst case DLL locking time = STOP_TIMER_VALUE = (NUM_CAL_ITERATIONS * (SAMPLE_DELAY + SAMPLE_COUNT) * DLL_CAL_CLK_PERIOD)

Default values chosen:

Worst case DLL locking time=1 ms = 1000us = STOP_TIMER_VALUE.

SAMPLE_COUNT=32 samples per one tap;

SAMPLE_DELAY=4 cycles

Tap value is decided by PD and filter logic.

Notes:

- *Software needs to calibrate DLL before using eMMC5.0 HS400/HS667 mode (before tuning process). Re-calibration is required whenever eMMC I/O clock frequency is changed. This can be done as a part of standard clock frequency change sequence.*
- *DLL calibration would work at when I/O CLK is running at 200 MHz and above.*
- *For I/O CLK frequency is below 200 MHz, software should calculate delay code as per below equation:*
- *Delay Code = (Delay Code at 200 MHz) * 200 MHz / Target Frequency*
- *Under 85 MHz, DLL delay code may reach its maximum code (128 taps) for FF chips. In this case, software should use 128 taps.*

- *Software can run DLL calibration at 200MHz once at boot time, save those values, scale and use them whenever frequency is changed. This is needed if software wants to do DFS.*

Vendor Tuning Control1 register

Different step size is required in SDR50 mode to cover two UI (100MHz => 2*10 ns)

With 70ps/tap trimmer resolution, we can cover almost 2UI using step_size=8 in SDR50 and step_size=4 in SDR104.

Tuning will be done in HS200 - SDR mode only.

HS200 - tuning at 200 MHz - UHS_SEL should be SDR104 for executing tuning

Before initiating data transfers in HS400 mode, tuning procedure should be executed in HS200 mode with I/O clock running at 200 MHz

For overclocked modes: Before initiating data transfers in HS667 mode, tuning procedure should be executed in HS200 mode with I/O clock running at 333 MHz

---

Note: *eMMC bus tuning will always be run in HS200 mode only.*

Use step_size = 1 to scan through all taps due to hardware issue.

Offset: 0x1c4 I Read/Write: R/W I Reset: 0x00000023 (0bxxxxxxxxxxxxxxxxxxxxxxxxxxx010x011) I Default: 0x00000000

Bit	Reset	SW Default	Description
6:4	0x2	0x0	STEP_SIZE_SDR104_HS200: tap_val is incremented by step_size for every tuning iteration - used in SDR104/ HS200/HS400 mode increment = 2^step_size; step_size should be in range 0-4. Others are RSVD For overclocking modes, set this field to 0x1
2:0	0x3	0x0	STEP_SIZE_SDR50: tap_val is incremented by step_size for every tuning iteration - used in SDR50 mode increment = 2^step_size; step_size should be in range 0-4. Others are RSVD

32.9.5.19 SDMMCAB_VENDOR_TUNING_STATUS0_0

Vendor Tuning Status0 register

5:0	0xf	CLK_COUNT: Before gating second level clocks controller will wait for these many cycles. we can recover if any idle windows are missed in clken equation

32.9.5.22 SDMMCAB_VENDOR_PRESET_VAL0_0

Vendor Preset Value Registers

SD host specification defines one preset value register for each bus speed mode which should be set by host by some unique method.

Preset values vary based on the base frequency used which is in software (Tegra system driver) control.

Tegra System driver supposed to set BASE_CLK_FREQ in VENDOR_CLOCK_CNTRL register before handling over the control to SD host standard driver.

In the similar way, system driver should set below vendor preset values based on the base clock frequency and the desired card clock frequency in each bus speed mode

This should be done after every time SDMMC is reset and after every soft reset.

This is important as all SDMMC controllers follow the same register map, but could be programmed with different frequencies depending on the use case.

Default values are set assuming base clock frequency=208 MHz.

Offset: 0x1d4 I Read/Write: R/W I Reset: 0x00201000 (0bxx00000000100000000100000000000)

Bit	Reset	Description
29:20	0x2	SDCLK_FREQ_SEL_HIGH_SPEED: System software programs 10-bit divider value to generate SDCLK in default speed mode (<50 MHz,3.3V signaling). This value is readable in the standard via PRESET_SDR12_AND_HIGH_0_SDCLK_FREQ_VAL_LOW register field. Default value is 0x2 assuming 208 MHz base clock
19:10	0x4	SDCLK_FREQ_SEL_DEFAULT: System software programs 10-bit divider value to generate SDCLK in default speed mode (<25 MHz,3.3V signaling). This value is readable in the standard via PRESET_DEFAULT_AND_INIT_0_SDCLK_FREQ_VAL_HIGH register field. Default value is 0x4 assuming 208 MHz base clock
9:0	0x0	SDCLK_FREQ_SEL_INIT: System software programs 10-bit divider value to generate desired SDCLK frequency during initialization. This value is readable in the standard via PRESET_DEFAULT_AND_INIT_0_SDCLK_FREQ_VAL_LOW register field. For example, if 400 KHz SDCLK is desired at base clk freq=48 MHz, this register should be programmed with 0x3C

32.9.5.27 SDMMCAB_AUTO_CAL_INTERVAL_0

SDMEMCOMP pad calibration interval - Valid for SDMMC1/SDMMC3 Instances

Offset: 0x1e8 I Read/Write: R/W I Reset: 0x00000000 (0b00000000000000000000000000000000)

Bit	Reset	Description
31:0	0x0	AUTO_CAL_INTERVAL: 0: do calibration once Otherwise, auto-calibration occurs at intervals equivalent to the programmed number of microseconds.This feature is not supported from Tegra X1 due to movement of level shifters to COMP pad.Software should trigger calibration at regular intervals, if needed.

32.9.5.28 SDMMCAB_AUTO_CAL_STATUS_0

SDMEMCOMP pad calibration status - Valid for SDMMC1/SDMMC3 Instances

Offset: 0x1ec I Read/Write: RO I Reset: 0xXXXXXXXX (0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx)

Bit	Reset	Description
31	X	AUTO_CAL_ACTIVE: One when auto calibrate is active - valid only after auto calibrate sequence has completed (AUTO_CAL_ACTIVE == 0)
30:24	X	AUTO_CAL_PULLDOWN_ADJ: Pulldown code sent to pads
22:16	X	AUTO_CAL_PULLUP_ADJ: Pullup code sent to pads
14:8	X	AUTO_CAL_PULLDOWN: Pulldown code generated by auto-calibration
6:0	X	AUTO_CAL_PULLUP: Pullup code generated by auto-calibration

32.9.5.29 SDMMCAB_IO_SPARE_0

SPARE bits. These SPARE_OUT bits go to pipe -> pad and then come back as SPARE_IN

SPARE_OUT[3]: IO_SPARE[19] - used as MUX select which selects between one cycle delay and two cycle delay versions of cmd_oen to mask wdata of IB capture flop.

0x0: selects two cycle delayed version

0x1: selects one cycle delayed version - recommended

SPARE_OUT[2]: IO_SPARE[18] - used as active low enable for gating both CMD_IN and DAT_IN async FIFOs wdata when we are driving CMD/DAT lines.

0x0: write 1 when OEN is active and Zi value when OEN is not active into FIFO (default)

0x1: write Zi value into FIFO irrespective of OEN state.

Offset: 0x1f0 I Read/Write: R/W I Reset: 0xXXXXXXXX (0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx) I Default: 0x00080008

Bit	R/W	Reset	SW Default	Description
31:16	RW	X	0x8	SPARE_OUT:PROD value: Software should set SPARE_OUT[3]: IO_SPARE[19] to 1 before accessing SD/eMMC.
15:0	RO	X	0x8	SPARE_IN

32.9.5.30 SDMMCAB_SDMMCAB_MCCIF_FIFOCTRL_0

Memory Client Interface FIFO Control (where applicable) and Clock Gating Control Register.

Note: *The FIFO timing aspects of this register are no longer supported, but retained for software compatibility*

The clock override/ovr_mode fields of this register control the 2nd-level clock gating for the client and mc side of the mccif. All clock gating is enabled by default.

A '1' written to the rclk/wclk override field will result in one of the following:

With wclk/rclk override mode = LEGACY, the clock reverts to legacy mode of operation where the clock is on whenever the client clk is enabled.

With wclk/rclk override mode = ON, the clock is always on inside mccif and PC.

A '1' written to the cclk override field keeps client's clk always on inside mccif.

Offset: 0x1f4 I Read/Write: R/W I Reset: 0x00000000 (0bxxxxxxxxxxxx00000xxxxxxxxxxxxxxxx)

Bit	Reset	Description
20	0x0	SDMMCA_RCLK_OVR_MODE

32.9.5.31 SDMMCAB_TIMEOUT_WCOAL_SDMMCAB_0

Write Coalescing Time-Out Register

Note: *Write coalescing is no longer supported by the MCCIF clients.*

Registers are retained for software compatibility but are not used by the hardware.

Offset: 0x1f8 I Read/Write: R/W I Reset: 0x00000032 (0bxxxxxxxxxxxxxxxxxxxxxxxxx00110010)

Bit	Reset	Description
7:0	0x32	SDMMCWA_WCOAL_TMVAL

CHAPTER 33: SATA CONTROLLER

33.1 Overview

The Serial Advance Technology Attachment (SATA) controller enables a control path from a Tegra® X1 device to an external SATA device. An SSD/HDD/ODD/e-SATA drive can be connected. This is a one port configuration.

The SATA controller is compliant with SATA specification rev. 3.1 and AHCI specification rev. 1.3.1. This includes all errata, ENC, and TP, except DHU (direct head unload).

33.2 Device ID

The device ID for the SATA controller in Tegra X1 is 0x10E7. The AHCI driver needs to make sure the class code is set to 0x0106 and the program interface code is set to 0x01 (after boot) before it starts operating the controller in AHCI mode.

33.3 AUX Version of Pad Idle Detection

In Tegra X1, the pad supports VAUX bus idle detection. The Miscellaneous Register unit has been modified to support both the VCORE and VAUX versions of bus idle detection for detecting the OOB signaling, while adding the control to put the VCORE portion and/or the VAUX portion of the PAD in IDDQ mode when the SATA controller is power gated under the following conditions:

Table 211: SATA Controller Power-Gating Conditions

Link State	VCORE	VAUX	Note
Partial	ON	ON	VCORE portion is powered to maintain the common mode voltage. OOB detection using VCORE version with VAUX OOB detection disabled.
Slumber	OFF	ON	VAUX portion is used for OOB detection.

During LP0, the MUX between XUSB and SATA would keep the VAUX portion of the PAD in IDDQ, while the VCORE portion enters IDDQ when the system VCORE power rail is removed.

33.3.1 RX Lane Calibration

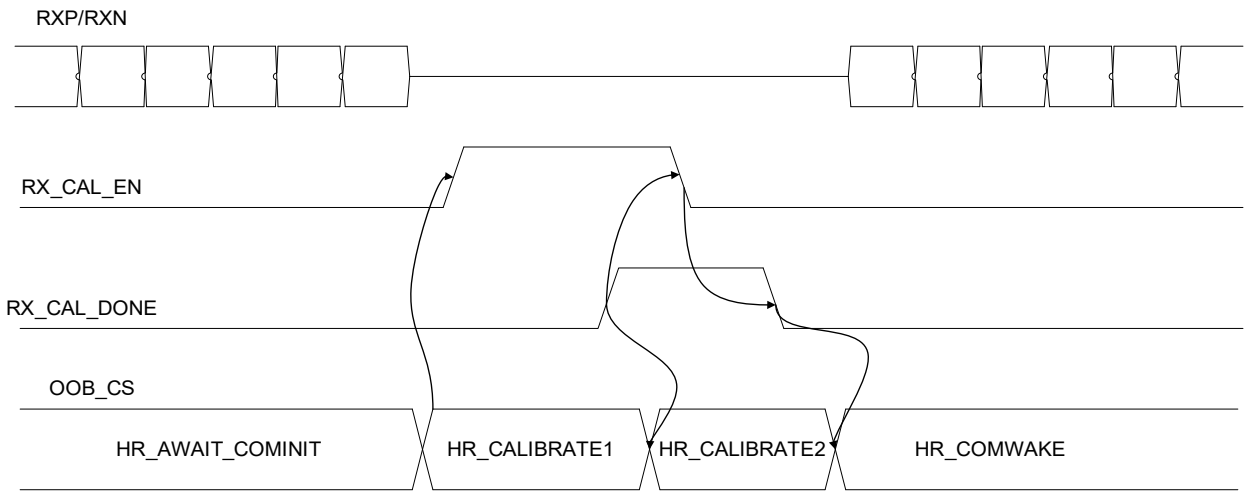
The RX lane calibration is added to the 20nm SATA pad to compensate the datapath offsets for 20nm pad. RX lane calibration should be performed during 2 instances

- Initial Power up sequence
- LP0 exit

The SATA specification supports calibration during OOB signaling. Calibration is performed after receiving the COMINIT from the drive and before sending the COMWAKE.

Also OOB signaling is performed for the above mentioned two events. So in order to support the RX lane calibration for the 20nm pad, a new calibration state has been added to the SATA OOB sequence. The SATA OOB RX calibration timing diagram is given below.

Figure 155: SATA OOB RX Calibration Timing Diagram



A Config bit enables or disables the RX calibration during OOB sequence.

33.3.2 PLL Calibration Sequence and Sleep State Addition

The 20 nm UPHY pad changes PLL power up sequences as below:

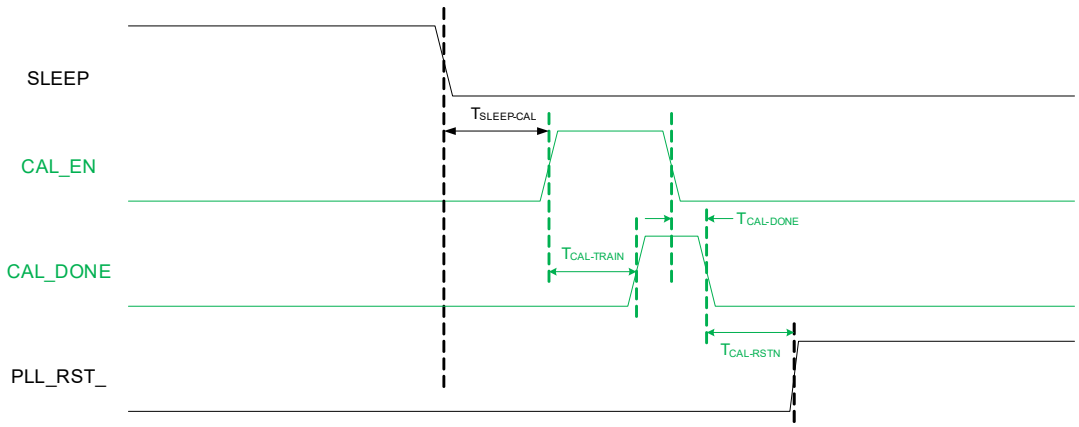
- PLL Calibration Sequence
- PLL Sleep state addition.

As with lane calibration, a PLL calibration sequence is recommended to be done during:

- Power up sequence
- LP0 exit

The following timing diagram explains the PLL Calibration training sequence:

Figure 156: PLL CAL Training Sequence



The PLL contains a low power state “SLEEP”, which drives the “PLL_SLEEP” pins to a particular value so that a particular portion of PLL can be shut off. The following table shows the different PLL_SLEEP states and their functionalities.

Table 212: PLL_SLEEP States

	Main Controls			References		Calibration		Clocks		
State	IDDQ	SLEEP	RST_	Bandgap	Reg	Resistor	PLL	VCO	Digital	Serial
Off	1	X (11)	X (0)	Off	Off	Off	Off	Off	Off	Off

Table 212: PLL_SLEEP States

	Main Controls			References		Calibration		Clocks		
Sleep3	0	11	X (0)	Off	Off	On/Off	Off	Off	Off	Off
Sleep2	0	10	X (0)	On	Off	On/Off	Off	Off	Off	Off
Sleep1	0	01	X (0)	On	On	On/Off	On/Off	Off	Off	Off
Reset	0	00	0	On	On	On/Off	On/Off	Active	Off	Off
Active	0	00	1	On	On	On/Off	On/Off	Active	Active	Auto-Control

The values driven on “PLL_SLEEP” state may be different for different IP’s. For SATA it is suggested to drive “Sleep3” value on “PLL_SLEEP” pins during SLEEP state.

33.4 Boot through SATA

When the SATA device is used for booting, the controller will operate in legacy PIO mode in the beginning phase of the booting process. Controller default class code is set to 0x0101 and the program interface code is set to 0x85 to indicate legacy PIO mode support. Boot code will need to change class code to 0x0106 and program interface code to 0x01 before it starts to operate controller in AHCI mode during the later phases of booting process. Also the AHCI driver needs to make sure 0x0106 and 0x01 are set before operating controller in AHCI mode.

33.5 MCCIF with Dual Channel Support

The Tegra X1 MCCIF has dual channel support. In order to support the 32-bit dual channel LPDDR-4 interface, the MCCIF has a dedicated response bus for each channel on the MSC bus. For a given request, the response can come from only one channel. However, multiple requests from an MCCIF can be outstanding to each channel at any point. So the MCCIF can receive responses from the two channels simultaneously.

33.6 Power-Gating Sequence

This section describes all the steps needed to achieve power gating.

- Wake events from the drives are supported
- Wake events can only happen in non LP0 mode
- No wake support in LP0 state
- The entire partition including the FPCI wrapper is power gated
- If there can be no wake event, the pads can be put in IDDQ mode. This is decided on the type of drive connected
- The wakeup of the partition (SAX) that hosts the SATA controller and the IPFS shall be initiated by software

33.6.1 Power-Gating Overview

Power gating and ungating can be initiated by software. Power gating should be done when the SATA link is in slumber mode, with no outstanding commands. The software should keep a backup of a set of registers in system memory as they lose value once the power is removed. This involves all the configuration space, extended configuration space registers and the MMIO space registers. Since the software is expected to know the state of registers inside the controller, it need not read the registers every time a power gating sequence is performed.

If hardware wake up is to be supported (for example, hot plug detection), the pads should be left in slumber. If hardware wake up is not needed, then the pads should be placed in the IDDQ mode. This is the preferred mode of operation. The bits pad_iddq_override_en and pad_iddq_override_value could be used to control the state of the pads.

33.6.2 Hardware Initiated Wake up

For a hardware-initiated wake up, the pads detect activity on the SATA link. Once the OOB sequence is detected, the bit oob_wake_detected unit is written. Note that the controller itself is not involved in this signal as it is power gated.

The signal from the pads that is of concern here is the rx_stat_idle. This signal must be monitored for any activity. This is an active low signal. There should be two bits that the software needs to read for the interrupt.

1. To log the status and send an interrupt to software (software controlled PG) or signal to the PMC (hardware controlled PG). There are three bits associated with this.
    a. A status bit SATA_L0_RX_STAT_IDLE in the register SATA_AUX_RX_STAT_INT_0. This bit shows the current status of rx_stat_idle. It is set to 1 whenever there is activity on the RX path, else it is set to 0.
    b. A sticky interrupt status bit SATA_RX_STAT_INT_STATUS in the register SATA_AUX_RX_STAT_INT_0. This is set whenever rx_stat_idle is set to 1 and will stay 1 until the interrupt is cleared by software.
    c. There are bits to set/clear the bits above. Writing a 1 to SATA_RX_STAT_INT_SET bit in SATA_AUX_RX_STAT_SET_0 register will set the status. Writing a 1 to SATA_RX_STAT_INT_CLR will clear this status.
2. To have a mask to enable / disable interrupts. This is done via central interrupt controller with the interrupt SATA_RX_STAT in PRI_ICTLR_* registers. Follow the same guidelines as any other units to enable/disable the SATA_RX_STAT interrupt.

The software clears the interrupt and the mask during normal operation.

33.6.3 Bits Required in Power Gating Sequences

The following bits are required in power gating sequences. Some of them are needed in both hardware and software sequencing methods. Some of them are required only in one of the modes of power gating. The bits could be named differently. The bits are –

- Oob_wake_en – this bit is to be placed in a non-power gated region. Its role is to enable wake events from the drive. This is enabled by writing a 1 to SATA_RX_STAT in PRI_ICTLR_* registers
- Oob_wake_detected – this bit shall be written when “oob_wake_en” is asserted and a wake is detected on the SATA link. The “rx_stat_idle” toggling shall assert this bit. In software mode of power gating, an interrupt needs to be sent to the SATA driver. This is the SATA_RX_STAT_INT_STATUS bit in register SATA_AUX_RX_STAT_INT_0.
- Pmc2sata_pg_info – this bit shall drive the signal pmc2sata_pg_info.

33.6.4 Software Initiated Power Gating / Ungating Sequence

Table 213: Steps involved in Power Gating

#	Description	Register Programming	Comments
1.	Driver decides to enter power gating, based on the fact that links are in slumber state and no commands are outstanding.		
2.	Driver programs a register in the PMC to indicate to SATA that it is entering power gating. This shall drive the pmc2sata_pg_info signal.	APBDEV_PMC_SATA_PWRGT_0.PG_INFO = 1	If driver detects a hardware wake from the drive before setting PG_INFO bit, it should bail out and should not begin the PG sequence.
3.	Driver would read out the registers in the SATA controller and save it in system memory.	Register list is in appendix.	The time taken for this would depend on the time taken for the software to read a register. Ideally, this should be done only once.
4.	Driver needs to read and set the rx_idle_t registers in the APBMISC block so idle threshold can be continuously driven while SAX is power-gated	Read SATA_AUX_MISC_CNTL_1_0 register L0_RX_IDLE_T_SAX field and write that value into same register L0_RX_IDLE_T_NPG field and write ‘1’ to L0_RX_IDLE_T_MUX field.	

Table 213: Steps involved in Power Gating

#	Description	Register Programming	Comments
5.	Driver should read the error and interrupt registers before entering power gating.	Read PxSERR and PxIS, and IS registers. Also read PxCI register to make sure that there are no outstanding commands. If (PxCI !=0) or any unexpected error, driver should bail out of PG sequence by setting APBDEV_PMC_SATA_PWRGT_0.PG_INFO = 0 Sets the bit rx_stat_idle_bypass to enable detection of a comwake.	If there is something unexpected or an error is detected or if HW wake is detected from the drive, then the software should bail out of PG sequence (clear PMC bit) Once PG_INFO=1 and/or rx_stat_idle bypass is enabled, HW wake could be detected via rx_stat_idle interrupt only. In that case, driver needs to wait until HBA is in active state (PxSSTS.DET=0x3 and PxSSTS.IPM=0x1) before issuing any new commands.
6.	The driver should gate SATA clocks and assert reset to SATA.	CLK_RST_CONTROLLER_CLK_OUT_ENB_V_0.SATA_CLKEN= '0' CLK_RST_CONTROLLER_RST_DEVICES_V_0.SATA_RESET=1 CLK_RST_CONTROLLER_RST_DEVICES_W_0.SATACOLD_RST=1	
7.	If HW wake up (example hot-plug or async notification) is needed: The driver shall write a bit in the Interrupt Controller in non-power gated region to enable the rx_stat interrupt generation on detection of rx_stat (OOB) wake.	Clear sata_rx_stat interrupt status and enable sata_rx_stat interrupt to start detecting rx_stat_idle changes from SATA pad when detecting OOB wake sequence: Write apb_misc sata_aux register RX_STAT_CLR bit[0] "SATA_RX_STAT_INT_CLR" field to '1' Write interrupt controller register PRI_ICTLR_CPU_IER_SET_0 bit[13] "SATA_RX_STAT" field to '1' The mapped status bit for sata_rx_stat interrupt in interrupt controller is at register PRI_ICTLR_ISR_0 bit[13] "SATA_RX_STAT"	At this point, sideband (PHY logic + interrupt controller) takes over interrupt generation.
8.	If HW wake up (example hot-plug or async notification) is needed: The driver shall place the SATA PADPLL in reset. If Hw wake up is not needed: Driver shall place the SATA PHY and SATA PADPLL in IDDQ.	a) SATA_PADPLL_RESET_SWCTL =1 SATA_PADPLL_RESET_OVERRIDE_VALUE=1 b) SATA_PADPLL_RESET_SWCTL =1 SATA_PADPLL_RESET_OVERRIDE_VALUE=1 SATA_PADPHY_IDDQ_SWCTL=1 SATA_PADPHY_IDDQ_OVERRIDE_VALUE=1 Wait for time specified in SATA_LANE_IDDQ2_PADPLL_IDDQ SATA_PADPLL_IDDQ_SWCTL=1 SATA_PADPLL_IDDQ_OVERRIDE_VALUE=1	The driver controls SATA PLL at run time (no HW low power sequencing).
9.	The driver reports that SATA is being powered down. If PCIE is not being used, the driver can set the PLLE to either reset or IDDQ. If HW wake up is needed and exit latency cannot be met with PLLE IDDQ mode, then PLLE can be set to reset. If HW wake up is not needed or PLLE IDDQ mode exit latency is sufficient: PLLE can be set to IDDQ.	a) PLLE_ENABLE_SWCTL=1 CLK_RST_CONTROLLER_PLLE_BASE_0.PLLE_ENABLE=0 b) PLLE_ENABLE_SWCTL=1 CLK_RST_CONTROLLER_PLLE_BASE_0.PLLE_ENABLE=0 PLLE_IDDQ_SWCTL=1 PLLE_IDDQ_OVERRIDE_VALUE=1	Wait Time= 1 µs
10.	The driver now shall power gate the controller. This shall also involve the setting of the clamps, and assertion of the resets.	APBDEV_PMC_PWRGATE_TOGGLE_0.SAX=1 << reset overrides exist in the CAR block.	The clamp value of the hardware is such that it shall place the SATA PAD PLL in IDDQ mode but it is overridden by software value as swctl on iddq/reset is enabled above.

Table 213: Steps involved in Power Gating

#	Description	Register Programming	Comments
11.	The driver indicates to the AHCI software, that power gating is complete.		This is more of an implicit step; returning of the PG API function indicates that power-gating is done.

Table 214: Steps involved in Power Ungating

#	Description	Register Programming	Comments
1	If hardware wake up is allowed and an OOB sequence is detected, an rx_stat interrupt will be sent by the interrupt controller Or, driver decides to wake up the controller.	When sata_rx_stat interrupt is detected and serviced, interrupt routine should disable this interrupt and clear the status by doing: Write interrupt controller register PRI_ICTLR_CPU_IER_CLR_0 bit[13] "SATA_RX_STAT" field to '1' Write apb_misc sata_aux register RX_STAT_CLR bit[0] "SATA_RX_STAT_INT_CLR" field to '1'	
2	If SATA PHY and SATA PADPLL are in IDDQ mode, driver brings them out of IDDQ mode.	Get SATA PHY and PLL out of IDDQ as below: SATA_PADPLL_IDDQ_OVERRIDE_VALUE=0 Wait for programmable delay of SATA_PADPLL_IDDQ2LANE_SLUMBER_DLY. Suggested value of this delay is 3 microseconds. SATAPAD_IDDQ_OVERRIDE_VALUE=0	

Table 214: Steps involved in Power Ungating

#	Description	Register Programming	Comments
3	The driver checks if PLLE is already turned on or not. Part (a): If PLLE is already turned on, it waits for 1 ms before moving on to next step. Part (b): If PLLE is off, it brings it up.	If PCIE is running, PLLE could be already running. Check that it is running by checking its PLLE_ENABLE and PLLE_LOCK bits. Part (a): If both bits are set, then the PLLE is already turned on. Wait for 1 ms . Part (b) If neither bit is set, then do PLLE training and init sequence. If using spread spectrum, set the following bits: CLK_RST_CONTROLLER_PLLE_SS_CNTL_0. PLLE_SSCBYP=1 CLK_RST_CONTROLLER_PLLE_SS_CNTL_0. PLLE_BYPASS_SS=1 CLK_RST_CONTROLLER_PLLE_SS_CNTL_0. PLLE_INTERP_RESET=1 Set PLLE_LOCK_ENABLE bit in CLK_RST_CONTROLLER_PLLE_MISC register to DISABLE (0). Set the PLLE_ENABLE and PLLE_ENABLE_CML bits to DISABLE (0) in CLK_RST_CONTROLLER_PLLE_BASE register. Also set PLLE_SETUP=0 and PLLE_EXT_SETUP_17_16=0 in CLK_RST_CONTROLLER_PLLE_MISC register. Check that PLLE_IDDQ_SWCTL=1 and PLLE_IDDQ_OVERRIDE_VALUE=1. If they are not set to 1, set them to 1. Then set PLLE_IDDQ_OVERRIDE_VALUE=0 to begin the training sequence. Wait for PLLE training sequence to finish by waiting until PLLE_PLL_READY bit is set to 1 in CLK_RST_CONTROLLER_PLLE_MISC register program PLLE parameters (most are the default Reset values) – set the following values: CLK_RST_CONTROLLER_PLLE_BASE register: PLLE_PLDIV_CML = 0xd PLLE_PLDIV = 0x18 PLLE_MDIV = 0x1 PLLE_NDIV = 0xc8 CLK_RST_CONTROLLER_PLLE_MISC register PLLE_SETUP = 0x7 (This is not the default) PLLE_LOCK_ENABLE = ENABLE (1) (This isn't default) If using spread spectrum, set the following bits: CLK_RST_CONTROLLER_PLLE_SS_CNTL_0.PLLE_SSCBYP=1 CLK_RST_CONTROLLER_PLLE_SS_CNTL_0.PLLE_BYPASS_SS=1 CLK_RST_CONTROLLER_PLLE_SS_CNTL_0.PLLE_INTERP_RESET=1 Enable the PLLE now by setting PLLE_ENABLE and PLLE_ENABLE_CML to ENABLE (1) in CLK_RST_CONTROLLER_PLLE_BASE register. Wait for PLLE to lock by waiting until PLLE_LOCK bit is set to 1 in CLK_RST_CONTROLLER_PLLE_MISC register. After PLLE_LOCK is detected, wait for an additional programmable delay of PLLE_LOCK_DLY. This will help in case the PLLE_LOCK gets asserted earlier. The suggested value of this additional delay is 25 microseconds. Do the following steps if you intend to use spread spectrum: program spread spectrum coefficients- CLK_RST_CONTROLLER_PLLE_SS_CNTL_0.PLLE_SSCMAX = 0x25, CLK_RST_CONTROLLER_PLLE_SS_CNTL_0.PLLE_SSCINCINTRV = 0x20, CLK_RST_CONTROLLER_PLLE_SS_CNTL_0.PLLE_SSCINC = 0x1. CLK_RST_CONTROLLER_PLLE_SS_CNTL_0.PLLE_BYPASS_SS=0 CLK_RST_CONTROLLER_PLLE_SS_CNTL_0.PLLE_SSCBYP=0 CLK_RST_CONTROLLER_PLLE_SS_CNTL_0.PLLE_INTERP_RESET=0 Enable CML clock for SATA by setting PLLE_CML1_OEN bit to 1 in CLK_RST_CONTROLLER_PLLE_AUX_0 register. If PLLE is already turned on, check that the SATA CML clock output is turned on. Otherwise, turn it on by setting PLLE_CML1_OEN bit to 1 in CLK_RST_CONTROLLER_PLLE_AUX_0 register.	

Table 214: Steps involved in Power Ungating

#	Description	Register Programming	Comments
4	The driver deasserts reset to SATA PADPLL and waits until it locks.	SATA_PADPLL_RESET_OVERRIDE_VALUE=0 Wait for Satapll_lockdet ='1'	Expected maximum time for SATA PADPLL to lock = 15 microseconds.
5	The driver toggles the power-gate SAX bit in the PMC to power-ungate SAX partition.	Toggle the SAX partition register bits in the PMC APBDEV_PMC_PWRGATE_TOGGLE_0.SAX=0 APBDEV_PMC_REMOVE_CLAMPING_CMD_0.SAX=1	
6	The power ungating is complete.		This is an implicit step. No action here.
7	Driver turns on the clocks to SATA and deasserts resets.	Software to ungate txclk and all SATA clocks, reset CLK_RST_CONTROLLER_CLK_OUT_ENB_V_0.SATA_CLKEN= '1', CLK_RST_CONTROLLER_RST_DEVICES_W_0.SATACOLD_RST= '0'? CLK_RST_CONTROLLER_RST_DEVICES_V_0.SATA_RESET =0	
8	Driver restores the registers of the controller.	Driver should restore the registers in the following order: IPFS, CFG, Ext CFG, BAR5. Make sure that any registers that change values based on customer design are restored to their proper values. During the restoration of the registers, the driver would now need to restore the register T_SATA0_CFG_POWER_GATE_SSTS_ RESTORED after the ssts_det, ssts_spd are restored. This register is used to tell the controller whether a drive existed earlier or not and move the PHY state machines into either HR_slumber or not.	Expected to take ~10 µs.
9	Driver needs to switch the rx_idle_t driven source back to from Sata controller after SAX is power-ungated	Write SATA_AUX_MISC_CNTL_1_0 register L0_RX_IDLE_T_MUX field to '0'.	
10	Driver can start to use main SATA interrupt instead of the rx_stat_t interrupt.	After SATA logic power-ungated we can start to use main interrupt from SATA controller and interrupt status mapped to interrupt controller register PRI_ICTLR_ISR_0 bit[23] "SATA_CTL"	
11	Set the bits in the CAR to allow hardware based low power sequencing.	SATAPAD_PLL_PLLE_IDDQ_RESET_SWCTL =0	
12	Driver indicates to the controller that the power ungating process is complete.	Clear bit in PMC APBDEV_PMC_SATA_PWRGT_0.Pmc2sata_pg_info = 0 Clears the bit rx_stat_idle_bypass to enable detection of a comwake.	

Note: *Wake up behavior when CPU is off: Wake up might include waking the CPU itself. If the CPU is powered down, the rx_stat interrupt causes flow controller/PMC to power up CPU, the CPU goes to reset vector handler code in OS kernel patch which will restore the CPU state, reinitialize the CPU, un-powergate SATA, restore the SATA state, and give control to AHCI software. If the CPU is powered up, the rx_stat interrupt signal generates a CPU interrupt, interrupt handler in driver shall un-powergate SATA and restore SATA state.*

33.6.5 Software Changes

In software initiated power gating and ungating, software controls the entry and exit of the power gating controller. In the hardware initiated wake up mode, the software needs to read the bit oob_wake_detected to determine if the controller needs to be power ungated. The software needs to keep a backup of all the registers in system memory and needs to reprogram them once in the power ungating process. The software needs to program the registers in the correct sequence as mentioned above.

The PxCMD.CR bit does not have the right value after register restoration following power-ungating. The software should not read that bit.

A software workaround is needed when software initiating power-gating. To prevent accidental COMRESET from being sent on the SATA link, software needs to set an override for hardware not to look at SATA PLL lockdet when shutting down the SATA

PLL. This can be done by writing SATA ext. config space register T_SATA<0>_CFG_MISC (0x550): write bit [10] to '1' and bit [8] to '0' (field T_SATA<0>_CFG__PHY_RESET_USAGE_MODE).

33.7 Address Translation

The BAR spaces and PCI Config space from the PCI bus environment are mapped as-is to an address space carved out of ARM (ordering of the registers is not changed). Tegra X1 devices do not follow the PCI specifications. They do not have any concept of the PCI configuration space, BAR space, and the extended configuration space. The system addressing is of 32 bits, unlike 40 bits in the PCI bus environment. The address can map up to 4 GB.

There is an address translation mechanism in the IPFS. With this address translation, a certain address range is mapped to the configuration space registers, and likewise for the BAR 5 and the extended configuration space registers.

The address mapping that is being done is explained in the "Address Translation Table" subsection. Even though, BAR 0 to Bar 4 are not applicable to Tegra X1 devices, they too have been allocated address ranges.

33.7.1 Address Translation Table

The next table shows how all of the SATA register spaces and SATA-IPFS registers are mapped to the Tegra X1 memory map. In Tegra X1 devices, 64KB APB space is allocated for all these registers and 512B APB space is allocated for SATA IOBIST registers.

Table 215: SATA Address Translation Table

Register Section		DFPCI address [39:0]	APB adr[31:0] for DFPCI mapping	PRI address [31:0]	APB adr[31:0] for PRI mapping
			*APB address 0x7002_0000 - 0x7002_0FFF is reserved for IPFS local registers		
1. SATA Configuration Space		Address starting with 0xFD_FE or 0xFE_0			
SATA configuration space 0x0 - 0x255	Start address	0xFD_FE00_5000	0x7002_1000	0x5010_0000	0x7002_9000
	End address	0xFD_FE00_50FF	0x7002_10FF	0x5010_00FF	0x7002_90FF
SATA extended configuration space 0x100 - 0xFFF	Start address	0xFE_0100_5000	0x7002_1100	0x5010_0100	0x7002_9100
	End address	0xFE_0F00_50FF	0x7002_1FFF	0x5010_0FFF	0x7002_9FFF

8. SATA IOBIST registers	Start address	Non accessible	N.A.	0x5050_0000	0x7002_D000
	End address	Non accessible	N.A.	0x5050_01F7	0x7002_D1F7
Note: In Tegra X1 devices, there is a standalone APB client created for SATA IOBIST register access, the PRI interface mapping from the SATA APB client is no longer valid					
The SATA IOBIST registers are mapped to 0x7000_6C00 - 0x7000_6DFF					

33.8 Programming Guidelines

33.8.1 Cold Boot

The IOPHY/UPHY of SATA is shared with XUSB. Refer to Chapter 22: USB Complex in this TRM for the IOPHY/UPHY PLL initialization sequence.

The IOPHY/UPHY lane ownership assignment is located in XUSB PADCTL, where the PAD parameter programming registers have also been moved to XUSB PADCTL. Refer to Chapter 22: USB Complex in this TRM for the IOPHY/UPHY PAD initialization sequence.

The PAD driver assigns the SPIO pins to the SATA controller:

- DA uses an available GPIO pin, if required:

The PAD driver assigns the PHY to the SATA controller:

- Program the following XUSB PADCTL registers to assign the static UPHY PAD and PLL parameters according to the platform-specific configuration (note the following lists all PAD and PLL registers; the driver should only program the ones whose value are different from the default values):
  - XUSB_PADCTL_UPHY_PLL_S0_CTL1_0
  - XUSB_PADCTL_UPHY_PLL_S0_CTL2_0
  - XUSB_PADCTL_UPHY_PLL_S0_CTL3_0
  - XUSB_PADCTL_UPHY_PLL_S0_CTL4_0
  - XUSB_PADCTL_UPHY_PLL_S0_CTL5_0
  - XUSB_PADCTL_UPHY_PLL_S0_CTL6_0
  - XUSB_PADCTL_UPHY_PLL_S0_CTL7_0
  - XUSB_PADCTL_UPHY_PLL_S0_CTL8_0
  - XUSB_PADCTL_UPHY_PLL_S0_CTL9_0
  - XUSB_PADCTL_UPHY_PLL_S0_CTL10_0
  - XUSB_PADCTL_UPHY_PLL_S0_CTL11_0
  - XUSB_PADCTL_UPHY_MISC_PAD_S0_CTL_1_0
  - XUSB_PADCTL_UPHY_MISC_PAD_S0_CTL_2_0
  - XUSB_PADCTL_UPHY_MISC_PAD_S0_CTL_3_0
  - XUSB_PADCTL_UPHY_MISC_PAD_S0_CTL_4_0

- XUSB_PADCTL_UPHY_MISC_PAD_S0_CTL_5_0
- XUSB_PADCTL_UPHY_MISC_PAD_S0_CTL_6_0
- XUSB_PADCTL_UPHY_MISC_PAD_S0_CTL_7_0
- XUSB_PADCTL_UPHY_MISC_PAD_S0_CTL_8_0
- XUSB_PADCTL_UPHY_MISC_PAD_S0_CTL_9_0

- Program the following XUSB PADCTL register to assign the PHY to SATA:
  - XUSB_PADCTL_USB3_PAD_MUX_0[SATA_PAD_LANE0] to 'SATA'

The PAD driver programs the clocks and deasserts the resets to the controllers:

- Set the following CAR register bits to '1' to enable the clocks to *SATA:*
  - CLK_RST_CONTROLLER_CLK_ENB_V_SET_0[SET_CLK_ENB_SATA]
  - CLK_RST_CONTROLLER_CLK_ENB_V_SET_0[SET_CLK_ENB_SATA_OOB]
- Program the following CAR register bits to set the source of the *SATA* clocks, where PLLP_OUT0 runs at 408 MHz:
  - CLK_RST_CONTROLLER_CLK_SOURCE_SATA_0[SATA_CLK_SRC] to 'PLLP_OUT0'
  - CLK_RST_CONTROLLER_CLK_SOURCE_SATA_0[SATA_CLK_DIVISOR] to '0x6'
  - CLK_RST_CONTROLLER_CLK_SOURCE_SATA_OOB_0[SATA_OOB_CLK_SRC] to 'PLLP_OUT0'
  - CLK_RST_CONTROLLER_CLK_SOURCE_SATA_OOB_0[SATA_OOB_CLK_DIVISOR] to '0x2'
- Set the following CAR register bits to '0' to deassert reset to *SATA:*
  - CLK_RST_CONTROLLER_RST_DEVICES_V_0[SWR_SATA_RST]
  - CLK_RST_CONTROLLER_RST_DEVICES_V_0[SWR_SATA_OOB_RST]
  - CLK_RST_CONTROLLER_RST_DEVICES_W_0[SWR_SATACOLD_RST]

The PAD driver brings the UPHY out of IDDQ:

- Program the following XUSB PADCTL registers to '1' to bring SATA IOPHY out of IDDQ.
  - XUSB_PADCTL_USB3_PAD_MUX_0[FORCE_SATA_PAD_IDDQ_DISABLE_MASK0]
  - Wait 200 µs

The SATA PEP driver initializes the IPFS registers:

- Program the following SATA IPFS registers to allow software accesses to the SATA's MMIO registers:
  - SATA_AXI_BAR5_START_0[AXI_BAR5_START] to '0x70020'
  - SATA_AXI_BAR5_SZ_0[AXI_BAR5_SIZE] to '0x00008'
  - SATA_FPCI_BAR5_0[FPCI_BAR5_START] to '0x40020000'
  - SATA_FPCI_BAR5_0[FPCI_BAR5_ACCESS_TYPE] to '0'
- Program the following SATA IPFS register to enable the SATA:
  - SATA_CONFIGURATION_0[EN_FPCI] to '1'

The SATA PEP driver initializes SATA's configuration registers.

- Program the following SATA configuration registers to initialize SATA:
  - T_SATA<0>_CFG_1_BUS_MASTER to '1'
  - T_SATA<0>_CFG_1_MEMORY_SPACE to '1'
  - T_SATA<0>_CFG_9_BASE_ADDRESS to '0x40020000'

The SATA PEP driver initializes SATA's AUX registers.

- Program the following SATA_AUX register to disable RX idle detection interrupt:
  - SATA_AUX_RX_STAT_INT_0[SATA_RX_STAT_INT_DISABLE] to ‘1’

The SATA PEP driver enables SATA’s second level clock gating.

- Program the following IPFS registers for IPFS clock gating:
  - SATA_CONFIGURATION_0[CLKEN_OVERRIDE] to ‘1’
- Program the following AHCI registers for TX clock gating:
  - T_AHCI_HBA_PLL_CTRL_SHUTDOWN_TXCLK_ON_SLUMBER to ‘1’
  - T_AHCI_HBA_PLL_CTRL_NO_CLAMP_SHUTDOWN to ‘1’

The SATA PEP driver programs SATA’s configuration registers for WARs.

- Program the following SATA_configuration registers to fix SQUELCH Filter
  - T_SATA0_CFG_PHY_0_MASK_SQUELCH to ‘1’
  - T_SATA<0>_NVOOB_COMMA_CNT to ‘3’b100’
  - T_SATA<0>_NVOOB_SQUELCH_FILTER_LENGTH to ‘2’b11’
  - T_SATA<0>_NVOOB_SQUELCH_FILTER_MODE to ‘2’b01’
- Program the following SATA_configuration registers to fix Gen3 devices detected as Gen1 devices
  - T_SATA0_CFG_PHY_0_USE_7BIT_ALIGN_DET_FOR_SPD to ‘1’
- Program the following SATA AHCI registers to disable SATA declaring support of DEVSLP
  - T_SATA0_AHCI_HBA_CAP2_BKDR_SUPPORTS_DEVSLP to ‘0’

33.8.2 Boot ROM Boot

The Boot ROM checks if the boot setting is set to boot from SATA.

- Read the following MISC register to determine if there is a boot from SATA:
  - APB_MISC_PP_STRAPPING_OPT_A_0[BOOT_SELECT] is ‘SATA’

The Boot ROM enables the memory controllers’ AHB redirection.

- Program the following CAR register to override MC ARC clock gating
  - CLK_RST_CONTROLLER_LVL2_CLK_GATE_OVRD_0[ARC_CLK_OVR_ON] to ‘1’.
- Program the following MC registers to enable the ARC path:
  - MC_IRAM_BOM_0[IRAM_BOM] to ‘0x4000_0’.
  - MC_IRAM_TOM_0[IRAM_TOM] to ‘0x4003_F’.

The Boot ROM initializes SATA by following steps listed in Section 33.8.1: Cold Boot above.

33.8.3 ELPG Entry

The SATA PEP driver performs context saves for SATA registers specified in Section 33.9.1: Registers for Save and Restore.

The SATA PEP driver switches PAD control to SATA’s AUX registers:

- Program the following SATA_AUX register to enable RX idle detection interrupt:
  - SATA_AUX_RX_STAT_INT_0[SATA_RX_STAT_INT_DISABLE] to ‘1’
- Program the following XUSB PADCTL registers to put the Vcore side of the UPHY to IDDQ:
  - XUSB_PADCTL_UPHY_MISC_PAD_S0_CTL_2_0[RX_IDDQ_OVRD] to ‘1’
  - XUSB_PADCTL_UPHY_MISC_PAD_S0_CTL_2_0[RX_IDDQ] to ‘1’

- XUSB_PADCTL_UPHY_MISC_PAD_S0_CTL_2_0[TX_IDDQ_OVRD] to ‘1’
- XUSB_PADCTL_UPHY_MISC_PAD_S0_CTL_2_0[TX_IDDQ] to ‘1’

The System Power Management driver flushes MCCIF and partition clients.

- Set the following MC register bits to ‘1’ to enable flush to SATA
  - MC_CLIENT_HOTRESET_CTRL_0[SATA_FLUSH_ENABLE]
- Read the following MC register to be ‘1’ to ensure flush to SATA is enabled
  - MC_CLIENT_HOTRESET_STATUS_0[SATA_HOTRESET_STATUS]

The System Power Management driver asserts reset to SATA then disables its clocks:

- Set the following CAR register bits to ‘1’ to assert reset to SATA:
  - CLK_RST_CONTROLLER_RST_DEVICES_V_0[SWR_SATA_RST]
  - CLK_RST_CONTROLLER_RST_DEVICES_V_0[SWR_SATA_OOB_RST]
  - CLK_RST_CONTROLLER_RST_DEVICES_W_0[SWR_SATACOLD_RST]
- Set the following CAR register bits to ‘1’ to disable the clocks to individual SATA partitions:
  - CLK_RST_CONTROLLER_CLK_ENB_V_CLR_0[CLR_CLK_ENB_SATA]
  - CLK_RST_CONTROLLER_CLK_ENB_V_CLR_0[CLR_CLK_ENB_SATA_OOB]

The System Power Management driver uses software overrides to power down the IOPHY/UPHY PLL.

- Set the following CAR register bits to ‘1’ to power down the PLL:
  - CLK_RST_CONTROLLER_SATA_PLL_CFG0_0[SATA_SEQ_PADPLL_PD_INPUT_VALUE]
  - CLK_RST_CONTROLLER_SATA_PLL_CFG0_0[SATA_SEQ_LANE_PD_INPUT_VALUE]
  - CLK_RST_CONTROLLER_SATA_PLL_CFG0_0[SATA_SEQ_RESET_PD_INPUT_VALUE]

The System Power Management driver disables the SATA power rails:

- Program the following PMC register bits in a single write to disable the power rail to SATA:
  - APBDEV_PMC_PWRGATE_TOGGLE_0[START] to ‘enable’
  - APBDEV_PMC_PWRGATE_TOGGLE_0[PARTID] to ‘SAX’
- Read the following PMC register bits to confirm the power gating status of SATA:
  - APBDEV_PMC_PWRGATE_STATUS_0[SAX] equals ‘OFF’

33.8.4 ELPG Exit

The System Power Management driver uses software overrides to enable the IOPHY/UPHY PLL.

- Set the following *CAR* register bits to ‘0’ to enable the PLL
  - CLK_RST_CONTROLLER_SATA_PLL_CFG0_0[SATA_SEQ_PADPLL_PD_INPUT_VALUE]
  - CLK_RST_CONTROLLER_SATA_PLL_CFG0_0[SATA_SEQ_LANE_PD_INPUT_VALUE]
  - CLK_RST_CONTROLLER_SATA_PLL_CFG0_0[SATA_SEQ_RESET_PD_INPUT_VALUE]

The System Power Management driver enables the SATA power rails:

- Program the following PMC register bits in a single write to disable the power rail to SATA:
  - APBDEV_PMC_PWRGATE_TOGGLE_0[START] to ‘enable’
  - APBDEV_PMC_PWRGATE_TOGGLE_0[PARTID] to ‘SAX’
- Read the following PMC register bits to confirm the power gating status of SATA:
  - APBDEV_PMC_PWRGATE_STATUS_0[SAX] equals ‘ON’

The System Power Management driver enables the SATA clocks:

- Set the following *CAR* register bits to '1' to enable the clocks to the SATA partition:
  - CLK_RST_CONTROLLER_CLK_ENB_V_SET_0[SET_CLK_ENB_SATA]
  - CLK_RST_CONTROLLER_CLK_ENB_V_SET_0[SET_CLK_ENB_SATA_OOB]

The System Power Management driver removes power clamps to SAX partitions:

- Set the following PMC register bits to '1' to remove the power clamps to the SATA partitions:
  - APBDEV_PMC_REMOVE_CLAMPING_CMD_0 [SAX]
- Read the following PMC register bits to confirm the power clamps to the SATA partition are removed:
  - APBDEV_PMC_REMOVE_CLAMPING_CMD_0 [SAX] equals '0'

The System Power Management driver deasserts reset to SATA.

- Set the following *CAR* register bits to '0' to assert reset to SATA:
  - CLK_RST_CONTROLLER_RST_DEVICES_V_0[SWR_SATA_RST]
  - CLK_RST_CONTROLLER_RST_DEVICES_V_0[SWR_SATA_OOB_RST]
  - CLK_RST_CONTROLLER_RST_DEVICES_W_0[SWR_SATACOLD_RST]

The System Power Management driver disables flushes of MCCIF and partition clients.

- Set the following MC register bits to '0' to disable flush to SATA
  - MC_CLIENT_HOTRESET_CTRL_0[SATA_FLUSH_ENABLE]

The SATA PEP driver performs context restores for SATA registers specified in Section 33.9.1: Registers for Save and Restore starting from the IPFS registers followed by the SATA configuration registers and finally the SATA MMIO registers.

The SATA PEP driver switches PAD control to SATA:

- Program the following XUSB_PADCTL registers to bring the Vcore side of the UPHY out of IDDQ:
  - XUSB_PADCTL_UPHY_MISC_PAD_S0_CTL_2_0[RX_IDDQ_OVRD] to '0'
  - XUSB_PADCTL_UPHY_MISC_PAD_S0_CTL_2_0[RX_IDDQ] to '0'
  - XUSB_PADCTL_UPHY_MISC_PAD_S0_CTL_2_0[TX_IDDQ_OVRD] to '0'
  - XUSB_PADCTL_UPHY_MISC_PAD_S0_CTL_2_0[TX_IDDQ] to '0'
- Program the following SATA_AUX registers to disable RX idle detection interrupt and clear RX idle interrupt:
  - SATA_AUX_RX_STAT_INT_0[SATA_RX_STAT_INT_DISABLE] to '0'
  - SATA_AUX_RX_STAT_CLR_0[SATA_RX_STAT_INT_CLR] to '1'

33.8.5 LP0

As part of the LP0 entry sequence, after setting the SATA controller to ELPG, the PAD driver should put the IOPHY to IDDQ:

- Program the following XUSB PADCTL registers to '0' to bring SATA IOPHY to IDDQ.
  - XUSB_PADCTL_USB3_PAD_MUX_0[FORCE_SATA_PAD_IDDQ_DISABLE_MASK0]

As part of the LP0 exit sequence, after restoring power to SATA, the PAD driver brings the IOPHY out of IDDQ:

- Program the following XUSB PADCTL registers to '1' to bring SATA IOPHY out of IDDQ:
  - XUSB_PADCTL_USB3_PAD_MUX_0[FORCE_SATA_PAD_IDDQ_DISABLE_MASK0]
  - Wait 200 µs

33.8.6 Handling of Unsolicited COMINITs

To detect unsolicited COMINITs, software should check whether PxIS.PCS is set to '1' on an interrupt. The Host Bus Adaptor (HBA) cannot guarantee that a device received a COMRESET because a COMINIT may appear to be solicited to the HBA if it happens to occur closely to an issued COMRESET. Therefore, when software detects that PxIS.PCS is set, software should first issue a COMRESET to ensure that the device receives a COMRESET. Then software should perform the appropriate actions to clear PxIS.PCS to '0'. To recover, software should perform error recovery actions for a fatal error condition (including restarting the controller). Then software should perform a re-enumeration to check whether a new device has been inserted.

33.9 SATA Registers

33.9.1 Registers for Save and Restore

The registers needed to be saved and restored are:

IPFS registers

Save and restore	Offset (hex)	Save and restore	Offset (hex)
SATA_FPCI_BAR5_0	94	SATA_MSI_EN_VEC6_0	158
SATA_MSI_BAR_SZ_0	C0	SATA_MSI_EN_VEC7_0	15C
SATA_MSI_AXI_BAR_ST_0	C4	SATA_CONFIGURATION_0	180
SATA_MSI_FPCI_BAR_ST_0	C8	SATA_FPCI_ERROR_MASKS_0	184
SATA_MSI_EN_VEC0_0	140	SATA_INTR_MASK_0	188
SATA_MSI_EN_VEC1_0	144	SATA_IPFS_INTR_ENABLE_0	198
SATA_MSI_EN_VEC2_0	148	SATA_CFG_REVID_0	1A0
SATA_MSI_EN_VEC3_0	14C	SATA_CLKGATE_HYSTERSIS_0	1BC
SATA_MSI_EN_VEC4_0	150	SATA_SATA_MCCIF_FIFOCTRL_0	1DC
SATA_MSI_EN_VEC5_0	154		

Configuration Space and Extended Configuration Space Registers

Note: *Registers present in both the SATA and SATA0 address spaces are listed as SATA<0>.*

Save and restore	Offset (hex)	Save and restore	Offset (hex)
T_SATA<0>_CFG_1	4	T_SATA<0>_CFG_LINK_0	174
T_SATA<0>_CFG_3	C	T_SATA<0>_CFG_LINK_1	178
T_SATA<0>_CFG_9	24	T_SATA<0>_CFG_LINK_2	17c
T_SATA<0>_CFG_10	28	MCP_SATA<0>_CFG_TRANS_0	1D0
T_SATA<0>_CFG_12	30	T_SATA0_ALPM_CTRL	238
T_SATA<0>_CFG_13	34	T_SATA0_AHCI_HBA_CTL_0	30C
T_SATA<0>_CFG_14	38	T_SATA0_AHCI_HBA_BIST_OVERRIDE_CTL	318
T_SATA<0>_CFG_15	3C	T_SATA0_AHCI_HBA_SPARE_1	320
T_SATA<0>_CFG_16	40	T_SATA0_AHCI_HBA_SPARE_2	324
T_SATA<0>_CFG_17	44	T_SATA0_AHCI_HBA_DYN_CLK_CLAMP	328
T_SATA<0>_CFG_18	48	T_SATA0_AHCI_CFG_ERR_CTRL	32C
T_SATA<0>_MSI_CTRL	B0	T_SATA0_AHCI_HBA_CTL_1	338
T_SATA<0>_MSI_ADDR1	B4	T_SATA0_AHCI_HBA_PRE_STAGING_CONTROL	340
T_SATA<0>_MSI_ADDR2	B8	T_SATA0_CFG_FPCI_0	430

Save and restore	Offset (hex)	Save and restore	Offset (hex)
T_SATA<0>_MSI_DATA	BC	T_SATA0_CFG_ESATA_CTRL	494
T_SATA<0>_MSI_QUEUE	C0	T_SATA<0>_CTL1	4A0
T_SATA<0>_MSI_MAP	EC	T_SATA<0>_CFG_CTL_GLUE	4B0
T_SATA0_CFG_PHY_POWER	124	T_SATA<0>_PHY_CTRL	534
T_SATA0_CFG_PHY_POWER_1	128	T_SATA<0>_CTRL	540
T_SATA<0>_CFG_PHY_1	12C	T_SATA<0>_LOW_POWER_COUNT	554

Save and Restore Following Protocol

(Program T_SATA<0>_INDEX to select port 0)

Save and restore	Offset (hex)	Save and restore	Offset (hex)
T_SATA<0>_CHXCFG1	530	T_SATA<0>_CHX_PHY_CTRL_3	6B0
T_SATA<0>_CHX_MISC	684	T_SATA<0>_CHX_PHY_CTRL_4	6B4
T_SATA<0>_CHXCFG3	700	T_SATA<0>_CHX_PHY_CTRL_5	6B8
T_SATA<0>_CHXCFG4_CHX	704	T_SATA<0>_CHX_PHY_CTRL_6	6BC
T_SATA<0>_CHX_PHY_CTRL1_GEN1	690	T_SATA<0>_PRBS_CHX – OP	714
T_SATA<0>_CHX_PHY_CTRL1_GEN2	694	T_SATA<0>_CHX_LINK0	750
T_SATA<0>_CHX_PHY_CTRL1_GEN3	698	T_SATA<0>_CHX_GLUE	7F0
T_SATA<0>_CHX_PHY_CTRL_2	69C		

BAR 5 Space Registers

Save and restore	Offset (hex)	Save and restore	Offset (hex)
T_AHCI_HBA_CCC_PORTS	18	T_AHCI_PORT_PXCLBU	104
T_AHCI_HBA_GHC	4	T_AHCI_PORT_PXFB	108
T_AHCI_HBA_CCC_CTL - OP (optional)	14	T_AHCI_PORT_PXFBU	10C
T_AHCI_HBA_EM_LOC	1C	T_AHCI_PORT_PXIE	114
T_AHCI_HBA_EM_CTL - OP	20	T_AHCI_PORT_PXCMD	118
T_AHCI_PORT_PXCLB	100	T_AHCI_PORT_PXSCTL	12C

Power-Gating Registers

These registers require save and restore across the power-gating sequence. Apart from this, the software is expected to save and restore the configuration space registers.

Save and restore	Offset (hex)	Save and restore	Offset (hex)
T_AHCI_HBA_SPARE_0	a4	T_AHCI_HBA_CCC_PORTS	18
T_AHCI_HBA_GHC	4	T_AHCI_HBA_CCC_CTL - OP (optional)	14
T_AHCI_HBA_EM_LOC	1c	T_AHCI_HBA_EM_CTL - OP	20
T_AHCI_PORT_PXCLB	100	T_AHCI_PORT_PXCLBU	104
T_AHCI_PORT_PXFB	108	T_AHCI_PORT_PXFBU	10c
T_AHCI_PORT_PXIE	114	T_AHCI_PORT_PXCMD	118
T_AHCI_HBA_SHUTDOWN_TIMER	ac	T_AHCI_HBA_PLL_CTRL	a8
T_AHCI_PORT_PXSCTL	12c	T_AHCI_PORT_PXFBS	140
T_AHCI_PORT_MP	17c		

Save and Restore via Backdoor Writes

Save and restore	Offset (hex)
T_AHCI_HBA_CAP_0 (T_SATA0_AHCI_HBA_CAP_BKDR)	0 (300*)
T_AHCI_HBA_PI (T_SATA0_AHCI_HBA_PI_BKDR)	0C (33C*)
T_AHCI_HBA_CAP2 (T_SATA0_AHCI_HBA_CAP2_BKDR)	24 (330*)
T_AHCI_PORT_PXTFD (T_SATA<0>_CHX_AHCI_PORT_PXTFD_BKDR)	120 (790*)
T_AHCI_PORT_PXSIG (T_SATA<0>_CHX_AHCI_PORT_PXSIG_BKDR)	124 (794*)
T_AHCI_PORT_PXSSTS (T_SATA<0>_CHX_AHCI_PORT_PXSSTS_BKDR)	128 (798*)

Note: ** Backdoor addresses for restore*

Registers to Read Only (Not Needed to Restore)

T_AHCI_HBA_BOHC 28
T_AHCI_PORT_INTR 174
T_AHCI_PORT_PXSERR 130

33.9.2 Registers Used in Power Gating/Ungating Sequence

Refer to the PMC and Clock and Reset Controller sections for the details of these registers:

- APBDEV_PMC_SATA_PWRGT_0
- CLK_RST_CONTROLLER_SATA_PLL_CFG0_0
- CLK_RST_CONTROLLER_PLLE_AUX_0

33.9.3 SATA Register Descriptions

33.9.3.1 SATA_AXI_BARi_SZ_0 Registers

There are eight SATA_AXI_BARi_SZ_0 registers (I = 0 through 7). The size of the address range associated with BARi is in 4K increments. A value of 0 signifies BARi is not used.

SATA_AXI_BAR0_START_0 through SATA_AXI_BAR4_START_0

- For BAR0 through BAR4 (i = 0 through 4):

Offset: 0x0 + (i * 0x4) | Read/Write: R/W | Reset: 0x00000001 (0b00000000000000000001)

Bit	Reset	Description
19:0	0x1	AXI_BARi_SIZE

SATA_AXI_BAR5_START_0

Offset: 0x14 | Read/Write: R/W | Reset: 0x00000002 (0b00000000000000000010)

Bit	Reset	Description
19:0	0x2	AXI_BAR5_SIZE

SATA_AXI_BAR6_START_0 through SATA_AXI_BAR7_START_0

- For BAR6 through BAR7 (i = 6 through 7)

Offset: 0x18 + (i * 0x4) | Read/Write: R/W | Reset: 0x00000000 (0b00000000000000000000)

Bit	Reset	Description
19:0	0x0	AXI_BARi_SIZE

33.9.3.2 SATA_AXI_BARi_START_0 Registers

There are eight SATA_AXI_BARi_START registers. The AXI target address is compared to the start/size for each BAR to determine if the access is to that BAR.

SATA_AXI_BAR0_START_0

Offset: 0x40 | Read/Write: R/W | Reset: 0x70022000 (0b01110000000000100010)

Bit	Reset	Description
31:12	0x70022	AXI_BAR0_START:The start of AXI address space for BAR0.

SATA_AXI_BAR1_START_0

Offset: 0x44 | Read/Write: R/W | Reset: 0x70023000 (0b01110000000000100011)

Bit	Reset	Description
31:12	0x70023	AXI_BAR1_START:The start of AXI address space for BAR1.

SATA_AXI_BAR2_START_0

Offset: 0x48 | Read/Write: R/W | Reset: 0x70024000 (0b01110000000000100100)

Bit	Reset	Description
31:12	0x70024	AXI_BAR2_START:The start of AXI address space for BAR2.

SATA_AXI_BAR3_START_0

Offset: 0x4c | Read/Write: R/W | Reset: 0x70025000 (0b01110000000000100101)

Bit	Reset	Description
31:12	0x70025	AXI_BAR3_START:The start of AXI address space for BAR3.

SATA_AXI_BAR4_START_0

Offset: 0x50 | Read/Write: R/W | Reset: 0x70026000 (0b01110000000000100110)

Bit	Reset	Description
31:12	0x70026	AXI_BAR4_START: The start of AXI address space for BAR4.

SATA_AXI_BAR5_START_0

Offset: 0x54 | Read/Write: R/W | Reset: 0x70027000 (0b01110000000000100111)

Bit	Reset	Description
31:12	0x70027	AXI_BAR5_START: The start of AXI address space for BAR5.

SATA_AXI_BAR6_START_0

Offset: 0x58 | Read/Write: R/W | Reset: 0x00000000 (0b00000000000000000000)

Bit	Reset	Description
31:12	0x0	AXI_BAR6_START: The start of AXI address space for BAR6.

SATA_AXI_BAR7_START_0

Offset: 0x5c | Read/Write: R/W | Reset: 0x00000000 (0b00000000000000000000)

Bit	Reset	Description
31:12	0x0	AXI_BAR7_START: The start of AXI address space for BAR7.

33.9.3.3 SATA_FPCI_BARi_0 Registers

There are eight SATA_FPCI_BARi_0 registers. All registers have these two fields:

- Bits [31:4]: FPCI_BARi_START: This field contains the start of FPCI address space mapped into the BARi range of PCI memory space. The 40-bit FPCI address is determined by a shift left 12 of the value of this field.
- Bit 0: FPCI_BARi_ACCESS_TYPE: This field indicates if the address region is memory mapped versus configuration or I/ O space.
  0 = Memory-mapped access (PW only)
  1 = I/O / config access (NPW only)

SATA_FPCI_BAR0_0 through SATA_FPCI_BAR5_0

For BAR0 through BAR5 (i = 0 through 5)

Offset: 0x80 + (i * 0x4) | Read/Write: R/W | Reset: 0xfdfc0001 (0b11111101111111000000000000000xxx1)

Bit	Reset	Description
31:4	0xfdfc000	FPCI_BARi_START
0	0x1	FPCI_BARi_ACCESS_TYPE

SATA_FPCI_BAR6_0 through SATA_FPCI_BAR7_0

Offset: 0x98 + (i* 0x4) | Read/Write: R/W | Reset: 0x00000001 (0b00000000000000000000000000000xxx1)

Bit	Reset	Description
31:4	0x0	FPCI_BARi_START
0	0x1	FPCI_BARi_ACCESS_TYPE

33.9.3.4 SATA_MSI_BAR_SZ_0

MSI BAR Size

Offset: 0xc0 | Read/Write: R/W | Reset: 0x00000000 (0b00000000000000000000)

Bit	Reset	Description
19:0	0x0	MSI_BAR_SIZE: The size of the address range associated with MSI BAR is in 4K increments. A value of 0 signifies MSI BAR is not used.

33.9.3.5 SATA_MSI_AXI_BAR_ST_0

MSI AXI BAR Start

Offset: 0xc4 | Read/Write: R/W | Reset: 0x00000000 (0b00000000000000000000)

Bit	Reset	Description
31:12	0x0	MSI_AXI_BAR_START: The start of upstream AXI address space for MSI BAR. The upstream FPCI address is compared to start/1KB range for MSI BAR to determine if the access is MSI. Bits 31:12 of MSI BAR start correspond to AXI address bits 31:12.

33.9.3.6 SATA_MSI_FPCI_BAR_ST_0

MSI FPCI BAR Start

Offset: 0xc8 | Read/Write: R/W | Reset: 0x00000000 (0b00000000000000000000000000000000)

Bit	Reset	Description
31:4	0x0	MSI_FPCI_BAR_START: The start of upstream FPCI address space for MSI BAR. The upstream FPCI address is compared to start/1KB range for MSI BAR to determine if the access is MSI. Bits 31:4 of MSI BAR start correspond to UFPCI address bits 39:12.

33.9.3.7 SATA_MSI_VECi_0 Registers

There are eight SATA_MSI_VECi_0 vector registers (i = 0 through 7). Each vector register corresponds to 32 of the possible 256 MSI vectors.VECTOR0 corresponds to MSI vectors 31-0.Vector7 corresponds to MSI vectors 255-223. When an upstream MSI is sent, the bit corresponding to the MSI vector is set to 1 by hardware if the corresponding enable bit is 1.The bit is set to 0 if a 1 is written to its location.

Offset: 0x100 + (i * 0x4) | Read/Write: R/W | Reset: 0x00000000 (0b00000000000000000000000000000000)

Bit	Reset	Description
31:0	0x0	MSI_VECTORi

33.9.3.8 SATA_MSI_EN_VEC0_0

There are eight SATA_MSI_EN_VECi_0 vector registers (i = 0 through 7). Each vector register corresponds to the enable bit for 32 of the possible 256 MSI vectors. ENABLE VECTOR0 corresponds to enable bits for MSI vectors 31-0. Vector7 corresponds to enable bits for MSI vectors 255-223. When an upstream MSI is sent, the bit corresponding to the MSI vector is set to 1 by hardware if the corresponding enable bit is 1.

Offset: 0x140 + (i * 0x4) | Read/Write: R/W | Reset: 0x00000000 (0b00000000000000000000000000000000)

Bit	Reset	Description
31:0	0x0	MSI_ENABLE_VECTORi

33.9.3.9 SATA_CONFIGURATION_0

Configuration

Offset: 0x180 | Read/Write: R/W | Reset: 0x800X8X40 (0b1xxxxxxxxxxx1xxx10xxxxxx01000000)

Bit	R/W	Reset	Description
31	RW	0x1	CLKEN_OVERRIDE: This can override the clock enable in case of malfunction.
18	RO	X	INITIATOR_READ_IDLE: This read-only bit provides status reads on the AFI upstream. A value of 1b indicates there are no outstanding reads to the initiator.
17	RO	X	INITIATOR_WRITE_IDLE: This read-only bit provides status writes on the AFI upstream. A value of 1b indicates there are no outstanding writes to the initiator.
15	RW	0x1	WDATA_LEAD_CYA: Used to enable/disable the handling of write data ahead of requests on the IPFS AXI target.
14	RW	0x0	WR_INTRLV_CYA: Used to enable/disable the handling of interleaved write requests on the IPFS AXI target
11	RO	X	TARGET_READ_IDLE: This read-only bit provides status reads to the IPFS target. A value of 1b indicates there are no outstanding reads to the downstream FPCI.
10	RO	X	TARGET_WRITE_IDLE: This read-only bit provides status writes to IPFS target. A value of 1b indicates there are no outstanding writes to the downstream FPCI.
9	RO	X	MSI_VEC_EMPTY: This read-only bit provides status on whether MSI Vector registers have any active bits valid or not.
7	RW	0x0	UFPCI_MSIAW: MSI After Write ordering rule. 1 = whenever MSI is ready assert the interrupt 0 = default behavior, apply MSIAW ordering rule
6	RW	0x1	UFPCI_PWPASSPW: Input to upstream FPCI 1 = whenever a write is ready, send it 0 = write goes only when outstanding PWs outside of new write's region are retired (default).
5	RW	0x0	UFPCI_PASSPW: Input to the upstream FPCI. Allow the upstream FPCI reads to pass writes.
4	RW	0x0	UFPCI_PWPASSNPW: Used for upstream FPCI. Allow upstream FPCI PWs to pass NPWs.
3	RW	0x0	DFPCI_PWPASSNPW: Used for the downstream FPCI. Allow downstream FPCI PWs to pass NPWs.
2	RW	0x0	DFPCI_RSPPASSPW: Input to the downstream FPCI. Allow downstream FPCI responses to pass writes.
1	RW	0x0	DFPCI_PASSPW: Input to the downstream FPCI. Allow downstream FPCI reads to pass writes.

Bit	R/W	Reset	Description
0	RW	0x0	EN_FPCI: When the IPFS device block is disabled, it is completely invisible on the IPFS bus; that is, it does not even process IPFS configuration accesses.

33.9.3.10 SATA_FPCI_ERROR_MASKS_0

FPCI Error Masks

Offset: 0x184 | Read/Write: R/W | Reset: 0x00000000 (0b000)

Bit	Reset	Description
2	0x0	MASK_FPCI_MASTER_ABORT: This bit allows an FPCI error to be forwarded to the AXI response when the FPCI error response indicates Master Abort. 1 = forward error 0 = return AXI OKAY response (2'b0)
1	0x0	MASK_FPCI_DATA_ERROR: This bit allows an FPCI error to be forwarded to the AXI response when the FPCI error response indicates Data Error. 1 = forward error 0 = return AXI OKAY response (2'b0)
0	0x0	MASK_FPCI_TARGET_ABORT: This bit allows an FPCI error to be forwarded to the AXI response when the FPCI error response indicates Target Abort. This bit also covers decode errors generated when there is no DEVSEL received. 1 = forward error 0 = return AXI OKAY response (2'b0)

33.9.3.11 SATA_INTR_MASK_0

Interrupt Masks

Offset: 0x188 | Read/Write: R/W | Reset: 0x00000000 (0b0xxxxxxx0xxxxxxx0)

Bit	Reset	Description
16	0x0	IP_INT_MASK: IP (SATA/AZA) interrupt to the CPU gated by a mask.
8	0x0	MSI_MASK: MSI to the CPU gated by a mask.
0	0x0	INT_MASK: Interrupt to the CPU gated by a mask.

33.9.3.12 SATA_INTR_CODE_0

Interrupt Control

Offset: 0x18c | Read/Write: R/W | Reset: 0x00000000 (0b00000)

Bit	Reset	Description
4:0	0x0	INT_CODE: Interrupt codes. If the code is 0, logging of the next interrupt is enabled 0 = INT_CODE_CLEAR: Clear interrupt code 1 = INT_CODE_INI_SLVERR: Interrupt code for CPU AXI SLVERR response to IPFS 2 = INT_CODE_INI_DECERR: Interrupt code for CPU AXI DECERR response to IPFS 3 = INT_CODE_TGT_SLVERR: Interrupt code for PCIe endpoint FPCI target abort or data error response to IPFS 4 = INT_CODE_TGT_DECERR: Interrupt code for PCIe2 FPCI master abort response to IPFS 5 = INT_CODE_TGT_WRERR: Interrupt code for bufferable write to non-posted write address region 6 = RSVD1: Reserved 7 = INT_CODE_DFPCI_DECERR: Interrupt code for PCIe2 response to downstream request when downstream FPCI address does not fall in a claimable downstream region 8 = INT_CODE_AXI_DECERR: Interrupt code for IPFS response to downstream request when AXI target address does not fall in any of IPFS downstream BARs 9 = INT_CODE_FPCI_TIMEOUT: Interrupt code for FPCI Timeout 10 = RSVD2: Reserved for future expansion 11 = RSVD3 12 = RSVD4 13 = RSVD5 14 = RSVD6 15 = INT_CODE_SM_FATAL_ERROR: Interrupt code for SM fatal error 16 = INT_CODE_SM_NON_FATAL_ERROR: Interrupt code for SM non-fatal error

33.9.3.13 SATA_INTR_SIGNATURE_0

Interrupt Signature

Offset: 0x190 | Read/Write: R/W | Reset: 0x00000000 (0b00000000000000000000000000000000x0)

Bit	Reset	Description
31:2	0x0	INT_INFO: For interrupt codes 1-5/7-8, this field contains address bits [31:2], either in FPCI memory space or AXI space. For FPCI generated errors, this field contains the FPCI address. For AXI/IPFS generated errors, this field contains the AXI address.
0	0x0	DIR: Indicates the direction of the AXI/FPCI transaction. If the signature type is 6 (sideband message), this field is 1. 1=rd 0=wr 0 = WRITE: Interrupt due to a write transaction 1 = READ: Interrupt due to a read transaction

33.9.3.14 SATA_UPPER_FPCI_ADDR_0

Upper FPCI Address

Offset: 0x194 | Read/Write: R/W | Reset: 0x00000000 (0b00000000)

Bit	Reset	Description
7:0	0x0	INT_INFO_UPPER: These 8 bits are the upper byte of the captured FPCI address (bits [39:32])when the interrupt code is 3, 4, or 7.

33.9.3.15 SATA_IPFS_INTR_ENABLE_0

IPFS Interrupt Enable

Offset: 0x198 | Read/Write: R/W | Reset: 0x00000000 (0b00xxxx00000000)

Bit	Reset	Description
13	0x0	EN_SM_NON_FATAL_ERROR: Enable bit for interrupt code 15
12	0x0	EN_SM_FATAL_ERROR: Enable bit for interrupt code 14
7	0x0	EN_FPCI_TIMEOUT: Enable bit for interrupt code 9
6	0x0	EN_AXI_DECERR: Enable bit for interrupt code 8
5	0x0	EN_DFPCI_DECERR: Enable bit for interrupt code 7
4	0x0	EN_TGT_WRERR: Enable bit for interrupt code 5
3	0x0	EN_TGT_DECERR: Enable bit for interrupt code 4
2	0x0	EN_TGT_SLVERR: Enable bit for interrupt code 3
1	0x0	EN_INI_DECERR: Enable bit for interrupt code 2
0	0x0	EN_INI_SLVERR: Enable bit for interrupt code 1

33.9.3.16 SATA_UFPCI_CONFIG_0

Upstream FPCI Configuration

Offset: 0x19c | Read/Write: R/W | Reset: 0x00000002 (0b00010)

Bit	Reset	Description
4:0	0x2	UNITID_T0C0: Upstream FPCI Unit ID for controller 0. HyperTransport, upstream FPCI request

33.9.3.17 SATA_CFG_REVID_0

CFG_REVID register

Offset: 0x1a0 | Read/Write: R/W | Reset: 0x000X10XX (0bxxxxxx0100xxxxxxx1)

Bit	R/W	Reset	Description
19	RO	X	DEV2SM_NONISO_REQUEST_PEND: Indicates if a non ISO request is pending. 0 = NO 1 = YES
18	RO	X	DEV2SM_ISO_REQUEST_PEND: Indicates if an ISO request is pending. 0 = NO 1 = YES
13:12	RW	0x1	STRAP_CPU_MODE: MCP: Mode to send MSI. Can be programmable 0 = NB_INTEL 1 = NB_AMD 2 = AMD 3 = TMTA
11	RW	0x0	CFG_REVID_WRITE_ENABLE: MCP: Enable to override the rev ID. Can be programmable 0 = CLEAR 1 = SET
10	RW	0x0	CFG_REVID_OVERRIDE: MCP: Can override the current revision ID. Can be programmable 0 = DISABLE 1 = ENABLE
4	RO	X	DEV2LEG_NONCOH_REQUEST_PEND: MCP: Tells the leg block that a non-coherent request is pending. 0 = NO 1 = YES
3	RO	X	DEV2LEG_COH_REQUEST_PEND: MCP comment: Tells the leg block that a coherent request is pending 0 = NO 1 = YES
2	RW	0x1	SM2DEV_FPCI_TIMEOUT_EN: FPCI timeout enable bit for Controller 0 = DISABLE 1 = ENABLE

33.9.3.18 SATA_FPCI_TIMEOUT_0

FPCI_TIMEOUT register

Offset: 0x1a4 | Read/Write: R/W | Reset: 0x000f0000 (0b11110000000000000000)

Bit	Reset	Description
19:0	0xf0000	SM2ALL_FPCI_TIMEOUT_THRESH: This sets the timeout threshold value for the FPCI bus. The counter starts counting when each queue (iso/niso- rd/wr) has a pending request in the FPCI wrapper. The count resets when the requests are popped.

33.9.3.19 SATA_TOM_0

Top of Memory Limit

Offset: 0x1a8 | Read/Write: R/W | Reset: 0x3fff0fff (0b11111111111111xxxx111111111111)

Bit	Reset	Description
29:16	0x3fff	LEG2ALL_TOM2: Top of Memory Limit 2.
11:0	0xfff	LEG2ALL_TOM1: Top of Memory Limit 1.

33.9.3.20 SATA_INITIATOR_ISO_PW_RESP_PENDING_0

Initiator ISO PW Response Pending

Offset: 0x1ac | Read/Write: RO | Reset: 0x000000XX (0bxxxxxxxx)

Bit	Reset	Description
7:0	X	NUM_INITIATOR_ISO_PW_RESP_PEND: Number of pending initiator ISO PW responses

33.9.3.21 SATA_INITIATOR_NISO_PW_RESP_PENDING_0

Initiator Non-ISO PW Response Pending

Offset: 0x1b0 | Read/Write: RO | Reset: 0x000000XX (0bxxxxxxxx)

Bit	Reset	Description
7:0	X	NUM_INITIATOR_NISO_PW_RESP_PEND: Number of pending initiator NISO PW responses

33.9.3.22 SATA_INTR_STATUS_0

IPFS Interrupt Status

Offset: 0x1b4 | Read/Write: RO | Reset: 0x0000000X (0bxxx)

Bit	Reset	Description
2	X	IP_INTR_STATUS: Status of IP (SATA/AZA) interrupt
1	X	MSI_INTR_STATUS: Status of MSI interrupt
0	X	IPFS_INTR_STATUS: Status of IPFS interrupt

33.9.3.23 SATA_DFPCI_BEN_0

Downstream FPCI Byte Enables

Offset: 0x1b8 | Read/Write: R/W | Reset: 0x00000000 (0b0xxxxxxxxxxxxxxxxxxxxxxxxxxxx0000)

Bit	Reset	Description
31	0x0	EN_DFPCI_BEN: Enable bit for BEN; when set, programmed BE is sent on the DFPCI bus
3:0	0x0	DFPCI_BYTE_ENABLE_N: Active low byte enables

33.9.3.24 SATA_CLKGATE_HYSTERESIS_0

Offset: 0x1bc | Read/Write: R/W | Reset: 0x00000014 (0b00010100)

Bit	Reset	Description
7:0	0x14	CLK_DISABLE_CNT: Number of IPFS clock cycles to wait after clock gating criteria is met to disable IPFS/ FPCI clocks

33.9.3.25 SATA_SATA_MCCIF_FIFOCTRL_0

Memory Client Interface FIFO Control (where applicable) and Clock Gating Control Register.

Note: *The FIFO timing aspects of this register are no longer supported, but retained for software compatibility*

The clock override/ovr_mode fields of this register control the second-level clock gating for the client and the MC side of the MCCIF. All clock gating is enabled by default.

A '1' written to the rclk/wclk override field will result in one of the following:

- With wclk/rclk override mode = LEGACY, the clock reverts to legacy mode of operation where the clock is on whenever the client clock is enabled.
- With wclk/rclk override mode = ON, the clock is always on inside the MCCIF and PC. A '1' written to the cclk override field keeps the client's clock always on inside the MCCIF.

Offset: 0x1dc | Read/Write: R/W | Reset: 0x00000000 (0b00000xxxxxxxxxxxx0000)

Bit	Reset	Description
20	LEGACY	SATA_RCLK_OVR_MODE: 0 = LEGACY 1 = ON
19	LEGACY	SATA_WCLK_OVR_MODE: 0 = LEGACY 1 = ON
18	0x0	SATA_CCLK_OVERRIDE
17	0x0	SATA_RCLK_OVERRIDE
16	0x0	SATA_WCLK_OVERRIDE
3	DISABLE	SATA_MCCIF_RDCL_RDFAST: 0 = DISABLE 1 = ENABLE
2	DISABLE	SATA_MCCIF_WRMC_CLLE2X: 0 = DISABLE 1 = ENABLE
1	DISABLE	SATA_MCCIF_RDMC_RDFAST: 0 = DISABLE 1 = ENABLE
0	DISABLE	SATA_MCCIF_WRCL_MCLE2X: 0 = DISABLE 1 = ENABLE

33.9.3.26 SATA_ORDERING_RULES_0

Offset: 0x1e0 | Read/Write: R/W | Reset: 0x00000000 (0b000)

Bit	Reset	Description
3	0x0	UPSTREAM_MSIAW: Modified upstream MSIAW ordering. 0 = Tegra X1 MSIAW behavior 1 = Tegra 3 MSIAW behavior
2	0x0	UPSTREAM_RESPAW: Modified RespAW ordering. 0 = Tegra X1 RespAW behavior 1 = Tegra 3 RespAW behavior
1	0x0	UPSTREAM_RAW: Modified RAW ordering. 0 = Tegra X1 RAW behavior 1 = Tegra 3 RAW behavior

33.9.3.27 SATA_A2F_UFPCI_CFG0_0

Offset: 0x1e4 | Read/Write: R/W | Reset: 0x00000050 (0b00000000xxxxx0000000000001010000)

Bit	Reset	Description
31:24	0x0	STATIC_WAIT_IDLE_CNTR
18:16	0x0	STATIC_UFPCI_UFA_STARVE_CNTR_PRI1
15:12	0x0	STATIC_UFPCI_UFA_STARVE_CNTR_PRI0
11:10	0x0	STATIC_UFPCI_RR_BURST_SZ_PRI1
9:8	0x0	STATIC_UFPCI_RR_BURST_SZ_PRI0
7	0x0	STATIC_WAIT_CLAMP_EN
6	0x1	STATIC_UFPCI_UFA_DYN_BLOCK_EN
5	0x0	STATIC_UFPCI_UFA_BLK_COHERENT
4:2	0x4	STATIC_UFPCI_BLOCK_CMD_THRESHOLD

Bit	Reset	Description
1	0x0	STATIC_CYA_UFA_ARB
0	0x0	STATIC_CYA_BACK2BACK_UPSTREAM_BLOCK

33.9.3.28 SATA_A2F_UFPCI_CFG1_0

Offset: 0x1e8 | Read/Write: R/W | Reset: 0x00000000 (0b00000000)

Bit	Reset	Description
7:0	0x0	STATIC_WAIT_UNCLAMP_CNTR

33.9.4 SATA AHCI Register Descriptions

Refer to the SATA specification for the definitions of these registers.

33.9.5 SATA and SATA0 FPCI Register Descriptions

This subsection describes the SATA and SATA0 FPCI registers. The SATA and SATA0 register sets are very similar. The register names and fields are shown as SATA<0> when both register sets are applicable.

For example, T_SATA<0>_CFG_0 defines two registers: T_SATA_CFG_0 and TSATA0_CFG_0. The register named T_SATA0_CFG_PHY_POWER is present only in the SATA0 register set.

See Chapter 2: Address Map in this TRM for the mapping of both register sets.

33.9.5.1 PCI Configuration Registers

Refer to the SATA specification for the definitions of these registers.

T_SATA<0>_CFG_0

PCI Vendor and Device ID Register

Offset: 0x00 | Read/Write: R | Reset: 0x0F70XXXX

Bit	R/W	Reset	Description
31:16	R	0F70h	T_SATA<0>_CFG_0_DEVICE_ID_UNIT: The DEVICE_ID bits identify the particular device. This identifier is allocated by the vendor. DEVICE_ID_FUNC bits contain the function number from the Configuration Address bits 10-8. DEVICE_ID_UNIT bits contain the Unit number within the chip. The Unit and Function are defined by parameters per block. D84h: DEVICE_ID_UNIT_MCP89 D84h: DEVICE_ID_UNIT_MCP89_PATA_DT D85h: DEVICE_ID_UNIT_MCP89_PATA_NB D88h: DEVICE_ID_UNIT_MCP89_AHCI_DT D89h: DEVICE_ID_UNIT_MCP89_AHCI_NB 580h: DEVICE_ID_UNIT_MCP89_AHCI_LINUX D8Ch: DEVICE_ID_UNIT_MCP89_RAID_DT D8Dh: DEVICE_ID_UNIT_MCP89_RAID_NB F70h: DEVICE_ID_UNIT_SATA (default)
15:0	R	10DEh	T_SATA<0>_CFG_0_VENDOR_ID: The VENDOR_ID bits identify the manufacturer of the device. Valid vendor identifiers are allocated by the PCI SIG to ensure uniqueness. VENDOR_ID is the joint SGS/NVIDIA PCI vendor ID. 10DEh: VENDOR_ID_NVIDIA

T_SATA<0>_CFG_1

PCI Device Control Register

The Device Control Command register provides coarse control over a device's ability to generate and respond to PCI cycles.

Offset: 0x04 | Read/Write: R/W | Reset: 0xXXXX0XXX

Bit	R/W	Reset	Description
31	R	0h	T_SATA<0>_CFG_1_DETECTED_PERR: The DETECTED_PERR bit indicates that the device has detected a parity error, even if parity error handing is disabled. (Bit 6 - T_SATA<0>_FPCI_PERR_DISABLED) 0h: DETECTED_PERR_NOT_ACTIVE
30	RW1C	0	T_SATA<0>_CFG_1_SIGNALED_SERR: The SIGNALED_SERR bit indicates that the device has asserted SERR#. NOTE: this field is reset by Cold Reset 0h: SIGNALED_SERR_NOT_ACTIVE (default) 1h: SIGNALED_SERR_ACTIVE 1h: SIGNALED_SERR_CLEAR
29	RW1C	0	T_SATA<0>_CFG_1_RECEIVED_MASTER: The RECEIVED_MASTER bit indicates that a master device's transaction (except for Special Cycle) was terminated with a master-abort. This means that no device on the PCI bus responded to the address of the mastered transaction. All master devices must implement this bit. When this bit is set, an interrupt is signaled in the PBUS_INTR_0 register. NOTE: this field is reset by Cold Reset 0h: RECEIVED_MASTER_NO_ABORT (default) 1h: RECEIVED_MASTER_ABORT 1h: RECEIVED_MASTER_CLEAR
28	RW1C	0	T_SATA<0>_CFG_1_RECEIVED_TARGET: The RECEIVED_TARGET bit indicates that a master device's transaction was terminated with a target-abort. All master devices must implement this bit. When this bit is set, an interrupt is signaled in the PBUS_INTR_0 register. NOTE: this field is reset by Cold Reset 0h: RECEIVED_TARGET_NO_ABORT (default) 1h: RECEIVED_TARGET_ABORT 1h: RECEIVED_TARGET_CLEAR
27	R	0h	T_SATA<0>_CFG_1_SIGNALED_TARGET: The SIGNALED_TARGET bit indicates that the device has terminated a transaction with target-abort. Devices that will never signal target-abort do not need to implement this bit. When this bit is set, an interrupt is signaled in the PBUS_INTR_0 register. 0h: SIGNALED_TARGET_NO_ABORT
26:25	R	0h	T_SATA<0>_CFG_1_DEVSEL_TIMING: The DEVSEL_TIMING bits contain the timing of DEVSEL#. There are three allowable timings for assertion of DEVSEL#. These are encoded as 00b for fast, 01b for medium, and 10b for slow (11b is reserved). These bits are read only and must indicate the slowest time that a device asserts DEVSEL# for any bus command except Configuration Read and Configuration Write. Positive decode devices are required to respond with fast DEVSEL# (0-cycle). Only the subtractive function will respond with medium DEVSEL# to accept the cycle for the subtractive bus. 0h: DEVSEL_TIMING_FAST 1h: DEVSEL_TIMING_MEDIUM 2h: DEVSEL_TIMING_SLOW
24	R	0h	T_SATA<0>_CFG_1_MASTER_DATA_PERR: 0h: MASTER_DATA_PERR_NOT_ACTIVE
23	R	1h	T_SATA<0>_CFG_1_FAST_BACK2BACK: The FAST_BACK2BACK bit indicates that the device is capable of handling back-to-back transfers when the transactions are not to the same agent. This bit can be set to 1 if the device can accept these transactions, and must be set to 0 otherwise. 1h: FAST_BACK2BACK_CAPABLE 0h: FAST_BACK2BACK_INCAPABLE
22	R	0	Reserved
21	R	1h	T_SATA<0>_CFG_1_66MHZ: The 66MHZ bit indicates that the device is capable of 66 MHz PCI Bus operation. This value is initialized by a strapping bit. 1h: 66MHZ_CAPABLE 0h: 66MHZ_INCAPABLE
20	R	1h	T_SATA<0>_CFG_1_CAPLIST: The CAPLIST bit indicates that the device configuration space includes a capabilities list starting at the offset indicated by T_SATA<0>_CFG_13. 1h: CAPLIST_PRESENT 0h: CAPLIST_NOT_PRESENT

Bit	R/W	Reset	Description
19	R	None	T_SATA<0>_CFG_1_INTR_STATUS: The INTR_STATUS bit is read-only and reflects the state of the interrupt in the device/function. Only when the INTR_DISABLE bit in the command register is a 0 and this INTR_STATUS bit is a 1, will the device's/function's INTx# signal be asserted. Setting the INTR_DISABLE bit to 1 has no effect on the state of this bit. 0h: INTR_STATUS_0 1h: INTR_STATUS_1
18:11	R	0	Reserved
10	R/W	0	T_SATA<0>_CFG_1_INTR_DISABLE: The INTR_DISABLE bit indicates that it could disable the device/function from asserting INTx#. A value of 0 enables the assertion of INTx#, and a value of 1 disables the assertion of INTx# signal. The Device Status register is used to record status information for PCI bus related events. 0h: INTR_DISABLE_ON (default) 1h: INTR_DISABLE_OFF
9	R	0h	T_SATA<0>_CFG_1_BACK2BACK: 0h: BACK2BACK_DISABLED 1h: BACK2BACK_ENABLED
8	R/W	0	T_SATA<0>_CFG_1_SERR: 0h: SERR_DISABLED (default) 1h: SERR_ENABLED
7	R	0h	T_SATA<0>_CFG_1_STEP: 0h: STEP_DISABLED 1h: STEP_ENABLED
6	R	0h	T_SATA<0>_CFG_1_PERR: 0h: PERR_DISABLED 1h: PERR_ENABLED
5	R	0h	T_SATA<0>_CFG_1_PALETTE_SNOOP: The PALETTE_SNOOP bit indicates that VGA compatible devices should snoop their palette registers. When this bit is set, special palette snooping behavior is enabled (i.e., device must not respond). When the bit is reset, the device should treat palette accesses like all other accesses. VGA compatible devices should implement this bit. PALETTE_SNOOP is writable. 0h: PALETTE_SNOOP_DISABLED 1h: PALETTE_SNOOP_ENABLED
4	R	0h	T_SATA<0>_CFG_1_WRITE_AND_INVAL: The WRITE_AND_INVAL bit indicates that the device can use the Memory Write and Invalidate command when the transfer is aligned and 16 bytes and the contents of the Cache Line Size Register is 4 DWORDS. When this bit is 1, masters may generate the command. When it is 0, Memory Write must be used instead. State after RST# is 0. This bit must be implemented by master devices that can generate the Memory Write and Invalidate command. 0h: WRITE_AND_INVAL_DISABLED 1h: WRITE_AND_INVAL_ENABLED
3	R	0h	T_SATA<0>_CFG_1_SPECIAL_CYCLE: 0h: SPECIAL_CYCLE_DISABLED 1h: SPECIAL_CYCLE_ENABLED
2	R/W	0	T_SATA<0>_CFG_1_BUS_MASTER: The BUS_MASTER bit indicates that the device can act as a master on the PCI bus. A value of 0 disables the device from generating PCI accesses. A value of 1 allows the device to behave as a bus master. BUS_MASTER is writable. 0h: BUS_MASTER_DISABLED (default) 1h: BUS_MASTER_ENABLED
1	R/W	0	T_SATA<0>_CFG_1_MEMORY_SPACE: The MEMORY_SPACE bit indicates that the device will respond to memory space accesses. A value of 0 disables the device response. A value of 1 allows the device to respond to Memory space accesses. MEMORY_SPACE is writable. 0h: MEMORY_SPACE_DISABLED (default) 1h: MEMORY_SPACE_ENABLED
0	R/W	0	T_SATA<0>_CFG_1_IO_SPACE: The IO_SPACE bit indicates that the device will respond to I/O space accesses. A value of 0 disables the device response. A value of 1 allows the device to respond to I/O space accesses. IO_SPACE is writable. 0h: IO_SPACE_DISABLED (default) 1h: IO_SPACE_ENABLED

T_SATA<0>_CFG_2

PCI Revision ID and Class Code Register

This register provides a way to configure the SATA channel to operate in either compatibility or native PCI mode.

Offset: 0x08 | Read/Write: R | Reset: 0xXXXXxxA1

Bit	R/W	Reset	Description
31:16	R	101h	T_SATA<0>_CFG_2_CLASS_CODE: The CLASS_CODE bits identify the generic function of the device and (in some cases) a specific register-level programming interface. The register is broken into three byte-size fields. The upper byte (at offset 0BH) is a base class code which broadly classifies the type of function the device performs. The middle-byte (at offset 0AH)is a sub-class code which identifies more specifically the function of the device. The lower byte (at offset 09H) identifies a specific register-level programming interface (if any) so that device independent software can interact with the device. 101h: CLASS_CODE_0101
15	R	1h	T_SATA<0>_CFG_2_SATA_BUS_MASTER: This bit defines the Bus mastering capability of SATA controller. SATA implements a back door register which can be used to change the class code. This register is T_SATA<0>_CFG_38_BKDOOR_CLASS_CODE. This provides BIOS a way to change the class code. 1h: SATA_BUS_MASTER_YES
14:12	R	0	Reserved
11	R	None (SATA) 0h (SATA0)	T_SATA<0>_CFG_2_SEC_PROG_IND: Secondary Programmable Indicator. Set to indicate it is programmable and can operate in both compatibility or native PCI mode. 0h: SEC_PROG_IND_NO (SATA0 only)
10	R	1 (SATA0)	T_SATA0_CFG_2_SEC_OP_MODE: Secondary Operating Mode 0 = Compatibility Mode (Use Legacy Addresses) 1 = Native Mode (Use Addresses Define in PCI I/O BARs) 1h: SEC_OP_MODE_INIT (default) (SATA0 only) 0h: SEC_OP_MODE_COMP 1h: SEC_OP_MODE_NTV
9	R	None (SATA) 0h (SATA0)	T_SATA<0>_CFG_2_PRI_PROG_IND: Primary Programmable Indicator. Set to indicate it is programmable and can operate in both compatibility or native PCI mode. 0h: PRI_PROG_IND_NO
8	R	1 (SATA0)	T_SATA0_CFG_2_PRI_OP_MODE: Primary Operating Mode 0 = Compatibility Mode (Use Legacy Addresses) 1 = Native Mode (Use Addresses Define in PCI I/O BARs) 1h: PRI_OP_MODE_INIT (default): (SATA0 only) 0h: PRI_OP_MODE_COMP 1h: PRI_OP_MODE_NTV
7:0	R	A1h	T_SATA<0>_CFG_2_REVISION_ID: The REVISION_ID bits specify a device specific revision identifier. The value is chosen by the vendor. Zero is an acceptable value. This field should be viewed as a vendor defined extension to the DEVICE_ID. A1h: REVISION_ID_VAL (default) A1h: REVISION_ID_A1 A2h: REVISION_ID_A2

T_SATA<0>_CFG_3

PCI Configuration Register

Offset: 0x0c | Read/Write: R/W | Reset: 0x00XXXXXX

Bit	R/W	Reset	Description
31:24	R	0	Reserved
23	R	0h	T_SATA<0>_CFG_3_HEADER_TYPE_FUNC: 0h: HEADER_TYPE_FUNC_SINGLE 1h: HEADER_TYPE_FUNC_MULTI

Bit	R/W	Reset	Description
22:16	R	0h	T_SATA<0>_CFG_3_HEADER_TYPE_DEVICE: The HEADER_TYPE bits identify the layout of the bytes 10h: through 3FH in configuration space and also whether or not the device contains multiple functions. Bit 7 in this register is used to identify a multi-function device. If the bit is 0, then the device is single function. If the bit is 1, then the device has multiple functions. Bits 6 through 0 specify the layout of bytes 10h: through 3Fh. The LATENCY_TIMER and HEADER_TYPE are defined by parameters per block. 0h: HEADER_TYPE_DEVICE_NON_BRIDGE 1h: HEADER_TYPE_DEVICE_P2P_BRIDGE
15:11	R	0h	T_SATA<0>_CFG_3_LATENCY_TIMER: The LATENCY_TIMER bits contain, in units of PCI bus clocks, the value of the Latency Timer for this PCI bus master. This register must be implemented as writable by any master that can burst more than two data phases. This register may be implemented as read-only for devices that burst two or fewer data phases, but the hardwired value must be limited to 16 or less. A typical implementation would be to build the five high-order bits (leaving the bottom three as read-only), resulting in a timer granularity of eight clocks. At reset, the register should be set to 0 (if programmable). LATENCY_TIMER bits are writable. 0h: LATENCY_TIMER_0_CLOCKS 1h: LATENCY_TIMER_8_CLOCKS 1Eh: LATENCY_TIMER_240_CLOCKS 1Fh: LATENCY_TIMER_248_CLOCKS
10:8	R	0	Reserved
7:0	R	0h	T_SATA<0>_CFG_3_CACHE_LINE_SIZE: 0h: CACHE_LINE_SIZE_0 20h: CACHE_LINE_SIZE_32 40h: CACHE_LINE_SIZE_64

T_SATA<0>_CFG_4

PCI Configuration Register

Offset: 0x10 | Read/Write: R/W | Reset: 0x0000000X (SATA) / 0x00000001 (SATA0)

Bit	R/W	Reset	Description
31:3	R/W	0	T_SATA<0>_CFG_4_BASE_ADDRESS: The BASE_ADDRESS bits contain the base address of the device. The number of upper bits that a device actually implements depends on how much of the address space the device will respond to. A device that wants a 1 MB memory address space (using a 32-bit base address register) would build the top 12 bits of the address register, hardwiring the other bits to 0. Power-up software can determine how much address space the device requires by writing a value of all 1's to the register and then reading the value back. The device will return 0's in all address bits which are not required, effectively specifying the address space required. When T_SATA<0>_CFG_2_PRI_OP_MODE is cleared, T_SATA_CFG_4 and T_SATA_CFG_5 will always read 32'h00000000. And when T_SATA<0>_CFG_2_SEC_OP_MODE is cleared, T_SATA<0>_CFG_6 and T_SATA_CFG_7 will always read 32'h00000000. 0h: BASE_ADDRESS_00 (default) 0h: BASE_ADDRESS_NTV_PCA
2:1	R	0	Reserved

PCI Configuration Register

Offset: 0x38 | Read/Write: R | Reset: 0xXXXXXXXX

Bit	R/W	Reset	Description
31:0	R	0h	T_SATA<0>_CFG_14_RESERVED: The RESERVED bits are reserved for future use. 0h: RESERVED_0

T_SATA<0>_CFG_15

PCI Configuration Register

Offset: 0x3c | Read/Write: R/W | Reset: 0xXXXXXX00 (SATA) / 0xXXXX0100 (SATA0)

Bit	R/W	Reset	Description
31:24	R	1h	T_SATA<0>_CFG_15_MAX_LAT: The MAX_LAT bits contain the maximum time the device requires to gain access to the PCI bus. This read-only register is used to specify the device's desired settings for Latency Timer values. The value specifies a period of time in units of 1/4 microsecond. Values of 0 indicate that the device has no major requirements for the settings of Latency Timers. MAX_LAT is nonzero. The INTR_PIN, MIN_GNT, and MAX_LAT are configurable per block. 0h: MAX_LAT_NO_REQUIREMENTS 1h: MAX_LAT_250NS

Bit	R/W	Reset	Description
23:16	R	3h	T_SATA<0>_CFG_15_MIN_GNT: The MIN_GNT bits contain the length of the burst period a device needs assuming a clock rate of 33 MHz. This read-only register is used to specify the device's desired settings for Latency Timer values. The value specifies a period of time in units of 1/4 microsecond. Values of 0 indicate that the device has no major requirements for the settings of Latency Timers. MIN_GNT is nonzero. 0h: MIN_GNT_NO_REQUIREMENTS 3h: MIN_GNT_750NS
15:8	R	1 (SATA0)	T_SATA0_CFG_15_INTR_PIN: The INTR_PIN bits contain the interrupt pin the device (or device function) uses. A value of 1 corresponds to INTA#. A value of 2 corresponds to INTB#. A value of 3 corresponds to INTC#. A value of 4 corresponds to INTD#. Devices (or device functions) that don't use an interrupt pin must put a 0 in this register. 0h: INTR_PIN_NONE (SATA0 only) 1h: INTR_PIN_INTA (default) (SATA0 only) 2h: INTR_PIN_INTB 3h: INTR_PIN_INTC 4h: INTR_PIN_INTD
7:0	R/W	0	T_SATA<0>_CFG_15_INTR_LINE: The INTR_LINE bits contain the interrupt routing information. The register is read/write and must be implemented by any device (or device function) that uses an interrupt pin. POST software will write the routing information into this register as it initializes and configures the system. The value in this register tells which input of the system interrupt controller(s) the device's interrupt pin is connected to. Device drivers and operating systems can use this information to determine priority and vector information. INTR_LINE is initialized to 0xff (no connection) at reset. Some PCI BIOS' can't handle aliased INTR_LINEs. If T_SATA<0>_CFG_2_PRI_OP_MODE or T_SATA<0>_CFG_2_SEC_OP_MODE are set, this register will read whatever value written by software. If both the bits are cleared the register will always return 00h: 0h: INTR_LINE_IRQ0 (default) 1h: INTR_LINE_IRQ1 Fh: INTR_LINE_IRQ15 FFh: INTR_LINE_UNKNOWN

33.9.5.2 Device Specific Configuration Registers

The CFG_16 through CFG_63 registers are Device Specific PCI configuration registers.

Offset: 0x118 | Read/Write: R/W | Reset: 0x00543210

Bit	R/W	Reset	Description
31:0	R/W	00543210h	T_SATA<0>_CROSS_BAR_PHY_SEL: This register contains the phy_select - indicates how a Lane (brick) is connected to the port. NOTE: this field is reset by Cold Reset 543210h: PHY_SEL_DEFAULT (default)

T_SATA<0>_PMUCTL

SATA PHY Control Register

This register contains various bits to control the PHY.

FORCE_CORE_CLAMP -- is used to enable core clock clamp. Software can only set this bit when the controller is idle. Any downstream cycle, including a read to this register, will wake up core clock automatically, and core_act_sts will change to 0x0. Software needs no future action to un-clamp the clock. But software needs to write 1 to this bit to re-clamp the clock when the controller is idle.

Note: *Wake from core clock clamp can be done by a downstream cycle which will trigger the core_wake signal to PMU; or by hotplug event which will trigger the dev_wake signal.*

DEV_STS_HOLD -- # of txclk cycles to hold the dev_act_tog and dev_act_sts. CORE_STS -- current core_act_sts. DEV_STS -- current dev_act_sts.

26:0	R	0h	T_SATA0_CTL_SHADOW_RSVD: 0h: RSVD_VAL

T_SATA0_CFG_FPCI_0

This register applies to SATA0 register space only.

Offset: 0x430 | Read/Write: R/W | Reset: 0xXXXXXXXX

Bit	R/W	Reset	Description
31	R/W	0	T_SATA0_CFG_FPCI_0_AHCI_MODE_DEP_ON_EN: When class code is 0106, ahci_mode will be one When class code is 0101, ahci_mode will be zero in other cases ahci_mode will depend on ahci_en if this bit is set, if bit is zero ahci_mode will be one NOTE: this field is reset by Cold Reset 1h: AHCI_MODE_DEP_ON_EN_YES 0h: AHCI_MODE_DEP_ON_EN_NO (default)
30	R/W	1	T_SATA0_CFG_FPCI_0_SEND_MSG_ON_NEW_INTR: This is used in the case of multiple MSI. This is to disbale/ enable sending interrupts when a new bit is written in pxis and if a some bits are cleared but not all and there is a posedge on a bit in pxie (see the AHCI specification, section 10.7.2) 1h: SEND_MSG_ON_NEW_INTR_INIT (default)
29	R/W	1	T_SATA0_CFG_FPCI_0_SEND_NEW_MSG_IS_NOT_ZERO: This is used in the case of a single MSI to send new message (intr), if software clears some bits of IS but not all (see the AHCI specification, section 10.7.2) 1h: SEND_NEW_MSG_IS_NOT_ZERO_INIT (default)
28:0	R	0h	T_SATA0_CFG_FPCI_0_RSVD: 0h: RSVD_VAL

T_SATA<0>_IDE1

When 40-bit addressing mode is enabled, bits [39:32] of the prd_base are loaded.

Offset: 0x490 | Read/Write: R/W | Reset: 0x00000000

Bit	R/W	Reset	Description
31:0	R/W	0	T_SATA<0>_IDE1_OLD_IDE_TIMING: 0h: OLD_IDE_TIMING_DEFAULT (default)

T_SATA0_CFG_ESATA_CTRL

This register implements settings for controlling behavior of the AHCI SM during error conditions.

This register applies to SATA0 register space only.

Offset: 0x494 | Read/Write: R/W | Reset: 0xXXXX0000

Bit	R/W	Reset	Description
31:16	R	0h	T_SATA0_CFG_ESATA_CTRL_RSVD: 0h: RSVD_VAL
15:8	R/W	0	T_SATA0_CFG_ESATA_CTRL_TX_PEAK_LIMIT: NOTE: this field is reset by Cold Reset 0h: TX_PEAK_LIMIT_INIT (default)
7:0	R/W	0	T_SATA0_CFG_ESATA_CTRL_TX_AMP_LIMIT: NOTE: this field is reset by Cold Reset 0h: TX_AMP_LIMIT_INIT (default)

T_SATA<0>_FEATURE

Feature Register

The feature options are shown in the following table.

Bit	Feature
31	NBP enable
30:13	Reserved
12:11	RAID function by SW programming
10	Reserved
9	Only 4 SATA ports supported
8	Software feature
7	Only 2 SATA ports supported
6	AHCI disabled
5	eSATA disabled
4	Aggressive power management disabled
3	Staggered spin-up disabled
2	iSCSI disabled
1	SATA Gen2 enabled
0	Advanced storage features disabled

Offset: 0x498 | Read/Write: R/W | Reset: 0xXX00XXXX

Bit	R/W	Reset	Description

T_SATA<0>_CTL1

Miscellaneous CTL1

Offset: 0x4a0 | Read/Write: R/W | Reset: 0xXXXXXX01

Bit	R/W	Reset	Description
31	R	0	Reserved
30:10	R	0h	T_SATA<0>_CTL1_RSVD_30_10: 0h: RSVD_30_10_VAL
9	R/W	1	T_SATA<0>_CTL1_BLK_NONPIO_IDP: BLK_NONPIO_IDP is used to suppress the nonpio read in the case of idp read. At default 1 value the second read will be blocked. At 0 both reads will occur. 1h: BLK_NONPIO_IDP_DEFAULT (default)
8:1	R	0	Reserved
0	R/W	1	T_SATA<0>_CTL1_SATA_ADNVCD_SPD_NEGO: ADNVCD_SPD_NEGO turns on an advanced way of detecting SATA speeds. SATA will mix detecting the two supported speeds. Otherwise it detects gen2 first and then gen1. NOTE: this field is reset by Cold Reset 1h: SATA_ADNVCD_SPD_NEGO_YES (default) 0h: SATA_ADNVCD_SPD_NEGO_NO

T_SATA<0>_BKDOOR_CC

This register is used to backdoor update the programming interface field and class code of the register at address 0x8 (T_SATA<0>_CFG_2[15:8]). Note that the default value of the programming interface field is 0x85 for SATA<0> and 0x8A for SATA1.

To update the programming interface field, the BIOS needs to do the following:

1. Read T_SATA<0>_CFG_SATA_BACKDOOR_PROG_IF_EN - Address 54C

2. Write 1 to T_SATA<0>_CFG_SATA_BACKDOOR_PROG_IF_EN
3. Write the desired programming interface value to T_SATA<0>_BKDOOR_CC[15:8]
4. Restore T_SATA<0>_CFG_SATA_BACKDOOR_PROG_IF_EN to the value read in step#1

Offset: 0x4a4 | Read/Write: R/W | Reset: 0x01018AXX (SATA) / 0x010185XX (SATA0)

Bit	R/W	Reset	Description
31:16	R/W	0101h	T_SATA<0>_BKDOOR_CC_CLASS_CODE: NOTE: this field is reset by Cold Reset 101h: CLASS_CODE_INIT (default)
15:8	R/W	8A (SATA) 85h (SATA0)	T_SATA<0>_BKDOOR_CC_PROG_IF: NOTE: this field is reset by Cold Reset 85h: PROG_IF_INIT (default)
7:0	R	0h	T_SATA<0>_BKDOOR_CC_RSVD_0: 0h: RSVD_0_VAL

T_SATA<0>_CFG_CTRL_1

Offset: 0x4a8 | Read/Write: R/W | Reset: 0x00000000

Bit	R/W	Reset	Description
31:2	R	0	Reserved
1	R/W	0	T_SATA<0>_CFG_CTRL_1_SATA_CAP: This bit controls whether or not SATA capability is enabled or not. By default it is enabled. NOTE: this field is reset by Cold Reset 1h: SATA_CAP_DISABLE 0h: SATA_CAP_ENABLE (default)
0	R/W	0	T_SATA<0>_CFG_CTRL_1_48BIT_ADDRESS_DISABLE: 48BIT_ADDRESS_DISABLE is used to disable 48-bit addressing mode. The SATA implementation of 48-bit addressing is such that this bit is no longer needed. It can be removed safely and is currently ignored in SATA. NOTE: this field is reset by Cold Reset 0h: 48BIT_ADDRESS_DISABLE_NO (default) 1h: 48BIT_ADDRESS_DISABLE_YES

T_SATA0_CFG_POWER_GATE

This register applies to SATA0 register space only.

Offset: 0x4ac | Read/Write: R/W | Reset: 0xXX000000

Bit	R/W	Reset	Description
31:24	R	0h	T_SATA0_CFG_POWER_GATE_RSVD: 0h: RSVD_VAL
23	R/W	0	T_SATA0_CFG_POWER_GATE_SSTS_RESTORED: 0h: SSTS_RESTORED_DEFAULT (default) 1h: SSTS_RESTORED_YES
22	R	0	T_SATA0_CFG_POWER_GATE_PHY_NOT_IN_SLUMBER: 0h: PHY_NOT_IN_SLUMBER_INIT (default)

5	R/W	0	T_SATA0_CFG_CTL_GLUE_HOLD_REQ_DEVCLK_CLAMP_2: NOTE: this field is reset by Cold Reset 0h: HOLD_REQ_DEVCLK_CLAMP_2_INIT (default)
4	R/W	0	T_SATA0_CFG_CTL_GLUE_HOLD_REQ_DEVCLK_CLAMP_1: NOTE: this field is reset by Cold Reset 0h: HOLD_REQ_DEVCLK_CLAMP_1_INIT (default)
3	R/W	1	T_SATA0_CFG_CTL_GLUE_LOCKDET_OVR_LOGIC_FIX: NOTE: this field is reset by Cold Reset 1h: LOCKDET_OVR_LOGIC_FIX_INIT (default)
2	R/W	0	T_SATA0_CFG_CTL_GLUE_OVERRIDE_LOCKDET_FOR_NVA: NOTE: this field is reset by Cold Reset 0h: OVERRIDE_LOCKDET_FOR_NVA_INIT (default)
1	R/W	1	T_SATA0_CFG_CTL_GLUE_USE_OVERRIDE_LOCKDET: NOTE: this field is reset by Cold Reset 1h: USE_OVERRIDE_LOCKDET_YES (default) 0h: USE_OVERRIDE_LOCKDET_NO
0	R/W	1	T_SATA0_CFG_CTL_GLUE_FIX_FPCI_WRDAT: When set to one adds a clock delay which is necessary for correct operation This bit will be removed once the platform emulation could do writes to BAR5 space NOTE: this field is reset by Cold Reset 1h: FIX_FPCI_WRDAT_YES (default) 0h: FIX_FPCI_WRDAT_NO

T_SATA0_CFG_CTL_FA

This register applies to SATA0 register space only.

Offset: 0x4bc | Read/Write: R/W | Reset: 0x00000083

Bit	R/W	Reset	Description
31:8	R	0	Reserved
7:3	R/W	10h	T_SATA0_CFG_CTL_FA_CFG_EATER: 10h: CFG_EATER_DEFAULT (default)
2	R/W	0	T_SATA0_CFG_CTL_FA_USE_CFG_EATER: 1h: USE_CFG_EATER_YES 0h: USE_CFG_EATER_NO (default)

Bit	R/W	Reset	Description
1	R/W	1	T_SATA0_CFG_CTL_FA_EAT_CLK: 1h: EAT_CLK_YES (default) 0h: EAT_CLK_NO
0	R/W	1	T_SATA0_CFG_CTL_FA_FPCI_CLK_IS_128MHZ: 1h: FPCI_CLK_IS_128MHZ_YES (default) 0h: FPCI_CLK_IS_128MHZ_NO

T_SATA<0>_PERF0

Offset: 0x4f0 | Read/Write: R/W | Reset: 0x00000800

Bit	R/W	Reset	Description
31:29	R	0	Reserved
28	R/W	0	T_SATA<0>_PERF0_DONT_DELAY_ROK: Setting DONT_DELAY_ROK turns on an optimization feature that should help performance on DMA reads. Transport layer then completes the current transfer even when busmaster has not yet drained all of the Receive FIFO. Setting this bit to _TRUE should result in better performance and therefore it is the preferred mode of operation. This is not the default Reset value and it is expected that the BIOS or Driver will enable this feature. NOTE: this field is reset by Cold Reset 0h DONT_DELAY_ROK_FALSE (default) 1h: DONT_DELAY_ROK_TRUE
27	R	0	Reserved
26:25	R/W	0	T_SATA<0>_PERF0_SATA_PLL_POWERDOWN: NOTE: this field is reset by Cold Reset 1h: SATA_PLL_POWERDOWN_YES 0h SATA_PLL_POWERDOWN_NO (default)
24:12	R	0	Reserved
11:7	R/W	10h	T_SATA<0>_PERF0_MIN_FPCI_CLK_FREQ: This field set the minimum frequency at which the fpci_clk should run in increments of 1/16th. It provides SW to override value set by frequency adjuster unit. Note that the actual frequency level is maximum of all the controllers. NOTE: this field is reset by Cold Reset 10h MIN_FPCI_CLK_FREQ_16 (default)
6:0	R	0	Reserved

T_SATA<0>_PERF1

This register is used to configure some of the SATA implementation options.

Offset: 0x4f4 | Read/Write: R/W | Reset: 0x00005A6E

Bit	R/W	Reset	Description
31:24	R/W	0	T_SATA<0>_PERF1_MAX_WATER_MARK: The MAX_WATER_MARK field tracks the maximum occupancy of the two i2f_fifos. The purpose of this field is to give us guidance on the setting of HIGH_WATER_MARK field. Ideally, the HIGH_WATER_MARK field should be set so that the MAX_WATER_MARK field almost hit full. Note that MAX_WATER_MARK field is only 8 bits wide, so it can only track the lower 8 bits of the fifo level. The MSB value can be inferred from the MSB value of the 9 bit HIGH_WATER_MARK field. T_SATA<0>_CFG_39_RXDATA_IB_DELAY[0] enables resetting SSTATUS_DET and SSTATUS_SPD fields to 0 when channels enter into partial or slumber low power modes. By default this bit is 0 and these fields are not reset. NOTE: this field is reset by Cold Reset 0h MAX_WATER_MARK_0 (default)
23:16	R	0	Reserved
15:8	R/W	5Ah	T_SATA<0>_PERF1_HIGH_WATER_MARK_PIO: Bit 13:8 of the register is used for PIO reads high water mark. For PIO reads, fifo depth is 48. But each entry is 32bit, that is it contains only one dword. So, if mark is set at Y, there is headroom for (48-Y) dwords for drive to react to us sending HOLD. 5Ah HIGH_WATER_MARK_PIO_INIT (default)

Bit	R/W	Reset	Description
7:0	R/W	6Eh	T_SATA<0>_PERF1_HIGH_WATER_MARK: This field configures the read fifo limit at which point the host starts sending HOLD primitives to back-off the data transfer from device. This field is only relevant during READs and should typically be set to as high a value without running the risk of overflowing the Fifo. Bit5:0 of the register is used for DMA read high water mark. For DMA reads, fifo depth is 48. And, each entry is 64bit, that is it contains two dwords. So, if the watermark is set at X then there is headroom for (48-X)*2 dwords for drive to react to controller sending HOLD. 6Eh HIGH_WATER_MARK_INIT (default)

T_SATA0_SPARE_0

Spare register on cold reset with zero as the default value.

This register applies to SATA0 register space only.

Offset: 0x520 | Read/Write: R/W | Reset: 0x00000000

Bit	R/W	Reset	Description
31:0	R/W	0	T_SATA0_SPARE_0_RSVD: 0h RSVD_DEFAULT (default)

T_SATA0_SPARE_1

T_SATA<0>_LDT

LDT Unit ID Register

The CFG_19 register contains the LDT Unit ID(s) for the Device. The Unit IDs are used by the device as a transaction ID on the LDT interface to uniquely identify where the request originated. Some devices will support 2 Unit IDs, 1 for isochronous requests and the other for non-isochronous requests.

13	R	Unknown	T_SATA<0>_CFG_SATA_CTRL_SATA_GEN2_CAPABLE: SATA_GEN2_CAPABLE is read-only register that reflects the value of bond_sata2. If high, GEN2 speed is enabled, if low, only GEN1 speed is available. This register is also used to send near end loopback and reset the channels. The MIN_ON_TIME bits set the additional time the activity led remains lit after a transaction. This keeps the LED from being a dim flicker during short burst. 1h CTRL_SATA_GEN2_CAPABLE_YES 0h CTRL_SATA_GEN2_CAPABLE_NO

Bit	R/W	Reset	Description
12	R/W	0	T_SATA<0>_CFG_SATA_BACKDOOR_PROG_IF_EN: NOTE: this field is reset by Cold Reset 1h BACKDOOR_PROG_IF_EN_YES 0h BACKDOOR_PROG_IF_EN_NO (default)
11:7	R/W	0	T_SATA<0>_CFG_SATA_PORT2UNITID_MAPPING: NOTE: this field is reset by Cold Reset 0h PORT2UNITID_MAPPING_DEFAULT (default)
6	R/W	0	T_SATA<0>_CFG_SATA_MSI_CAP_DISABLE: Normally, the T_SATA<0>_CFG_17_NEXT_PTR field points to T_SATA<0>_MSI_CTRL (0xB0). However, if SATA_MSI_CAP_DISABLE is set to _YES, then the T_SATA<0>_CFG_17_NEXT_PTR field would point to _NULL. If future capabilities are added beyond the MSI pointer, then care should be taken to ensure that CFG_17_NEXT_PTR bypasses the T_SATA<0>_MSI_CTRL address and points to the next capabilities pointer instead of _NULL. NOTE: this field is reset by Cold Reset 0h MSI_CAP_DISABLE_NO (default) 1h MSI_CAP_DISABLE_YES
5	R/W	1	T_SATA<0>_CFG_SATA_MSIX_CAP_DISABLE: 0h MSIX_CAP_DISABLE_NO 1h MSIX_CAP_DISABLE_YES (default)
4	R/W	0	T_SATA<0>_CFG_SATA_USE_40B_ADDR: If this bit is set then SATA uses NVIDIA style 40b addressing while DMAing data. It gets upper 8 bits from the 23:16 bits of the prd count associated with the prd address. NOTE: this field is reset by Cold Reset 0h USE_40B_ADDR_NO (default) 1h USE_40B_ADDR_YES
3	R/W	0	T_SATA<0>_CFG_SATA_ERROR_HANDLING: NOTE: this field is reset by Cold Reset 0h ERROR_HANDLING_NO (default) 1h ERROR_HANDLING_YES
2	R/W	0	T_SATA<0>_CFG_SATA_CTRL_RAID_MODE_CTRL: CTRL_RAID_MODE was originally intended to allow customers to downgrade their RAID capability in the SBIOS. Setting this bit to 0 would allow only RAID 0 and RAID 1 support in the driver while setting to 1 would allow all RAID support. Setting this bit to 1 modifies the DeviceID of the SATA controller which would be a key to the driver. NOTE: this field is reset by Cold Reset 0h CTRL_RAID_MODE_CTRL_OEM (default) 1h CTRL_RAID_MODE_CTRL_CHANNEL
1	R	Unknown	T_SATA<0>_CFG_SATA_CTRL_STORAGE_FEATURE: STORAGE_FEATURE goes to both SATA and IDE config spaces. This is a general purpose bit that SW can use to distinguish between Advanced and Basic storage controller modes. This bit will be interpreted to either allow or not allow RAID 0+1 or 5 mode. ADVANCED mode will allow all RAID modes and BASIC will allow only RAID 0 and RAID 1 modes. It is strongly encouraged to keep the meaning of this STORAGE_FEATURE bit the same for future chips and to create new bits if necessary. This will allow SW compatibility. 1h CTRL_STORAGE_FEATURE_BASIC 0h CTRL_STORAGE_FEATURE_ADVANCED
0	R	0h	T_SATA<0>_CFG_SATA_RSVD_0: 0h RSVD_0_VAL

31:0	R/W	7FFFFFFFh	T_SATA<0>_AO_SPARE_1_RSVD: 7FFFFFFFh RSVD_DEFAULT (default)

T_SATA<0>_INDEX

Index Mask Register

This register implements mask to select writes to channel specific registers. A write to any CHX field in this manual will affect corresponding register for channel n if the nth bit is set in this mask register. If mask register has no bits set then the write will not change any register.

A read from a CHX field will return data corresponding to the channel which has its mask set. If more than one bits are set in mask, then the returned data will be logical OR of register values corresponding to the channels which have mask bits set. If no mask bit is set then the returned value will be 0x00.

The following comment is no longer valid, separate registers are implemented for GEN[1,2,3] Further PEAK and AMP fields can be set differently for gen1 and gen2. A write to these fields will affect the setting for Genx if the bit corresponding to Genx is set in this register.

T_SATA<0>_CHXCFG3

Serial ATA Control Register

This register is used to send the SATA BIST activate command to the SATA device. The BIST code (byte) is loaded then a '1' is written to bit zero.

Offset: 0x700 | Read/Write: R/W | Reset: 0xXXXX0000

Bit	R/W	Reset	Description
31:16	R	None	T_SATA<0>_CHXCFG3_CHX_PRBS_ERROR_CNT: 0h CHX_PRBS_ERROR_CNT_0
15:8	R/W	0	T_SATA<0>_CHXCFG3_CHX_BIST_CODE: NOTE: this field is reset by Cold Reset 0h CHX_BIST_CODE_DEFAULT (default)
7:2	R	0	Reserved
1	R	0	T_SATA<0>_CHXCFG3_CHX_BIST_STAT: NOTE: this field is reset by Cold Reset 1h CHX_BIST_STAT_BUSY 0h CHX_BIST_STAT_NOT_BUSY (default)
0	RW1C	0	T_SATA<0>_CHXCFG3_CHX_BIST_SEND: NOTE: this field is reset by Cold Reset 1h CHX_BIST_SEND_NOW 0h CHX_BIST_SEND_INIT (default)

T_SATA<0>_CHXCFG4_CHX

Offset: 0x704 | Read/Write: R/W | Reset: 0x0000000a

Bit	R/W	Reset	Description
31:13	R	0	Reserved
12	R/W	0	T_SATA<0>_CHXCFG4_CHX_SW_COMWAKE_PI: NOTE: this field is reset by Cold Reset 0h SW_COMWAKE_PI_INIT (default)
11:8	R/W	0	T_SATA<0>_CHXCFG4_CHX_PHY_ALIGN_NUM_CNT: The PHY_ALIGN_NUM_CNT field configures the number of ALIGN primitive pairs that are inserted by the phy interface block into the output stream. The field value represents a number which is one less than the number of ALIGN pairs to send. So, for e.g., a value of 0 (default) would send 1 ALIGN pair (i.e 2 ALIGNs) every PHY_ALIGN_DWORD_CNT DWORDs. In other words, every PHY_ALIGN_DWORD_CNT DWORDs, the phy-interface sends out (PHY_ALIGN_NUM_CNT+1)*2 ALIGNs NOTE: this field is reset by Cold Reset 0h PHY_ALIGN_NUM_CNT_INIT (default)
7:0	R/W	0Ah	T_SATA<0>_CHXCFG4_CHX_PHY_ALIGN_DWORD_CNT: The PHY_ALIGN_DWORD_CNT field configures the number of DWORDs sent before the required (PHY_ALIGN_NUM_CNT + 1) number of ALIGN primitive pairs are inserted by the phy-interface block into the output stream. For example, the default PHY_ALIGN_DWORD_CNT setting of 254 and default PHY_ALIGN_NUM_CNT of 0 implies an output stream of 254 DWORDs, 2 ALIGNs, 254 DWORDs, 2 ALIGNs, and so on. To disable insertion of ALIGN primitives, set this field to zero. NOTE: this field is reset by Cold Reset Ah PHY_ALIGN_DWORD_CNT_INIT (default)

T_SATA<0>_PRBS_CHX

This register contains control bits for the IOBIST PRBS generator and checker. Setting PI_LOOPBACK will select the PRBS as the TX data source. Setting PRBS_EN will cause the PRBS to start running. PRBS_SEED contains the 10-bit initial value for the PRBS.

Offset: 0x714 | Read/Write: R/W | Reset: 0xXXXXX001

33.9.5.3 DMA Control Registers

I/O Mapped Registers behind a BAR.

T_SATA_PRI_CMD

Bus Master SATA Primary Channel Command Register

The Primary command register allows host to control the SATA primary channel bus mastering.

Offset: 0x000 | Read/Write: R/W | Reset: 0x0X

Bit	R/W	Reset	Description
7:4	R	0	Reserved
3	R/W	0h	T_SATA_PRI_CMD_BM_RW: Read or Write Control. This bit sets the direction of the bus master transfer. When set to zero, PCI bus master reads are performed. When set to one, PCI bus master writes are performed. This bit must NOT be changed when the bus master function is active. 0h BM_RW_READ (default) 1h BM_RW_WRITE
2:1	R	0	Reserved
0	RW1C	None	T_SATA_PRI_CMD_BM_SS: Start/Stop Bus Master. Writing a '1' to this bit enables bus master operation of the controller. Bus master operation begins when this bit is detected changing from a zero to a one. The controller will transfer data between the SATA device and memory only when this bit is set. Master operation can be halted by writing a '0' to this bit. All state information is lost when a '0' is written; Master mode operation cannot be stopped and then resumed. If this bit is reset while bus master operation is still active (i.e., the Bus Master SATA Active bit of the Bus Master SATA Status register for that SATA channel is set) and the drive has not yet finished its data transfer (The Interrupt bit in the Bus Master SATA Status register for that SATA channel is not set), the bus master command is said to be aborted and data transferred from the drive may be discarded before being written to system memory. This bit is intended to be reset after the data transfer is completed, as indicated by either the Bus Master SATA Active bit or the Interrupt bit of the Bus Master SATA Status register for that SATA channel being set, or both. 0h BM_SS_STOP 1h BM_SS_START

T_SATA_PRI_STS

Bus Master SATA Primary Channel Status Register

The Primary channel status registers allows host to check the capabilities and the status of Primary channel bus mastering.

Offset: 0x002 | Read/Write: R/W | Reset: 0xXX

Bit	R/W	Reset	Description
7	R	0h	T_SATA_PRI_STS_SMPLX: Simplex only. This read-only bit is a 0. This indicates that both bus master channels (primary and secondary) can be operated at the same time. 0h SMPLX_NO 1h SMPLX_YES
6	R/W	0h	T_SATA_PRI_STS_DMA1: Drive 1 DMA Capable. This read/write bit is set by device dependent code (BIOS or device driver) to indicate that drive 1 for this channel is capable of DMA transfers, and that the controller has been initialized for optimum performance. 0h DMA1_NO (default) 1h DMA1_YES
5	R/W	0h	T_SATA_PRI_STS_DMA0: Drive 0 DMA Capable. This read/write bit is set by device dependent code (BIOS or device driver) to indicate that drive 0 for this channel is capable of DMA transfers, and that the controller has been initialized for optimum performance. 0h DMA0_NO (default) 1h DMA0_YES
4:3	R	0	Reserved

Bit	R/W	Reset	Description
2	RW1C	0h	T_SATA_PRI_STS_INTR: Interrupt. This bit is set by the rising edge of the SATA interrupt line. This bit is cleared when a '1' is written to it by software. Software can use this bit to determine if an SATA device has asserted its interrupt line. When this bit is read as a one, all data transferred from the drive is visible in system memory. 0h INTR_NO (default) 1h INTR_YES 1h INTR_CLEAR
1	R	0h	T_SATA_PRI_STS_ERR: Error status '0' = No error '1' = Error occurred 0h ERR_NO 1h ERR_YES
0	R	0h	T_SATA_PRI_STS_BMSATAA: Bus Master SATA Active. This bit is set when the Start bit is written to the Command register. This bit is cleared when the last transfer for a region is performed, where EOT for that region is set in the region descriptor. It is also cleared when the Start bit is cleared in the Command register. When this bit is read as a zero, all data transferred from the drive during the previous bus master command is visible in system memory, unless the bus master command was aborted. 0h BMSATAA_NACTV (default) 1h BMSATAA_ACTV

T_SATA_PRI_PRD_ADD

Primary Channel Descriptor Table Pointer Register

Offset: 0x004 | Read/Write: R/W | Reset: 0x00000000

Bit	R/W	Reset	Description
31:2	R/W	0h	T_SATA_PRI_PRD_ADD_DW: Base address of Descriptor table. Corresponds to A[31:2] 0h DW_0 (default)
1:0	R	0	Reserved

T_SATA_SEC_CMD

Bus Master SATA Secondary Channel Command Register

The Secondary command register allows host to control the SATA Secondary channel bus mastering.

Offset: 0x008 | Read/Write: R/W | Reset: 0x0X

Bit	R/W	Reset	Description
7:4	R	0	Reserved
3	R/W	0h	T_SATA_SEC_CMD_BM_RW: Read or Write Control. This bit sets the direction of the bus master transfer. When set to zero, PCI bus master reads are performed. When set to one, PCI bus master writes are performed. This bit must NOT be changed when the bus master function is active. 0h BM_RW_READ (default) 1h BM_RW_WRITE
2:1	R	0	Reserved
0	RW1C	None	T_SATA_SEC_CMD_BM_SS: Start/Stop Bus Master. Writing a '1' to this bit enables bus master operation of the controller. Bus master operation begins when this bit is detected changing from a zero to a one. The controller will transfer data between the SATA device and memory only when this bit is set. Master operation can be halted by writing a '0' to this bit. All state information is lost when a '0' is written; Master mode operation cannot be stopped and then resumed. If this bit is reset while bus master operation is still active (i.e., the Bus Master SATA Active bit of the Bus Master SATA Status register for that SATA channel is set) and the drive has not yet finished its data transfer (The Interrupt bit in the Bus Master SATA Status register for that SATA channel is not set), the bus master command is said to be aborted and data transferred from the drive may be discarded before being written to system memory. This bit is intended to be reset after the data transfer is completed, as indicated by either the Bus Master SATA Active bit or the Interrupt bit of the Bus Master SATA Status register for that SATA channel being set, or both. 0h BM_SS_STOP 1h BM_SS_START

T_SATA_SEC_STS

Bus Master SATA Secondary Channel Status Register

The Secondary channel status registers allows host to check the capabilities and the status of Secondary channel Bus mastering

Offset: 0x00a | Read/Write: R/W | Reset: 0xXX

Bit	R/W	Reset	Description
7	R	0h	T_SATA_SEC_STS_SMPLX: Simplex only. This read-only bit is a 0. This indicates that both bus master channels (primary and secondary) can be operated at the same time. 0h SMPLX_NO 1h SMPLX_YES
6	R/W	0h	T_SATA_SEC_STS_DMA1: Drive 1 DMA Capable. This read/write bit is set by device dependent code (BIOS or device driver) to indicate that drive 1 for this channel is capable of DMA transfers, and that the controller has been initialized for optimum performance. 0h DMA1_NO (default) 1h DMA1_YES
5	R/W	0h	T_SATA_SEC_STS_DMA0: Drive 0 DMA Capable. This read/write bit is set by device dependent code (BIOS or device driver) to indicate that drive 0 for this channel is capable of DMA transfers, and that the controller has been initialized for optimum performance. 0h DMA0_NO (default) 1h DMA0_YES
4:3	R	0	Reserved
2	RW1C	0h	T_SATA_SEC_STS_INTR: Interrupt. This bit is set by the rising edge of the SATA interrupt line. This bit is cleared when a '1' is written to it by software. Software can use this bit to determine if an SATA device has asserted its interrupt line. When this bit is read as a one, all data transferred from the drive is visible in system memory. 0h INTR_NO (default) 1h INTR_YES 1h INTR_CLEAR
1	R	0h	T_SATA_SEC_STS_ERR: Error status '0' = No error '1' = Error occurred 0h ERR_NO 1h ERR_YES
0	R	0h	T_SATA_SEC_STS_BMSATAA: Bus Master SATA Active. This bit is set when the Start bit is written to the Command register. This bit is cleared when the last transfer for a region is performed, where EOT for that region is set in the region descriptor. It is also cleared when the Start bit is cleared in the Command register. When this bit is read as a zero, all data transferred from the drive during the previous bus master command is visible in system memory, unless the bus master command was aborted. 0h BMSATAA_NACTV (default) 1h BMSATAA_ACTV

T_SATA_SEC_PRD_ADD

Secondary Channel Descriptor Table Pointer Register

Secondary channel PRD table address provides a pointer to base Physical Resource Descriptor Table in the memory. The table is doubleword aligned and must not cross a 64K byte boundary. Also addresses and count in the PRD table are assumed to be aligned are even numbers.

Offset: 0x00c | Read/Write: R/W | Reset: 0x00000000

Bit	R/W	Reset	Description
31:2	R/W	0h	T_SATA_SEC_PRD_ADD_DW: Base address of Descriptor table. Corresponds to A[31:2] 0h DW_0 (default)
1:0	R	0	Reserved

2	RW	0x0	SATA_RX_STAT_INT_DISABLE: SATA rx_stat interrupt disable 1 = Disables interrupt assertion when rx_stat interrupt status is set 0 = Enables interrupt assertion when rx_stat interrupt status is set 0 = ENABLE 1 = DISABLE
1	RO	X	SATA_L0_RX_STAT_IDLE: SATA pad L0 rx_stat_idle status 1: Rx path is idle 0: Rx path is active 0 = NO 1 = YES
0	RO	X	SATA_RX_STAT_INT_STATUS: SATA rx_stat interrupt status from the SATA pad 1 = rx_stat interrupt is pending 0 = rx_stat interrupt is not pending 0 = NONE 1 = PENDING

33.9.6.3 SATA_AUX_RX_STAT_SET_0

RX_STAT_SET Register

Offset: 0x1110 | Read/Write: R/W | Reset: 0x00000000 (0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx000)

Bit	Reset	Description
1	0x0	SATA_DEV_ATTEN_INT_SET: SATA dev_atten interrupt is set (this bit is auto-cleared). Set the interrupt status bit to '1' when register is written. The read back value is always '0'.
0	0x0	SATA_RX_STAT_INT_SET: SATA rx_stat interrupt is set (this bit is auto-cleared). Set the interrupt status bit to '1' when register is written. The read back value is always '0'.

33.9.6.4 SATA_AUX_RX_STAT_CLR_0

RX_STAT_CLR Register

Offset: 0x1114 | Read/Write: R/W | Reset: 0x00000000 (0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx000)

Bit	Reset	Description
1	0x0	SATA_DEV_ATTEN_INT_CLR: SATA dev_atten interrupt is cleared (this bit is auto-cleared). Clear the interrupt status bit to '1' when register is written. The read back value is always '0'.
0	0x0	SATA_RX_STAT_INT_CLR: SATA rx_stat interrupt is cleared (this bit is auto-cleared). Clear the interrupt status bit to '1' when register is written. The read back value is always '0'.

33.9.6.5 SATA_AUX_SPARE_CFG0_0

SPARE_CFG0 Register

Offset: 0x1118 | Read/Write: R/W | Reset: 0x000000XX (0bxxxxxxxxxxxxxxxxx0000000xxxxxxxx)

Bit	R/W	Reset	Description
14	RW	0x0	MDAT_TIMER_AFTER_PG_VALID: Indicates that the MDAT timer value in the above field is to be loaded in the SATA register space.
13:8	RW	0x0	MDAT_TIMER_AFTER_PG: MDAT timer value to be updated by the SW (PEP driver) before power-ungating the SATA controller.
5:0	RO	X	MDAT_TIMER_BEFORE_PG: MDAT timer value loaded from the SATA register space before SATA is power-gated.

33.9.6.6 SATA_AUX_SPARE_CFG1_0

SPARE_CFG1 Register

Offset: 0x111c | Read/Write: R/W | Reset: 0xffff0000 (0b11111111111111110000000000000000)

Bit	Reset	Description
31:0	-65536	SPARE: Spare register bits

33.9.6.7 SATA_AUX_PAD_PLL_CTRL_0_0

SATA PAD PLL Control Register

Offset: 0x1120 | Read/Write: R/W | Reset: 0x3X3X0000 (0bxx11xxx0xx11xxx100000x0000000000)

Bit	R/W	Reset	Description
29:28	RW	0x3	PLL1_REFCLK_NDIV
27	RO	X	PLL1_LOCKDET
24	RW	0x0	PLL1_MODE
21:20	RW	0x3	PLL0_REFCLK_NDIV: Select feedback divider for PLL.

Bit	R/W	Reset	Description
19	RO	X	PLL0_LOCKDET: Status signal indicating whether PLL is locked within the desired resolution. Forced high when the PLL is in test modes enabled by either PLL_BYPASS_EN or PLL_EMULATION_ON. 0 = Not locked 1 = Locked 0 = NOT_LOCKED 1 = LOCKED
16	RW	0x1	PLL0_MODE
15:12	RW	0x0	REFCLK_SEL: 00 = Internal CML reference clock 01 = Internal CMOS reference clock 1x = External reference clock 0 = INT_CML 1 = INT_CMOS 2 = EXT
11	RW	0x0	REFCLK_TERM100
9	RW	0x0	PLL_CKBUFPD_OVRD
8	RW	0x0	PLL_CKBUFPD_M
7	RW	0x0	PLL_CKBUFPD_BL
6	RW	0x0	PLL_CKBUFPD_BR
5	RW	0x0	PLL_CKBUFPD_TL
4	RW	0x0	PLL_CKBUFPD_TR
3	RW	0x0	SPARE_BIT_2: Reserved bit.
2	RW	0x0	PLL_EMULATION_RSTN: Digital reset for clock divider during emulation mode, hold low (reset) and release to High to set divider phase. No effect during normal operation. 0 = Reset hold 1 = Reset released/active 0 = ASSERT 1 = DEASSERT
1	RW	0x0	SPARE_BIT_1: Reserved bit.
0	RW	0x0	SPARE_BIT_0: Reserved bit. 0 = LOW 1 = HIGH

33.9.6.8 SATA_AUX_PAD_PLL_CTRL_1_0

Offset: 0x1124 | Read/Write: R/W | Reset: 0xXX441020 (0bxxxxxxxx010001000x01000000100000)

Bit	R/W	Reset	Description
31:24	RO	X	PLL_MISC_OUT: Reserved.
23:20	RW	0x4	PLL1_CP_CNTL: Charge-pump current control for PLL1.
19:16	RW	0x4	PLL0_CP_CNTL: Charge-pump current control for PLL0.
15	RW	0x0	PLL_BYPASS_EN: Bypass PLL serial output clocks with input reference clock.
13	RW	0x0	PLL_EMULATION_ON: Enable clock bypass for emulation mode.
12	RW	0x1	TCLKOUT_EN: Enable test clock output pads, TSTCLKP/N.
11:8	RW	0x0	TCLKOUT_SEL: Select internal clock source to bring out through the TSTCLKP/N pads.
7	RW	0x0	XDIGCLK4P5_EN: Enable XDIGCLK4P5 clock output to core.
6	RW	0x0	REFCLKBUF_EN: Enable REFCLKBUF clock output to core.
5	RW	0x1	TXCLKREF_EN: Enable TXCLKREF clock to core.
4	RW	0x0	TXCLKREF_SEL: Select the post divider for TXCLKREF clock.
3	RW	0x0	XDIGCLK_EN: Enable XDIGCLK output clock.
2:0	RW	0x0	XDIGCLK_SEL: Select the output frequency of XDIGCLK.

33.9.6.9 SATA_AUX_PAD_PLL_CTRL_2_0

Offset: 0x1128 | Read/Write: R/W | Reset: 0x0000XX80 (0b0000xxxx00000000x0xxxxxx1xx00000)

Bit	R/W	Reset	Description
31:28	RW	0x0	PLL_TEMP_CNTL
23:18	RW	0x0	PLL_BW_CNTL
17:16	RW	0x0	PLL_BGAP_CNTL
15	RO	X	RCAL_DONE: Status signal to indicate calibration status.
14	RW	0x0	RCAL_RESET: Reset the resistor calibration logic.
12:8	RO	X	RCAL_VAL: Setting of current active resistor calibration code
7	RW	0x1	RCAL_BYPASS: Bypass resistor calibration logic.
4:0	RW	0x0	RCAL_CODE: Sets resistor calibration code when logic is bypassed.

33.9.6.10 SATA_AUX_PAD_PLL_CTRL_3_0

Offset: 0x112c | Read/Write: R/W | Reset: 0x00000000 (0bxxxxxxxxxxxxxxxxxxxxx000000000000)

Bit	Reset	Description
11:0	0x0	PLL_MISC_CNTL

33.9.6.11 SATA_AUX_PAD_L0_AUX_CTRL_0_0

Offset: 0x1130 | Read/Write: R/W | Reset: 0x00000X00 (0bxxxxxxxxxxxxxxxxxxxxxxxxxxx000000)

Bit	R/W	Reset	Description
9	RO	X	AUX_RX_IDLE_STATUS
8	RO	X	AUX_TX_RDET_STATUS
5	RW	0x0	AUX_HOLD_EN
4	RW	0x0	AUX_RX_IDLE_MODE
3	RW	0x0	AUX_RX_IDLE_EN
2	RW	0x0	AUX_RX_TERM_EN
1	RW	0x0	AUX_TX_RDET_EN
0	RW	0x0	AUX_TX_TERM_EN

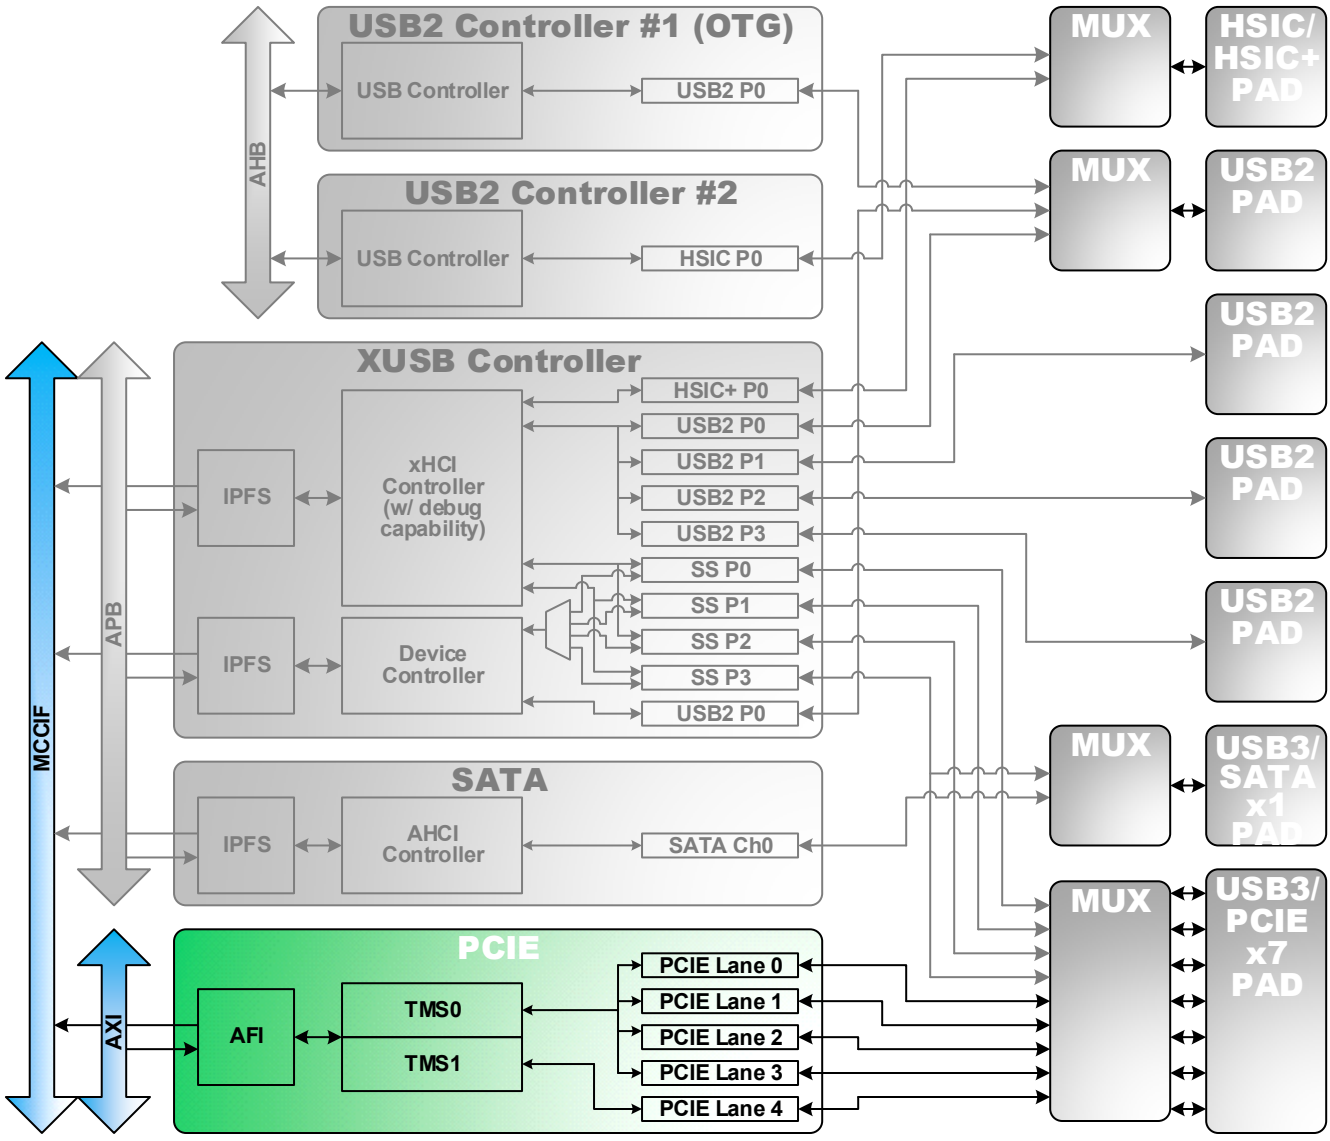
CHAPTER 34: PCI EXPRESS (PCIe) CONTROLLER

Tegra® X1 devices support up to 2 PCIe® root port controllers. The PCIe controllers support the following configurations:

- the first controller 4 lanes; the second 1 lane (x4 + x1)
- the first controller 2 lanes; the second 1 lane (x2 + x1)

Both controllers support upstream and downstream AXI interfaces that serve as the control path from the Tegra X1 device to the external PCIe device. Both PCIe controllers support Gen1 (2.5 GT/s/lane) and Gen2 (5.0 GT/s/lane) speeds.

Figure 157: PCIe Interface



34.1 Supported Configurations

The lane mappings for the configurations are internal to the PCIe root port controller. For supported configurations details, refer to Section 22.7: USB PADCTL in the USB Complex chapter.

34.2 L1 PM Substate Support

The Tegra X1 PCIe controller supports the L1 PM substate for power savings. Tegra X1 processor support all three substates: L1.0, L1.1, and L1.2 as defined in the ECN entitled *L1 PM Substates with CLKREQ* (see www.pcisig.com) L1.0 is equivalent to L1. L1.1 enables turning off EIDLE exit detection circuitry in the PHY, and L1.2 enables turning off both EIDLE exit detection circuitry and common mode voltage regulators.

Tegra X1 processors save more power with L1 PM substate support by turning off EIDLE exit detection circuitry in the PHY (in both L1.1 and L1.2 substates) and common mode voltage regulators in the L1.2 substate.

Latency Tolerance Reporting (LTR) has been added to enhance Power Management substate support.

34.3 Programming Guidelines

34.3.1 Root Port Initialization Sequence

This section describes the PCIe root port initialization. This can be used as reference for the initialization sequence for software and Tegra shell for bring-up.

The initialization sequence involves bringing PCIE partition out of power gating as partitions stay in power gated state after the system cold boots. PLL, clocks, and pads used by PCIE are initialized while AFI and PCIE are under reset, followed by setting up the AFI and PCIE controller. Lastly, the reset to the connected PCIE device is deasserted to allow the link to be initialized where SW can access the connected device for enumeration.

Note: *The format for register writes used in this section is register name followed by field name in square brackets followed by the value: <register name>[field name] value.*

The PCIe root port initialization sequence is summarized in the following steps:

1. Set PCIEXCLK reset
   - CLK_RST_CONTROLLER_RST_DEV_U_SET_0[SET_PCIEXCLK_RST] 1
2. Set PCIE reset
   - CLK_RST_CONTROLLER_RST_DEV_U_SET_0[SET_PCIE_RST] 1
3. Set AFI reset
   - CLK_RST_CONTROLLER_RST_DEV_U_SET_0[SET_AFI_RST] 1
4. Set PEX_USB_UPHY reset
   - CLK_RST_CONTROLLER_RST_DEV_Y_SET_0[SET_PEX_USB_UPHY_RST] 1
5. Set XUSB_PADCTL reset
   - CLK_RST_CONTROLLER_RST_DEV_W_SET_0[SET_XUSB_PADCTL_RST] 1
6. Enable PLLe (refer to Section 22.8.4: Cold Boot, with no Recovery Mode or Boot from USB in the USB Complex chapter)
7. Restore AFI and PCIE power by setting following registers bits
   - APBDEV_PMC_PWRGATE_TOGGLE_0[START] enable
   - APBDEV_PMC_PWRGATE_TOGGLE_0[PARTID] PCX

     Then confirm the power restore by reading the following fields:
   - APBDEV_PMC_PWRGATE_STATUS_0[PCX] equals ‘ON’
8. AFI and PCIE power clamping is removed by setting the following register fields:
   - APBDEV_PMC_REMOVE_CLAMPING_CMD_0 [PCX]

     and then confirm the power clamping removal by reading the flowing field

- APBDEV_PMC_REMOVE_CLAMPING_CMD_0[PCX] equals ‘0’

9. Enable AFI Clock
   - CLK_RST_CONTROLLER_CLK_ENB_U_SET_0[SET_CLK_ENB_AFI] 1
10. Enable PCIe Clock
   - CLK_RST_CONTROLLER_CLK_ENB_U_SET_0[SET_CLK_ENB_PCIE] 1
11. Clear XUSB_PADCTL reset
   - CLK_RST_CONTROLLER_RST_DEV_W_CLR_0[CLR_XUSB_PADCTL_RST] 1
12. Enable UPHY PLL (refer to Section 22.8.4: Cold Boot, with no Recovery Mode or Boot from USB)
    UPHY reset is cleared in the sequence
13. Disable the IDDQ for all lanes for PCIe tests.
   - XUSB_PADCTL_USB3_PAD_MUX_0[FORCE_PCIE_PAD_IDDQ_DISABLE_MASK0] 1
   - XUSB_PADCTL_USB3_PAD_MUX_0[FORCE_PCIE_PAD_IDDQ_DISABLE_MASK1] 1
   - XUSB_PADCTL_USB3_PAD_MUX_0[FORCE_PCIE_PAD_IDDQ_DISABLE_MASK2] 1
   - XUSB_PADCTL_USB3_PAD_MUX_0[FORCE_PCIE_PAD_IDDQ_DISABLE_MASK3] 1
   - XUSB_PADCTL_USB3_PAD_MUX_0[FORCE_PCIE_PAD_IDDQ_DISABLE_MASK4] 1
14. Clear AUX_MUX_LP0 related bits in register XUSB_PADCTL_ELPG_PROGRAM_1_0
   - XUSB_PADCTL_ELPG_PROGRAM_1_0[AUX_MUX_LP0_CLAMP_EN] 0
   - XUSB_PADCTL_ELPG_PROGRAM_1_0[AUX_MUX_LP0_CLAMP_EN_EARLY] 0
   - XUSB_PADCTL_ELPG_PROGRAM_1_0[AUX_MUX_LP0_VCORE_DOWN] 0
15. Wait 200 us
16. Set Lane IDDQ and SLEEP Override
   - XUSB_PADCTL_UPHY_MISC_PAD_P0_CTL_2_0[TX_PWR_OVRD] 1
   - XUSB_PADCTL_UPHY_MISC_PAD_P0_CTL_2_0[RX_PWR_OVRD] 1
   - XUSB_PADCTL_UPHY_MISC_PAD_P1_CTL_2_0[TX_PWR_OVRD] 1
   - XUSB_PADCTL_UPHY_MISC_PAD_P1_CTL_2_0[RX_PWR_OVRD] 1
   - XUSB_PADCTL_UPHY_MISC_PAD_P2_CTL_2_0[TX_PWR_OVRD] 1
   - XUSB_PADCTL_UPHY_MISC_PAD_P2_CTL_2_0[RX_PWR_OVRD] 1
   - XUSB_PADCTL_UPHY_MISC_PAD_P3_CTL_2_0[TX_PWR_OVRD] 1
   - XUSB_PADCTL_UPHY_MISC_PAD_P3_CTL_2_0[RX_PWR_OVRD] 1
   - XUSB_PADCTL_UPHY_MISC_PAD_P4_CTL_2_0[TX_PWR_OVRD] 1
   - XUSB_PADCTL_UPHY_MISC_PAD_P4_CTL_2_0[RX_PWR_OVRD] 1
   - XUSB_PADCTL_UPHY_MISC_PAD_P0_CTL_2_0[TX_IDDQ] 1
   - XUSB_PADCTL_UPHY_MISC_PAD_P0_CTL_2_0[RX_IDDQ] 1
   - XUSB_PADCTL_UPHY_MISC_PAD_P1_CTL_2_0[TX_IDDQ] 1
   - XUSB_PADCTL_UPHY_MISC_PAD_P1_CTL_2_0[RX_IDDQ] 1
   - XUSB_PADCTL_UPHY_MISC_PAD_P2_CTL_2_0[TX_IDDQ] 1
   - XUSB_PADCTL_UPHY_MISC_PAD_P2_CTL_2_0[RX_IDDQ] 1
   - XUSB_PADCTL_UPHY_MISC_PAD_P3_CTL_2_0[TX_IDDQ] 1
   - XUSB_PADCTL_UPHY_MISC_PAD_P3_CTL_2_0[RX_IDDQ] 1

- XUSB_PADCTL_UPHY_MISC_PAD_P4_CTL_2_0[TX_IDDQ] 1
- XUSB_PADCTL_UPHY_MISC_PAD_P4_CTL_2_0[RX_IDDQ] 1
- XUSB_PADCTL_UPHY_MISC_PAD_P0_CTL_2_0[TX_IDDQ_OVRD] 1
- XUSB_PADCTL_UPHY_MISC_PAD_P0_CTL_2_0[RX_IDDQ_OVRD] 1
- XUSB_PADCTL_UPHY_MISC_PAD_P1_CTL_2_0[TX_IDDQ_OVRD] 1
- XUSB_PADCTL_UPHY_MISC_PAD_P1_CTL_2_0[RX_IDDQ_OVRD] 1
- XUSB_PADCTL_UPHY_MISC_PAD_P2_CTL_2_0[TX_IDDQ_OVRD] 1
- XUSB_PADCTL_UPHY_MISC_PAD_P2_CTL_2_0[RX_IDDQ_OVRD] 1
- XUSB_PADCTL_UPHY_MISC_PAD_P3_CTL_2_0[TX_IDDQ_OVRD] 1
- XUSB_PADCTL_UPHY_MISC_PAD_P3_CTL_2_0[RX_IDDQ_OVRD] 1
- XUSB_PADCTL_UPHY_MISC_PAD_P4_CTL_2_0[TX_IDDQ_OVRD] 1
- XUSB_PADCTL_UPHY_MISC_PAD_P4_CTL_2_0[RX_IDDQ_OVRD] 1

17. Update Lane Mux Ownership (illustrative example for x4_x1)
    - XUSB_PADCTL_USB3_PAD_MUX_0 PCIE_PAD_LANE0 0x0
    - XUSB_PADCTL_USB3_PAD_MUX_0 PCIE_PAD_LANE1 0x3
    - XUSB_PADCTL_USB3_PAD_MUX_0 PCIE_PAD_LANE2 0x3
    - XUSB_PADCTL_USB3_PAD_MUX_0 PCIE_PAD_LANE3 0x3
    - XUSB_PADCTL_USB3_PAD_MUX_0 PCIE_PAD_LANE4 0x3
18. Clear Lane IDDQ and SLEEP Override
    - XUSB_PADCTL_UPHY_MISC_PAD_P0_CTL_2_0[TX_PWR_OVRD] 0
    - XUSB_PADCTL_UPHY_MISC_PAD_P0_CTL_2_0[RX_PWR_OVRD] 0
    - XUSB_PADCTL_UPHY_MISC_PAD_P1_CTL_2_0[TX_PWR_OVRD] 0
    - XUSB_PADCTL_UPHY_MISC_PAD_P1_CTL_2_0[RX_PWR_OVRD] 0
    - XUSB_PADCTL_UPHY_MISC_PAD_P2_CTL_2_0[TX_PWR_OVRD] 0
    - XUSB_PADCTL_UPHY_MISC_PAD_P2_CTL_2_0[RX_PWR_OVRD] 0
    - XUSB_PADCTL_UPHY_MISC_PAD_P3_CTL_2_0[TX_PWR_OVRD] 0
    - XUSB_PADCTL_UPHY_MISC_PAD_P3_CTL_2_0[RX_PWR_OVRD] 0
    - XUSB_PADCTL_UPHY_MISC_PAD_P4_CTL_2_0[TX_PWR_OVRD] 0
    - XUSB_PADCTL_UPHY_MISC_PAD_P4_CTL_2_0[RX_PWR_OVRD] 0
    - XUSB_PADCTL_UPHY_MISC_PAD_P0_CTL_2_0[TX_IDDQ_OVRD] 0
    - XUSB_PADCTL_UPHY_MISC_PAD_P0_CTL_2_0[RX_IDDQ_OVRD] 0
    - XUSB_PADCTL_UPHY_MISC_PAD_P1_CTL_2_0[TX_IDDQ_OVRD] 0
    - XUSB_PADCTL_UPHY_MISC_PAD_P1_CTL_2_0[RX_IDDQ_OVRD] 0
    - XUSB_PADCTL_UPHY_MISC_PAD_P2_CTL_2_0[TX_IDDQ_OVRD] 0
    - XUSB_PADCTL_UPHY_MISC_PAD_P2_CTL_2_0[RX_IDDQ_OVRD] 0
    - XUSB_PADCTL_UPHY_MISC_PAD_P3_CTL_2_0[TX_IDDQ_OVRD] 0
    - XUSB_PADCTL_UPHY_MISC_PAD_P3_CTL_2_0[RX_IDDQ_OVRD] 0
    - XUSB_PADCTL_UPHY_MISC_PAD_P4_CTL_2_0[TX_IDDQ_OVRD] 0
    - XUSB_PADCTL_UPHY_MISC_PAD_P4_CTL_2_0[RX_IDDQ_OVRD] 0

19. Configure the pin mux
    a. (L1SS disabled)
       PINMUX_AUX_PEX_L0_CLKREQ_N_0[TRISTATE] 1
       PINMUX_AUX_PEX_L1_CLKREQ_N_0[TRISTATE] 1
    b. Configure reset pad
       PINMUX_AUX_PEX_L0_RST_N_0[TRISTATE] 0
       PINMUX_AUX_PEX_L1_RST_N_0[TRISTATE] 0
20. Clear AFI reset
    - CLK_RST_CONTROLLER_RST_DEV_U_CLR_0[CLR_AFI_RST] 1
21. Program AFI registers
    a. Enable Gen2 speed
       AFI_FUSE_0[FUSE_PCIE_T0_GEN2_DIS] 0
    b. Enable PCIE devices
       AFI_PCIE_CONFIG_0[PCIEC0_DISABLE_DEVICE] 0
       AFI_PCIE_CONFIG_0[PCIEC1_DISABLE_DEVICE] 0
    c. Program XBAR config (not required for Tegra X1 as this is default value and only supported config)
       AFI_PCIE_CONFIG_0[SM2TMS0_XBAR_CONFIG] 1
    d. Enable FPCI interface
       AFI_CONFIGURATION_0[EN_FPCI] 1
    e. Set register for PLL power down
       AFI_PLLE_CONTROL_0[BYPASS_PADS2PLLE_CONTROL] 0
       AFI_PLLE_CONTROL_0[BYPASS_PCIE2PLLE_CONTROL] 0
       AFI_PLLE_CONTROL_0[PADS2PLLE_CONTROL_EN] 1
       AFI_PLLE_CONTROL_0[PCIE2PLLE_CONTROL_EN] 1
    f. Power up bias pad by register programming
       AFI_PEXBIAS_CTRL_0[PEX_BIAS_PWRD] 0
    g. Override refclk initially as some EP may not assert clkreq on boot and for platform not supporting clock power management this is necessary
       AFI_PEX0_CTRL_0[PEX0_REFCLK_OVERRIDE_EN] 1
       AFI_PEX1_CTRL_0[PEX1_REFCLK_OVERRIDE_EN] 1
    h. Enable refclk and clkreq pad
       AFI_PEX0_CTRL_0[PEX0_REFCLK_EN] 1
       AFI_PEX0_CTRL_0[PEX0_CLKREQ_EN] 0
       AFI_PEX1_CTRL_0[PEX1_REFCLK_EN] 1
       AFI_PEX1_CTRL_0[PEX1_CLKREQ_EN] 0
    i. Assert EP reset
       AFI_PEX0_CTRL_0[PEX0_RST_L] 0
       AFI_PEX1_CTRL_0[PEX1_RST_L] 0
    j. Wait for reset to get applied

k. Release EP reset

AFI_PEX0_CTRL_0[PEX0_RST_L] 1

AFI_PEX1_CTRL_0[PEX1_RST_L] 1

22. Clear PCIe controller reset

- CLK_RST_CONTROLLER_RST_DEV_U_CLR_0[CLR_PCIE_RST] 1

23. Program PCIe register

a. Configure refclk pad

PCIE2_PADS_REFCLK_CFG0_0 0x90b890b8

b. Configure UPHY electrical settings

PCIE2_RP_ECTL_2_R1_0[RX_CTLE_1C] 0x000F

PCIE2_RP_ECTL_2_R2_0[RX_CTLE_1C] 0x008F

PCIE2_RP_ECTL_5_R1_0[RX_EQ_CTRL_L_1C] 0x55010000

PCIE2_RP_ECTL_6_R1_0[RX_EQ_CTRL_H_1C] 0x00000001

PCIE2_RP_ECTL_5_R2_0[RX_EQ_CTRL_L_1C] 0x55010000

PCIE2_RP_ECTL_6_R2_0[RX_EQ_CTRL_H_1C] 0x00000001

PCIE2_RP_ECTL_4_R1_0[RX_CDR_CTRL_1C] 0x0067

PCIE2_RP_ECTL_4_R2_0[RX_CDR_CTRL_1C] 0x00C7

PCIE2_RP_ECTL_2_R1_1[RX_CTLE_1C] 0x000F

PCIE2_RP_ECTL_2_R2_1[RX_CTLE_1C] 0x008F

PCIE2_RP_ECTL_5_R1_1[RX_EQ_CTRL_L_1C] 0x55010000

PCIE2_RP_ECTL_6_R1_1[RX_EQ_CTRL_H_1C] 0x00000001

PCIE2_RP_ECTL_5_R2_1[RX_EQ_CTRL_L_1C] 0x55010000

PCIE2_RP_ECTL_6_R2_1[RX_EQ_CTRL_H_1C] 0x00000001

PCIE2_RP_ECTL_4_R1_1[RX_CDR_CTRL_1C] 0x0067

PCIE2_RP_ECTL_4_R2_1[RX_CDR_CTRL_1C] 0x00C7

c. Enable PCA

PCIE2_RP_VEND_CYA2_0 PCA_ENABLE 1

PCIE2_RP_VEND_CYA2_1 PCA_ENABLE 1

d. Enable clock clamping and change threshold for TMS clock clamping

PCIE2_RP_PRIV_MISC_0[TMS_CLK_CLAMP_ENABLE] 1

PCIE2_RP_PRIV_MISC_0[CTLR_CLK_CLAMP_ENABLE] 1

PCIE2_RP_PRIV_MISC_0[TMS_CLK_CLAMP_THRESHOLD] 0xF

PCIE2_RP_PRIV_MISC_0[CTLR_CLK_CLAMP_THRESHOLD] 0xF

PCIE2_RP_PRIV_MISC_1[TMS_CLK_CLAMP_ENABLE] 1

PCIE2_RP_PRIV_MISC_1[CTLR_CLK_CLAMP_ENABLE] 1

PCIE2_RP_PRIV_MISC_0[TMS_CLK_CLAMP_THRESHOLD] 0xF

PCIE2_RP_PRIV_MISC_0[CTLR_CLK_CLAMP_THRESHOLD] 0xF

e. Configure PCIE2_RP_VEND register to enable ASPM

PCIE2_RP_VEND_XP1_0[CYA] 0x4

PCIE2_RP_VEND_XP1_1[CYA] 0x4

f. Set BIST register

PCIE2_RP_VEND_XP_BIST_0 0x10000001

PCIE2_RP_VEND_XP_BIST_1 0x10000001

g. Enable opportunistic update FC and ACK to send out update FC and ACK when link is idle

PCIE2_RP_VEND_XP_0[OPPORTUNISTIC_ACK] 1

PCIE2_RP_VEND_XP_0[OPPORTUNISTIC_UPDATEFC] 1

PCIE2_RP_VEND_XP_1[OPPORTUNISTIC_ACK] 1

PCIE2_RP_VEND_XP_1[OPPORTUNISTIC_UPDATEFC] 1

h. Update flow control threshold for X1 controller

PCIE2_RP_VEND_XP_0[UPDATE_FC_THRESHOLD] 0x60

PCIE2_RP_VEND_XP_1[UPDATE_FC_THRESHOLD] 0x60

i. Set CLKREQ assertion delay

PCIE2_RP_L1_PM_SUBSTATES_1_CYA_0[CHK_CLKREQ_ASSERTED_DLY] 0x4F

PCIE2_RP_L1_PM_SUBSTATES_1_CYA_1[CHK_CLKREQ_ASSERTED_DLY] 0x4F

j. Software tuning for the de-skew retry time

PCIE2_RP_VEND_CYA0_0[DSK_RESET_PULSE_WIDTH] 0x9

PCIE2_RP_VEND_CYA0_1[DSK_RESET_PULSE_WIDTH] 0x9

k. Power saving for sleep/idle

PCIE2_RP_VEND_XP_PAD_PWRDN_0[DISABLED] 1

PCIE2_RP_VEND_XP_PAD_PWRDN_0[DYNAMIC] 1

PCIE2_RP_VEND_XP_PAD_PWRDN_0[L1] 1

34.3.2 Enable Advance Error Reporting

PCIe design support Advance Error Reporting. Standard settings used for this feature are as follows:

1. Enable error reporting for all error types
    - PCIE2_RP_DEVICE_CONTROL_STATUS_0[CORR_ERROR_REPORTING_ENABLE] 1
    - PCIE2_RP_DEVICE_CONTROL_STATUS_0[NON_FATAL_ERROR_REPORTING_ENABLE] 1
    - PCIE2_RP_DEVICE_CONTROL_STATUS_0[FATAL_ERROR_REPORTING_ENABLE] 1
    - PCIE2_RP_DEVICE_CONTROL_STATUS_0[UNSUPP_REQ_REPORTING_ENABLE] 1
    - PCIE2_RP_DEVICE_CONTROL_STATUS_0[ENABLE_RELAXED_ORDERING] 1
    - PCIE2_RP_DEVICE_CONTROL_STATUS_1[CORR_ERROR_REPORTING_ENABLE] 1
    - PCIE2_RP_DEVICE_CONTROL_STATUS_1[NON_FATAL_ERROR_REPORTING_ENABLE] 1
    - PCIE2_RP_DEVICE_CONTROL_STATUS_1[FATAL_ERROR_REPORTING_ENABLE] 1
    - PCIE2_RP_DEVICE_CONTROL_STATUS_1[UNSUPP_REQ_REPORTING_ENABLE] 1
    - PCIE2_RP_DEVICE_CONTROL_STATUS_1[ENABLE_RELAXED_ORDERING] 1
2. Enable error indication to AFI
    - PCIE2_RP_RCR_0[SERR_COR] 1
    - PCIE2_RP_RCR_0[SERR_NONFAT] 1
    - PCIE2_RP_R1CR_0[SERR_FAT] 1
    - PCIE2_RP_RCR_1[SERR_COR] 1
    - PCIE2_RP_RCR_1[SERR_NONFAT] 1
    - PCIE2_RP_R1CR_1[SERR_FAT] 1
    - PCIE2_RP_INTR_BCR_0[SERR_FORWARD] 1
    - PCIE2_RP_INTR_BCR_1[SERR_FORWARD] 1

34.3.3 Address Space Mapping in AFI and PCIe

Tegra X1 address space is defined based on AXI and there is one single address domain. As well, PCIe inherits three address domains from Legacy PCI and these domains are memory, I/O, and, configuration. For I/O and configuration space, software needs to use SO (Strongly Ordered) or DEV (Device) mem type to guarantee 4 byte transactions.

The BAR mappings in AFI allow conversions from Tegra X1 AXI address space to the HyperTransport address space recognized by PCIe Root Port controllers. PCIe Root Port controllers decode the HyperTransport addresses to generate PCIe requests to different address spaces. AFI provides 8 sets of address mapping registers that allow software to set up address mappings required by the address space conversions. This allows more flexibility for software to allocate and map system addresses to different address spaces under one or more PCIe controllers.

This register defines the starting address in the AXI address space to be mapped to FPCI address.

- AFI_AXI_BAR*_START_0[AXI_BAR*_START]

This register defines the size of the AXI address space to be mapped to FPCI address space.

- AFI_AXI_BAR*_SZ_0[AXI_BAR0_SIZE]

This register defines the starting address space in the FPCI address where AXI address to be mapped to.

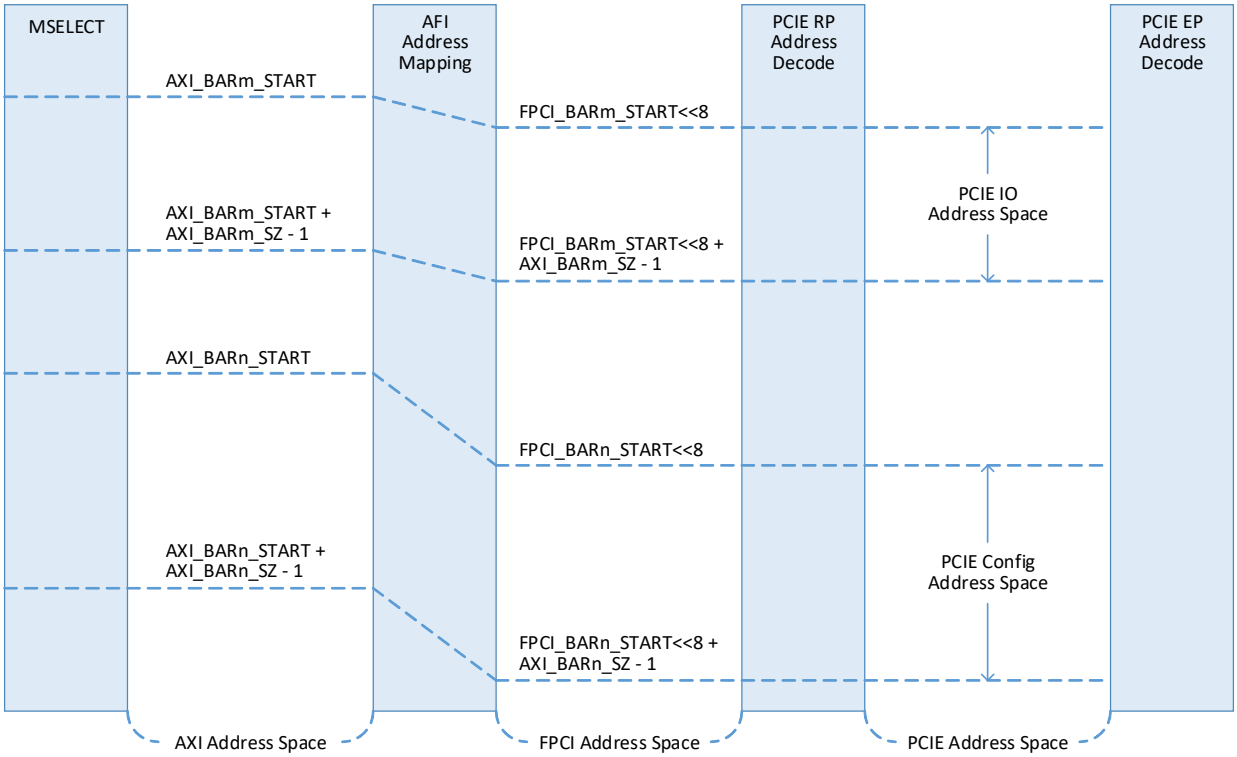
- AFI_FPCI_BAR0_0[FPCI_BAR*_START]

This address defines whether the write requests that are converted to FPCI addresses should also be converted to posted requests.

- AFI_FPCI_BAR0_0[FPCI_BAR*_ACCESS_TYPE]

The following figure illustrates an example of the address space conversion and decoding.

Figure 158: Address Space Conversion and Decoding



The following subsections describe how to set up the address mapping in AFI.

34.3.3.1 PCIE Configuration Requests

The configuration registers of the PCIE Root Port controllers are allocated outside the PCIE configuration address space as listed in Section 34.4: PCIe Registers. The BAR address mapping in AFI is used for defining the Type 1 configuration address space for accessing configuration registers of connected external PCIE endpoints.

For Type 1 configuration address space, AFI_FPCI_BAR0_0[FPCI_BAR*_START] should be set to 0xFE10_000.

As configuration write requests are defined as non-posted, writes in PCIE, AFI_FPCI_BAR0_0[FPCI_BAR*_ACCESS_TYPE] should be set to IO/Config Access.

Closed System

In a closed system where connected external devices are determined by platform configurations of the vendors, the size of the configuration address space can be limited. The equation to calculate the size of the Type 1 config space is:

- 1MB * Number of PCI Bus Allocated

Open System

In an open system where connected external devices can be determined by end users, the size of the configuration address space should be defined as 256 MB. Software performs PCI compliant device discovery and enumeration to identify and set up connected PCIE endpoints.

Since the system interface of the PCIE Root Port controllers follow the HyperTransport definition, SW should generate AXI requests with addresses following the HyperTransport definition of Type 1 configuration requests, where:

- Bus Number[7:0]= AXI_ADDRESS[23:16]
- Device Number[4:0]= AXI_ADDRESS[15:11]
- Function Number[3:0]= AXI_ADDRESS[10:8]
- Register Number[11:0]= {AXI_ADDRESS[27:24], AXI_ADDRESS[7:0]}

34.3.3.2 PCIE I/O Requests

The BAR address mapping in AFI is used for defining the I/O address space for accessing I/O registers of connected external PCIE endpoints.

For I/O address space, AFI_FPCI_BAR0_0[FPCI_BAR*_START] should be set to 0xFDFC_000.

As configuration write requests are defined as non-posted, writes in PCIE, AFI_FPCI_BAR0_0[FPCI_BAR*_ACCESS_TYPE] should be set to IO/Config Access.

Closed System

In a closed system where connected external devices are determined by platform configurations of the vendors, the size of the I/O address space can be limited.

If none of the connected devices require I/O address spaces as identified by their PCI BAR registers, the size of the I/O address space should be set to 0 to disable the I/O address space mapping.

If some of the connected devices require I/O address spaces as identified by their PCI BAR registers, the size of the I/O address space should be set to cover the sum of all I/O spaces required by the devices.

Open System

In an open system where connected external devices can be determined by end users, the size of the I/O address space should be defined as 32 MB. Software performs PCI compliant device discovery and enumeration to identify and set up connected PCIE endpoints.

34.3.3.3 PCIE Memory Requests

While the AXI addresses can be directly used to access the memory mapped registers of the PCIE endpoints, AFI has to perform the conversion of non-posted AXI write requests to the posted PCIE memory write requests. Thus, memory space is also required to be defined in AFI.

For memory address space, AFI_FPCI_BAR0_0[FPCI_BAR*_START] could be set to match AFI_AXI_BAR*_START_0[AXI_BAR*_START].

As memory write requests are defined as posted, writes in PCIE, AFI_FPCI_BAR0_0[FPCI_BAR*_ACCESS_TYPE] should be set to Memory Access.

Closed System

In a closed system where connected external devices are determined by platform configurations of the vendors, the size of the memory address space can be limited. The size of the memory address space should be set to cover the sum of all memory spaces required by the devices as identified by their PCI BAR registers.

Open System

In an open system where connected external devices can be determined by end users, the size of the memory address space should be set to cover the remaining AXI address space allocated to PCIE.

34.3.4 PCIE Hierarchy Enumeration

Following PCI/PCIE specification, the PCIE hierarchy enumeration is performed via depth first search to discover all devices attach to the PCIE controllers and initialize their CFG registers.

The following register bits should be set to enable PCIE to forward DMA requests and accept MMIO and IOIO requests from CPU:

- PCIE2_RP_DEV_CTRL_0[BUS_MASTER] 1’b1
- PCIE2_RP_DEV_CTRL_0[MEMORY_SPACE] 1’b1
- PCIE2_RP_DEV_CTRL_0[IO_SPACE] 1’b1
- PCIE2_RP_DEV_CTRL_1[BUS_MASTER] 1’b1
- PCIE2_RP_DEV_CTRL_1[MEMORY_SPACE] 1’b1
- PCIE2_RP_DEV_CTRL_1[IO_SPACE] 1’b1

The configuration register space of the PCIE hierarchy below each PCIE root port is accesses by using the AFI address mapping to convert the Tegra MMIO addresses to PCIE config addresses. The following PCIE registers should be programmed accordingly for access configuration register spaces below the root ports:

- PCIE2_RP_BN_LT_0[SEC_BUS_NUMBER]
- PCIE2_RP_BN_LT_0[SUB_BUS_NUMBER]
- PCIE2_RP_BN_LT_1[SEC_BUS_NUMBER]
- PCIE2_RP_BN_LT_1[SUB_BUS_NUMBER]

The IOIO register space of the PCIE hierarchy below each PCIE root port is accesses by using the AFI address mapping to convert the Tegra MMIO addresses to PCIE IOIO addresses. The following PCIE registers should be programmed accordingly for access IOIO register spaces below the root ports:

- PCIE2_RP_IO_BL_SS_0[IO_BASE]
- PCIE2_RP_IO_BL_SS_0[IO_LIMIT]
- PCIE2_RP_IO_BL_SS_1[IO_BASE]
- PCIE2_RP_IO_BL_SS_1[IO_LIMIT]

The IOIO register space of the PCIE hierarchy below each PCIE root port is accesses by using the AFI address mapping to shift the Tegra MMIO addresses to PCIE MMIO addresses. The following PCIE registers should be programmed accordingly for access MMIO register spaces below the root ports:

- PCIE2_RP_MEM_BL_0[MEM_BASE]
- PCIE2_RP_MEM_BL_0[MEM_LIMIT]
- PCIE2_RP_PRE_BL_0[PREFETCH_MEM_BASE]
- PCIE2_RP_PRE_BL_0[PREFETCH_MEM_LIMIT]
- PCIE2_RP_MEM_BL_1[MEM_BASE]
- PCIE2_RP_MEM_BL_1[MEM_LIMIT]
- PCIE2_RP_PRE_BL_1[PREFETCH_MEM_BASE]
- PCIE2_RP_PRE_BL_1[PREFETCH_MEM_LIMIT]

34.3.5 ELPG

The PCIE partition consists of both PCIE controllers. The PCIE partition can be put to power gating (ELPG) when both controllers have their links either in L2/3 or in disconnected states. The Tegra SOC is in running state when the PCIE partition is in ELPG.

1. Context Save/Restore

   In general, to ensure a controller correctly resume its operation after it exited power gating, software is required to perform context save and restore operations, where context is saved before the controller is put to ELPG and context is restored after the controller is bring out of ELPG. A controller's context can include register values, state machine states, and/or buffer statuses.

   Since all connected PCIE links are required to be put to L2/L3 for PCIE to be put to ELPG, software is not required to perform context save/restore for PCIE. This is because PCIE hierarchy reset is required to bring the links out of L2/L3, where software is required to re-enumerate the PCIE fabric. Thus for PCIE, SW should re-initialize AFI, PCIE Root Ports, and the PCIE hierarchy after exited ELPG or LP0.

2. PE_WAKE# in ELPG

   PCIE devices can assert PE_WAKE# to request the link to be bring to L0, which requires the PCIE partition to be powered. SW is notified of the assertion of PE_WAKE# by interrupt generated by the GPIO unit.

   GPIO interrupt generation to reflect PE_WAKE# assertion should be enabled before PCIE partition is put into ELPG by programming of the following register fields:

   GPIO_CNF_0.DD[BIT_3] to 'GPIO'

   GPIO_CNF_0.DD[LOCK_3] to 'DISABLE'

   GPIO_OE_0.DD[BIT_3] to 'TRI_STATE'

   GPIO_INT_LVL_0.DD[EDGE_3] to '0'

   GPIO_INT_LVL_0.DD[BIT_3] to 'LOW'

   GPIO_INT_ENB_0.DD[BIT_3] to 'ENABLE'

   After exiting ELPG, the PE_WAKE# interrupt should be disabled and the wake status should be cleared by programming the following register fields.

   GPIO_INT_ENB_0.DD[BIT_3] to 'DISABLE'

   GPIO_INT_CLR_0.DD[BIT_3] to 'CLEAR'

3. Power Gating Entry

   Partition power gating sequences consist of putting the lanes to IDDQ, asserting the resets to PCIE/AFI, disabling the clocks to PCIE/AFI, and remove the power to the partition, where power clamps are automatically enable by removing the power.

   IOPHY are put to IDDQ by setting the following register bits. Only lanes owned by PCIE should be programmed.

   - XUSB_PADCTL_USB3_PAD_MUX_0[FORCE_PCIE_PAD_IDDQ_DISABLE_MASK0] 1'b0
   - XUSB_PADCTL_USB3_PAD_MUX_0[FORCE_PCIE_PAD_IDDQ_DISABLE_MASK1] 1'b0
   - XUSB_PADCTL_USB3_PAD_MUX_0[FORCE_PCIE_PAD_IDDQ_DISABLE_MASK2] 1'b0
   - XUSB_PADCTL_USB3_PAD_MUX_0[FORCE_PCIE_PAD_IDDQ_DISABLE_MASK3] 1'b0
   - XUSB_PADCTL_USB3_PAD_MUX_0[FORCE_PCIE_PAD_IDDQ_DISABLE_MASK4] 1'b0

   AFI and PCIE resets are asserted by setting the following register bits:

   - CLK_RST_CONTROLLER_RST_DEV_U_SET_0[SET_AFI_RST] 1'b1
   - CLK_RST_CONTROLLER_RST_DEV_U_SET_0[SET_PCIE_RST] 1'b1
   - CLK_RST_CONTROLLER_RST_DEV_U_SET_0[SET_PCIEXCLK_RST] 1'b1

   AFI and PCIE clocks are enabled by setting the following register bits:

- CLK_RST_CONTROLLER_CLK_OUT_ENB_U_CLR_0[CLR_CLK_ENB_AFI] 1’b1
- CLK_RST_CONTROLLER_CLK_OUT_ENB_U_CLR_0[CLR_CLK_ENB_PCIE] 1’b1

AFI and PCIE power is removed by setting the following register fields:

- APBDEV_PMC_PWRGATE_TOGGLE_0[START] to ‘enable’
- APBDEV_PMC_PWRGATE_TOGGLE_0[PARTID] to ‘PCX’

Then confirm the power removal by reading the following fields:

- APBDEV_PMC_PWRGATE_STATUS_0[PCX] equals ‘OFF’

4. Power Gating Exit

   Partition power ungating sequences consist of disable the power clamp to the partition, enabling the clocks to PCIE/ AFI, remove the power clamps, and deasserting the resets to PCIE/AFI.

   AFI and PCIE power is restored by setting the following register fields:

   - APBDEV_PMC_PWRGATE_TOGGLE_0[START] to ‘enable’
   - APBDEV_PMC_PWRGATE_TOGGLE_0[PARTID] to ‘PCX’

   Then confirm the power restore by reading the following fields:

   - APBDEV_PMC_PWRGATE_STATUS_0[PCX] equals ‘ON’

   AFI and PCIE clocks are enabled by setting the following register bits:

   - CLK_RST_CONTROLLER_CLK_OUT_ENB_U_SET_0[SET_CLK_ENB_AFI] 1’b1
   - CLK_RST_CONTROLLER_CLK_OUT_ENB_U_SET_0[SET_CLK_ENB_PCIE] 1’b1

   AFI and PCIE power clamping is removed by setting the following register fields:

   - APBDEV_PMC_REMOVE_CLAMPING_CMD_0 [PCX]

   Then confirm the power clamps removal by reading the following fields:

   - APBDEV_PMC_REMOVE_CLAMPING_CMD_0 [PCX] equals ‘0’

   AFI and PCIE resets are deasserted by setting the following register bits:

   - CLK_RST_CONTROLLER_RST_DEV_U_CLR_0[CLR_AFI_RST] 1’b1
   - CLK_RST_CONTROLLER_RST_DEV_U_CLR_0[CLR_PCIE_RST] 1’b1

   IOPHY are brought out of IDDQ by setting the following register bits. Only lanes owned by PCIE should be programmed.

   - XUSB_PADCTL_USB3_PAD_MUX_0[FORCE_PCIE_PAD_IDDQ_DISABLE_MASK0] 1’b1
   - XUSB_PADCTL_USB3_PAD_MUX_0[FORCE_PCIE_PAD_IDDQ_DISABLE_MASK1] 1’b1
   - XUSB_PADCTL_USB3_PAD_MUX_0[FORCE_PCIE_PAD_IDDQ_DISABLE_MASK2] 1’b1
   - XUSB_PADCTL_USB3_PAD_MUX_0[FORCE_PCIE_PAD_IDDQ_DISABLE_MASK3] 1’b1
   - XUSB_PADCTL_USB3_PAD_MUX_0[FORCE_PCIE_PAD_IDDQ_DISABLE_MASK4] 1’b1

   PCIE XCLK domain reset is deasserted by setting the following CAR register bits:

   - CLK_RST_CONTROLLER_RST_DEV_U_CLR_0[CLR_PCIEXCLK_RST] 1’b1

34.3.6 LP0

PCIE partition must be put to ELPG before the system can enter LP0. PCIE partition can either be brought out of ELPG once the system exited LP0 or be kept under ELPG until the connected device signals wake event. Thus assertion of PE_WAKE# should be set as an LP0 wake event. The programming sequence of PCIE to support LP0 is identical to put PCIE in and out of ELPG.

- PE_WAKE# in LP0

The LP0 wake event triggered by the assertion PE_WAKE# should be enabled before the system goes into LP0 by programming of the following register fields:

- APBDEV_PMC_WAKE_LVL_0[EVENT[14]] to ‘ACTIVE_LOW’
- APBDEV_PMC_WAKE_MASK_0[EVENT[14]] to ‘ENABLE’

After exiting LP0, the PE_WAKE# wake event should be disabled and the wake status should be cleared by programming the following register fields.

- APBDEV_PMC_WAKE_MASK_0[EVENT[14]] to ‘DISABLE’
- APBDEV_PMC_WAKE_STATUS_0[EVENT[14]] to 1’b1

34.4 PCIe Registers

The PCI Express® registers are located as follows:

Table 216: PCIe Register Mapping

Name	Location	Description
NV_PCIE_AXI_RP_T0C0	NV_ADDRESS_MAP_PCIE_BASE	Start of PCIe extended config space for controller 0
NV_PCIE_AXI_RP_T0C1	(NV_PCIE_AXI_RP_T0C0) + 4096	Start of PCIe extended config space for controller 1
NV_PCIE_AXI_PCA_UFPCI_T0C0	(NV_PCIE_AXI_RP_T0C1) + 4096	Start of PCIe pca0 space
NV_PCIE_AXI_PCA_XCLK_T0C0	(NV_PCIE_AXI_PCA_UFPCI_T0C0) + 256)	Start of PCIe pca1 space
NV_PCIE_AXI_PADS	(NV_PCIE_AXI_RP_T0C1) + 8192	Start of PCIe pads space

34.4.1 PCI Compatible Configuration Registers

This section lists the Type 1 PCI Header registers as defined in PCI-to-PCI Bridge Architecture Specification, Revision 1.2.

34.4.1.1 T_PCIE2_RP_DEV_ID

This register implements the Device ID and Vendor ID registers as defined by the PCI 2.0 Specification.

Device ID and Vendor ID Register

Offset: 0x00 | Read/Write: RO

Bit	Reset	Description
31:16	None	T_PCIE2_RP_DEV_ID_DEVICE_ID: The DEVICE_ID bits identify the particular device. This identifier is allocated by the vendor. NVIDIA uses unique Device IDs for Root Complexes with different Maximum Link Widths. FAEh: DEVICE_ID_TMS0_CTLR0_W4 FAFh: DEVICE_ID_TMS0_CTLR1_W1
15:0	10DEh	T_PCIE2_RP_DEV_ID_VENDOR_ID: The VENDOR_ID bits identify the manufacturer of the device. Valid vendor identifiers are allocated by the PCI SIG to ensure uniqueness. 10DEh: VENDOR_ID_NVIDIA (default)

34.4.1.2 T_PCIE2_RP_DEV_CTRL

Command and Status Register

Offset: 0x04 | Read/Write: R/W

Bit	R/W	Reset	Description
31	RW1C	0h	T_PCIE2_RP_DEV_CTRL_DETECTED_PERR: This bit is set by the Primary side device whenever it receives a Poisoned TLP, regardless of the state the Parity Error Response bit in the Command register. 0h: DETECTED_PERR_NOT_ACTIVE (default) 1h: DETECTED_PERR_ACTIVE 1h: DETECTED_PERR_SET

Bit	R/W	Reset	Description
30	RW1C	0h	T_PCIE2_RP_DEV_CTRL_SIGNALED_SERR: This bit is set when the Primary side device sends an ERR_FATAL or ERR_NONFATAL message, and the SERR Enable bit is set. 0h: SIGNALED_SERR_NOT_ACTIVE (default) 1h: SIGNALED_SERR_ACTIVE 1h: SIGNALED_SERR_SET
29	RW1C	0h	T_PCIE2_RP_DEV_CTRL_RECEIVED_MASTER: This bit is set when the Primary side Requester receives a Completion with Unsupported Request Completion Status. 0h: RECEIVED_MASTER_NO_ABORT (default) 1h: RECEIVED_MASTER_ABORT 1h: RECEIVED_MASTER_SET
28	RW1C	0h	T_PCIE2_RP_DEV_CTRL_RECEIVED_TARGET: This bit is set when the Primary side Requester receives a Completion with Completer Abort Completion Status. 0h: RECEIVED_TARGET_NO_ABORT (default) 1h: RECEIVED_TARGET_ABORT 1h: RECEIVED_TARGET_SET
27	RW1C	0h	T_PCIE2_RP_DEV_CTRL_SIGNALED_TARGET: This bit is set when the Primary side device completes a Request using Completer Abort Completion Status. 0h: SIGNALED_TARGET_NO_ABORT (default) 1h: SIGNALED_TARGET_ABORT 1h: SIGNALED_TARGET_SET
26:25	R	0h	T_PCIE2_RP_DEV_CTRL_DEVSEL_TIMING: Does not apply to PCI Express. Hardwired to 0. 0h: DEVSEL_TIMING_FAST (default) 1h: DEVSEL_TIMING_MEDIUM 2h: DEVSEL_TIMING_SLOW
24	RW1C	0h	T_PCIE2_RP_DEV_CTRL_MASTER_DATA_PERR: Master Data Parity Error bit. This bit is set by the Primary side Requester if the Parity Error Response bit in the Command register is 1b and either of the following two conditions occurs: * Requester receives a Completion marked poisoned * Requester poisons a write Request If the Parity Error Response bit is 0b, this bit is never set. 0h: MASTER_DATA_PERR_NOT_ACTIVE (default) 1h: MASTER_DATA_PERR_ACTIVE 1h: MASTER_DATA_PERR_SET
23	R	0h	T_PCIE2_RP_DEV_CTRL_FAST_BACK2BACK: Does not apply to PCI Express. Hardwired to 0. 0h: FAST_BACK2BACK_INCAPABLE (default) 1h: FAST_BACK2BACK_CAPABLE
22	R	0	Reserved
21	R	0h	T_PCIE2_RP_DEV_CTRL_66MHZ: Does not apply to PCI Express. Hardwired to 0. 0h: 66MHZ_INCAPABLE (default) 1h: 66MHZ_CAPABLE
20	R	1h	T_PCIE2_RP_DEV_CTRL_CAPLIST: The CAPLIST bit indicates that the device configuration space includes a capabilities list. Hardwired to 1. 1h: CAPLIST_PRESENT (default) 0h: CAPLIST_NOT_PRESENT
19	R	0h	T_PCIE2_RP_DEV_CTRL_INTR_STATUS: The INTR_STATUS bit indicates that an INTx interrupt message is pending internally to the device. 0h: INTR_STATUS_NOT_ACTIVE (default) 1h: INTR_STATUS_ACTIVE
18:11	R	0	Reserved
10	R/W	0h	T_PCIE2_RP_DEV_CTRL_INTR_DISABLE: The INTR-DISABLE bit controls the ability of the device to generate INTx interrupt messages. When set, devices are prevented from generating INTx interrupt messages. 0h: INTR_DISABLE_INIT (default) 1h: INTR_DISABLE_YES 0h: INTR_DISABLE_NO

Bit	R/W	Reset	Description
9	R	0h	T_PCIE2_RP_DEV_CTRL_BACK2BACK: Does not apply to PCI Express. Hardwired to 0. 0h: BACK2BACK_DISABLED (default) 1h: BACK2BACK_ENABLED
8	R/W	0h	T_PCIE2_RP_DEV_CTRL_SERR: SERR Enable bit. This bit, when set, enables reporting of Non-fatal and Fatal errors detected by the Root Complex. In addition, this bit, when set, enables transmission by the primary interface of ERR_NONFATAL and ERR_FATAL error messages forwarded from the secondary interface. This bit does not affect the transmission of forwarded ERR_COR messages. 0h: SERR_DISABLED (default) 1h: SERR_ENABLED
7	R	0h	T_PCIE2_RP_DEV_CTRL_STEP: Does not apply to PCI Express. Hardwired to 0. 0h: STEP_DISABLED (default) 1h: STEP_ENABLED
6	R/W	0h	T_PCIE2_RP_DEV_CTRL_PERR: Parity Error Response bit. This bit, when set, controls the reporting of parity errors detected by the root complex (see Master Data Parity Error bit in the Status register). 0h: PERR_DISABLED (default) 1h: PERR_ENABLED
5	R	0h	T_PCIE2_RP_DEV_CTRL_PALETTE_SNOOP: Does not apply to PCI Express. Hardwired to 0. 0h: PALETTE_SNOOP_DISABLED (default) 1h: PALETTE_SNOOP_ENABLED
4	R	0h	T_PCIE2_RP_DEV_CTRL_WRITE_AND_INVAL: Does not apply to PCI Express. Hardwired to 0. 0h: WRITE_AND_INVAL_DISABLED (default) 1h: WRITE_AND_INVAL_ENABLED
3	R	0h	T_PCIE2_RP_DEV_CTRL_SPECIAL_CYCLE: Does not apply to PCI Express. Hardwired to 0. 0h: SPECIAL_CYCLE_DISABLED (default) 1h: SPECIAL_CYCLE_ENABLED
2	R/W	0h	T_PCIE2_RP_DEV_CTRL_BUS_MASTER: The BUS_MASTER bit controls the ability of the root complex to issue memory and I/O read/write requests. It controls forwarding of memory or I/O requests from the secondary interface to the primary interface. 0h: BUS_MASTER_DISABLED (default) 1h: BUS_MASTER_ENABLED
1	R/W	0h	T_PCIE2_RP_DEV_CTRL_MEMORY_SPACE: The MEMORY_SPACE bit indicates that the device will respond to memory space accesses on the primary interface. A value of 0 disables the device response on the primary interface. A value of 1 allows the device to forward memory transactions from the primary interface to the secondary interface. 0h: MEMORY_SPACE_DISABLED (default) 1h: MEMORY_SPACE_ENABLED
0	R/W	0h	T_PCIE2_RP_DEV_CTRL_IO_SPACE: The IO_SPACE bit indicates that the device will respond to I/O space accesses on the primary interface. A value of 0 disables the device response on the primary interface. A value of 1 allows forwarding of I/O accesses from the primary interface to the secondary interface. 0h: IO_SPACE_DISABLED (default) 1h: IO_SPACE_ENABLED

34.4.1.3 T_PCIE2_RP_REV_CC

This register implements the Revision ID and Class Code registers as defined by the PCI 2.0 Specification.

Revision ID and Class Code Registers

Offset: 0x08 | Read/Write: RO

Bit	Reset	Description
31:8	60400h	T_PCIE2_RP_REV_CC_CLASS_CODE: The CLASS_CODE bits identify the generic function of the device and (in some cases) a specific register-level programming interface. The register is broken into three byte-size fields. The upper byte (bits 31:24) is a base class code which broadly classifies the type of function the device performs. The middle-byte (bits 23:16) is a sub-class code which identifies more specifically the function of the device. The lower byte (bits 15:8) identifies a specific register-level programming interface, if any, so that device independent software can interact with the device. 60400h: CLASS_CODE_HOST (default) 60400h: CLASS_CODE_P2P
7:0	None	T_PCIE2_RP_REV_CC_REVISION_ID: The REVISION_ID bits specify a device specific revision identifier. The top nibble is the Major Revision and the bottom nibble is the Minor Revision. The Major Revision is changed every time there is an all layer change to the Controller (A, B, C ...). The Minor Revision is updated through metal edits each time there is a metal revision changing the functionality of this block. A1h: REVISION_ID_VAL

34.4.1.4 T_PCIE2_RP_MISC_1

This register implements the Cache Line Size, Latency Timer, Header Type, and BIST registers as defined by the PCI 2.0 Specification.

Cache Line Size Latency Timer Header Type and BIST Registers

Offset: 0x0c | Read/Write: R/W

Bit	R/W	Reset	Description
31:24	R	0h	T_PCIE2_RP_MISC_1_BIST: The BIST register field is optional and not used. Hardwired to 0. 0h: BIST_ZERO (default)
23	R	0h	T_PCIE2_RP_MISC_1_HEADER_TYPE1: The HEADER_TYPE bits identify the layout of the bytes 10h through 3Fh in configuration space and also whether or not the device contains multiple functions. Bit 23 in this register is used to identify a multi-function device. If the bit is 0, then the device is single function. If the bit is 1, then the device has multiple functions. 0h: HEADER_TYPE1_SINGLEFUNC (default) 1h: HEADER_TYPE1_MULTIFUNC
22:16	R	1h	T_PCIE2_RP_MISC_1_HEADER_TYPE0: The HEADER_TYPE bits identify the layout of the bytes 10h through 3Fh in configuration space and also whether or not the device contains multiple functions. Bits 22:16 in this register specify the layout of bytes 10h through 3Fh. PCI-Express Root Port Devices always employ Type 1 headers, hence this field is hardwired to 1h. 0h: HEADER_TYPE0_NON_BRIDGE 1h: HEADER_TYPE0_P2P_BRIDGE (default)
15:11	R	0h	T_PCIE2_RP_MISC_1_PLATENCY_TIMER: The primary/master latency timer does not apply to PCI Express. Hardwired to 0. 0h: PLATENCY_TIMER_0_CLOCKS (default)
10:8	R	0	Reserved
7:0	R/W	0h	T_PCIE2_RP_MISC_1_CACHE_LINE_SIZE: The cache line size register is set by the system firmware and the operating system to system cache line size. However, note that legacy PCI software may not always be able to program this field correctly especially in case of Hot-Plug devices. This field is implemented by PCI Express devices as a read-write field for legacy compatibility purposes but has no impact on any PCI Express device functionality. 0h: CACHE_LINE_SIZE_0_BYTES (default)

34.4.1.5 T_PCIE2_RP_BAR_0

This register implements the Base Address Register 0 as defined by the PCI-to-PCI Bridge Architecture Specification, Revision 1.2. It is unused and hardwired to 0.

Base Address Register 0

Offset: 0x10 | Read/Write: RO

Bit	Reset	Description
31:0	0h	T_PCIE2_RP_BAR_0_RESERVED: 0h: RESERVED_0 (default)

34.4.1.6 T_PCIE2_RP_BAR_1

This register implements the Base Address Register 1 as defined by the PCI-to-PCI Bridge Architecture Specification, Revision 1.2. It is unused and hardwired to 0.

Base Address Register 1

Offset: 0x14 | Read/Write: RO

Bit	Reset	Description
31:0	0h	T_PCIE2_RP_BAR_1_RESERVED: 0h: RESERVED_0 (default)

34.4.1.7 T_PCIE2_RP_BN_LT

This register implements the Primary Bus Number, Secondary Bus Number, Subordinate Bus Number, and Secondary Latency Timer registers as defined by the PCI-to-PCI Bridge Architecture Specification, Revision 1.2.

Primary Bus□Secondary Bus□Subordinate Bus Numbers□and Secondary Latency Timer Registers

Offset: 0x18 | Read/Write: R/W

Bit	R/W	Reset	Description
31:27	R	0h	T_PCIE2_RP_BN_LT_SLATENCY_TIMER: This field does not apply to PCI Express. Hardwired to 0. 0h: SLATENCY_TIMER_0_CLOCKS (default)
26:24	R	0	Reserved
23:16	R/W	0h	T_PCIE2_RP_BN_LT_SUB_BUS_NUMBER: The Subordinate Bus Number field is used to record the bus number of the highest numbered PCI bus segment which is behind the bridge. Configuration software programs the value in this field. The bridge uses this field in conjunction with the Secondary Bus Number field to determine when to respond to a Type 1 configuration transaction on the primary interface. 0h: SUB_BUS_NUMBER_0 (default) 1h: SUB_BUS_NUMBER_1 2h: SUB_BUS_NUMBER_2 FFh: SUB_BUS_NUMBER_255
15:8	R/W	0h	T_PCIE2_RP_BN_LT_SEC_BUS_NUMBER: The Secondary Bus Number field is used to record the bus number of the PCI bus segment to which the secondary interface of the bridge is connected. Configuration software programs the value in this field. The bridge uses this field to decode Type 1 configuration transactions on the primary interface and convert them to Type 0 accesses on the secondary interface. 0h: SEC_BUS_NUMBER_0 (default) 1h: SEC_BUS_NUMBER_1 2h: SEC_BUS_NUMBER_2 FFh: SEC_BUS_NUMBER_255
7:0	R/W	0h	T_PCIE2_RP_BN_LT_PRI_BUS_NUMBER: The Primary Bus Number field is used to record the bus number of the PCI bus segment to which the primary interface of the bridge is connected. Configuration software programs the value in this field. The bridge uses this field to decode Type 1 configuration transactions on the secondary interface that must be converted to Special Cycle transactions on the primary interface. 0h: PRI_BUS_NUMBER_0 (default)

34.4.1.8 T_PCIE2_RP_IO_BL_SS

This register implements the I/O Base, I/O Limit, and Secondary Status register as defined by the PCI-to-PCI Bridge Architecture Specification, Revision 1.2.

The I/O Base and I/O Limit fields define an address range that is used by the bridge to determine when to forward I/O transactions from one interface to the other.

The Secondary Status field is similar in function and bit definition to the Command and Status register defined above; however, its bits reflect status conditions of the secondary interface (the Command and Status register reflects the status conditions of the primary interface).

I/O Base I/O Limit and Secondary Status Register

Offset: 0x1c | Read/Write: R/W

Bit	R/W	Reset	Description
31	RW1C	0h	T_PCIE2_RP_IO_BL_SS_DETECTED_PERR: This bit is set when the Secondary side device receives a Poisoned TLP, regardless of the state the Parity Error Response bit in the Bridge Control register. 0h: DETECTED_PERR_NOT_ACTIVE (default) 1h: DETECTED_PERR_ACTIVE 1h: DETECTED_PERR_SET
30	RW1C	0h	T_PCIE2_RP_IO_BL_SS_RECEIVED_SERR: This bit is set when the Secondary side device receives an ERR_FATAL or ERR_NONFATAL message. 0h: RECEIVED_SERR_NOT_ACTIVE (default) 1h: RECEIVED_SERR_ACTIVE 1h: RECEIVED_SERR_SET
29	RW1C	0h	T_PCIE2_RP_IO_BL_SS_RECEIVED_MASTER: This bit is set when the Secondary side device receives a Completion with Unsupported Request Completion Status. 0h: RECEIVED_MASTER_NO_ABORT (default) 1h: RECEIVED_MASTER_ABORT 1h: RECEIVED_MASTER_SET
28	RW1C	0h	T_PCIE2_RP_IO_BL_SS_RECEIVED_TARGET: This bit is set when the Secondary side device receives a Completion with Completer Abort Completion Status. 0h: RECEIVED_TARGET_NO_ABORT (default) 1h: RECEIVED_TARGET_ABORT 1h: RECEIVED_TARGET_SET
27	RW1C	0h	T_PCIE2_RP_IO_BL_SS_SIGNALED_TARGET: This bit is set when the Secondary side device completes a Request using Completer Abort Completion Status. 0h: SIGNALED_TARGET_NO_ABORT (default) 1h: SIGNALED_TARGET_ABORT 1h: SIGNALED_TARGET_SET
26:25	R	0h	T_PCIE2_RP_IO_BL_SS_DEVSEL_TIMING: Does not apply to PCI Express. Hardwired to 0. 0h: DEVSEL_TIMING_FAST (default) 1h: DEVSEL_TIMING_MEDIUM 2h: DEVSEL_TIMING_SLOW
24	RW1C	0h	T_PCIE2_RP_IO_BL_SS_MASTER_DATA_PERR: Master Data Parity Error bit. This bit is set by the Secondary side Requester if the Parity Error Response Enable bit in the Bridge Control register is 1b and either of the following two conditions occurs: * Requester receives a Completion marked poisoned * Requester poisons a write Request If the Parity Error Response bit is 0b, this bit is never set. 0h: MASTER_DATA_PERR_NOT_ACTIVE (default) 1h: MASTER_DATA_PERR_ACTIVE 1h: MASTER_DATA_PERR_SET
23	R	0h	T_PCIE2_RP_IO_BL_SS_FAST_BACK2BACK: Does not apply to PCI Express. Hardwired to 0. 0h: FAST_BACK2BACK_INCAPABLE (default) 1h: FAST_BACK2BACK_CAPABLE
22	R	0	Reserved
21	R	0h	T_PCIE2_RP_IO_BL_SS_66MHZ: Does not apply to PCI Express. Hardwired to 0. 0h: 66MHZ_INCAPABLE (default) 1h: 66MHZ_CAPABLE
20:16	R	0	Reserved

Bit	R/W	Reset	Description
15:12	R/W	0h	T_PCIE2_RP_IO_BL_SS_IO_LIMIT: This field corresponds to address bits AD[15:12] of the I/O limit. For the purpose of address decoding, the bridge assumes that the lower 12 address bits of the I/O limit are 0xFFF. The I/O Limit field can be programmed to a smaller value than the I/O Base register if there are no I/O addresses on the secondary side of the bridge. 0h: IO_LIMIT_ADDRESS_0 (default) 1h: IO_LIMIT_ADDRESS_256 2h: IO_LIMIT_ADDRESS_512 Fh: IO_LIMIT_ADDRESS_64K
11:8	R	1h	T_PCIE2_RP_IO_BL_SS_IO_LIMIT_SUPPORT: Identifies the I/O addressing support. When 0h, the device supports only 16-bit addressing. When 1h, it supports 32-bit addressing, in which case the I/O Limit Upper 16 Bits register is used to extend the I/O limit to 32 bits. Hardwired to 1h. 0h: IO_LIMIT_SUPPORT_16 1h: IO_LIMIT_SUPPORT_32 (default)
7:4	R/W	0h	T_PCIE2_RP_IO_BL_SS_IO_BASE: This field corresponds to address bits AD[15:12] of the I/O base address. For the purpose of address decoding, the bridge assumes that the lower 12 address bits, AD[11:0], of the I/O base address are zero. 0h: IO_BASE_ADDRESS_0 (default) 1h: IO_BASE_ADDRESS_256 2h: IO_BASE_ADDRESS_512 Fh: IO_BASE_ADDRESS_64K
3:0	R	1h	T_PCIE2_RP_IO_BL_SS_IO_BASE_SUPPORT: Identifies the I/O addressing support. When 0h, the device only supports 16-bit addressing. When 1h, it supports 32-bit addressing, in which case the I/O Base Upper 16 Bits register is used to extend the I/O base address to 32 bits. Hardwired to 1h. 0h: IO_BASE_SUPPORT_16 1h: IO_BASE_SUPPORT_32 (default)

34.4.1.9 T_PCIE2_RP_MEM_BL

This register implements the Memory Base and Memory Limit registers as defined by the PCI-to-PCI Bridge Architecture Specification, Revision 1.2.

The Memory Base and Memory Limit fields define an address range that is used by the bridge to determine when to forward memory-mapped I/O transactions from one interface to the other.

Memory Base and Memory Limit Registers

Offset: 0x20 | Read/Write: R/W

Bit	R/W	Reset	Description
31:20	R/W	0h	T_PCIE2_RP_MEM_BL_MEM_LIMIT: This field corresponds to address bits AD[31:20] of the memory-mapped I/O limit. For the purpose of address decoding, the bridge assumes that the lower 20 address bits, AD[19:0], of the memory-mapped I/O limit are 0xFFFFF. The Memory Limit field must be programmed to a smaller value than the Memory Base field if there are no memory-mapped I/O addresses on the secondary side of the bridge. 0h: MEM_LIMIT_ADDRESS_0 (default) 1h: MEM_LIMIT_ADDRESS_1MEG 2h: MEM_LIMIT_ADDRESS_2MEG FFFh: MEM_LIMIT_ADDRESS_4GIG
19:16	R	0	Reserved
15:4	R/W	1h	T_PCIE2_RP_MEM_BL_MEM_BASE: This field corresponds to address bits AD[31:20] of the memory-mapped I/O base address. For the purpose of address decoding, the bridge assumes that the lower 20 address bits, AD[19:0], of the memory-mapped I/O base address are zero. 0h: MEM_BASE_ADDRESS_0 1h: MEM_BASE_ADDRESS_1MEG (default) 2h: MEM_BASE_ADDRESS_2MEG FFFh: MEM_BASE_ADDRESS_4GIG
3:0	R	0	Reserved

34.4.1.10 T_PCIE2_RP_PRE_BL

This register implements the Prefetchable Memory Base and Prefetchable Memory Limit registers as defined by the PCI-to-PCI Bridge Architecture Specification, Revision 1.2.

The Prefetchable Memory Base and Prefetchable Memory Limit fields define an address range that is used by the bridge to determine when to forward prefetchable memory transactions from one interface to the other.

Prefetchable Memory Base and Prefetchable Memory Limit Registers

Offset: 0x24 | Read/Write: R/W

Bit	R/W	Reset	Description
31:20	R/W	0h	T_PCIE2_RP_PRE_BL_PREFETCH_MEM_LIMIT: This field corresponds to address bits AD[31:20] of the prefetchable memory limit. For the purpose of address decoding, the bridge assumes that the lower 20 address bits, AD[19:0], of the prefetchable memory limit are 0xFFFFF. The Prefetchable Memory Limit field must be programmed to a smaller value than the Prefetchable Memory Base field if there is no prefetchable memory on the secondary side of the bridge. 0h: PREFETCH_MEM_LIMIT_ADDRESS_0 (default) 1h: PREFETCH_MEM_LIMIT_ADDRESS_1MEG 2h: PREFETCH_MEM_LIMIT_ADDRESS_2MEG FFFh: PREFETCH_MEM_LIMIT_ADDRESS_4GIG
19:16	R	1h	T_PCIE2_RP_PRE_BL_L64BIT: Identifies the prefetchable memory addressing support. When 0h, the device supports only 32-bit addressing. When 1h, it supports 64-bit addressing, in which case the Prefetchable Limit Upper 32 Bits register is used to extend the prefetchable memory limit to 64 bits. Hardwired to 1h. 1h: L64BIT_YES (default)
15:4	R/W	1h	T_PCIE2_RP_PRE_BL_PREFETCH_MEM_BASE: This field corresponds to address bits AD[31:20] of the prefetchable memory base address. For the purpose of address decoding, the bridge assumes that the lower 20 address bits, AD[19:0], of the Prefetchable memory base address are zero. 0h: PREFETCH_MEM_BASE_ADDRESS_0 1h: PREFETCH_MEM_BASE_ADDRESS_1MEG (default) 2h: PREFETCH_MEM_BASE_ADDRESS_2MEG FFFh: PREFETCH_MEM_BASE_ADDRESS_4GIG
3:0	R	1h	T_PCIE2_RP_PRE_BL_B64BIT: Identifies the prefetchable memory addressing support. When 0h, the device supports only 32-bit addressing. When 1h, it supports 64-bit addressing, in which case the Prefetchable Base Upper 32 Bits register is used to extend the prefetchable memory base address to 64 bits. Hardwired to 1h. 1h: B64BIT_YES (default)

34.4.1.11 T_PCIE2_RP_PRE_BU32

This register implements the Prefetchable Memory Base Upper 32 Bits register as defined by the PCI-to-PCI Bridge Architecture Specification, Revision 1.2.

Prefetchable Memory Base Upper 32 Bits Register

Offset: 0x28 | Read/Write: R/W

Bit	Reset	Description
31:0	0h	T_PCIE2_RP_PRE_BU32_BASE_UPPER_BITS: This register specifies the upper 32 bits, corresponding to AD[63:32], of the 64-bit prefetchable memory base address. 0h: BASE_UPPER_BITS_0 (default)

34.4.1.12 T_PCIE2_RP_PRE_LU32

This register implements the Prefetchable Memory Limit Upper 32 Bits register as defined by the PCI-to-PCI Bridge Architecture Specification, Revision 1.2.

Prefetchable Memory Limit Upper 32 Bits Register

Offset: 0x2c | Read/Write: R/W

Bit	Reset	Description
31:0	0h	T_PCIE2_RP_PRE_LU32_LIMIT_UPPER_BITS: This register specifies the upper 32 bits, corresponding to AD[63:32], of the 64-bit prefetchable memory limit. 0h: LIMIT_UPPER_BITS_0 (default)

34.4.1.13 T_PCIE2_RP_IO_BL_U16

This register implements the I/O Base Upper 16 Bits and I/O Limit Upper 16 Bits registers as defined by the PCI-to-PCI Bridge Architecture Specification, Revision 1.2.

I/O Base Upper 16 Bits and I/O Limit Upper 16 Bits Register

Offset: 0x30 | Read/Write: R/W

Bit	Reset	Description
31:16	0h	T_PCIE2_RP_IO_BL_U16_LIMIT_UPPER_BITS: This field specifies the upper 16 bits, corresponding to AD[31:16], of the 32-bit I/O limit. 0h: LIMIT_UPPER_BITS_0 (default)
15:0	0h	T_PCIE2_RP_IO_BL_U16_BASE_UPPER_BITS: This field specifies the upper 16 bits, corresponding to AD[31:16], of the 32-bit I/O base address. 0h: BASE_UPPER_BITS_0 (default)

34.4.1.14 T_PCIE2_RP_CAP_PTR

This register implements the Capabilities Pointer register as defined by the PCI 2.0 Specification.

Capabilities Pointer

Offset: 0x34 | Read/Write: RO

Bit	Reset	Description
31:8	0	Reserved
7:0	40h	T_PCIE2_RP_CAP_PTR_CAP_PTR: The CAP_PTR bits indicate the offset into configuration space where the capabilities list begins. 40h: CAP_PTR_PM (default)

34.4.1.15 T_PCIE2_RP_ROM_BA

This register implements the optional Expansion ROM Base Address register as defined by the PCI-to-PCI Bridge Architecture Specification, Revision 1.2. It is unused and hardwired to 0.

Expansion ROM Base Address Register

Offset: 0x38 | Read/Write: RO

Bit	Reset	Description
31:0	0h	T_PCIE2_RP_ROM_BA_RESERVED: 0h: RESERVED_0 (default)

34.4.1.16 T_PCIE2_RP_INTR_BCR

This register implements the Interrupt Line, Interrupt Pin, and Bridge Control registers as defined by the PCI 2.0 Specification and PCI-to-PCI Bridge Architecture Specification, Revision 1.2.

Interrupt Line Interrupt Pin and Bridge Control Registers

Offset: 0x3c | Read/Write: R/W

Bit	R/W	Reset	Description
31:28	R	0	Reserved
27	R	0h	T_PCIE2_RP_INTR_BCR_DIS_TIMER_SERR: Does not apply to PCI Express. Hardwired to 0. 0h: DIS_TIMER_SERR_DISABLED (default) 1h: DIS_TIMER_SERR_ENABLED
26	R	0h	T_PCIE2_RP_INTR_BCR_DIS_TIMER_STATUS: Does not apply to PCI Express. Hardwired to 0. 0h: DIS_TIMER_STATUS_NOT_ACTIVE (default) 1h: DIS_TIMER_STATUS_ACTIVE
25	R	0h	T_PCIE2_RP_INTR_BCR_SECONDARY_DIS_TIMER: Does not apply to PCI Express. Hardwired to 0. 0h: SECONDARY_DIS_TIMER_LONG (default) 1h: SECONDARY_DIS_TIMER_SHORT
24	R	0h	T_PCIE2_RP_INTR_BCR_PRIMARY_DIS_TIMER: Does not apply to PCI Express. Hardwired to 0. 0h: PRIMARY_DIS_TIMER_LONG (default) 1h: PRIMARY_DIS_TIMER_SHORT
23	R	0h	T_PCIE2_RP_INTR_BCR_FAST_B2B: Does not apply to PCI Express. Hardwired to 0. 0h: FAST_B2B_DISABLED (default) 1h: FAST_B2B_ENABLED
22	R/W	0h	T_PCIE2_RP_INTR_BCR_SB_RESET: Setting this bit triggers a hot reset on the corresponding PCI Express Port. 0h: SB_RESET_DISABLED (default) 1h: SB_RESET_ENABLED
21	R	0h	T_PCIE2_RP_INTR_BCR_MABORT: Does not apply to PCI Express. Hardwired to 0. 0h: MABORT_DISABLED (default) 1h: MABORT_ENABLED
20	R/W	0h	T_PCIE2_RP_INTR_BCR_VGA_16BITIO: When enabled, allows full 16-bit decode of I/O address range for VGA. 0h: VGA_16BITIO_DISABLED (default) 1h: VGA_16BITIO_ENABLED
19	R/W	0h	T_PCIE2_RP_INTR_BCR_VGA_ADDRESS: When enabled the P2P bridge will claim all of the legacy VGA addresses. Memory address range: 000A_0000 - 000B_FFFF I/O address ranges: 3B0-3BB, 3C0-3DF (including all aliases if VGA_16BITIO is not set). 0h: VGA_ADDRESS_DISABLED (default) 1h: VGA_ADDRESS_ENABLED
18	R/W	0h	T_PCIE2_RP_INTR_BCR_ISA_ADDRESS: Modifies the response by the bridge to ISA I/O addresses. This applies only to I/O addresses that are enabled by the I/O Base and I/O Limit registers and are in the first 64 KB of PCI I/O address space (0000 0000h to 0000 FFFFh). If this bit is set, the bridge will block any forwarding from primary to secondary of I/O transactions addressing the last 768 bytes in each 1-KB block. 0h: ISA_ADDRESS_DISABLED (default) 1h: ISA_ADDRESS_ENABLED
17	R/W	0h	T_PCIE2_RP_INTR_BCR_SERR_FORWARD: This bit controls forwarding of ERR_COR, ERR_NONFATAL and ERR_FATAL from secondary to primary. 0h: SERR_FORWARD_DISABLED (default) 1h: SERR_FORWARD_ENABLED
16	R/W	0h	T_PCIE2_RP_INTR_BCR_PERR_RESP: This bit controls the response to Poisoned TLPs. 0h: PERR_RESP_DISABLED (default) 1h: PERR_RESP_ENABLED

Bit	R/W	Reset	Description
15:8	R	1h	T_PCIE2_RP_INTR_BCR_INTR_PIN: This field contains the interrupt pin the device (or device function) uses. A value of 1 corresponds to INTA#. A value of 2 corresponds to INTB#. A value of 3 corresponds to INTC#. A value of 4 corresponds to INTD#. Devices (or device functions) that do not use an interrupt pin must put a 0 in this field. 0h: INTR_PIN_NONE 1h: INTR_PIN_INTA (default) 2h: INTR_PIN_INTB 3h: INTR_PIN_INTC 4h: INTR_PIN_INTD
7:0	R/W	0h	T_PCIE2_RP_INTR_BCR_INTR_LINE: This field contains the interrupt routing information. The field must be implemented by any device (or device function) that uses an interrupt pin. POST software will write the routing information into this field as it initializes and configures the system. The value in this field tells which input of the system interrupt controller(s) the device's interrupt pin is connected to. Device drivers and operating systems can use this information to determine priority and vector information. INTR_LINE is written to 0xff (no connection) by software if the bridge does not use an interrupt pin. Some PCI BIOSes cannot handle aliased INTR_LINEs. Some PCI BIOSes cannot handle INTR_LINE initialized to 0xff. 0h: INTR_LINE_IRQ0 (default) 1h: INTR_LINE_IRQ1 Fh: INTR_LINE_IRQ15 FFh: INTR_LINE_UNKNOWN

34.4.2 PCI Subsystem ID and Subsystem Vendor ID Capability Registers

This section lists the PCI Subsystem ID and Subsystem Vendor ID Capabilities List registers as defined in PCI-to-PCI Bridge Architecture Specification, Revision 1.2.

34.4.2.1 T_PCIE2_RP_SS_0

This register implements the first register of the Subsystem ID and Subsystem Vendor ID Capability list item, as defined by the PCI-to-PCI Bridge Architecture Specification, Revision 1.2.

Subsystem ID and Subsystem Vendor ID Capability Register 0

Offset: 0x40 | Read/Write: RO

Bit	Reset	Description
31:16	0	Reserved
15:8	48h	T_PCIE2_RP_SS_0_NEXT_PTR: This read-only field points to the next capabilities list item. 48h: NEXT_PTR_PM (default)
7:0	Dh	T_PCIE2_RP_SS_0_CAP_ID: This read-only field is used to detect the presence of the SSID/SSVID registers in a PCI-to-PCI bridge. Hardwired to 0Dh. Dh: CAP_ID_SS (default)

34.4.2.2 T_PCIE2_RP_SS_1

This register implements the second register of the.Subsystem ID and Subsystem Vendor ID Capability list item, as defined by the PCI-to-PCI Bridge Architecture Specification, Revision 1.2.

Subsystem ID and Subsystem Vendor ID Capability Register 1

Offset: 0x44 | Read/Write: RO

Bit	Reset	Description
31:16	0h	T_PCIE2_RP_SS_1_SSID: The SSID identifies the particular add-in card or subsystem and is assigned by the vendor. 0h: SSID_INIT (default)
15:0	10DEh	T_PCIE2_RP_SS_1_SSVID: The SSVID identifies the manufacturer of the add-in card or subsystem. The SSVID is assigned by PCI-SIG to ensure uniqueness (the Vendor ID is used as the SSVID also). 10DEh: SSVID_INIT (default)

34.4.3 PCI Power Management Capability Structure Registers

This section lists the PCI Power Management Capabilities List registers as defined in PCI Express Base Specification, Revision 3.0.

34.4.3.1 T_PCIE2_RP_PM_0

This register implements the Power Management Capabilities register as defined in Section 7.6 of PCI Express Specifications.

Power Management Capabilities Register

Offset: 0x48 | Read/Write: RO

Bit	Reset	Description
31:27	1Fh	T_PCIE2_RP_PM_0_PME_SUPPORT: This 5-bit field indicates the power states in which the function may assert PME#. A value of 0b for any bit indicates that the function is not capable of asserting the PME# signal while in that power state. bit(11) XXXX1b = PME# can be asserted from D0 bit(12) XXX1Xb = PME# can be asserted from D1 bit(13) XX1XXb = PME# can be asserted from D2 bit(14) X1XXXb = PME# can be asserted from D3hot bit(15) 1XXXXb = PME# can be asserted from D3cold Bits 31, 30, and 27 must be set to 1b for PCI-PCI Bridge structures representing Ports on Root Complexes/ Switches to indicate that the Bridge will forward PME Messages. 1Fh: PME_SUPPORT_YES (default) 0h: PME_SUPPORT_NO
26	0h	T_PCIE2_RP_PM_0_D2_SUPPORT: If this bit is a "1", this function supports the D2 Power Management State. 1h: D2_SUPPORT_YES 0h: D2_SUPPORT_NO (default)
25	0h	T_PCIE2_RP_PM_0_D1_SUPPORT: If this bit is a "1", this function supports the D1 Power Management State. 1h: D1_SUPPORT_YES 0h: D1_SUPPORT_NO (default)
24:22	0h	T_PCIE2_RP_PM_0_AUX_CURRENT: This 3 bit field reports the 3.3Vaux auxiliary current requirements for the PCI function. Bit 3.3Vaux 8 7 6 Max. Current Required 1 1 1 375 mA 1 1 0 320 mA 1 0 1 270 mA 1 0 0 220 mA 0 1 1 160 mA 0 1 0 100 mA 0 0 1 55 mA 0 0 0 0 (self powered) 0h: AUX_CURRENT_0 (default)
21	0h	T_PCIE2_RP_PM_0_DEV_SPEC_INIT: The Device Specific Initialization bit indicates whether special initialization of this function is required (beyond the standard PCI configuration header) before the generic class device driver is able to use it. Note that this bit is not used by some operating systems. Microsoft Windows and Windows NT, for instance, do not use this bit to determine whether to use D3. Instead, they use the driver's capabilities to determine this. A "1" indicates that the function requires a device specific initialization sequence following transition to the D0 uninitialized state. 0h: DEV_SPEC_INIT_NOT_NEEDED (default) 1h: DEV_SPEC_INIT_NEEDED
20	0	Reserved
19	0h	T_PCIE2_RP_PM_0_PME_CLOCK: Does not apply to PCI Express. Must be hardwired to 0. 0h: PME_CLOCK_NOT_NEEDED (default) 1h: PME_CLOCK_NEEDED

Bit	Reset	Description
18:16	3h	T_PCIE2_RP_PM_0_PCIPM_REV: A value of 010b indicates that this function complies with Revision 1.1 of the PCI Power Management Interface Specification. 3h: PCIPM_REV_12 (default) 2h: PCIPM_REV_11
15:8	50h	T_PCIE2_RP_PM_0_NEXT_PTR: This read-only field points to the next capabilities list item. 50h: NEXT_PTR_MSI (default)
7:0	1h	T_PCIE2_RP_PM_0_CAP_ID: This read-only field is used to detect the presence of the Power Management Capability registers in a PCI-to-PCI bridge. Hardwired to 01h. 1h: CAP_ID_PM (default)

34.4.3.2 T_PCIE2_RP_PM_1

This register implements the Power Management Status/Control register as defined in Section 7.6 of PCI Express Specification.

Power Management Status/Control Register

Offset: 0x4c | Read/Write: R/W

Bit	R/W	Reset	Description
31:24	R	0h	T_PCIE2_RP_PM_1_PME_DATA: The PME Data register is not implemented. Hardwired to 0. 0h: PME_DATA_UNS (default)
23	R	0h	T_PCIE2_RP_PM_1_PME_BPCC: The bus power/clock control mechanism is not used. Hardwired to 0. 0h: PME_BPCC_UNS (default)
22	R	0h	T_PCIE2_RP_PM_1_PME_B2B3: The bus power/clock control mechanism is not used. Therefore the B2/B3 support bit is hardwired to 0. 0h: PME_B2B3_UNS (default)
21:16	R	0	Reserved
15	RW1C	0h	T_PCIE2_RP_PM_1_PME_STATUS: This bit is set when the function would normally assert the PME# signal independent of the state of the PME_En bit. Writing a "1" to this bit will clear it and cause the function to stop asserting a PME# (if enabled). Writing a "0" has no effect. This bit is sticky and must be explicitly cleared by the operating system each time the operating system is initially loaded. NOTE: This field is reset by Cold Reset 0h: PME_STATUS_NOT_ACTIVE (default) 1h: PME_STATUS_ACTIVE 1h: PME_STATUS_SET
14:13	R	0h	T_PCIE2_RP_PM_1_PME_DATA_SCALE: The PME Data register is not implemented. Hardwired to 0. 0h: PME_DATA_SCALE_UNS (default)
12:9	R	0h	T_PCIE2_RP_PM_1_PME_DATA_SEL: The PME Data register is not implemented. Hardwired to 0. 0h: PME_DATA_SEL_UNS (default)
8	R/W	0h	T_PCIE2_RP_PM_1_PME: A "1" enables the function to assert PME#. When "0", PME# assertion is disabled. This bit is sticky and must be explicitly cleared by the operating system each time it is initially loaded. NOTE: This field is reset by Cold Reset 0h: PME_DISABLE (default) 1h: PME_ENABLE
7:2	R	0	Reserved

Bit	R/W	Reset	Description
1:0	R/W	0h	T_PCIE2_RP_PM_1_PWR_STATE: This 2-bit field is used both to determine the current power state of a function and to set the function into a new power state. The definition of the field values is given below. 00b - D0 01b - D1 10b - D2 11b - D3hot If software attempts to write an unsupported, optional state to this field, the write operation must complete normally on the bus; however, the data is discarded and no state change occurs. 0h: PWR_STATE_D0 (default) 1h: PWR_STATE_D1 2h: PWR_STATE_D2 3h: PWR_STATE_D3HOT

34.4.4 PCI MSI Capability Structure Registers

This section lists the PCI MSI Capabilities List registers as defined in PCI Local Bus Specification, Revision 2.0.

34.4.4.1 T_PCIE2_RP_MSI_CTRL

The MSI capability structure is required for all PCI Express devices that are capable of generating interrupts.

MSI enables a device to request service by writing a system-specified message to a system-specified address. The transaction address specifies the message destination and the transaction data specifies the message. System software initializes the message destination and message during device configuration.

MSI Control and Capability Registers

Offset: 0x50 | Read/Write: R/W

Bit	R/W	Reset	Description
31:24	R	0h	T_PCIE2_RP_MSI_CTRL_RSVD: The RSVD field is reserved by the specification. 0h: RSVD_0 (default)
23	R	1h	T_PCIE2_RP_MSI_CTRL_64BIT_CAP: The 64BIT_CAP field indicates if the function is capable of generating a 64-bit message address. If 1, the function is capable. 1h: 64BIT_CAP_TRUE (default)
22:20	R/W	0h	T_PCIE2_RP_MSI_CTRL_MULT_EN: The MULT_EN field indicates the number of allocated messages. It is always aligned to a power of 2. 0h: MULT_EN_CODE0 (default) 1h: MULT_EN_CODE2 2h: MULT_EN_CODE4 3h: MULT_EN_CODE8
19:17	R	1h	T_PCIE2_RP_MSI_CTRL_MULT_CAP: The MULT_CAP field determines the number of requested messages. It should always be a power of 2. 1h: MULT_CAP_CODE2 (default)
16	R/W	0h	T_PCIE2_RP_MSI_CTRL_MSI: The MSI bit controls if the function is permitted to use message signaled interrupt to request service. If 1, the function is permitted to use MSI and prohibits the use of INTx messages. 0h: MSI_DISABLE (default) 1h: MSI_ENABLE
15:8	R	None	T_PCIE2_RP_MSI_CTRL_NEXT_PTR: The NEXT_PTR field points to the next item in the capabilities list. 60h: NEXT_PTR_MSIMAP 80h: NEXT_PTR_PCIEXP
7:0	R	5h	T_PCIE2_RP_MSI_CTRL_CAP_ID: This read-only field is used to detect the presence of the Message Signaled Interrupt Capability registers in a PCI-to-PCI bridge. Hardwired to 05h. 5h: CAP_ID_MSI (default)

34.4.4.2 T_PCIE2_RP_MSI_LOW_ADDR

The contents of this register specify the lower 32 bits of the Dword aligned address for the MSI memory write transaction.

MSI Message Lower Address Register

Offset: 0x54 | Read/Write: R/W

Bit	R/W	Reset	Description
31:2	R/W	0h	T_PCIE2_RP_MSI_LOW_ADDR_DWORD: Bits 31:2 of the address. 0h: DWORD_0 (default)
1:0	R	0h	T_PCIE2_RP_MSI_LOW_ADDR_RSVD: The address is always DWORD aligned, hence bits 1:0 of this register are hardwired to 0. 0h: RSVD_0 (default)

34.4.4.3 T_PCIE2_RP_MSI_UPPER_ADDR

The contents of this register specify the upper 32 bits of the 64-bit MSI message address.

MSI Message Upper Address Register

Offset: 0x58 | Read/Write: R/W

Bit	Reset	Description
31:0	0h	T_PCIE2_RP_MSI_UPPER_ADDR_DWORD: Bits 63:32 of the address. 0h: DWORD_0 (default)

34.4.4.4 T_PCIE2_RP_MSI_DATA

The contents of this register specify the data that is written to the MSI message address.

MSI Message Data Register

Offset: 0x5c | Read/Write: R/W

Bit	R/W	Reset	Description
31:16	R	0h	T_PCIE2_RP_MSI_DATA_RSVD: 0h: RSVD_0 (default)
15:0	R/W	0h	T_PCIE2_RP_MSI_DATA_DATA: The MSI message data. 0h: DATA_0 (default)

34.4.5 PCI Express Capability Structure Registers

This section list the PCI Express Capability List registers as defined in PCI Express Base Specification, Revision 3.0.

34.4.5.1 T_PCIE2_RP_PCI_EXPRESS_CAPABILITY

The PCI Express Capability List register enumerates the PCI Express Capability Structure in PCI 2.3 configuration space capability list. It also identifies PCI Express device type and associated capabilities.

PCI Express Capability List Register

Offset: 0x80 | Read/Write: RO

Bit	Reset	Description
31:30	0	Reserved

Bit	Reset	Description
29:25	0h	T_PCIE2_RP_PCI_EXPRESS_CAPABILITY_INTERRUPT_MESSAGE_NUMBER: If this function is allocated more than one MSI interrupt number, this register is required to contain the offset between the base Message Data and the MSI Message that is generated when any of the status bits in either the Slot Status register or the Root Port Status register of this capability structure are set. Hardware is required to update this field so that it is correct if the number of the MSI Messages assigned to the device changes. 0h: INTERRUPT_MESSAGE_NUMBER_ZERO (default)
24	1h	T_PCIE2_RP_PCI_EXPRESS_CAPABILITY_SLOT_IMPLEMENTED: This bit when set indicates that the PCI Express Link associated with this port is connected to a slot (as compared to being connected to an integrated component or being disabled). This field is valid for the following PCI Express device/Port Types: * Root Port of PCI Express Root Complex. * Downstream Port of PCI Express Switch. 1h: SLOT_IMPLEMENTED_INIT (default)
23:20	4h	T_PCIE2_RP_PCI_EXPRESS_CAPABILITY_DEVICE_PORT_TYPE: Indicates the type of PCI Express logical device. Defined encodings are: 0000b = PCI Express Endpoint device. 0001b = Legacy PCI Express Endpoint device. 0100b = Root Port of PCI Express Root Complex. 0101b = Upstream Port of PCI Express Switch. 0110b = Downstream Port of PCI Express Switch. 0111b = PCI Express-to-PCI/PCI-X Bridge. 1000b = PCI/PCI-X to PCI Express Bridge 4h: DEVICE_PORT_TYPE_INIT (default)
19:16	2h	T_PCIE2_RP_PCI_EXPRESS_CAPABILITY_VERSION: Indicates PCI_SIG defined PCI Express capability structure version number. Must be 1h for versions 1.0a and 1.1 of the PCI-Express Specification. Must be 2h for devices compliant to the Express Capabilities Register Expansion ECN. 2h: VERSION_INIT (default) 1h: VERSION_1 2h: VERSION_2
15:8	0h	T_PCIE2_RP_PCI_EXPRESS_CAPABILITY_LIST_NEXT_CAPABILITY_PTR: The offset to the next PCI capability structure or 0h if no other items exist in the linked list of capabilities. 0h: LIST_NEXT_CAPABILITY_PTR_INIT (default)
7:0	10h	T_PCIE2_RP_PCI_EXPRESS_CAPABILITY_LIST_CAPABILITY_ID: Indicates PCI Express Capability Structure. This field must return a Capability ID of 10h indicating that this is a PCI Express Capability Structure. 10h: LIST_CAPABILITY_ID_INIT (default)

34.4.5.2 T_PCIE2_RP_DEVICE_CAPABILITY

The Device Capabilities register identifies PCI Express device specific capabilities.

Device Capabilities Register

Offset: 0x84 | Read/Write: RO

Bit	Reset	Description
31:28	0	Reserved
27:26	0h	T_PCIE2_RP_DEVICE_CAPABILITY_CAPTURED_SLOT_POWER_LIMIT_SCALE: Specifies the scale used for the Slot Power Limit Value. Range of Values: 00b = 1.0x 01b = 0.1x 11b = 0.01x 11b = 0.001x This value is set by the Set_Slot_Power_Limit message or hardwired to 00b. The default value is all 00b. 0h: CAPTURED_SLOT_POWER_LIMIT_SCALE_INIT (default)
25:18	0h	T_PCIE2_RP_DEVICE_CAPABILITY_CAPTURED_SLOT_POWER_LIMIT_VALUE: In combination with the Slot Power Limit Scale value, specifies the upper limit on power supplied by slot. Power limit (in Watts) is calculated by multiplying the value in this field by the value in the Slot Power Limit Scale field. This value is set by the Set_Slot_Power_Limit message or hardwired to 0000_0000b. The default value is 0000_0000b. 0h: CAPTURED_SLOT_POWER_LIMIT_VALUE_INIT (default)

Bit	Reset	Description
17:16	0	Reserved
15	1h	T_PCIE2_RP_DEVICE_CAPABILITY_ROLE_BASED_ERR_REPORTING: This bit, when set, indicates that the device implements the functionality originally defined in the Error Reporting ECN for PCI Express Base Specification 1.0a and later incorporated into PCI Express Base Specification 1.1. 1h: ROLE_BASED_ERR_REPORTING_INIT (default)
14	0h	T_PCIE2_RP_DEVICE_CAPABILITY_POWER_INDICATOR_PRESENT: This bit, when set, indicates that a Power Indicator is implemented on the card or module. 0h: POWER_INDICATOR_PRESENT_INIT (default)
13	0h	T_PCIE2_RP_DEVICE_CAPABILITY_ATTENTION_INDICATOR_PRESENT: This bit, when set, indicates that an Attention Indicator is implemented on the card or module. 0h: ATTENTION_INDICATOR_PRESENT_INIT (default)
12	0h	T_PCIE2_RP_DEVICE_CAPABILITY_ATTENTION_BUTTON_PRESENT: This bit when set indicates that an Attention Button is implemented on the card or module. 0h: ATTENTION_BUTTON_PRESENT_INIT (default)
11:9	0h	T_PCIE2_RP_DEVICE_CAPABILITY_ENDPOINT_L1_ACCEPTABLE_LATENCY: This field indicates acceptable latency that an Endpoint can withstand due to the transition from L1 state to the L0 state. It is essentially an indirect measure of the Endpoint's internal buffering. 000b -- Less than 1 µs. 001b -- 1 µs to less than 2 µs. 010b -- 2 µs to less than 4 µs. 011b -- 4 µs to less than 8 us. 100b – 8 µs to less than 16 µs. 101b -- 16 µs to less than 32 µs. 110b -- 32 µs-64 µs. 111b -- More than 64 µs. 0h: ENDPOINT_L1_ACCEPTABLE_LATENCY_INIT (default)
8:6	0h	T_PCIE2_RP_DEVICE_CAPABILITY_ENDPOINT_L0S_ACCEPTABLE_LATENCY: This field indicates the acceptable total latency that an Endpoint can withstand due to the transition from L0s state to the L0 state. It is essentially an indirect measure of the Endpoint's internal buffering. 000b -- Less than 64 ns. 001b -- 64 ns to less than 128 ns. 010b -- 128 ns to less than 256 ns. 011b -- 256 ns to less than 512 ns. 100b -- 512 ns to less than 1 µs. 101b -- 1 µs to less than 2 µs. 110b -- 2 µs-4µs. 111b -- More than 4 µs. 0h: ENDPOINT_L0S_ACCEPTABLE_LATENCY_INIT (default)
5	None	T_PCIE2_RP_DEVICE_CAPABILITY_EXTENDED_TAG_FIELD_SIZE: This field indicates the maximum supported size of the Tag field. Defined encodings are: 0b = 5-bit Tag field supported. 1b = 8-bit Tag field supported.
4:3	0h	T_PCIE2_RP_DEVICE_CAPABILITY_PHANTOM_FUNCTIONS_SUPPORTED: This field indicates the support for use of unclaimed function numbers to extend the number of outstanding transactions allowed by logically combining unclaimed function numbers (called Phantom Functions) with the Tag identifier. This field indicates the number of most significant bits of the function number portion of Requester ID that are logically combined with the Tag identifier. Defined encodings are: 00b -- No function number bits used for Phantom Functions; device may implement all function numbers. 01b -- First most significant bit of the function number in Requester ID used for Phantom Functions; device may implement functions 0-3. Functions 0, 1, 2 and 3 may claim functions 4, 5, 6, and 7 as Phantom Functions respectively. 10b -- First two most significant bits of the function number in Requester ID used for Phantom Functions; device may implement functions 0-1. Function 0 may claim functions 2, 4 and 6 as Phantom Functions, function 1 may claim functions 3, 5 and 7 as Phantom Functions. 11b -- All three bits of function number in Requester ID used for Phantom Functions; device must be a single function 0 device that may claim all other functions as Phantom Functions. Note: The Phantom Function support for the device must be enabled by the corresponding control field in the Device Control Register. 0h: PHANTOM_FUNCTIONS_SUPPORTED_INIT (default)

Bit	Reset	Description
2:0	0h	T_PCIE2_RP_DEVICE_CAPABILITY_MAX_PAYLOAD_SIZE: This field indicates the maximum payload size that the device can support for TLP's. 000b --128B maximum payload size 001b -- 256B maximum payload size 010b -- 512B maximum payload size 011b -- 1024B maximum payload size 100b -- 2048B maximum payload size 101b -- 4096B maximum payload size 110b -- Reserved 111b -- Reserved 0h: MAX_PAYLOAD_SIZE_INIT (default)

34.4.5.3 T_PCIE2_RP_DEVICE_CONTROL_STATUS

The Device Control register controls PCI Express device specific parameters. It also provides information about PCI Express device specific parameters.

Device Control and Device Status Registers

Offset: 0x88 | Read/Write: R/W

Bit	R/W	Reset	Description
31:22	R	0	Reserved
21	R	0h	T_PCIE2_RP_DEVICE_CONTROL_STATUS_TRANSACTIONS_PENDING: This bit when set indicates that a device has issued Non Posted requests which have not been completed. A device reports this bit cleared only when all Completions for any outstanding Non-Posted Requests have been received. 0h: TRANSACTIONS_PENDING_INIT (default)
20	R	0h	T_PCIE2_RP_DEVICE_CONTROL_STATUS_AUX_POWER_DETECTED: Devices that require AUX power report this bit as set if AUX power is detected by the device. 0h: AUX_POWER_DETECTED_INIT (default)
19	RW1C	0h	T_PCIE2_RP_DEVICE_CONTROL_STATUS_UNSUPP_REQUEST_DETECTED: This bit indicates that the device received an Unsupported Request. Errors are logged in this register regardless of whether error reporting is enabled or not in the Device Control Register. NOTE: This field is reset by Cold Reset 0h: UNSUPP_REQUEST_DETECTED_INIT (default) 1h: UNSUPP_REQUEST_DETECTED_SET
18	RW1C	0h	T_PCIE2_RP_DEVICE_CONTROL_STATUS_FATAL_ERROR_DETECTED: This bit indicates status of fatal errors detected. Errors are logged in this register regardless of whether error reporting is enabled or not in the Device Control register. For devices supporting Advanced Error Handling, errors are logged in this register regardless of the settings of the correctable error mask register. 0h: FATAL_ERROR_DETECTED_INIT (default) 1h: FATAL_ERROR_DETECTED_SET
17	RW1C	0h	T_PCIE2_RP_DEVICE_CONTROL_STATUS_NON_FATAL_ERROR_DETECTED: This bit indicates status of non-fatal errors detected. Errors are logged in this register regardless of whether error reporting is enabled or not in the Device Control register. For devices supporting Advanced Error Handling, errors are logged in this register regardless of the settings of the correctable error mask register. NOTE: This field is reset by Cold Reset 0h: NON_FATAL_ERROR_DETECTED_INIT (default) 1h: NON_FATAL_ERROR_DETECTED_SET
16	RW1C	0h	T_PCIE2_RP_DEVICE_CONTROL_STATUS_CORR_ERROR_DETECTED: This bit indicates status of correctable errors detected. Errors are logged in this register regardless of whether error reporting is enabled or not in the Device Control register. For devices supporting Advanced Error Handling, errors are logged in this register regardless of the settings of the correctable error mask register. Default value of this field is 0. NOTE: This field is reset by Cold Reset 0h: CORR_ERROR_DETECTED_INIT (default) 1h: CORR_ERROR_DETECTED_SET
15	R	0	Reserved

Bit	R/W	Reset	Description
14:12	R/W	2h	T_PCIE2_RP_DEVICE_CONTROL_STATUS_MAX_READ_REQUEST_SIZE: This field sets the maximum Read Request size for the Device as a Requester. The Device must not generate read requests with size exceeding the set value. Defined encodings for this field are: 000b -- 128B maximum payload size 001b -- 256B maximum payload size 010b -- 512B maximum payload size 011b -- 1024B maximum payload size 100b -- 2048B maximum payload size 101b -- 4096B maximum payload size 110b -- Reserved 111b – Reserved Devices that do not generate Read Requests larger than 128 bytes are permitted to implement this field as Read Only (RO) with: a value of 000b. 2h: MAX_READ_REQUEST_SIZE_INIT (default)
11	R/W	1h	T_PCIE2_RP_DEVICE_CONTROL_STATUS_ENABLE_NO_SNOOP: If this bit is set to 1, the device is permitted to set the No Snoop Bit in the Requester Attributes of transactions it initiates that do not require hardware enforced cache coherency. Even when this bit is set to 1, a device may only set the No Snoop attribute on a transaction when it can guarantee that the address of the transaction is not stored in any cache in the system. This bit may be hardwired to 0 if a device never sets the No Snoop attribute in transactions it initiates. 1h: ENABLE_NO_SNOOP_INIT (default)
10	R/W	0h	T_PCIE2_RP_DEVICE_CONTROL_STATUS_AUXILLARY_POWER_PM_ENABLE: This bit when set enables a device to draw AUX power independent of PME AUX power. AUX power is allocated as requested in the AUX_Current field of the Power Management Capabilities Register (PMC), independent of the PME_En bit in the Power Management Control/Status Register (PMCSR). For multi-function devices, a component is allowed to draw AUX power if at least one of the functions has this bit set. Devices that do not implement this capability hardwire this bit to 0. NOTE: This field is reset by Cold Reset 0h: AUXILLARY_POWER_PM_ENABLE_INIT (default)
9	R	0h	T_PCIE2_RP_DEVICE_CONTROL_STATUS_PHANTOM_FUNCTIONS_ENABLE: When set, this bit enables a device to use unclaimed functions as Phantom Functions to extend the number of outstanding transaction identifiers. If the bit is cleared, the device is not allowed to use Phantom Functions. Devices that do not implement this capability hardwire this bit to 0. 0h: PHANTOM_FUNCTIONS_ENABLE_INIT (default)
8	R/W	0h	T_PCIE2_RP_DEVICE_CONTROL_STATUS_EXTENDED_TAG_FIELD_ENABLE: When set, this bit enables a device to use an 8-bit Tag field as a requester. If the bit is cleared, the device is restricted to a 5-bit Tag field. Devices that do not implement this capability hardwire this bit to 0. 0h: EXTENDED_TAG_FIELD_ENABLE_INIT (default)
7:5	R/W	0h	T_PCIE2_RP_DEVICE_CONTROL_STATUS_MAX_PAYLOAD_SIZE: This field sets the maximum TLP payload size for the device. As a receiver, the device must handle TLP's as large as the set value; as transmitter, the device must not generate TLPs exceeding the set value. Permissible values that can be programmed are indicated by the Max_Payload_Size supported in the Device Capabilities register. Defined encodings for this field are: • 000b -- 128B maximum payload size • 001b -- 256B maximum payload size • 010b -- 512B maximum payload size • 011b -- 1024B maximum payload size • 100b -- 2048B maximum payload size • 101b -- 4096B maximum payload size • 110b -- Reserved • 111b -- Reserved 0h: MAX_PAYLOAD_SIZE_INIT (default)
4	R/W	1h	T_PCIE2_RP_DEVICE_CONTROL_STATUS_ENABLE_RELAXED_ORDERING: If this bit is set, the device is permitted to set the Relaxed Ordering bit in the Attributes field of transactions it initiates that do not require strong write ordering. This bit may be hardwired to 0 if a device never sets the Relaxed Ordering Attribute in transactions it initiates as a requester. 1h: ENABLE_RELAXED_ORDERING_INIT (default)

Bit	R/W	Reset	Description
3	R/W	0h	T_PCIE2_RP_DEVICE_CONTROL_STATUS_UNSUPP_REQ_REPORTING_ENABLE: This bit enables reporting of Unsupported Requests when set. For a multi-function device, this bit controls error reporting for each function from point-of-view of the respective function. Note: The reporting of error messages (ERR_COR, ERR_NONFATAl, ERR_FATAL) received by Root Port is controlled exclusively by Root Control Register. 0h: UNSUPP_REQ_REPORTING_ENABLE_INIT (default)
2	R/W	0h	T_PCIE2_RP_DEVICE_CONTROL_STATUS_FATAL_ERROR_REPORTING_ENABLE: This bit controls reporting of fatal errors. For a multi-function device, this bit controls error reporting for each function from point-of-view of the respective function. 0h: FATAL_ERROR_REPORTING_ENABLE_INIT (default)
1	R/W	0h	T_PCIE2_RP_DEVICE_CONTROL_STATUS_NON_FATAL_ERROR_REPORTING_ENABLE: This bit controls reporting of non-fatal errors. For a multi-function device, this bit controls error reporting for each function from point-of-view of the respective function. 0h: NON_FATAL_ERROR_REPORTING_ENABLE_INIT (default)
0	R/W	0h	T_PCIE2_RP_DEVICE_CONTROL_STATUS_CORR_ERROR_REPORTING_ENABLE: This bit controls reporting of correctable errors. For a multi-function device, this bit controls error reporting for each function from point-of-view of the respective function. 0h: CORR_ERROR_REPORTING_ENABLE_INIT (default)

34.4.5.4 T_PCIE2_RP_LINK_CAPABILITIES

The Link Capabilities Register identifies PCI Express Link specific capabilities.

Link Capabilities Register

Offset: 0x8c | Read/Write: RO

Bit	Reset	Description
31:24	None	T_PCIE2_RP_LINK_CAPABILITIES_PORT_NUMBER: This field indicates the PCI Express port number for the given PCI Express Link.
23:22	None	T_PCIE2_RP_LINK_CAPABILITIES_RESERVED: Reserved.
21	0h	T_PCIE2_RP_LINK_BW_NOTIFY: 0h: INIT (default)
20	1h	T_PCIE2_RP_LINK_CAPABILITIES_LINKACTV_REPORTING: For a Downstream Port, this bit must be set to 1b if the component supports the optional capability of reporting the DL_Active state of the Data Link Control and Management State Machine. For a hot-plug capable Downstream Port (as indicated by the Hot-Plug Capable field of the Slot Capabilities register), this bit must be set to 1b. 1h: LINKACTV_REPORTING_INIT (default)
19	0h	T_PCIE2_RP_LINK_CAPABILITIES_SURPRISE_DOWN_ERPT_CAP: For a Downstream Port, this bit must be set to 1b if the component supports the optional capability of detecting and reporting a Surprise Down error condition. 0h: SURPRISE_DOWN_ERPT_CAP_INIT (default)
18	0h	T_PCIE2_RP_LINK_CAPABILITIES_CLOCK_PM: 0h: CLOCK_PM_INIT (default)
17:15	2h	T_PCIE2_RP_LINK_CAPABILITIES_L1_EXIT_LATENCY: This field indicates the L1 exit latency for the given PCI Express Link. The value reported indicates the length of time this Port requires to complete transition from L1 to L0. Defined encodings are: 000b -- Less than 1 µs. 001b -- 1 µs to less than 2 µs. 010b -- 2 µs to less than 4 µs. 011b -- 4 µs to less than 8 µs. 100b -- 8 µs to less than 16 µs. 101b -- 16 µs to less than 32 µs. 110b -- 32 µs-64 µs. 111b -- More than 64 us. 2h: L1_EXIT_LATENCY_INIT (default)

Bit	Reset	Description
14:12	3h	T_PCIE2_RP_LINK_CAPABILITIES_L0S_EXIT_LATENCY: This field indicates the L0s exit latency for the given PCI Express Link. The value reported indicates the length of time this Port requires to complete transition from L0s state to L0. Defined encodings are: 000b -- Less than 64 ns. 001b -- 64 ns to less than 128 ns. 010b -- 128 ns to less than 256 ns. 011b -- 256 ns to less than 512 ns. 100b -- 512 ns to less than 1 µs. 101b -- 1 µs to less than 2 µs. 110b -- 2 µs-4 µs. 111b -- Reserved. 3h: L0S_EXIT_LATENCY_INIT (default)
11:10	11h	T_PCIE2_RP_LINK_CAPABILITIES_ACTIVE_STATE_LINK_PM_SUPPORT: This field indicates the level of active state power management supported on the given PCI Express Link. Defined encodings are: 00b -- Reserved 01b -- L0s Entry Supported 10b -- Reserved 11b -- L0s and L1 Supported 11h: ACTIVE_STATE_LINK_PM_SUPPORT_INIT (default)
9:4	None	T_PCIE2_RP_LINK_CAPABILITIES_MAX_LINK_WIDTH: This field indicates the maximum width of the given PCI Express Link. Defined encodings are: 000000b -- Reserved 000001b -- x1 000010b -- x2 000100b -- x4 001000b -- x8 001100b -- x12 010000b -- x16 100000b -- x32
3:0	2h	T_PCIE2_RP_LINK_CAPABILITIES_MAX_LINK_SPEED: This field indicates the maximum link speed of the given PCI Express Link. Defined encodings are: 0001b = 2.5 Gb/s Link All other encodings are reserved. 2h: MAX_LINK_SPEED_INIT (default)

34.4.5.5 T_PCIE2_RP_LINK_CONTROL_STATUS

The Link Control register controls PCI Express Link specific parameters. It also provides information about PCI Express Link specific parameters.

Link Control and Link Status Registers

Offset: 0x90 | Read/Write: R/W

Bit	R/W	Reset	Description
31	RW1C	0h	T_PCIE2_RP_LINK_CONTROL_STATUS_AUTO_BANDWIDTH
30	RW1C	0h	T_PCIE2_RP_LINK_CONTROL_STATUS_BW_MANAGEMENT
29	R	None	T_PCIE2_RP_LINK_CONTROL_STATUS_DL_LINK_ACTIVE: This bit indicates the status of the Data Link Control and Management State Machine. It returns a 1b to indicate the DL_Active state, 0b otherwise. This bit must be implemented if the corresponding Data Link Layer Active Capability bit is implemented. Otherwise, this bit must be hardwired to 0b.
28	R	None	T_PCIE2_RP_LINK_CONTROL_STATUS_SLOT_CLOCK_CONFIG: This bit indicates that the component uses the same physical reference clock that the platform provides on the connector. If the device uses an independent clock irrespective of the presence of a reference on the connector, this bit must be clear.
27	R	None	T_PCIE2_RP_LINK_CONTROL_STATUS_LINK_TRAINING: This read-only bit indicates that Link training is in progress; hardware clears this bit once training is complete. Note: This field is not applicable and reserved for endpoint devices and Upstream Ports of Switches.

Bit	R/W	Reset	Description
26	R	None	T_PCIE2_RP_LINK_CONTROL_STATUS_UNDEFINED: The value read from this bit is undefined. In previous versions of this specification, this bit was used to indicate a Link Training Error. System software must ignore the value read from this bit. System software is permitted to write any value to this bit.
25:20	R	None	T_PCIE2_RP_LINK_CONTROL_STATUS_NEG_LINK_WIDTH: This field indicates the negotiated width of the given PCI Express Link. Defined encodings are: 000001b -- x1 000010b -- x2 000100b -- x4 001000b -- x8 001100b -- x12 010000b -- x16 100000b -- x32
19:16	R	1h	T_PCIE2_RP_LINK_CONTROL_STATUS_LINK_SPEED: This field indicates the negotiated Link Speed of the given PCI Express Link. Defined encodings are: 0001b = 2.5 Gb/s PCI Express Link 0010b = 5.0 Gb/s PCI Express Link All other encodings are reserved. 1h: LINK_SPEED_GEN1 (default) 2h: LINK_SPEED_GEN2 (default)
15:12	R	0	Reserved
11	R/W	0h	T_PCIE2_RP_LINK_CONTROL_STATUS_AUTO_BANDWIDTH_INT_EN: 0h: AUTO_BANDWIDTH_INT_EN_INIT (default)
10	R/W	0h	T_PCIE2_RP_LINK_CONTROL_STATUS_BW_MANAGEMENT_INT_EN: 0h: BW_MANAGEMENT_INT_EN_INIT (default)
9	R/W	0h	T_PCIE2_RP_LINK_CONTROL_STATUS_HW_AUTO_WIDTH_DISABLE: 0h: HW_AUTO_WIDTH_DISABLE_DEFAULT (default)
8	R	0h	T_PCIE2_RP_LINK_CONTROL_STATUS_CLOCK_PM: 0h: CLOCK_PM_DEFAULT (default)
7	R/W	0h	T_PCIE2_RP_LINK_CONTROL_STATUS_EXTENDED_SYNCH: This bit when set forces extended transmission of FTS ordered sets in FTS and extra TS2 at exit from L1 prior to entering L0. This mode provides external devices monitoring the link time to achieve bit and symbol lock before the link enters L0 state and resumes communication. Default value for this bit is 0. 0h: EXTENDED_SYNCH_INIT (default)
6	R/W	0h	T_PCIE2_RP_LINK_CONTROL_STATUS_COMMON_CLOCK_CONFIGURATION: This bit when set indicates that this component and the component at the opposite end of this Link are operating with a distributed common reference clock. A value of 0 indicates that this component and the component at the opposite end of this Link are operating with asynchronous reference clock. Components utilize this common clock configuration information to report the correct L0s and L1 Exit Latencies. 0h: COMMON_CLOCK_CONFIGURATION_INIT (default)
5	R	0h	T_PCIE2_RP_LINK_CONTROL_STATUS_RETRAIN_LINK: This bit initiates Link retraining when set. This field is not applicable and reserved for endpoint devices and Upstream Ports of a Switch. This bit always returns 0 when read. 0h: RETRAIN_LINK_INIT (default)
4	R/W	0h	T_PCIE2_RP_LINK_CONTROL_STATUS_LINK_DISABLE: This bit disables the Link when set to 1b. This field is not applicable and reserved for endpoint devices and Upstream Ports of a Switch. Writes to this bit are immediately reflected in the value read from the bit, regardless of the actual Link State. 0h: LINK_DISABLE_INIT (default)
3	R	0h	T_PCIE2_RP_LINK_CONTROL_STATUS_READ_COMPLETION_BOUNDARY: Encodings are: 0b = 64 byte 1b = 128 byte This field is hardwired for a Root Port and returns its RCB support capabilities. Devices that do not implement this feature must hardwire the field to 0b. This field is R/W for devices other than Root Ports. 0h: READ_COMPLETION_BOUNDARY_INIT (default)
2	R	0	Reserved

Bit	R/W	Reset	Description
1:0	R/W	0h	T_PCIE2_RP_LINK_CONTROL_STATUS_ACTIVE_STATE_LINK_PM_CONTROL: This field controls the level of active state PM supported on the given PCI Express Link. Defined encodings are: 00b -- Reserved 01b -- L0s Entry Supported 10b -- Reserved 11b -- L0s and L1 Supported 0h: ACTIVE_STATE_LINK_PM_CONTROL_INIT (default)

34.4.5.6 T_PCIE2_RP_SLOT_CAPABILITIES

The Slot Capabilities register identifies PCI Express slot specific capabilities.

Slot Capabilities Register

Offset: 0x94 | Read/Write: RO

Bit	Reset	Description
31:19	None	T_PCIE2_RP_SLOT_CAPABILITIES_PHYSICAL_SLOT_NUMBER: This hardware initialized field indicates the physical slot number attached to this Port. This field must be hardware initialized to a value that assigns a slot number that is globally unique within the chassis. These registers should be initialized to 0 for ports connected to devices that are either integrated on the system board or integrated within the same silicon as the Switch device or Root Port.
18	0h	T_PCIE2_RP_SLOT_CAPABILITIES_NO_CMD_COMPLETED_SUPPORT: When set to 1, this bit indicates that this slot does not generate software notification when an issued command is completed by the Hot Plug Controller. 0h: NO_CMD_COMPLETED_SUPPORT_INIT (default)
17	0h	T_PCIE2_RP_SLOT_CAPABILITIES_ELECTROMECHANICAL_INTERLOCK_PRESENT: Indicates that the ElectroMechanical Interlock mechanism is implemented. 0h: ELECTROMECHANICAL_INTERLOCK_PRESENT_NO (default)
16:15	None	T_PCIE2_RP_SLOT_CAPABILITIES_SLOT_POWER_LIMIT_SCALE: This field Specifies the scale used for the Slot Power Limit Value. Range of values: 00b = 1.0x 01b = 0.1x 10b = 0.01x 11b = 0.001x This field must be implemented if the Slot Implemented bit is set. The default value prior to hardware/firmware initialization is 00b.
14:7	None	T_PCIE2_RP_SLOT_CAPABILITIES_SLOT_POWER_LIMIT_VALUE: In combination with the Slot Power Limit Scale value, this field specifies the upper limit on power supplied by slot. Power limit (in watts) is calculated by multiplying the value in this field by the value in the Slot Power Limit Scale field. This field must be implemented if the Slot Implemented bit is set. The default value prior to hardware/firmware initialization is 0000_0000b.
6	0h	T_PCIE2_RP_SLOT_CAPABILITIES_HOT_PLUG_CAPABLE: This bit when set indicates that this slot is capable of supporting Hot-plug operations. 0h: HOT_PLUG_CAPABLE_NO (default)
5	0h	T_PCIE2_RP_SLOT_CAPABILITIES_HOT_PLUG_SURPRISE: This bit when set indicates that a device present in this slot might be removed from the system without any prior notification. 0h: HOT_PLUG_SURPRISE_NO (default)
4	0h	T_PCIE2_RP_SLOT_CAPABILITIES_POWER_INDICATOR_PRESENT: This bit when set indicates that a Power Indicator is implemented on the chassis for this slot. 0h: POWER_INDICATOR_PRESENT_NO (default)
3	0h	T_PCIE2_RP_SLOT_CAPABILITIES_ATTENTION_INDICATOR_PRESENT: This bit when set indicates that an Attention Indicator is implemented on the chassis for this slot. 0h: ATTENTION_INDICATOR_PRESENT_NO (default)
2	0h	T_PCIE2_RP_SLOT_CAPABILITIES_MRL_SENSOR_PRESENT: This bit when set indicates that an Attention Indicator is implemented on the chassis for this slot. 0h: MRL_SENSOR_PRESENT_NO (default)
1	0h	T_PCIE2_RP_SLOT_CAPABILITIES_POWER_CONTROLLER_PRESENT: This bit when set indicates that a Power Controller is implemented for this slot. 0h: POWER_CONTROLLER_PRESENT_NO (default)

Bit	Reset	Description
0	0h	T_PCIE2_RP_SLOT_CAPABILITIES_ATTENTION_BUTTON_PRESENT: This bit when set indicates that an Attention Button is implemented on the chassis for this slot. 0h: ATTENTION_BUTTON_PRESENT_NO (default)

34.4.5.7 T_PCIE2_RP_SLOT_CONTROL_STATUS

The Slot Control Register controls PCI Express Slot specific parameters. It also provides information about PCI Express Slot specific parameters.

Slot Control and Slot Status Registers

Offset: 0x98 | Read/Write: R/W

Bit	R/W	Reset	Description
31:25	R	0	Reserved
24	RW1C	0h	T_PCIE2_RP_SLOT_CONTROL_STATUS_DL_LAYER_STATE_CHANGED: When set to 1, this field enables software notification when Data Link Layer Active field is changed 0h: DL_LAYER_STATE_CHANGED_INIT (default) 1h: DL_LAYER_STATE_CHANGED_SET
23	R	None	T_PCIE2_RP_SLOT_CONTROL_STATUS_ELECTROMECHANICAL_INTERLOCK_STATE: This bit when set physically locks the add-in card which the user is trying to remove, till software releases it by resetting the bit. Indicates the current state of the interlock, that is, whether the card is electro-mechanically engaged or disengaged 0b: disengaged 1b: engaged Software reads this bit to determine what state the card is in 1h: ELECTROMECHANICAL_INTERLOCK_STATE_YES
22	R	None	T_PCIE2_RP_SLOT_CONTROL_STATUS_PRESENCE_DETECT_STATE: This bit indicates the presence of a card in the slot. The bit reflects the Presence Detect status determined via an in-band mechanism or via the Present Detect pins as defined in the PCI Express Card Electromechanical Specification. Defined encodings are: 0b = Slot Empty. 1b = Card Present in slot. This field is required to be implemented on all Switch devices and Root Ports. The presence detect field for Switch devices or Root Ports not connected to slots should be hardwired to 1. This field is required if a slot is implemented. 1h: PRESENCE_DETECT_STATE_YES
21	R	0h	T_PCIE2_RP_SLOT_CONTROL_STATUS_MRL_SENSOR_STATE: This bit reports the status of the MRL sensor if it is implemented. Defined encodings are: 0b = MRL Closed. 1b = MRL Open. 0h: MRL_SENSOR_STATE_INIT (default)
20	RW1C	0h	T_PCIE2_RP_SLOT_CONTROL_STATUS_COMMAND_COMPLETED: This bit is set when the hot plug controller completes an issued command. 0h: COMMAND_COMPLETED_INIT (default) 1h: COMMAND_COMPLETED_SET
19	RW1C	0h	T_PCIE2_RP_SLOT_CONTROL_STATUS_PRESENCE_DETECT_CHANGED: This bit is set when a Presence Detect change is detected. 0h: PRESENCE_DETECT_CHANGED_INIT (default) 1h: PRESENCE_DETECT_CHANGED_SET
18	RW1C	0h	T_PCIE2_RP_SLOT_CONTROL_STATUS_MRL_SENSOR_CHANGED: This bit is set when a MRL Sensor state change is detected. 0h: MRL_SENSOR_CHANGED_INIT (default) 1h: MRL_SENSOR_CHANGED_SET
17	RW1C	0h	T_PCIE2_RP_SLOT_CONTROL_STATUS_POWER_FAULT_DETECTED: This bit is set when the Power Controller detects a power fault at this slot. 0h: POWER_FAULT_DETECTED_INIT (default) 1h: POWER_FAULT_DETECTED_SET
16	RW1C	0h	T_PCIE2_RP_SLOT_CONTROL_STATUS_ATTN_BUTTON_PRESSED: This bit is set when the attention button is pressed. 0h: ATTN_BUTTON_PRESSED_INIT (default) 1h: ATTN_BUTTON_PRESSED_SET
15:13	R	0	Reserved

Bit	R/W	Reset	Description
12	R/W	0h	T_PCIE2_RP_SLOT_CONTROL_STATUS_DL_LAYER_STATE_CHANGED_ENABLE: This bit is set when the value reported in the Data Link Layer Link Active field of the Link Status register is changed 0h: DL_LAYER_STATE_CHANGED_ENABLE_INIT (default)
11	R	0h	T_PCIE2_RP_SLOT_CONTROL_STATUS_ELECTROMECHANICAL_INTERLOCK_CONTROL: indicates that the slot supports electromechanical interlock mechanism 0h: ELECTROMECHANICAL_INTERLOCK_CONTROL_INIT (default)
10	R/W	0h	T_PCIE2_RP_SLOT_CONTROL_STATUS_POWER_CONTROLLER_CONTROL: When read this bit returns the current state of the Power applied to the slot; when written sets the power state of the slot per the defined encodings. 0b = Power On. 1b = Power Off. 0h: POWER_CONTROLLER_CONTROL_INIT (default)
9:8	R/W	1h	T_PCIE2_RP_SLOT_CONTROL_STATUS_POWER_INDICATOR_CONTROL: Reads to this bit return the current state of the Power Indicator; writes to this bit set the Power Indicator. 00b = Reserved 01b = On 10b = Blink 11b = Off Writes to this bit also cause the Port to send the appropriate POWER_INDICATOR_* messages. 1h: POWER_INDICATOR_CONTROL_INIT (default)
7:6	R/W	3h	T_PCIE2_RP_SLOT_CONTROL_STATUS_ATTN_INDICATOR_CONTROL: Reads to this field return the current state of the Attention Indicator; writes to this field set the Attention Indicator. Defined encodings are: 00b = Reserved 01b = On 10b = Blink 11b = Off Writes to this field also cause the Port to send the appropriate ATTENTION_INDICATOR_* messages. 3h: ATTN_INDICATOR_CONTROL_INIT (default)
5	R/W	0h	T_PCIE2_RP_SLOT_CONTROL_STATUS_HOT_PLUG_INTERRUPT_ENABLE: This bit when set enables generation of hot plug interrupt on enabled hot plug events. 0h: HOT_PLUG_INTERRUPT_ENABLE_INIT (default)
4	R/W	0h	T_PCIE2_RP_SLOT_CONTROL_STATUS_COMMAND_COMPLETED_INTERRUPT_ENABLE: This bit when set enables the generation of hot plug interrupt when a command is completed by the Hot plug controller. 0h: COMMAND_COMPLETED_INTERRUPT_ENABLE_INIT (default)
3	R/W	0h	T_PCIE2_RP_SLOT_CONTROL_STATUS_PRESENCE_DETECT_CHANGED_ENABLE: This bit when set enables the generation of hot plug interrupt or wake message on a presence detect changed event. 0h: PRESENCE_DETECT_CHANGED_ENABLE_INIT (default)
2	R/W	0h	T_PCIE2_RP_SLOT_CONTROL_STATUS_MRL_SENSOR_CHANGED_ENABLE: This bit when set enables the generation of hot plug interrupt or wake message on a MRL sensor changed event. 0h: MRL_SENSOR_CHANGED_ENABLE_INIT (default)
1	R/W	0h	T_PCIE2_RP_SLOT_CONTROL_STATUS_POWER_FAULT_DETECTED_ENABLE: This bit when set enables the generation of hot plug interrupt or wake message on a power fault event. 0h: POWER_FAULT_DETECTED_ENABLE_INIT (default)
0	R/W	0h	T_PCIE2_RP_SLOT_CONTROL_STATUS_ATTN_BUTTON_PRESSED_ENABLE: This bit when set enables the generation of hot plug interrupt or wake message on an attention button pressed event. 0h: ATTN_BUTTON_PRESSED_ENABLE_INIT (default)

34.4.5.8 T_PCIE2_RP_RCR

The Root Control Register controls PCI Express Root Complex specific parameters. Bit positions 31:4 of this address are reserved.

Root Control Register

Offset: 0x9c | Read/Write: R/W

Bit	R/W	Reset	Description
31:4	R	0	Reserved
3	R/W	0h	T_PCIE2_RP_RCR_PME_INT: The PME_INT bit is enable bit for generating interrupt upon receipt of a PME message as reflected in the PMESTAT bit of Root Status Register. 0h: PME_INT_DIS (default)
2	R/W	0h	T_PCIE2_RP_RCR_SERR_FAT: The SERR_FAT bit is enable bit for generating System Error if a fatal error (ERR_FATAL) is reported by any of the devices in the hierarchy associated with this Root Port, or by the Root Port itself. 0h: SERR_FAT_DIS (default)
1	R/W	0h	T_PCIE2_RP_RCR_SERR_NONFAT: The SERR_NONFAT bit is enable bit for generating System Error if a non-fatal error (ERR_NONFATAL) is reported by any of the devices in the hierarchy associated with this Root Port, or by the Root Port itself. 0h: SERR_NONFAT_DIS (default)
0	R/W	0h	T_PCIE2_RP_RCR_SERR_COR: The SERR_COR bit is enable bit for generating System Error if a correctable error (ERR_COR) is reported by any of the devices in the hierarchy associated with this Root Port, or by the Root Port itself. 0h: SERR_COR_DIS (default)

34.4.5.9 T_PCIE2_RP_RSR

The Root Status Register provides information about PCI Express device specific parameters. Bit positions 31:18 are reserved.

Root Status Register

Offset: 0xA0 | Read/Write: R/W

Bit	R/W	Reset	Description
31:18	R	0	Reserved
17	R	None	T_PCIE2_RP_RSR_PMEPEND: The PMEPEND bit indicates that another PME is pending when the PMESTAT bit is set. When the PMESTAT bit is cleared by software, the PME is delivered by hardware by setting the PMESTAT bit again and updating the REQID appropriately. The PMEPEND bit is cleared by hardware if no more PMEs are pending.
16	RW1C	0h	T_PCIE2_RP_RSR_PMESTAT: The PMESTAT bit indicates that PME was asserted by the requester ID indicated in the PME Requester ID field. Subsequent PMEs are kept pending until the status register is cleared by software by writing a 1. 0h: PMESTAT_NOT_ACTIVE (default) 1h: PMESTAT_ACTIVE 1h: PMESTAT_SET
15:0	R	None	T_PCIE2_RP_RSR_REQID: The REQID field indicates the PCI requester ID of the last PME requester.

34.4.5.10 T_PCIE2_RP_DEVICE_CAPABILITIES_2

Device Capabilities 2 Register

Offset: 0xA4 | Read/Write: RO

Bit	Reset	Description
31:12	0h	T_PCIE2_RP_DEVICE_CAPABILITIES_2_RESERVED_2: Unused bits in this register. 0h: RESERVED_2_INIT (default)
11	1h	T_PCIE2_RP_DEVICE_CAPABILITIES_2_LTR_MECH_SUP: Indicates if LTR Capability is supported. 1h: LTR_MECH_SUP_INIT

Bit	Reset	Description
10:5	0h	T_PCIE2_RP_DEVICE_CAPABILITIES_2_RESERVED: Unused bits in this register. 0h: RESERVED_1_INIT (default)
4	1h	T_PCIE2_RP_DEVICE_CAPABILITIES_2_CPL_TO_DIS_SUP: Support disabling the completion timeout mechanism. 1h: CPL_TO_DIS_SUP_0 (default)
3:0	3h	T_PCIE2_RP_DEVICE_CAPABILITIES_2_CPL_TO_RANGES_SUP: Completion timeout ranges supported by the Root Port. Ranges A and B are currently supported by the PCIe 2.0 design. 3h: CPL_TO_RANGES_SUP_0 (default)

34.4.5.11 T_PCIE2_RP_DEVICE_CONTROL_STATUS_2

Device Control 2 and Device Status 2 Registers

This register is primarily used for Root Port Completion Timeout values. Bits 31:5 are reserved.

Offset: 0xA8 | Read/Write: R/W

Bit	Reset	Description
31:11	0h	T_PCIE2_RP_DEVICE_CONTROL_STATUS_2_RESERVED_2: 0h: RESERVED_2_INIT
10	1h	T_PCIE2_RP_DEVICE_CONTROL_STATUS_2_LTR_MECH_EN: This field is used to enable/disable the LTR Mechanism. By default, the LTR Mechanism is enabled. 1h: LTR_MECH_EN_DEFAULT
9:5	0h	T_PCIE2_RP_DEVICE_CONTROL_STATUS_2_RESERVED: Unused bits in this register. 0h: RESERVED_INIT (default)
4	0h	T_PCIE2_RP_DEVICE_CONTROL_STATUS_2_CPL_TO_DISABLE: Disables completion timeout, making the Root Port always wait endlessly for a completion to a request. 0h: CPL_TO_DISABLE_DEFAULT (default)
3:0	0h	T_PCIE2_RP_DEVICE_CONTROL_STATUS_2_CPL_TO_VALUE: This field determines the range and hence the timeout values for Completions expected from the endpoint. Range A: 50 µs to 100 ms (80 µs in design) 1 ms to 10 ms (5 ms in design) Range B: 16 ms to 55 ms (40 ms in design) 65 ms to 210 ms (140 ms in design) Default: 50 µs to 50 ms (10 ms in design) Note: When CPL_TO_OVERRIDE is enabled, the value in this field is ignored, and the value in CPL_TO_CUSTOM_VALUE is used. 1h: CPL_TO_VALUE_RANGE_A_LO 2h: CPL_TO_VALUE_RANGE_A_HI 5h: CPL_TO_VALUE_RANGE_B_LO 6h: CPL_TO_VALUE_RANGE_B_HI 0h: CPL_TO_VALUE_DEFAULT (default)

34.4.5.12 T_PCIE2_RP_LINK_CAPABILITIES_2

Link Capabilities 2 Register

This is a placeholder register and is hardwired to 0. There are no capabilities that require this register.

Offset: 0xac | Read/Write: RO

Bit	Reset	Description
31:0	0h	T_PCIE2_RP_LINK_CAPABILITIES_2_BITS: 0h: BITS_0

34.4.5.13 T_PCIE2_RP_LINK_CONTROL_STATUS_2

Link Control 2 and Link Status 2 Registers

Offset: 0xB0 | Read/Write: R/W

Bit	R/W	Reset	Description
31:17	R	0h	T_PCIE2_RP_LINK_CONTROL_STATUS_2_RESERVED_STATUS: 0h: RESERVED_STATUS_DEFAULT (default)
16	R	None	T_PCIE2_RP_LINK_CONTROL_STATUS_2_CURRENT_DEEMPHASIS_LEVEL: 1h: CURRENT_DEEMPHASIS_LEVEL_3P5 0h: CURRENT_DEEMPHASIS_LEVEL_6
15:13	R	0h	T_PCIE2_RP_LINK_CONTROL_STATUS_2_RESERVED_CONTROL: 0h: RESERVED_CONTROL_DEFAULT (default)
12	R/W	0h	T_PCIE2_RP_LINK_CONTROL_STATUS_2_COMPLIANCE_DEEMPHASIS: NOTE: This field is reset by Cold Reset. 0h: COMPLIANCE_DEEMPHASIS_INIT (default)
11	R/W	0h	T_PCIE2_RP_LINK_CONTROL_STATUS_2_COMPLIANCE_SOS: NOTE: This field is reset by Cold Reset. 0h: COMPLIANCE_SOS_INIT (default)
10	R/W	0h	T_PCIE2_RP_LINK_CONTROL_STATUS_2_ENTER_MODIFIED_COMPLIANCE: When this bit is set to 1, the device transmits the modified compliance pattern if the LTSSM enters Polling. Compliance state. Default value is 0b. NOTE: This field is reset by Cold Reset. 0h: ENTER_MODIFIED_COMPLIANCE_INIT (default)
9:7	R/W	0h	T_PCIE2_RP_LINK_CONTROL_STATUS_2_TRANSMIT_MARGIN: This field controls the value of the non-deemphasized voltage level at the transmitter pins. Encodings: 000b: 800-1200mV for full swing and 400-600mV for half-swing 001b-010b: Values must be monotonic with a non-zero slope 011b: 200-400mV for full-swing and 100-200mV for half-swing 100b-111b: reserved Default value is 0b. NOTE: This field is reset by Cold Reset. 0h: TRANSMIT_MARGIN_INIT (default)
6	R	None	T_PCIE2_RP_LINK_CONTROL_STATUS_2_SELECTABLE_DEEMPHASIS: When link is operating at 5GT/s speed, selects the level of de-emphasis. This value is initialized by hardware and/or BIOS. Encodings: 1b: -3.5dB 0b: -6dB Default value is 1b.
5	R	0h	T_PCIE2_RP_LINK_CONTROL_STATUS_2_HW_AUTO_SPEED_DISABLE: Link speed change is disabled if set to 1b. Default value is 0b. 0h: HW_AUTO_SPEED_DISABLE_INIT
4	R/W	0h	T_PCIE2_RP_LINK_CONTROL_STATUS_2_ENTER_COMPLIANCE: If set to 1b forces link to enter compliance mode at the speed indicated by Target Link Speed field. Default value is 0b. NOTE: This field is reset by Cold Reset. 0h: ENTER_COMPLIANCE_INIT (default)
3:0	R/W	2h	T_PCIE2_RP_LINK_CONTROL_STATUS_2_TARGET_LINK_SPEED: This field sets an upper limit on the link operational speed by restricting the values advertised in training sequences. Defined encodings: 0001b: 2.5GT/s (Gen1) 0010b: 5GT/s (Gen2) Other encodings are reserved. Default value is 0. NOTE: This field is reset by Cold Reset. 0h: TARGET_LINK_SPEED_GEN2_DIS 1h: TARGET_LINK_SPEED_2P5 2h: TARGET_LINK_SPEED_5P0 (default)

34.4.5.14 T_PCIE2_RP_SLOT_CAPABILITIES_2

Slot Capabilities 2 Register

This is a placeholder register and is hardwired to 0. There are no capabilities that require this register.

Offset: 0xB4 | Read/Write: RO

Bit	Reset	Description
31:0	0h	T_PCIE2_RP_SLOT_CAPABILITIES_2_BITS: 0h: BITS_0

34.4.5.15 T_PCIE2_RP_SLOT_CONTROL_STATUS_2

Slot Control 2 and Slot Status 2 Registers

This is a placeholder register and is hardwired to 0. There are no capabilities that require this register.

Offset: 0xB8 | Read/Write: RO

Bit	Reset	Description
31:0	0h	T_PCIE2_RP_SLOT_CONTROL_STATUS_2_BITS: 0h: BITS_0

34.4.6 Error Reporting Capability Registers

This section lists the PCI Express Advanced Error Reporting Capability List registers as defined in PCI Express Base Specification, Revision 3.0.

34.4.6.1 T_PCIE2_RP_ERPTCAP

PCI Express Extended Capability Header Register

This is the Advanced Error Reporting Enhanced Capability Header register.

Offset: 0x100 | Read/Write: RO

Bit	R/W	Reset	Description
31:20	R	None	T_PCIE2_RP_ERPTCAP_NEXT_PTR: 000h: NONE (default) 140h: L1_SUBSTATE
19:16	R	0h	T_PCIE2_RP_ERPTCAP_VERSION: 0h: VERSION_0 (default) 1h: VERSION_1
15:0	R	0h	T_PCIE2_RP_ERPTCAP_ID: 0h: ID_NONE (default) 1h: ID_AER

34.4.6.2 T_PCIE2_RP_ERPTCAP_UCERR

Uncorrectable Error Status Register

Offset: 0x104 | Read/Write: R/W

Bit	R/W	Reset	Description
31:21	R	0	Reserved
20	RW1C	0h	T_PCIE2_RP_ERPTCAP_UCERR_UNSUP_REQ_ERR: Unsupported Request Error Status NOTE: this field is reset by Cold Reset 0h: UNSUP_REQ_ERR_FALSE (default) 1h: UNSUP_REQ_ERR_TRUE 1h: UNSUP_REQ_ERR_CLEAR

Bit	R/W	Reset	Description
19	RW1C	0h	T_PCIE2_RP_ERPTCAP_UCERR_ECRC_ERR: ECRC Error Status NOTE: this field is reset by Cold Reset 0h: ECRC_ERR_FALSE (default) 1h: ECRC_ERR_TRUE 1h: ECRC_ERR_CLEAR
18	RW1C	0h	T_PCIE2_RP_ERPTCAP_UCERR_MF_TLP: Malformed TLP Status NOTE: this field is reset by Cold Reset 0h: MF_TLP_FALSE (default) 1h: MF_TLP_TRUE 1h: MF_TLP_CLEAR
17	RW1C	0h	T_PCIE2_RP_ERPTCAP_UCERR_RCV_OVFL: Receiver Overflow Status NOTE: this field is reset by Cold Reset 0h: RCV_OVFL_FALSE (default) 1h: RCV_OVFL_TRUE 1h: RCV_OVFL_CLEAR
16	RW1C	0h	T_PCIE2_RP_ERPTCAP_UCERR_UNEXP_COMP: Unexpected Completion Status NOTE: this field is reset by Cold Reset 0h: UNEXP_COMP_FALSE (default) 1h: UNEXP_COMP_TRUE 1h: UNEXP_COMP_CLEAR

34.4.6.8 T_PCIE2_RP_ERPTCAP_HDR_LOG_DW0

This register is 16 bytes wide. The header is captured such that the fields of the header read by software in the same way the headers are presented in the specification, when the register is read using Dword accesses. Therefore, byte 0 of the header is located in byte 3 of the Header Log register, byte 1 of the header is in the byte 2 of the header Log register, and so forth.

Header Log Register

Offset: 0x11C | Read/Write: R

Bit	R/W	Reset	Description

34.4.6.14 T_PCIE2_RP_ERPTCAP_ERR_ID

This register identifies the source (Requester ID) of first correctable and uncorrectable (non-fatal/fatal) errors reported in the Root Error Status register.

Root Error Status Register

Offset: 0x134 | Read/Write: R

Bit	R/W	Reset	Description
31:16	R	None	T_PCIE2_RP_ERPTCAP_ERR_ID_ERR_COR: 0h: ERR_COR_DEFAULT (default)
15:0	R	None	T_PCIE2_RP_ERPTCAP_ERR_ID_ERR_UNCOR: 0h: ERR_UNCOR_DEFAULT (default)

34.4.7 L1 PM Substate Capability Registers

This section lists the PCI Express L1 PM Substate Capability List registers as defined in L1 PM Substate ECN.

34.4.7.1 T_PCIE2_L1_PM_SUBSTATES_EXT_CAP

PCI Express Extended Capability Header Register

Offset: 0x140 | Read/Write: R

Bit	R/W	Reset	Description
31:20	R	0h	T_PCIE2_RP_L1_PM_SUBSTATES_EXT_CAP_NEXT_CAP: This field contains the offset to the next PCI Express Capability structure. 0h: NULL
19:16	R	1h	T_PCIE2_RP_L1_PM_SUBSTATES_EXT_CAP_VERSION: This field is a PCI-SIG defined version number that indicates the version of the Capability structure present. 1h: L1_SUBSTATES
15:0	R	1Eh	T_PCIE2_RP_L1_PM_SUBSTATES_EXT_CAP: This field is a PCISIG defined ID number that indicates the nature and format of the Extended Capability. 1Eh: ID_L1_SUBSTATES

34.4.7.2 T_PCIE2_L1_PM_SUBSTATES_CAP

L1 PM Substates Capability Register

Offset: 0x144 | Read/Write: R

Bit	R/W	Reset	Description
23:19	R	00101b	T_PCIE2_RP_L1_PM_SUBSTATES_CAP_T_PWRON_VALUE: This register along with the Port T_POWER_ON Scale field in the L1 PM Substates Capabilities register sets the time (in µs) that this Port requires the port on the opposite side of Link to wait in L1.2.Exit after sampling CLKREQ# asserted before actively driving the interface. The value of Port T_POWER_ON is calculated by multiplying the value in this field by the scale value in the Port T_POWER_ON Scale field in the L1 PM Substates Capabilities register. Default value is 00101b Required for all Ports that support L1.2, otherwise this field is of type RsvdP. This register is driven by T_PCIE2_RP_L1_PM_SUBSTATES_CYA_T_PWRON_VALUE if L1.2 is supported else this register is driven with 0's.
17:16	R	00b	T_PCIE2_RP_L1_PM_SUBSTATES_CAP_T_PWRON_SCALE: Specifies the scale used for the Port T_POWER_ON Value field in the L1 PM Substates Capabilities register. 00b = 2 µs (default) 01b = 10 µs 10b = 100 µs 11b = Reserved Required for all Ports that support L1.2, otherwise this field is of type RsvdP. This field is driven by T_PCIE2_RP_L1_PM_SUBSTATES_CYA_T_PWRON_SCALE if L1.2 is supported else this field is driven with 0's.

Bit	R/W	Reset	Description
15:8	R	0xFF	T_PCIE2_RP_L1_PM_SUBSTATES_CAP_CM_RESTORE_TIME: Time (in µs) required for this Port to re-establish common mode. Required for all Ports that support L1.2, otherwise this field is of type RsvdP. This field is driven by T_PCIE2_RP_L1_PM_SUBSTATES_CYA_CM_RESTORE_TIME if L1.2 is supported else this field is driven with 0's. The value ranges from 0 to 255 µs (the units are in microseconds), default setting is 0xFF(255)
4	R	1h	T_PCIE2_RP_L1_PM_SUBSTATES_CAP_L1_PM_SUBSTATES_SUPPORTED: When set this bit indicates that this Port supports L1 PM Substates. For compatibility with possible future extensions, software must not enable L1 PM Substates unless this bit is set. 0h: DISABLE 1h: ENABLE
3	R	1h	T_PCIE2_RP_L1_PM_SUBSTATES_CAP_ASPM_L1_1_SUPPORTED: When set this bit indicates that ASPM L1.1 is supported. 0h: DISABLE 1h: ENABLE
2	R	1h	T_PCIE2_RP_L1_PM_SUBSTATES_CAP_ASPM_L1_2_SUPPORTED: When set this bit indicates that ASPM L1.2 is supported. 0h: DISABLE 1h: ENABLE
1	R	1h	T_PCIE2_RP_L1_PM_SUBSTATES_CAP_PCI_PM_L1_1_SUPPORTED: When set this bit indicates that PCI-PM L1.1 is supported. 0h: DISABLE 1h: ENABLE
0	R	1h	T_PCIE2_RP_L1_PM_SUBSTATES_CAP_PCI_PM_L1_2_SUPPORTED: When set this bit indicates that PCI-PM L1.2 is supported. 0h: DISABLE 1h: ENABLE

34.4.7.3 T_PCIE2_RP_L1_PM_SUBSTATES_CTRL1

L1 PM Substates Control 1 Register

Offset: 0x148 | Read/Write: R/W

Bit	R/W	Reset	Description
31:29	R/W	000b	T_PCIE2_RP_L1_PM_SUBSTATES_CTRL1_LTR_L1_2_THRES_SCALE: This field provides a scale for the value contained within the LTR_L1.2_THRESHOLD_Value. Encoding is the same as the LatencyScale fields in the LTR Message. Hardware operation is undefined if software writes a Not-Permitted value to this field. Required for all Ports that support ASPM L1.2; otherwise this field is of type RsvdP. 000b: INIT
25:16	R/W	0000000000b	T_PCIE2_RP_L1_PM_SUBSTATES_CTRL1_LTR_L1_2_THRES_VAL: Along with the LTR_L1.2_THRESHOLD_Scale, this field indicates the LTR threshold used to determine if entry into L1 results in L1.1 (if enabled) or L1.2 (if enabled). Required for all Ports that support ASPM L1.2; otherwise this field is of type RsvdP. 0000000000b: INIT
15:8	R/W	FFh	T_PCIE2_RP_L1_PM_SUBSTATES_CTRL1_CM_RESTORE_TIME: FFh: INIT
3	R/W	0b	T_PCIE2_RP_L1_PM_SUBSTATES_CTRL1_ASPM_L1_1_EN: When set this bit enables ASPM L1.1. Required for both Upstream and Downstream Ports. For Ports that do not support ASPM L1.1, this bit is permitted to be hardwired to 0. 0b: INIT
2	R/W	0b	T_PCIE2_RP_L1_PM_SUBSTATES_CTRL1_ASPM_L1_2_EN: When set this bit enables ASPM L1.2. Required for both Upstream and Downstream Ports. For Ports that do not support ASPM L1.2, this bit is permitted to be hardwired to 0. 0b: INIT
1	R/W	0b	T_ PCIE2_RP_L1_PM_SUBSTATES_CTRL1_PCIPM_L1_1_EN: When set this bit enables PCI-PM L1.1. Required for both Upstream and Downstream Ports. 0b: INIT

Bit	R/W	Reset	Description
0	R/W	0b	T_PCIE2_RP_L1_PM_SUBSTATES_CTRL1_PCIPM_L1_2_EN: When set this bit enables PCI-PM L1.2. Required for both Upstream and Downstream Ports. For Ports that do not support PCI-PM L1.2 this bit is permitted to be hardwired to 0. 0b: INIT

34.4.7.4 T_PCIE2_RP_L1_PM_SUBSTATES_CTRL2

L1 PM Substates Control 2 Register

Offset: 0x14c | Read/Write: R/W

Bit	R/W	Reset	Description
7:3	R/W	00101b	T_PCIE2_RP_L1_PM_SUBSTATES_CTRL2_T_PWRON_VALUE: Along with the T_POWER_ON Scale sets the minimum amount of time (in us) that the Port must wait in L1.2.Exit after sampling CLKREQ# asserted before actively driving the interface. T_POWER_ON is calculated by multiplying the value in this field by the value in the T_POWER_ON Scale field. Required for all Ports that support L1.2; otherwise this field is of type RsvdP. 00101b: INIT
1:0	R/W	00b	T_PCIE2_RP_L1_PM_SUBSTATES_CTRL2_T_PWRON_SCALE: Specifies the scale used for the Port T_POWER_ON Value field in the L1 PM Substates Capabilities register. 00b = 2 µs 01b = 10 µs 10b = 100 µs 11b = Reserved Required for all Ports that support L1.2; otherwise this field is of type RsvdP. 00b: INIT

34.4.8 NVIDIA Private Registers

The following sections list the private registers defined to configure the operation of NVIDIA® PCIE Root Port controller. These registers are defined outside of the standard PCI Capabilities and PCI Express Extended Capabilities lists. Thus, they cannot be discovered and traversed by standard PCI/PCIE drivers.

34.4.8.1 T_PCIE2_RP_LTR_REP_VAL

L1 PM Substates Diagnostics Register

This register captures the latest LTR value reported by the endpoint. LTR messages are decoded and the LTR values for no snoop and snoop reported in the message are stored in this register. Values are valid only if LTR capability is enabled.

Offset: 0xC10 | Read/Write: R

Bit	R/W	Reset	Description
31:16	R	None	T_PCIE2_RP_LTR_REP_VAL_NO_SNOOP: 0h: NO_SNOOP_INIT
15:0	R	None	T_PCIE2_RP_LTR_REP_VAL_SNOOP: 0h: SNOOP_INIT

34.4.8.2 T_PCIE2_RP_L1_1_ENTRY_COUNT

This register reflects the number of times the link entered the L1.1.

Offset: 0xC14 | Read/Write: R/W

Bit	R/W	Reset	Description
31	R/W	0	T_PCIE2_RP_L1_1_ENTRY_COUNT_RESET: When set to 1 by software, it will clear the T_PCIE2_RP_L1_1_ENTRY_COUNT_VALUE. Will be set to 0 by hardware once the T_PCIE2_RP_L1_1_ENTRY_COUNT_VALUE is cleared. 0: RESET_INIT 0: RESET_DONE (default) 1: RESET_PENDING
30	R/W	0	T_PCIE2_RP_L1_1_ENTRY_COUNT_FREEZE: 0: FREEZE_INIT (default)
29:16	R	0	Reserved
15:0	R	0	T_PCIE2_RP_L1_1_ENTRY_COUNT_VALUE: This field reflects the number of times the link entered the L1.1 state. 0h: VALUE_INIT (default)

34.4.8.3 T_PCIE2_RP_L1_2_ENTRY_COUNT

This register reflects the number of times the link entered the L1.2_ENTRY state, but was forced to exit to L1.0 and then L0 because it saw clkreq# asserted while it was in this state.

Offset: 0xC18 | Read/Write: R/W

Bit	R/W	Reset	Description
31	R/W	0	T_PCIE2_RP_L1_2_ENTRY_COUNT_RESET: When set to 1 by software, it will clear the T_PCIE2_RP_L1_2_ENTRY_COUNT_VALUE. Will be set to 0 by hardware once the T_PCIE2_RP_L1_2_ENTRY_COUNT_VALUE is cleared. 0: RESET_INIT 0: RESET_DONE (default) 1: RESET_PENDING
30	R/W	0	T_PCIE2_RP_L1_2_ENTRY_COUNT_FREEZE: 0: FREEZE_INIT (default)
29:16	R	0	Reserved
15:0	R	0	T_PCIE2_RP_L1_2_ENTRY_COUNT_VALUE: This field reflects the number of times the link entered the L1.2 ENTRY state, but was forced to exit to L1.0 and then L0 because it saw clkreq# asserted while it was in this state. 0h: VALUE_INIT (default)

34.4.8.4 T_PCIE2_RP_L1_2_ABORT_COUNT

Offset: 0xC1C | Read/Write: R/W

Bit	R/W	Reset	Description
31	R/W	0	T_PCIE2_RP_L1_2_ABORT_COUNT_RESET: When set to 1 by software, it will clear the T_PCIE2_RP_L1_2_ABORT_COUNT_VALUE. Will be set to 0 by hardware once the T_PCIE2_RP_L1_2_ABORT_COUNT_VALUE is cleared. 0: RESET_INIT 0: RESET_DONE (default) 1: RESET_PENDING
30	R/W	0	T_PCIE2_RP_L1_2_ABORT_COUNT_FREEZE: 0: FREEZE_INIT (default)
29:16	R	0	Reserved
15:0	R	0	T_PCIE2_RP_L1_2_ABORT_COUNT_VALUE: This field reflects the number of times the link entered the L1.2 ENTRY state, but was forced to exit to L1.0 and then L0 because it saw clkreq# asserted while it was in this state. 0h: VALUE_INIT (default)

34.4.8.5 T_PCIE2_RP_PIPE_CTL

This register controls (enabling /disabling) the pipelines added to meet timing on various interfaces. A value of 0 disables the extra pipeline.

Offset: 0xD5C | Read/Write: R/W

Bit	R/W	Reset	Description
31:9	R	0	Reserved
8	R/W	1h	T_PCIE2_RP_PIPE_CTL_UFA2WRR_PWTOP: 1h: UFA2WRR_PWTOP_INIT (default)
7	R/W	1h	T_PCIE2_RP_PIPE_CTL_UBFI2DFI_P2P: 1h: UBFI2DFI_P2P_INIT (default)
6	R/W	1h	T_PCIE2_RP_PIPE_CTL_TXBA2DFI_WR: 1h: TXBA2DFI_WR_INIT (default)
5	R/W	1h	T_PCIE2_RP_PIPE_CTL_CMDQ2UFARB: 1h: CMDQ2UFARB_INIT (default)
4	R/W	1h	T_PCIE2_RP_PIPE_CTL_UBFI2DFI_NTT: 1h: UBFI2DFI_NTT_INIT (default)
3	R/W	1h	T_PCIE2_RP_PIPE_CTL_PCA: 1h: PCA_INIT (default)
2	R/W	1h	T_PCIE2_RP_PIPE_CTL_DFIREQ: 1h: DFIREQ_INIT (default)
1	R/W	1h	T_PCIE2_RP_PIPE_CTL_DFIRSP: 1h: DFIRSP_INIT (default)
0	R/W	1h	T_PCIE2_RP_PIPE_CTL_DFI2UBFI: 1h: DFI2UBFI_INIT (default)

34.4.8.6 T_PCIE2_RP_RX_HDR_LIMIT

These register defines the upstream header logical partition sizes. These buffers reside in UBFI. RXL provides the write interface. The buffers constitute asynchronous boundary of xclk -> ufpci_clk.

Offset: 0xE00 | Read/Write: R/W

Bit	R/W	Reset	Description
31:24	R	0	Reserved
23:16	R/W	0h	T_PCIE2_RP_RX_HDR_LIMIT_CPL: Programs the size of the Completion Header Buffer. This field must be programmed with an even value. 0h: CPL_INIT (default)
15:8	R/W	0h	T_PCIE2_RP_RX_HDR_LIMIT_PW: Programs the size of the Posted Write Header Buffer. When ISO PWs are enabled, this field must be halved, and programmed before both ufpci_reset_ and xreset_. This field must be programmed with an even value. 0h: PW_INIT (default)
7:0	R/W	0h	T_PCIE2_RP_RX_HDR_LIMIT_NP: Programs the size of the Non-Posted (Read and Write) Header Buffer. When ISO NPs are enabled, this field must be halved, and programmed before both ufpci_reset_ and xreset_. This field must be programmed with an even value. 0h: NP_INIT (default)

34.4.8.7 T_PCIE2_RP_RX_DATA_LIMIT

These buffers reside in UBFI. RXL provides the write interface. The buffers constitute asynchronous boundary of xclk -> ufpci_clk.

Offset: 0xE04 | Read/Write: R/W

Bit	R/W	Reset	Description
31:28	R	0	Reserved
27:20	R/W	0h	T_PCIE2_RP_RX_DATA_LIMIT_CPL: Programs the size of the Completions Data Buffer. This field must be programmed with an even value. 0h: CPL_INIT (default)

Bit	R/W	Reset	Description
19:8	R/W	0h	T_PCIE2_RP_RX_DATA_LIMIT_PW: Programs the size of the Posted Writes Data Buffer. When ISO PWs are enabled, this field must be halved, and programmed before both ufpci_reset_ and xreset_. This field must be programmed with an even value. 0h: PW_INIT (default)
7:0	R/W	0h	T_PCIE2_RP_RX_DATA_LIMIT_NP: Programs the size of the Non-Posted Write Header Buffer. This field must be programmed with an even value. 0h: NP_INIT (default)

34.4.8.8 T_PCIE2_RP_TX_HDR_LIMIT

These buffers reside in TXBA. DFI provides the write interface. These buffers constitute an asynchronous boundary of dfpci_clk -> xclk.

Offset: 0xE08 | Read/Write: R/W

Bit	R/W	Reset	Description
31:24	R/W	0	T_PCIE2_RP_TX_HDR_LIMIT_NPT: 0h: NPT_INIT (default)
23:16	R/W	0h	T_PCIE2_RP_TX_HDR_LIMIT_CPL: Programs the size of the downstream Completions Header Buffer. This must be programmed with a value greater than 3 (or left alone at its default value of 0x0). 0h CPL_INIT (default)
15:8	R/W	0h	T_PCIE2_RP_TX_HDR_LIMIT_PW: Programs the size of the downstream Posted Writes Header Buffer. 0h: PW_INIT (default)
7:0	R/W	0h	T_PCIE2_RP_TX_HDR_LIMIT_NP: Programs the size of the downstream Non Posted Header Buffer. This should be programmed with the same value as TX_DATA_LIMIT_NP. 0h: NP_INIT (default)

34.4.8.9 T_PCIE2_RP_TX_DATA_LIMIT

These buffers reside in TXBA. DFI provides the write interface. These buffers constitute an asynchronous boundary of dfpci_clk -> xclk.

Offset: 0xE0C | Read/Write: R/W

Bit	R/W	Reset	Description
31:16	R	0	Reserved
15:8	R/W	0h	T_PCIE2_RP_TX_DATA_LIMIT_PW: Programs the size of the downstream Posted Writes Data Buffer. 0h: PW_INIT (default)
7:0	R/W	0h	T_PCIE2_RP_TX_DATA_LIMIT_NP: Programs the size of the downstream Non Posted Data Buffer. This should be programmed with same value as TX_HDR_LIMIT_NP. 0h: NP_INIT (default)

34.4.8.10 T_PCIE2_RP_UFPCI

This register controls upstream FPCI control and arbitration in UBFI and performance fields.

Offset: 0xE10 | Read/Write: R/W

Bit	R/W	Reset	Description
31:28	R	0	Reserved
27:23	R/W	0h	T_PCIE2_RP_UFPCI_ISO_WEIGHT: 0h: ISO_WEIGHT_INIT (default)
22	R/W	0h	T_PCIE2_RP_UFPCI_ISO_CONTROL_ENABLE: 0h: ISO_CONTROL_ENABLE_INIT (default)

Bit	R/W	Reset	Description
21	R/W	0h	T_PCIE2_RP_UFPCI_ISOPW2HPISO: If set, converts posted writes with TC >= tc2isomap to HP_ISO writes instead of ISO writes. 0h: ISOPW2HPISO_INIT (default)
20	R/W	0h	T_PCIE2_RP_UFPCI_ISONP2HPISO: If set, converts nonposted reads with TC >= tc2isomap to HP_ISO reads instead of ISO reads. 0h: ISONP2HPISO_INIT (default)
19:12	R/W	0h	T_PCIE2_RP_UFPCI_REQ_PEND_PERIOD: The following timers are reset when they hit the value in REQ_PEND_PERIOD 1. noniso_timer - feeds into tms*2sm_iso_pending if system_stutter is supported 2. iso_timer - feeds into tms*2sm_noniso_pending if system_stutter is supported 3. coh_timer - feeds into tms*2sm_coh_request_pend 4. noncoh_timer - feeds into tms*2sm_noncoh_request_pend 0h: REQ_PEND_PERIOD_INIT (default)
11:10	R/W	1h	T_PCIE2_RP_UFPCI_WRR_GRANT_BURST: This field controls the length of time for which a particular controller gets arbitration within a TMS. It relates to time multiplexed inter-TMS arbitration for controllers within a TMS. 1h: WRR_GRANT_BURST_INIT (default)
9:5	R/W	0h	T_PCIE2_RP_UFPCI_PW_PRI_OVR_COUNT: If a posted write has received this number of grants when the priority was swapped to posted write, its priority will be reset. 0h: PW_PRI_OVR_COUNT_INIT (default)
4:0	R/W	0h	T_PCIE2_RP_UFPCI_PW_STARV_COUNT: If an NP has received this number of grants over a posted write while there are posted writes pending, then swap the priority to the posted write. 0h: PW_STARV_COUNT_INIT (default)

34.4.8.11 T_PCIE2_RP_MISC0

This register controls miscellaneous fields.

Offset: 0xE14 | Read/Write: R/W

Bit	R/W	Reset	Description
31	R/W	0h	T_PCIE2_RP_MISC0_SHORT_RXL_TIMER: This bit is used for simulations only, to test the completion timeout feature in RXL. It shortens the wait period for a completion to 1 µs. 0h: SHORT_RXL_TIMER_INIT (default)
30	R/W	0h	T_PCIE2_RP_MISC0_P2P_SMALL_ISA_HOLE: When set, this bit controls the peer2peer settings on address ranges 64'hA_0000 to 64'hF_FFFF. It is used to omit address ranges A, B, C, D, E and F from being peer2peer. 0h: P2P_SMALL_ISA_HOLE_INIT (default)
29	R/W	0h	T_PCIE2_RP_MISC0_P2P_F: If 0 and P2P_SMALL_ISA_HOLE=1, all transactions falling within ranges 64'hF_0000 and 64'hF_FFFF will have the fpci2ufa_cmd_peer2peer bit equal to 0. Else the fpci2ufa_cmd_peer2peer bit will be set according to TOM1 and TOM2 registers. 0h: P2P_F_INIT (default)
28	R/W	0h	T_PCIE2_RP_MISC0_P2P_E: If 0 and P2P_SMALL_ISA_HOLE=1, all transactions falling within ranges 64'hE_0000 and 64'hE_FFFF will have the fpci2ufa_cmd_peer2peer bit equal to 0. Else the fpci2ufa_cmd_peer2peer bit will be set according to TOM1 and TOM2 registers. 0h: P2P_E_INIT (default)
27	R/W	0h	T_PCIE2_RP_MISC0_P2P_D: If 0 and P2P_SMALL_ISA_HOLE=1, all transactions falling within ranges 64'hD_0000 and 64'hD_FFFF will have the fpci2ufa_cmd_peer2peer bit equal to 0. Else the fpci2ufa_cmd_peer2peer bit will be set according to TOM1 and TOM2 registers. 0h: P2P_D_INIT (default)
26	R/W	0h	T_PCIE2_RP_MISC0_P2P_C: If 0 and P2P_SMALL_ISA_HOLE=1, all transactions falling within ranges 64'hC_0000 and 64'hC_FFFF will have the fpci2ufa_cmd_peer2peer bit equal to 0. Else the fpci2ufa_cmd_peer2peer bit will be set according to TOM1 and TOM2 registers. 0h: P2P_C_INIT (default)
25	R/W	0h	T_PCIE2_RP_MISC0_P2P_B: If 0 and P2P_SMALL_ISA_HOLE=1, all transactions falling within ranges 64'hB_0000 and 64'hB_FFFF will have the fpci2ufa_cmd_peer2peer bit equal to 0. Else the fpci2ufa_cmd_peer2peer bit will be set according to TOM1 and TOM2 registers. 0h: P2P_B_INIT (default)

Bit	R/W	Reset	Description
24	R/W	0h	T_PCIE2_RP_MISC0_P2P_A: If 0 and P2P_SMALL_ISA_HOLE=1, all transactions falling within ranges 64'hA_0000 and 64'hA_FFFF will have the fpci2ufa_cmd_peer2peer bit equal to 0. Else the fpci2ufa_cmd_peer2peer bit will be set according to TOM1 and TOM2 registers. 0h: P2P_A_INIT (default)
23	R/W	0h	T_PCIE2_RP_MISC0_NISONC2HPISO: When set, all upstream Noniso, Non-coherent, Non-peer2peer reads will be upgraded to HPISO Reads. This upgrade is available for all controllers in a TMS if any one of the controllers has iso buffers. 0h: NISONC2HPISO_INIT (default)
22	R	0	Reserved
21	R/W	1h	T_PCIE2_RP_MISC0_AUTO_XCLK_FREQ_EN: When set, the xclk for a TMS will switch dynamically (by hardware itself) between 250 and 500. 250: if all root ports in that TMS are in Gen1. 500: If any root port in that TMS is in Gen2. This bit is valid only for Root Port 0 of that TMS, and don't care for others. 1h: AUTO_XCLK_FREQ_EN_INIT (default)
20	R/W	0h	T_PCIE2_RP_MISC0_RXL_CLEAR_DROP: Clears the DROP ALL status of the receiver. DROP ALL occurs on fatal errors such as Receiver Overflow and Malformed TLPs. Once set, RXL will not allow any other transactions upstream. 0h: RXL_CLEAR_DROP_INIT (default)
19:4	R/W	FFh	T_PCIE2_RP_MISC0_P2P_BURST_SIZE: FFh: P2P_BURST_SIZE_INIT (default)
3	R/W	0h	T_PCIE2_RP_MISC0_ISO_PW_ENABLE: Enables ISO posted write transactions for packets with TC >= TC2ISOMAP, on controllers that have iso buffers. 0h: ISO_PW_ENABLE_INIT (default)
2	R/W	0h	T_PCIE2_RP_MISC0_ISO_NP_ENABLE: Enables ISO NP transactions for packets with TC >= TC2ISOMAP, on controllers that have iso buffers. 0h: ISO_NP_ENABLE_INIT (default)
1	R/W	0h	T_PCIE2_RP_MISC0_NATIVE_P2P_ENABLE: Enables native peer2peer transactions on controllers that support it. Posted Write peer2peer transactions will use a shortcut through the design to enable high performance peer2peer accesses. 0h: NATIVE_P2P_ENABLE_INIT (default)
0	R/W	0h	T_PCIE2_RP_MISC0_ENABLE_CLUMPING: When set, enables unitid clumping on controllers that support it. Controllers that support unitid clumping will resort to using its unitid+1 and an additional 32 source tags when it has exhausted its allotted use of first 32 source tags. 0h: ENABLE_CLUMPING_INIT (default)

34.4.8.12 T_PCIE2_RP_TXBA0

This register is specific to the TXBA sub-unit in PCIe 2.0 and controls:

- Replay buffer limits
- Completion merging limits
- Replay timer control fields

Offset: 0xE18 | Read/Write: R/W

Bit	R/W	Reset	Description
31:16	R/W	0h	T_PCIE2_RP_TXBA0_REPLAY_TIMER_EXPIRY: When TXBA0_USE_REPLAY_TIMER_OFFSET is 1, the value programmed into TXBA0_REPLAY_TIMER_EXPIRY is added to the replay timer that hardware calculates. When this bit is 0, the value in TXBA0_REPLAY_TIMER_EXPIRY is selected (if its non-zero) instead of the hardware value. 0h: REPLAY_TIMER_EXPIRY_INIT (default)
15:13	R	0	Reserved
12	R/W	0h	T_PCIE2_RP_TXBA0_USE_REPLAY_TIMER_OFFSET: 0h: USE_REPLAY_TIMER_OFFSET_INIT (default)

Bit	R/W	Reset	Description
11	R/W	0h	T_PCIE2_RP_TXBA0_CMPL_MERGE_UPTO_64DW: Similar to above field, but the upper limit is 64 DW. When neither 32DW/64DW is set, nor completion merging is enabled, maximum merging supported is 128DW. 0h: CMPL_MERGE_UPTO_64DW_INIT (default)
10	R/W	0h	T_PCIE2_RP_TXBA0_CMPL_MERGE_UPTO_32DW: When set, split completions that have payloads up to 32 DWs will be merged. Completions that belong to the same read request, but have payloads greater than 32 DWs will have one fragment merged up to 32 DWs, in addition to one or more packets containing the rest of the payload (which will also be merged using the same rule). 0h: CMPL_MERGE_UPTO_32DW_INIT (default)
9	R/W	1h	T_PCIE2_RP_TXBA0_CMPL_MERGE_DISABLE: Disables completion merging. By default, completion merging is disabled. 1h: CMPL_MERGE_DISABLE_INIT (default)
8:0	R/W	0h	T_PCIE2_RP_TXBA0_REPLAY_BUF_LIMIT: This field exists per controller. It decides how much of the replay buffer (which is shared among all the controllers in a TMS) is used for the controller. The range of values can be anything from 0 (when controller is disabled) to full depth of the replay buffer size (when there are no other controllers). 0h: REPLAY_BUF_LIMIT_INIT (default)

34.4.8.13 T_PCIE2_RP_TXBA1

This register is specific to the TXBA sub-unit in PCIe 2.0.It controls:

- Replay buffer limits
- Completion merging limits
- Replay timer control fields

Offset: 0xE1C | Read/Write: R/W

Bit	R/W	Reset	Description
31:16	R	0	Reserved
15:8	R/W	0	T_PCIE2_RP_TXBA1_CMPL_MERGE_THRESHOLD: Completion merging is enabled only if the number of valid completions exceeds this programmed register. This is used to control the bandwidth vs. latency consideration. The maximum meaningful value of this field is the maximum number of outstanding completions (which is also size of header buffer allocated to the controller). 0h: CMPL_MERGE_THRESHOLD_INIT (default)
7:4	R/W	4h	T_PCIE2_RP_TXBA1_CM_OVER_PW_BURST: This field and the PW_OVER_CM_BURST field are input into the downstream arbiter. If there are several downstream posted writes and downstream Completion Merges (CMs), the TXBA arbiter runs PW_OVER_CM_BURST many posted writes before switching to CM. Once the arbiter starts running completions, it runs CM_OVER_PW_BURST completions before switching back to posted writes. 4h: CM_OVER_PW_BURST_INIT (default)
3:0	R/W	4h	T_PCIE2_RP_TXBA1_PW_OVER_CM_BURST: This field and the CM_OVER_PW_BURST field are inputs into the downstream arbiter. If there are several downstream posted writes and downstream CMs, the TXBA arbiter runs PW_OVER_CM_BURST many posted writes before switching to CM. Once the arbiter starts running completions, it runs CM_OVER_PW_BURST completions before switching back to PW. 4h: PW_OVER_CM_BURST_INIT (default)

34.4.8.14 T_PCIE2_RP_FORCEFC

This register updates FC priority flip threshold. Updated FCs become high priority (equivalent priority to UpdateFC timer expiring) if the number of outstanding credits to return for each type exceeds the set threshold.

If the threshold is set to 0, this feature is disabled.

Offset: 0xE20 | Read/Write: R/W

Bit	R/W	Reset	Description
31:24	R/W	0h	T_PCIE2_RP_FORCEFC_NPD_UNRET_THRESH: 0h: NPD_UNRET_THRESH_INIT (default)

Bit	R/W	Reset	Description
23:16	R/W	0h	T_PCIE2_RP_FORCEFC_NPH_UNRET_THRESH: 0h: NPH_UNRET_THRESH_INIT (default)
15:8	R/W	0h	T_PCIE2_RP_FORCEFC_PWD_UNRET_THRESH: 0h: PWD_UNRET_THRESH_INIT (default)
7:0	R/W	0h	T_PCIE2_RP_FORCEFC_PWH_UNRET_THRESH: 0h: PWH_UNRET_THRESH_INIT (default)

34.4.8.15 T_PCIE2_RP_TIMEOUT0

This is the LINK LTSSM Timeout 0 register.

Note: *The value of this register is correct only for the default frequency of clk25m. If the clk25m frequency is changed, then software is responsible for changing the value of this register.*

Offset: 0xE24 | Read/Write: R/W

Bit	R/W	Reset	Description
31:24	R/W	14h	T_PCIE2_RP_TIMEOUT0_PAD_SPDCHNG_GEN2: Amount of time to wait for pads to change speed from Gen1 to Gen2. Measured in units of clk25m clock periods. Default value is 7 (~500 ns). Note: This value is correct only for the default frequency of clk25m. If the clk25m frequency is changed, then software is responsible for changing the value of this register. 14h: PAD_SPDCHNG_GEN2_INIT (default) 7h: PAD_SPDCHNG _GEN2_12MHZ_CLK25M 7h: PAD_SPDCHNG _GEN2_13MHZ_CLK25M 9h: PAD_SPDCHNG _GEN2_16_8MHZ_CLK25M Ah: PAD_SPDCHNG _GEN2_19_2MHZ_CLK25M Dh: PAD_SPDCHNG _GEN2_24MHZ_CLK25M Eh: PAD_SPDCHNG _GEN2_26MHZ_CLK25M 14h: PAD_SPDCHNG_GEN2_38_4MHZ_CLK25M
23:8	R/W	300h	T_PCIE2_RP_TIMEOUT0_PAD_PWRUP_CM: Amount of time to wait for pads to power up (e.g., L1 wake) if common-mode voltage was not maintained during power down (i.e., L1P). Measured in units of clk25m clock periods. Default value is 0xF0 (~20 µs). Note: This value is correct only for the default frequency of clk25m. If the clk25m frequency is changed, then software is responsible for changing the value of this register. 300h: PAD_PWRUP_CM_INIT (default) F0h: PAD_PWRUP_CM_12MHZ_CLK25M 104h: PAD_PWRUP_CM_13MHZ_CLK25M 150h: PAD_PWRUP_CM_16_8MHZ_CLK25M 180h: PAD_PWRUP_CM_19_2MHZ_CLK25M 1E0h: PAD_PWRUP_CM_24MHZ_CLK25M 208h: PAD_PWRUP_CM_26MHZ_CLK25M 300h: PAD_PWRUP_CM_38_4MHZ_CLK25M
7:0	R/W	14h	T_PCIE2_RP_TIMEOUT0_PAD_PWRUP: Amount of time to wait for pads to power up (e.g., L1 wake) if common-mode voltage was maintained during power down (i.e., L1). Measured in units of clk25m clock periods (83 ns when using a 12 MHz clk25m clock). Default value is 7 (~500 ns). Note: This value is correct only for the default frequency of clk25m. If the clk25m frequency is changed, then software is responsible for changing the value of this register. 14h: PAD_PWRUP_INIT (default) 7h: PAD_PWRUP_12MHZ_CLK25M 7h: PAD_PWRUP_13MHZ_CLK25M 9h: PAD_PWRUP_16_8MHZ_CLK25M Ah: PAD_PWRUP_19_2MHZ_CLK25M Dh: PAD_PWRUP_24MHZ_CLK25M Eh: PAD_PWRUP_26MHZ_CLK25M 14h: PAD_PWRUP_38_4MHZ_CLK25M

34.4.8.16 T_PCIE2_RP_TIMEOUT1

This is the LINK LTSSM Timeout 1 register.

Offset: 0xE28 | Read/Write: R/W

Bit	R/W	Reset	Description
31:24	R/W	E8h	T_PCIE2_RP_TIMEOUT1_RCVRY_SPD_UNSUCCESS_EIDLE: Amount of time to wait in E-Idle after an unsuccessful speed change. Measured in units of clk25m clock periods (83 ns when using a 12 MHz clock). Note: This value is correct only for the default frequency of clk25m. If the clk25m frequency is changed, then software is responsible for changing the value of this field. E8h: RCVRY_SPD_UNSUCCESS_EIDLE_INIT (default) 49h: UNSUCCESS_EIDLE_12MHZ_CLK25M 4Eh: UNSUCCESS_EIDLE_13MHZ_CLK25M 65h: UNSUCCESS_EIDLE_16_8MHZ_CLK25M 74h: UNSUCCESS_EIDLE_19_2MHZ_CLK25M 91h: UNSUCCESS_EIDLE_24MHZ_CLK25M 9Dh: UNSUCCESS_EIDLE_26MHZ_CLK25M E8h: UNSUCCESS_EIDLE_38_4MHZ_CLK25M
23:16	R/W	20h	T_PCIE2_RP_TIMEOUT1_RCVRY_SPD_SUCCESS_EIDLE: Amount of time to wait in E-Idle after a successful speed change. Measured in units of clk25m clock periods. Note: This value is correct only for the default frequency of clk25m. If the clk25m frequency is changed, then software is responsible for changing the value of this field. 20h: RCVRY_SPD_SUCCESS_EIDLE_INIT (default) Ah: SUCCESS_EIDLE_12MHZ_CLK25M Bh: SUCCESS_EIDLE_13MHZ_CLK25M Eh: SUCCESS_EIDLE_16_8MHZ_CLK25M 10h: SUCCESS_EIDLE_19_2MHZ_CLK25M 14h: SUCCESS_EIDLE_24MHZ_CLK25M 15h: SUCCESS_EIDLE_26MHZ_CLK25M 20h: SUCCESS_EIDLE_38_4MHZ_CLK25M
15:0	R/W	2E8h	T_PCIE2_RP_TIMEOUT1_PAD_SPDCHNG_GEN1: Amount of time to wait for pads to change speed from Gen2 to Gen1. Measured in units of 1 µs. 2E8h: PAD_SPDCHNG_GEN1_INIT (default)

34.4.8.17 T_PCIE2_RP_PRBS

This is the PRBS Results register.

Offset: 0xE34 | Read/Write: R

Bit	R/W	Reset	Description
31:16	R	None	T_PCIE2_RP_PRBS_LOCKED: Each bit indicates that particular lane has locked onto the incoming PRBS pattern and is beginning to count bit errors. For example, if LOCKED[n] is set, lane n has successfully locked onto the incoming PRBS pattern.
15:0	R	None	T_PCIE2_RP_PRBS_ERR_COUNT_OVERFLOW: Each bit indicates number of bit mismatches during PRBS run exceeded 65K for that particular lane. For example, if ERR_COUNT_OVERFLOW[n] is set, lane n registers > 65K bit mismatches.

34.4.8.18 T_PCIE2_RP_PRBS_ERR

This is the PRBS Results register.

Offset: 0xE38 | Read/Write: R/W

Bit	R/W	Reset	Description
31:16	R	0h	T_PCIE2_RP_LANE_PRBS_ERR_COUNT: Number of bit errors detected in the incoming PRBS stream after achieving PRBS lock for the selected lane programmed in ERR_SELECT register.
15:4	R	0	Reserved
3:0	R/W	0h	T_PCIE2_RP_LANE_PRBS_ERR_SELECT: Selects which lane number's Error Count shows up in the ERR_COUNT register 0h: SELECT_INIT (default)

34.4.8.19 T_PCIE2_RP_EIDLE_INFER_TO_0

This is an EIDLE inference timeout register.

Offset: 0xE3C | Read/Write: R/W

Bit	R/W	Reset	Description
31:16	R/W	500h	T_PCIE2_RP_EIDLE_INFER_TO_0_RCVRCFG_SUC_SPEED: Infer E-Idle after this amount of time while in Recovery.RcvrCfg or Recovery. Speed and successful_speed_negotiation = 1. Measured in units of UI (Rx symbol times). 500h: RCVRCFG_SUC_SPEED_INIT (default)
15:0	R/W	80h	T_PCIE2_RP_EIDLE_INFER_TO_0_L0_LPBK: Infer E-Idle after this amount of time while in L0 or Loopback. Active Slave. Measured in units of µs. 80h: L0_LPBK_INIT (default)

34.4.8.20 T_PCIE2_RP_EIDLE_INFER_TO_1

This is an EIDLE inference timeout register.

Offset: 0xE40 | Read/Write: R/W

Bit	R/W	Reset	Description
31:16	R/W	3E80h	T_PCIE2_RP_EIDLE_INFER_TO_1_UNSUC_SPEED_GEN2: Infer E-Idle after this amount of time while in Recovery. Speed and successful_speed_negotiation = 0 and operating in Gen2 speed. Measured in units of UI (rx symbol times). 3E80h: UNSUC_SPEED_GEN2_INIT (default)
15:0	R/W	7D0h	T_PCIE2_RP_EIDLE_INFER_TO_1_UNSUC_SPEED_GEN1: Infer E-Idle after this amount of time while in Recovery. Speed and successful_speed_negotiation = 0 and operating in Gen1 speed. Measured in units of UI (rx symbol times). 7D0h: UNSUC_SPEED_GEN1_INIT (default)

34.4.8.21 T_PCIE2_RP_LTSSM_DBGREG

This is the LTSSM debug register.

Offset: 0xE44 | Read/Write: R/W

Bit	R/W	Reset	Description
31	RW1C	0h	T_PCIE2_RP_LTSSM_DBGREG_LINKFSM31: 0h: LINKFSM31_INIT (default) 1h: LINKFSM31_CLEAR
30	RW1C	0h	T_PCIE2_RP_LTSSM_DBGREG_LINKFSM30: 0h: LINKFSM30_INIT (default) 1h: LINKFSM30_CLEAR

34.4.8.24 T_PCIE2_RP_LTSSM_TRACE_CONTROL

This is the LTSSM Trace Control register. LTSSM state changes are stored in a RAM. This register controls storing of this change in the RAM.

Offset: 0xE50 | Read/Write: R/W

Bit	R/W	Reset	Description
31:14	R	0	Reserved
13:11	R/W	0h	T_PCIE2_RP_LTSSM_TRACE_CONTROL_TRIG_PRX_LTSSM_MINOR: 0h: TRIG_PRX_LTSSM_MINOR_INIT (default)
10:8	R/W	0h	T_PCIE2_RP_LTSSM_TRACE_CONTROL_TRIG_PTX_LTSSM_MINOR: 0h: TRIG_PTX_LTSSM_MINOR_INIT (default)
7:4	R/W	0h	T_PCIE2_RP_LTSSM_TRACE_CONTROL_TRIG_LTSSM_MAJOR: 0h: TRIG_LTSSM_MAJOR_INIT (default)
3	R/W	0h	T_PCIE2_RP_LTSSM_TRACE_CONTROL_TRIG_ON_EVENT: when this bit is set, LTSSM changes will start storing only after its state has reached the state specified in T_PCIE2_RP_LTSSM_TRACE_CONTROL_TRIG_LTSSM_MAJOR, T_PCIE2_RP_LTSSM_TRACE_CONTROL_TRIG_PTX_LTSSM_MINOR and T_PCIE2_RP_LTSSM_TRACE_CONTROL_TRIG_PRX_LTSSM_MINOR state. T_PCIE2_RP_LTSSM_ 0h: TRIG_ON_EVENT_INIT (default)
2	R/W	0h	T_PCIE2_RP_LTSSM_TRACE_CONTROL_CLEAR_RAM: When written with 1, will clear all entries in RAM. 0h: CLEAR_RAM_INIT (default)
1	R/W	0h	T_PCIE2_RP_LTSSM_TRACE_CONTROL_WRAP_EN: When this bit is set, the RAM is updated every time LTSSM state change happens irrespective of whether the write pointer has wrapped around. When this bit is clear, the RAM update is stopped when the RAM is full. RAM needs to be cleared by writing to T_PCIE2_RP_LTSSM_TRACE_CONTROL_CLEAR_RAM before it can start storing new trace. 0h: WRAP_EN_INIT (default) 0h: WRAP_EN_CLEAR 1h: WRAP_EN_SET
0	R/W	1h	T_PCIE2_RP_LTSSM_TRACE_CONTROL_STORE_EN: This bit controls whether RAM needs to be updated whenever an ltssm_state change happens. 1h: STORE_EN_INIT (default) 0h: STORE_EN_CLEAR 1h: STORE_EN_SET

34.4.8.25 T_PCIE2_RP_LTSSM_TRACE_STATUS

This register helps to check the LTSSM trace which has been stored in RAM.

Offset: 0xE54 | Read/Write: R/W

Bit	R/W	Reset	Description
31:22	R	0	Reserved
21:19	R	None	T_PCIE2_RP_LTSSM_TRACE_STATUS_PRX_LTSSM_MINOR: This field returns the data prx_ltssm_minor in ltssm_trace RAM point by T_PCIE2_RP_LTSSM_TRACE_STATUS_READ_ADDR
18:16	R	None	T_PCIE2_RP_LTSSM_TRACE_STATUS_PTX_LTSSM_MINOR: This field returns the data ptx_ltssm_minor in ltssm_trace RAM point by T_PCIE2_RP_LTSSM_TRACE_STATUS_READ_ADDR
15:12	R	None	T_PCIE2_RP_LTSSM_TRACE_STATUS_LTSSM_MAJOR: This field returns the data ltssm_major in ltssm_trace RAM point by T_PCIE2_RP_LTSSM_TRACE_STATUS_READ_ADDR
11	R	None	T_PCIE2_RP_LTSSM_TRACE_STATUS_READ_DATA_VALID: This field returns the data_valid in ltssm_trace RAM point by T_PCIE2_RP_LTSSM_TRACE_STATUS_READ_ADDR. Data valid bit is set an entry is written to that location of RAM.
10:6	R/W	0h	T_PCIE2_RP_LTSSM_TRACE_STATUS_READ_ADDR: This is the read address to LTSSM trace RAM 0h: READ_ADDR_INIT (default)
5:1	R	None	T_PCIE2_RP_LTSSM_TRACE_STATUS_WRITE_PTR: This field indicates the current location of write pointer. This is especially useful when writing to this RAM is enabled even when RAM is full and write pointer is allowed to wrap around.
0	R	None	T_PCIE2_RP_LTSSM_TRACE_STATUS_RAM_FULL: This field indicates whether all entries in RAM have been written. This is especially useful when writing to this RAM is enabled even when RAM is full and write pointer is allowed to wrap around.

34.4.8.26 T_PCIE2_RP_PG

This register helps power gate the PCIe TMS in NVIDIA-specific ways.

Offset: 0xE58 | Read/Write: R/W

Bit	R/W	Reset	Description
31:3	R	0	Reserved
2	R/W	0h	T_PCIE2_RP_PG_RCVD_PME_TO_ACK_INTR_EN: This field enables generation of interrupt on reception of PME TO ACK TLP. 1h RCVD_PME_TO_ACK_INTR_EN_ENABLED 0h RCVD_PME_TO_ACK_INTR_EN_DISABLED (default)
1	RW1C	0h	T_PCIE2_RP_PG_RCVD_PME_TO_ACK: When the root port receives a PME TO ACK TLP, it sets this field. software can write 1 to this field to clear it to 0. NOTE: this field is reset by Cold Reset 0h RCVD_PME_TO_ACK_INIT (default) 1h RCVD_PME_TO_ACK_CLEAR
0	R/W	0h	T_PCIE2_RP_PG_SEND_PME_TO_MSG: Writing 1 to this field when from previous value of 0 causes the root port to send a PME TO message downstream. When the PME TO message is sent to lower stages of the root port (txtf), this field is automatically cleared to 0 by the root port. 0h SEND_PME_TO_MSG_INIT (default) 1h SEND_PME_TO_MSG_SEND_NOW

34.4.8.27 T_PCIE2_RP_VAR_RANGE0

The PCIe Legacy I/O Decode Range Control Registers allow a programmable I/O address range below 4K to be redirected to a PCIe bus downstream from a RP. This is normally not possible due to the definition of the standard I/O Base/Limit registers in the P2P register set. The purpose is to allow legacy devices on PCIe endpoints to operate at their PC legacy default address ranges.

The range is controlled by a pair of generic 12 bit base/limit address register. The ranges can be mapped anywhere in the lower 4K I/O address space. I/O addresses above 4K can be allocated via standard PCI PnP mechanisms.

Offset: 0xE5C | Read/Write: R/W

Bit	R/W	Reset	Description
31:18	R/W	0h	T_PCIE2_RP_VAR_RANGE0_LIMIT: Top address for the variable range positive decode addresses. This will be set to the highest address in the range that the PCIE RP is to decode. Both this range and the base must be set properly for any cycles to be decoded. LIMIT[1:0] always 11'b 0h: LIMIT_DEFAULT (default)
17:16	R	0h	T_PCIE2_RP_VAR_RANGE0_RSVD1: 0h: RSVD1_ZER0 (default)
15:2	R/W	0h	T_PCIE2_RP_VAR_RANGE0_BASE: Base address for the variable range positive decode addresses. This will be set to the lowest address in the range that the PCIE RP is to decode. Both the base and the limit must be set properly for any cycles to be decoded. BASE must be DWORD aligned 0h: BASE_DEFAULT (default)
1	R	0h	T_PCIE2_RP_VAR_RANGE0_RSVD0: 0h: RSVD0_ZER0 (default)
0	R/W	0h	T_PCIE2_RP_VAR_RANGE0_ENABLE: If set then positively decode the variable I/O address range defined in T_PCIE2_VAR_RANGE0. 1h: ENABLE_YES 0h: ENABLE_NO (default)

34.4.8.28 T_PCIE2_RP_VAR_RANGE1

The PCIe Legacy I/O Decode Range Control Registers allow a programmable I/O address range below 4K to be redirected to a PCIe bus downstream from a RP. This is normally not possible due to the definition of the standard I/O Base/Limit registers in the P2P register set. The purpose is to allow legacy devices on PCIe endpoints to operate at their PC legacy default address ranges.

The range is controlled by a pair of generic 12-bit base/limit address register. The ranges can be mapped anywhere in the lower 4K I/O address space. I/O addresses above 4K can be allocated via standard PCI PnP mechanisms.

34.4.8.43 T_PCIE2_RP_VEND_XP

This register contains fields unique to NVIDIA's implementation of PCI Express devices.

Offset: 0xF00 | Read/Write: R/W

Bit	R/W	Reset	Description
31	R/W	0h	T_PCIE2_RP_VEND_XP_FORCE_COMPLIANCE: 0h: FORCE_COMPLIANCE_INIT (default)
30	R	None	T_PCIE2_RP_VEND_XP_DL_UP: This read-only bit tells status of Data Link Layer in XP. This bit was added before the DL Link Active Reporting feature was introduced in the PCI Express Specification. It asserts when the DL enters the InitFC2 phase of training. This means that DL_UP will assert before the DL_LINK_ACTIVE bit asserts.

Bit	R/W	Reset	Description
29	R/W	0h	T_PCIE2_RP_VEND_XP_INTERLEAVE_DLLPS: Setting this bit will cause the DL to schedule Ack and UpdateFC packets earlier or later than their respective timer expiration times in order to decrease the likelihood of losing efficiency by sending two DLLPs consecutively. 0h: INTERLEAVE_DLLPS_INIT (default)
28	R/W	0h	T_PCIE2_RP_VEND_XP_OPPORTUNISTIC_UPDATEFC: If this bit is set, the DL will send any pending UpdateFC packet whenever it has nothing else to send, instead of waiting for the UpdateFC timer to expire. 0h: OPPORTUNISTIC_UPDATEFC_INIT (default)
27	R/W	0h	T_PCIE2_RP_VEND_XP_OPPORTUNISTIC_ACK: If this bit is set, the DL will send pending Acks whenever it has nothing else to send, instead of waiting for the Ack Timer to expire. 0h: OPPORTUNISTIC_ACK_INIT (default)
26	R/W	0h	T_PCIE2_RP_VEND_XP_TRAIN_ERR_ENABLE: Enables reporting of training errors. 0h: TRAIN_ERR_ENABLE_INIT (default)
25:18	R/W	0h	T_PCIE2_RP_VEND_XP_UPDATE_FC_THRESHOLD: This field specifies an override for the UpdateFC frequency. Setting this field to a non-zero value will cause the TL to use the programmed value MULTIPLIED BY TWO as the UpdateFC timer limit instead of the default value which is based on the negotiated width as described in section 2.6.1.2 of the PCI Express Base Specification, Rev 1.0a. The UpdateFC timer limit corresponds to the UpdateFC Transmission Latency Limit listed in table 2-28 of the specification, except that it should *not* include the InternalDelay. 0h: UPDATE_FC_THRESHOLD_INIT (default)
17:2	R	None	T_PCIE2_RP_VEND_XP_PRBS_STAT: This field returns the results of loopback mode testing. Each bit represents the status of one lane (1 == PASS).
1	R/W	0h	T_PCIE2_RP_VEND_XP_PRBS_EN: Enables the root port as loopback master using PRBS-23 as the test pattern. 0h: PRBS_EN_DISABLED (default) 1h: PRBS_EN_ENABLED
0	R/W	0h	T_PCIE2_RP_VEND_XP_EMULATION: Enables emulation mode operation. 0h: EMULATION_OFF (default) 1h: EMULATION_ON

34.4.8.44 T_PCIE2_RP_VEND_XP1

This register contains fields unique to NVIDIA's implementation of PCI Express devices.

Offset: 0xF04 | Read/Write: R/W

Bit	R/W	Reset	Description
31:29	R/W	2h	T_PCIE2_RP_VEND_XP1_L1_EXIT_LATENCY: This field indicates the L1 exit latency for the given PCI Express Link. The value reported indicates the length of time this Port requires to complete transition from L1 to L0. The value is reflected in the LINK_CAPABILITIES register. Defined encodings are: 000b: Less than 1 µs 001b: 1 µs to less than 2 µs 010b: 2 µs to less than 4 µs 011b: 4 µs to less than 8 µs 100b: 8 µs to less than 16 µs 101b: 16 µs to less than 32 µs 110b: 32 µs-64 µs 111b: More than 64 µs 2h: L1_EXIT_LATENCY_INIT (default) 0h: L1_EXIT_LATENCY_LT_1 1h: L1_EXIT_LATENCY_LT_2 2h: L1_EXIT_LATENCY_LT_4 3h: L1_EXIT_LATENCY_LT_8 7h: L1_EXIT_LATENCY_GT_64

Bit	R/W	Reset	Description
28	R/W	0h	T_PCIE2_RP_VEND_XP1_FORCE_DOWNSTREAM_NO_SNOOP: When this bit is set and ENABLE_NO_SNOOP bit is also set, NO_SNOOP bit is set on all downstream TLPs (except for I/O and Config, for which NO_SNOOP is never set) 1h: FORCE_DOWNSTREAM_NO_SNOOP_YES 0h: FORCE_DOWNSTREAM_NO_SNOOP_NO (default)
27	R/W	0h	T_PCIE2_RP_VEND_XP1_FORCE_UPSTREAM_NONCOH: When set this bit causes all upstream memory traffic (except MSI) to be non-coherent. 0h: FORCE_UPSTREAM_NONCOH_INIT (default) 1h: FORCE_UPSTREAM_NONCOH_ENABLED 0h: FORCE_UPSTREAM_NONCOH_DISABLED
26:19	R/W	0h	T_PCIE2_RP_VEND_XP1_LINK_PVT_CTL: bit[0] : ACK_L1_NO_WAIT Enable behavior described in the Errata C7 of the PCI Express Base Specification, v1.0a, 7 October 2003. Software should always set this bit to 1. When this bit is set to 1 on an upstream component, that component will not wait to accumulate the minimum number of credits required to send the largest possible packet for any FC type before sending PM_Request_Ack DLLPs downstream. After receiving a PM_Enter_L1 DLLP, it will begin sending PM_Request_Ack DLLPs as soon as it has received acknowledgment for the last TLP that has been sent. bit [1]: L23_READY_NO_D3 Enable entry into the L2/3 Ready state when the component is not in the D3 PMCSR state. If this bit is set to 0, the component will not allow the link to enter the L2/3 Ready state if it is not in D3. If the bit is set to 1, the link will enter L2/3 Ready after the component receives a PME_Turn_Off message, regardless of the PMCSR state. bit [2]: L1_ASPM_SUPPORT This bit determines the reported value of L1 ASPM support in the link capability register (ACTIVE_STATE_LINK_PM_SUPPORT, bit 11). bit [3]: DONT_MERGE_PMASNAK With the default setting for this bit (0), a group of PM_Active_State_Request_L1 DLLPs from the endpoint will cause a single PM_ASPM_Nak TLP to be sent. If this bit is set to 1, multiple PM_ASPM_Nak TLP messages will be sent, possibly as many as one PM_ASPM_Nak TLP for each PM_Active_State_Request_L1 DLLP. bit [4]: IGNORE_L0S This bit overrides the L0s setting for the Active Sate PM Control register. If bit[4] == 0 (do not override), then bit 0 of the T_PCIE2_RP_LINK_CONTROL_STATUS register is used to determine if the Tx side drivers should enter L0s or not. If bit[4] == 1 (override), then bit 0 of T_PCIE2_RP_LINK_CONTROL_STATUS is ignored, and Tx.L0s is not entered. bit [7]: NP_REQ_TIMEOUT If set, disable downstream NP request timeout. This is for debug purposes to hang instead of timeout. 0h: LINK_PVT_CTL_INIT (default)
18:10	R/W	0h	T_PCIE2_RP_VEND_XP1_ACK_TIMER_LIMIT: This field overrides the Ack Timer Limit for this root port. Setting this field to a non-zero value will cause the DL to use the programmed value for the Ack Timer Limit instead of the default value, which is based on the negotiated width as described in section 3.5.3.1 of the PCI Express Base Specification, Rev 1.0a. The Ack Timer Limit corresponds to the Unadjusted Ack Transmission Latency Limit listed in table 3-5 of the specification, except that it should include the Tx_L0s_Adjustment, and should *not* include the InternalDelay. 0h: ACK_TIMER_LIMIT_INIT (default)
9	R	0	Reserved
8	R/W	1h	T_PCIE2_RP_VEND_XP1_RNCTRL_GEN2_WAIT_FOR_FIRST_EIES: When this bit is programmed to 1, in the Config.LinkWidth.Start state, the inactive lanes that are activated will wait for the next EIEOS transmission before sending the first packet. If programmed to 0, it will not wait for the next EIEOS transmission before sending the first packet. 1h: RNCTRL_GEN2_WAIT_FOR_FIRST_EIES_INIT (default)
7	R	0h	T_PCIE2_RP_VEND_XP1_RNCTRL_EN: When this bit is programmed to a 1, it triggers the dynamic link width re-negotiation procedure in XP. This bit is a constant and always returns a value of 0 on a read. 0h: RNCTRL_EN_ZERO (default)
6	R/W	1h	T_PCIE2_RP_VEND_XP1_RNCTRL_GEN2_LINK_UPGRADE: When this bit is programmed to 1, it selects the 2.0-compliant link width upgrade protocol. If programmed to 0, it selects the NV-proprietary link width upgrade protocol. 1h: RNCTRL_GEN2_LINK_UPGRADE_INIT (default)
5:0	R/W	10h	T_PCIE2_RP_VEND_XP1_RNCTRL_MAXWIDTH: This field indicates the maximum link width required at the end of dynamic link width re-negotiation process. The default value is 16. 10h: RNCTRL_MAXWIDTH_INIT (default)

34.4.8.45 T_PCIE2_RP_VEND_XP2

This register contains fields unique to NVIDIA's implementation of PCI Express devices.

Offset: 0xF08 | Read/Write: R/W

Bit	R/W	Reset	Description
31:24	R/W	0h	T_PCIE2_RP_VEND_XP2_L0S_UPDATE_WAKE: Setting this field to a non-zero value will cause the DL to wake the PL out of L0s in advance of sending it an UpdateFC packet. When the DL sees that there are fewer cycles left in the UpdateFC timer than the value in the L0S_UPDATE_WAKE register, it will tell the PL to wake out of L0s. 0h: L0S_UPDATE_WAKE_INIT (default)
23:18	R	0	Reserved
17:8	R/W	3FFh	T_PCIE2_RP_VEND_XP2_L0S_THRESHOLD: This field controls the idle time required for TxL0s entry from L0, in symbol times (250 MHz clocks). Once the XP detects that it has no more DLLPs/TLPs to send, it will insert precisely (L0S_THRESHOLD + 1) logical idles between the END symbol of the last DLLP/TLP and the COM of the IDL Ordered Set. If L0S_THRESHOLD == 0x3FF, the L0s entry latency is instead (endpoint N_FTS)*4 symbol times, where (endpoint N_FTS) is the N_FTS value advertised by the endpoint during training. Therefore, the threshold can be set to anywhere from 1 to 1023 symbol times (4ns to 4092ns). 3FFh: L0S_THRESHOLD_INIT (default) 3FFh: L0S_THRESHOLD_REMOTE_NFTS
7:0	R/W	0h	T_PCIE2_RP_VEND_XP2_L0S_ACK_WAKE: Setting this field to a non-zero value will cause the DL to wake the PL out of L0s in advance of sending it an Ack packet. When the DL sees that there are fewer cycles left in the Ack timer than the value in the L0S_ACK_WAKE register, it will tell the PL to awaken from L0s. 0h: L0S_ACK_WAKE_INIT (default)

34.4.8.46 T_PCIE2_RP_VEND_XV_TIMEOUT

XP Extended Control Register 2

This register contains fields unique to NVIDIA's implementation of PCI Express devices.

Offset: 0xF0C | Read/Write: R/W | Reset: 0x030000fa (0b000000110000xxxxxxxxxx0011111010)

Bit	Reset	Description
31:20	N333	N100MS_DFPCI: 24 = N250 48 = N333
19:10	0	Reserved
9:0	DDEFAULT	MICROSECOND: 250 = DDEFAULT 250 = N250 278 = N278 313 = N313 357 = N357 417 = N417 500 = N500 555 = N555

34.4.8.47 T_PCIE2_RP_VEND_SLOT_STRAP

This register contains fields unique to NVIDIA's implementation of PCI Express devices.

This is a back-door register used to set various bits in the Slot Capabilities Register, which is part of the PCI-Express Capability Structure, as defined by the PCI-Express Specification. The bits listed here map 1:1 with the bits in the Slot Capabilities Register.

Note: *Bits marked "Reserved" may actually be writable in some chips. Therefore writes to this register must not change the default POR values for the bits marked "Reserved".*

Offset: 0xF20 | Read/Write: R/W

Bit	R/W	Reset	Description
31:19	R/W	0h	T_PCIE2_RP_VEND_SLOT_STRAP_PHYSICAL_SLOT_NUMBER: The physical numbering of the slots is left up to the board designer. The board designer must communicate the physical slot numbers to the SBIOS developer as well. 0h: PHYSICAL_SLOT_NUMBER_INIT (default)
18:17	R	0	Reserved
16:15	R/W	0h	T_PCIE2_RP_VEND_SLOT_STRAP_SLOT_POWER_LIMIT_SCALE: This field must be programmed according to the unique power-rail capabilities of each board design. Board designers are responsible for communicating the power limits of each slot to the SBIOS developers. 0h: SLOT_POWER_LIMIT_SCALE_INIT (default)
14:7	R/W	0h	T_PCIE2_RP_VEND_SLOT_STRAP_SLOT_POWER_LIMIT_VALUE: This field must be programmed according to the unique power-rail capabilities of each board design. Board designers are responsible for communicating the power limits of each slot to the SBIOS developers. 0h: SLOT_POWER_LIMIT_VALUE_INIT (default)
6:0	R	0	Reserved

34.4.8.48 T_PCIE2_RP_XP_REF

This register contains diagnostic bits used in XP.

Offset: 0xF30 | Read/Write: R/W

Bit	Reset	Description
31:14	0x01D4C	CPL_TO_CUSTOM_VALUE: User-specified value to use for completion timeout. Program this register to the desired completion timeout value in ns divided by16 divided by the clock period of clk25m (83.33 ns). Default value is 0x1d4c, which works out to be 10 ms. This value has meaning only when CPL_TO_OVERRIDE is enabled. 0x0001D4C: INIT
13	0	CPL_TO_OVERRIDE: Enables the user override mode for completion timeout. Default is disabled. 0: INIT 1: ENABLE 0: DISABLE
12	1	ADVANCE_BY_2_CYA: Diagnostic bit. Default is enabled. 1: INIT 1: ENABLE 0: DISABLE
11	1	NAK_SCHEDULE_CYA: Diagnostic bit. Default is enabled. 1: INIT 1: ENABLE 0: DISABLE
10	1	RXL2LINK_NPT_EMPTY_CYA: Diagnostic bit. Default is enabled. 1: INIT 1: ENABLE 0: DISABLE
9	1	L2_READ_FIX_EN: Diagnostic bit. When enabled, Downstream FPCI transactions are retried in Link Config state. 1: INIT 1: ENABLE 0: DISABLE
8	0	MICROSECOND_ENABLE: When enabled, use the counter value from REF_MICROSECOND_LIMIT. When disabled, use the hard-coded value. 0: INIT 1: ENABLE 0: DISABLE

Bit	Reset	Description
7:0	0x27	MICROSECOND_LIMIT: Counter value to be used to reset the one microsecond counter used for UpdateFC scheduling. Note: This value is correct only for the default frequency of clk25m. If the clk25m frequency is changed, then software is responsible for changing the value of this register. 0x27: INIT 0xC: 12MHZ_CLK25M 0xD: 13MHZ_CLK25M 0x11: 16_8MHZ_CLK25M 0x14: 19_2MHZ_CLK25M 0x18: 24MHZ_CLK25M 0x1A: 26MHZ_CLK25M 0x27: 38_4MHZ_CLK25M

34.4.8.49 T_PCIE2_RP_VEND_CTL1

This register contains fields unique to NVIDIA's implementation of PCI Express devices. This is a control register for general feature and function control.

Offset: 0xF48 | Read/Write: R/W

Bit	R/W	Reset	Description
31:22	R	0	Reserved
21	R/W	1h	T_PCIE2_RP_VEND_CTL1_POLLING_RESET_FIX_EN: 1h: POLLING_RESET_FIX_EN_INIT (default) 1h: POLLING_RESET_FIX_EN_ENABLE 0h: POLLING_RESET_FIX_EN_DISABLE
20	R/W	1h	T_PCIE2_RP_VEND_CTL1_HOTPLUG_IN_TRAFFIC_EN: 1h: HOTPLUG_IN_TRAFFIC_EN_INIT (default) 1h: HOTPLUG_IN_TRAFFIC_EN_ENABLE 0h: HOTPLUG_IN_TRAFFIC_EN_DISABLE
19	R/W	0h	T_PCIE2_RP_VEND_CTL1_NISO2ISO: When set to 1, all upstream non-ISO-PW and non-ISO-NP will be upgraded to ISO. 0h: NISO2ISO_INIT (default) 1h: NISO2ISO_ENABLE 0h: NISO2ISO_DISABLE
18	R/W	0h	T_PCIE2_RP_VEND_CTL1_ALLOW_UPSTREAM_CMPL_OVERTAKE_PW: When set to 1, the UBFI allows the CPL to bypass posted writes regardless of the RO bit 0h: ALLOW_UPSTREAM_CMPL_OVERTAKE_PW_DIS (default) 1h: ALLOW_UPSTREAM_CMPL_OVERTAKE_PW_EN
17	R/W	0h	T_PCIE2_RP_VEND_CTL1_SPLIT_ARB_BLOCK_COH: When set to 0, take the single ufpci2fpci_arb_block_coherent as input. When set to 1, take the separate inputs of ufa2fpci_arb_block_coherent_pw and ufa2fpci_arb_block_coherent_np. 0h: SPLIT_ARB_BLOCK_COH_INIT (default) 0h: SPLIT_ARB_BLOCK_COH_DIS 1h: SPLIT_ARB_BLOCK_COH_EN
16	R/W	0h	T_PCIE2_RP_VEND_CTL1_HIDE_MSIMAP: 0h: HIDE_MSIMAP_DIS (default) 1h: HIDE_MSIMAP_EN
15	R/W	1h	T_PCIE2_RP_VEND_CTL1_LINKACTV_REPORTING: This is a backdoor bit for setting the Data Link Layer Link Active Reporting Capable bit (bit 20 of the Link Capabilities Register). This bit *MUST* be set whenever hot-plug is enabled. Otherwise, it can be set as desired. 1h: LINKACTV_REPORTING_CAPABLE (default) 0h: LINKACTV_REPORTING_NOT_CAPABLE
14	R/W	1h	T_PCIE2_RP_VEND_CTL1_P2P_ISO2NISO: If set, forces upstream peer-to-peer ISO requests to be peer-to-peer NONISO. 1h: P2P_ISO2NISO_EN (default) 0h: P2P_ISO2NISO_DIS
13	R/W	0h	T_PCIE2_RP_VEND_CTL1_ERPT: This bit, when 0, hides the entire AER Capability structure from the capabilities list. It causes the "next pointer" of the previous capability to point to NULL. Normally, AER is the last capability in the list. 1h: ERPT_EN 0h: ERPT_DIS (default)

Bit	R/W	Reset	Description
12	R/W	0h	T_PCIE2_RP_VEND_CTL1_HIDE_MSI_CAP: This bit, when 1, hides the entire MSI Capability structure from the capabilities list. It causes the "next pointer" of the previous capability to point to the capability that comes after MSI. 0h: HIDE_MSI_CAP_DIS (default) 1h: HIDE_MSI_CAP_EN
11:5	R	0	Reserved
4	R/W	0h	T_PCIE2_RP_VEND_CTL1_ACCEPT_MSGD1: When set, allows acceptance of NVIDIA specific vendor type message with data. 0h: ACCEPT_MSGD1_DIS (default) 1h: ACCEPT_MSGD1_EN
3:1	R/W	7h	T_PCIE2_RP_VEND_CTL1_TC2ISO_MAP: This field specifies TC2ISO_MAP[2:0]. Upstream traffic with TC[2:0] >= TC2ISO_MAP[2:0] are sent as ISO requests on UFPCI Since TC[2:0] == 0 can never be sent to ISO channel, TC2ISO_MAP[2:0] == 0 is used to force ALL traffic to NONISO 7h: TC2ISO_MAP_7 (default)
0	R/W	0h	T_PCIE2_RP_VEND_CTL1_P2P_BLOCK_P2P_ONLY: When set, ignores ufa2fpci_arb_block_coherent for upstream peer2peer requests. 1h: P2P_BLOCK_P2P_ONLY_EN 0h: P2P_BLOCK_P2P_ONLY_DIS (default)

34.4.8.50 T_PCIE2_RP_VEND_XP_BIST

This register contains fields unique to NVIDIA's implementation of PCI Express devices.

IOBIST and Characterization Control Register

Offset: 0xF4C | Read/Write: R/W

Bit	R/W	Reset	Description
31	R	0	Reserved
30	R/W	0h	T_PCIE2_RP_VEND_XP_BIST_GOTO_DETECT_ON_SURPRISE_EIDLE: 0h: GOTO_DETECT_ON_SURPRISE_EIDLE_INIT (default)
29	R/W	0h	T_PCIE2_RP_VEND_XP_BIST_ENABLE_SERR_REPORTING: 0h: ENABLE_SERR_REPORTING_INIT (default)
28	R/W	1h	T_PCIE2_RP_VEND_XP_BIST_GOTO_L1_L2_AFTER_DLLP_DONE: 1h: GOTO_L1_L2_AFTER_DLLP_DONE_INIT (default)
27	R/W	0h	T_PCIE2_RP_VEND_XP_BIST_CTRL_IGNORE_LPBK_EXIT: 0h: CTRL_IGNORE_LPBK_EXIT_INIT (default)
26	R/W	0h	T_PCIE2_RP_VEND_XP_BIST_CTRL_RELAX_LPBK_ENTRY: 0h: CTRL_RELAX_LPBK_ENTRY_INIT (default)
25	R/W	0h	T_PCIE2_RP_VEND_XP_XP_BIST_CTRL_FORCE_PRBS_RST: 0h: INIT (default)
24	R/W	0h	T_PCIE2_RP_VEND_XP_FORCE_DEEMPHASIS_ADVERTISED_EN: 0h: INIT (default)
23	R	0h	Reserved
22	R/W	0h	T_PCIE2_RP_VEND_XP_FORCE_RECEIVER_COMPLIANCE_EN: 0h: INIT (default)
21	R/W	0h	T_PCIE2_RP_VEND_XP_FORCE_COMPLIANCE_GEN2_SPEED_EN: 0h: INIT (default)
20	R/W	0h	T_PCIE2_RP_VEND_XP_BIST_FORCE_COMPLIANCE_AND_ADVERTISE_MODE: 0h: FORCE_COMPLIANCE_AND_ADVERTISE_MODE_INIT (default)
19:0	R	0	Reserved

34.4.8.51 T_PCIE2_RP_VEND_XP_FTS

This register contains fields unique to NVIDIA's implementation of PCI Express devices.

Offset: 0xF54 | Read/Write: R/W

Bit	R/W	Reset	Description
31:24	R/W	80h	T_PCIE2_RP_VEND_XP_FTS_TS_DETECT_START: 80h: TS_DETECT_START_INIT (default)
23:16	R/W	40h	T_PCIE2_RP_VEND_XP_FTS_FTS_DETECT_START: This field represents the number of symbol times to wait before the root port begins looking at FTS ordered sets when exiting L0s -- the incoming data is essentially ignored during this time. 40h: FTS_DETECT_START_INIT (default)
15:8	R	None	T_PCIE2_RP_VEND_XP_FTS_N_FTS_REMOTE: NV_XVE_PRIV_XP_N_FTS_REMOTE represents the N_FTS value advertised by the remote device as recorded from the N_FTS symbol of the received TS ordered sets.
7:0	R/W	1Fh	T_PCIE2_RP_VEND_XP_FTS_N_FTS: This field represents the N_FTS value to advertise to the device on the other side of the link. NOTE: If this field is modified from its default (POR) value, the Replay Timer Limit in T_PCIE2_RP_VEND_XP1 must be adjusted accordingly. 1Fh: N_FTS_INIT (default)

34.4.8.52 T_PCIE2_RP_VEND_XP_STATS0

This register contains fields unique to NVIDIA's implementation of PCI Express devices.

Offset: 0xF58 | Read/Write: R/W

Bit	R/W	Reset	Description
31:29	R	0	Reserved
28	R/W	0h	T_PCIE2_RP_VEND_XP_STATS0_FAILED_L0S_EXITS_INF: When set to 1, the failed L0s exits counter accumulates indefinitely (i.e. the one millisecond timer is ignored). 0h: FAILED_L0S_EXITS_INF_INIT (default)
27:25	R	0	Reserved
24	R	0h	T_PCIE2_RP_VEND_XP_STATS0_FAILED_L0S_EXITS_LC: Loads the current value from the failed L0s exits counter into the VEND_XP_STATS1 register, and then clears the failed L0s exits counter. The counter begins counting again immediately after it is cleared. Write a 1 to this field to trigger the load-and-clear operation. 0h: FAILED_L0S_EXITS_LC_INIT (default)
23:21	R	0	Reserved
20	R/W	0h	T_PCIE2_RP_VEND_XP_STATS0_NAKS_RCVD_INF: When set to 1, the NAKs received counter accumulates indefinitely (i.e. the 64 microsecond timer is ignored). 0h: NAKS_RCVD_INF_INIT (default)
19:17	R	0	Reserved
16	R	0h	T_PCIE2_RP_VEND_XP_STATS0_NAKS_RCVD_LC: Loads the current value from the NAKs received counter into the VEND_XP_STATS1 register, and then clears the NAKs received counter. The counter begins counting again immediately after it is cleared. Write a 1 to this field to trigger the load-and-clear operation. 0h: NAKS_RCVD_LC_INIT (default)
15:13	R	0	Reserved
12	R/W	0h	T_PCIE2_RP_VEND_XP_STATS0_CRC_ERRORS_INF: When set to 1, the CRC error counter accumulates indefinitely (i.e. the 64 microsecond timer is ignored). 0h: CRC_ERRORS_INF_INIT (default)
11:9	R	0	Reserved
8	R	0h	T_PCIE2_RP_VEND_XP_STATS0_CRC_ERRORS_LC: Loads the current value from the CRC error counter into the VEND_XP_STATS1 register, and then clears the CRC error counter. The counter begins counting again immediately after it is cleared. Write a 1 to this field to trigger the load-and-clear operation. 0h: CRC_ERRORS_LC_INIT (default)
7:5	R	0	Reserved
4	R/W	0h	T_PCIE2_RP_VEND_XP_STATS0_8B10B_ERRORS_INF: When set to 1, the 8b/10b error counter accumulates indefinitely (i.e. the one microsecond timer is ignored). 0h: 8B10B_ERRORS_INF_INIT (default)

Bit	R/W	Reset	Description
3:1	R	0	Reserved
0	R	0h	T_PCIE2_RP_VEND_XP_STATS0_8B10B_ERRORS_LC: Loads the current value from the 8B/10B error counter into the VEND_XP_STATS1 register, and then clears the 8b/10b error counter. The counter begins counting again immediately after it is cleared. Write a 1 to this field to trigger the load-and-clear operation. Note: This counter will count the number of 8b10b errors in a time window of size 14 clk25m clock periods from the time a 1 is written into this field. Depending on the clock frequency of clk25m, this window will be sized differently. Default is 12 clock periods (1 us). 0h: 8B10B_ERRORS_LC_INIT (default)

34.4.8.53 T_PCIE2_RP_VEND_XP_STATS1

This register contains fields unique to NVIDIA's implementation of PCI Express devices.

Offset: 0xF5C | Read/Write: R

Bit	R/W	Reset	Description
31:24	R	None	T_PCIE2_RP_VEND_XP_STATS1_FAILED_L0S_EXITS: Counts the number of times the RX side of the XP went into Recovery in one millisecond, due to a failed attempt to exit L0s. Saturates at 255 (counter does not roll over to 0).
23:16	R	None	T_PCIE2_RP_VEND_XP_STATS1_NAKS_RCVD: Counts the number of NAKs received from the endpoint in 64 microseconds. Saturates at 255 (counter does not roll over to 0).
15:8	R	None	T_PCIE2_RP_VEND_XP_STATS1_CRC_ERRORS: Counts the number of CRC errors detected in 64 microseconds. Saturates at 255 (counter does not roll over to 0).
7:0	R	None	T_PCIE2_RP_VEND_XP_STATS1_8B10B_ERRORS: Counts the number of 8b/10b errors detected in one microsecond. Saturates at 255 (counter does not roll over to 0).

34.4.8.54 T_PCIE2_RP_VEND_ERROR_COUNT

This register contains 8-bit saturating counters for some of RXL and TXBA reported errors.

Offset: 0xF60 | Read/Write: R

Bit	R/W	Reset	Description
31:24	R	0	Reserved
23:16	R	None	T_PCIE2_RP_VEND_ERROR_COUNT_REPLAY: Counts the number of times that TXBA replays. Saturates at 8'hFF. Can be cleared by writing 1 to PRIV_ERRSTS_REPLAY_STARTED_ERR.
15:8	R	None	T_PCIE2_RP_VEND_ERROR_COUNT_BAD_TLP: Counts bad tlps reported by RXL (sum of lcrcl_err and bad_seq). Saturates at 8'hFF. Can be cleared by writing 1 to ERPTCAP_CERR_BAD_TLP
7:0	R	None	T_PCIE2_RP_VEND_ERROR_COUNT_LCRC_ERR: Counts LCRCL Errors reported by RXL. Saturates at 8'hFF. Can be cleared by writing 1 to PRIV_ERRSTS_LCRC_ERR.

34.4.8.55 T_PCIE2_RP_CFG_MISC

This register contains fields unique to NVIDIA's implementation of PCI Express devices.

Offset: 0xF64 | Read/Write: R/W

Bit	R/W	Reset	Description
31:8	R	0	Reserved
7:0	R/W	0h	T_PCIE2_RP_CFG_MISC_MUTE_IDLE: MUTE mode is a power management feature in which cpu_clk and m2clk can be gated, if all the units are idle. A particular unit is idle when it has no outstanding transactions to be sent out. The MUTE_IDLE field is used to delay the idle assertion from xvr to clk. It should be programmed to cover the synchronization delay from cpu_clk to m2clk. 0h: MUTE_IDLE_MIN (default) FFh: MUTE_IDLE_MAX

34.4.8.56 T_PCIE2_RP_PRIV_XP_INIT_RECOVERY

Each new time frame, the number of 8B/10B errors is counted. As soon as the number of 8B/10B errors is equal to the threshold, the link is sent into recovery. If at the end of the time frame, the number of 8B/10B errors is smaller than the threshold, a new time frame is started in which the 8B/10B errors are counted.

Offset: 0xF68 | Read/Write: R/W

Bit	R/W	Reset	Description
31	R/W	0h	T_PCIE2_RP_PRIV_XP_INIT_RECOVERY_8B10B_ERROR_ENABLE: This bit enables the feature T_PCIE2_RP_ERRORRATE_8B10B_ENABLE_OFF disables the feature T_PCIE2_RP_ERRORRATE_8B10B_ENABLE_ON enables the feature 0h: 8B10B_ERROR_ENABLE_INIT (default)
30:20	R/W	64h	T_PCIE2_RP_PRIV_XP_INIT_RECOVERY_8B10B_ERROR_WINDOW: Programs the timeframe in multiples of 1 microsecond. 64h: 8B10B_ERROR_WINDOW_100US (default)
19:0	R/W	9C4h	T_PCIE2_RP_PRIV_XP_INIT_RECOVERY_8B10B_ERROR_THRESHOLD: Bit [21:1] programs the 8B/10B error threshold. If the number of errors in the programmed timeframe is equal to the threshold, the link is sent into recovery. 9C4h: 8B10B_ERROR_THRESHOLD_2500 (default)

34.4.8.57 T_PCIE2_RP_PRIV_XP_LCTRL_2

Offset: 0xF6C | Read/Write: R/W

Bit	R/W	Reset	Description
31	R	None	T_PCIE2_RP_PRIV_XP_LCTRL_2_UPCONFIGURE_CAPABLE: Gen2 link width up-configure capability of remote device as recorded from data rate id of received TS ordered sets.
30	R/W	0h	T_PCIE2_RP_PRIV_XP_LCTRL_2_REV2P0_COMPLIANCE_DIS: To disable advertising rev2.0 support and link width up-configure capability. 0h: REV2P0_COMPLIANCE_DIS_INIT (default)
29	R/W	1h	T_PCIE2_RP_PRIV_XP_LCTRL_2_EIDLE_INFERENCE_EN: To disable electrical idle inference. It is enabled by default. 1h: EIDLE_INFERENCE_EN_INIT (default)
28	R/W	1h	T_PCIE2_RP_PRIV_XP_LCTRL_2_SURPRISE_IDLE_USE_STAT_IDLE: When set, use idle status signals from the pad to detect surprise electrical idle entry when running in Gen1 speed. 1h: SURPRISE_IDLE_USE_STAT_IDLE_INIT (default)
27	R/W	1h	T_PCIE2_RP_PRIV_XP_LCTRL_2_ALLOW_SPEED_CHANGE_FROM_L1: When set to 1, allow speed change to be initiated from the L1 or Rx_L0s link states. 1h: ALLOW_SPEED_CHANGE_FROM_L1_INIT (default)
26:24	R/W	0h	T_PCIE2_RP_PRIV_XP_LCTRL_2_RECOVERY_SPEED_TIMEOUT_ADJ: To adjust the minimum length of time the transmitter stays in electrical idle in the Recover.Sped state. The value denotes the time in microseconds added. 0h: RECOVERY_SPEED_TIMEOUT_ADJ_INIT (default)
23:20	R/W	6h	T_PCIE2_RP_PRIV_XP_LCTRL_2_N_EIE_SYMBOLS: This represents the number of K28.7 symbols transmitted prior to transmitting the first FTS ordered set in the Tx.L0s.FTS state when running in Gen2 speed. 6h: N_EIE_SYMBOLS_INIT (default)
19	R/W	0h	T_PCIE2_RP_PRIV_XP_LCTRL_2_DEEMPHASIS_STRAP: This is the backdoor register for BIOS to write an initial value to the HWInit register PCIE2_RP_LINK_CONTROL_STATUS_2_SELECTABLE_DEEMPHASIS. 0 = -6db 1 = -3.5db 0h: DEEMPHASIS_STRAP_INIT (default)

Bit	R/W	Reset	Description
18	R/W	0h	T_PCIE2_RP_PRIV_XP_LCTRL_2_ENFORCE_DEEMPHASIS: Forces root port to use de-emphasis value specific in Link Control 2 Selectable De-emphasis field instead of the value requested by the endpoint (advertised in TSs). This bit is reserved for endpoint. Default value is 0b. Functionality of this bit is no longer needed since TX_PEAK_R2_SEL1/SEL0 registers provide complete control over AMP/PEAK/PEAK_PRE settings in gen2. NOTE: this field is reset by Cold Reset 0h: ENFORCE_DEEMPHASIS_INIT (default)
17	R/W	0h	T_PCIE2_RP_PRIV_XP_LCTRL_2_POLLING_PREDETERMINED_LANES: When set to 1, only lane 0 or 15 needs to detect an exit from electrical idle before moving from Polling.Active to Polling.Config. This bit is not yet implemented. 0h: POLLING_PREDETERMINED_LANES_DISABLE (default)
16	R/W	0h	T_PCIE2_RP_PRIV_XP_LCTRL_2_AUTONOMOUS_CHANGE: When set to 1, it indicates that the Upstream port-initiated link width/speed change is not caused by a link reliability issue. 0h: AUTONOMOUS_CHANGE_INIT (default)
15:12	R	1h	T_PCIE2_RP_PRIV_XP_LCTRL_2_DATA_RATE_SUPPORTED_REMOTE: Gen2 data rate supported by other side as recorded from data rate identifier of received TS ordered sets. 1h: DATA_RATE_SUPPORTED_REMOTE_2P5 (default) 2h: DATA_RATE_SUPPORTED_REMOTE_5P0_2P5
11:8	R/W	2h	T_PCIE2_RP_PRIV_XP_LCTRL_2_DATA_RATE_SUPPORTED: When set to 4'b01, the supported link speed reported in the Link Capabilities Register is 2.5 Gb/s. When set to 4'b10, the supported link speeds reported in the Link Capabilities Register are 5.0 Gb/s and 2.5 Gb/s. 1h: DATA_RATE_SUPPORTED_2P5 2h: DATA_RATE_SUPPORTED_5P0_2P5 (default)
7:4	R/W	2h	T_PCIE2_RP_PRIV_XP_LCTRL_2_TARGET_LINK_SPEED: Specifies the link rate to change to. This is reflected in the data rate advertised in the data rate identifier field of TS ordered sets. 1h: TARGET_LINK_SPEED_2P5 2h: TARGET_LINK_SPEED_5P0 (default)
3	R/W	0h	T_PCIE2_RP_PRIV_XP_LCTRL_2_CTL_TX_MARGIN_OVERRIDE: 0h: CTL_TX_MARGIN_OVERRIDE_DISABLED (default) 1h: CTL_TX_MARGIN_OVERRIDE_ENABLED
2	R	0	Reserved
1	R/W	0h	T_PCIE2_RP_PRIV_XP_LCTRL_2_ADVERTISED_RATE_CHANGE: A write of 1 to this bit triggers the LTSSM to enter Recovery state, without setting the speed change bit, to change the advertised rate. This bit returns a value of 0 on a read. 0h: ADVERTISED_RATE_CHANGE_ZERO (default)
0	R/W	0h	T_PCIE2_RP_PRIV_XP_LCTRL_2_SPEED_CHANGE: A write of 1 to this bit triggers the link speed negotiation procedure. This bit returns a value of 0 on a read. 0h: SPEED_CHANGE_ZERO (default)

34.4.8.58 T_PCIE2_RP_PRIV_XP_PAD_PWRUP

Offset: 0xF74 | Read/Write: R/W

Bit	R/W	Reset	Description
31:24	R	0	Reserved
23:16	R/W	0h	T_PCIE2_RP_PRIV_XP_PAD_PWRUP_PMRX_PWRUP_THRESHOLD: It is the time to hold CDR at reset in Recovery.RcvrLock while waiting for power rails to be stable 0h: PMRX_PWRUP_THRESHOLD_INIT (default)
15:0	R	0	Reserved

34.4.8.59 T_PCIE2_RP_PRIV_XP_RECOVERY_REASONS

This register records the reasons for going into the recovery state. Each bit represents a different reason. Search for "recovery_reason" in the linkfsm to see what each bit means, as it likely will change from project to project. Writing a 0 clears the register and enters into "record ALL recoveries encountered" mode. Writing a 1 clears the register and enters into "record NEXT recovery encountered" mode. The default mode is "record ALL"

Offset: 0xF84 | Read/Write: R/W

4	R/W	0h	T_PCIE2_RP_VEND_CTL2_GEN2_PROTOCOL_DISABLE: This will disable Gen2 protocol and will force the use of Gen 1.1 protocol. 0h: GEN2_PROTOCOL_DISABLE_OFF (default) 1h: GEN2_PROTOCOL_DISABLE_ON
3	R	0	Reserved
2	R/W	1h	T_PCIE2_RP_VEND_CTL2_DEV_CAP_EXTENDED_TAG_FIELD_SIZE: This is shadow field of the T_PCIE2_RP_DEVICE_CAPABILITY_EXTENDED_TAG_FIELD_SIZE. Values written to this field will be reflected in EXTENDED_TAG_FIELD_SIZE of T_PCIE2_RP_DEVICE_CAPABILITY. 1h: DEV_CAP_EXTENDED_TAG_FIELD_SIZE_8B (default) 0h: DEV_CAP_EXTENDED_TAG_FIELD_SIZE_5B
1	R/W	0h	T_PCIE2_RP_VEND_CTL2_DIS_MA_TA_EP_MERGE: When set disables the logic which takes care of merging of EP/MA/TA when merging is enabled on CPL packet (downstream). 1h: DIS_MA_TA_EP_MERGE_ON 0h: DIS_MA_TA_EP_MERGE_OFF (default)
0	R	0	Reserved

34.4.8.69 T_PCIE2_RP_PRIV_XP_CONFIG

Offset: 0xFAC | Read/Write: R/W

Bit	R/W	Reset	Description
31:2	R	0	Reserved
1:0	R/W	0h	T_PCIE2_RP_PRIV_XP_CONFIG_LOW_PWR_DURATION: Meant for selection of different types of the information logging for the Health and Performance counters. Primarily, this register supports the selection of different information for the low power duration count. It is used for selecting the Low power information to be presented in the T_PCIE2_RP_PRIV_XP_DURATION_IN_LOW_PWR_100NS register. TX_L0S, RX_L0S and L1 collect the duration for which LTSSM was in that state. DURATION_IDLE selection gives following IDLE = Duration(TX_L0S && RX_L0S) + Duration of L1 0h: LOW_PWR_DURATION_TX_L0S (default) 1h: LOW_PWR_DURATION_RX_L0S 2h: LOW_PWR_DURATION_L1 3h: LOW_PWR_DURATION_IDLE

34.4.8.70 T_PCIE2_RP_PRIV_XP_DURATION_IN_LOW_PWR_100NS

This register counts the duration in multiples of 100ns for the type of low power information selected by the T_PCIE2_RP_PRIV_XP_CONFIG_LOW_PWR_DURATION register.

Note: *This actually reports in multiples of clk25m time periods that fit into 100ns:*

Actual time = int(100 / clk25m time period) * 100NS_VALUE

For example, when clk25m = 12 MHz, the time period is 83.33 ns, so this status register reports time = 100_NS_VALUE x 83.33 ns.

Offset: 0xFB0 | Read/Write: R

31:8	R	0	Reserved

Bit	R/W	Reset	Description
7:0	R/W	3h	T_PCIE2_RP_VEND_XP3_SA_ERROR_LIMIT: Specifies the number of misaligned COM symbols needed before declaring loss of Symbol Alignment. When Symbol Alignment is lost, the error bit for all subsequent symbols is asserted until 1 good COM symbol is seen. Then the error bit is deasserted and the counter tracking misaligned COM symbols is reset. Set to 0 to disable this feature. Note: Since 8B/10B and symbol alignment errors are indistinguishable, symbol alignment errors (when error limit is hit) will contribute to all 8B/10B error counts including the Goto Recovery on 8B/10B errors feature. This is useful to speed up link retraining after losing symbol alignment. 3h: SA_ERROR_LIMIT_INIT (default)

34.4.8.79 T_PCIE2_RP_XP_CTL_1

This register contains control registers used in XP.

Offset: 0xFEC | Read/Write: R/W

Bit	R/W	Reset	Description
31	R	1h	T_PCIE2_RP_XP_CTL_1_CYA_RP_INITIATED_L2_WAKE_ON_TLP_PENDING: 1h: CYA_RP_INITIATED_L2_WAKE_ON_TLP_PENDING_INIT (default)
30:28	R/W	1h	T_PCIE2_RP_XP_CTL_1_SPARE: 1h SPARE_INIT (default)
27	R/W	1h	T_PCIE2_RP_XP_CTL_1_EXIT_L1_AT_CLKREQ_ASSERTION: When set, the LTSSM will exit L1 when clkreq assertion happens. NOTE : This feature only applies to downstream port 0h: EXIT_L1_AT_CLKREQ_ASSERTION_DISABLED 1h: EXIT_L1_AT_CLKREQ_ASSERTION_ENABLED (default)
26	R/W	1h	T_PCIE2_RP_XP_CTL_1_NEW_IOBIST_CTRL: This bit when set will enable control signals from iobist to take effect. Some of the control signal will be are enabling/disabling scrambling, enabling and disabling checking for SKP symbols. 0h: NEW_IOBIST_CTRL_DISABLED 1h: NEW_IOBIST_CTRL_ENABLED (default)
25	R/W	0h	T_PCIE2_RP_XP_CTL_1_OLD_IOBIST_EN: This bit when set will enable old iobist, else it will enable new iobist. 0h: OLD_IOBIST_EN_INIT (default)
24:19	R/W	0h	T_PCIE2_RP_XP_CTL_1_EIOS_DEBOUNCE_TIMER: This is the number of xclks for which the rx_data_en signals need to be deasserted before asserting again. 0h: EIOS_DEBOUNCE_TIMER_INIT (default)
18	R/W	0h	T_PCIE2_RP_XP_CTL_1_DISABLE_RX_LANE_AFTER_EIOS: Disable rx_lane_en after EIOS is seen in any of the enabled lane during recovery.Rlock and Recovery.Config in order to avoid coupling. 0h: DISABLE_RX_LANE_AFTER_EIOS_INIT (default)
17	R/W	0h	T_PCIE2_RP_XP_CTL_1_ENABLE_DESKEW_FOR_SPDCH_NEGOTIATION: When set to 0, forces LTSSM to disable deskew in Recovery.RcvrCfg state if the transition from Recovery.RcvrLock to RcvrCfg state is due to LTSSM detecting eight consecutive training set on any of the lanes but not all of the lanes, and speed change bit is set to 1. When set to 1, LTSSM will always enable deskew in Recovery.RcvrCfg state. 0h: ENABLE_DESKEW_FOR_SPDCH_NEGOTIATION_INIT (default)
16	R/W	0h	T_PCIE2_RP_XP_CTL_1_BYPASS_CONFIG_PWRUP: When set to 0, forces LTSSM to go from Recovery.RcvrLock to Config.Pwrup if LTSSM sees training set on some but not all the active lanes. This bit only takes effect when the link is operating in dynamically reduced link width and specification-defined link width resize is enabled. When set to 1, LTSSM will go from Recovery.RcvrLock to Config.LinkStart directly, bypassing Config.Pwrup, when LTSSM sees training set on some but not all the active lanes. 0h: BYPASS_CONFIG_PWRUP_INIT (default)
15	R/W	0h	T_PCIE2_RP_XP_CTL_1_RESET_TS_CTRL_ON_ERROR: When set to 1, in Config.LinkStart state, LTSSM will reset the internal TS_CTRL0 register if an 8B/10B error is present on any symbol of the training set. When set to 0, in Config.LinkStart state, LTSSM will reset the internal TS_CTRL0 register if 8B/10B error is present on symbols 0, 4 or 5 only. 0h: RESET_TS_CTRL_ON_ERROR_INIT (default)
14	R/W	0h	T_PCIE2_RP_XP_CTL_1_RX_EIDLE_EXIT_TIMER_IN_CONFIG: When set to 1, T_PCIE2_RP_XP_IDLE_TIMER_1_RX_EIDLE_EXIT will be applied in Config.LinkStart only. When set to 0, T_PCIE2_RP_XP_IDLE_TIMER_1_RX_EIDLE_EXIT will be applied in Config.LinkStart, Recovery and Polling. 0h: RX_EIDLE_EXIT_TIMER_IN_CONFIG_INIT (default)

Bit	R/W	Reset	Description
13	R/W	1h	T_PCIE2_RP_XP_CTL_1_FORCE_RESET_IN_CONFIG: When set to 1, LTSSM will force receiver logic to be reset when enabling lanes in Config.LinkStart state for PCIe 2.0 specification-defined link width upconfiguration. 1h: FORCE_RESET_IN_CONFIG_INIT (default)
12	R/W	1h	T_PCIE2_RP_XP_CTL_1_LINK_RESIZE_PWRDN_CTL: 1h: LINK_RESIZE_PWRDN_CTL_INIT (default)
11	R/W	1h	T_PCIE2_RP_XP_CTL_1_ALLOW_SPEED_CHANGE_FROM_L0S: When set to 1, LTSSM will initiate link speed/width/advertised rate change while RX side is in L0s link state. 1h: ALLOW_SPEED_CHANGE_FROM_L0S_INIT (default)
10	R/W	0h	T_PCIE2_RP_XP_CTL_1_PRESERVE_TX_PACKET_ON_DL_RETRAIN: When set to 1, LTSSM will wait for framer to be idle before entering Recovery for DL initiated link retrain. Note: Setting this bit to 1 could prevent LTSSM to enter Recovery on a replay rollover event if the retry buffer is very full. 0h: PRESERVE_TX_PACKET_ON_DL_RETRAIN_INIT (default)
9	R/W	0h	T_PCIE2_RP_XP_CTL_1_PRESERVE_TX_PACKET_ON_RECOVERY: Note: Setting this bit to 1 does not work if L1 ASPM is enabled as it will cause hang during L1 negotiation if Root Port initiate entry to Recovery. Note: During DL init sequence, if link is retrained, setting this bit to 1 would hang the chip. 0h: PRESERVE_TX_PACKET_ON_RECOVERY_INIT (default)
8	R/W	1h	T_PCIE2_RP_XP_CTL_1_PRESERVE_TX_PACKET_ON_WIDTH_CHANGE: When set to 1, LTSSM will wait for framer to be idle before entering Recovery for link width change. 1h: PRESERVE_TX_PACKET_ON_WIDTH_CHANGE_INIT (default)
7	R/W	1h	T_PCIE2_RP_XP_CTL_1_PRESERVE_TX_PACKET_ON_SPEED_CHANGE: When set to 1, LTSSM will wait for framer to be idle before entering Recovery for link speed change or advertised rate change. 1h: PRESERVE_TX_PACKET_ON_SPEED_CHANGE_INIT (default)
6	R/W	0h	T_PCIE2_RP_XP_CTL_1_RESET_LANE_ENABLE_ORIG_IN_DETECT: This field will allow lane_enable_original to be reset in Detect state. 0h: RESET_LANE_ENABLE_ORIG_IN_DETECT_INIT (default)
5:2	R/W	0h	T_PCIE2_RP_XP_CTL_1_IDLE_TO_L0_DELAY: This field sets the number of clocks that the LTSSM will delay the transition from Recovery.Idle to L0.Normal link state or Config.Idle to L0.Normal link state. 0h: IDLE_TO_L0_DELAY_INIT (default)
1	R/W	0h	T_PCIE2_RP_XP_CTL_1_LWLO_HUNT_ON_BAD_TS1: When set to 1, the LWLOFSM hunt timer does not reset when any lane receives an error on the TS1 ordered set in the Config.LinkStart, Config.LinkAccept, Config.LaneWait, and Config.LaneAccept states. When set to 0, the LWLOFSM hunt timer will reset when any lane receives the first error on the TS1 ordered set after any lanes has locked and hunt timer has started counting in the Config.LinkStart, Config.LinkAccept, Config.LaneWait, and Config.LaneAccept states. 0h: LWLO_HUNT_ON_BAD_TS1_INIT (default)
0	R/W	0h	T_PCIE2_RP_XP_CTL_1_FORCE_SA_IN_CONFIG: When set to 1, enables symbol alignment in Config.LinkAccept, Config.LaneWait, Config.LaneAccept, and Config.Complete states. 0h: FORCE_SA_IN_CONFIG_INIT (default)

34.4.8.80 T_PCIE2_RP_PRIV_XP_L1BEACON

Offset: 0xFF0 | Read/Write: R/W

Bit	R/W	Reset	Description
31:10	R	0	Reserved
9:2	R/W	0h	T_PCIE2_RP_PRIV_XP_L1BEACON_N_EIE_SYMBOLS: It is the number of EIE symbols sent in L1 Beacon Entry/Exist state 40h: N_EIE_SYMBOLS_INIT (default)
1	R/W	0h	T_PCIE2_RP_PRIV_XP_L1BEACON_TX_BYP_CTRL: 0h: TX_BYP_CTRL_DEFAULT (default) 0h: TX_BYP_CTRL_ONLYL0 1h: TX_BYP_CTRL_ALLLANES
0	R/W	0h	T_PCIE2_RP_PRIV_XP_L1BEACON_EN: 0h: EN_DEFAULT (default)

34.4.8.81 T_PCIE2_RP_TIMEOUT3

Offset: 0xFF4 | Read/Write: R/W

Bit	R/W	Reset	Description
31:24	R/W	Ch	T_PCIE2_RP_TIMEOUT3_RX_L0S_IDLE_TIME_GEN2: This field controls the amount of time LTSSM delays the detection of electrical idle exit in the RX_L0s state at Gen2 speed of operation. Ch: RX_L0S_IDLE_TIME_GEN2_INIT (default)
23:16	R/W	4h	T_PCIE2_RP_TIMEOUT3_RX_L0S_IDLE_TIME_GEN1: This field controls the amount of time LTSSM delays the detection of electrical idle exit in the RX_L0s state at Gen1 speed of operation. 4h: RX_L0S_IDLE_TIME_GEN1_INIT (default)
15:8	R/W	FFh	T_PCIE2_RP_TIMEOUT3_TX_L0S_IDLE_TIME: This field controls the minimum amount of time LTSSM stays in TX_L0S_IDLE state. Measured in units of clk25m clock periods (83 ns when using 12 MHz clock) scaled with xclk frequency. A setting of 8'hFF disables the delay. FFh: TX_L0S_IDLE_TIME_INIT (default)
7:4	R/W	0h	T_PCIE2_RP_TIMEOUT3_RX_EIDLE_EXIT_DELAY: This field controls the amount of time the LTSSM delays the detection of TS ordered set when exiting out of electrical idle state. Each increment represents 2^X microseconds. A setting of 0 disables the delay. 0h: RX_EIDLE_EXIT_DELAY_INIT (default)
3:0	R/W	0h	T_PCIE2_RP_TIMEOUT3_TX_EIDLE_EXIT_DELAY: This field controls the amount of time the LTSSM delays the transmission of TS ordered sets when exiting out of electrical idle state. Unit is in microseconds. Each increment represents 2^X microseconds. A setting of 0 disables the delay. 0h: TX_EIDLE_EXIT_DELAY_INIT (default)

34.4.8.82 T_PCIE2_RP_XP_CTL_2

This register contains controls bits used in XP.

Offset: 0xFF8 | Read/Write: R/W

Bit	R/W	Reset	Description
31:24	R	0	Reserved
23	R/W	1h	T_PCIE2_RP_XP_CYA_2_RX_CAL_EN 1h: RX_CAL_EN_INIT
22	R/W	1h	T_PCIE2_RP_XP_CYA_2_AUX_RX_IDLE_EN 1h: RX_IDLE_EN_INIT
21	R/W	0h	T_PCIE2_RP_XP_CYA_2_OVERRIDE_AUX_RX_IDLE_EN 0h: RX_IDLE_EN_INIT
20	R/W	1h	T_PCIE2_RP_XP_CTL_2_WAIT_FOR_LOCKDET_DURING_L1_EXIT
19:12	R/W	FFh	T_PCIE2_RP_XP_CTL_2_ECO351987_HOLDOFF_CNTR_LIMIT FFh: ECO351987_HOLDOFF_CNTR_LIMIT_INIT (default)
11	R/W	1h	T_PCIE2_RP_XP_CTL_2_USE_QUALIFIED_TS_CTL_BITS 1h USE_QUALIFIED_TS_CTL_BITS_INIT (default)
10:9	R	0	Reserved
8	R/W	0h	T_PCIE2_RP_XP_CTL_2_CONFIG_LINKSTART_REQUIRE_PAD_LANE_NUM. Forces the LTSSM training set detector to require PAD in the lane number symbol of training set in Config.LinkStart state: 0h: INIT (default)
7:0	R/W	40h	T_PCIE2_RP_XP_CTL_2_LOOPBACK_EXIT_THRESHOLD. Programs the maximum amount of time spent in the Loopback.Exit state as loopback slave. Units are in xclk. The setting of 0 disables the timer in Loopback.Exit state such that loopback slave relies on detection of electrical idle data to exit from Loopback. The default is 64 xclks: 40h: INIT (default)

34.4.8.83 T_PCIE2_RP_VEND_XP_STATS2

This register contains fields unique to NVIDIA’s implementation of PCI Express devices.

Offset: 0xFFC | Read/Write: R/W

Bit	R/W	Reset	Description
31:16	R	0	Reserved
15:0	R/W	0h	T_PCIE2_RP_VEND_XP_STATS2_8B10B_ERR_LANEMASK: Each individual bit represents the corresponding logical lane. When set to 1, the 8B/10B error from that specific lane will be masked out from the counter in T_PCIE2_RP_VEND_XP_STATS1_8B10B_ERRORS 0h: 8B10B_ERR_LANEMASK_INIT (default) FFFEh: 8B10B_ERR_LANEMASK_LN0 FFFDh: 8B10B_ERR_LANEMASK_LN1 FFFBh: 8B10B_ERR_LANEMASK_LN2 FFF7h: 8B10B_ERR_LANEMASK_LN3 FFEFh: 8B10B_ERR_LANEMASK_LN4 FFDFh: 8B10B_ERR_LANEMASK_LN5 FFBFh: 8B10B_ERR_LANEMASK_LN6 FF7Fh: 8B10B_ERR_LANEMASK_LN7

34.5 AFI Registers

34.5.1 AFI_AXI_BARi_SZ_0

There are 9 AXI BAR SIZE registers, where i = 0 through 8.

BAR0: Offset: 0x0 | Read/Write: R/W | Reset: 0x0003f000 (0bxxxxxxxxxxxx0011111000000000000)
BAR1 – BAR5: Offset: 0x4 + (i – 1) * 0x4, where i = 1 – 5 | Read/Write: R/W | Reset: 0x00000000 (0bxxxxxxxxxxxx00000000000000000000)
BAR6 – BAR8: Offset: 0x134 + (i – 6) * 0x4, where i = 6 – 8 | Read/Write: R/W | Reset: 0x00000000 (0bxxxxxxxxxxxx00000000000000000000)

Bit	Description
19:0	AXI_BARi_SIZE: The size of the address range associated with BARi is in 4K increments. A value of 0 signifies BARi is not used.

34.5.2 AFI_AXI_BARi_START_0

There are 9 AXI BAR START registers, where i = 0 through 8.

BAR0: Offset: 0x18 | Read/Write: R/W | Reset: 0x01000000 (0b00000001000000000000xxxxxxxxxxxx)
BAR1 – BAR5: Offset: 0x1c + (i – 1) * 0x4, where i = 1 – 5 | Read/Write: R/W | Reset: 0x00000000 (0b00000000000000000000xxxxxxxxxxxx)
BAR6 – BAR8: Offset: 0x140 + (i – 6) * 0x4, where i = 6 – 8 | Read/Write: R/W | Reset: 0x00000000 (0b00000000000000000000xxxxxxxxxxxx)

Bit	Description
31:12	AXI_BARi_START: The start of AXI address space for BARi. The AXI target address is compared to start/size for each BAR to determine if the access is to that BAR.

34.5.3 AFI_FPCI_BARi_0

There are 9 FPCI BAR registers, where i = 0 through 8.

BAR0: Offset: 0x30 | Read/Write: R/W | Reset: 0x00010001 (0b00000000000000010000000000000xxx1)
BAR1 – BAR5: Offset: 0x34 + (i – 1) * 0x4, where i = 1 – 5 | Read/Write: R/W | Reset: 0x00000001 (0b00000000000000000000000000000xxx1)
BAR6 – BAR8: Offset: 0x14c + (i – 6) * 0x4, where i = 6 – 8 | Read/Write: R/W | Reset: 0x00000001 (0b00000000000000000000000000000xxx1)

Bit	Description
31:4	FPCI_BARi_START: The start of FPCI address space mapped into the BARi range of PCI memory space. The 40-bit FPCI address is determined by a shift left 8 of the value of this register.

Bit	Description
0	FPCI_BARi_ACCESS_TYPE: Indicates if the address region is memory mapped versus configuration or I/O space. 1=Memory mapped access (PW only) 0=IO/config access (NPW only)

34.5.4 AFI_MSI_BAR_SZ_0

Do not use this reserved space.

MSI BAR Size

Offset: 0x60 | Read/Write: R/W | Reset: 0x00000000 (0bxxxxxxxxxxxxx00000000000000000000)

Bit	Reset	Description
19:0	0x0	MSI_BAR_SIZE

34.5.5 AFI_MSI_FPCI_BAR_ST_0

MSI FPCI BAR Start

Offset: 0x64 | Read/Write: R/W | Reset: 0x58540000 (0b01011000010101000000000000xxxx)

Bit	Reset	Description
31:4	0x5854000	MSI_FPCI_BAR_START: The start of upstream FPCI address space for MSI BAR. The upstream FPCI address is compared to start/1KB range for MSI BAR to determine if the access is MSI. Bits 31:4 of MSI BAR start correspond to UFPCI address bits 39:12.

34.5.6 AFI_MSI_AXI_BAR_ST_0

MSI AXI BAR Start

Offset: 0x68 | Read/Write: R/W | Reset: 0x80000000 (0b10000000000000000000xxxxxxxxxxxx)

Bit	Reset	Description
31:12	0x80000	MSI_AXI_BAR_START: The start of upstream AXI address space for MSI BAR. The upstream FPCI address is compared to start/1KB range for MSI BAR to determine if the access is MSI. Bits 31:12 of MSI BAR start correspond to AXI address bits 31:12.

34.5.7 AFI_MSI_VECi_0

MSI Vector

There are 8 MSI Vector registers (AFI_MSI_VECi), where i is a value from 0 to 7.

Offset: 0x6c + (i * 4) | Read/Write: R/W | Reset: 0x00000000 (0b00000000000000000000000000000000)

Bit	Reset	Description
31:0	0x0	MSI_VECTORi: Each vector register corresponds to 32 of the possible 256 MSI vectors.VECTOR0 corresponds to MSI vectors 31-0.Vector7 corresponds to MSI vectors 255-223.When an upstream MSI is sent, the bit corresponding to the MSI vector is set to 1 by hardware if the corresponding enable bit is 1.The bit is set to 0 if a 1 is written to its location.

34.5.8 AFI_MSI_EN_VEC0_0

MSI Enable Vector

There are 8 MSI Enable Vector registers (AFI_MSI_EN_VECi), where i is a value from 0 to 7.

Offset: 0x8c + (i * 4) | Read/Write: R/W | Reset: 0x00000000 (0b00000000000000000000000000000000)

Bit	Reset	Description
31:0	0x0	MSI_ENABLE_VECTORi: Each vector register corresponds to the enable bit for 32of the possible 256 MSI vectors. ENABLE VECTOR0 corresponds to enable bits for MSI vectors 31-0. Vector7 corresponds to enable bits for MSI vectors 255-223.When an upstream MSI is sent, the bit corresponding to the MSI vector is set to 1 by hardware if the corresponding enable bit is 1.

34.5.9 AFI_CONFIGURATION_0

Configuration

Offset: 0xac | Read/Write: R/W | Reset: 0x00fXXX40 (0b0xxxxxxx11111xxx10xxxxxx01000000)

Bit	R/W	Reset	Description
31	RW	0x0	CLKEN_OVERRIDE: This can override the clock enable in case of malfunction.
23	RW	0x1	SPARSE_WSTRB: Diagnostic bit for enabling sparse WSTRB.
22	RW	0x1	UNALIGNED_BYTE_ACCESS: Diagnostic bit for unaligned byte access.
21	RW	0x1	UPSTREAM_RAW_RESPAW_MSIAW: Diagnostic bit for upstream RAW, RESPAW, and MSIAW.
20	RW	0x1	MSG_PLL_PWR_DWN_CYA:
19	RW	0x1	PW_NO_DEVSEL_ERR_CYA: Setting this bit disables detection of DECERR due to no devsel for DS PWs only.
18	RO	X	INITIATOR_READ_IDLE: This read-only bit provides status reads on AFI upstream. A value of 1b indicates there are no outstanding reads to the initiator.
17	RO	X	INITIATOR_WRITE_IDLE: This read-only bit provides status writes on AFI upstream. A value of 1b indicates there are no outstanding writes to the initiator.
15	RW	0x1	WDATA_LEAD_CYA: This bit is used to enable/disable the handling of write data ahead of requests on mselect
14	RW	0x0	WR_INTRLV_CYA: This bit is used to enable/disable the handling of interleaved write requests on mselect
13	RO	X	PE1_PRSNT_L_IN: This read-only bit is 0 when a card is present in PCIe slot 1
12	RO	X	PE0_PRSNT_L_IN: This read-only bit is 0 when a card is present in PCIe slot 0
11	RO	X	TARGET_READ_IDLE: This read-only bit provides status reads to AFI target. A value of 1b indicates there are no outstanding reads to the downstream FPCI.
10	RO	X	TARGET_WRITE_IDLE: This read-only bit provides status writes to AFI target. A value of 1b indicates there are no outstanding writes to the downstream FPCI.
9	RO	X	MSI_VEC_EMPTY: This read-only bit provides status on whether MSI Vector registers have any valid active bits.
7	RW	0x0	UFPCI_MSIAW: MSI After Write ordering rule. 1 = whenever MSI is ready assert the interrupt 0 = default behavior, apply MSIAW ordering rule
6	RW	0x1	UFPCI_PWPASSPW: Input to upstream FPCI 1 = whenever write is ready, send it; 0 = write goes only when outstanding PWs outside of new write's region are retired (default).
5	RW	0x0	UFPCI_PASSPW: Input to upstream FPCI. Allow upstream FPCI reads to pass writes.
4	RW	0x0	UFPCI_PWPASSNPW: Used for upstream FPCI. Allow upstream FPCI PWs to pass NPWs.
3	RW	0x0	DFPCI_PWPASSNPW: Used for downstream FPCI. Allow downstream FPCI PWs to pass NPWs.
2	RW	0x0	DFPCI_RSPPASSPW: Input to downstream FPCI. Allow downstream FPCI responses to pass writes
1	RW	0x0	DFPCI_PASSPW: Input to downstream FPCI. Allow downstream FPCI reads to pass writes.
0	RW	0x0	EN_FPCI: When the PCI device block is disabled, it is completely invisible on the PCI bus, i.e., it does not even process PCI configuration accesses.

34.5.10 AFI_FPCI_ERROR_MASKS_0

FPCI Error Masks

Offset: 0xb0 | Read/Write: R/W | Reset: 0x00000000 (0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxx000)

Bit	Reset	Description
2	0x0	MASK_FPCI_MASTER_ABORT: This bit allows an FPCI error to be forwarded to AXI response when the FPCI error response indicates Master Abort. 1 = forward error 0 = return AXI OKAY response (2'b0)
1	0x0	MASK_FPCI_DATA_ERROR: This bit allows an FPCI error to be forwarded to AXI response when the FPCI error response indicates Data Error. 1 = forward error 0 = return AXI OKAY response (2'b0)
0	0x0	MASK_FPCI_TARGET_ABORT: This bit allows an FPCI error to be forwarded to AXI response when FPCI error response indicates Target Abort. This bit also covers a decode error generated when there is no devsel received. 1 = forward error, 0 = return AXI OKAY response (2'b0)

34.5.11 AFI_INTR_MASK_0

Interrupt Masks

Offset: 0xb4 | Read/Write: R/W | Reset: 0x00000000 (0bxxxxxxxxxxxxxxxxxxxxxxxx0xxxxxx0)

Bit	Reset	Description
8	0x0	MSI_MASK: MSI to CPU complex gated by mask.
0	0x0	INT_MASK: Interrupt to CPU complex gated by mask.

34.5.12 AFI_INTR_CODE_0

Interrupt Code

Detected errors are logged in an error signature register as specified here. The error signature register always stores the first error that occurred after enabling the error capture. The interrupt code register logs the interrupt ID shown in the ID column of Table 217 below. This register stores the ID for the associated interrupt when current ID in the register is zero. Software must write zero to the register to re-enable it to store subsequent interrupts. For ID=6, the capture information is the sideband message bits. There is an associated interrupt generated to the CPU. Since FPCI address is 40 bits, a separate capture register is used for the upper 8 bits of the address.

Offset: 0xb8 | Read/Write: R/W | Reset: 0x00000000 (0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxx00000)

Bit	Reset	Description
4:0	0x0	INT_CODE: If the code is 0, logging of the next interrupt is enabled. See Table 217 for the system messages. 0 = INT_CODE_CLEAR: Clear interrupt code 1 = INT_CODE_INI_SLVERR: Interrupt code for CPU complex AXI SLVERR response to AFI 2 = INT_CODE_INI_DECERR: Interrupt code for CPU complex AXI DECERR response to AFI 3 = INT_CODE_TGT_SLVERR: Interrupt code for PCIe endpoint FPCI target abort or data error response to AFI 4 = INT_CODE_TGT_DECERR: Interrupt code for PCIe2 FPCI master abort response to AFI 5 = INT_CODE_TGT_WRERR: Interrupt code for bufferable write to non-posted write address region 6 = INT_CODE_SM_MSG: Interrupt code for PCIe2 system management message 7 = INT_CODE_DFPCI_DECERR: Interrupt code for PCIe2 response to downstream request when the downstream FPCI address does not fall in a claimable downstream region 8 = INT_CODE_AXI_DECERR: Interrupt code for AFI response to downstream request when the mselect AXI address does not fall in any of AFI downstream BARs 9 = INT_CODE_FPCI_TIMEOUT: Interrupt code for FPCI Timeout 10 = INT_CODE_PE_PRSNT_SENSE: Interrupt code for Slot Present Pin Change 11 = INT_CODE_PE_CLKREQ_SENSE: Interrupt code for Slot Clock Request Change 12 = INT_CODE_CLKCLAMP_SENSE: Interrupt code for TMS Clock Clamp Change 13 = INT_CODE_RDY4PD_SENSE: Interrupt code for TMS Ready for power down 14 = INT_CODE_P2P_ERROR: Interrupt code for Peer2Peer errors

Table 217: System Messages

Error/Message	ID	Capture Information
AXI Slave error	1	Bits [31:2] of Initiator AXI address, direction of transaction
AXI Decode error	2	
AXI Slave error – PCIe target abort or data error	3	Bits [39:2] of Target FPCI address, direction of transaction
AXI Decode error – PCIe master abort	4	
AXI Decode error – write to NPW address region > 4B	5	Bits[39:2] of Target AXI address, direction of transaction
PCIe 2.0 Sideband message	6	Sideband UnitID, Bits[4:0] of sideband message
FPCI Decode error – not in PCIe 2.0 memory space	7	Bits[39:2] of Target FPCI address, direction of transaction
AXI Decode error – not in AFI BAR or register space	8	Bits [31:2] of Target AXI address, direction of transaction
FPCI Timeout	9	None
Slot Present Pin Change	10	Bits [2:0] capture status of slots 2-0 present pin
Slot Clock Request Change	11	Bits [2:0] capture status of slots 2-0 clock request
TMS Clock Clamp Change	12	Bit [0] captures level of clock clamp
TMS Ready for power down	13	None – all 3 controllers are ready for power down
Peer-to-peer error	14	Error response from endpoint device (tms02ufa_cmd_error), Bits[39:2] of Target FPCI address, direction of transaction

34.5.13 AFI_INTR_SIGNATURE_0

Interrupt Signature

Offset: 0xbc | Read/Write: R/W | Reset: 0x00000000 (0b00000000000000000000000000000x0)

Bit	Reset	Description
31:2	0x0	INT_INFO: For interrupt codes 1-5/7-8, this field contains address bits [31:2], either in FPCI memory space or AXI space. If the interrupt code is 6, the information field INT_INFO[12:0] contains sideband information {sideband unitid, 3'b0, tms02sm_msg[4:0]}. For FPCI generated errors, the information field contains FPCI address. For AXI/AFI generated errors, the information field contains AXI address. For interrupt code 10, this field contains the status of slots 2-0 present pin. For interrupt code 11, this field contains the status of slots 2-0 clock request For interrupt code 12, this field contains level of clock clamp
0	0x0	DIR: Indicates the direction of the AXI/FPCI transaction. 1=rd 0=wr If signature type is 6 (sideband message), this field is 1. 0 = WRITE: Interrupt due to a write transaction 1 = READ: Interrupt due to a read transaction

34.5.14 AFI_UPPER_FPCI_ADDR_0

Upper FPCI Address

Offset: 0xc0 | Read/Write: R/W | Reset: 0x00000000 (0bxxxxxxxxxxxxxxxx00xxxxxxxx00000000)

Bit	Reset	Description
17:16	0x0	P2P_ERR_RESP: These 2 bits are for the captured endpoint device error response (tms02ufa_cmd_error) when the interrupt code is 14.
7:0	0x0	INT_INFO_UPPER: These 8 bits are the upper byte of captured FPCI address (bits[39:32]) when the interrupt code is 3, 4, or 7. These bits determine the region in the Hypertransport Address Map that was accessed.

34.5.15 AFI_SM_INTR_ENABLE_0

Sideband Message Interrupt Enable

Offset: 0xc4 | Read/Write: R/W | Reset: 0x00000000 (0bxxxxxxxxxxxxxxxxxx000000000000000)

Bit	Reset	Description
14:0	0x0	ENABLE_MESSAGE: Each bit in this register enables a corresponding message shown in the table below.

Table 218: Message Types

[1:0]	[3:2]	[4]	Enable bit	MSG_TYPE	Description
00	00	1	0	Interrupt	INTA Assertion.
	01		1		INTB Assertion.
	10		2		INTC Assertion.
	11		3		INTD Assertion.
	00	0	4		INTA Deassertion
	01		5		INTB Deassertion
	10		6		INTC Deassertion
	11		7		INTD Deassertion
01	00	0	8	Error	Correctable Error
	01		9		Uncorrectable Non-Fatal Error
	10		10		Uncorrectable Fatal Error
10	00	0	11	PME	PME assertion.
10	01	0	12	Hotplug	Hotplug SCI assertion
11	00	1	13	Interrupt	Root Port Interrupt Assertion
11	00	0	14		Root Port Interrupt Deassertion

34.5.16 AFI_AFI_INTR_ENABLE_0

AFI Interrupt Enable

See the AFI_INTR_CODE_0 register for details on the interrupt codes.

Offset: 0xc8 | Read/Write: R/W | Reset: 0x00000000 (0bxxxxxxxxxxxxxxxxxxxx0000000000000)

Bit	Reset	Description
12	0x0	EN_P2P_ERR: Enable bit for interrupt code 14
11	0x0	EN_RDY4PD_SENSE: Enable bit for interrupt code 13
10	0x0	EN_CLKCLAMP_SENSE: Enable bit for interrupt code 12
9	0x0	EN_PE_CLKREQ_SENSE: Enable bit for interrupt code 11
8	0x0	EN_PE_PRSNT_SENSE: Enable bit for interrupt code 10
7	0x0	EN_FPCI_TIMEOUT: Enable bit for interrupt code 9
6	0x0	EN_AXI_DECERR: Enable bit for interrupt code 8
5	0x0	EN_DFPCI_DECERR: Enable bit for interrupt code 7
4	0x0	EN_TGT_WRERR: Enable bit for interrupt code 5
3	0x0	EN_TGT_DECERR: Enable bit for interrupt code 4
2	0x0	EN_TGT_SLVERR: Enable bit for interrupt code 3
1	0x0	EN_INI_DECERR: Enable bit for interrupt code 2
0	0x0	EN_INI_SLVERR: Enable bit for interrupt code 1

34.5.17 AFI_FPCI_TIMEOUT_0

Do not use this reserved space.

FPCI Timeout

Offset: 0xd8 | Read/Write: R/W | Reset: 0x00000000 (0b0xxxxxxxxxxx00000000000000000000)

Bit	Reset	Description
31	0x0	SM2TMS0_FPCI_TIMEOUT_EN
19:0	0x0	SM2ALL_FPCI_TIMEOUT_THRESH

34.5.18 AFI_PCIE_THROTTLE_0

PCIe Throttle

Offset: 0xec | Read/Write: R/W | Reset: 0x00000000 (0b0xxxxxxxxxxxxxxx000000000000x000)

Bit	Reset	Description
31	0x0	SM2PCIE_THROT_EN: Override THERM MGMT
15:4	0x0	SM2PCIE_THROT_PERIOD: Override THERM MGMT period
2:0	0x0	SM2PCIE_THROT_DUTY_CYCLE: Override THERM MGMT duty cycle

34.5.19 AFI_PME_0

PCIe PME

Offset: 0xf0 | Read/Write: R/W | Reset: 0x00000XX0 (0bxxxxxxxxxxxxxxxxxxxxxxxx0xxxxxx0)

Bit	R/W	Reset	Description
11	RO	X	TMS0C12SM_PRESENCE_STATE: PCIe Link Presence State
10	RO	X	TMS0C12SM_PME_ACK: PCIe Endpoint PME Ack
9	RO	X	TMS0C12SM_PME: PCIe Endpoint PME message
8	RW	0x0	SM2TMS0C1_PME_TO: SM (system management) to PCIe PME Turn Off
6	RO	X	TMS0C02SM_PRESENCE_STATE: PCIe Link Presence State
5	RO	X	TMS0C02SM_PME_ACK: PCIe Endpoint PME Ack
4	RO	X	TMS0C02SM_PME: PCIe Endpoint PME message
0	RW	0x0	SM2TMS0C0_PME_TO: SM (system management) to PCIe PME Turn Off

34.5.20 AFI_REQ_PENDING_0

Request Pending

Offset: 0xf4 | Read/Write: RO | Reset: 0x000000XX (0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx)

Bit	Reset	Description
7	X	TMS0C12SM_NONISO_PENDING: SM (system management) status that a Non-ISO request is pending from PCIe to FPCI
6	X	TMS0C12SM_ISO_PENDING: SM (system management) status that an ISO request is pending from PCIE to FPCI
5	X	TMS0C12SM_NONCOH_REQUEST_PEND: SM (system management) status that a Non-coherent request is pending from PCIe to FPCI
4	X	TMS0C12SM_COH_REQUEST_PEND: SM (system management) status that a coherent request is pending from PCIe to FPCI
3	X	TMS0C02SM_NONISO_PENDING: SM (system management) status that a Non-ISO request is pending from PCIe to FPCI
2	X	TMS0C02SM_ISO_PENDING: SM (system management) status that an ISO request is pending from PCIe to FPCI
1	X	TMS0C02SM_NONCOH_REQUEST_PEND: SM (system management) status that a Non-coherent request is pending from PCIe to FPCI
0	X	TMS0C02SM_COH_REQUEST_PEND: SM (system management) status that a coherent request is pending from PCIe to FPCI

34.5.21 AFI_PCIE_CONFIG_0

PCIe Config

Offset: 0xf8 | Read/Write: R/W | Reset: 0x00103025 (0bxxxxxxxx0001xxx00011xxx00010x101)

Bit	Reset	Description
23:20	0x1	SM2TMS0_XBAR_CONFIG: SM (system management) configuration of PCIe crossbar. 1 = XBAR_4_1: x4_x1 configuration 0 = XBAR_2_1: x2_x1 configuration
16:12	0x3	UNITID_T0C1: T0C1 Upstream FPCI Unit ID. HyperTransport, upstream FPCI request. The downstream FPCI unit ID should remain 0.
8:4	0x2	UNITID_T0C0: T0C0 Upstream FPCI Unit ID. HyperTransport, upstream FPCI request
2	0x1	PCIEC1_DISABLE_DEVICE: Disables PCIe Controller 1 (default on)
1	0x0	PCIEC0_DISABLE_DEVICE: Disables PCIe Controller 0 (default off)
0	0x1	SM2TGIO_SLOT_EMPTY_PD_CYA: Indicates PCIe slot empty. Overrides PCIe slot present input.

34.5.22 AFI_REV_ID_0

Revision ID

Offset: 0xfc | Read/Write: R/W | Reset: 0x00000000 (0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx00)

Bit	Reset	Description
1	0x0	CFG_REVID_WRITE_ENABLE: Write Enable for PCI backdoor rev ID override value.
0	0x0	CFG_REVID_OVERRIDE: Override for PCI config revision ID read-only register. This allows backdoor changes to rev ID for metal spins.

34.5.23 AFI_TOM_0

Top of Memory Limit

Offset: 0x100 | Read/Write: R/W | Reset: 0x3f3f0fff (0bxx11111100111111xxxx111111111111)

Bit	Reset	Description
29:16	0x3f3f	DLDT2ALL_TOM2: Top of Memory Limit 2. Determines peer-to-peer range as:{TOM2: 26'b0} to 0xFC_FFFF_FFFF
11:0	0xfff	DLDT2ALL_TOM1: Top of Memory Limit 1. Determines peer-to-peer range as:{TOM1:: 26'b0} to 0xFFFF_FFFF (except MSI region)

34.5.24 AFI_FUSE_0

PCIe Fuse

Offset: 0x104 | Read/Write: R/W | Reset: 0x00000336 (0bxxxxxxxxxxxxxxxxxxxxxx011x011x11x)

Bit	Reset	Description
10:8	0x3	FUSE_PCIE_WIDTH_T0C1: Configure PCIe as x1, x2, x4, x8, or x16. This should remain at 3'b011
6:4	0x3	FUSE_PCIE_WIDTH_T0C0: Configure PCIe as x1, x2, x4, x8, or x16. This should remain at 3'b011
2	0x1	FUSE_PCIE_T0_GEN2_DIS: Disable Gen 2 capability of PCIe.
1	0x1	FUSE_PCIE_SLI_DIS: Disable SLI capability for the GPU. This should remain on.

34.5.25 AFI_PMU_0

PMU Interface

Offset: 0x108 | Read/Write: R/W | Reset: 0x0XXXX000 (0bxxxxxxxxxxxxxxxxxxxx00000000xxx0)

Bit	R/W	Reset	Description
24	RO	X	CTLR_T0_C1_2PMU_TOG: PMU toggle response from PCIe

Bit	R/W	Reset	Description
23:20	RO	X	CTLR_T0_C1_2PMU_STATUS: PMU Status
16	RO	X	CTLR_T0_C0_2PMU_TOG: PMU toggle response from PCIe
15:12	RO	X	CTLR_T0_C0_2PMU_STATUS: PMU Status
11:8	RW	0x0	PMU2CTLR_T0_C1_LOAD_INDICATOR_SCALE: PMU Load Indicator Scale for T0C1
7:4	RW	0x0	PMU2CTLR_T0_C0_LOAD_INDICATOR_SCALE: PMU Load Indicator Scale for T0C0
0	RW	0x0	PMU2ALL_LI_UPDATE_FAST_TOG: PMU Load Indicator Enable. This is used for wall-plug applications and should remain off.

34.5.26 AFI_PCIE_CLK_CONFIG_STATUS_0

PCIE2 CLK Config/Status

Offset: 0x10c | Read/Write: R/W | Reset: 0x0XXXXX00 (0bxxxxxxxxxxxxxxxxxxxxxxxxxxxx00000)

Bit	R/W	Reset	Description
27:24	RO	X	PCIE2CLK_TMS0GRP2_PAD_MACRO_CLK_SEL: Clock select to pad macro. This should remain at 0.
23:20	RO	X	PCIE2CLK_TMS0GRP1_PAD_MACRO_CLK_SEL: Clock select to pad macro. This should remain at 0.
19:16	RO	X	PCIE2CLK_TMS0GRP0_PAD_MACRO_CLK_SEL: Clock select to pad macro. This should remain at 0.
13	RO	X	PCIE2CLK_TMS0C1_DIS_XTXCLK1X: Request to gate T0C1 XTXCLK1X when in low power mode.
12	RO	X	PCIE2CLK_TMS0C0_DIS_XTXCLK1X: Request to gate T0C0 XTXCLK1X when in low power mode.
11	RO	X	PCIE2CLK_TMS0_CLAMP_CLK_L1: Request to gate TMS/FPCI clocks when in low power mode.
10	RO	X	PCIE2CLK_TMS0C1_SEL_XTXCLK1X_GEN2: Request to select Gen2 speed clock (500 MHz) for T0C1 XTXCLK1X. This is generated when register settings for PCIe2 specify Gen2 speed clocks.
9	RO	X	PCIE2CLK_TMS0C0_SEL_XTXCLK1X_GEN2: Request to select Gen2 speed clock (500 MHz) for T0C0 XTXCLK1X. This is generated when register settings for PCIe2 specify Gen2 speed clocks. This should remain low.
8	RO	X	PCIE2CLK_TMS0_SEL_XCLK_GEN2: Request to select Gen2 speed clock (500 MHz) for XCLK. This is generated when register settings for PCIe2 specify Gen2 speed clocks. This should remain low.
4	RW	0x0	CLK2PCIE_TMS0C1_OFF_XTXCLK1X: Acknowledge to disable T0C1 XTXCLK1X request. Used for clock gating.
3	RW	0x0	CLK2PCIE_TMS0C1_RDY_XTXCLK1X_GEN2: Acknowledge to select T0C1 XTXCLK1X Gen2 request. This should remain low.
2	RW	0x0	CLK2PCIE_TMS0C0_OFF_XTXCLK1X: Acknowledge to disable T0C0 XTXCLK1X request. Used for clock gating.
1	RW	0x0	CLK2PCIE_TMS0C0_RDY_XTXCLK1X_GEN2: Acknowledge to select T0C0 XTXCLK1X Gen2 request. This should remain low.
0	RW	0x0	CLK2PCIE_TMS0_RDY_XCLK_GEN2: Acknowledge to select XCLK Gen2 request. This should remain low.

34.5.27 AFI_PEX0_CTRL_0

PCIe PHY and Sideband Signal Interface

Offset: 0x110 | Read/Write: R/W | Reset: 0x00000000 (0bxxxxxxxxxxxxxxxxxxxxxxxxxxxx00x00)

Bit	Reset	Description
4	0x0	PEX0_REFCLK_OVERRIDE_EN: PEX0 enable to override refclk to be enabled always if PEX0_REFCLK_EN is set
3	0x0	PEX0_REFCLK_EN: PEX0 enable to clkout pad
1	0x0	PEX0_CLKREQ_EN: PEX0 enable clkreq to control clkout pad
0	0x0	PEX0_RST_L: PEX0 external pe0_rst_l register

34.5.28 AFI_PEX0_STATUS_0

Offset: 0x114 | Read/Write: RO | Reset: 0x0000000X (0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx)

Bit	Reset	Description
0	X	PEX0_CLKREQ_L: Status of the PEX0 pe0_clkreq_l input

34.5.29 AFI_PEX1_CTRL_0

Offset: 0x118 | Read/Write: R/W | Reset: 0x00000000 (0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx00x00)

Bit	Reset	Description
4	0x0	PEX1_REFCLK_OVERRIDE_EN: PEX1 enable to override refclk to be enabled always if PEX1_REFCLK_EN is set
3	0x0	PEX1_REFCLK_EN: PEX1 enable to clkout pad
1	0x0	PEX1_CLKREQ_EN: PEX1 enable clkreq to control clkout pad
0	0x0	PEX1_RST_L: PEX1 external pe1_rst_l register

34.5.30 AFI_PEX1_STATUS_0

Offset: 0x11c | Read/Write: RO | Reset: 0x0000000X (0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx)

Bit	Reset	Description
0	X	PEX1_CLKREQ_L: Status of the PEX1 pe1_clkreq_l input

34.5.31 AFI_INITIATOR_ISO_PW_RESP_PENDING_0

Initiator ISO PW Response Pending

Offset: 0x158 | Read/Write: RO | Reset: 0x0000XXXX (0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx)

Bit	Reset	Description
15:8	X	NUM_INITIATOR_ISO_PW_RESP_PEND_T0C1: Number of pending initiator ISO PW responses for controller 1
7:0	X	NUM_INITIATOR_ISO_PW_RESP_PEND_T0C0:Number of pending initiator ISO PW responses for controller 0

34.5.32 AFI_INITIATOR_NISO_PW_RESP_PENDING_0

Initiator Non-ISO PW Response Pending

Offset: 0x15c | Read/Write: RO | Reset: 0x0000XXXX (0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx)

Bit	Reset	Description
15:8	X	NUM_INITIATOR_NISO_PW_RESP_PEND_T0C1: Number of pending initiator NISO PW responses for controller 1
7:0	X	NUM_INITIATOR_NISO_PW_RESP_PEND_T0C0: Number of pending initiator NISO PW responses for controller 0

34.5.33 AFI_PLLE_CONTROL_0

PLLE Controls

Offset: 0x160 | Read/Write: R/W | Reset: 0x00000002 (0bxxxxxxxxxxxxxxxxxxxxxxx00xxxxxx10)

Bit	Reset	Description
9	0x0	BYPASS_PADS2PLLE_CONTROL: Overrides PCIe PADS CLKREQ control of the PLLE.
8	0x0	BYPASS_PCIE2PLLE_CONTROL: Overrides PCIe2 CLOCK CLAMP control of the PLLE.
1	0x1	PADS2PLLE_CONTROL_EN: When active, all CLKREQs going inactive indicate DISABLE to the PLLE. When SATA, PCIe2, and PADS all indicate DISABLE to the PLLE, then the PLLE is disabled.
0	0x0	PCIE2PLLE_CONTROL_EN: When active, PCIE2 CLOCK CLAMP going active signal DISABLE to PLLE. When SATA, PCIe2, and PADS all indicate DISABLE to the PLLE, then the PLLE is disabled.

34.5.34 AFI_BUST_CONTROL_0

Bus Trace Module Controls

Offset: 0x164 | Read/Write: R/W | Reset: 0x00X00000 (0bxxxxxxxxxxx0xx00000000000000000)

Bit	R/W	Reset	Description
21	RO	X	PCIE_RXL_BUST_TRIG_OUT0_T0: Bus trigger from bus trace module in PCIe2

Bit	R/W	Reset	Description
20	RW	0x0	TRACE_EXTERNAL_START: Start signal to bus trace module in PCIe2
17:16	RW	0x0	PCIE_RXL_BUST_BUS_TRACE_MUX_SEL_T0: MUX select to bus trace module in PCIe2
15:0	RW	0x0	CHIP_ID: Chip ID to bus trace module in PCIe2

34.5.35 AFI_PEXBIAS_CTRL_0

Offset: 0x168 | Read/Write: R/W | Reset: 0x00000001 (0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx1)

Bit	Reset	Description
0	0x1	PEX_BIAS_PWRD: PEX clock bias pad power down

34.5.36 AFI_P2PBOM_CTRL_0

Offset: 0x16c | Read/Write: R/W | Reset: 0x00000000 (0bxxxxxxxxxxxx00000000000000000000)

Bit	Reset	Description
19:0	0x0	P2P_BASE:Peer-to-peer Bottom of Memory - connects to bits 39:20 of p2p_base_63_to_20 with the top bits tied to 0

34.5.37 AFI_P2PTOM_CTRL_0

Offset: 0x170 | Read/Write: R/W | Reset: 0x000003ff (0bxxxxxxxxxxxx00000000001111111111)

Bit	Reset	Description
19:0	0x3ff	P2P_LIMIT:Peer-to-peer Top of Memory - connects to bits 39:20 of p2p_limit_63_to_20 with the top bits tied to 0

34.5.38 AFI_CLKGATE_HYSTERESIS_0

Clock Gate Hysteresis

Offset: 0x174 | Read/Write: R/W | Reset: 0x00000014 (0bxxxxxxxxxxxxxxxxxxxxxxxx00010100)

Bit	Reset	Description
7:0	0x14	CLK_DISABLE_CNT: Number of AFI clock cycles to wait after clock gating criteria is met to disable the AFI/FPCI clocks

34.5.39 AFI_SPARE_REG0_0

Bit 31 is used as a Diagnostics bit to bypass both AXI target RAW and peer2peer RAW address comparison logic (default value is 1).

If 1, reads push all pending writes. Address range detection is bypassed.

If 0, reads only push pending writes that are in the same small address range.

Offset: 0x180 | Read/Write: R/W | Reset: 0xffff0000 (0b11111111111111110000000000000000)

Bit	Reset	Description
31:0	-65536	IPFS_SPARE_REG: Spare Register.

34.5.40 AFI_A2F_UFPCI_CFG0_0

Offset: 0x184 | Read/Write: R/W | Reset: 0x00000050 (0b00000000xxxxx0000000000001010000)

Bit	Reset	Description
31:24	0x0	STATIC_WAIT_IDLE_CNTR
18:16	0x0	STATIC_UFPCI_UFA_STARVE_CNTR_PRI1
15:12	0x0	STATIC_UFPCI_UFA_STARVE_CNTR_PRI0

Bit	Reset	Description
11:10	0x0	STATIC_UFPCI_RR_BURST_SZ_PRI1
9:8	0x0	STATIC_UFPCI_RR_BURST_SZ_PRI0
7	0x0	STATIC_WAIT_CLAMP_EN
6	0x1	STATIC_UFPCI_UFA_DYN_BLOCK_EN
5	0x0	STATIC_UFPCI_UFA_BLK_COHERENT
4:2	0x4	STATIC_UFPCI_BLOCK_CMD_THRESHOLD
1	0x0	STATIC_CYA_UFA_ARB
0	0x0	STATIC_CYA_BACK2BACK_UPSTREAM_BLOCK

34.5.41 AFI_A2F_UFPCI_CFG1_0

Offset: 0x188 | Read/Write: R/W | Reset: 0x00000000 (0bxxxxxxxxxxxxxxxxxxxxxxxxx00000000)

Bit	Reset	Description
7:0	0x0	STATIC_WAIT_UNCLAMP_CNTR

34.5.42 AFI_MSG_0

Reserved.

Offset: 0x190 | Read/Write: R/W | Reset: 0xXXX0XXX0 (0b000xxxxx0xxxxxxx000xxxxx0xxxxxxx)

Bit	R/W	Reset	Description
31	RW	0x0	TMS0C12SM_MSG_ERR_FATAL:PCIE FATAL ERROR MSG
30	RW	0x0	TMS0C12SM_MSG_ERR_NONFATAL:PCIE NONFATAL ERROR MSG

34.5.43 AFI_AFI_MCCIF_FIFOCTRL_0

Memory Client Interface FIFO Control (where applicable) and Clock Gating Control Register

Note: *The FIFO timing aspects of this register are no longer supported, but retained for software compatibility*

The clock override/ovr_mode fields of this register control the second-level clock gating for the client and MC side of the MCCIF. All clock gating is enabled by default.

A '1' written to the rclk/wclk override field will result in one of the following:

- With wclk/rclk override mode = LEGACY, the clock reverts to legacy mode of operation where the clock is on whenever the client clock is enabled.
- With wclk/rclk override mode = ON, the clock is always on inside MCCIF and PC. A '1' written to the cclk override field keeps client's clock always on inside MCCIF.

Offset: 0x7cc | Read/Write: R/W | Reset: 0x00000000 (0bxxxxxxxxxxxx00000xxxxxxxxxxxx0000)

Bit	Reset	Description
20	LEGACY	AFI_RCLK_OVR_MODE: 0 = LEGACY 1 = ON
19	LEGACY	AFI_WCLK_OVR_MODE: 0 = LEGACY 1 = ON
18	0x0	AFI_CCLK_OVERRIDE
17	0x0	AFI_RCLK_OVERRIDE
16	0x0	AFI_WCLK_OVERRIDE
3	DISABLE	AFI_MCCIF_RDCL_RDFAST: 0 = DISABLE 1 = ENABLE
2	DISABLE	AFI_MCCIF_WRMC_CLLE2X: 0 = DISABLE 1 = ENABLE
1	DISABLE	AFI_MCCIF_RDMC_RDFAST: 0 = DISABLE 1 = ENABLE
0	DISABLE	AFI_MCCIF_WRCL_MCLE2X: 0 = DISABLE 1 = ENABLE

34.5.44 AFI_ORDERING_RULES_0

This register is reserved.

Offset: 0x7d0 | Read/Write: R/W | Reset: 0x00000000 (0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx000x)

Bit	Reset	Description
3	0x0	UPSTREAM_MSIAW
2	0x0	UPSTREAM_RESPAW
1	0x0	UPSTREAM_RAW

CHAPTER 35: I2C CONTROLLER

The I^2C controller (I2C) implements an I^2C 3.0 specification-compliant I^2C master and slave controller. The I^2C controller supports multiple masters and slaves. It supports Standard mode (up to 100 Kbits/s), Fast mode (up to 400 Kbits/s), and Fast mode plus (Fm+, up to 1 Mbits/s).

Tegra® X1 devices have six instances of this controller. All six instances have identical I2C master functionality. There are also three additional I2C instances in the TSEC, CL-DVFS, and VI modules.

The I^2C controller supports DMA for the Master controller over the APB bus. There is no DMA support for the Slave controller. The I^2C controller also supports packet mode transfers where the data to be transferred is encapsulated in a predefined packet format as payload and sent to the I^2C controller over the APB bus. The header of the packet specifies the type of operation to be performed, the size and other parameters (described in detail in subsequent sections).

35.1 Features

- Standard (up to 100 Kbits/s), Fast (up to 400 Kbits/s), and Fm+ (up to 1 Mbits/s) modes of operation.
- Single master
- Clock stretching by the slave
- One to eight-word burst data transfers in DMA mode for the Master controller
- 4 Kbyte transfers in packet mode. Can be extended beyond 4 Kbytes by breaking up transfers into multiple packets (in both DMA and non-DMA modes)
- 7-bit or 10-bit addressing transactions
- Master is capable of data transfers to/from two or more slaves consecutively with a repeated-start condition
- Bus clear operations to address SDA driven LOW issues
- General call addressing
- Recognition and transfer of data to peripherals that do not send an acknowledge (ACK)
- Master supports DMA for packet mode transfers

Note: *Neither multi-master mode nor high-speed (HS) operation mode are supported. References to those below should be ignored and corresponding register bits should be treated as reserved.*

35.2 Clocking

The I^2C controller has three clock domains:

- The Host interface runs on the APB clock (pclk). The APB clock is derived from the system clock and can be 1.0, ½, or ¼ times the system clock (sclk).
- The I^2C interface controller clock runs on a frequency up to 136 MHz (maximum). The 136 MHz clock is derived from PLLP. Even though you can mux between PLLP, PLLC, PLLM, and OSC clocks, PLLP is always selected and used in normal operation.
- The time-out logic runs on a 32 kHz clock.

35.3 Functionality

The I^2C Master can be programmed for either a single slave transaction or a two-slave transaction. The two-slave transaction is generally useful in a random read from an external device. When reading from an external device, the random read-address needs to be set with an initial dummy-write to the device, followed by a repeated-start and a read transaction to the same device.

35.3.1 Bus Clear Master Operation

Bus clear logic helps to resolve I2C bus hang issues. If the data line (SDA) is permanently stuck low because a slave device is pulling it low continuously for some unknown reason, the I2C master loses the bus arbitration and stops driving the I2C bus. In this case, software can use the Bus Clear master to get the SDA line released by sending clock pulses on the SCL line. Per the I2C specification, the device that held the bus Low should release it sometime within 9 clock pulses. But if the device needs more clock pulses than the default 9 pulses, software has an option to do so by programming a configurable register bit field (I2C_I2C_BUS_CLEAR_CONFIG_0[BC_SCLK_THRESHOLD]) to the required number of clock pulses.

35.3.1.1 Bus Clear Programming Procedure

The Bus Clear operation starts with an ARB_LOST notification from the I^2C controller. The ARB_LOST notification could be due to many reasons. When software initiates Tegra-I2C for a data transfer at this time, the master could back off if it does not win the bus in the bus-arbitration procedure. Other cases for ARB_LOST are programming issues such as controller register configuration, pinmuxing, and pin tri-state clear.

If it was determined that ARB_LOST notification is due to a slave device continuously pulling the SDA line low, the bus clear operation can be initiated to recover the bus with the following steps:

1. Reset the I2C controller using module reset after the ARB_LOST notification from the controller.
2. Program the I2C_I2C_BUS_CLEAR_CONFIG_0[BC_SCLK_THRESHOLD] bit field to the required number of clock pulses.
3. Select the STOP or NO_STOP condition using the I2C_I2C_BUS_CLEAR_CONFIG_0[BC_STOP_COND] bit field.
4. Program I2C_I2C_BUS_CLEAR_CONFIG_0[BC_TERMINATE] as needed. Always use the BC_TERMINATE = IMMEDIATE option.

Note: *If BC_TERMINATE =THRESHOLD settings are required to be used in any application with BC_STOP_COND = STOP settings, perform BusClear one more time. In the second BusClear iteration, use the BC_TERMINATE = IMMEDIATE settings with BC_STOP_COND = STOP settings.*

---

5. Set the I2C_I2C_CONFIG_LOAD_0[MSTR_CONFIG_LOAD] register bit field to 1, and wait until this bit field is auto-cleared to zero by hardware.
6. Set the I2C_I2C_BUS_CLEAR_CONFIG_0[BC_ENABLE] bit field to start the bus clear operation. Hardware auto clears this bit after the bus clear operation is done.
7. Once enabled, the bus clear logic starts sending clock pulses on the SCL line.
8. Based on BC_TERMINATE settings, the Bus Clear logic:
   - IMMEDIATE: Sends clock pulses until SDA is released or the threshold count is reached, whichever is earlier or
   - THRESHOLD: Sends the threshold number of clock pulses irrespective of SDA line release status (released before threshold is reached or not-released with threshold count reached)
9. If SDA is released within the programmed number of clock pulses:
   - The Bus Clear logic terminates the transaction with STOP/NO-STOP condition based on the BC_STOP_COND settings.
   - Then it sets the bus_clear operation status in the I2C_I2C_BUS_CLEAR_STATUS_0[BC_STATUS] register bit field.

- It sets the BUS_CLEAR DONE bit field in I2C_INTERRUPT_STATUS_REGISTER_0 and also interrupts the system if the corresponding interrupt enable bit is set in I2C_INTERRUPT_MASK_REGISTER_0. So software has to wait until it receives the BUS_CLEAR_DONE interrupt if the interrupt mechanism is used or the BUS_CLEAR_DONE status bit is set if the status-polling mechanism used before going for a BUS CLEAR operation successful/fail status check in I2C_I2C_BUS_CLEAR_STATUS_0[BC_STATUS].
- After receiving BUS_CLEAR_DONE interrupt, check if I2C_I2C_BUS_CLEAR_CONFIG_0[BC_ENABLE] bit is auto-cleared by hardware. If this bit is not cleared, it means, I2C clock settings are not correct. Fix the clocks programming.

35.3.2 Low-Power Operation

I^2C is a low-speed serial interface with only two bus lines (SCL, SDA) required. So from the I^2C specification side, there is no low-power operation specifically defined for the interface. But to save the power, use the lowest possible speed, if performance is not needed. The following bus speeds are supported by I^2C:

- Standard mode (Sm), with a bit rate up to 100 kbit/s
- Fast mode (Fm), with a bit rate up to 400 kbit/s
- Fast mode Plus (Fm+), with a bit rate up to 1 Mbit/s

35.3.2.1 Low Power Programming

Program the CLK_SOURCE_I2C register (for example: I2C1instance clock source address 0x60006124) and the I2C_CLK_DIVISOR registers such that the required data rate can be achieved at the minimum possible module clock so that power can be saved.

35.3.2.2 IDLE Power Programming

In single Master bus configurations, when the module is not used or interface is idle, disable the module clock by clearing the CLK_ENB_I2C bits in the CAR module.

For example, the I2C1 clock enable bit is CLK_RST_CONTROLLER_CLK_OUT_ENB_L_0[CLK_ENB_I2C1]. Software can clear this bit when it is seen that no transfers are needed from the I2C1 instance.

35.4 PWR-I2C Bus Sharing by the I2C5 and CLDVFS-I2C Controllers

It is possible for the I2C5 and CLDVFS-I2C controllers to try to access the PWR-I2C bus simultaneously in an application. To avoid bus conflicts, the CL-DVFS module provides a bus arbitration mechanism that grants the interface bus based on the requests to either the CLDVFS-I2C or I2C5 controller in round-robin fashion. If software intends to disable the CL-DVFS clock for some reason (for example, power saving), it has to put the CL-DVFS module in RESET by programming its reset to 1. So the I2C5 controller always gets the bus grant this way and the bus does not hang.

For the I2C5 controller to work properly, one of the following should occur:

- CLDVFS is in RESET

or

- CLDVFS is out of reset and its clocks are running

The I2C5 controller will not work if the CL-DVFS module is out of reset and the clocks to the CL-DVFS module are disabled. This is because the interface bus grant arbiter in the CL-DVFS cannot work because its clock is no longer toggling.

35.5 Software Interfaces

A typical peripheral controller might require the following steps to communicate or control an external peripheral:

1. Set up the registers
2. Program the ‘go’ bit to start the interaction with the external peripheral

3. The peripheral controller collects the response from the peripheral and interrupts software
4. Software reads the response

35.5.1 Packet Flow

Information exchange between the hardware peripheral controller and software as described above can be classified into:

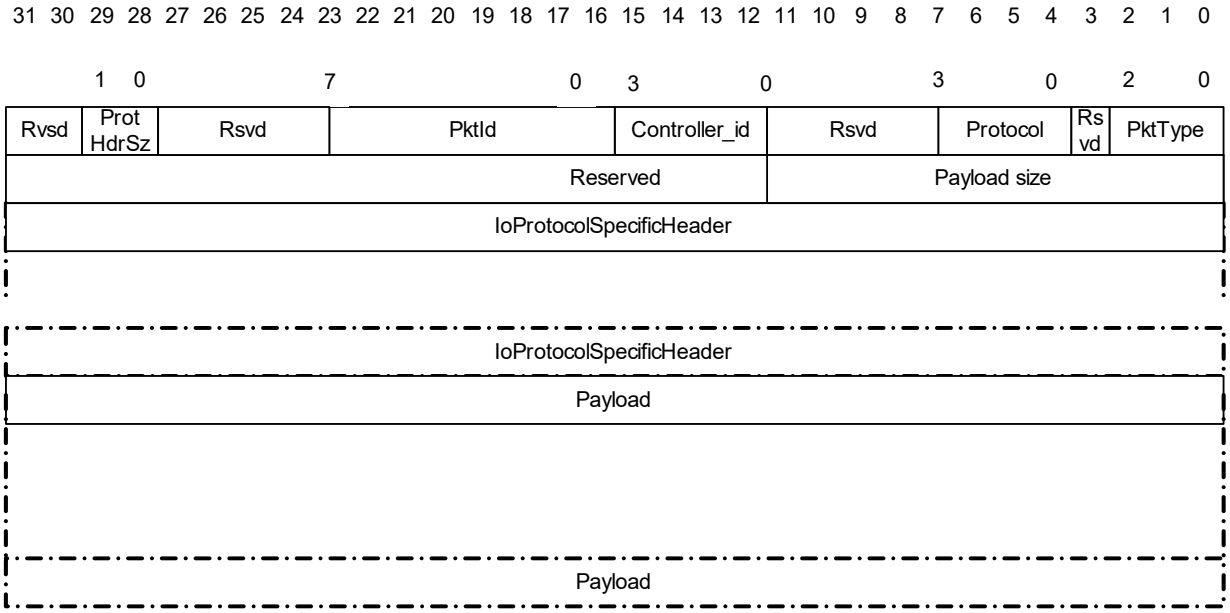
- 'Request' flow which can represent the register writes
- 'Response' flow for peripheral controller responses sent back to software, and
- 'Interrupt' flow for out-of-band handshakes between hardware and software

Packets within a flow can be exchanged in a manner that requires full intervention from the CPU (PIO mode) or least intervention from the CPU (DMA mode). The I2C I/O packet structure is described below:

35.5.2 I/O Packet Format

An I/O packet consists of a header and payload. The header consists of two parts: two words of generic header and 1-4 words of protocol-specific header.

Figure 159: I/O Packet



35.5.2.1 I/O Packet Word 0

Word 0 of the I/O packet contains the Generic Header Word 0. The contents of generic header word 0 are described in the table below.

Table 219: Generic I/O Header Word 0

Bits	Field Value	Description
31:30	Reserved	Reserved
29:28	ProtHdrSz	Size of the protocol-specific header in words 0 = 1 words 1 = 2 words 2 = 3 words 3 = 4 words For I2C, ProtHdrSz = 0 for request packets and 1 for response packets
27:24	Reserved	Reserved

Table 219: Generic I/O Header Word 0

Bits	Field Value	Description
23:16	PktId	PktId is an 8-bit field that identifies the packet. A peripheral controller might choose to log the packet ID for a packet that causes errors
15:12	Controller ID	There might be multiple controllers supporting any format. For example, there might be 4 I2C controllers. The Controller ID field specifies the controller for which this packet is destined.
11:8	Reserved	Reserved
7:4	Protocol	The protocol is indicated in this field 0 = reserved 1= I2C 2-15 = reserved
3	Reserved	Reserved
2:0	PktType	Packet type information 0 = request 1 = response 2 = interrupt 3 = stop 4-7 = reserved

35.5.2.2 I/O Packet Word 1

Word 1 of the I/O packet contains Generic Header Word 1. The contents of Generic Header Word 1 are described in the table below.

Table 220: Generic I/O Header Word 1

Bits	Field Value	Description
31:12	Reserved	Reserved
11:0	PayloadSize	Payload size in bytes

Note: *Payload Size: For request packets that transmit data, the total packet size is payload_size + 8 bytes of generic header + protocol-specific header. However, for request packets with a read command, the payload size indicates the amount of data to be received. Hence the packet size = 8 bytes of generic header + protocol-specific header, because there is no payload in this packet, just the receive command.*

35.5.3 Transferring Packets

Packets can be transferred using PIO or DMA modes. A peripheral controller can choose to implement one or both modes. The header is a minimum of three words with the first two words reserved for packet information and the third word reserved for protocol-specific requirements. A minimum of four words is needed to transfer one byte to the external peripheral.

35.5.4 Protocol-Specific Header

Depending on the implementation of the peripheral controller and the interface protocol, the header words can be defined. No restriction is placed on the organization of the fields or the number of protocol-specific words (a minimum of one word and a maximum of four words) that a particular implementation chooses.

I2C has one word with the Protocol-Specific Header. The contents of the I2C protocol-specific header are described in the next section.

35.5.5 I2C Master Packet Protocol Specific Headers

The I2C master supports two kinds of packets.

- Transmit packets that flow from Host to Controller.

- Receive data packets that flow from Controller to Host.

Table 221: I2C Master Transmit Packet Header

Bit	Name	Description
31:26	Reserved	Reserved
25	RESP_PKT_FREQ	Reserved Program 0.
24	RESP_PKT_ENABLE	Reserved. Program 0.
23	Reserved	Reserved
22	HS_MODE	Enable High speed mode (3.4 MHz operation)
21	CONTINUE_ON_NACK	Enable mode to handle devices that do not generate ACK upon the reception of a byte.
20	SEND_START_BYTE	1 = Send a start byte at the beginning of the transaction
19	READ/WRITE	1= READ
18	Address mode	1=10-bit mode 0 = 7-bit mode
17	IE	Generate interrupt upon packet completion
16	REPEAT_START/STOP	1 = Put a repeat start condition on the bus (to continue transaction) 0 = Put a stop condition on the bus
15	ContinueXfer	This bit overrides the REPEAT_START/STOP command above. 0: Introduce repeat start or stop condition based on bit 16. 1: Continue with current transfer without stop or repeat start condition.
14:12	HS_MASTER_ADDR	High Speed mode Master code
11:10	Reserved	Reserved
9:0	SLAVE_ADDR	Slave address. Bit 0 is ignored for 7-bit addressing, but should always match bit 19 (READ/WRITE).

35.5.6 I2C Master Speed Modes Support in Normal Mode vs Packet Mode

Table 222: Speed Modes in Normal/Packet Mode

Normal Mode	Packet Mode
Standard Mode (SM, 100KHz) Fast Mode (FM, 400KHz) Fast Mode Plus (FM+, 1MHz)	Standard Mode (SM, 100KHz) Fast Mode (FM, 400KHz) Fast Mode Plus (FM+, 1MHz)

35.6 Programming Guidelines

35.6.1 I2C Frequency Divisor Register

The FREQUENCY DIVISOR register (CLK_SOURCE_I2C register, whose address is: 0x60006124 for I2C1) must be programmed as a function of the CLK_SOURCE selected for I2C as follows:

Standard/Fast-mode/Fm+:

$$SCL\ Rate\ = \frac{I2Cx\_CLK\_SRC}{(I2Cx\_CLK\_DIVISOR + 1) * (TLOW + THIGH + 2 + Round\_Trip\_Delay\_In\_DivClk\_cycles) * (I2C\_CLK\_DIVISOR\_STD\_FAST\_MODE + 1)}$$

Where x = 1, 2, 3… 6

Note: *I2C_CLK_DIVISOR_STD_FAST_MODE settings should be such that it meets the following the requirement.*

$$\frac{(I2Cx\_CLK\_DIVISOR + 1) * (I2C\_CLK\_DIVISOR\_STD\_FAST\_MODE + 1) * 1000}{I2Cx\_CLK\_SRC\ in\ MHz} > \frac{Minimum\ SCL\ LowPeriod\ in\ nanosec}{5}$$

Table 223: Standard Mode Examples: SCL Low Period (minimum) = 4700 ns

I2C_CLK_SRC	I2C_CLK_SRC Frequency (MHz)	I2C_CLK_DIVISOR	I2C_CLK_DIVISOR_STD_FAST_MODE	Time Period (ns) = ((I2C_CLK_DIVISOR+1)*(I2C_CLK_DIVISOR_STD_FAST_MODE+1)*1000)/I2C_CLK_SRC	Time Period greater than minimum SCL Low Period/5 (4700/5 = 940ns) ?
PLLP_OUT0	408	2	128	948.5294118	YES
PLLP_OUT0	408	19	19	980.3921569	YES
CLK_M	19.2	0	23	1250	YES

Table 224: Fast Mode Examples: SCL Low Period (minimum) = 1300 ns

I2C_CLK_SRC	I2C_CLK_SRC Frequency (MHz)	I2C_CLK_DIVISOR	I2C_CLK_DIVISOR_STD_FAST_MODE	Time Period (ns) = ((I2C_CLK_DIVISOR+1)*(I2C_CLK_DIVISOR_STD_FAST_MODE+1)*1000)/I2C_CLK_SRC	Time Period greater than minimum SCL Low Period/5 (1300/5 = 260ns) ?
PLLP_OUT0	408	2	13	102.9411765	YES
CLK_M	38.4	0	3	104.1666667	YES

Table 225: Fast Mode Plus Examples: SCL Low Period (minimum) = 500 ns

I2C_CLK_SRC	I2C_CLK_SRC Frequency (MHz)	I2C_CLK_DIVISOR	I2C_CLK_DIVISOR_STD_FAST_MODE	Time Period (ns) = ((I2C_CLK_DIVISOR+1)*(I2C_CLK_DIVISOR_STD_FAST_MODE+1)*1000)/I2C_CLK_SRC	Time Period greater than minimum SCL Low Period/5 (1300/5 = 260ns) ?
PLLP_OUT0	408	2	13	102.9411765	YES
CLK_M	38.4	0	3	104.1666667	YES

Table 226: Example Settings for Various I2C Speeds

Source	PLLP_OUT0	I2C Source Div (Programmed value is 1 minus always)	(Tlow+1)+ (Thigh+1)	SM/FM Div (Programmed Value is 1 minus always)	I2C Frequency	Debounce
PLLP	408 MHz	3 (2)	((4+1) + (2+1)) = 8	17 (16)	1 MHz (FM+)	0
PLLP	408 MHz	5 (4)	((4+1) + (2+1)) = 8	26 (25)	392 kHz (FM)	2
PLLP	408 MHz	20 (19)	((4+1) + (3+1)) = 9	23 (22)	98.5 kHz (SM)	2

Debounce will impact the I2C interface data rate in the following way.

For example, if CLK_SOURCE = 408 MHz and Source Div = 5:

I2C_Clock frequency = 408/5 = 81.6 MHz ➔ I2C clock period = 12.25 ns

Chip internal delay = 10 ns, Load_Delay = 55 ns, Debounce = 2, Synchronizer Delay = 3

Round_Trip_Delay = (10 ns + 55 ns + 9*12.25 ns) = ~175.25 ns

FM+ speed case: STD_FM_Div = 10

STD_FM_Div * I2C_Clk_Period = 10*12.255 ns = 122.55 ns

Round_Trip_Delay in I2C_Div cycles = Round_Trip_Delay/(STD_FM_Div * I2C_Clk_Period) = 1. (Rounded down to the nearest integer.)

So I2C SCL rate = $\frac{408MHz}{5*(8+1)*10}$ = 906 KHz

If Debounce is disabled, the Round_Trip_delay (in I2C_Div cycles) becomes zero (rounded down).

So I2C SCL rate = $\frac{408MHz}{5*(8)*10}$ = 1002 KHz = 1.02 MHz

Table 227: I2C Data Rate Variation with Debounce

I2C Mode	Clock Source	Source Clock Frequency	I2C Source Divisor (Programmed value is always 1 minus always)	SM/FM Divisor (Programmed value is always 1 minus always)	Debounce Value	I2C SCL Frequency
FM+	PLLP_OUT0	408 MHz	5 (4)	10 (9)	0	1016 kHz
			5 (4)	10 (9)	Range: 5 to 1	906 kHz
			5 (4)	10 (9)	Range: 7 to 6	816 kHz
FM	PLLP_OUT0	408 MHz	5 (4)	26 (25)	Range: 7 to 0	392 kHz
SM	PLLP_OUT0	408 MHz	20 (19)	26 (25)	Range: 7 to 0	98 kHz

The clock enable (bit 12 of the CLK_OUT_ENB.L register) must also be given to the I2C controller, before any of the registers are written.

35.6.2 I2C Command ADDR Registers

These registers, I2C_CMD_ADDR0 and I2C_CMD_ADDR1, contain the address of the slave with which a transaction is intended. The I^2C Master Controller can be programmed to transact with both 7-bit and 10-bit addressed slaves. Bit [0] of the I2C_CNFG register determines the size of the slave address to be transacted. If a 7-bit or a 10-bit slave address is chosen, the respective address is taken from I2C_CMD_ADDR0 [9:0], and the Read/Write command is taken from bits 6 and 7 of the I2C_CNFG Register. In a 2 Slave configuration, the slave 1 address (7-bit or 10-bit) is taken from I2C_CMD_ADDR0 [9:0] and Slave 2 address (7-bit or 10-bit) from I2C_CMD_ADDR1 [9:0]. The transfer length is the same in 2 slave operation and is taken from the I2C_CNFG [LENGTH] bit field. In 2-slave operation, the maximum possible transfer size is 4 bytes.

35.6.3 I2C Data Registers

There are two data registers, I2C_CMD_DATA1and I2C_CMD_DATA2, each with 32-bit length, which are to be loaded with the data to be transmitted or received (I2C_SL_RCVD register).

35.6.4 I2C Configuration Register

This register is to be configured with the following data:

- Number of bytes to be transmitted or received
- Select for 7-bit or 10-bit slave address
- Program to send a Start Byte
- Single or two slave operations

- Support of NOACK from an external peripheral

The I2C_CNGF [9] bit is used to issue a “Begin-Transaction” command to the I^2C Master Controller. This bit is auto cleared by the hardware, and other bits of the register are masked for writes, when this bit is programmed to be one. Hence, the firmware should first configure all the other registers and bits [8:0] of the I2C_CNFG register before the I2C_CNFG [9] bit is programmed to one.

35.6.5 I2C Configuration Load Register

This CONFIG load register transfers the software programmed configuration in the I2C registers to hardware internal registers used in the logic. It has three bit fields:

- MSTR_CONFIG_LOAD for regular master and Bus Clear master logic
- SLV_CONFIG_LOAD for slave controller logic
- TIMEOUT_CONFIG_LOAD for SMBUS timeout logic.

Software must set these fields to 1 for the actual register configuration to take effect. Thus software is programming only shadow registers through regular configuration. When these load_config bit fields are set to 1, it causes the regular/shadow registers configuration to be transferred to the hardware internal active registers. So software has to set these bit fields at the end of all regular register configurations. However, in normal or non-packet mode, these bit fields should be set to 1 before the I2C_I2C_CNFG_0[SEND] bit is set to 1. The I2C_I2C_CNFG_0[SEND] bit triggers a transfer on the I2C bus and should be programmed at the end of the entire configuration. These config_load bits are hardware auto-clear bits. Hardware clears these bit fields once the register configuration is moved to hardware internal active registers. So software must wait until these bits are auto-cleared before continuing with further programming.

Below are the register bit fields associated with each CONFIG_LOAD bit.

MSTR_CONFIG_LOAD needs to be set for the following registers:

- I2C_I2C_CNFG_0
- I2C_I2C_CMD_ADDR0_0
- I2C_I2C_CMD_ADDR1_0
- I2C_I2C_CMD_DATA1_0
- I2C_I2C_CMD_DATA2_0
- I2C_I2C_CLK_DIVISOR_REGISTER_0
- I2C_I2C_BUS_CLEAR_CONFIG_0
- I2C_I2C_INTERFACE_TIMING_0_0
- I2C_I2C_INTERFACE_TIMING_1_0
- I2C_I2C_HS_INTERFACE_TIMING_0_0
- I2C_I2C_HS_INTERFACE_TIMING_1_0

SLV_CONFIG_LOAD covers the following registers:

- I2C_I2C_SL_CNFG_0
- I2C_I2C_SL_ADDR1_0
- I2C_I2C_SL_ADDR2_0
- I2C_I2C_TLOW_SEXT_0[RST_SL_ON_TIMEOUT]
- I2C_I2C_SL_DELAY_COUNT_0

TIMEOUT_CONFIG_LOAD covers the following register bit fields:

- I2C_I2C_TLOW_SEXT_0[TIMEOUT]

- I2C_I2C_TLOW_SEXT_0[TLOW_SEXT]
- I2C_I2C_TLOW_SEXT_0[TLOW_MEXT]
- I2C_I2C_TLOW_SEXT_0[TIMEOUT_EN]
- I2C_I2C_TLOW_SEXT_0[TLOW_SEXT_EN]
- I2C_I2C_TLOW_SEXT_0[TLOW_MEXT_EN]

35.6.6 I2C Controller Status Register

This register (I2C_STATUS) gives the status of the I^2C Master operation. It includes the busy status of the I^2C Master controller and the completion status of the command executed.

35.6.7 I2C Interface Timing Registers

These registers provide flexibility to tune the I2C interface bus timing for Master controller data transfers. Separate bit fields are provided for non-HS mode (STD/FM/FM+) timing.

35.6.8 I2C Slave ADDR Registers

There are two slave ADDR registers that are used to configure the address of the internal slave, I2C_SL_ADDR1 and I2C_SL_ADDR2. The bit [0] of I2C_SL_ADDR2 determines the address-size of the internal slave. When this bit is programmed to zero, the 7-bit slave address is taken from I2C_SL_ADDR1 [6:0]. When this bit is programmed to one, the most significant two bits of the 10-bit slave address are taken from I2C_SL_ADDR2[2:1] and the least significant bits are taken from I2C_SL_ADDR1[7:0].

35.6.9 I2C Controller Slave Status Register

This register (I2C_SL_STATUS) contains the status of I2C Slave.

It has the following status bits:

1. Bit 3 contains Receive Interrupt.
2. Bit 2 contains New Transaction Received.
3. Bit 1 is for Direction of transfer.
4. Bit 4 contains END_TRANS bit. This bit is set when an I2C transfer is complete (as indicated by either a STOP or NoACK from master).
5. Bit 5 contains RST_SL. The byte received following the receipt of general call address is 0x06. Therefore, the programmable part of the slave address needs to be reset and reprogrammed.
6. Bit 6 contains REPROG_SL. The byte received following the receipt of general call address is 0x04. Therefore reprogram the programmable part of the slave address.
7. Bit 7 contains HW_MSTR_INT. When set, this bit indicates that master address has been transmitted after general call address.
8. Bits [14:8] contain the hardware master address. The contents of this field are meaningful only when bit 7 (HW_MSTR_INT) is set.

Note: *The I2C Slave Controller generates an interrupt at the completion of each data byte received in the byte mode of operation. In response to this interrupt, firmware must read the I2C_SL_STATUS register to confirm the cause of the interrupt and the direction of data transfer. If the interrupt is due to a data byte received (R/W=0), firmware must read the data register and write-1 to I2C_SL_STATUS [SL_IRQ] to clear the interrupt and get the SCL line released. If the interrupt is due to read operation (R/W=1), data should be written to I2C_SL_RCVD in order to release the SCL line from clock stretching. The I2C Controller will delay the release of the ACK handshake on the I2C bus until the SL_IRQ bit has been cleared by the firmware. SW has to write-1 to clear I2C_SL_STATUS register bits.*

I2C_SL_STATUS needs to be either polled or the I2C interrupt must be enabled for transfers to occur in slave mode.

If Tegra X1 slave is receiving data,

- I2C_SL_STATUS[SL_IRQ] bit being set indicates that byte has been received.
- Check the transfer direction from RNW field.
- Read data byte from I2C_SL_RCVD register.
- Write 1 to I2C_SL_STATUS [SL_IRQ] to clear SL_IRQ which causes the bus to be released.
- SL_IRQ is set again upon reception of next byte.

If Tegra X1 slave is transmitting data,

- I2C_SL_STATUS[SL_IRQ] bit being set indicates that address has been received.
- Check the transfer direction from the RNW field.
- Write 1 to I2C_SL_STATUS [SL_IRQ] to clear SL_IRQ.
- Write data byte to the I2C_SL_RCVD register. This write causes the bus to be released.
- SL_IRQ is set again upon transfer of the byte. Another byte can be written to continue the operation.

Slave stretches the SCL line in the following cases:

- Pending Interrupts from I2C_SL_STATUS register after a byte received in write or a data byte needs to be sent in read operation. Software has to clear them by writing 1 to the register bit fields which releases the SCL line.
- TX-FIFO is empty and no data is available to send to Master during read operation. Software to write data to TX-FIFO to get the SCL line released.
- RX-FIFO is full and no room is left in the FIFO to receive any more data from Master. Software to read the RX-FIFO to allow the SCL line released
- During address cycle, the SCL stretch happens after ACK bit. The stretch time includes the interrupt clear time and the SL_DELAY_COUNT. If it is read operation, the clock stretch is extended until data byte is written to the I2C_SL_RCVD register.
- During data phase, the SCL stretch happens before and after ACK bit. The stretch before ACK is for a duration of SL_DELAY_COUNT and the stretch time after ACK bit is the interrupt clear time plus the SL_DELAY_COUNT period. If it is the read operation, the clock stretch is extended until data byte is written to the I2C_SL_RCVD register.

35.6.10 Clock Gating Over Ride Enable Register

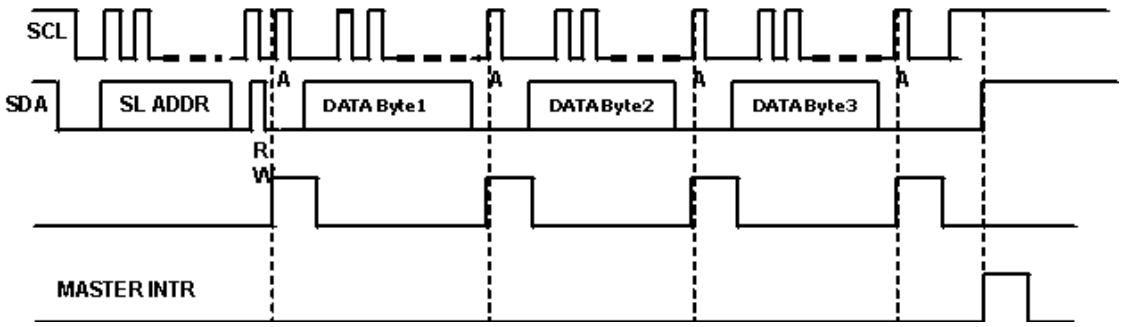
2nd level clock gating improves the power saving function. I2C implements SLCG in both the master and slave controller logic to save power. It is ENABLED by default. For any reason, if clock gating needs to be disabled, it can be done through the programmable I2C_CLKEN_OVERRIDE register. Separate bit fields are provided for master, bus clear master, and slave controllers.

35.6.11 Interrupt Generation in Non-Packet (Normal) Mode

In non-packet mode, the I2C controller generates interrupts upon the completion of transmission or reception of the specified number of bytes. A Master interrupt is generated when the number of bytes of the transaction, as programmed in the LENGTH field of the I2C_CNFG register, is complete.

A Slave-interrupt is generated at the transmission/reception of each byte of data including address byte by the internal slave as shown in figure below. Slave interrupts are to be cleared by the firmware as mentioned above.

Figure 160: Interrupt Generation: Master Reads from Internal Slave



35.7 Programming Guidelines for Master in Normal Mode

35.7.1 Programming Model for Master-Transmit

The following is a programming example for 7 byte writes from master to an external slave:

1. Program the I2C_CLK_DIVISOR register to get the required data rate based on I2C CLK_SOURCE register programming in CAR module.
2. Write slave address in I2C_CMD_ADDR0 register based on 7-bit/10-bit addressing mode.
3. Write first 4 bytes data in I2C_CMD_DATA1 register.
4. Write remaining 3 bytes in I2C_CMD_DATA2 register.
5. Program I2C_CNFG[DEBOUNCE_CNT] to the required value.
6. Set I2C_CNFG[A_MOD] to Seven or Ten_bit addressing based on slave device address width.
7. Program I2C_CNFG [LENGTH]. This bit field works in (n+1) fashion so for 7 bytes transfer, 6 needs to be programmed in LENGTH bit field.
8. Set I2C_CNFG [SLV2] = 0 as this is one slave access.
9. Set CMD1 = 0 for write operation.
10. Set NOACK to 0 or 1 based on Slave type.
11. Set MSTR_CONFIG_LOAD bit in I2C_CONFIG_LOAD register.
12. Wait until I2C_CONFIG_LOAD[MSTR_CONFIG_LOAD] is auto-cleared by hardware to 0.
13. Set I2C_CNFG [SEND] to 1 to begin write transaction on the interface.
14. Wait until the transaction is complete. For this, either wait until interrupt is received or I2C_STATUS[BUSY] bit becomes zero.
15. Check I2C_STATUS [CMD1_STAT] to see if the transaction is successful or NOACK from the slave for any of the bytes transferred.

35.7.2 Programming Model for Master-Receive

Read operation is divided into two steps based on random read or immediate read after a write. In a typical random read,

1. Write command: Send slave register/memory index first from which the data needs to be read.
2. Send read command to read the data.

The above operation can be done in two separate configurations or in a single configuration using Repeated Start in 2-slave configuration:

1. Write: Sending slave’s 1-byte register index first.

a. Write slave address in I2C_CMD_ADDR0 register based on 7-bit/10-bit addressing mode.
b. Write the slave internal register index (from which the data has to be read) in I2C_CMD_DATA1 register.
c. Program I2C_CNFG[DEBOUNCE_CNT] to the required value.
d. Set I2C_CNFG[A_MOD] to Seven or Ten_bit addressing based on slave device address width.
e. Write slave register index byte in I2C_CMD_DATA1 register.
f. Program I2C_CNFG[LENGTH] = 0 for 1 byte register index transfer.
g. Set I2C_CNFG[SLV2] = 0.
h. Set I2C_CNFG[CMD1] = 0 for write operation.
i. Set I2C_CNFG[NOACK] to 0 or 1 based on Slave type.
j. Set MSTR_CONFIG_LOAD bit in I2C_CONFIG_LOAD register.
k. Wait until I2C_CONFIG_LOAD[MSTR_CONFIG_LOAD] is auto-cleared by hardware to 0.
l. Set I2C_CNFG[SEND] to begin write transaction on the interface.
m. Wait until the transaction is complete. For this, either wait until interrupt is received or I2C_STATUS [BUSY] bit becomes zero.
n. Check I2C_STATUS[CMD1_STAT] to see if the transaction is successful or NOACK from the slave.

2. Read: Send read command.
   a. Program I2C_CNFG[LENGTH] = 6 for 7-bytes read.
   b. Set I2C_CNFG[SLV2] = 0 as this is one slave access.
   c. Set I2C_CNFG[CMD1] = 1 for read operation.
   d. Set MSTR_CONFIG_LOAD bit in I2C_CONFIG_LOAD register.
   e. Wait until I2C_CONFIG_LOAD[MSTR_CONFIG_LOAD] is auto-cleared by hardware to 0.
   f. Set I2C_CNFG[SEND] to begin write transaction on the interface.
   g. Wait until the transaction is complete. For this, either wait until interrupt is received or I2C_STATUS [BUSY] bit becomes zero.
   h. Check I2C_STATUS[CMD1_STAT] to see if the transaction is successful or NOACK from the slave.
   i. Read first 4 bytes data in I2C_CMD_DATA1 register.
   j. Read remaining 3 bytes in I2C_CMD_DATA2 register.
3. Read using repeated-start in 2-slave mode. Note that the maximum transfer size possible in 2-slave mode is 4 bytes.
   a. Write slave address in I2C_CMD_ADDR0 register with LSB bit set to “0”.
   b. Write slave address in I2C_CMD_ADDR1 register with LSB bit set to “1”.
   c. Write the slave internal register index byte (from which the data has to be read) in I2C_CMD_DATA1 register.
   d. Program I2C_CNFG[DEBOUNCE_CNT] to the required value as needed.
   e. Set I2C_CNFG[A_MOD] to Seven or Ten_bit addressing.
   f. Program I2C_CNFG[LENGTH] = 0 for 1 byte transfer.
   g. Set I2C_CNFG[SLV2] = 1.
   h. Set I2C_CNFG[CMD1] = 0 for write operation.
   i. Set I2C_CNFG[CMD2] = 1 for read operation.
   j. Set I2C_CNFG[NOACK] to 0 or 1 based on Slave type.
   k. Set MSTR_CONFIG_LOAD bit in I2C_CONFIG_LOAD register.
   l. Wait until I2C_CONFIG_LOAD[MSTR_CONFIG_LOAD] is auto-cleared by hardware to 0.

m. Finally set I2C_CNFG[SEND] to begin write transaction on the interface.

n. Wait until the transaction is complete. For this, either wait until interrupt is received or I2C_STATUS [BUSY] bit becomes zero.

o. Check I2C_STATUS [CMD1_STAT] to see if the transaction is successful or NOACK from the slave.

p. Read data from I2C_CMD_DATA2 register.

35.7.2.1 Example Transfers in Normal Mode

Write Example:

This programming example is for 7 byte writes from master to an external slave.

Program the I2C_CLK_DIVISOR register to get the required data rate based on I2C CLK_SOURCE register programming in CAR module

1. Write the slave address in the I2C_CMD_ADDR0 register based on 7-bit/10-bit addressing mode
2. Write the first 4 bytes of data in the I2C_CMD_DATA1 register
3. Write the remaining 3 bytes in I2C_CMD_DATA2 register
4. Program I2C_CNFG[DEBOUNCE_CNT] to the required value as needed
5. Set I2C_CNFG[A_MOD] to 7-bit or 10-bit addressing
6. Program I2C_CNFG [LENGTH]. This bit field works in (n+1) fashion; so for a 7-byte transfer, 6 needs to be programmed in the LENGTH bit field
7. Set I2C_CNFG [SLV2] = 0 as this is one slave access
8. Set CMD1 = 0 for write operation
9. Set NOACK to 0 or 1 based on Slave type
10. Set the MSTR_CONFIG_LOAD bit in the I2C_CONFIG_LOAD register
11. Set I2C_CNFG [SEND] to 1 to begin a write transaction on the interface
12. Wait until the transaction is complete, either until an interrupt is received or the I2C_STATUS[BUSY] bit becomes zero.
13. Check I2C_STATUS [CMD1_STAT] to see if the transaction is successful or there is a NOACK from the slave for any of the bytes transferred.

Read Example:

A read operation is divided into two steps based on random read or immediate read after a write. In a typical random read:

1. Write command: Send slave register/memory index first from which the data needs to be read.
2. Send read command to read the data. This operation can be done in two separate configurations or in a single configuration using Repeated Start in 2-slave configuration.

These steps are described in detail below:

- Write: Sending slave's 1-byte register index first.
  a. Write the slave address in I2C_CMD_ADDR0 register based on 7-bit/10-bit addressing mode.
  b. Write the slave's internal register index (from which the data has to be read) in the I2C_CMD_DATA1 register.
  c. Program I2C_CNFG[DEBOUNCE_CNT] to the required value as needed.
  d. Set I2C_CNFG[A_MOD] to 7-bit or 10-bit addressing.
  e. Write the slave register index byte in the I2C_CMD_DATA1 register.
  f. Program I2C_CNFG[LENGTH] = 0 for a 1 byte register index transfer.
  g. Set I2C_CNFG[SLV2] = 0.
  h. Set I2C_CNFG[CMD1] = 0 for write operation.

i. Set I2C_CNFG[NOACK] to 0 or 1 based on the Slave type.

j. Set the MSTR_CONFIG_LOAD bit in the I2C_CONFIG_LOAD register.

k. Set I2C_CNFG[SEND] to begin the write transaction on the interface.

l. Wait until the transaction is complete. (Wait until either an interrupt is received or the I2C_STATUS [BUSY] bit becomes zero).

m. Check I2C_STATUS[CMD1_STAT] to see if the transaction is successful or there is a NOACK from the slave.

- Read: Send read command.

a. Program I2C_CNFG[LENGTH] = 6 for 7-bytes read.

b. Set I2C_CNFG[SLV2] = 0 because this is one slave access.

c. Set I2C_CNFG[CMD1] = 1 for read operation.

d. Set the MSTR_CONFIG_LOAD bit in the I2C_CONFIG_LOAD register.

e. Set I2C_CNFG[SEND] to begin write transaction on the interface.

f. Wait until the transaction is complete. (Wait until either an interrupt is received or the I2C_STATUS [BUSY] bit becomes zero).

g. Check I2C_STATUS[CMD1_STAT] to see if the transaction is successful or there is a NOACK from the slave.

h. Read the first 4 bytes data in the I2C_CMD_DATA1 register.

i. Read the remaining 3 bytes in the I2C_CMD_DATA2 register.

- Read using repeated-start in 2-slave mode.

a. Write the slave address in the I2C_CMD_ADDR0 register with the LSB bit set to “0”.

b. Write the slave address in the I2C_CMD_ADDR1 register with the LSB bit set to “1”.

c. Write the slave internal register index byte (from which the data has to be read) in the I2C_CMD_DATA1 register.

d. Program I2C_CNFG[DEBOUNCE_CNT] to the required value as needed.

e. Set I2C_CNFG[A_MOD] to 7-bit or 10-bit addressing.

f. Program I2C_CNFG[LENGTH] = 0 for 1 byte transfer.

g. Set I2C_CNFG[SLV2] = 1.

h. Set I2C_CNFG[CMD1] = 0 for write operation.

i. Set I2C_CNFG[CMD2] = 1 for read operation.

j. Set I2C_CNFG[NOACK] to 0 or 1 based on the Slave type.

k. Set the MSTR_CONFIG_LOAD bit in the I2C_CONFIG_LOAD register.

l. Set I2C_CNFG[SEND] to begin the write transaction on the interface.

m. Wait until the transaction is complete. (Wait until either an interrupt is received or the I2C_STATUS [BUSY] bit becomes zero).

n. Check I2C_STATUS [CMD1_STAT] to see if the transaction is successful or there is a NOACK from the slave

o. Read data from the I2C_CMD_DATA2 register.

35.8 Programming Guidelines for Packet-Based Interface

35.8.1 Packet Based Interface Registers

The following registers are used for a packet based interface:

- I2C_I2C_TX_PACKET_FIFO_0
- I2C_I2C_RX_FIFO_0

- I2C_PACKET_TRANSFER_STATUS_0
- I2C_I2C_HS_INTERFACE_TIMING_0_0
- I2C_I2C_HS_INTERFACE_TIMING_1_0
- I2C_I2C_INTERFACE_TIMING_0_0
- I2C_I2C_INTERFACE_TIMING_1_0
- I2C_FIFO_CONTROL_0
- I2C_FIFO_STATUS_0
- I2C_INTERRUPT_MASK_REGISTER_0
- I2C_INTERRUPT_STATUS_REGISTER_0
- I2C_I2C_INTERRUPT_SOURCE_REGISTER_0
- I2C_I2C_INTERRUPT_SET_REGISTER_0
- I2C_I2C_CLKEN_OVERRIDE_0
- I2C_I2C_DEBUG_CONTROL_0
- I2C_I2C_CLK_DIVISOR_REGISTER_0
- I2C_I2C_CNFG_0
- I2C_I2C_CONFIG_LOAD_0

All other registers/fields have no meaning in packet mode and should be used only normal mode.

35.8.2 Programming Packet Header and Payload

Software should post the packets to I2C_TX_PACKET_FIFO. It writes the packet header followed by the payload to the I2C_TX_PACKET_FIFO register. The header size can vary from 3 to 4 words. For I2C, the size is 3 words header for request packets and 4 words for response packets. The first two words of the header contain a generic header. The third word of the packet (and fourth as well for response packets) contains I2C transaction-specific information. The payload contains the actual data to be written to the slave. In case of read operations, payload is nil, and hence, the packet contains only a header.

35.8.3 Reading from the RX FIFO

The data received from the I2C bus is pushed into the I2C_I2C_RX_FIFO_0. In PIO mode, a request interrupt is generated when the FIFO attention level is reached and if the corresponding interrupt enable bit is set. Software then reads the I2C_I2C_RX_FIFO_0 register to get the data. In DMA mode, a request is asserted to DMA after the attention level is reached.

35.8.4 Programming REPEAT_START/STOP bit in the protocol specific header

This field indicates whether to put a stop or repeated-start condition after the current transaction. By default, this bit is zero and a stop condition is put on the bus. If this bit is set to 1, a repeat start is put on the bus instead before proceeding with the next packet. REPEAT_START/STOP bit can be used for combining read operations and write operations within a single transaction with repeat start, or to do transfers beyond the 4Kbyte limit. This bit is present in the protocol specific header.

35.8.5 Programming ContinueXfer bit in the protocol specific header

I2C supports transfer sizes beyond 4Kbytes without repeat start condition again by combining multiple packets. This is in addition to the ability of using repeat start condition to do continuous transfers over 4Kbyte limit. With ContinueXfer, the current transfer would continue without stop or repeat start condition.

35.8.6 Transfers with START Byte

Transfers that need a longer start procedure can use the START Byte feature. In this mode, START Byte (8‘b00000001) is transmitted after the START condition and a dummy acknowledge (NACK) would be received. And actual transfer would start

with a Repeated START condition then. For START byte transfers, set SEND_START_BYTE to 1 in the protocol specific header of the packet.

35.8.7 Transfers with Slaves having No-ACK capability

There could be slave devices which do not generate ACK upon reception of a byte. I2C Master has the capability to do the transfers with these devices too. This would be done by setting CONTINUE_ON_NACK bit field of the protocol specific header to 1. In this case, the I2C master ignores the NACK bit and continues the transfers.

35.8.8 HS_MODE transfers

HS_MODE transfers are supported in packet mode only. For HS transfers, write HS master code byte in HS_MASTER_ADDR field of the protocol specific header and set HS_MODE bit to 1. If HS_MODE bit is programmed to 0, all the transfers would be done in non-HS modes (Standard/Fm/Fm+) based on the I2C clocks frequency programming. In HS mode, Master code bytes are transmitted in (Standard/Fm/Fm+) speed mode and the data transfers occurs in HS mode. I2C_I2C_HS_INTERFACE_TIMING_0_0 and I2C_I2C_HS_INTERFACE_TIMING_1_0 registers are used for HS timing generation on the I2C bus.

35.8.9 FIFO Control

In DMA mode, I2C_FIFO_CONTROL_0 [TX_FIFO_TRIG] indicates the number of words that need to be empty in I2C_I2C_TX_PACKET_FIFO_0 for the DMA trigger to be asserted. I2C_FIFO_CONTROL_0[RX_FIFO_TRIG] indicates the number of words that need to be full in I2C_I2C_RX_FIFO_0 for the DMA trigger to be asserted.

In PIO mode, INTERRUPT_STATUS_REGISTER [TFIFO_DATA_REQ] is set if the I2C_I2C_TX_PACKET_FIFO_0 empty count is more than the value programmed in TX_FIFO_TRIG. Similarly, INTERRUPT_STATUS_REGISTER [RFIFO_DATA_REQ] is set if I2C_I2C_RX_FIFO_0 full count is more than the value programmed in RX_FIFO_TRIG. CPU will be interrupted if status bits are set and their corresponding INT_EN is set in the INTERRUPT_MASK_REGISTER. The depth of TX and RX FIFOs is 8 words.

For Transmit and Receive Data requests in DMA or PIO mode, the I2C_I2C_CNFG_0[PACKET_MODE_EN] bit needs to be set to 1 along with FIFO_TRIG level settings. Otherwise, requests are not generated.

35.8.10 FIFO Status

This register indicates the number of entries that are empty in the TX FIFO (TX_FIFO_EMPTY_CNT) and the number of entries that are full in the RX FIFO (RX_FIFO_FULL_CNT).

35.8.11 Interrupt Status Register

This register (INTERRUPT_STATUS_REGISTER) gives the status of I2C Master in Packet Mode operation and also the status of Slave controller in FIFO mode and SMBUS timeout status. The register bits are set to 1 when the corresponding event happens. And the bit fields are sticky. Once set to 1, they will be stay 1. Write 1 to clear them to 0. However, TFIFO_DATA_REQ and RFIFO_DATA_REQ fields are exception to this as they depend on the FIFO trigger levels and cannot be cleared.

35.8.12 Interrupt Mask Register

This register (I2C_INTERRUPT_MASK_REGISTER_0) contains the interrupt enable bits for the status bits given in INTERRUPT_STATUS_REGISTER. A separate interrupt enable bit is available for each bit field of INTERRUPT_STATUS_REGISTER. Setting an INT_EN bit in this register enables signaling an interrupt to the system when a corresponding status bit is set in the INTERRUPT_STATUS_REGISTER. Clearing it masks the interrupt.

Note: *Interrupt enable bit fields “ARB_LOST_INT_EN/NOACK_INT_EN/TFIFO_OVF_INT_EN / RFIFO_UNF_INT_EN” not only just work as enables for interrupts generation of corresponding events in packet mode but also have special impact how the packets are parsed in packet*

mode. It is important to set them in packet mode. Refer to Section 35.8.15: Error Handling for details.

35.8.13 Interrupt Source Register

This is a read-only register (I2C_INTERRUPT_SOURCE_REGISTER) which returns the AND of Interrupt Mask and Interrupt Status Registers bit fields. A bit field in this register is set if the corresponding bit fields in I2C_INTERRUPT_MASK_REGISTER_0 and INTERRUPT_STATUS_REGISTER are set to 1.

Example:

I2C_INTERRUPT_SOURCE_REGISTER[ARB_LOST] = AND(I2C_INTERRUPT_MASK_REGISTER [ARB_LOST_INT_EN], INTERRUPT_STATUS_REGISTER [ARB_LOST])

35.8.14 Packet Transfer Status

In addition to I2C_INTERRUPT_STATUS_REGISTER_0, packet transfer status can be obtained from the I2C_PACKET_TRANSFER_STATUS_0 register as well as with additional information of the packet. Software can read this register to know which packet is currently being transferred, how many bytes are transferred in the on-going packet or packet is successfully transferred, or any Bus loss or NACK happened during the transfer.

1. TRANSFER_PKT_ID gives the ID of on-going packet or last transmitted packet ID.
2. TRANSFER_BYTENUM gives the information about the number of bytes that have been transferred so far in the current packet. Once the packet transfer is done, this field becomes zero.
3. TRANSFER_COMPLETE field is set when a packet (with STOP=1) is successfully transferred.
4. ARB_LOST shows the loss of the bus.
5. NOACK_FOR_ADDR for the Noack received for address byte.
6. NOACK_FOR_DATA for the Noack received for data byte.
7. CONTROLLER_BUSY shows PACKET_MODE_EN bit status. It would be 1 as long as packet mode is enabled.

35.8.15 Error Handling

In case of an error, for example, due to NOACK or loss of arbitration or TX-FIFO overflow or RX-FIFO underflow, the following steps describe the sequence to be followed before proceeding to any further transactions.

When an error occurs, the I2C controller stops further packet transfers and sets the corresponding status bits in I2C_INTERRUPT_STATUS_REGISTER for the event (ARB_LOST/NOACK/TFIFO_OVF/ RFIFO_UNF) to occur.

- PACKET_TRANSFER_STATUS register is updated with the current error packet ID, at which the error occurs.
- Software should reset the I2C controller.
- In the case of DMA transfer, DMA needs to be disabled.
- Release the reset to I2C controller.
- Redo the I2C configuration and restart the DMA if used.

In packet mode, special care should be taken to handle error recovery. If an error occurs during the transfer of a packet then the controller should be reset and DMA needs to be restarted (if using DMA transfer) and the entire packet needs to be resent since there is no accurate way of knowing how many bytes made it to the I2C slave.

The Repeat-Start bit in packet mode can complicate the situation further. When back-to-back packets are sent to a slave with repeat start bit set, and an error occurs, then it is not known during which packet transfer the error occurred. Therefore, the entire stream of packets that were sent back-to-back using repeat start needs to be resent.

On the receive case, it is simpler since if an error occurs, and bytes for a packet have already been received, then that packet can be deemed complete. Only incomplete transfers need to be retried.

Note: *Note: Hardware needs interrupts to be enabled in the beginning before a packet is posted to its TX-FIFO. Otherwise, the I2C controller could potentially parse stale data in the TX-FIFO in error cases, as described in the steps below.*

Hardware functionality in packet mode:

1. When packet_mode_en is 1, I2C hardware parses the entries (packets) in TX-FIFO, provided there is no pending errors status (for example, I2C_INTERRUPT_MASK_REGISTER [ARB_LOST_INT_EN] && INTERRUPT_STATUS_REGISTER [ARB_LOST] should be 0) that software has to attend for previous transfers.
2. If enough entries (minimum, packet header) are available in the FIFO, hardware parses the packet and starts driving the I2C bus. It puts the Start condition and address byte on the bus when the packet header is available. If payload (data) is also available along with packet header in the FIFO, it continues driving it and finishes the transfer. Otherwise, it holds the I2C bus until payload is posted by software.
3. If the I2C controller sees ARB_LOST or NACK during its transfer on the bus, it stops the transfer immediately, sets ARB_LOST/NACK to 1 in I2C status register and alerts software by signaling an interrupt to the system.
4. Then it flushes the FIFO and goes to IDLE state. It starts again here.
5. It checks if there are any pending interrupts that software has to attend.
6. ((ARB_LOST status && ARB_LOST_INT_EN) == 1).
7. If the condition is not true, it goes ahead and checks if any entries are in the FIFO. If yes, for hardware, it is a new packet posted by software after attending the ARB_LOST (if any) of the previous transaction.

Consider this case where software does not set interrupt enable bits in the beginning of the I2C controller configuration. It could lead to hardware parsing the stale data in the TX-FIFO.

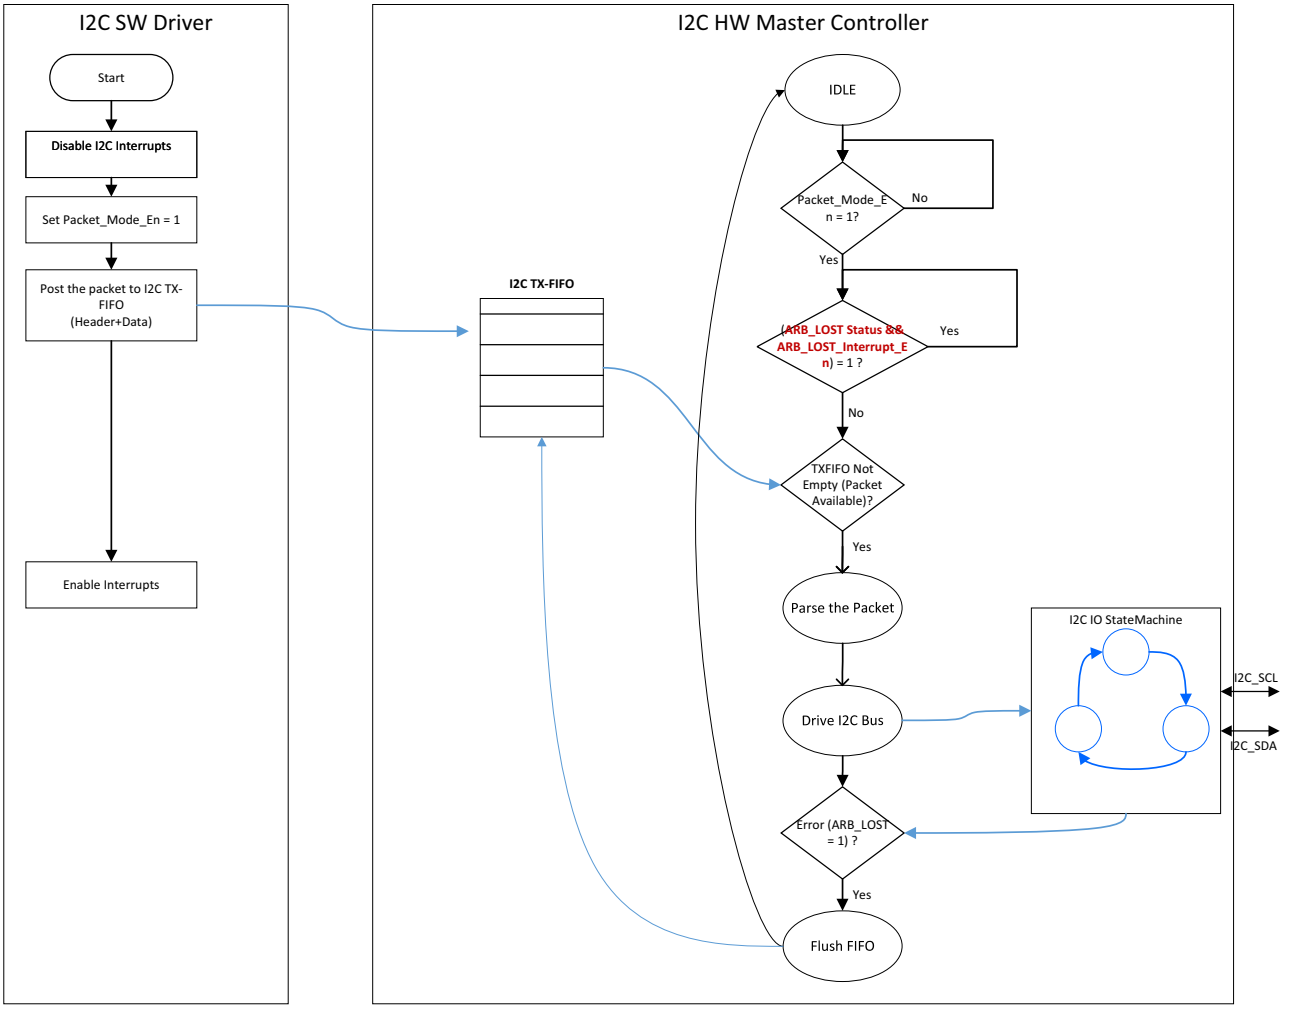
Example software I2C driver steps:

1. Disables all I2C interrupts in the beginning.
2. Sets packet_mode_en to 1.
3. Posts the packet to TX-FIFO. This triggers the hardware to initiate a transfer on the I2C bus when a minimum three entries (packet header) are available in the FIFO.
4. Fills the FIFO until it is full or the entire packet is posted if the packet size is less than or equal to FIFO size (32 bytes).
5. Enables the interrupts.
6. Wait on interrupts (transfer completion or error or tx_data_req to post remaining payload).

If hardware sees ARB_LOST from the I2C bus during software steps 3 and 4 above, this leaves a scope for hardware to parse the stale data in the FIFO as the interrupts are still disabled at this point. Software does not get interrupt so it continues to post the data and hardware, internally, finishes its FIFO flush step and comes to the idle state to check if hardware has posted any new packet. So there is an overlap here.

The above steps are described in the flowchart given below.

Figure 161: Software I2C Driver Flow



35.8.16 Slave Usage in FIFO Mode

Slave data transfers can be done using FIFO. Data can be transmitted and received through I2C_I2C_SLV_TX_PACKET_FIFO_0 and I2C_I2C_SLV_RX_FIFO_0 registers, respectively. For this, FIFO_XFER_EN bit in I2C_I2C_SL_CNFG_0 register needs to be set.

In FIFO-XFER mode, the slave by default works in one byte mode. For example, initially when a single byte is received, ACK is withheld and SLV_RX_BUFFER_FILLED interrupt is generated. Software should indicate whether to ACK this byte or not by writing into ACK_LAST_BYTE field of I2C_I2C_SL_CNFG_0 register. Note that ACK_LAST_BYTE_VALID field also needs to be set to indicate to hardware that ACK_LAST_BYTE is being updated. When software receives interrupt due to SLV_RX_BUFFER_FILLED, it can check ACK_WITHHELD of I2C_I2C_SLV_PACKET_STATUS_0 register to see if the slave is withholding the ACK for the last byte.

Software can update the buffer size from default to any number by programming I2C_I2C_SL_CNFG_0[BUFFER_SIZE].

35.8.17 WithHold Ack Feature

In FIFO mode, slave holds off ACK on the very last byte of transfer until the host explicitly indicates to I2C to release the bus by ACKing the last byte. Host is responsible for providing this indication to I2C slave in a timely fashion before timeouts happen in SMBUS applications.

35.8.18 Slave Read/Write Transfer Switching Status

Separate status bits are available to report slave data transfer switching from read to write and vice versa. I2C_INTERRUPT_STATUS_REGISTER_0 [SLV_RD2WR] indicates that there is a switch from read to write with repeated-start condition on the I2C bus and current Read transaction needs to be closed and start with a Write transaction. SLV_RD2WR status bit is set if the read to write switching happens before programmed buffer size completes. For example, the software programmed Slave buffer size to 10 bytes. But the Master device switched the transfer direction from current read to write before all 10bytes are transferred with a repeated-start on the bus. Then the SLV_RD2WR bit is set indicating read to write switching happened.

Similarly I2C_INTERRUPT_STATUS_REGISTER_0 [SLV_WR2RD] indicates the switching from Write to Read. Unlike SLV_RD2WR bit, this status bit is set if switching happens any time during transfer irrespective of the programmed buffer size is less than or equal to the actual data transferred.

35.9 Programming Guidelines for Master in Packet Mode

35.9.1 Programming Model for Master-Transmit Interrupt Method

1. Initial configuration

   Before accessing I2C controller, set up the following:

   a. I2C Clocks programming

   b. Pinmux programming

   c. I2C controller reset release

2. I2C Controller registers initialization:

   a. Write I2C_I2C_TLOW_SEXT_0 = 0x0.

   b. Write I2C_I2C_CMD_ADDR0_0 = 0x0.

   c. Write I2C_I2C_CMD_ADDR1_0 = 0x0.

   d. Write I2C_I2C_CMD_DATA1_0 = 0x0.

   e. Write I2C_I2C_CMD_DATA2_0 = 0x0.

   f. Write I2C_I2C_CLKEN_OVERRIDE_0 = 0x0.

   g. Write I2C_I2C_DEBUG_CONTROL_0 = 0x0.

   h. Write I2C_I2C_INTERRUPT_SET_REGISTER_0 = 0x0.

3. Program I2C_I2C_CLK_DIVISOR_REGISTER_0 register based on the required I2C bus speed. Refer to Section 35.6.1: I2C Frequency Divisor Register for details.

4. Configure I2C interface timing registers. Recommendation is to use default or PROD settings. But if needed, these registers can be programmed to achieve the required I2C interface timing:

   a. Write I2C_I2C_INTERFACE_TIMING_0_0 = 0x0204

   b. Write I2C_I2C_INTERFACE_TIMING_1_0 = 0x04070404

   c. Write I2C_I2C_HS_INTERFACE_TIMING_0_0 = 0x0308

   d. Write I2C_I2C_HS_INTERFACE_TIMING_1_0 = 0x0b0b0b0b

5. Configure FIFO trigger levels for data requests in PIO mode. The settings below are for example only. Program this bit field to the required trigger levels.

   a. Write I2C_FIFO_CONTROL_0[TX_FIFO_TRIG] = 0x3 (0x3 = System gets request from I2C controller when at least 4 words are empty in the I2C_I2C_TX_PACKET_FIFO_0)

6. Configure I2C Master to packet mode:

   a. Write I2C_I2C_CNFG_0[MULTI_MASTER_MODE] = DISABLE

b. Write I2C_I2C_CNFG_0[HS_RND_TRIP_DLY_EFFECT] = DISABLE.
c. Write I2C_I2C_CNFG_0[MSTR_CLR_BUS_ON_TIMEOUT] = 0.
d. Write I2C_I2C_CNFG_0[DEBOUNCE_CNT] = 0x2 //Example only, program as required. Refer to Section 35.6.1: I2C Frequency Divisor Register for details.
e. Write I2C_I2C_CNFG_0[NEW_MASTER_FSM] = ENABLE.
f. Write I2C_I2C_CNFG_0[PACKET_MODE_EN] = GO.
g. Write I2C_I2C_CNFG_0[SEND] = NOP.
h. Write I2C_I2C_CNFG_0[NOACK] = DISABLE.
i. Write I2C_I2C_CNFG_0[CMD2] = DISABLE.
j. Write I2C_I2C_CNFG_0[CMD1] = DISABLE.
k. Write I2C_I2C_CNFG_0[START] = DISABLE.
l. Write I2C_I2C_CNFG_0[SLV2] = DISABLE.
m. Write I2C_I2C_CNFG_0[LENGTH] = 0.
n. Write I2C_I2C_CNFG_0[A_MOD] = 0.

7. Activate the configuration:
   a. I2C_I2C_CONFIG_LOAD_0[TIMEOUT_CONFIG_LOAD] = ENABLE
   b. I2C_I2C_CONFIG_LOAD_0[SLV_CONFIG_LOAD] = DISABLE
   c. I2C_I2C_CONFIG_LOAD_0[MSTR_CONFIG_LOAD] = ENABLE
   d. Wait for I2C_I2C_CONFIG_LOAD_0[TIMEOUT_CONFIG_LOAD] and I2C_I2C_CONFIG_LOAD_0[MSTR_CONFIG_LOAD] bits to get cleared by the hardware.
8. Enable Interrupts for I2C Master controller in packet mode:
   a. Write I2C_INTERRUPT_MASK_REGISTER_0[ARB_LOST_INT_EN] = ENABLE.
   b. Write I2C_INTERRUPT_MASK_REGISTER_0[NOACK_INT_EN] = ENABLE.
   c. Write I2C_INTERRUPT_MASK_REGISTER_0[TFIFO_OVF_INT_EN] = ENABLE.
   d. Write I2C_INTERRUPT_MASK_REGISTER_0[ALL_PACKETS_XFER_COMPLETE_INT_EN] = ENABLE.
   e. Write I2C_INTERRUPT_MASK_REGISTER_0[PACKET_XFER_COMPLETE_INT_EN] = ENABLE.
   f. Write I2C_INTERRUPT_MASK_REGISTER_0[TFIFO_DATA_REQ_INT_EN] = ENABLE.

This completes the configuration. Next step is, posting the packets to I2C controller to initiate data transfers on the I2C bus.

1. Packets posting based on TFIFO data requests:
   a. There could be one or more packets that need to be transferred from I2C.
   b. One packet transfer size (in words) = packet_header (in words) +payload_size (in words).
   c. Total transfer size = packet1_transfer_size + packet2_transfer_size +…….+packetN_transfer_size
   d. When the TX_FIFO attention level is reached, I2C sets the I2C_INTERRUPT_STATUS_REGISTER_0[TFIFO_DATA_REQ] bit and sends an interrupt to system if the interrupt is enabled with I2C_INTERRUPT_MASK_REGISTER_0[TFIFO_DATA_REQ_INT_EN] = ENABLE setting.
2. Transmit Data Request Interrupt handling:
   a. Read I2C_I2C_INTERRUPT_SOURCE_REGISTER_0 register and check which bit fields are set to 1.
   b. For master transmit data requests, I2C_I2C_INTERRUPT_SOURCE_REGISTER_0[TFIFO_DATA_REQ]is set to 1.

c. Disable the interrupt by writing I2C_INTERRUPT_MASK_REGISTER_0[TFIFO_DATA_REQ_INT_EN] = DISABLE

d. Write the packet words to I2C_I2C_TX_PACKET_FIFO_0. The total words size that would be written for every tfifo_data_req request should be less than or equal to the FIFO trigger level. Otherwise, it will cause the TX_FIFO to overflow.

e. Decrement the total transfer size with the number of words written to the FIFO in the previous step (total_transfer_size = total_transfer_size - #words written to TX_FIFO). Check if the new transfer size is zero. If not zero, enable interrupt for TFIFO_DATA_REQ with I2C_INTERRUPT_MASK_REGISTER_0[TFIFO_DATA_REQ_INT_EN] = ENABLE and wait for the new interrupt.

The above steps continue until all the packets are posted to the I2C_I2C_TX_PACKET_FIFO_0.

Packet parsing: once a packet is available in the TX_FIFO, I2C parses it and starts doing transfers on the I2C bus. The transfers could be successful or unsuccessful. The following sections describe how to identify and handle such transfers.

1. Successful transfers:

   a. Once a packet is transmitted successfully by the I2C Master, I2C_INTERRUPT_STATUS_REGISTER_0[PACKET_XFER_COMPLETE] bit will be set to 1 to reflect the status. And if the packet header is configured to put STOP condition on the bus as the last packet of that transfer, I2C_INTERRUPT_STATUS_REGISTER_0[ALL_PACKETS_XFER_COMPLETE] bit will also be set.

   b. If interrupt enables are set, corresponding bits are set in I2C_I2C_INTERRUPT_SOURCE_REGISTER_0 register and signals an interrupt to the system.

2. Interrupt handling for successful transfers:

   a. Read I2C_I2C_INTERRUPT_SOURCE_REGISTER_0 register and check which bit fields are set to 1.

   b. If a packet is transmitted successfully, I2C_I2C_INTERRUPT_SOURCE_REGISTER_0 [PACKET_XFER_COMPLETE] is set. If the packet was configured to have STOP bit, I2C_I2C_INTERRUPT_SOURCE_REGISTER_0[ALL_PACKETS_XFER_COMPLETE] would also be set.

   c. Clear them by writing-1 to I2C_INTERRUPT_STATUS_REGISTER_0[PACKET_XFER_COMPLETE] and I2C_INTERRUPT_STATUS_REGISTER_0[ALL_PACKETS_XFER_COMPLETE] bits accordingly. This will clear the interrupt.

3. Transfers completion:

   a. Use PACKET_XFER_COMPLETE (if packets have RepeatedStart or ContinueXfer settings) or ALL_PACKETS_XFER_COMPLETE alerts (if packets have only STOP) to track how many packets are successfully transferred to the I2C bus. When all packets are transferred successfully to the bus, it matches the total alerts that I2C signals to the system.

1. Unsuccessful transfers:

   A packet transfer could be unsuccessful due to various reasons. I2C master logs this information in I2C_INTERRUPT_STATUS_REGISTER_0 register. A transfer could be unsuccessful due to I2C bus related ARB_LOST/NACK events or TX_PACKET_FIFO overflow errors.

   a. I2C_INTERRUPT_STATUS_REGISTER_0[ARB_LOST] is set to 1 if I2C master sees the bus is already occupied by some other device when a transfer is initiated or if a slave device pulls the SDA line low continuously for some unknown reason.

   b. I2C_INTERRUPT_STATUS_REGISTER_0[NOACK] is set to 1 if slave device responds with NACK for address or data byte transfer of a transaction.

   c. I2C_INTERRUPT_STATUS_REGISTER_0[TFIFO_OVF] is set to 1 if DMA or CPU writes to I2C_I2C_TX_PACKET_FIFO_0 even it is full.

   d. When any of these error events happens, I2C controller stops further packets transfers and flushes the data from the I2C_I2C_TX_PACKET_FIFO_0.

   e. If interrupt enables are set, corresponding bits are set in I2C_I2C_INTERRUPT_SOURCE_REGISTER_0 register and signals an interrupt to the system.

2. Interrupt handling for unsuccessful transfers:

a. Read I2C_I2C_INTERRUPT_SOURCE_REGISTER_0 register and check which bit fields are set to 1 (ARB_LOST/NOACK/TFIFO_OVF).

b. In all these cases, I2C controller reset is required. Follow the below sequence before going for further transfers

c. Reset the I2C controller.

d. Redo the Controller configuration. And go for the transfers.

Note: *I2C issues the DATA requests to the system based on FIFO trigger levels settings and the I2C_I2C_CNFG_0[PACKET_MODE_EN] setting. PACKET_MODE_EN bit needs to be set to 1 for request generation.*

35.9.2 Programming Model for Master-Transmit DMA Method

1. Initial configuration

   Before accessing I2C controller, set up the following:

   a. I2C Clocks programming

   b. Pinmux programming

   c. I2C controller reset release

2. I2C controller registers initialization:

   a. Write I2C_I2C_TLOW_SEXT_0 = 0x0.

   b. Write I2C_I2C_CMD_ADDR0_0 = 0x0.

   c. Write I2C_I2C_CMD_ADDR1_0 = 0x0.

   d. Write I2C_I2C_CMD_DATA1_0 = 0x0.

   e. Write I2C_I2C_CMD_DATA2_0 = 0x0.

   f. Write I2C_I2C_CLKEN_OVERRIDE_0 = 0x0.

   g. Write I2C_I2C_DEBUG_CONTROL_0 = 0x0.

   h. Write I2C_I2C_INTERRUPT_SET_REGISTER_0 = 0x0.

3. Program I2C_I2C_CLK_DIVISOR_REGISTER_0 register based on the required I2C bus speed. Refer to Section 35.6.1: I2C Frequency Divisor Register for details.

4. Configure I2C interface timing registers:

   Recommendation is to use default or PROD settings. But if needed, these registers can be programmed to achieve the required I2C interface timing.

   a. Write I2C_I2C_INTERFACE_TIMING_0_0 = 0x0204.

   b. Write I2C_I2C_INTERFACE_TIMING_1_0 = 0x04070404.

   c. Write I2C_I2C_HS_INTERFACE_TIMING_0_0 = 0x0308.

   d. Write I2C_I2C_HS_INTERFACE_TIMING_1_0 = 0x0b0b0b0b.

5. Configure FIFO trigger levels for DMA requests:

   The settings below are for example only. Program this bit field to the required trigger levels.

   a. Write I2C_FIFO_CONTROL_0[TX_FIFO_TRIG] = 0x3 (0x3 = DMA gets request from I2C controller when at least 4 words are empty in the I2C_I2C_TX_PACKET_FIFO_0).

6. Enable Interrupts for I2C Master controller in packet mode.

   a. Write I2C_INTERRUPT_MASK_REGISTER_0[ARB_LOST_INT_EN] = ENABLE.

   b. Write I2C_INTERRUPT_MASK_REGISTER_0[NOACK_INT_EN] = ENABLE.

c. Write I2C_INTERRUPT_MASK_REGISTER_0[TFIFO_OVF_INT_EN] = ENABLE.

d. Write I2C_INTERRUPT_MASK_REGISTER_0[ALL_PACKETS_XFER_COMPLETE_INT_EN] = ENABLE for tracking packet transfers completion status.

e. Write I2C_INTERRUPT_MASK_REGISTER_0[PACKET_XFER_COMPLETE_INT_EN] = ENABLE for tracking packet transfers completion status.

7. Post I2C packets (headers and data) to the memory for the write transfers. Refer to Section 35.5.1: Packet Flow for packets structure. Program RESP_PKT_ENABLE = 0 in the packet header.

8. Configure DMA for I2C transfers.

   Note the following when configuring DMA for I2C transfers:

   a. Set DMA source pointer to the memory location where the I2C packets are stored.

   b. Set DMA destination pointer to I2C instance baseaddress + I2C_I2C_TX_PACKET_FIFO offset.

   c. DMA burst size should match I2C_FIFO_CONTROL_0[TX_FIFO_TRIG] level settings.

   d. Configure DMA to Flow control mode.

   e. DMA transfer size should match the total packets size in words. E.g. 3 Write packets. 1st packet=3bytes transfer, 2nd packet=8bytes transfer and 3rd packet=11bytes transfer. Total size = 4+5+6=15 words.

9. Configure I2C Master to packet mode:

   a. Write I2C_I2C_CNFG_0[MULTI_MASTER_MODE] = DISABLE.

   b. Write I2C_I2C_CNFG_0[HS_RND_TRIP_DLY_EFFECT] = DISABLE.

   c. Write I2C_I2C_CNFG_0[MSTR_CLR_BUS_ON_TIMEOUT] = 0.

   d. Write I2C_I2C_CNFG_0[DEBOUNCE_CNT] = 0x2 //Example only, program as required. Refer to Section 35.6.1: I2C Frequency Divisor Register for details.

   e. Write I2C_I2C_CNFG_0[NEW_MASTER_FSM] = ENABLE.

   f. Write I2C_I2C_CNFG_0[PACKET_MODE_EN] = GO.

   g. Write I2C_I2C_CNFG_0[SEND] = NOP.

   h. Write I2C_I2C_CNFG_0[NOACK] = DISABLE.

   i. Write I2C_I2C_CNFG_0[CMD2] = DISABLE.

   j. Write I2C_I2C_CNFG_0[CMD1] = DISABLE.

   k. Write I2C_I2C_CNFG_0[START] = DISABLE.

   l. Write I2C_I2C_CNFG_0[SLV2] = DISABLE.

   m. Write I2C_I2C_CNFG_0[LENGTH] = 0.

   n. Write I2C_I2C_CNFG_0[A_MOD] = 0.

10. Activate the configuration:

    a. I2C_I2C_CONFIG_LOAD_0[TIMEOUT_CONFIG_LOAD] = ENABLE.

    b. I2C_I2C_CONFIG_LOAD_0[SLV_CONFIG_LOAD] = DISABLE.

    c. I2C_I2C_CONFIG_LOAD_0[MSTR_CONFIG_LOAD] = ENABLE.

    d. Wait for I2C_I2C_CONFIG_LOAD_0[TIMEOUT_CONFIG_LOAD] and I2C_I2C_CONFIG_LOAD_0[MSTR_CONFIG_LOAD] bits to get cleared by the hardware.

    With this, it will initiate the write transfers from I2C master to the bus. The transfers could be successful or unsuccessful. The following sections describe how to identify and handle such transfers.

11. Successful transfers:

    a. Once a packet is transmitted successfully by the I2C Master, I2C_INTERRUPT_STATUS_REGISTER_0[PACKET_XFER_COMPLETE] bit will be set to 1 to reflect the status.

If the packet header configured to put STOP condition on the bus as the last packet of that transfer, I2C_INTERRUPT_STATUS_REGISTER_0[ALL_PACKETS_XFER_COMPLETE] bit will also be set.

b. If interrupt enables are set, corresponding bits are set in I2C_I2C_INTERRUPT_SOURCE_REGISTER_0 register and signals an interrupt to the system.

12. Interrupt handling for successful transfers:

    a. Read I2C_I2C_INTERRUPT_SOURCE_REGISTER_0 register and check which bit fields are set to 1.

    b. If a packet is transmitted successfully, I2C_I2C_INTERRUPT_SOURCE_REGISTER_0 [PACKET_XFER_COMPLETE] is set. And if the packet was configured to have STOP bit, I2C_I2C_INTERRUPT_SOURCE_REGISTER_0[ALL_PACKETS_XFER_COMPLETE] would also be set.

    c. Clear them by writing-1 to I2C_INTERRUPT_STATUS_REGISTER_0[PACKET_XFER_COMPLETE] and I2C_INTERRUPT_STATUS_REGISTER_0[ALL_PACKETS_XFER_COMPLETE] bits accordingly. This clears the interrupt.

13. Transfers completion:

    a. Check DMA status to know if all the packets are transferred to I2C controller from memory.

    b. Use PACKET_XFER_COMPLETE (if packets have RepeatedStart or ContinueXfer settings) or ALL_PACKETS_XFER_COMPLETE alerts (if packets have only STOP) to track how many packets are successfully transferred to the I2C bus. When all packets are transferred successfully to the bus, it matches the total number of alerts that I2C signals to the system.

1. Unsuccessful transfers

   A packet transfer could be unsuccessful due to various reasons. I2C master logs this information in I2C_INTERRUPT_STATUS_REGISTER_0 register. The transfer could be unsuccessful due to I2C bus related ARB_LOST/NACK events or TX_PACKET_FIFO Overflow errors.

   a. I2C_INTERRUPT_STATUS_REGISTER_0[ARB_LOST] will be set to 1 if I2C master sees the bus is already occupied by some other device when a transfer is initiated or if a slave device pulls the SDA line low continuously for some unknown reason.

   b. I2C_INTERRUPT_STATUS_REGISTER_0[NOACK] will be set to 1 if slave device responds with NACK for address or data byte transfer of a transaction.

   c. I2C_INTERRUPT_STATUS_REGISTER_0[TFIFO_OVF] will be set to 1 if DMA or CPU writes to I2C_I2C_TX_PACKET_FIFO_0 even it is full.

   d. When any of these error events happens, I2C controller stops further packets transfers and flushes the data from the I2C_I2C_TX_PACKET_FIFO_0.

   e. If interrupt enables are set, corresponding bits are set in I2C_I2C_INTERRUPT_SOURCE_REGISTER_0 register and signals an interrupt to the system.

2. Interrupt handling for unsuccessful transfers:

   a. Read I2C_I2C_INTERRUPT_SOURCE_REGISTER_0 register and check which bit fields are set to 1 (ARB_LOST/NOACK/TFIFO_OVF).

   b. In all these cases, I2C controller reset is required. Follow the sequence below before going for further transfers.

   c. Assert I2C controller reset.

   d. Disable DMA.

   e. Release I2C controller reset.

   f. Redo the I2C configuration, including DMA and go for the transfers.

Notes:

- *I2C issues the requests to DMA based on FIFO trigger levels settings and the I2C_I2C_CNFG_0[PACKET_MODE_EN] setting. PACKET_MODE_EN bit needs to be set to 1 for requests generation.*

- *Packet transfer status is also available in I2C_PACKET_TRANSFER_STATUS_0 register. SW can read this register to know which packet is currently being transferred (TRANSFER_PKT_ID), how many bytes are transferred in the on-going packet (TRANSFER_BYTENUM) or if the previous packet with STOP setting is successfully transferred (TRANSFER_COMPLETE and TRANSFER_PKT_ID) or any ARB_LOST/ NACK event happened (ARB_LOST, NOACK_FOR_ADDR/NOACK_FOR_DATA).*

35.9.3 Programming Model for Master-Receive DMA Method

1. Initial configuration

   Before accessing I2C controller, set up the following:

   a. I2C Clocks programming

   b. Pinmux programming

   c. I2C controller reset release

2. I2C controller registers initialization:

   a. Write I2C_I2C_TLOW_SEXT_0 = 0x0.

   b. Write I2C_I2C_CMD_ADDR0_0 = 0x0.

   c. Write I2C_I2C_CMD_ADDR1_0 = 0x0.

   d. Write I2C_I2C_CMD_DATA1_0 = 0x0.

   e. Write I2C_I2C_CMD_DATA2_0 = 0x0.

   f. Write I2C_I2C_CLKEN_OVERRIDE_0 = 0x0.

   g. Write I2C_I2C_DEBUG_CONTROL_0 = 0x0.

   h. Write I2C_I2C_INTERRUPT_SET_REGISTER_0 = 0x0.

3. Program I2C_I2C_CLK_DIVISOR_REGISTER_0 register based on the required I2C bus speed. Refer to Section 35.6.1: I2C Frequency Divisor Register for details.

4. Configure I2C interface timing registers.

   Recommendation is to use default or PROD settings. But if needed, these registers can be programmed to achieve the required I2C interface timing.

   a. Write I2C_I2C_INTERFACE_TIMING_0_0 = 0x0204.

   b. Write I2C_I2C_INTERFACE_TIMING_1_0 = 0x04070404.

   c. Write I2C_I2C_HS_INTERFACE_TIMING_0_0 = 0x0308.

   d. Write I2C_I2C_HS_INTERFACE_TIMING_1_0 = 0x0b0b0b0b.

5. Configure FIFO trigger levels for DMA requests.

   The settings below are for example only. Program the bit fields to the required trigger levels.

   a. Write I2C_FIFO_CONTROL_0[TX_FIFO_TRIG] = 0x1 (0x1 = DMA gets request from I2C controller when at least 2 words are empty in the I2C_I2C_TX_PACKET_FIFO_0).

   b. Write I2C_FIFO_CONTROL_0[RX_FIFO_TRIG] = 0x3 (0x3 = DMA gets request from I2C controller when at least 4 words are full in the I2C_I2C_RX_FIFO_0).

6. Enable Interrupts for I2C Master controller in packet mode:

   a. Write I2C_INTERRUPT_MASK_REGISTER_0[ARB_LOST_INT_EN] = ENABLE.

   b. Write I2C_INTERRUPT_MASK_REGISTER_0[NOACK_INT_EN] = ENABLE.

   c. Write I2C_INTERRUPT_MASK_REGISTER_0[TFIFO_OVF_INT_EN] = ENABLE.

   d. Write I2C_INTERRUPT_MASK_REGISTER_0[RFIFO_UNF_INT_EN] = ENABLE.

e. Write I2C_INTERRUPT_MASK_REGISTER_0[ALL_PACKETS_XFER_COMPLETE_INT_EN] = ENABLE for tracking packet transfers completion status.

f. Write I2C_INTERRUPT_MASK_REGISTER_0[PACKET_XFER_COMPLETE_INT_EN] = ENABLE for tracking packet transfers completion status.

7. Prepare and save I2C packets in the memory for the read transfers.

   Refer to Section 35.5.1: Packet Flow for packets structure. Program RESP_PKT_ENABLE = 0 in the packet header.

8. Configure DMA for I2C transfers.

   Only I2C programming details are given in this doc. DMA programming model is out of scope for this document. Refer to the DMA programming guidelines document. And note the following when configuring DMA for I2C transfers:

   a. For packets transfer from memory to I2C controller, if DMA CH0 is used.

   - Set DMA CH0 source pointer to the memory location where the I2C packets are stored.
   - Set DMA CH0 destination pointer to I2C instance base-address + I2C_I2C_TX_PACKET_FIFO offset.
   - DMA burst size should match I2C_FIFO_CONTROL_0[TX_FIFO_TRIG] level settings.
   - Configure DMA to Flow control mode.
   - DMA CH0 transfer size should match the total packets size in words. Since it is read packets only, only packet headers would be there. For example, 3 Read packets. Total size = 3+3+3= 9 words.

   b. To transfer the received-data from I2C controller to memory, if DMA CH1 is used.

   - Set DMA CH1 source pointer to I2C instance base-address + I2C_I2C_RX_FIFO_0 offset.
   - Set DMA CH1 destination pointer to the memory location where the I2C data needs to be saved.
   - DMA CH1 burst size should match I2C_FIFO_CONTROL_0[RX_FIFO_TRIG] level settings.
   - Configure DMA to Flow control mode.
   - DMA Transfer size should match the total words that need to be read from I2C_I2C_RX_FIFO_0.

9. Configure I2C Master to packet mode:

   a. Write I2C_I2C_CNFG_0[MULTI_MASTER_MODE] = DISABLE.

   b. Write I2C_I2C_CNFG_0[HS_RND_TRIP_DLY_EFFECT] = DISABLE.

   c. Write I2C_I2C_CNFG_0[MSTR_CLR_BUS_ON_TIMEOUT] = 0.

   d. Write I2C_I2C_CNFG_0[DEBOUNCE_CNT] = 0x2 //Example only, program as required. Refer to Section 35.6.1: I2C Frequency Divisor Register for details.

   e. Write I2C_I2C_CNFG_0[NEW_MASTER_FSM] = ENABLE.

   f. Write I2C_I2C_CNFG_0[PACKET_MODE_EN] = GO.

   g. Write I2C_I2C_CNFG_0[SEND] = NOP.

   h. Write I2C_I2C_CNFG_0[NOACK] = DISABLE.

   i. Write I2C_I2C_CNFG_0[CMD2] = DISABLE.

   j. Write I2C_I2C_CNFG_0[CMD1] = DISABLE.

   k. Write I2C_I2C_CNFG_0[START] = DISABLE.

   l. Write I2C_I2C_CNFG_0[SLV2] = DISABLE.

   m. Write I2C_I2C_CNFG_0[LENGTH] = 0.

   n. Write I2C_I2C_CNFG_0[A_MOD] = 0.

10. Activate the configuration

    a. I2C_I2C_CONFIG_LOAD_0[TIMEOUT_CONFIG_LOAD] = ENABLE.

    b. I2C_I2C_CONFIG_LOAD_0[SLV_CONFIG_LOAD] = DISABLE.

c. I2C_I2C_CONFIG_LOAD_0[MSTR_CONFIG_LOAD] = ENABLE.

d. Wait for I2C_I2C_CONFIG_LOAD_0[TIMEOUT_CONFIG_LOAD] and I2C_I2C_CONFIG_LOAD_0[MSTR_CONFIG_LOAD] bits to get cleared by the hardware.

With this, it initiates the read transfers by the I2C master on the bus. The transfers could be successful or unsuccessful. The following sections describe how to identify and handle such transfers.

11. Successful transfers:

    a. Once a packet transfer is successfully done by the I2C Master, I2C_INTERRUPT_STATUS_REGISTER_0[PACKET_XFER_COMPLETE] bit is set to 1 to reflect the status. If the packet header configured to put STOP condition on the bus as the last packet of that transfer, I2C_INTERRUPT_STATUS_REGISTER_0[ALL_PACKETS_XFER_COMPLETE] bit will also be set.

    b. If interrupt enables are set, corresponding bits are set in I2C_I2C_INTERRUPT_SOURCE_REGISTER_0 register and signals an interrupt to the system.

12. Interrupt handling for successful transfers:

    a. Read I2C_I2C_INTERRUPT_SOURCE_REGISTER_0 register and check which bit fields are set to 1.

    b. If a packet is transmitted successfully, I2C_I2C_INTERRUPT_SOURCE_REGISTER_0 [PACKET_XFER_COMPLETE] is set. And if the packet was configured to have STOP bit, I2C_I2C_INTERRUPT_SOURCE_REGISTER_0[ALL_PACKETS_XFER_COMPLETE] would also be set.

    c. Clear them by writing-1 to I2C_INTERRUPT_STATUS_REGISTER_0[PACKET_XFER_COMPLETE] and I2C_INTERRUPT_STATUS_REGISTER_0[ALL_PACKETS_XFER_COMPLETE] bits accordingly. This clears the interrupt.

13. Transfers completion:

    a. Check DMA status to know if all the packets are transferred to I2C controller from memory.

    b. Use PACKET_XFER_COMPLETE (if packets have RepeatedStart or ContinueXfer settings) or ALL_PACKETS_XFER_COMPLETE (if packets have only STOP) alerts to track how many packets are successfully transferred to the I2C bus. When all packets are transferred successfully to the bus, it matches the total number of alerts that I2C sends to the system.

    c. Check DMA status if it read all the data bytes from I2C controller and saved it to the memory.

1. Unsuccessful transfers:

   A packet transfer could be unsuccessful due to various reasons. I2C master logs this information in I2C_INTERRUPT_STATUS_REGISTER_0 register. The transfer could be unsuccessful due to I2C bus related ARB_LOST/NACK events or TX_PACKET_FIFO overflow errors or I2C_I2C_RX_FIFO_0 underflow errors.

   a. I2C_INTERRUPT_STATUS_REGISTER_0[ARB_LOST] will be set to 1 if I2C master sees the bus is already occupied by some other device when a transfer is initiated or if a slave device pulls the SDA line low continuously for some unknown reason.

   b. I2C_INTERRUPT_STATUS_REGISTER_0[NOACK] will be set to 1 if slave device responds with NACK for address or data byte transfer of a transaction.

   c. I2C_INTERRUPT_STATUS_REGISTER_0[TFIFO_OVF] will be set to 1 if DMA or CPU writes to I2C_I2C_TX_PACKET_FIFO_0 even it is full.

   d. I2C_INTERRUPT_STATUS_REGISTER_0[RFIFO_UNF] will be set to 1 if DMA or CPU reads I2C_I2C_RX_FIFO_0 even it is empty.

   e. When any of these error events happens, I2C controller stops further packets transfers and flushes the data from the FIFOs.

   f. If interrupt enables are set, corresponding bits are set in I2C_I2C_INTERRUPT_SOURCE_REGISTER_0 register and signals an interrupt to the system.

2. Interrupt handling for unsuccessful transfers:

   a. Read I2C_I2C_INTERRUPT_SOURCE_REGISTER_0 register and check which bit fields are set to 1 (ARB_LOST/NOACK/TFIFO_OVF/ RFIFO_UNF).

b. In all these cases, I2C controller reset is required. Follow the sequence below before going for further transfers

c. Assert I2C controller reset.

d. Disable DMA.

e. Release I2C controller reset.

f. Redo the I2C configuration, including DMA. And go for the transfers.

35.10 Programming Guidelines for Slave in Byte Mode

35.10.1 Programming Model for Slave-Receive in 7-bit addressing Mode (transfer direction not changed)—Interrupt Method

1. Initial configuration

   Before accessing I2C controller, set up the following:

   a. I2C Clocks programming

   b. Pinmux programming

   c. I2C controller reset release

2. I2C controller registers initialization

   a. Write I2C_FIFO_CONTROL = 0x0.

   b. Write I2C_I2C_INTERRUPT_SET_REGISTER = 0x0.

   c. Write I2C_I2C_CLKEN_OVERRIDE = 0x0.

   d. Write I2C_I2C_DEBUG_CONTROL = 0x0.

   e. Write I2C_I2C_TLOW_SEXT_0 = 0x0.

   f. Write I2C_I2C_SL_INT_SET_0 = 0x0.

   g. Write I2C_I2C_SL_DELAY_COUNT_0 = 0x1e.

3. Select Slave Address Register and configure it in 7-bit addressing mode:

   a. Write I2C_I2C_SL_ADDR1_0[SL_ADDR1] = 0.

   b. Write 7-bit slave address in I2C_I2C_SL_ADDR1_0[SL_ADDR0] = {1'b0,SlaveAddress[6:0]}.

   c. To use SL_ADDR0 bit field for Slave address, write I2C_I2C_SL_ADDR2_0[SELECT_SLAVE] = 0.

   d. Write I2C_I2C_SL_ADDR2_0[SL1_ADDR_HI] = 0.

   e. Write I2C_I2C_SL_ADDR2_0[SL1_VLD] = SEVEN_BIT_ADDR_MODE.

   f. Write I2C_I2C_SL_ADDR2_0[SL_ADDR_HI] = 0.

   g. Write I2C_I2C_SL_ADDR2_0[VLD] = SEVEN_BIT_ADDR_MODE.

4. Configure Interrupt Mask registers to enable the interrupts

   a. Write I2C_INTERRUPT_MASK_REGISTER_0 = 0x0.

   b. Write I2C_I2C_SL_INT_MASK_0[HW_MSTR_INT] = DISABLE.

   c. Write I2C_I2C_SL_INT_MASK_0[REPROG_SL] = DISABLE.

   d. Write I2C_I2C_SL_INT_MASK_0[RST_SL] = DISABLE.

   e. Write I2C_I2C_SL_INT_MASK_0[END_TRANS] = ENABLE.

   f. Write I2C_I2C_SL_INT_MASK_0[SL_IRQ] = ENABLE.

   g. Write I2C_I2C_SL_INT_MASK_0[RCVD] = ENABLE.

   h. Write I2C_I2C_SL_INT_MASK_0[ZA] = DISABLE.

5. Configure SL_CNFG register to enable the Slave Controller:
   a. Write I2C_I2C_SL_CNFG_0[ENABLE_SL] = 1.
   b. Write I2C_I2C_SL_CNFG_0[PKT_MODE_EN] = 0.
   c. Write I2C_I2C_SL_CNFG_0[NEWSL] = 1.
   d. Write I2C_I2C_SL_CNFG_0[FIFO_XFER_EN] = 0.
   e. Write I2C_I2C_SL_CNFG_0[SLV_XFER_ERR_CLK_STRETCH_EN] = 0.
   f. Write I2C_I2C_SL_CNFG_0[BUFFER_SIZE] = 0.
   g. Write I2C_I2C_SL_CNFG_0[ACK_LAST_BYTE_VALID] = 0.
   h. Write I2C_I2C_SL_CNFG_0[RESP] = 0.
   i. Write I2C_I2C_SL_CNFG_0[ACK_WITHHOLD_EN] = 0.
   j. Write I2C_I2C_SL_CNFG_0[ACK_LAST_BYTE] = 0.
   k. Write I2C_I2C_SL_CNFG_0[NACK] = DISABLE.
6. Activate the configuration with I2C_CONFIG_LOAD register programming:
   a. I2C_I2C_CONFIG_LOAD_0[TIMEOUT_CONFIG_LOAD] = ENABLE.
   b. I2C_I2C_CONFIG_LOAD_0[SLV_CONFIG_LOAD] = ENABLE.
   c. I2C_I2C_CONFIG_LOAD_0[MSTR_CONFIG_LOAD] = DISABLE
7. Wait for the hardware to clear the I2C_CONFIG_LOAD register bit fields:
   a. Wait until I2C_I2C_CONFIG_LOAD_0[TIMEOUT_CONFIG_LOAD] becomes zero.
   b. Wait until I2C_I2C_CONFIG_LOAD_0[SLV_CONFIG_LOAD] becomes zero.

   With this, Slave controller would be ready for the data transfers. Start a Write transaction from the I2C Master device.
8. Slave Response to Address Phase of the Write Transaction

   When Slave receives address byte from the bus and if the address matches its programmed address, it does the following:
   a. Sets I2C_I2C_SL_STATUS_0[RNW] bit field with received address byte[0] bit which indicates transfer direction. 0 = WRITE, 1=READ.
   b. Saves the received address byte in I2C_I2C_SL_RCVD_0 register.
   c. Sets I2C_I2C_SL_STATUS_0[RCVD] and I2C_I2C_SL_STATUS_0[SL_IRQ] bits indicating that a new transaction is received.
   d. Generates an interrupt to the system if interrupt enables bits (I2C_I2C_SL_INT_MASK_0[RCVD], I2C_I2C_SL_INT_MASK_0[SL_IRQ]) are set.
   e. And holds the I2C bus by doing clock stretching (holds I2C SCL line low) until the interrupt is cleared.
9. New transaction Interrupt handling:
   a. Read I2C_I2C_SL_INT_SOURCE_0 register and check which bit fields are set to 1.
   b. Each bit field signifies an event occurrence.
   c. If a bit field is set to 1, it means, the current interrupt is because of the relevant event to this bit.
   d. In the new transaction received case, I2C_I2C_SL_INT_SOURCE_0[RCVD] and I2C_I2C_SL_INT_SOURCE_0[SL_IRQ] bits are set to 1.
   e. Check I2C_I2C_SL_STATUS_0[RNW] bit status. For write transactions, I2C_I2C_SL_STATUS_0[RNW] = WRITE is set.
   f. Clear I2C_I2C_SL_STATUS_0[RCVD] and I2C_I2C_SL_STATUS_0[SL_IRQ] bits by writing-1 to them.
   g. This clears the interrupt and releases the SCL line allowing the Master to go to next phase of the transaction.

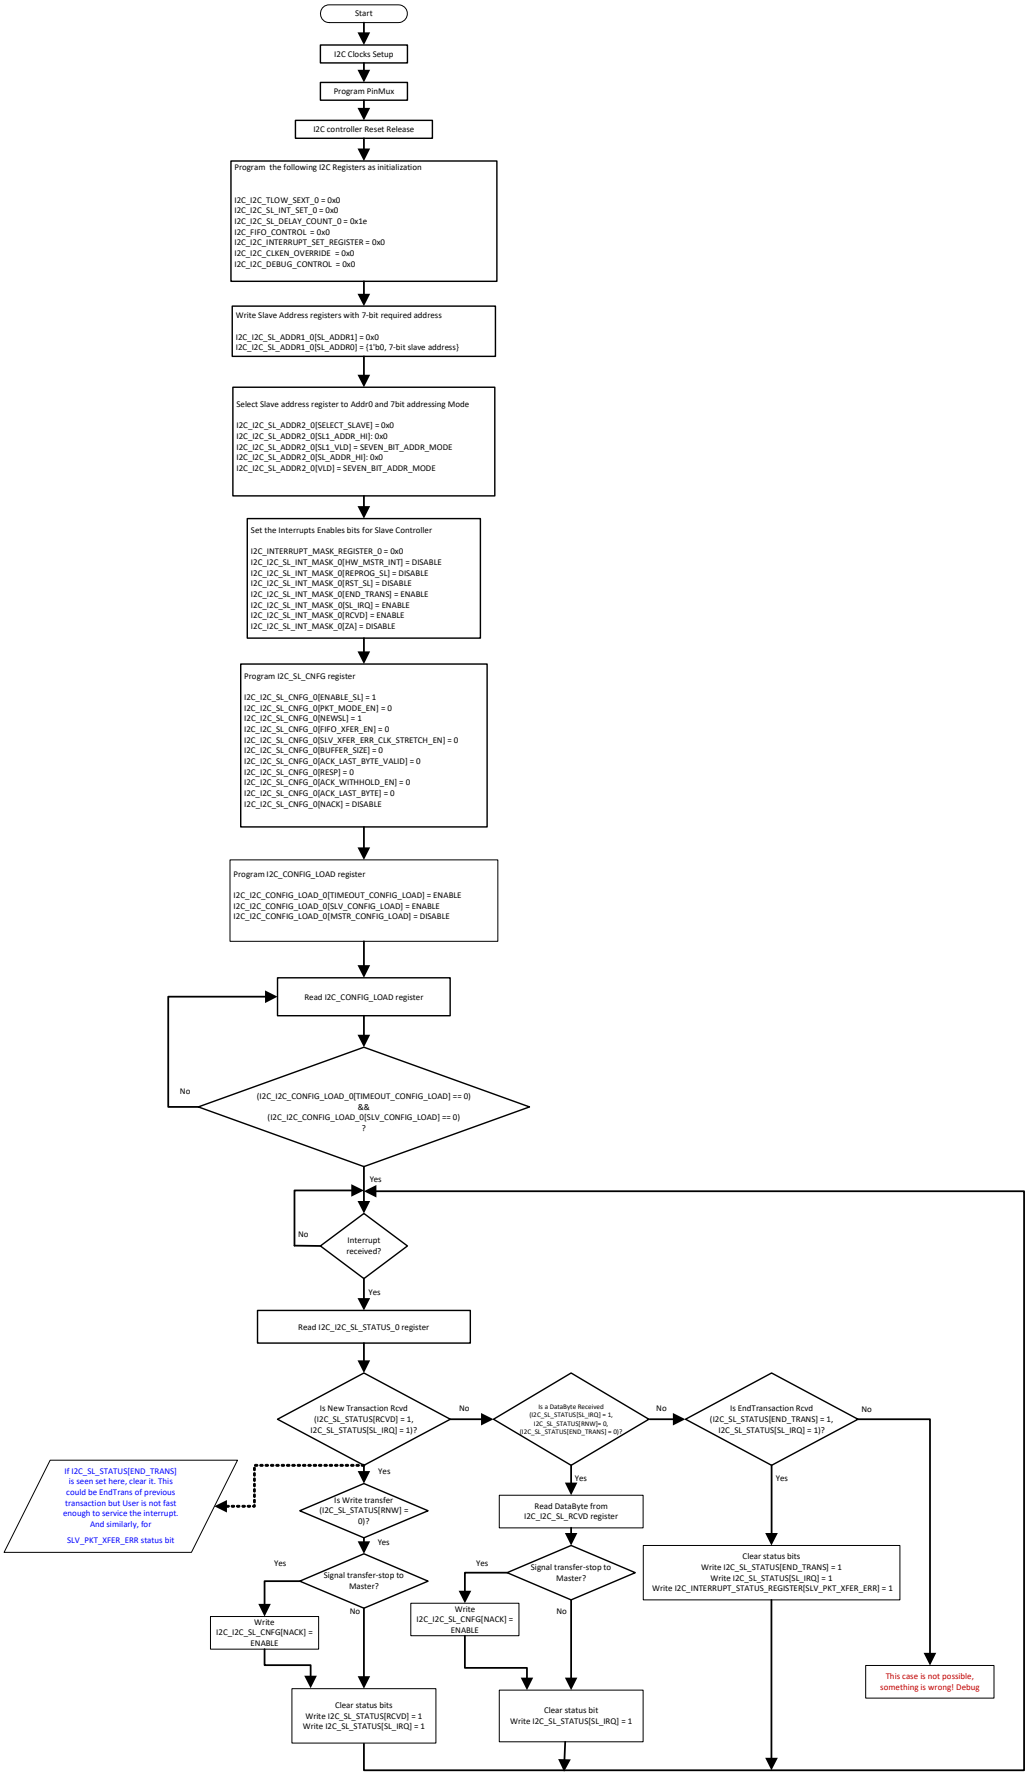
10. Slave Response to Data Phase of the Write Transaction
11. When a Master sends a data byte, the Slave controller does the following.
    a. Saves the received byte in I2C_I2C_SL_RCVD_0 register.
    b. Sets I2C_I2C_SL_STATUS_0[SL_IRQ] bit indicating a byte received.
    c. Generates an interrupt to the system if interrupt enable bit I2C_I2C_SL_INT_MASK_0[SL_IRQ] is set.
    d. Slave holds the I2C bus by doing clock stretching (holds I2C SCL line low) until the interrupt is cleared.
12. Interrupts handling when received a data byte:
    a. Read I2C_I2C_SL_INT_SOURCE_0 register and check which bit fields are set to 1.
    b. In the data_byte received case, I2C_I2C_SL_INT_SOURCE_0[SL_IRQ] bit is set to 1
    c. Read the data byte from I2C_I2C_SL_RCVD_0 register
    d. To continue with the transfer, keep I2C_I2C_SL_CNFG_0[NACK] = DISABLE setting. Otherwise, to signal the Master to stop the transfer, configure I2C_I2C_SL_CNFG_0[NACK] = ENABLE
    e. Clear I2C_I2C_SL_STATUS_0[SL_IRQ] by writing-1 to it. This clears the interrupt and releases the SCL line allowing the Master to go ahead with next phase of the transaction
13. Slave Response to STOP condition of the Write transaction

    If Master sends STOP condition next, Slave does the following
    a. Sets I2C_I2C_SL_STATUS_0[END_TRANS] and I2C_I2C_SL_STATUS_0[SL_IRQ] bits indicating STOP condition is received
    b. Generates an interrupt to the system if Interrupt bits (I2C_I2C_SL_INT_MASK_0[END_TRANS], I2C_I2C_SL_INT_MASK_0[SL_IRQ]) are enabled.
14. Interrupts handling when Stop condition is received:
    a. Read I2C_I2C_SL_INT_SOURCE_0 register and check which bit fields are set to 1.
    b. In the STOP condition case, I2C_I2C_SL_INT_SOURCE_0[END_TRANS] and I2C_I2C_SL_INT_SOURCE_0[SL_IRQ] bits are set to 1
    c. Clear I2C_I2C_SL_STATUS_0[END_TRANS] and I2C_I2C_SL_STATUS_0[SL_IRQ] bits by writing-1 to them. This clears the interrupt.

Notes:

- *If Master terminates the transaction while the Slave controller is ready to accept the data, I2C_INTERRUPT_STATUS_REGISTER_0[SLV_PKT_XFER_ERR] bit is set at the end of the transaction when STOP condition is received. This bit can be cleared by writing-1 to it or it can be ignored.*
- *If the Slave controller sends NACK to any of the bytes during the write transfer, Master terminates the transaction after seeing NACK bit. In this case, No status bits (END_TRANS, SL_IRQ or SLV_PKT_XFER_ERR) is set when STOP condition is received. No interrupts either.*

Figure 162: Flowchart for Slave-Receive (transfer direction not changed) Programming Model



35.10.2 Programming Model for Slave-Transmit in 7-bit addressing Mode (transfer direction not changed)—Interrupt Method

1. Initial configuration

   Before accessing I2C controller, set up the following:

   a. I2C Clocks programming

   b. Pinmux programming

   c. I2C controller reset release

2. I2C controller registers initialization:

   a. Write I2C_FIFO_CONTROL = 0x0.

   b. Write I2C_I2C_INTERRUPT_SET_REGISTER = 0x0.

   c. Write I2C_I2C_CLKEN_OVERRIDE = 0x0.

   d. Write I2C_I2C_DEBUG_CONTROL = 0x0.

   e. Write I2C_I2C_TLOW_SEXT_0 = 0x0.

   f. Write I2C_I2C_SL_INT_SET_0 = 0x0.

   g. Write I2C_I2C_SL_DELAY_COUNT_0 = 0x1e.

3. Select Slave Address Register and configure it in 7-bit addressing mode:

   a. Write I2C_I2C_SL_ADDR1_0[SL_ADDR1] = 0.

   b. Write 7-bit slave address in I2C_I2C_SL_ADDR1_0[SL_ADDR0] = {1'b0, SlaveAddress[6:0]}.

   c. To use SL_ADDR0 bit field for Slave address, write I2C_I2C_SL_ADDR2_0[SELECT_SLAVE] = 0.

   d. Write I2C_I2C_SL_ADDR2_0[SL1_ADDR_HI] = 0.

   e. Write I2C_I2C_SL_ADDR2_0[SL1_VLD] = SEVEN_BIT_ADDR_MODE.

   f. Write I2C_I2C_SL_ADDR2_0[SL_ADDR_HI] = 0.

   g. Write I2C_I2C_SL_ADDR2_0[VLD] = SEVEN_BIT_ADDR_MODE.

4. Configure Interrupt Mask registers to enable the interrupts:

   a. Write I2C_INTERRUPT_MASK_REGISTER_0 = 0x0.

   b. Write I2C_I2C_SL_INT_MASK_0[HW_MSTR_INT] = DISABLE.

   c. Write I2C_I2C_SL_INT_MASK_0[REPROG_SL] = DISABLE.

   d. Write I2C_I2C_SL_INT_MASK_0[RST_SL] = DISABLE.

   e. Write I2C_I2C_SL_INT_MASK_0[END_TRANS] = ENABLE.

   f. Write I2C_I2C_SL_INT_MASK_0[SL_IRQ] = ENABLE.

   g. Write I2C_I2C_SL_INT_MASK_0[RCVD] = ENABLE.

   h. Write I2C_I2C_SL_INT_MASK_0[ZA] = DISABLE.

5. Configure SL_CNFG register to enable the Slave Controller:

   a. Write I2C_I2C_SL_CNFG_0[ENABLE_SL] = 1.

   b. Write I2C_I2C_SL_CNFG_0[PKT_MODE_EN] = 0.

   c. Write I2C_I2C_SL_CNFG_0[NEWSL] = 1.

   d. Write I2C_I2C_SL_CNFG_0[FIFO_XFER_EN] = 0.

   e. Write I2C_I2C_SL_CNFG_0[SLV_XFER_ERR_CLK_STRETCH_EN] = 0.

   f. Write I2C_I2C_SL_CNFG_0[BUFFER_SIZE] = 0.

g. Write I2C_I2C_SL_CNFG_0[ACK_LAST_BYTE_VALID] = 0.

h. Write I2C_I2C_SL_CNFG_0[RESP] = 0.

i. Write I2C_I2C_SL_CNFG_0[ACK_WITHHOLD_EN] = 0.

j. Write I2C_I2C_SL_CNFG_0[ACK_LAST_BYTE] = 0.

k. Write I2C_I2C_SL_CNFG_0[NACK] = DISABLE.

6. Activate the configuration with I2C_CONFIG_LOAD register programming:

   a. I2C_I2C_CONFIG_LOAD_0[TIMEOUT_CONFIG_LOAD] = ENABLE.

   b. I2C_I2C_CONFIG_LOAD_0[SLV_CONFIG_LOAD] = ENABLE.

   c. I2C_I2C_CONFIG_LOAD_0[MSTR_CONFIG_LOAD] = DISABLE.

7. Wait for the hardware to clear the I2C_CONFIG_LOAD register bit fields:

   a. Wait until I2C_I2C_CONFIG_LOAD_0[TIMEOUT_CONFIG_LOAD] becomes zero.

   b. Wait until I2C_I2C_CONFIG_LOAD_0[SLV_CONFIG_LOAD] becomes zero.

   With this, Slave controller would be ready for the data transfers. Start a Read transaction from the I2C Master device.

8. Slave Response to Address phase of Read transaction

   When Slave receives address byte from the bus and if the address matches its programmed address, it does the following.

   a. Sets I2C_I2C_SL_STATUS_0[RNW] bit field with received address byte[0] bit which indicates transfer direction. 0 = WRITE, 1=READ.

   b. Saves the received address byte in I2C_I2C_SL_RCVD_0 register.

   c. Sets I2C_I2C_SL_STATUS_0[RCVD] and I2C_I2C_SL_STATUS_0[SL_IRQ] bits indicating that a new transaction is received.

   d. Generates an interrupt to the system if Interrupt enables bits (I2C_I2C_SL_INT_MASK_0[RCVD], I2C_I2C_SL_INT_MASK_0[SL_IRQ]) are set.

   e. And holds the I2C bus by doing clock stretching (holds I2C SCL line low) until the interrupt is cleared and a data byte is available in I2C_I2C_SL_RCVD_0 register.

9. New transaction Interrupt handling:

   a. Read I2C_I2C_SL_INT_SOURCE_0 register and check which bit fields are set to 1.

   b. In the new transaction received case, I2C_I2C_SL_INT_SOURCE_0[RCVD] and I2C_I2C_SL_INT_SOURCE_0[SL_IRQ] bits are set to 1.

   c. Check I2C_I2C_SL_STATUS_0[RNW] bit status. For read transactions, I2C_I2C_SL_STATUS_0[RNW] = READ is set.

   d. Clear I2C_I2C_SL_STATUS_0[RCVD] and I2C_I2C_SL_STATUS_0[SL_IRQ] bits by writing-1 to them. This clears the interrupt.

   e. Write Data byte to I2C_I2C_SL_RCVD_0 register. This releases the SCL line. The Master can read this byte now.

10. Slave Response to Data phase of Read transaction.

    If Master ACKs previous byte transfer, it means, Master wants to continue the read operation further. The Slave controller does the following in this case

    a. Sets I2C_I2C_SL_STATUS_0[SL_IRQ] bit indicating a request to transmit a data byte.

    b. Generates an interrupt to the system if interrupt enable bit I2C_I2C_SL_INT_MASK_0[SL_IRQ] is set.

    c. Slave holds the I2C bus by doing clock stretching (holds I2C SCL line low) until a data byte is available in I2C_I2C_SL_RCVD_0 register to transmit to the bus.

11. Interrupts handling in data byte transmit case:

    a. Read I2C_I2C_SL_INT_SOURCE_0 register and check which bit fields are set to 1.

b. In the data transmit case, only I2C_I2C_SL_INT_SOURCE_0[SL_IRQ] bit is set to 1.

c. Clear I2C_I2C_SL_STATUS_0[SL_IRQ] bit by writing-1 to it. This clears the interrupt.

d. Write a Data byte to I2C_I2C_SL_RCVD_0 register. This will release the SCL line and allow the Master to continue the transfer.

12. Slave Response to End of the Read transaction

    If Master NACKs the previous byte transfer, it means, the Master wants to end the transaction. The Slave controller does the following then:

    a. Sets I2C_I2C_SL_STATUS_0[END_TRANS] and I2C_I2C_SL_STATUS_0[SL_IRQ] bits indicating the end of current transaction.

    b. Generates an interrupt to the system if interrupt bits (I2C_I2C_SL_INT_MASK_0[END_TRANS], I2C_I2C_SL_INT_MASK_0[SL_IRQ]) are enabled.

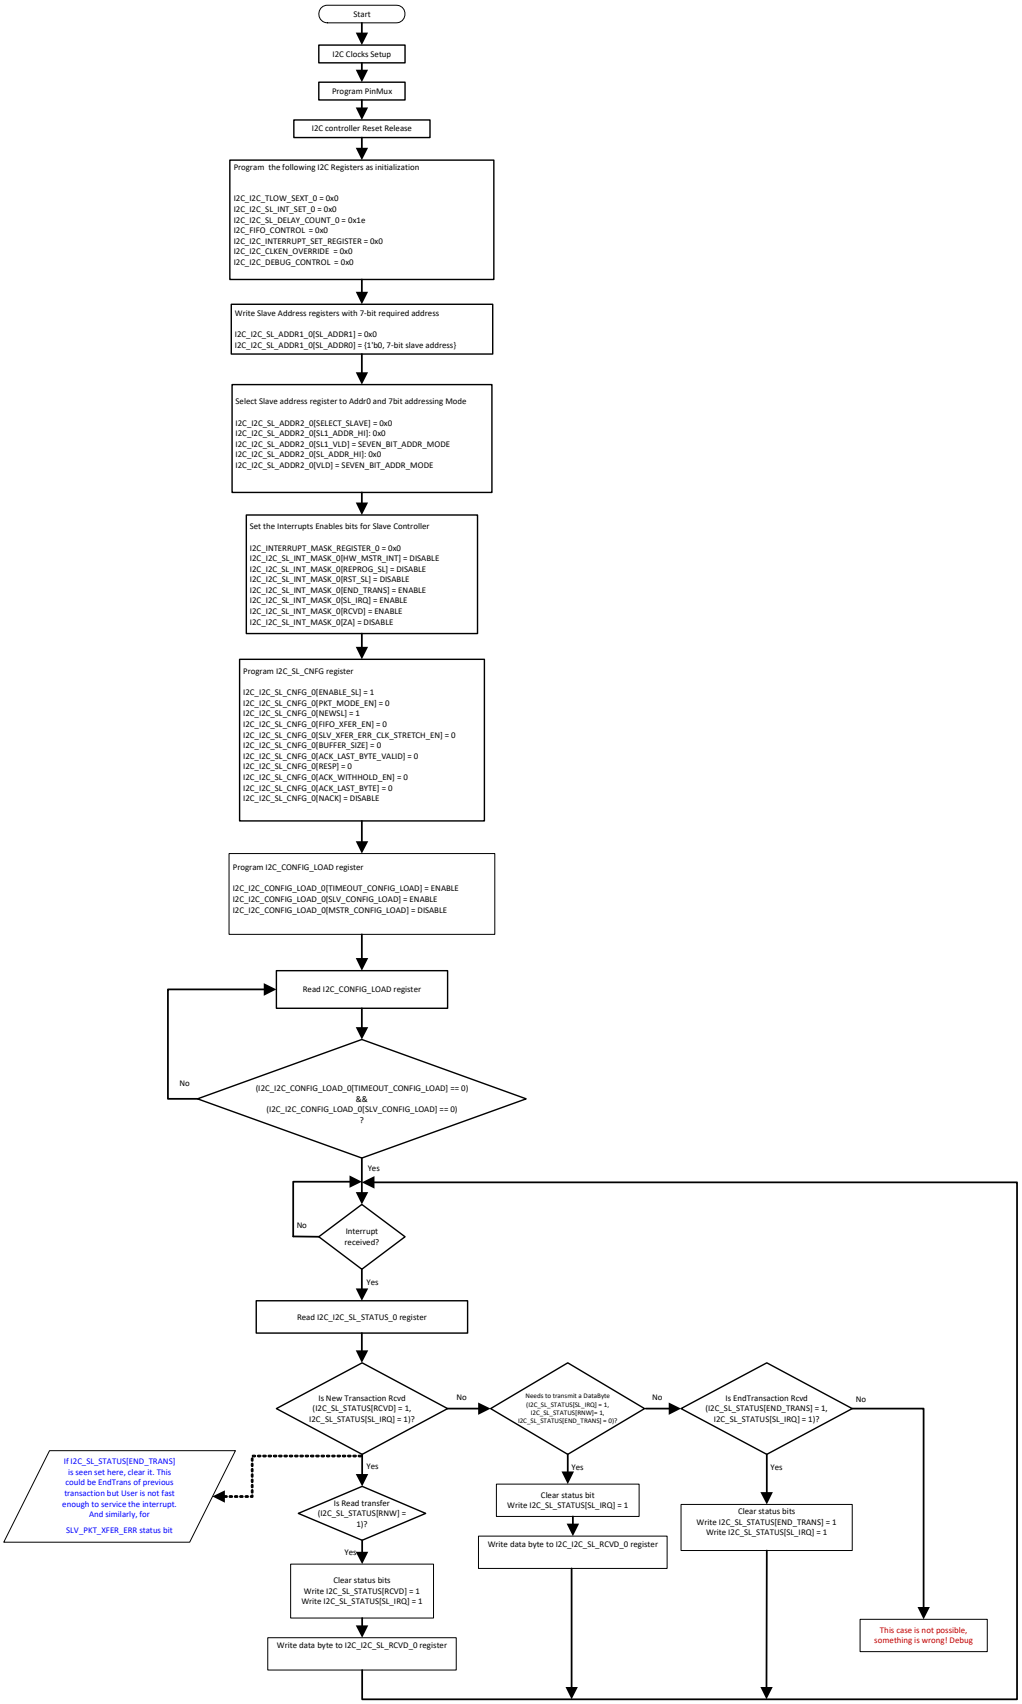
13. Interrupts handling when transaction END is received during read:

    a. Read I2C_I2C_SL_INT_SOURCE_0 register and check which bit fields are set to 1.

    b. In the transaction END case, I2C_I2C_SL_INT_SOURCE_0[END_TRANS] and I2C_I2C_SL_INT_SOURCE_0[SL_IRQ] bits are set to 1.

    c. Clear I2C_I2C_SL_STATUS_0[END_TRANS] and I2C_I2C_SL_STATUS_0[SL_IRQ] bits by writing-1 to them. This clears the interrupt.

Figure 163: Flowchart for Slave-Transmit (transfer direction not changed) Programming Model



35.10.3 Programming Model for Slave-Receive-Transmit (transfer direction changed from Receive-to-Transmit with RepeatedStart) in 7-bit addressing Mode□Interrupt Method

1. Initial configuration

   Before accessing the I2C controller, set up the following.

   a. I2C Clocks programming

   b. Pinmux programming

   c. I2C controller reset release

2. I2C controller registers initialization:

   a. Write I2C_FIFO_CONTROL = 0x0.

   b. Write I2C_I2C_INTERRUPT_SET_REGISTER = 0x0.

   c. Write I2C_I2C_CLKEN_OVERRIDE = 0x0.

   d. Write I2C_I2C_DEBUG_CONTROL = 0x0.

   e. Write I2C_I2C_TLOW_SEXT_0 = 0x0.

   f. Write I2C_I2C_SL_INT_SET_0 = 0x0.

   g. Write I2C_I2C_SL_DELAY_COUNT_0 = 0x1e.

3. Select Slave Address Register and configure it in 7-bit addressing mode:

   a. Write I2C_I2C_SL_ADDR1_0[SL_ADDR1] = 0.

   b. Write 7-bit slave address in I2C_I2C_SL_ADDR1_0[SL_ADDR0] = {1'b0, SlaveAddress[6:0]}.

   c. To use SL_ADDR0 bit field for Slave address, write I2C_I2C_SL_ADDR2_0[SELECT_SLAVE] = 0.

   d. Write I2C_I2C_SL_ADDR2_0[SL1_ADDR_HI] = 0.

   e. Write I2C_I2C_SL_ADDR2_0[SL1_VLD] = SEVEN_BIT_ADDR_MODE.

   f. Write I2C_I2C_SL_ADDR2_0[SL_ADDR_HI] = 0.

   g. Write I2C_I2C_SL_ADDR2_0[VLD] = SEVEN_BIT_ADDR_MODE.

4. Configure Interrupt Mask registers to enable the interrupts:

   a. Write I2C_INTERRUPT_MASK_REGISTER_0[SLV_WR2RD_INT_EN] = ENABLE

   b. Write I2C_I2C_SL_INT_MASK_0[HW_MSTR_INT] = DISABLE.

   c. Write I2C_I2C_SL_INT_MASK_0[REPROG_SL] = DISABLE.

   d. Write I2C_I2C_SL_INT_MASK_0[RST_SL] = DISABLE.

   e. Write I2C_I2C_SL_INT_MASK_0[END_TRANS] = ENABLE.

   f. Write I2C_I2C_SL_INT_MASK_0[SL_IRQ] = ENABLE.

   g. Write I2C_I2C_SL_INT_MASK_0[RCVD] = ENABLE.

   h. Write I2C_I2C_SL_INT_MASK_0[ZA] = DISABLE.

5. Configure SL_CNFG register to enable the Slave Controller:

   a. Write I2C_I2C_SL_CNFG_0[ENABLE_SL] = 1.

   b. Write I2C_I2C_SL_CNFG_0[PKT_MODE_EN] = 0.

   c. Write I2C_I2C_SL_CNFG_0[NEWSL] = 1.

   d. Write I2C_I2C_SL_CNFG_0[FIFO_XFER_EN] = 0.

   e. Write I2C_I2C_SL_CNFG_0[SLV_XFER_ERR_CLK_STRETCH_EN] = 0.

   f. Write I2C_I2C_SL_CNFG_0[BUFFER_SIZE] = 0.

g. Write I2C_I2C_SL_CNFG_0[ACK_LAST_BYTE_VALID] = 0.

h. Write I2C_I2C_SL_CNFG_0[RESP] = 0.

i. Write I2C_I2C_SL_CNFG_0[ACK_WITHHOLD_EN] = 0.

j. Write I2C_I2C_SL_CNFG_0[ACK_LAST_BYTE] = 0.

k. Write I2C_I2C_SL_CNFG_0[NACK] = DISABLE.

6. Activate the configuration with I2C_CONFIG_LOAD register programming:

   a. I2C_I2C_CONFIG_LOAD_0[TIMEOUT_CONFIG_LOAD] = ENABLE

   b. I2C_I2C_CONFIG_LOAD_0[SLV_CONFIG_LOAD] = ENABLE

   c. I2C_I2C_CONFIG_LOAD_0[MSTR_CONFIG_LOAD] = DISABLE

7. Wait for the hardware to clear the I2C_CONFIG_LOAD register bit fields:

   a. Wait until I2C_I2C_CONFIG_LOAD_0[TIMEOUT_CONFIG_LOAD] becomes zero.

   b. Wait until I2C_I2C_CONFIG_LOAD_0[SLV_CONFIG_LOAD] becomes zero.

   With this, Slave controller would be ready for the data transfers. Start a transaction from the I2C Master device.

8. Slave Response to Address phase of Write transaction:

   When Slave receives address byte from the bus and if the address matches its programmed address, it does the following:

   a. Sets I2C_I2C_SL_STATUS_0[RNW] bit field with received address byte[0] bit which indicates transfer direction. 0 = WRITE, 1=READ.

   b. Saves the received address byte in I2C_I2C_SL_RCVD_0 register.

   c. Sets I2C_I2C_SL_STATUS_0[RCVD] and I2C_I2C_SL_STATUS_0[SL_IRQ] bits indicating that a new transaction is received.

   d. Generates an interrupt to the system if interrupt enables bits (I2C_I2C_SL_INT_MASK_0[RCVD], I2C_I2C_SL_INT_MASK_0[SL_IRQ]) are set.

   e. And holds the I2C bus by doing clock stretching (holds I2C SCL line low) until the interrupt is cleared.

9. New transaction Interrupt handling:

   a. Read I2C_I2C_SL_INT_SOURCE_0 register and check which bit fields are set to 1.

   b. Each bit field signifies an event occurrence.

   c. If a bit field is set to 1, it means, the current interrupt is because of the relevant event to this bit.

   d. In the new transaction received case, I2C_I2C_SL_INT_SOURCE_0[RCVD] and I2C_I2C_SL_INT_SOURCE_0[SL_IRQ] bits are set to 1.

   e. Check I2C_I2C_SL_STATUS_0[RNW] bit status. For write transactions, I2C_I2C_SL_STATUS_0[RNW] = WRITE is set.

   f. Clear I2C_I2C_SL_STATUS_0[RCVD] and I2C_I2C_SL_STATUS_0[SL_IRQ] bits by writing-1 to them.

   g. This clears the interrupt and releases the SCL line allowing the Master to go to next phase of the transaction.

10. Slave Response to Data phase of the Write transaction

    When a Master sends a data byte, the Slave controller does the following:

    a. Saves the received byte in I2C_I2C_SL_RCVD_0 register.

    b. Sets I2C_I2C_SL_STATUS_0[SL_IRQ] bit indicating a byte received.

    c. Generates an interrupt to the system if interrupt enable bit I2C_I2C_SL_INT_MASK_0[SL_IRQ] is set.

    d. Slave holds the I2C bus by doing clock stretching (holds I2C SCL line low) until the interrupt is cleared.

11. Interrupts handling when received a data byte:

a. Read I2C_I2C_SL_INT_SOURCE_0 register and check which bit fields are set to 1.

b. In the data_byte received case, I2C_I2C_SL_INT_SOURCE_0[SL_IRQ] bit is set to 1.

c. Read the data byte from I2C_I2C_SL_RCVD_0 register.

d. To continue with the transfer, keep I2C_I2C_SL_CNFG_0[NACK] = DISABLE setting. Otherwise, to signal the Master to stop the transfer, configure I2C_I2C_SL_CNFG_0[NACK] = ENABLE.

e. Clear I2C_I2C_SL_STATUS_0[SL_IRQ] by writing-1 to it. This clears the interrupt and releases the SCL line allowing the Master to go ahead with next phase of the transaction.

12. Slave Response to Write-to-Read Transfer Direction change with RepeatedStart condition

When a Master sends RepeatedStart condition and changes the transfer direction from write to read, the Slave controller does the following:

a. Sets I2C_I2C_SL_STATUS_0[RNW] bit field with received address byte[0] bit which indicates the new transfer direction. 0 = WRITE, 1=READ.

b. Saves the received address byte in I2C_I2C_SL_RCVD_0 register.

c. Sets I2C_I2C_SL_STATUS_0[RCVD] and I2C_I2C_SL_STATUS_0[SL_IRQ] bits indicating that a new transaction is received.

d. Generates an interrupt to the system if interrupt enables bits (I2C_I2C_SL_INT_MASK_0[RCVD], I2C_I2C_SL_INT_MASK_0[SL_IRQ]) are set.

e. And holds the I2C bus by doing clock stretching (holds I2C SCL line low) until the interrupt is cleared and a data byte is available in I2C_I2C_SL_RCVD_0 register to transmit to the Master.

13. New transaction Interrupt handling:

a. Read I2C_I2C_SL_INT_SOURCE_0 register and check which bit fields are set to 1.

b. In the new transaction received case, I2C_I2C_SL_INT_SOURCE_0[RCVD] and I2C_I2C_SL_INT_SOURCE_0[SL_IRQ] bits are set to 1.

c. Check I2C_I2C_SL_STATUS_0[RNW] bit status. For read transactions, it would be I2C_I2C_SL_STATUS_0[RNW] = READ.

d. Clear I2C_I2C_SL_STATUS_0[RCVD] and I2C_I2C_SL_STATUS_0[SL_IRQ] bits by writing-1 to them. This clears the interrupt.

e. This will set I2C_INTERRUPT_STATUS_REGISTER_0[SLV_WR2RD] bit to 1 now. And interrupt will be generated. Clear the interrupt by writing-1 to I2C_INTERRUPT_STATUS_REGISTER_0[SLV_WR2RD] bit field

f. I2C_INTERRUPT_STATUS_REGISTER_0[SLV_TX_BUFFER_REQ] bit will be set now. This can be ignored.

g. Write Data byte to I2C_I2C_SL_RCVD_0 register. This will release the SCL line. The Master can read the byte now.

14. Slave Response to Data phase of Read transaction

If Master ACKs previous byte of the read transfer, it means, Master wants to continue the read operation further. The Slave controller does the following in this case:

a. Sets I2C_I2C_SL_STATUS_0[SL_IRQ] bit indicating a request to transmit a data byte.

b. Generates an interrupt to the system if interrupt enable bit I2C_I2C_SL_INT_MASK_0[SL_IRQ] is set.

c. Slave holds the I2C bus by doing clock stretching (holds I2C SCL line low) until a data byte is available in I2C_I2C_SL_RCVD_0 register to transmit to the bus.

15. Interrupts handling in data byte transmit case:

a. Read I2C_I2C_SL_INT_SOURCE_0 register and check which bit fields are set to 1.

b. In the data transmit case, only I2C_I2C_SL_INT_SOURCE_0[SL_IRQ] bit is set to 1.

c. Clear I2C_I2C_SL_STATUS_0[SL_IRQ] bit by writing-1 to it. This clears the interrupt.

d. Write a Data byte to I2C_I2C_SL_RCVD_0 register. This will release the SCL line and allow the Master to continue the transfer

16. Slave Response to End of the Read transaction

    If Master NACKs the previous byte transfer, it means, the Master wants to end the transaction. The Slave controller does the following then:

    a. Sets I2C_I2C_SL_STATUS_0[END_TRANS] and I2C_I2C_SL_STATUS_0[SL_IRQ] bits indicating the end of current transaction.

    b. Generates an interrupt to the system if interrupt bits (I2C_I2C_SL_INT_MASK_0[END_TRANS], I2C_I2C_SL_INT_MASK_0[SL_IRQ]) are enabled.

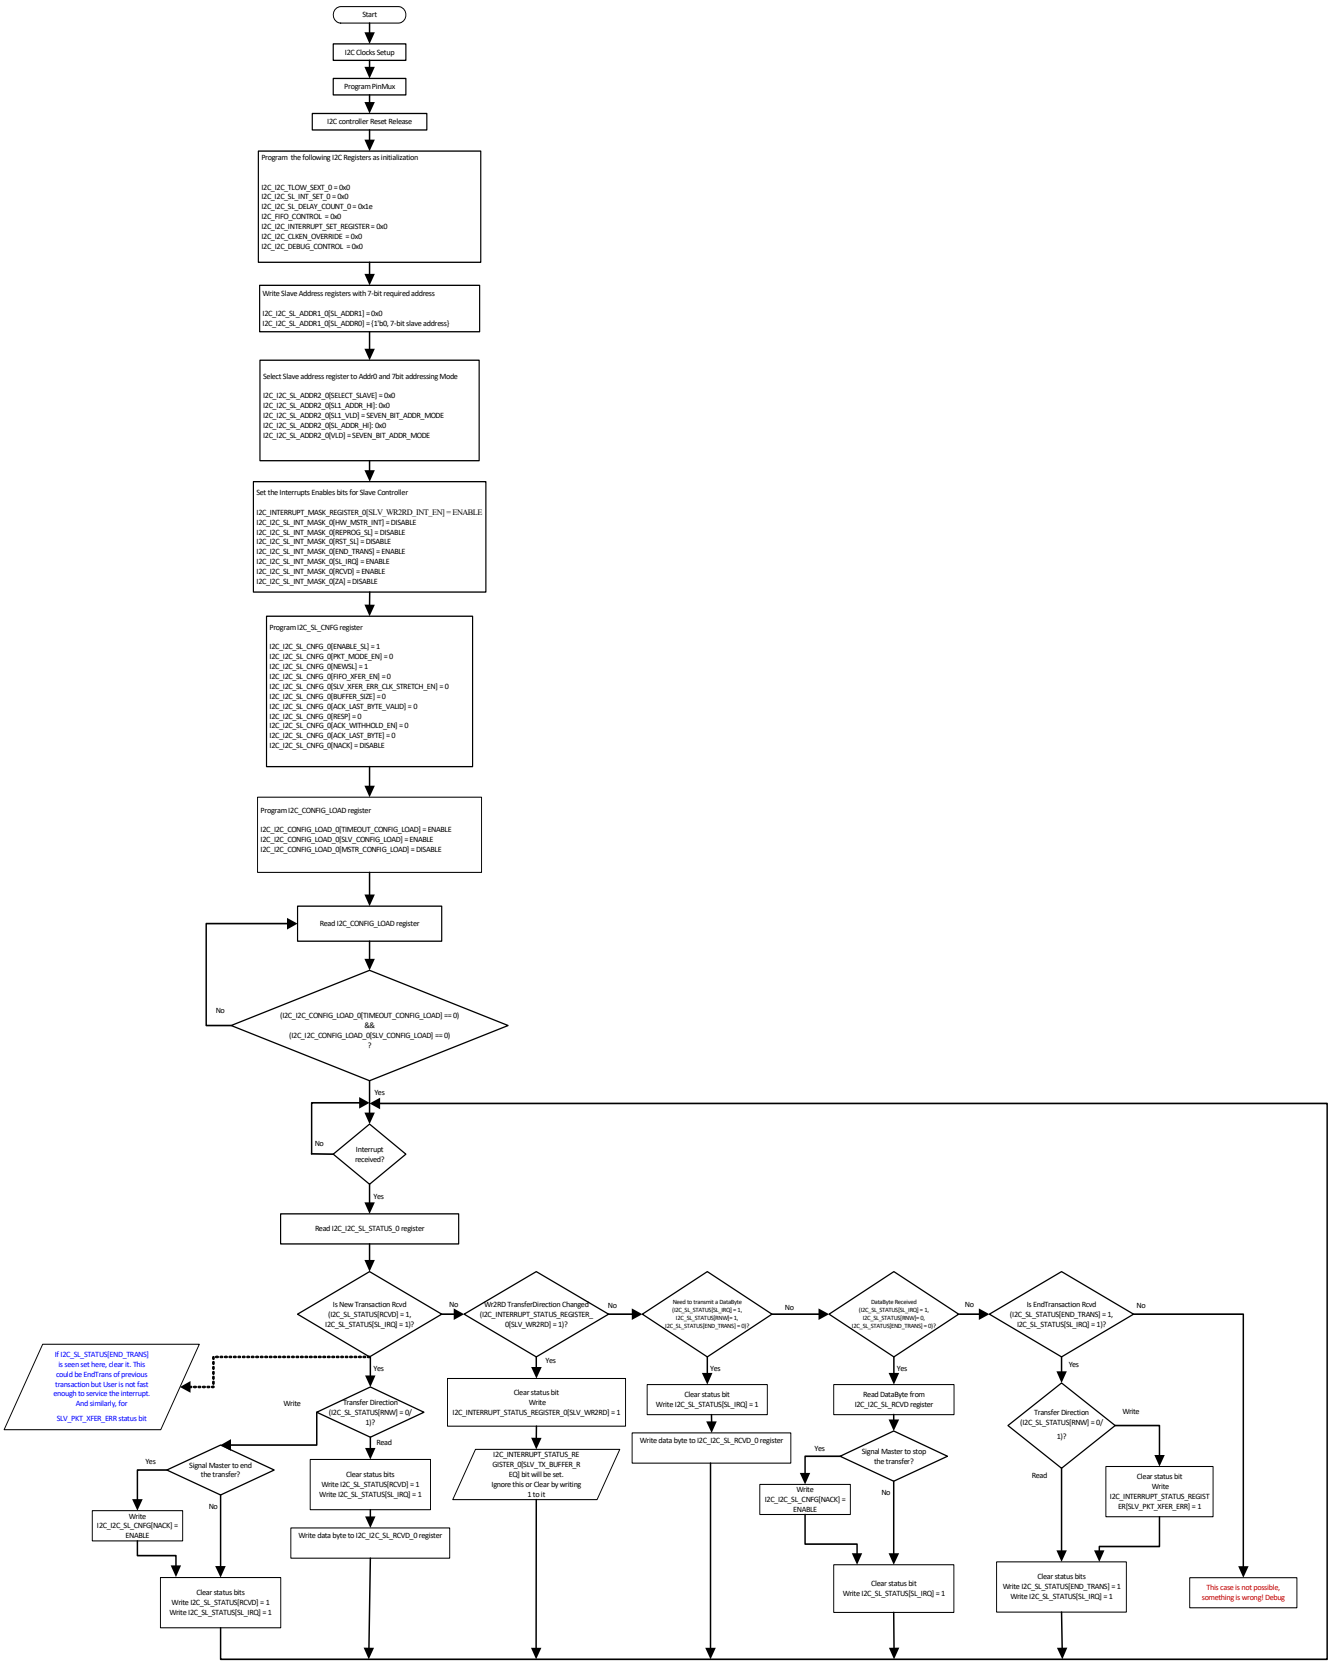
17. Interrupts handling when transaction END is received during read:

    a. Read I2C_I2C_SL_INT_SOURCE_0 register and check which bit fields are set to 1.

    b. In the transaction END case, I2C_I2C_SL_INT_SOURCE_0[END_TRANS] and I2C_I2C_SL_INT_SOURCE_0[SL_IRQ] bits are set to 1.

    c. Clear I2C_I2C_SL_STATUS_0[END_TRANS] and I2C_I2C_SL_STATUS_0[SL_IRQ] bits by writing-1 to them. This clears the interrupt.

Figure 164: Flowchart for Slave-Receive-Transmit (transfer direction changed) Programming Model



35.10.4 Programming Model for Slave-Transmit-Receive (transfer direction changed from Transmit-to-Receive with RepeatedStart) in 7-bit addressing Mode□Interrupt Method

1. Initial configuration

   Before accessing the I2C controller, setup the following.

   a. I2C Clocks programming

   b. Pinmux programming

   c. I2C controller reset release

2. I2C controller registers initialization

   a. Write I2C_FIFO_CONTROL = 0x0

   b. Write I2C_I2C_INTERRUPT_SET_REGISTER = 0x0

   c. Write I2C_I2C_CLKEN_OVERRIDE = 0x0

   d. Write I2C_I2C_DEBUG_CONTROL = 0x0

   e. Write I2C_I2C_TLOW_SEXT_0 = 0x0

   f. Write I2C_I2C_SL_INT_SET_0 = 0x0

   g. Write I2C_I2C_SL_DELAY_COUNT_0 = 0x1e

3. Select Slave Address Register and configure it in 7-bit addressing mode:

   a. Write I2C_I2C_SL_ADDR1_0[SL_ADDR1] = 0

   b. Write 7-bit slave address in I2C_I2C_SL_ADDR1_0[SL_ADDR0] = {1'b0, SlaveAddress[6:0]}

   c. To use SL_ADDR0 bit field for Slave address, write I2C_I2C_SL_ADDR2_0[SELECT_SLAVE] = 0

   d. Write I2C_I2C_SL_ADDR2_0[SL1_ADDR_HI] = 0

   e. Write I2C_I2C_SL_ADDR2_0[SL1_VLD] = SEVEN_BIT_ADDR_MODE

   f. Write I2C_I2C_SL_ADDR2_0[SL_ADDR_HI] = 0

   g. Write I2C_I2C_SL_ADDR2_0[VLD] = SEVEN_BIT_ADDR_MODE

4. Configure Interrupt Mask registers to enable the interrupts

   a. Write I2C_INTERRUPT_MASK_REGISTER_0 = 0x0

   b. Write I2C_I2C_SL_INT_MASK_0[HW_MSTR_INT] = DISABLE

   c. Write I2C_I2C_SL_INT_MASK_0[REPROG_SL] = DISABLE

   d. Write I2C_I2C_SL_INT_MASK_0[RST_SL] = DISABLE

   e. Write I2C_I2C_SL_INT_MASK_0[END_TRANS] = ENABLE

   f. Write I2C_I2C_SL_INT_MASK_0[SL_IRQ] = ENABLE

   g. Write I2C_I2C_SL_INT_MASK_0[RCVD] = ENABLE

   h. Write I2C_I2C_SL_INT_MASK_0[ZA] = DISABLE

5. Configure SL_CNFG register to enable the Slave Controller:

   a. Write I2C_I2C_SL_CNFG_0[ENABLE_SL] = 1

   b. Write I2C_I2C_SL_CNFG_0[PKT_MODE_EN] = 0

   c. Write I2C_I2C_SL_CNFG_0[NEWSL] = 1

   d. Write I2C_I2C_SL_CNFG_0[FIFO_XFER_EN] = 0

   e. Write I2C_I2C_SL_CNFG_0[SLV_XFER_ERR_CLK_STRETCH_EN] = 0

   f. Write I2C_I2C_SL_CNFG_0[BUFFER_SIZE] = 0

g. Write I2C_I2C_SL_CNFG_0[ACK_LAST_BYTE_VALID] = 0

h. Write I2C_I2C_SL_CNFG_0[RESP] = 0

i. Write I2C_I2C_SL_CNFG_0[ACK_WITHHOLD_EN] = 0

j. Write I2C_I2C_SL_CNFG_0[ACK_LAST_BYTE] = 0

k. Write I2C_I2C_SL_CNFG_0[NACK] = DISABLE

6. Activate the configuration with I2C_CONFIG_LOAD register programming:

   a. I2C_I2C_CONFIG_LOAD_0[TIMEOUT_CONFIG_LOAD] = ENABLE

   b. I2C_I2C_CONFIG_LOAD_0[SLV_CONFIG_LOAD] = ENABLE

   c. I2C_I2C_CONFIG_LOAD_0[MSTR_CONFIG_LOAD] = DISABLE

7. Wait for the hardware to clear the I2C_CONFIG_LOAD register bit fields:

   a. Wait until I2C_I2C_CONFIG_LOAD_0[TIMEOUT_CONFIG_LOAD] becomes zero

   b. Wait until I2C_I2C_CONFIG_LOAD_0[SLV_CONFIG_LOAD] becomes zero

   With this, Slave controller would be ready for the data transfers. Start a transaction from I2C Master device.

8. Slave Response to Address phase of Read transaction

   When Slave receives address byte from the bus and if the address matches its programmed address, it does the following.

   a. Sets I2C_I2C_SL_STATUS_0[RNW] bit field with received address byte[0] bit which indicates transfer direction. 0 = WRITE, 1=READ

   b. Saves the received address byte in I2C_I2C_SL_RCVD_0 register

   c. Sets I2C_I2C_SL_STATUS_0[RCVD] and I2C_I2C_SL_STATUS_0[SL_IRQ] bits indicating that a new transaction is received.

   d. Generates an interrupt to the system if Interrupt enables bits (I2C_I2C_SL_INT_MASK_0[RCVD], I2C_I2C_SL_INT_MASK_0[SL_IRQ]) are set

   e. And holds the I2C bus by doing clock stretching (holds I2C SCL line low) until the interrupt is cleared and a data byte is available in I2C_I2C_SL_RCVD_0 register

9. New transaction Interrupt handling:

   a. Read I2C_I2C_SL_INT_SOURCE_0 register and check which bit fields are set to 1.

   b. In the new transaction received case, I2C_I2C_SL_INT_SOURCE_0[RCVD] and I2C_I2C_SL_INT_SOURCE_0[SL_IRQ] bits are set to 1

   c. Check I2C_I2C_SL_STATUS_0[RNW] bit status. For read transactions, I2C_I2C_SL_STATUS_0[RNW] = READ is set.

   d. Clear I2C_I2C_SL_STATUS_0[RCVD] and I2C_I2C_SL_STATUS_0[SL_IRQ] bits by writing-1 to them. This clears the interrupt.

   e. Write Data byte to I2C_I2C_SL_RCVD_0 register. This will release the SCL line. The Master can read this byte now.

10. Slave Response to Data phase of Read transaction

    If Master ACKs previous byte transfer, it means, Master wants to continue the read operation further. The Slave controller does the following in this case.

    a. Sets I2C_I2C_SL_STATUS_0[SL_IRQ] bit indicating a request to transmit a data byte.

    b. Generates an interrupt to the system if interrupt enable bit I2C_I2C_SL_INT_MASK_0[SL_IRQ] is set

    c. Slave holds the I2C bus by doing clock stretching (holds I2C SCL line low) until a data byte is available in I2C_I2C_SL_RCVD_0 register to transmit to the bus.

11. Interrupts handling in data byte transmit case:

a. Read I2C_I2C_SL_INT_SOURCE_0 register and check which bit fields are set to 1.

b. In the data transmit case, only I2C_I2C_SL_INT_SOURCE_0[SL_IRQ] bit is set to 1

c. Clear I2C_I2C_SL_STATUS_0[SL_IRQ] bit by writing-1 to it. This clears the interrupt.

d. Write a Data byte to I2C_I2C_SL_RCVD_0 register. This will release the SCL line and allow the Master to continue the transfer.

12. Slave Response to Read-to-Write Transfer Direction change with RepeatedStart condition

    When Master wants to send RepeatedStart condition to change the transfer direction from read to write, it will NACK the last byte of the read transfer before sending Repeated condition.

    Slave does the following when this happens:

    a. Sets I2C_I2C_SL_STATUS_0[END_TRANS] and I2C_I2C_SL_STATUS_0[SL_IRQ] bits indicating the end of read transaction.

    b. Generates an interrupt to the system if interrupt enables bits (I2C_I2C_SL_INT_MASK_0[END_TRANS], I2C_I2C_SL_INT_MASK_0[SL_IRQ]) are set.

13. Interrupts handling when transaction END is received during read:

    a. Read I2C_I2C_SL_INT_SOURCE_0 register and check which bit fields are set to 1.

    b. In the transaction END case, I2C_I2C_SL_INT_SOURCE_0[END_TRANS] and I2C_I2C_SL_INT_SOURCE_0[SL_IRQ] bits are set to 1.

    c. Clear I2C_I2C_SL_STATUS_0[END_TRANS] and I2C_I2C_SL_STATUS_0[SL_IRQ] bits by writing-1 to them. This clears the interrupt.

14. When New Transaction (READ) starts with RepeatedStart, Slave does the following after receiving the address byte of the new transaction:

    a. Sets I2C_I2C_SL_STATUS_0[RNW] bit field with received address byte[0] bit which indicates transfer direction. 0 = WRITE, 1=READ.

    b. Saves the received address byte in I2C_I2C_SL_RCVD_0 register.

    c. Sets I2C_I2C_SL_STATUS_0[RCVD] and I2C_I2C_SL_STATUS_0[SL_IRQ] bits indicating that a new transaction is received.

    d. Generates an interrupt to the system if interrupt enables bits (I2C_I2C_SL_INT_MASK_0[RCVD], I2C_I2C_SL_INT_MASK_0[SL_IRQ]) are set.

    e. And holds the I2C bus by doing clock stretching (holds I2C SCL line low) until the interrupt is cleared.

15. New transaction Interrupt handling:

    a. Read I2C_I2C_SL_INT_SOURCE_0 register and check which bit fields are set to 1.

    b. In the new transaction received case, I2C_I2C_SL_INT_SOURCE_0[RCVD] and I2C_I2C_SL_INT_SOURCE_0[SL_IRQ] bits are set to 1.

    c. Check I2C_I2C_SL_STATUS_0[RNW] bit status. For write transactions, I2C_I2C_SL_STATUS_0[RNW] = WRITE is set.

    d. Clear I2C_I2C_SL_STATUS_0[RCVD] and I2C_I2C_SL_STATUS_0[SL_IRQ] bits by writing-1 to them. This clears the interrupt and releases the SCL line allowing the Master to go to next phase of the transaction.

16. Slave Response to Data phase of the Write transaction:

    When a Master sends a data byte, the Slave controller does the following.

    a. Saves the received byte in I2C_I2C_SL_RCVD_0 register.

    b. Sets I2C_I2C_SL_STATUS_0[SL_IRQ] bit indicating a byte received.

    c. Generates an interrupt to the system if interrupt enable bit I2C_I2C_SL_INT_MASK_0[SL_IRQ] is set.

    d. Slave holds the I2C bus by doing clock stretching (holds I2C SCL line low) until the interrupt is cleared.

17. Interrupts handling when received a data byte:

a. Read I2C_I2C_SL_INT_SOURCE_0 register and check which bit fields are set to 1.

b. In the data_byte received case, I2C_I2C_SL_INT_SOURCE_0[SL_IRQ] bit is set to 1

c. Read the data byte from I2C_I2C_SL_RCVD_0 register.

d. To continue with the transfer, keep I2C_I2C_SL_CNFG_0[NACK] = DISABLE setting. Otherwise, to signal the Master to stop the transfer, configure I2C_I2C_SL_CNFG_0[NACK] = ENABLE.

e. Clear I2C_I2C_SL_STATUS_0[SL_IRQ] by writing-1 to it. This clears the interrupt and releases the SCL line allowing the Master to go ahead with next phase of the transaction.

18. Slave Response to STOP condition of the Write transaction

    If Master sends STOP condition next, Slave does the following:

    a. Sets I2C_I2C_SL_STATUS_0[END_TRANS] and I2C_I2C_SL_STATUS_0[SL_IRQ] bits indicating STOP condition is received.

    b. Generates an interrupt to the system if Interrupt bits (I2C_I2C_SL_INT_MASK_0[END_TRANS], I2C_I2C_SL_INT_MASK_0[SL_IRQ]) are enabled.

19. Interrupts handling when Stop condition is received:

    a. Read I2C_I2C_SL_INT_SOURCE_0 register and check which bit fields are set to 1.

    b. In the STOP condition case, I2C_I2C_SL_INT_SOURCE_0[END_TRANS] and I2C_I2C_SL_INT_SOURCE_0[SL_IRQ] bits are set to 1.

    c. Clear I2C_I2C_SL_STATUS_0[END_TRANS] and I2C_I2C_SL_STATUS_0[SL_IRQ] bits by writing-1 to them. This clears the interrupt.

Notes:

- *If Master terminates the transaction while the Slave controller is ready to accept the data during write transfer, I2C_INTERRUPT_STATUS_REGISTER_0[SLV_PKT_XFER_ERR] bit is set at the end of the transaction when STOP condition is received. This bit can be cleared by writing-1 to it or it can be ignored.*
- *If the Slave controller sends NACK to any of the bytes during the write transfer, the Master terminates the transaction after seeing NACK bit. In this case, no status bits (END_TRANS, SL_IRQ or SLV_PKT_XFER_ERR) are set when the STOP condition is received. No interrupts either.*

35.11 I2C Registers

Refer to Section 1.4: Reading Register Tables in the Introduction chapter for the register table protocol as well as recommendations for accessing registers.

35.11.1 I2C_I2C_CNFG_0

IC Controller Configuration Register (Master)

The I2C_CNFG register is used to configure:

- the number of bytes to be transmitted or received
- the slave device type (either a 7-bit device or a 10-bit device)
- enable mode to send Start-byte or not
- to select either a single slave transaction or two slave transaction
- enable mode to handle devices that do not generate an ACK.

Offset: 0x0 | Read/Write: R/W | Reset: 0x00020800 (0bxxxxxxxxxxxxxxx100000100000000000)

Bit	Reset	Description
17	ENABLE	MULTI_MASTER_MODE: used to select single or multi master mode 0=single master 1=multi_master In single_master mode, no arbitration checks happen 0 = DISABLE 1 = ENABLE
15	0x0	MSTR_CLR_BUS_ON_TIMEOUT: When this bit is set, the I2C master will put STOP condition on the bus. 0 = NOP 1 = Put STOP condition on the I2C bus
14:12	0x0	DEBOUNCE_CNT: Debounce period for SDA and SCL lines. 0 = No debounce 1 = 2T 2 = 4T 3 = 6T, etc. where T is the period of the fixed PLL clock source coming to I2C. Maximum debounce period is 14T. A debounce period of > 50 ns is desirable.
11	0x1	NEW_MASTER_FSM: Maintained for backward compatibility. 0 = DISABLE 1 = ENABLE
10	0x0	PACKET_MODE_EN: Write 1 to initiate transfer in packet mode. 0 = NOP 1 = GO
9	0x0	SEND: Writing a 1 causes the master to initiate the transaction in normal mode. This bit is cleared by hardware when the transaction is done. Firmware should first configure all other registers and bits [8:0] of this register before this bit is programmed to one. 0 = NOP 1 = GO
8	0x0	NOACK: Enable mode to handle devices that do not generate an ACK. 1 = Do not look for an ACK at the end of the enable. 0 = DISABLE 1 = ENABLE
7	0x0	CMD2: Read/Write Command for Slave 2: 1 - Read Transaction; 0 - Write Transaction. For a 7-bit slave address, this bit must match with the LSB of address byte for slave 2. Valid only when bit 4 of this register is set.
6	0x0	CMD1: Read/Write Command for Slave 1: 1 - Read Transaction; 0 - Write Transaction. Command for Slave 1: For a 7-bit slave address, this bit must match with the LSB of address byte for slave 1.
5	0x0	START: 1 = Yes, a Start byte needs to be sent. 0 = DISABLE 1 = ENABLE
4	0x0	SLV2: 1 = Enables a two-slave transaction. 0 = No command for Slave 2 present.
3:1	0x0	LENGTH: The number of bytes to be transmitted per transaction. 000 = 1 byte ... 111 = 8 bytes. In a two slave transaction, the number of bytes should be programmed to be less than 011.
0	0x0	A_MOD: Address mode defines whether a 7-bit or a 10-bit slave address is programmed. 1 = 10-bit device address. 0 = 7-bit device address.

35.11.2 I2C_I2C_CMD_ADDR0_0

I2C Slave-1 Address

I2C_CMD_ADDR0 is programmed with the 7-bit or 10-bit address of slave 1 to which the transaction is intended.

Offset: 0x4 | Read/Write: R/W | Reset: 0x00000000 (0bxxxxxxxxxxxxxxxxxxxxxxxx0000000000)

Bit	Reset	Description
9:0	0x0	ADDR0: For 7-bit mode, the address is written in I2C_CMD_ADDR0[7:1], and I2C_CMD_ADDR0[0] indicates the read/write transaction. The I2C_CMD_ADDR0[0] bit must match the I2C_CNFG[6] bit. For 10-bit mode, the address is written in I2C_CMD_ADDR0[9:0], and I2C_CNFG[6] indicates the read/write transaction.

35.11.3 I2C_I2C_CMD_ADDR1_0

I2C Slave-2 Address

I2C_CMD_ADDR1 is programmed with the 7-bit or 10-bit address of slave 2 to which the transaction is intended.

Offset: 0x8 | Read/Write: R/W | Reset: 0x00000000 (0bxxxxxxxxxxxxxxxxxxxxxxxx0000000000)

Bit	Reset	Description
9:0	0x0	ADDR1: For 7-bit mode, the address is written in I2C_CMD_ADDR0[7:1], and I2C_CMD_ADDR0[0] indicates the read/write transaction. The I2C_CMD_ADDR0[0] bit must match the I2C_CNFG[7] bit. For 10-bit mode, the address is written in I2C_CMD_ADDR0[9:0], and I2C_CNFG[7] indicates the read/write transaction.

35.11.4 I2C_I2C_CMD_DATA1_0

I2C Controller Data 1: Transmit/Receive

The four least significant bytes of data to be transmitted are loaded into this register when the I2C Master is in Write mode.

The four least significant bytes of data are read through this register when the I2C Master is in Read mode.

Offset: 0xc | Read/Write: R/W | Reset: 0x00000000 (0b00000000000000000000000000000000)

Bit	Reset	Description
31:24	0x0	DATA4: Fourth data byte to be sent/received
23:16	0x0	DATA3: Third data byte to be sent/received
15:8	0x0	DATA2: Second data byte to be sent/received
7:0	0x0	DATA1: First data byte to be sent/received

35.11.5 I2C_I2C_CMD_DATA2_0

I2C Controller Data 2: Transmit/Receive

The four most significant bytes of data to be transmitted are loaded into the register when the I2C Master is in Write mode.

The four most significant bytes of data are read through this register when the I2C Master is in Read mode.

Offset: 0x10 | Read/Write: R/W | Reset: 0x00000000 (0b00000000000000000000000000000000)

Bit	Reset	Description
31:24	0x0	DATA8: Eighth data byte to be sent/received
23:16	0x0	DATA7: Seventh data byte to be sent/received
15:8	0x0	DATA6: Sixth data byte to be sent/received
7:0	0x0	DATA5: Fifth data byte to be sent/received

35.11.6 I2C_I2C_STATUS_0

I2C Controller Status (Master)

I2C_STATUS gives the status of the I2C Master operation.

Offset: 0x1c | Read/Write: RO | Reset: 0x00000XXX (0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx)

Bit	Reset	Description
8	X	BUSY: 0 = NOT_BUSY 1 = BUSY
7:4	X	CMD2_STAT: Slave 2 status: Transaction for Slave 2 for byte x failed. x is 'h0 to 'ha. 35.11.7 I2C_I2C_SL_CNFG_0

I2C Controller Configuration (Slave)

I2C_SL_CNFG register is used to configure, enable mode of slave ACK.

Enable mode of the slave response to the general call address.

The register should be programmed when the I^2C controller is configured as a slave.

Offset: 0x20 | Read/Write: R/W | Reset: 0x00000004 (0bxxxxxxxxxxxx00000000000000000100)

Bit	Reset	Description
20	0x0	FIFO_XFER_EN: If this bit is disabled, data is always communicated via the I2C_SL_RCVD register. If enabled, data is communicated through FIFOs 0 = DISABLE 1 = ENABLE
19:8	0x0	BUFFER_SIZE: Payload size in bytes
7	0x0	ACK_LAST_BYTE_VALID: Acknowledge the last byte valid (write-only). This bit qualifies the ACK_LAST_BYTE field. 0 = DISABLE 1 = ENABLE
6	0x0	ACK_LAST_BYTE: Acknowledge the last byte. 0 = DISABLE 1 = ENABLE
5	0x0	ACK_WITHHOLD_EN: ACK Withhold Feature Enable 0 = DISABLE 1 = ENABLE
4	0x0	PKT_MODE_EN: Packet Mode Enable 0 = DISABLE 1 = ENABLE
3	0x0	ENABLE_SL: By writing zero to this field, the slave can be turned off 0 = DISABLE 1 = ENABLE

Bit	Reset	Description
2	0x1	NEWSL: New Slave. 1 - Use new slave. 0 = DISABLE 1 = ENABLE
1	0x0	NACK: Disable Slave ACK. 1 – The slave will not acknowledge reception of address or data byte. 0 = DISABLE 1 = ENABLE
0	0x0	RESP: Slave response to the general call address (zero address). 0 = DISABLE 1 = ENABLE

35.11.8 I2C_I2C_SL_RCVD_0

I2C Controller Slave Receive/Transmit Data (Slave)

Offset: 0x24 | Read/Write: R/W | Reset: 0x00000000 (0bxxxxxxxxxxxxxxxxxxxxxxxxx00000000)

Bit	Reset	Description

35.11.9 I2C_I2C_SL_STATUS_0

I2C Controller Slave Status (Slave)

Offset: 0x28 | Read/Write: R/W | Reset: 0x0000XX0X (0bxxxxxxxxxxxxxxxxxxxxxxxx000000x0)

Bit	R/W	Reset	Description
14:8	RO	X	HW_MSTR_ADR: Hardware master address received via general call addressing. This field is meaningful only if HW_MSTR_INT is set.
7	RW	0x0	HW_MSTR_INT: 1 = Interrupt has been generated by slave. Hardware Master Address is received after General Call Address. Received Hardware Master Address. 0 = No event.
6	RW	0x0	REPROG_SL: 1 = Interrupt has been generated by the slave after the General Call Address is 0x04. Reprogram slave address. 0 = No action.
5	RW	0x0	RST_SL: 1 = Interrupt has been generated by slave after the General Call Address is 0x06. Reset and reprogram slave address. 0 = No action.
4	RW	0x0	END_TRANS: 1 = Interrupt has been generated by slave. Transaction completed as indicated by stop/repeat start condition. 0 = No transaction occurred or transaction in progress.
3	RW	0x0	SL_IRQ: 1 = Interrupt has been generated by slave. 0 = No interrupt generated. 0 = UNSET 1 = SET
2	RW	0x0	RCVD: New Transaction Received status. 1 = Transaction occurred. 0 = No transaction occurred. 0 = NO_TRANSACTION_OCCURED 1 = TRANSACTION_OCCURED
1	RO	X	RNW: Slave Transaction status. 0 = WRITE 1 = READ
0	RW	0x0	ZA: Zero Address Status 1 = Yes, slave responded. 0 = No, slave did not respond. 0 = NO_SLAVE_RESPONSE 1 = SLAVE_RESPONSE

35.11.10 I2C_I2C_SL_ADDR1_0

I2C Controller Slave Address 1 Register (Slave)

Offset: 0x2c | Read/Write: R/W | Reset: 0x00000000 (0bxxxxxxxxxxxxxxxx0000000000000000)

Bit	Reset	Description
15:8	0x0	SL_ADDR1: For a 10-bit slave address, this field is the least significant 8 bits.
7:0	0x0	SL_ADDR0: For a 10-bit slave address, this field is the least significant 8 bits.

35.11.11 I2C_I2C_SL_ADDR2_0

I2C Controller Slave Address 2 Register (Slave)

Offset: 0x30 | Read/Write: R/W | Reset: 0x00000000 (0bxxxxxxxxxxxxxxxx0xxxxx000xxxxx000)

Bit	Reset	Description
16	0x0	SELECT_SLAVE: 0 = Use slave addr0. 1 = Use slave addr1.
10:9	0x0	SL1_ADDR_HI: In 7-bit address mode, these bits are don’t care. In 10-bit address mode, they represent the 2 MSBs of the address.
8	0x0	SL1_VLD: 0 = 7-bit addressing. 0 = SEVEN_BIT_ADDR_MODE 1 = TEN_BIT_ADDR_MODE
2:1	0x0	SL_ADDR_HI: In 7-bit address mode, these bits are don’t care. In 10-bit address mode, they represent the 2 MSBs of the address.
0	0x0	VLD: 0 = 7-bit addressing. 1 - 10 bit addressing. 0 = SEVEN_BIT_ADDR_MODE 1 = TEN_BIT_ADDR_MODE

35.11.12 I2C_I2C_TLOW_SEXT_0

I2C Controller SMBUS Timeout Thresholds

Offset: 0x34 | Read/Write: R/W | Reset: 0x00000000 (0bxxxx00000000000000000000000000)

Bit	Reset	Description
27	0x0	RST_SL_ON_TIMEOUT: Reset Slave state machine on time-out
26	0x0	TLOW_MEXT_EN: Enable TLOW_MEXT counter
25	0x0	TLOW_SEXT_EN: Enable TLOW_SEXT counter
24	0x0	TIMEOUT_EN: Enable TIMEOUT counter
23:16	0x0	TLOW_MEXT: Cumulative clock low extend time (master device) accumulated over a byte transfer period in milliseconds (START to ACK, ACK to ACK, or ACK to STOP).
15:8	0x0	TLOW_SEXT: Cumulative clock low extend time (slave device) accumulated over a complete transfer (START till STOP)
7:0	0x0	TIMEOUT: Clock low time-out period in milliseconds

35.11.13 I2C_I2C_SL_DELAY_COUNT_0

I2C Slave Controller Delay Count

Offset: 0x3c | Read/Write: R/W | Reset: 0x0000001e (0bxxxxxxxxxxxxxxxx0000000000011110)

Bit	Reset	Description
15:0	0x1e	SL_DELAY_COUNT: The value determines the timing between an address cycle and a subsequent data cycle or two consecutive data cycles on the bus. The I2C_SL_DELAY_COUNT is valid only when an internal slave is accessed. I2C_SL_DELAY_COUNT has to be programmed such that TIMING = T * DLY, where T is the period of the clock source selected for I2C, DLY is I2C_SL_DELAY_COUNT, and TIMING is the desired timing. A value of >= 1250 ns is recommended.

35.11.14 I2C_I2C_SL_INT_MASK_0

I2C Controller Slave Mask (Slave)

Offset: 0x40 | Read/Write: R/W | Reset: 0x000000fd (0bxxxxxxxxxxxxxxxxxxxxxxxxx111111x1)

Bit	Reset	Description

0	0x0	ZA: 0 = UNSET 1 = SET

Note: *Program the field PACKET_MODE_EN of I2C_CNFG register while working in packet mode.*

The set of registers given below describe the interface for packet mode only. With packet mode interface changes, normal mode registers and the operation are not affected. The transition from normal mode to packet mode is suggested because packet mode allows:

- There is no restriction on the number of bytes before and the after the repeated start
- The number of bytes that can be transferred with a single command is not limited to 8.

Though a packet can contain 4 Kbytes, because any number of packets can be pushed into the FIFO, there is no limit on the number of bytes that can be transferred.

- The transactions to different slaves can be chained together with repeat start and there is no limit on the number of slaves it can address.

35.11.17 I2C_I2C_TX_PACKET_FIFO_0

A packet contains header and payload. For I2C, the header size is 3 words. The first two words of the header contain generic information. The third word contains I2C transaction-specific information. The payload contains actual data to be written to the slave. For read operations, the payload is nil. Thus, the packet contains a header only.

Offset: 0x50 | Read/Write: R/W | Reset: 0x00000000 (0b00000000000000000000000000000000)

Bit	Reset	Description
31:0	0x0	TX_PACKET: Software writes packets into this register. A packet may contain generic information

35.11.18 I2C_I2C_RX_FIFO_0

Header or I2C Specific Header or Data

Offset: 0x54 | Read/Write: RO | Reset: 0xXXXXXXXX (0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx)

Bit	Reset	Description
31:0	X	RD_DATA: Software reads data from this register, causes a pop

35.11.23 I2C_INTERRUPT_STATUS_REGISTER_0

This register indicates the status bit for which the interrupt is set. If the interrupt is set, write a 1 to clear it. However, the TFIFO_DATA_REQ and RFIFO_DATA_REQ fields depend on the FIFO trigger levels and cannot be cleared.

Slv_rd2wr indicates there is a switch from read to write by repeat start and the current read transaction needs to be closed and started with a write transaction. Similarly, slv_wr2rd indicates a switch from write to read.

35.11.26 I2C_I2C_INTERRUPT_SET_REGISTER_0

This write-only register can be used to set the interrupt status bit. A write to this register causes the bits in the status register to be set if the corresponding bit in the write data is 1'b1. A read always returns 'h0.

35.11.27 I2C_I2C_SLV_TX_PACKET_FIFO_0

Offset: 0x78 | Read/Write: R/W | Reset: 0x00000000 (0b00000000000000000000000000000000)

Bit	Reset	Description
31:0	0x0	TX_PACKET: Software writes packets into this register. A packet may contain generic information.

35.11.28 I2C_I2C_SLV_RX_FIFO_0

Header or I2C Specific Header or Data

Offset: 0x7c | Read/Write: RO | Reset: 0xXXXXXXXX (0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx)

Bit	Reset	Description
31:0	X	RD_DATA: Software reads data from this register, causes a pop.

35.11.29 I2C_I2C_SLV_PACKET_STATUS_0

Offset: 0x80 | Read/Write: RO | Reset: 0x0XXXXXX0 (0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx)

Bit	Reset	Description
25	X	ACK_WITHHELD: Indicates that an ACK is withheld for the last byte and the slave is waiting for the host to explicitly command the slave to acknowledge the last byte. 0 = Bus is released. 1 = ACK is withheld
24	X	TRANSFER_COMPLETE: All the packets have been transferred successfully
23:16	X	TRANSFER_PKT_ID: The current packet ID for which the transaction is happening on the bus
15:4	X	TRANSFER_BYTENUM: The number of bytes transferred in the current packet

35.11.30 I2C_I2C_BUS_CLEAR_CONFIG_0

Offset: 0x84 | Read/Write: R/W | Reset: 0x00090004 (0bxxxxxxxx00001001xxxxxxxxxxxx100)

Bit	Reset	Description
23:16	0x9	BC_SCLK_THRESHOLD: send the clock pulses until this threshold is met
2	0x1	BC_STOP_COND: 0 = NO_STOP: Do not send a stop condition at the end of the bus clear operation 1 = STOP: Send a stop condition at the end of the bus clear operation
1	0x0	BC_TERMINATE: 0 = THRESHOLD: Irrespective of SDA release status during bus clear, terminate the bus clear only after the threshold is reached. 1 = IMMEDIATE: Terminate the bus clear operation immediately when SDA is released or threshold count is reached, whichever is earlier
0	0x0	BC_ENABLE: Starts bus clear operation. Hardware auto-clears this bit upon bus clear transaction completion

35.11.31 I2C_I2C_BUS_CLEAR_STATUS_0

Offset: 0x88 | Read/Write: RO | Reset: 0x00000000 (0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx)

Bit	Reset	Description
0	X	BC_STATUS: 0 = NOT_CLEARED: Indicates SDA is not released by the slave. Its status is still low. 1 = CLEARED: SDA is released

35.11.32 I2C_I2C_CONFIG_LOAD_0

Spare Register

Offset: 0x8c | Read/Write: R/W | Reset: 0x00000000 (0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxx000)

Bit	Reset	Description
2	0x0	TIMEOUT_CONFIG_LOAD: This bit loads the timeout configuration from the pclk domain to the receive (i2c_slow_clk) domain. Software has to set this bit finally after doing the required registers configuration for the logic to take the updates. Once the internal update is done, hardware auto clears this bit. Since the hardware would be busy with internal update, software should not write again until this bit is cleared by hardware. 0 = DISABLE 1 = ENABLE

Bit	Reset	Description
1	0x0	SLV_CONFIG_LOAD: This bit loads the slave configuration from the pclk domain to the receive (i2c_clk) domain. Software has to set this bit finally after doing the required registers configuration for the slave controller to take updates. Once the internal update is done, hardware auto clears this bit. Since the hardware would be busy with internal update, software should not write again until this bit is cleared by hardware. 0 = DISABLE 1 = ENABLE
0	0x0	MSTR_CONFIG_LOAD: This bit loads the master configuration from the pclk domain to the receive (i2c_clk) domain. Software has to set this bit finally after doing the required registers configuration like I2C_I2C_CNFG_0 bit fields etc. Once the internal update is done, hardware auto clears this bit. Since the hardware would be busy with internal update, software should not write again until this bit is cleared by hardware. 0 = DISABLE 1 = ENABLE

35.11.33 I2C_I2C_INTERFACE_TIMING_0_0

Register for Standard/Fast/FM+ mode timing

Offset: 0x94 | Read/Write: R/W | Reset: 0x00000204 (0bxxxxxxxxxxxxxxxxxx000010xx000100)

Bit	Reset	Description
13:8	0x2	THIGH: High period of the SCL clock
5:0	0x4	TLOW: Low period of the SCL clock

35.11.34 I2C_I2C_INTERFACE_TIMING_1_0

Register for Standard/Fast/FM+ mode timing

Offset: 0x98 | Read/Write: R/W | Reset: 0x04070404 (0bxx000100xx000111xx000100xx000100)

Bit	Reset	Description
29:24	0x4	TBUF: Bus free time between STOP and START conditions
21:16	0x7	TSU_STO: Setup time for STOP condition
13:8	0x4	THD_STA: Hold time for a (repeated) START condition
5:0	0x4	TSU_STA: Setup time for a Repeated START condition

35.11.35 I2C_I2C_HS_INTERFACE_TIMING_0_0

I2C interface timing register for HS mode transfers. Because HS master code is sent in Std/FM/FM+ modes, Standard/Fast/FM+ timing registers need to be programmed along with HS timing registers.

Offset: 0x9c | Read/Write: R/W | Reset: 0x00000308 (0bxxxxxxxxxxxxxxxxxx000011xx001000)

Bit	Reset	Description
13:8	0x3	HS_THIGH: High period of the SCL clock
5:0	0x8	HS_TLOW: Low period of the SCL clock

35.11.36 I2C_I2C_HS_INTERFACE_TIMING_1_0

I2C interface timing register for HS mode transfers. Because HS master code is sent in Std/FM/FM+ modes, Standard/Fast/FM+ timing registers need to be programmed along with HS timing registers.

Offset: 0xa0 | Read/Write: R/W | Reset: 0x000b0b0b (0bxxxxxxxxxx001011xx001011xx001011)

Bit	Reset	Description
21:16	0xb	HS_TSU_STO: Setup time for STOP condition
13:8	0xb	HS_THD_STA: Hold time for a (repeated) START condition
5:0	0xb	HS_TSU_STA: Setup time for a Repeated START condition

CHAPTER 36: UART CONTROLLER

There are four Universal Asynchronous Receiver/Transmitters (UARTs) built into Tegra® X1 devices. These UARTs support both 16450 and 16550 compatible modes. A fifth UART is located in the Audio Processing Engine (APE).

36.1 Functional Description

36.1.1 UARTs A through D

All UARTs provide serial data synchronization and data conversion (parallel-to-serial and serial-to-parallel) for both receiver and transmitter sections. Synchronization for serial data stream is accomplished by adding start and stop bits to the transmit data to form a data character. Data integrity is accomplished by attaching a parity bit to the data character. The parity bit can be checked by the receiver for any transmission bit errors.

The interface supports word lengths from five to eight bits, an optional parity bit, and one or two stop bits. If enabled, parity can be odd, even, or forced to a defined state. Interrupts can be generated from any of 10 sources.

The UART controller supports both 16450 and 16550 compatible modes. The default mode is 16450. This mode provides independent 16-byte FIFOs for transmit and receive operations and is selected by the FIFO control register. It also includes a 16-bit programmable baud rate generator and an 8-bit scratch register, 8 modem control lines, and 2 DMA handshake lines that are used to indicate when the FIFOs are ready to transfer data to the CPU.

The UARTs support a device clock of up to 200 MHz. Each symbol requires 16 clock cycles for proper sampling and processing of the input data stream. Thus, the maximum baud rate is 200/16 = 12.5M. Because 1 symbol = 1 bit, the data rate is 12.5 Mbps.

All four UARTs are identical.

36.1.2 Hardware Features

The features supported by UART A, UART B, UART C, and UART D are:

- Synchronization for the serial data stream with start and stop bits to transmit data to and from a data character
- Data integrity by attaching a parity bit to the data character
- Support for word lengths from 5 to 8 bits, with an optional parity bit, and 1 or 2 stop bits
- Support for both 16450- and 16550-compatible modes. The default mode is 16450.
- DMA capable for both TX and RX
- 8 bit x 36 deep TX FIFO
- 11 bit x 36 deep RX FIFO
  - 3 bits of 11 bits per entry will log the RX errors in FIFO mode (break, framing, and parity errors as bits 10,9,8 of the FIFO entry)
- Auto sense baud detection
- Timeout interrupts to indicate if the incoming stream stopped
- Flow control support on RTS and CTS
- Internal loopback
- SIR encoding/decoding (3/16 or 4/16 baud pulse widths to transmit bit 0)

36.1.3 Hardware Signaling

All UARTs in the Tegra X1 device are implemented by a hardware block that supports modem control signals. For all UARTs, the DSRn and DCDn input signals are tied high (active); the RIn input signal is tied low; and the DTRn output signal is not connected.

Table 228: Serial Bus Interface Signals

Signal Name	Description
Outputs	
TXD	Transmit Data Port
RTS	Request to Send
DTRn	Data Terminal Ready
Inputs	
RXD	Receiver Data Port
CTS	Clear to Send
DSRn	Data Set Ready
DCDn	Data Carrier Detect
RIn	Ring Indicator

Note: *The DSR, DCD and RI modem control signals do not control any hardware other than generating interrupts and status on change.*

36.2 UART Programming Guidelines

36.2.1 16450 Mode Programming

1. Program pin mux settings to select a UART
2. Enable the UART clocks
3. For enabling internal loopback, program MCR[4] to 1
4. Program FCR[0] to 0
5. Enable interrupts in the IER register as needed
6. Write data into the THR register
7. Wait for a THR interrupt, if enabled, or poll for LSR[5]
8. During a receive, wait for an RDR interrupt or poll for LSR[0]/LSR[9]
9. Read the UART.LSR register to clear interrupts

36.2.2 16550 Mode Programming

1. Program pin mux settings to select a UART
2. Enable the UART clocks
3. For enabling internal loopback, program MCR[4] to 1
4. Program FCR[0] to 1
5. Program trigger levels as required
6. Enable interrupts in the IER register as needed
7. Write data into the THR register
8. Wait for a THR interrupt, if enabled, or poll for LSR[5]

9. During a receive, wait for an RDR interrupt or poll for LSR[0]/LSR[9]
10. Read the UART.LSR register to clear interrupts
11. The APB-DMA requester numbers for UARTs A, B, C, and D are 8, 9, 10, and 19, respectively

36.2.3 Transmitter and Receiver Holding Registers

The serial transmitter section consists of a Transmit Hold Register (THR) and Transmit Shift Register (TSR). The status of transmit hold register is provided in the Line Status Register (LSR). Writing to this register (THR) transfers the contents of data bus (D [7:0]) to the Transmit Holding Register whenever the Transmit Holding Register or Transmit Shift Register is empty. The Transmit Holding Register empty flag is set to 1 when the transmitter is empty or data is transferred to the Transmit Shift Register. Note that a write operation is performed when the Transmit Holding Register empty flag is set.

The serial receiver section also contains an 8-bit Receiver Holding/Buffer Register (RBR). Receive data is removed from the UART and received by the processor by reading the RBR. The receiver contains a mechanism for preventing false starts as follows: On the falling edge of the start bit, the receiver internal counter starts to count 7.5 clocks (16x clock), which is the center of the start bit. If the input goes high before counter reaches mid-point sampling, RX_FSM is moved back to the IDLE state and that is treated as a start bit glitch. Verifying the start bit prevents the receiver from assembling a false data character due to a low going noise spike on the RX input. Receiver status codes are posted in the Line Status Register.

36.2.4 FIFO Interrupt Mode Operation

When the receive FIFO (FCR bit 0 = 1) and receive interrupts (IER bit 0 = 1) are enabled, a receiver interrupt occurs as follows:

- The receive data available interrupts are issued to the CPU when the FIFO has reached its programmed trigger level; it is cleared as soon as the FIFO drops below its programmed trigger level.
- The ISR receive data available indication also occurs when the FIFO trigger level is reached, and like the interrupt, it is cleared when the FIFO drops below the trigger level.
- The data ready bit (LSR bit 0) is set as soon as a character is transferred from the shift register to the receiver FIFO. It is reset when the FIFO is empty.

36.2.5 FIFO Polled Mode Operation

When FCR bit 0 = 1; clearing IER bits [3:0] to zero puts the UART in the FIFO polled mode of operation. Since the receiver and transmitter are controlled separately, either one or both can be in the polled mode operation by using the line status register as follows:

- LSR bit 0 is set when the number of entries is greater than or equal to trigger level programmed
- LST bits [4:1] specify which error(s) have occurred
- LSR bit 5 indicates when the transmit FIFO is empty
- LSR bit 6 indicates when both transmit FIFO and transmit shift registers are empty
- LSR bit 7 indicates when there are any errors in the receive FIFO
- LSR bit 8 indicates when the transmit FIFO is full
- LSR bit 9 indicates RX FIFO empty status

The UART requires a two-step FIFO enable operation in order to enable receive trigger levels.

36.2.6 FIFO Enable Sequence Requirements

This sequence requires a minimum time interval of 3 * baud_clock_period between the point in time that the FIFO-enable write reaches the UART controller and the point in time that anything is written to the FIFO.

1. Write to the UART_FCR register to enable the FIFO.
2. Do a dummy read from a UART register with no read side-effects to ensure that the write reached the FIFO.

3. Delay for at least 3 * baud_clock_period before writing anything to the FIFO or expecting anything to enter the FIFO. (The delay is required to guarantee that FIFO is enabled internally in UART before any data is written to it.)

36.2.7 Programmable Baud Rate Generator

The UART contains a programmable baud rate generator that can take the UART clock input and divide it by any divisor from 1 to 2^{16}-1. Refer to the Clocking and Reset Controller section for definitions of the UART clocks. The output frequency of baudout is equal to 16X the transmission baud rate (Baudout=16 X baud rate). Customized baud rates are achieved by selecting proper divisor values for the MSB and LSB bits of the baud rate generator.

36.2.8 Enable Register (IER)

There is an Interrupt Enable Register for each UART. The Interrupt Enable Register(s) masks the incoming interrupts from the receiver ready, transmitter empty, line status, and modem status registers to the INT output pin.

36.2.9 Interrupt Identification Register (IIR)

The UART provides four level prioritized interrupt conditions to minimize software overhead during data character transfers. The Interrupt Identification Register (IIR) provides the source of the interrupt in a prioritized manner.

During the read cycle, the 16550 provides the highest interrupt level to be serviced by the CPU. No other interrupts are acknowledged until the particular interrupt is serviced. The prioritized interrupt levels are shown in the following table. The Receive Data Time-out mode is enabled when the UART is operating in the FIFO mode.

Receive time-out does not occur if receive FIFO is empty. The time-out counter is reset at the center of each stop bit received or each time the Receive Holding Register is read. The actual time out value is:

- T (Time out length in bits) = 4 X P (Programmed work length) + 12

To convert the time-out value to a character value, divide this number to its complete word length + parity (if used) + number of stop bits and start bit.

Example

If you program the word length = 7 with no parity and one stop bit, the time-out is:

- T = 4X7 (programmed word length) + 12 = 40 bits.
- Character time = 40/9
- [(Programmed word length = 7) + (stop bit = 1) + (start bit = 1)] =4.4 characters

Table 229: Prioritized Interrupt Levels

Priority	D3	D2	D1	D0	Interrupt Source Description
1	0	1	1	0	LSR (Receiver Line Status Register)
2	0	1	0	0	RXRDY (Received Data Ready)
2	1	1	0	0	RXRDY (Received Data Timeout)
3	0	0	1	0	TXRDY (Transmitter Holding Register)
4	0	0	0	0	MSR (Modem Status Register)

36.2.10 FIFO Control Register (FCR) Modes

The FIFO control register is used to enable the FIFOs, clear the FIFOs, set the receiver FIFO trigger level, and select the type of DMA signaling.

FCR bit 0 should be programmed to ‘1’ to operate the UART controller in FIFO (16450) mode. When FIFO mode is enabled, allow minimum of 3 baud cycles duration before writing TX_DATA into the THR_DLAB register.

The operation of the FCR in the four DMA modes is given below.

36.2.10.1 Transmit Operation in DMA Mode 0 or Mode 1

When the UART is in the 16450 mode (FCR bit 0 = 0) or in the FIFO mode (FCR bit 0 = 1, FCR bit 3 = 0) and when there are no characters in the transmit FIFO or Transmit Holding Register, the TXRDY* pin goes low. Once active, the TXRDY* pin goes high (inactive) after the first character is loaded into the Transmit Holding Register.

36.2.10.2 Receive Operation in DMA Mode 0

When the UART is in 16450 mode (FCR bit 0 = 0) or in the FIFO mode (FCR bit 0 = 1,FCR bit 3 = 0) and there is at least 1 character in the receive FIFO, the RXRDY* pin goes low. Once active, the RXRDY* pin goes high (inactive) when there are no more characters in the receiver.

36.2.10.3 Receive Operation in DMA Mode 1

When the UART is in the FIFO mode (FCR bit 0 = 1, FCR bit 3 = 1) and the trigger level or the timeout has been reached, the RXRDY* pin goes low. Once it is activated, it goes high (inactive) when there are no more characters in the FIFO.

36.2.11 Line Control Register (LCR)

The Line Control Register is used to specify the asynchronous data communication format. The word length, stop bits, and parity can be selected by writing appropriate bits in this register.

36.2.12 Modem Control Register (MCR)

This register controls the interface with the modem or a peripheral device (RS232).

Loopback Mode

If MCR[4] = 1, the loopback mode is enabled, and the following occurs:

The receiver input (RX), CTS, DSR, CD, and RI are disabled. Internally, the transmitter output is connected to the receiver input and DTR, RTS, OP1, and OP2 are connected to modem control inputs.

In this mode, the receiver and transmitter interrupts are fully operational, but the interrupt sources are now the lower four bits of the Modem Control Register instead of the four modem control inputs. The interrupts are controlled by the IER register.

Table 230: Modem Control Register (MCR)

Bit	Name	Description
7	N/A	Not used. Set to 0 internally.
6	RTS_EN	1 = Enable Hardware Flow Control using RTS 0 = Disable Hardware Flow Control
5	CTS_EN	1 = Enable Hardware Flow Control using CTS 0 = Disable Hardware Flow Control
4	LOOP	0 = Normal operating mode. 1 = Enable local loop-back mode (diagnostic).
3	OUT2	nOUT2 polarity
2	OUT1	nOUT1 polarity
1	RTS	1 = Force RTS (Request to Send) low 0 = Force RTS to high
0	DTR	1 = Force DTR (Data Terminal Ready) to low 1 = Force to high

36.2.13 Line Status Register (LSR)

The Line Status Register provides the status of data transfer to the CPU.

36.2.14 Modem Status Register (MSR)

The modem status register provides the current state of the control lines from the modem or peripheral to the CPU. Four bits of this register are used to indicate the changed information. These bits are set to 1 whenever a control input from the modem changes state. They are set to 0 whenever the CPU reads the register.

36.2.15 Scratchpad Register (SR)

Eight bits of information can be stored in this register. Information in this register does not affect the operation of the device in any way.

36.2.16 Autobaud Sense Register (ASR)

The UART can automatically determine the correct baud divisor by using the Autobaud Sense Register (UART offsets 0x3C). The most significant bit of this register is the valid flag. A write to this register will clear the valid flag and enable the autobaud process. When the first RX edge occurs, a counter running at 24 MHz starts counting. When another rx_edge occurs, the "complete" flag is set, the value is frozen, and the Autobaud Sense Value register is updated with the count value. The low 20 bits of the ASR give the number of clocks within a single bit. Because the UART uses 16x oversampling, the resulting value needs to be adjusted by shifting right 4 bits, then loading the resulting count in the divisor latch of the UART. (In the code snippet below, the lower 4 bits are rounded to give slightly greater accuracy.)

Because the speed determination is made by measuring the start bit, special characters must be sent by the transmitting UART to guarantee that the next character after the start bit is a 1. Since bit 0 (rightmost bit) is sent first, the ASCII Carriage Return character (CR) is sufficient to enable proper speed sense.

The following code snippet returns the values for DLH and DLL in r9, r8:

```
MOV r0, #1  ; dummy write data
STRB    r0, [r3, #U_ASR]; Start autobaud sense (r3 as uart_base)
; now poll the autobaud sense register MSB until Valid is true
wait4valid
 LDR    r2, [r3, #U_ASR]; Read ASR
 TST    r2, #0x80000000 ; the Valid bit (active high)
 BEQ    wait4valid
; autobaud sense check complete...
; r2 as number of 1x clocks in one bit time
; representing the number of 24MHz clocks in the start bit
; Since this represents 16 of the baud (16x) clocks, we
; will be dividing by 16 to get baud divisor, but first
; round to nearest by adding 8 before the divide:
 ADD    r4, r2, #8 ; add 1/2 resolution
 MOV    r6, r4, LSR #4 ; divide by 16... R6 will have total divisor
 AND    r8, r6, #0xFF  ; copy DLL to r8
 MOV    r9, r6, LSR #8 ; copy DLM to r9
 AND    r9, r9, #0xff ; mask upper bytes
```

36.2.17 Baud Rate Generator

The following table given below is a divisor table for the baud rate, assuming the oscillator is 24.000 MHz.

Table 231: Baud Rate Generator Programming

Baud Rate	Divisor
300	5000
1200	1250
2400	625

Table 231: Baud Rate Generator Programming

Baud Rate	Divisor
4800	312
9600	156
19.2K	78
38.4K	39
57.6K	26
115.2K	13

36.2.18 SIR Pulse Encoder/Decoder

The UART transmit (TX) data is passed through the SIR Pulse Encoder/Decoder module prior to being muxed out to the IR transmitter. This module converts transmitted zeros into a 3/16 Return-To-Zero (RZ) pulse.

Similarly, received (RX) data is bit-synchronized using the 16X baud clock and the original serial data recovered from the IR bit stream. This data is then sent to the UART for reception.

The signal generated in SIR is as follows:

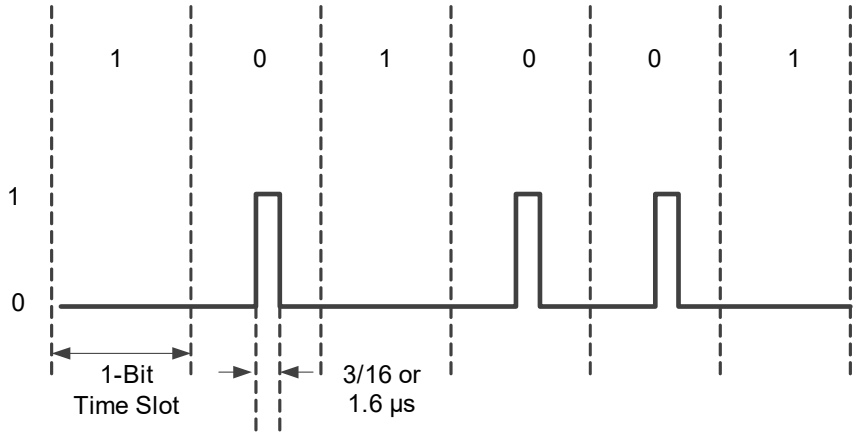
- On logic '1' the LED is off.
- On logic '0' a pulse is created starting the center of the bit time and lasting 3/16 of bit time period or 4/16 of bit time period depending on the current settings.

The figure below displays the output for the input 101001 (in sending order) in SIR encoding.

If SIR encoding/decoding has to be used in loopback mode, the following programming guideline/sequence is required:

1. Program SIR enable
2. Wait for a minimum of (4*baudclk)+ (4clk24m)
3. Program loopback enable

Figure 165: Output in Sending Order in SIR Encoding



36.2.19 UART Interrupts and Interrupt Service Routine (ISR)

There are multiple conditions on which a UART interrupt will be generated. Following are the interrupts available for the Tegra UART controller. Each of the interrupts is routed to an interrupt controller, if the corresponding Interrupt enable bit in the IER register is set.

1. EORD: This indicates an end of received data interrupt. This interrupt is set when UART RX detects there is no data being received for more than 4 character times. This is useful to determine that the transmitter is done with sending all its data. This interrupt is not generated if data is stopped because of handshaking.

2. RXT: RX_TIMEOUT interrupt occurs when data has been sitting in RX_FIFO for more than 4 character times due to some reason. One reason could be because there is not enough data to reach the trigger level. This interrupt needs to be handled by software to have data reception in a timely manner.
3. MSI: Modem status interrupt occurs when one of the CTS/RI/CD/DSR lines change state. The gap between state change for CTS toggle should be at least eight APB clock cycles and four APB cycles for RI/DSR and CD pins to allow internal synchronization and capture it as a delta change for interrupt generation. Each of the lines has a corresponding modem interrupt enable defined in the MIE register.
4. RXS: This interrupt indicates there are errors detected in the received data. The error could be break error/overrun error/parity error or framing error. A Break error occurs when a break condition (all zeros) has been detected on an RX line. An Overrun error indicates a new character reception from an external device when the RX FIFO is already full. Parity error occurs because of parity mismatch and framing error occurs when stop bit of a character received is '0' instead of '1'.
5. THR: This interrupt indicates the Transmit Holding Register is empty. In FIFO mode, this will be set when there is enough space in the FIFO based on trigger level setting so that software can start writing TX data into the THR register.
6. RDR: Receive data ready interrupt is asserted when number of entries in RX_FIFO has reached the trigger level programmed when in FIFO mode. This bit is an indicator to start reading the contents of RX_FIFO.

When uart_intr is asserted, software is expected to read the IIR register to know which interrupt occurred. The interrupts in the UART are prioritized and hence IIR always shows the current highest priority interrupt. If more than one interrupt is pending to be serviced, the one with the highest priority will be shown in IIR. When all interrupts have been serviced, IIR shows no_interrupt. The interrupt priority is defined per the encoding below (the priorities are listed highest to lowest):

IIR[3:0] priority level

- 0001: no interrupt
- 0110: Overrun Error, Parity Error, Framing Error, Break
- 0100: Receiver Data Available
- 1100: rx_timeout_intr
- 1000: eord_timeout_intr
- 0010: Transmitter Holding Register empty
- 0000: modem_status interrupt

The ISR (interrupt service routine) for UART interrupts is not same for all and varies depending on type of interrupt. This section summarizes the ISR expected for clearing each of the interrupt condition.

- RXS interrupt: LSR read clears this interrupt. RXS interrupt conditions include parity/break/overrun or framing error. Parity/break/framing errors also clear on RX FIFO pop operation.
- RDR/RX_TIMEOUT interrupt: These interrupts will be cleared on reading the Read buffer register
- EORD interrupt: IER[5] needs to be disabled to clear this interrupt. The bit can be re-enabled again to receive further interrupts.
- THR interrupt: IIR read or write to buffer data register will clear this interrupt. The interrupt keeps occurring until writes are performed to buffer the write register to fill the FIFO and reach the trigger level.
- Modem status interrupt: This interrupt clears on reading MSR register

Disabling interrupt_enable bit for any of the following interrupts will lead to clearing of uart_intr.

Bit	Reset	Description
3	0x0	IE_MSI: Interrupt Enable for Modem Status Interrupt 0 = DISABLE 1 = ENABLE

Bit	Reset	Description
2	0x0	IE_RXS: Interrupt Enable for Receiver Line Status Interrupt. The interrupt enable for RXS interrupt (IE_RXS) should be disabled whenever LSR is being polled/read to avoid spurious interrupts because of errors detected in RX data. LSR read is an interrupt clearing mechanism for RXS errors. 0 = DISABLE 1 = ENABLE
1	0x0	IE_THR: Interrupt Enable for Transmitter Holding Register Empty interrupt 0 = DISABLE 1 = ENABLE
0	0x0	IE_RHR: Interrupt Enable for Received Data Interrupt 0 = DISABLE 1 = ENABLE

Notes: *In case of an RX_TIMEOUT interrupt, once the interrupt is asserted, disabling only IE_RX_TIMEOUT before reading buffer data register might lead to a spurious case. At least one FIFO pop must have been done before disabling IE_RX_TIMEOUT only. IE_RHR, IE_THR, IE_RXS, or IE_MSI has to be disabled along with IE_RX_TIMEOUT in case IE has to be disabled before an RX FIFO pop operation.*

- *In the UART controller, status registers are also masked with corresponding IE bits unlike conventional controller's implementation.*

36.2.20 FIFO Flushing Guidelines

The UART controller provides TX_CLR and RX_CLR bits to flush the FIFOs. The FIFOs can be flushed independently or simultaneously by following the programming guidelines below:

Non-loopback mode:

- Simultaneous flush (TX_FLUSH and RX_FLUSH in single register write)
  a. Make sure there is no new data being written to TX buffer
  b. Program rts_enable to 0 (MCR[6])
  c. Make sure MCR[1] is 0
  d. Wait for 1 character time
  e. Issue flush requests - Program TX_CLR to 1 and RX_CLR to 1 (UART_IIR_FCR_0[2], UART_IIR_FCR_0[1])
  f. Wait 32 baud cycles
  g. Poll for TMTY to be '1' (UART_LSR_0[6])
  h. Poll for RDR to be '0' (UART_LSR_0[0])
  i. Re-enable rts_enable MCR[6]
  j. Perform new transfers
- Independent flush operations (TX/RX separately)

  TX flush:

  a. Make sure there is no new data being written to TX_buffer
  b. Program TX_CLR to 1 (UART_IIR_FCR_0[2] **-** TX_FLUSH request)
  c. Wait 32 baud cycles
  d. Poll for TMTY to be '1' (UART_LSR_0[6])
  e. Perform new transfers

  RX flush:

a. Program rts_enable to 0 (MCR[6])
b. Make sure MCR[1] is 0
c. Wait for 1 character time
d. Program RX_CLR to 1 (UART_IIR_FCR_0[1] **-** RX_FLUSH request)
e. Poll for RDR to be ‘0’ (UART_LSR_0[0])
f. Re-enable rts_enable MCR[6]
g. Perform new transfers

Loopback mode:

- Simultaneous flush operations do not work (TX_FLUSH and RX_FLUSH in a single register write). The only option is to disable the FIFO mode bit.
- Two independent flushes to be issued as mentioned below to flush both FIFOs:
  a. Program rts_enable to 0 (MCR[6])
  b. Make sure MCR[1] is 0
  c. Program TX_CLR to 1 (UART_IIR_FCR_0[2]**-** TX_FLUSH request)
  d. Wait 32 baud cycles
  e. Poll for TMTY to be ‘1’ (UART_LSR_0[6])
  f. Program RX_CLR to 1 (UART_IIR_FCR_0[1] **-** RX_FLUSH request)
  g. Poll for RDR to be ‘0’ (UART_LSR_0[0])
  h. Re-enable rts_enable MCR[6]
  i. Perform new transfers

36.2.21 Power-up Defaults

The Power-Up defaults are defined below:

- IER = 0
- IIR = 1
- LCR = 0
- MCR = 0
- LSR = 260 HEX
- MSR = Bits 0-3 = 0, Bits 4-7 = inputs line status
- TX = High
- RTS = High
- DTR = High
- RXRDY = Low
- TXRDY = Low
- INT = Low

36.3 UART Registers

Refer to Section 1.4: Reading Register Tables in the Introduction chapter for the register table protocol as well as recommendations for accessing registers.

The Tegra X1 UART is based on the 16550 industry standard Universal Asynchronous Receiver/Transmitter (UART), with enhancements to support autobaud detection and End-of-Received Data timeout detection.

The UART supports a device clock of up to 200 MHz, for a maximum baud rate of 12.5 Megabits per second.

The THR, RBR, and DLL registers all occupy the same address space.

- The Transmitter Holding Register (THR) is Write-Only, and can be accessed if the LSR.DLAB bit is clear.
- The Receiver Buffer Register (RBR) is Read-Only, and can be accessed if the LSR.DLAB bit is clear.
- The Divisor Latch LSByte Register (DLL) is Read/Write and can be accessed if the LSR.DLAB bit is set.

36.3.1 UART_THR_DLAB_0_0

UART Transmit Holding Register

Offset: 0x0 | Read/Write: R/W | Reset: 0x00000000 (0bxxxxxxxxxxxxxxxxxxxxxxxx00000000)

Bit	R/W	Reset	Description
7:0	RO	0x0	THR_A: Transmit holding register, holds the character to be transmitted by the UART. In FIFO mode, a write to this FIFO places the data at the end of the FIFO.
7:0	RO	X	RBR_A: Receive Buffer Register. Rx Data read from here.
7:0	RO	0x0	DLL_A: Divisor Latch LSB (low 8 bits of 16-bit Baud Divisor)

36.3.2 UART_IER_DLAB_0_0

The IER and DLH registers occupy the same address space, selected by the LSR.DLAB bit. The Interrupt Enable Register (IER) is selected if the LSR.DLAB bit is clear. The Divisor Latch MSByte register (DLM) is selected if the LSR.DLAB bit is set. The DLM register holds the upper 8 bits of the 16-bit Baud Divisor (16x).

UART Interrupt Enable por=0x00000000

RX_TIMEOUT occurs when data has been sitting in the Rx FIFO for more than 4 character times without being read because there is not enough data to reach the trigger level. Interrupt needed to handle this case so that all data is received in a timely manner. Note that this normally occurs at the end of an incoming data stream.

EORD (End of Receive Data) Interrupt occurs when the receiver detects that data stops coming in for more than 4 character times. This interrupt is useful for determining that the sending device has completed sending all its data. EORD timeout will not occur if the receiving data stream is stopped because of hardware handshaking.

To clear the EORD timeout interrupt you must DISABLE the EORD interrupt enable (IE_EORD).

Interrupt Enable and Divisor Latch MSByte Registers

Offset: 0x4 | Read/Write: R/W | Reset: 0x00000000 (0bxxxxxxxxxxxxxxxxxxxxxxxxxxxx000000)

Bit	Reset	Description
5	0x0	IE_EORD: Interrupt Enable for End of Received Data 0 = DISABLE 1 = ENABLE
4	0x0	IE_RX_TIMEOUT: Interrupt Enable for Rx FIFO timeout 0 = DISABLE 1 = ENABLE
3	0x0	IE_MSI: Interrupt Enable for Modem Status Interrupt 0 = DISABLE 1 = ENABLE
2	0x0	IE_RXS: Interrupt Enable for Receiver Line Status Interrupt 0 = DISABLE 1 = ENABLE

Bit	Reset	Description
1	0x0	IE_THR: Interrupt Enable for Transmitter Holding Register Empty interrupt 0 = DISABLE 1 = ENABLE
0	0x0	IE_RHR: Interrupt Enable for Received Data Interrupt 0 = DISABLE 1 = ENABLE

36.3.3 UART_IIR_FCR_0

The FCR and IIR registers occupy the same address space. The FIFO Control Register (FCR) is write-only. The Interrupt Identification Register (IIR) is read-only.

UART FIFO Control Register por=0x00000000

The DMA can run in one of two modes:

- If Mode0 is selected (NO_CHANGE), the Rx DMA request goes active whenever the Rx FIFO is not empty. Only single byte transactions can be performed in this mode. If the FIFO is not enabled, Mode0 MUST be used.
- If Mode1 is selected (CHANGE), the Rx DMA request goes active whenever the Rx FIFO trigger level is reached.

For best performance, always enable the FIFO and select DMA Mode 1.

For RX_TRIG, the FIFO_COUNT references the number of bytes in the receive FIFO.

For TX_TRIG, the FIFO_COUNT references the number of empty bytes in the transmit FIFO. For example, FIFO_COUNT_GREATER_16 means that there are at least 16 empty byte slots in the TX_FIFO.

UART Interrupt ID Register por=0x00000001

The Interrupt ID field indicates the current highest priority interrupt. If more than one interrupt is pending the one with the highest priority will be shown.

The table below shows the encoding. Priority flows from top (highest) to bottom (lowest).

Table 232: Interrupt ID Encoding

IIR[3:0]	Priority Level
0001	No interrupt
0110	Overrun Error, Parity Error, Framing Error, Break
0100	Receiver Data Available
1100	rx_timeout_intr
1000	eord_timeout_intr
0010	Transmitter Holding Register empty
0000	modem_status interrupt

UART FIFO Control and Interrupt Identification Registers

Offset: 0x8 | Read/Write: R/W | Reset: 0x00000000 (0bxxxxxxxxxxxxxxxxxxxxxxxxxx00000000)

Bit	Reset	Description
7:6	X	EN_FIFO: FIFO Mode Status 0=16450 mode(no FIFO) 1 = 16550 mode (FIFO) 1 = MODE_16550 0 = MODE_16450

Bit	Reset	Description
7:6	0x0	RX_TRIG: 0 = FIFO_COUNT_GREATER_1 1 = FIFO_COUNT_GREATER_4 2 = FIFO_COUNT_GREATER_8 3 = FIFO_COUNT_GREATER_16
5:4	0x0	TX_TRIG: 0 = FIFO_COUNT_GREATER_16 1 = FIFO_COUNT_GREATER_8 2 = FIFO_COUNT_GREATER_4 3 = FIFO_COUNT_GREATER_1
3	X	IS_PRI2: Encoded Interrupt ID Refer to IIR[3:0] table above 0 = DISABLE 1 = ENABLE
3	0x0	DMA: 0:DMA_MODE_0 1:DMA_MODE_1 0 = NO_CHANGE 1 = CHANGE
2	X	IS_PRI1: Encoded Interrupt ID Refer to IIR[3:0] table above 0 = DISABLE 1 = ENABLE
2	0x0	TX_CLR: 1 = Clears the contents of the transmit FIFO and resets its counter logic to 0 (the transmit shift register is not cleared or altered). This bit returns to 0 after clearing the FIFOs. 0 = NO_CLEAR 1 = CLEAR
1	X	IS_PRI0: Encoded Interrupt ID Refer to IIR[3:0] table above 0 = DISABLE 1 = ENABLE
1	0x0	RX_CLR: 1 = Clears the contents of the receive FIFO and resets its counter logic to 0 (the receive shift register is not cleared or altered). This bit returns to 0 after clearing the FIFO. 0 = NO_CLEAR 1 = CLEAR
0	X	IS_STA: Interrupt Pending if ZERO 0 = INTR_PEND 1 = NO_INTR_PEND
0	0x0	FCR_EN_FIFO: 1 = Enable the transmit and receive FIFOs. This bit should be enabled 0 = DISABLE 1 = ENABLE

36.3.4 UART_LCR_0

UART Line Control Register

Offset: 0xc │ Read/Write: R/W │ Reset: 0x00000000 (0bxxxxxxxxxxxxxxxxxxxxxxxxx00000000)

Bit	Reset	Description
7	0x0	DLAB: Divisor Latch Access Bit (set to allow programming of the DLH, DLM Divisors) 0 = DISABLE 1 = ENABLE
6	0x0	SET_B: Set BREAK condition -- Transmitter sends all zeroes to indicate BREAK 0 = NO_BREAK 1 = BREAK
5	0x0	SET_P: Set (force) parity to value in LCR [4] 0 = NO_PARITY 1 = PARITY

Bit	Reset	Description
4	0x0	EVEN: Even parity format. There will always be an even number of 1s in the binary representation (PAR = 1) 0 = DISABLE 1 = ENABLE
3	0x0	PAR: 0 = No parity sent 0 = NO_PARITY 1 = PARITY
2	0x0	STOP: 0 = Transmit 1 stop bit 1 = Transmit 2 stop bits (receiver always checks for 1 stop bit) 0 = DISABLE 1 = ENABLE
1:0	0x0	WD_SIZE: 3=Word length of 8 0 = WORD_LENGTH_5 1 = WORD_LENGTH_6 2 = WORD_LENGTH_7 3 = WORD_LENGTH_8

36.3.5 UART_MCR_0

The RTS and CTS pins are used for hardware handshaking with an external serial device. RTS (Request-To-Send) informs the device that the UART is ready to accept data. CTS (Clear-To-Send) comes from the RTS of the external device and indicates that data can be sent.

The RTS pin can be controlled manually with the RTS bit in the MCR or automatically by setting the RTS_EN bit.

If RTS_EN is set, the RTS pin automatically removes the Request-To-Send when the FIFO reaches the trigger level.

If the CTS_EN bit is set, the UART transmitter stops transmitting when the Clear-To-Send input is taken away.

UART Modem Control Register

Offset: 0x10 │ Read/Write: R/W │ Reset: 0x00000000 (0bxxxxxxxxxxxxxxxxxxxxxx00000000000)

Bit	Reset	Description
10	0x0	OLD_SIR_DECODE: Diagnostics bit to use the required SIR decode path. 0=new SIR decode path, 1=old SIR decode path 0 = DISABLE 1 = ENABLE
9:8	0x0	RI_POLARITY: Polarity selection bit for RI pin toggling to generate modem status interrupt. 0x0 - interrupt will be generated when RI pin toggles from low to high 0x1 - interrupt will be generated when RI pin toggles from high to low 0x2 - interrupt will be generated on RI delta change detection 0x3 – Reserved 0 = LOW_TO_HIGH 1 = HIGH_TO_LOW 2 = BOTH_EDGES 3 = RSVD
7	0x0	DEL_QUAL_CTS_EN: Diagnostics bit to use the old qualified CTS in TX state machine 1=use old qualified_cts 0= use the new qualified_cts in TX state machine 0 = DISABLE 1 = ENABLE
6	0x0	RTS_EN: 1 = Enable RTS Hardware Flow Control 0 = DISABLE 1 = ENABLE
5	0x0	CTS_EN: 1 = Enable CTS Hardware Flow Control 0 = DISABLE 1 = ENABLE

Bit	Reset	Description
4	0x0	LOOPBK: 1 = Enable internal loop back of Serial Out to In 0 = DISABLE 1 = ENABLE
3	0x0	OUT2: nOUT2 (Not Used) 0 = DISABLE 1 = ENABLE
2	0x0	OUT1: nOUT1 (Not Used) 0 = DISABLE 1 = ENABLE
1	0x0	RTS: 0 = Force RTS to high if RTS hardware flow control not enabled 0 = FORCE_RTS_HI 1 = FORCE_RTS_LOW
0	0x0	DTR: 1 = Force DTR to high 0 = FORCE_DTR_HI 1 = FORCE_DTR_LOW

36.3.6 UART_LSR_0

UART Line Status Register

POR = 0x00000260

Offset: 0x14 | Read/Write: RO | Reset: 0x00000XXX (0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx)

Bit	Reset	Description
9	X	RX_FIFO_EMPTY: 1=RX FIFO is empty 0=RX FIFO has at least one entry 0 = NOT_EMPTY 1 = EMPTY
8	X	TX_FIFO_FULL: Transmitter FIFO full status 0 = NOT_FULL 1 = FULL
7	X	FIFOE: 1 = Receive FIFO Error 0 = NO_ERR 1 = ERR
6	X	TMTY: Transmit Shift Register empty status 0 = NO_EMPTY 1 = EMPTY
5	X	THRE: 1 = Transmit Holding Register is Empty -- OK to write data 0 = FULL 1 = EMPTY
4	X	BRK: 1 = BREAK condition detected on line 0 = NO_BREAK 1 = BREAK
3	X	FERR: 1 = Framing Error 0 = NO_FRAME_ERR 1 = FRAME_ERR
2	X	PERR: 1 = Parity Error 0 = NO_PARITY_ERR 1 = PARITY_ERR
1	X	OVRF: 1 = Receiver Overrun Error 0 = NO_OVERRUN_ERROR 1 = OVERRUN_ERROR
0	X	RDR: 1 = Receiver Data Ready (Data available to read) 0 = NO_DATA_IN_FIFO 1 = DATA_IN_FIFO

36.3.7 UART_MSR_0

UART Modem Status Register

POR = 0x000000f0

Offset: 0x18 | Read/Write: R/W | Reset: 0x00000000 (0bxxxxxxxxxxxxxxxxxxxxxxxxx00000000)

Bit	Reset	Description
7	0x0	CD: State of Carrier detect pin 0 = DISABLE 1 = ENABLE
6	0x0	RI: State of Ring Indicator pin 0 = DISABLE 1 = ENABLE
5	0x0	DSR: State of Data set ready pin 0 = DISABLE 1 = ENABLE
4	0x0	CTS: State of Clear to send pin 0 = DISABLE 1 = ENABLE
3	0x0	DCD: Change (Delta) in CD state detected 0 = DISABLE 1 = ENABLE
2	0x0	DRI: Change (Delta) in RI state detected 0 = DISABLE 1 = ENABLE
1	0x0	DDSR: Change (Delta) in DSR state detected 0 = DISABLE 1 = ENABLE
0	0x0	DCTS: Change (Delta) in CTS state detected 0 = DISABLE 1 = ENABLE

36.3.8 UART_SPR_0

UART Scratchpad Register

Offset: 0x1c | Read/Write: R/W | Reset: 0x00000000 (0bxxxxxxxxxxxxxxxxxxxxxxxxx00000000)

Bit	Reset	Description
7:0	0x0	SPR_A: Scratchpad register (not used internally)

36.3.9 UART_IRDA_CSR_0

Bits [7:6] control the infrared (SIR) encoding. If enabled, each zero bit is transmitted as a short IR pulse. No pulse is sent during idle or '1' data bits. The IR pulse can be either 3/16 or 4/16 of a normal bit time.

The low 4 bits control signal polarity and apply whether or not SIR coding is enabled.

UART IrDA Pulse Coding CSR Register

Offset: 0x20 | Read/Write: R/W | Reset: 0x00000000 (0bxxxxxxxxxxxxxxxxxxxxxxxxx00xx0000)

Bit	Reset	Description
7	0x0	SIR_A: 1 = Enable SIR coder 0 = Disable SIR coder 0 = DISABLE 1 = ENABLE

Bit	Reset	Description
6	0x0	PWT_A: 0=3/16th Baud Pulse, 1=4/16 0 = BAUD_PULSE_3_14 1 = BAUD_PULSE_4_14
3	0x0	INVERT_RTS: Inverts the normally inactive high nRTS pin 0 = DISABLE 1 = ENABLE
2	0x0	INVERT_CTS: Inverts the normally inactive high nCTS pin 0 = DISABLE 1 = ENABLE
1	0x0	INVERT_TXD: Inverts the normally inactive high TXD pin 0 = DISABLE 1 = ENABLE
0	0x0	INVERT_RXD: Inverts the normally inactive high RXD pin 0 = DISABLE 1 = ENABLE

36.3.10 UART_RX_FIFO_CFG_0

Offset: 0x24 | Read/Write: R/W | Reset: 0x00000001 (0bxxxxxxxxxxxxxxxxxxxxxxxxxx0x000001)

Bit	Reset	Description
7	0x0	EN_RX_FIFO_TRIG: Enable use of RX_FIFO_TRIG count (obsoletes RX_TRIG when enabled) 0 = DISABLE 1 = ENABLE
5:0	0x1	RX_FIFO_TRIG: Set RX_FIFO trigger level (any value 1 thru 32)

36.3.11 UART_VENDOR_STATUS_0_0

UART Controller Status Register

Offset: 0x2c | Read/Write: RO | Reset: 0xXXXX000X (0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx)

Bit	Reset	Description
29:24	X	TX_FIFO_COUNTER: The entry in this field reflects the number of current entries in the TX FIFO
21:16	X	RX_FIFO_COUNTER: The entry in this field reflects the number of current entries in the RX FIFO
3	X	TX_OVERRUN: This bit is set to 1 when write data is issued to the TX FIFO when it is already full and gets cleared on register read (sticky bit until read) 0 = NO_OVERRUN 1 = OVERRUN
2	X	RX_UNDERRUN: This bit is set to 1 when a read is issued to an empty FIFO and gets cleared on register read (sticky bit until read) 0 = NO_UNDERRUN 1 = UNDERRUN
1	X	Reserved
0	X	Reserved

36.3.12 UART_ASR_0

The UART has autobaud sensing logic that can measure the width of the start bit of incoming data to determine baud rate. For this to work, the incoming character must have its LSB set. A <cr> works well (0x0d). The logic uses the UART device clock to count how wide the start pulse is, and the BUSY bit is set when the sensing is complete. The value in {RX_RATE_SENSE_H,RX_RATE_SENSE_L} should be divided by 16 with Round-to-Nearest, and the resulting value loaded into the DLM,DLL register pair to set the Baud Clock to 16X the Baud Rate.

UART Auto Sense Baud Register

Offset: 0x3c | Read/Write: R/W | Reset: 0x00000000 (0b00xxxxxxxxxxxxxx0000000000000000)

Bit	Reset	Description
31	0x0	VALID: This bit is set when the controller finishes counting the clocks between two successive clock edges after there is a write to ASR with don't care data. 0 = UN_SET 1 = SET
30	0x0	BUSY: This bit is set when there is a write to ASR and is reset when the controller finishes counting the clock edges between two successive clock edges. 0 = NO_BUSY 1 = BUSY
15:8	0x0	RX_RATE_SENSE_H: Shows bits [15:8] of the count of clock edges between two successive clock edges.
7:0	0x0	RX_RATE_SENSE_L: Shows bits [7:0] of the count of clock edges between two successive clock edges.

CHAPTER 37: SERIAL PERIPHERAL INTERFACE (SPI) CONTROLLER

The Serial Peripheral Interface (SPI) controller is a serial communications link between the processor and on-chip/off-chip serial peripheral devices such as sensors, ADC/DAC devices, and Flash controllers. Tegra® X1 devices support both Master and Slave modes of SPI operation on this interface. There are four SPI controllers in each Tegra X1 device with six pinmuxing options.

In this section:

- *Word* refers to 32-bit data in the TX or RX FIFO
- *Packet* refers to variable length data that is transmitted or received
  - Packet size can be any length from 4 to 32 bits in Master Unpacked mode or 8 to 32 bits in Slave Unpacked mode
  - In Packed Mode, packet size can be 4, 8, 16, or 32 bits

37.1 Functionality

The Tegra X1 SPI Controller works as a Master/Slave on the SPI bus. It has independent transmit and receive FIFOs of 64 x 32 bits each. Software can program the controller to generate transactions of a required packet length on the SPI bus, where a transaction is a sequence of packets in either direction.

The controller supports either APB DMA or program transfer to read and write from the FIFOs as required. At the end of each transaction, an interrupt can be generated, if enabled. Software uses transmit and receive operations in combination with chip select (CS) control to generate commands on the SPI bus.

The interface consists of four signals: Chip Select/Slave Select (CS_N), Clock (SCLK), Master Data Out and Slave Data In (MOSI), and Master Data In and Slave Data Out (MISO).

Features

- Master and Slave functionality
  - Master: All transmission format modes are supported for both transmit and receive operations
  - Slave (transmits): Modes 1 and 3 are supported
  - Slave (receives): All modes are supported
- Independent Rx and Tx FIFOs
- FIFO depth of 64 x 32 bits
- Programmable bit lengths, resulting in packet sizes of 4 to 32 bits
- PIO or DMA Mode depending on packet size

  Options include Packed/Unpacked, Full-Duplex Mode, Both Enable Bit (x2 Mode), Bidirectional, Least Significant Bit, Least Significant Byte First (Endian-ness), software or hardware chip-select polarity selection
- Programmable clock phase and polarity
- Programmable delay between consecutive transfers
- Packed mode support for bit lengths of 3 (4-bit packet size), 7 (8-bit packet size), and 15 (16-bit packet size)
- Chip select (CS) can be controlled by software or can be generated automatically by hardware on packet boundaries
- Maximum 4-chip support with programmable CS polarity for each chip select
- DMA support
- Simultaneous receive and transmit operations supported

- The maximum data rate is 65 Mbps in master mode and 45 Mbps in slave mode.

37.1.1 Transmission Format

Using the Mode field in the SPI Command1 Register, software sets one of the four modes in which the SPI controller works. The two bits of the Mode field specify the idle (inactive) state of SCLK before the chip select is asserted and the data transmitting/ receiving edges of SCLK. Mode [1] determines the SCLK polarity. If the polarity is 0, then the SCLK signal is 0 when idle and transitions to 1 when data transfer starts. If the clock polarity is 1, then the SCLK signal is 1 when idle and transitions to 0 when data transfer starts. Mode [0] is the SCLK phase control bit. If the clock phase is 0, then the receiver latches the data on the first transition of SCLK from the idle state. If the clock phase is 1, then the receiver latches the data on the second transition of SCLK.

Modes supported by the SPI controller are:

- Master: All transmission format modes are supported both for transmitting and receiving
- Slave: Modes 1 and 3 are supported for transmitting
- Slave: All modes are supported for receiving

The following table defines the four modes for the SPI protocol.

Table 233: SPI Modes with Clock Polarity and Phase

SPI Mode	Clock Polarity	Clock Phase	SCLK Inactive State	Data Latch IN	Data Latch OUT
0	0	0	Low	Latched IN on the positive edge of clock	Latched OUT on the negative edge of clock
1	0	1	Low	Latched IN on the negative edge of clock	Latched OUT on the positive edge of clock
2	1	0	High	Latched IN on the negative edge of clock	Latched OUT on the positive edge of clock
3	1	1	High	Latched IN on the positive edge of clock	Latched OUT on the negative edge of clock

37.1.2 Modes of Operation

37.1.2.1 Master and Slave Modes

The SPI controller can be configured to operate as a Master or Slave. When the M/S bit in the SPI Command1 Register is set, Master mode is selected; when the M/S bit in the SPI Command1 Register is cleared, Slave mode is selected. Only the SPI Master can initiate a transaction.

In Master mode, data from the Tx FIFO is transmitted on the MOSI pin. The data from the slave is received on the MISO pin and sent to the Rx FIFO. The Master can simultaneously transmit and receive on MOSI and MISO in Full-Duplex Mode.

In Slave mode, once software enables the SPI controller by setting the PIO bit, it simply waits for the Master to initiate a transaction. Before the transaction begins, the slave logic continuously polls the CS input. When the Master asserts CS and SCLK is transmitted to the Slave, the Slave data is transmitted from the Tx FIFO on MISO and data from MOSI is received in the Rx FIFO. The Slave can also simultaneously transmit and receive on MOSI and MISO in Full-Duplex Mode.

Table 234: Master Mode Port Configuration

Name	Direction	Description
MOSI	Bidirectional	Output in Full-Duplex/Tx Mode Input in Both_Enable Rx Mode
MISO	Bidirectional	Input in Full-Duplex/Rx Mode
SCLK	Output	Output in Both_Enable TX Mode
CS_#x	Output	Slave select signal to x, where x is a number between 0 to 3

Table 235: Slave Mode Port Configuration

Name	Direction	Description
MISO	Bidirectional	Output in Full-Duplex/Tx Mode Input in Both_Enable Rx Mode
MOSI	Bidirectional	Input in Full-Duplex/Rx Mode Output in Both_Enable TX Mode
SCLK	Input	Synchronization clock received from the Master
CS_#	Input	Select signal

When the SPI controller is configured to interface with multiple slaves, the controller has one CS signal for each slave, up to a maximum of four slaves. During a transfer, the master asserts CS specified in the CS_SEL bits in SPI Command1 Register. There can be no more than one slave transmitting data during any particular transfer.

37.1.2.2 DMA and PIO Modes

PIO and DMA are the two main operational modes for the SPI controller. PIO mode is used when the number of packets to the transmitter or receiver is less than or equal to 64. DMA mode is used when the number of packets to the transmitter or receiver is greater than 64. In PIO or DMA mode, the SPI controller sends an interrupt to the processor at the end of each transfer. In this mode software configures the number of packets and number of bits in each packet to be transmitted/received. The limitation of PIO Mode is that it can be used only if the maximum number of packets that can be transferred is less than or equal to 64 packets (the FIFO depth is 64). If software wants to transmit/receive more than 64 packets in PIO Mode, it has to reconfigure the SPI controller every 64 packets.

To send/receive more than 64 packets, the SPI Controller can be configured in DMA mode (enabled by writing 1 to the DMA_EN bit in the SPI DMA Control Register). The SPI controller transmits or receives the number of packets as indicated by the BLOCK_SIZE field in the SPI Block Size Register. BLOCK_SIZE is a 16-bit field, so 2^{16} packets (amounting to 256 KB) can be transmitted/received in a single software configuration.

37.1.2.3 Continuous Mode

Continuous Mode means:

- In Master Mode, the SPI Controller can transfer data continuously with an external device, unless interrupted by software.
- In Slave Mode, the SPI Controller can transfer data continuously with an external device, unless interrupted by software or an external Master de-asserts chip select (CS). In the CS de-assert case, the SPI controller can generate an interrupt based on intr mask bit.

Notes:

- *This mode can be enabled only in DMA mode, NOT in PIO mode. The SPI Controller will not consider the "DMA_BLOCK_SIZE" register in this mode.*
- *To perform two consecutive back-to-back continuous mode transfers, the SPI controller must be reset after the first continuous mode transfer before the subsequent continuous mode transfer can occur.*
- *In SPI slave continuous mode, the last data packet is not pushed into the RX FIFO if CS has been de-asserted at the 0xffff(+1) boundary by the external master. The last packet will be pushed into the slave buffer when CS comes back the next time; otherwise it is lost.*

SPI Controller Configured as Master

When the SPI Controller is configured as a Master, it can transfer any amount of data unless software disables the SPI Controller by clearing (write 1 to clear) the DMA_EN bit. The SPI Controller generates CS and Sclk accordingly throughout the data transfer. Along with the SPI Controller, the APB DMA also needs to be configured in Continuous Mode. Refer to the APB section in this TRM for more information.

- Errors and Interrupt generation:

  In Master Continuous Mode, the SPI controller will not generate TX_FIFO Underrun or RX_FIFO Overrun errors. These errors generally occur in slave mode when the APB DMA does not write data into the TX_FIFO or does not read data from the RX_FIFO fast enough due to system bandwidth/arbitration issues. In such cases, the SPI Controller keeps waiting for the APB DMA to write data into the TX_FIFO or read data from the RX_FIFO. During such waiting periods (Idle periods), the SPI Controller stops generating Sclk but keeps CS asserted. Once data is available in the TX_FIFO or enough space is available in RX_FIFO, the SPI Controller resumes the data transfer and generates Sclk, continuing the CS in the asserted state.

- Disabling the SPI Controller in Master Continuous Mode:

  In Master Continuous Mode, the SPI Controller can be disabled only by clearing (write 1 to clear) the DMA_EN bit by software. The SPI Controller will not be disabled in any other way by hardware.

  - Generally software is recommended to clear (write 1 to clear) the DMA_EN bit when the Controller is in the Idle state.
  - If software clears the DMA_EN bit during the Active state (when a transaction is in process, i.e., CS is asserted and Sclk is present), the SPI Controller will write the last received partial/full word (whatever is present in the shift register) up to the point before disabling the DMA_EN bit into the RX_FIFO and increments the blk_count_received register.

SPI Controller Configured as Slave

When the SPI Controller is configured as a Slave, it can transfer any amount of data unless:

- Software disables the SPI Controller by clearing the DMA_EN bit (write 1 to clear) (or)
- External SPI Master Device de-asserts Chip Select.
- External SPI Master Stops sending Sclk for SLV_IDLE_COUNT No.of Clocks.

Errors and Interrupt Generation

In Slave Continuous Mode, the SPI controller will generate TX_FIFO Underrun or RX_FIFO Overrun errors. These errors generally occur when APB DMA does not write data into the TX_FIFO or does not read data from RX_FIFO fast enough due to system bandwidth/arbitration issues. In such cases, the SPI Controller generates an error condition, sets the TX_FIFO_URN or RX_FIFO_OVR bits, and generates an interrupt. If an Overflow happens, data in the RX_FIFO will not be corrupted.

Disabling the SPI Controller in Slave Continuous Mode:

In Slave Continuous Mode, the SPI Controller can be disabled by software clearing the DMA_EN bit.

Generally, software is recommended to clear the DMA_EN bit when the SPI Controller is in the Idle state (the Idle state is defined as when there is no input Sclk to the Tegra SPI slave from the External Master device and/or CS is inactive).

If software clears the DMA_EN bit during the Active state (the Active state is defined as when there is an input Sclk to the Tegra SPI slave from the External Master device and CS is active), the SPI Controller will write the last received partial/full word (whatever is present in shift register) into the RX_FIFO and increments blk_count_received register.

Disabling the SPI Controller by an External Master Device

When the SPI Controller is configured in Slave Continuous Mode, the External Master can start a data transfer by generating CS and Sclk to the Slave SPI. Once the External Master finishes the data transfer (tx, rx, or both), it will stop generating Sclk and then de-assert CS. The SPI Slave treats this as an end of transaction and generates an Interrupt along with clearing the DMA_EN bit. The SPI Controller will write the last received partial/full word (whatever is present in the shift register before CS is de-asserted) into the RX_FIFO and increments the blk_count_received register. This will be true even if CS is deasserted in an unaligned word boundary (i.e., CS deassertion can happen only at a packet boundary).

In Slave Error cases (RX_FIFO_OVR), the blk_count_received register is incremented first and then the RX_FIFO is written. So when RX_FIFO_OVR happens, the blk_count_received also shows 1 word extra compared to what is actually present in the RX_FIFO.

The SPI Controller will not generate a CS_deassert interrupt at the very end when the actual programmed blk_size is done. That time CS is de-asserted by the master normally. Software will get a done interrupt in this case.

CS_INACTIVE Bit in SPI FIFO Control/Status Register

In the CS de-assert case, the SPI controller can generate interrupts provided the interrupt Mask bit is set low by the software and sets the CS_INACTIVE bit of SPI FIFO Control/Status Register indicating CS is de-asserted by an External Master. Software has to clear this bit while addressing the interrupt. If interrupt Mask bit is set high, the CS_INACTIVE bit of the SPI FIFO Control/Status Register will still be set high by the SPI Controller, but the interrupt is not generated.

Notes:

- *If the CS deassert interrupt mask is set low (i.e., the interrupt is enabled), the SPI Slave Controller generates an interrupt if CS is de-asserted and all the data in the RX shift register, until the point CS is de-asserted, is written into the RX_FIFO.*
- *If the CS deassert interrupt mask is set high (i.e., the interrupt is disabled), the SPI Slave Controller does not generate an interrupt if CS is de-asserted and treats it as a PAUSE condition and it DOES NOT write all the data in the RX shift register into the RX_FIFO until the CS is asserted back.*
- *In both the above cases, CS deassertion Interrupt generation is independent of the Clock provided by the External Master.*

FRAME_END in SPI FIFO Control/Status Register

In Slave Continuous Mode, if Sclk is not received for the number of clocks specified in the SLV_IDLE_COUNT field and CS is asserted, then the continuous mode is terminated and this status bit is set. Continuous Mode is terminated if the condition is met. In this case, an interrupt is generated.

Currently, software has two use cases:

- In Slave Continuous mode, software mainly will use the pause feature (mask the CS de-assert interrupt), because the use case will be such that there will be continuous audio steaming and it is not desired for the slave to be stopped based on CS de-assert.
- In Slave non-continuous mode, where the use case is based on variable length data coming in from the external master, software will use the non-pause feature (enable the CS de-assert interrupt) so that software can read the received chunk of data based on the CS de-assert interrupt.

In the Non-Pause case, continuous mode termination can happen with CS deasserted or DMA disabled.
In the Pause case, continuous mode termination can happen only with DMA disable. Until the DMA is disabled, it is the same continuous mode transaction and continues forever until the DMA is disabled.

37.1.2.4 Packed and Unpacked Modes

SPI communication can be carried out in Packed or Unpacked Mode. These are both present in DMA and PIO Modes.

- Packed Mode: In Packed Mode, data can be transmitted/received with each packet size equal to 4, 8, 16, or 32 bits. The PACKED field and BIT_LEN field in the DMA Command1 Register determine if the mode Packed or Unpacked and the length of each packet. If the BIT_LEN field is set to 03h, each packet is 4 bits long and each word in the Tx/Rx FIFO contains 8 such packets. Similarly, if BIT_LEN is 07h, the packet length is 8. If BIT_LEN is 0Fh, the packet length is 16. If BIT_LEN is 1Fh, the packet length is 32. In Packed Mode, if BIT_LEN is set to 03h and if the number of packets is set to a non-multiple of 8 (for example, 9), the last word in FIFO contains only the ninth packet with 4 valid bits; 28 extra invalid bits will be ignored by the controller for transmits and will contain invalid data for receives.
- Unpacked Mode: If BIT_LEN is set to 03h, then each word in the Tx/Rx FIFO has 4 bits with the remaining bits in each word being ignored. BIT_LEN can be any value from 3 to 31 in Unpacked Mode.

37.1.2.5 Bidirectional Mode

Bidirectional mode is selected when the BIDIR bit is set in the SPI Command1 Register. In this mode, the SPI controller uses only one serial data pin for the interface with external device(s). The M/S bit decides which pin to use. The MOSI pin becomes the serial data I/O (MOMI) pin for the Master Mode, and the MISO pin becomes serial data I/O (SISO) pin for the Slave Mode. The SPI controller does not use the MISO pin in Master Mode and the MOSI pin in Slave Mode.

Table 236: Bidirectional Mode Port Configuration for Master (M/S Bit Set)

Name	Direction	Description
MOSI > MOMI	Bidirectional	Data Output and Input to Slave(s)
MISO > --	--	--
SCLK	Output	Synchronization clock to all Slaves
CS	Output	Slave select signal to x, where x is a number from 0 to 3, inclusive

Table 237: Bidirectional Mode Port Configuration for Slave (M/S Bit Cleared)

Name	Direction	Description
MOSI > --	--	--
MISO > SISO	Bidirectional	Data Output and Input from Slave(s)
SCLK	Input	Synchronization clock
CS	Input	Select signal

37.1.2.6 Both Enable Bit Mode (SPI x2 Mode)

The Both Enable Bit Mode is selected when the BOTH_EN_BIT bit is set in the SPI Command1 Register. In Both Enable Bit Mode, a packet from the Tx FIFO is transmitted or received on both MOSI and MISO data lines. Even bits are transmitted or received on the MOSI data line and odd bits are transmitted or received on the MISO data line. This is the same in both Master and Slave Modes.

37.1.2.7 En_LE_Bit and En_LE_Byte Modes

Note: *En_LE_Bit is Enable Little Endian Bit, and En_LE_Byte is Enable Little Endian Byte.*

These two bits allow a data packet to be transmitted or received in Little Endian or Big Endian format. Once a data packet is read from the Tx FIFO, it undergoes a two-step pre-processing based on En_LE_Byte and En_LE_Bit.

Step 1. In this step, En_LE_Byte configures whether a packet has to be arranged internally according to the Little Endian byte format or Big Endian byte format. For example, if a 2-byte packet is written into the FIFO by software as Byte 1,Byte 0, setting En_LE_Byte = 0 makes the SPI controller arrange the packet internally as Byte 0,Byte 1(Big Endian format). If En_LE_Byte = 1, the SPI controller internally arranges the packet as Byte 1,Byte 0 (Little Endian format) before the packet is transmitted.

Step 2. In this step, the output of Step 1 is taken, and data is put on the MOSI/MISO line according to En_LE_Bit. If En_LE_Bit is set to 0, the most significant bit of the output of Step 1 is put on the MOSI/MISO line first. If En_LE_Bit is set to 1, the least significant bit of Step 1 output is put on the MOSI/MISO line.

These steps are illustrated in the following table.

Step 1	FIFO Packet (MSB - LSB)	Byte	Output of Step 1
	Byte 1, Byte 0	0	Byte 0, Byte 1
		1	Byte 1, Byte 0

Step 1	FIFO Packet (MSB - LSB)	Byte	Output of Step 1
Step 2	Output of Step 1	Bit	Data Transmitted on MOSI (Right-most Bit Sent First)
	Byte 0, Byte 1	0	Byte 1 (0), Byte 1 (1), …, Byte 0 (6), Byte 0 (7)
	Byte 0, Byte 1	1	Byte 0 (7), Byte 0 (6), …, Byte 1 (1), Byte 1 (0)
	Byte 1, Byte 0	0	Byte 0 (0), Byte 0 (1), …, Byte 1 (6), Byte 1 (7)
	Byte 1, Byte 0	1	Byte 1 (7), Byte 1 (6), …, Byte 0 (1), Byte 0 (0)

Similarly for Receive operations, the first packet received will be internally rearranged first based on En_LE_Bit, then the output of the previous step will be rearranged based on En_LE_Byte before writing the final packet into the Rx FIFO.

The following examples explain the effect of these two bits:

- Unpacked Mode
  - Tx: The following example shows how a 20-bit length packet from the FIFO is transmitted. The right-most bit in Column D in the table below is transmitted first. B.7-B.0 indicates that bit 0 is transmitted first followed by bit 1 until bit 7, which is transmitted last.

A	B	C	D
FIFO WORD: 20 (MSB) – 0 (LSB)	En_LE_Bit	En_LE_Byte	Data Transmitted on MOSI/MISO Line
	0	0	16, 17,18, 19, 20, B.8-B.15, B.0-B.7
	0	1	B.0-B.7, B.8-B.15, 16, 17, 18, 19, 20
	1	0	B.7-B.0, B.15-B.8, 20, 19, 18, 17, 16
	1	1	B.20-B.0

  - Rx: The following example shows how a 20-bit length packet from the FIFO is received. The right-most bit in Column D in the table below is received last on the MOSI/MISO lines. B.7-B.0 indicates that bit 7 is received first followed by bit 6 until bit 0, which is received last. B.20 – B.0 are always written into the FIFO after the En_LE_Byte and En_LE_Bit transformations.

A	B	C	D
FIFO WORD: 20 (MSB) – 0 (LSB)	En_LE_Bit	En_LE_Byte	Data Received on MOSI/MISO Line
	0	0	B.7-B.0, B.15-B.8, 20, 19, 18, 17, 16
	0	1	20, 19, 18,17, 16, B.15-B.8, B.7-B.0
	1	0	16, 17, 18, 19, 20, B.8-B.15, B.0-B.7
	1	1	B.0-B.20

- Packed Mode
  - Tx: The following example shows how 3 16-bit packets are transmitted. Column B indicates the valid packets to be transmitted. Because FIFO Word2 is not transmitted entirely, valid packets are only from B.15-B.0. In Column D, P1(0 -15) indicates Packet1 of Column B is transmitted, B.15 is transmitted first, and B.0 is transmitted last.

A	B: Valid Packets	B	C	D
FIFO WORD1: 31 (MSB) – 0 (LSB)	P1(15-0), P0(15-0)	En_LE_Bit	En_LE_Byte	Data Transmitted on MOSI/MISO Line
FIFO WORD2: 31 (MSB) – 0 (LSB)	P2(15-0)	0	0	P2(8-15), P2(0-7), P1(8-15), P1(0-7), P0(8-15), P0(0-7)
		0	1	P2(0-7), P2(8-15), P1(0-7), P1(8-15), P0(0-7), P0(8-15)
		1	0	P2(7-0), P2(15-8), P1(7-0), P1(15-8), P0(7-0), P0(15-8)

A	B: Valid Packets	B	C	D
		1	1	P2(15-8), P2(7-0), P1(15-8), P1(7-0), P0(15-8), P0(7-0)

- Rx: The following example shows how 3 16-bit packets are received. Column B indicates the valid received packets in the Rx FIFO. In column D, P1(0 -15) indicates Packet1 of Column B is received, B.0 is received first, and B.15 is received last.

A	B: Valid Packets	B	C	D
FIFO WORD1: 31 (MSB) – 0 (LSB)	P1(15-0), P0(15-0)	En_LE_Bit	En_LE_Byte	Data Received on MOSI/MISO Line
FIFO WORD2: 31 (MSB) – 0 (LSB)	P2(15-0)	0	0	P0(7-0), P0(15-8), P1(7-0), P1(15-8), P2(7-0), P2(15-8)
		0	1	P0(15-8), P0(7-0), P1(15-8), P1(7-0), P2(15-8), P2(7-0)
		1	0	P0(8-15), P0(0-7), P1(8-15), P1(0-7), P2(8-15), P2(0-7)
		1	1	P0(15-8), P0(7-0), P1(15-8), P1(7-0), P2(15-8), P2(7-0)

37.2 SPI Programming Guidelines

There are two basic modes of operation: DMA and PIO modes. It is required that software sets up all parameters in the SPI Command1 and Command2 registers, SPI CS Timing 1 and 2 registers, SPI FIFO Control/Status register, SPI DMA Control register, and SPI Block Size register before enabling the PIO bit in any of these modes.

37.2.1 DMA Mode

This mode is enabled by writing 1 to the DMA bit in the SPI DMA Control register. In this mode, the SPI controller transmits or receives the number of packets as indicated by the BLOCK_SIZE field in the SPI Block Size register.

If the PACKED bit is set and BIT_LEN is set to 7, then all FIFO words contain 4 packets to transfer (transmit or receive). Packets will be transferred as per the En_LE_Bit and En_LE_Byte bit configurations (see the En_LE_Bit and En_LE_Byte Modes section), with packet 0 in byte 0 of the FIFO and packet 3 in byte 3 of the FIFO.

In Unpacked Mode, if BIT_LEN is set to N, each packet will consist of (N + 1) bits. These bits will be transmitted/received in the Tx_FIFO/Rx_FIFO as per the En_LE_Bit and En_LE_Byte bit configurations (see the En_LE_Bit and En_LE_Byte Modes section). Any remaining bits in the FIFO will be ignored by the hardware. The maximum packet length is 32, which can be selected by setting BIT_LEN to 31. In this case, all data bits in the FIFO contain valid packet data.

A DMA request will be generated to APB_DMA in this mode depending on the setting of Tx_TRIG and Rx_TRIG. If transmits are enabled, setting Tx_TRIG to 00 will generate a Tx DMA request whenever the Tx FIFO has one word of space available (if not full). Setting Tx_TRIG to 01 will generate a Tx DMA request whenever the Tx FIFO has 4 words of space available. If receives are enabled, setting Rx_TRIG to 00 will generate an Rx DMA request whenever the Rx FIFO has one word of data available (is not empty). Setting Rx_TRIG to 01 will generate an Rx DMA request whenever the Rx FIFO has 4 words of data available.

37.2.2 PIO Mode

This mode is enabled by writing 1 to the PIO bit in the SPI Command1 register. In this mode, the SPI controller transmits/ receives as many packets as configured by software in the SPI Block Size Register.

Note: *Software must wait for the RDY bit, whether in polling mode or interrupt mode, for confirmation of transfer completion.*

PIO Mode has the same features as DMA Mode. The difference between PIO Mode and DMA Mode is that in PIO Mode, the maximum number of packets that can be transmitted or received is less than or equal to 64.

37.2.3 Interrupt Generation

The SPI controller generates an interrupt to the processor at the end of a transfer in PIO Mode or when an error is detected (both in PIO and DMA Modes) if the IE.TX or IE.RX bit in the SPI DMA Control register is enabled for transmit and receive modes of operation, respectively.

If IE.TX is enabled during transmits, an interrupt is generated whenever RDY or one of the FIFO status bits in the SPI FIFO Control/Status Register is set by the hardware. During transmits, when the SPI controller is configured as a Slave, if software/APB DMA cannot fill the transmit FIFO fast enough, hardware will set the Tx_FIFO_UNR bit and an underrun condition is generated. If software tries to write to a full Tx FIFO, hardware sets the Tx_FIFO_OVF bit as an indication that software attempted to overflow the Tx FIFO. Hardware makes sure that the overflowing data is never written to the Tx FIFO.

If IE.RX is enabled during receives, an interrupt is generated whenever RDY or one of the status bits in the SPI FIFO Control/Status Register is set by the hardware. During receives, when the SPI controller is configured as a Slave, if software/APB DMA cannot read the receive FIFO fast enough, hardware will set the Rx_FIFO_OVF bit and an overflow condition is generated. However, if software tries to read from an empty Rx FIFO, hardware sets the RXF_UNR bit as an indication that software attempted to underrun the Rx FIFO.

The interrupt can be cleared by writing a 1 to the source of the interrupt. If the interrupt is generated by assertion of RDY, then writing a 1 to the RDY bit clears the interrupt. If the interrupt is generated by assertion of Tx_FIFO_OVF, then writing a 1 to the TXF_OVF bit clears the interrupt. If the interrupt is generated by assertion of Rx_FIFO_UNR, then writing a 1 to RXF_UNR bit clears the interrupt.

Guideline for DMA use cases: In DMA Mode, if interrupts are enabled, the SPI software driver has to deal with 3 interrupts: one from the SPI controller and two from the Tx and Rx APB DMA channels. This might make it complicated for the driver and also stresses the system. In such cases, software can use the Rx DMA interrupt as the final one at which point all hardware activities can be assumed to be complete. But, in variable transfer lengths (continuous mode), software has to rely on the controller's interrupts.

37.2.4 Clock Initialization and Control

The SPI controller runs at 50 MHz at its interface to external SPI devices. The internal SPI controller clock (spi_clk) should run at the same frequency as the outgoing Interface Clock (Sclk_Out) in Master Mode. In Slave Mode, the internal SPI interface clock frequency has to be 50% greater than the external clock (Sclk_in).

The SPI clock is selected from different clock sources using a generic clock switch module. The clock switch module supports glitch-free switching of clock from one source to another. There are 4 clock sources:

- osc_clk
- pllP_out
- pllC_out
- pllM_out0

The selected clock is divided by an 8-bit value written in the divider register. The clock is then trimmed, and gated branches are generated for the SPI instances.

> ***Note:*** *The ratio between the slave core clock and the slave interface clock must be maintained between 1.5x and 4x. For example if the slave interface clock is running at 10 MHz, the slave core clock must not be less than 10x1.5 MHz and not greater than 10x4 MHz.*

The CLK_RST_CONTROLLER_CLK_OUT_ENB_H_0, CLK_RST_CONTROLLER_CLK_OUT_ENB_V_0, and CLK_RST_CONTROLLER_CLK_OUT_ENB_U_0 registers in the CAR (Clock and Reset) block contain the enable bits for the SPI controller. In addition, the clock source and divider registers (CLK_SOURCE_SBC1, CLK_SOURCE_SBC2,

CLK_SOURCE_SBC3, CLK_SOURCE_SBC4, CLK_SOURCE_SBC5, and CLK_SOURCE_SBC6) contain the 2-bit field SBCx_CLK_SRC to determine the PLL clock source, while the SBCx_CLK_DIVISOR field determines the divide ratio.

See Chapter 5: Clock and Reset Controller for more information on clock configuration.

Controller Reset

The SPI controller can be reset by writing 1 to SPI1 (bit 11) in the RST_DEVICES.H (0x6000:6008) register. Software needs to write a 0 to this bit to bring the SPI controller out of reset.

See the Clock and Reset Controller section for more information on SPI controller reset.

Slave Mode GPIO Synchronization

Because SPI does not support flow control, the GPIO is required to have the proper communication to avoid any clock loss from the Master. GPIO can be used in the following way for proper synchronization:

- SPI slave client software will write to the Config registers of the SPI controller and make the SPI slave ready.
- After that the slave client software will toggle GPIO to inform the Master that the Slave is ready.
- Then the SPI master sends SCLK to the slave device.

If there is no GPIO to tell the Master that the Slave is ready, there is a chance to lose clock/data.

Guidelines

This section provides guidelines for programming the SPI controller:

- Program all the required register fields (no particular order is required except for the PIO/DMA bit, which has to be programmed last):
  - Clock Mode
  - Packed/Unpacked Mode
  - Tx_EN/Rx_EN
  - BOTH_EN_BIT
  - En_LE_Bit/En_LE_Byte
  - BIT_LEN and BLOCK_SIZE values
  - CS_SW_HW (software based or hardware based)
    - If CS_SW_HW is set, the value on CS_SW_VAL will be driven out.
    - When CS HW is used program the Setup & Hold Values in CS Timing Register.
  - Program the DMA Trig values appropriately, if DMA Mode is used
  - Enable interrupts if PIO Mode is used
- Lastly, program PIO or DMA to indicate the start of transfer.

Once software enables PIO/DMA, no required bits can be changed until the end of transfer except for PIO/DMA bit. Clearing the PIO/DMA bit will end the transaction. In case the SPI controller is configured to Receive Mode and software clears the PIO/DMA bit, then the partial data which the controller received until then will be written into the FIFO. This is true both for Master and Slave.

Do not enable conflicting features. For example, avoid enabling BOTH_EN_BIT along with bidirectional (BIDIR) mode.

In Slave Mode after PIO or DMA is set, hardware first waits for the CS to go low by one of the 4 Masters. Then on reception of Sclk, transfer begins. If CS or Sclk is removed by the Master in the middle of a transfer, software must terminate the transaction by clearing the PIO/DMA bit. In case of Rx, hardware then writes the last received packet (incomplete packet) to the Rx FIFO. If software does not clear the PIO/DMA bit, the SPI controller will just keep waiting for the Sclk from the Master. If Sclk resumes later, the transaction continues from where it paused earlier.

If any error conditions occur, hardware will set the corresponding status bits in the SPI FIFO Control/Status register and stop the transfer. If IE is enabled, an interrupt is generated. Software has to clear the source of the interrupt by writing a 1 to it, after the completion of ISR.

Special Guidelines for Slave Mode

Software should not program the controller register when the interface clock is toggling. Software can disable the external clock input before programming the registers and then re-enable it once all the registers bits are programmed.

Error Conditions

When the SPI controller is configured as a Master, the following error scenarios can happen:

- Tx_FIFO overflow

  Tx_FIFO overflow happens when the CPU/APB_DMA writes into the Tx FIFO when it is full. In this case, the SPI controller will end the transaction by setting the PIO/DMA_EN bit to 0, and flag the error bit along with the Tx_FIFO_OVF bit in the SPI FIFO Control/Status register. The SPI controller will generate an interrupt if interrupts are enabled. Software has to clear the error bit and the Tx_FIFO_OVF bit. To start a new transaction, software has to flush the FIFOs by writing to the TX_FIFO_FLUSH/RX_FIFO_FLUSH bits in the SPI FIFO Control/Status register.

- Rx_FIFO overflow

  Rx_FIFO overflow happens when the CPU/APB_DMA writes into the Rx FIFO when it is full in BOTH_EN Mode. In this case, the SPI controller will end the transaction by setting the PIO/DMA_EN bit to 0, and flag the error bit along with Rx_FIFO_OVF bit in the SPI FIFO Control/Status register. The SPI controller will generate an interrupt if interrupts are enabled. Software has to clear the error bit and the Rx_FIFO_OVF bit. To start a new transaction, software has to flush the FIFOs by writing to the TX_FIFO_FLUSH/RX_FIFO_FLUSH bits in the SPI FIFO Control/Status register.

- Tx_FIFO underrun

  Tx_FIFO underrun happens when the CPU/APB_DMA reads from the Tx FIFO when it is empty. In this case, the SPI controller will end the transaction by setting the PIO/DMA_EN bit to 0, and flag the error bit along with the Tx_FIFO_UNR bit in the SPI FIFO Control/Status register. The SPI controller will generate an interrupt if interrupts are enabled. Software has to clear the error bit and the Tx_FIFO_UNR bit. To start a new transaction, software has to flush the FIFOs by writing to the TX_FIFO_FLUSH/RX_FIFO_FLUSH bits in the SPI FIFO Control/Status register.

- Rx_FIFO underrun

  Rx_FIFO underrun happens when the CPU/APB_DMA reads from the Rx FIFO in BOTH_EN Mode. In this case, the SPI controller will end the transaction by setting the PIO/DMA_EN bit to 0, and flag the error bit along with the Rx_FIFO_UNR bit in the SPI FIFO Control/Status register. The SPI controller will generate an interrupt if interrupts are enabled. Software has to clear the error bit and the Rx_FIFO_UNR bit, along with the Interrupt bit. To start a new transaction, software has to flush the FIFOs by writing to the TX_FIFO_FLUSH/RX_FIFO_FLUSH bits in the SPI FIFO Control/Status register.

Note: *In Master Mode, all the errors above can happen only when the CPU/APB_DMA reads/writes an empty/full FIFO. The SPI controller will never write/read a full/empty FIFO. Instead the controller will pause (stops sending clocks to the slave with chip select being in an active state) whenever the FIFOs are full/empty.*

When the SPI controller is configured as a Slave, the following error scenarios can happen:

- Tx_FIFO overflow

  Tx_FIFO overflow happens when the CPU/APB_DMA or the SPI controller writes into the Tx FIFO when it is full. In this case, the SPI controller will end the transaction by setting the PIO/DMA_EN bit to 0, and flag the error bit along with Tx_FIFO_OVF bit in the status register. The SPI controller will generate an interrupt if interrupts are enabled. Software has to clear the error bit and Tx_FIFO_OVF bit. To start a new transaction, software has to disable the Master from sending clocks and then flush the FIFOs by writing to the TX_FIFO_FLUSH/RX_FIFO_FLUSH bits in the SPI FIFO Control/Status register.

- Rx_FIFO overflow

Rx_FIFO overflow happens when the CPU/APB_DMA or the SPI controller writes into Rx FIFO when it is full in BOTH_EN Mode. In this case, the SPI controller will end the transaction by setting the PIO/DMA_EN bit to 0, and flag the error bit along with Rx_FIFO_OVF bit in the status register. The SPI controller will generate an interrupt if interrupts are enabled. Software has to clear the error bit and Rx_FIFO_OVF bit along with the Interrupt bit. To start a new transaction, software has to disable the Master from sending clocks and flush the FIFOs by writing to the TX_FIFO_FLUSH/RX_FIFO_FLUSH bits in the SPI FIFO Control/Status register.

- Tx_FIFO underrun

  Tx_FIFO underrun happens when the CPU/APB_DMA or the SPI controller reads from Tx FIFO when it is empty. In this case, the SPI controller will end the transaction by setting the PIO/DMA_EN bit to 0, and flag the error bit along with the TX_FIFO_UNR bit in the SPI FIFO Control/Status register. The SPI controller will generate an interrupt if interrupts are enabled. Software has to clear the error bit and TX_FIFO_UNR bit along with the Interrupt bit. To start a new transaction, software has to disable the Master from sending clocks and flush the FIFOs by writing to the TX_FIFO_FLUSH/RX_FIFO_FLUSH bits in the SPI FIFO Control/Status register.

- Rx_FIFO underrun

  Rx_FIFO underrun happens when the CPU/APB_DMA or the SPI controller reads from the Rx FIFO in BOTH_EN Mode. In this case, the SPI controller will end the transaction by setting the PIO/DMA_EN bit to 0, and flag the error bit along with the RX_FIFO_UNR bit in the SPI FIFO Control/Status register. The SPI controller will generate an interrupt if interrupts are enabled. Software has to clear the error bit and RX_FIFO_UNR bit along with the Interrupt bit. To start a new transaction, software has to disable the Master from sending clocks and flush the FIFOs by writing to the TX_FIFO_FLUSH/RX_FIFO_FLUSH bits in the SPI FIFO Control/Status register.

- CS_inactive

  When the SPI controller is configured as a Slave and cs_active between packets is set, if an external Master deasserts the chip select in the middle of a transaction, the SPI controller will end the transaction by setting the PIO/DMA_EN bit to 0, and sets the CS_INACTIVE bit in the SPI FIFO Control/Status register. The SPI controller will generate an interrupt if interrupts are enabled. Software has to clear the CS_INACTIVE bit. To start a new transaction, software has to disable the Master from sending clocks and flush the FIFOs by writing to the TX_FIFO_FLUSH/RX_FIFO_FLUSH bits in the SPI FIFO Control/Status register.

  It is software's responsibility to read the data that is left out of the RX FIFO for CS inactive. For example, if the interrupt trigger is set for 4 words, and external master has taken the CS off in between the transfer, and, at that point of time, the RX FIFO has only 2 words, it is software's responsibility to read out those 2 words or flush the FIFO.

- Frame_End

  When the SPI controller is configured as a Slave and DMA-continuous and cs_active between packets is set, if an external Master stops sending clocks for more than slave_idle_clock_count programmed in the register, the SPI controller will end the transaction by setting the DMA bit to 0, and sets the FRAME_END bit in the SPI FIFO Control/Status register. The SPI controller will generate an interrupt if interrupts are enabled. Software has to clear the FRAME_END bit along with the Interrupt bit. To start a new transaction, software has to disable the Master from sending clocks and flush the FIFOs by writing to the TX_FIFO_FLUSH/RX_FIFO_FLUSH bits in the SPI FIFO Control/Status register. If the Master resumes the clk within "slave_idle_clock_count", the SPI controller will also pause and resume the transaction whenever ext_clk is available.

  There are three scenarios for continuous mode pause:

  Assuming SLV_IDLE_CNT = 255:

  - Master stops sending the clock but the CS is asserted for > 255 cycles, frame end is asserted.
  - Master stops sending the clock when CS is asserted for 100 cycles, then CS is de-asserted for some time. After the CS is asserted again, master does not send the clocks for > 155 cycles then frame end is asserted.
  - Master stops sending the clock when CS is asserted for 100 cycles and then CS is de-asserted for some time. After the CS is asserted again, master resumes sending the clock before 155 cycles, then frame end is not asserted.

Programming Trimmers

The 3 programmable trimmers in the SPI controller are used only in Master Mode:

- SPI-Tx trimmer

This trimmer is used in Master Tx mode to adjust/center the outgoing data with respect to the outgoing clock.

- SPI-Rx trimmer

  This trimmer is used in Master Rx mode to delay the loopback clock to the Rx shift registers. This trimmer is used to adjust the Master SCLK with respect to the SPI slave device's Tx data.

- SPI-Spare Control Register Byte1

  This 3-bit trimmer controls the internal timing of the Master mode Rx datapath. This trimmer along with the SPI Rx trimmer may be set independently to adjust the loopback clock delay. This trimmer adjusts the programmable delay on the u_spi_slave_rx* flops in inbound paths. These are half cycle paths, and delays have been added to increase Setup margin on these paths.

- The SPI controller has a programmable delay chain with a 3-tap delay chain. The 3 taps use 100D, 100D, and 60D and are programmed as follows:
  - 000: Bypass through each mux: will see 3 muxes in path
  - 001: 60D
  - 010: 100D
  - 100: 100D
  - 011: 60D + 100D
  - 110: 100D + 100D
  - 101: 100D+60D
  - 111: 100D+100D+60D
- Spare cells used as control for these delay taps:
  - (u_spi1_shift_padmacro/spi_spare_control_byte1_in_reg_2_,
  - u_spi1_shift_padmacro/spi_spare_control_byte1_in_reg_1_,
  - u_spi1_shift_padmacro/spi_spare_control_byte1_in_reg_0_)

37.3 SPI Controller Registers

Refer to Section 1.4: Reading Register Tables in the Introduction chapter for the register table protocol as well as recommendations for accessing registers.

There are four sets of the SPI controller registers, one for each of the four SPI controllers. The register descriptions below give the offset of each register within its SPI controller's address range. See Chapter 2: Address Map for the starting address of each SPI controller.

37.3.1 SPI_COMMAND_0

SPI Command1 Register

This register is used to set the bit length and to select the transfer mode.

Chip Select can also be selected to be in hardware mode as software mode with both active high and active low polarities to support devices with varying CS polarities.

Offset: 0x0 │ Read/Write: R/W │ Reset: 0x43d00000 (0b01000011110100000000xxxxx000000)

Bit	Reset	Description
31	0x0	PIO: Program 1 after all the other bits in the SPI_COMMAND2 and SPI_COMMAND1 registers are programmed to start the transfer. Hardware clears this bit automatically after the transfer is done. Clearing of this bit by software will stop the shifter and latch the partial data into the buffer (in Receive Mode). 0 = STOP (default) 1 = GO

Bit	Reset	Description
30	0x1	M/S: Master/Slave mode select. 0 = Slave Mode (external clock) 1 = Master Mode (internal clock) (default)
29:28	0x0	MODE: The SPI interface clock mode has to be programmed according to the device with which it is communicating. 0 = Mode 0 (default) 1 = Mode 1 2 = Mode 2 3 = Mode 3 Master: All modes are supported both for Tx and Rx. Slave: Modes 1and 3 are supported for Tx. Slave: All modes are supported for Rx.
27:26	0x0	CS_SEL: In Master Mode, these bits are programmed to select a slave in the multi-slave environment. 0 = Selects CS0 (default) 1 = Selects CS1 2 = Selects CS2 3 = Selects CS3
25	0x1	CS_POL_INACTIVE#3: In Master or Slave Mode, the inactive value of the external device's cs value, which is connected to CS3, needs to be programmed. 1 = CS3 Inactive value of External device is high, 0 = CS3 Inactive value of External device is low 0 = LOW 1 = HIGH (default)
24	0x1	CS_POL_INACTIVE#2: In Master or Slave Mode, the inactive value of the external device's cs value, which is connected to CS2, needs to be programmed, 1 = CS2 Inactive value of External device is high, 0 = CS2 Inactive value of External device is low 0 = LOW 1 = HIGH (default)
23	0x1	CS_POL_INACTIVE#1: In Master or Slave Mode, the inactive value of the external device's cs value, which is connected to CS1, needs to be programmed. 1 = CS1 Inactive value of External device is high, 0 = CS1 Inactive value of External device is low 0 = LOW 1 = HIGH (default)
22	0x1	CS_POL_INACTIVE#0: In Master or Slave Mode, the inactive value of the external device's cs value, which is connected to CS0, needs to be programmed. 1 = CS0 Inactive value of External device is high, 0 = CS0 Inactive value of External device is low 0 = LOW 1 = HIGH (default)
21	0x0	CS_SW_HW: Software control of the SPI_CS signal in Master Mode. In Slave Mode, this bit need not be programmed. 1 = CS controlled by software; 0 = CS controlled by hardware 0 = SPI _CS#(CS_SEL) is driven to the active state during packet transfers by the hardware (default) 1 = SPI _CS#(CS_SEL) is driven with the value in the CS_SW_VAL bit
20	0x1	CS_SW_VAL: CS signal value in Master Mode. In Slave Mode, this bit need not be programmed. If CS_SW_HW is 1, then the value in CS_SW_VAL is driven out on CS. If CS_SW_HW is 0, then this bit has no effect. 0 = CS is LOW 1 = CS is HIGH (default)
19:18	0x0	IDLE.SDA: Inactive data signal format. Controls the output enable of the SDA line when the controller is inactive and not doing data transfers. 0 = Drive low. (Master Mode) (default) 1 = Drive high. (Master Mode) 2 = External Pull Down. (Slave Mode) 3 = External Pull high. (Slave Mode)
17	0x0	BIDIR: Bidirectional Transfer Control Bit: This bit enables the bidirectional mode of the transfer. 0 = Normal Mode (default) 1 = Bidirectional Mode
16	0x0	En_LE_Bit: 1 = Enable Little Endian Bit. 0 = Disable Little Endian Bit 0 = LAST 1 = FIRST
15	0x0	En_LE_Byte: 1 = Enable Little Endian Byte. 0 = Disable Little Endian Byte 0 = LAST 1 = FIRST

Bit	Reset	Description
14	0x0	BOTH_EN_BIT (x2 Mode): Both MISO and MOSI can also be used to transmit or receive at the same time when this bit is set. Even bits from the Tx FIFO packet are transmitted/ received on MOSI, and Odd bits from the Tx FIFO packet are transmitted/received on MISO. Refer to the Both Enable Bit Mode (SPI x2 Mode) section for more information. 0 = Normal Mode (default) 1 = Transmit/Receive on both MISO and MOSI at the same time when the Tx_EN and Rx_EN bits are set
12	0x0	Rx_EN: Receive enable. Setting this bit to 1 enables the controller to receive the data. 0 = DISABLE (default) 1 = ENABLE
11	0x0	Tx_EN: Transmit enable. Setting this bit to 1 enables the controller to transmit the data. 0 = DISABLE (default) 1 = ENABLE
10:6	N/A	Reserved for future use. Always write zeros.
5	0x0	PACKED: Packed mode enable bit.. 0 = Unpacked Mode (default) 1 = Packed Mode. This is only valid if the BIT_LEN field is set to either 3 (4-bit transfer), 7 (8-bit transfer), 15 (16-bit transfer), or 31 (32-bit transfer).
4:0	0x0	BIT_LEN: This field is used during PIO and DMA transfers. It represents the number of bits transmitted/received in either Packed or Unpacked Mode. The minimum bit length in Master Mode is 4 and the minimum length in Slave Mode is 1 byte (BIT_LEN = 7). The default is 0. 3 = 4-bit transfer N = N+1-bit transfer 31 = 32-bit transfer

37.3.2 SPI_COMMAND2_0

SPI Command2 Register

Offset: 0x4 | Read/Write: R/W | Reset: 0x00000000 (0bxxxxxxxxxxxxxxxxxxxxx000000000000)

Bit	Reset	Description
31:12	N/A	Reserved for future use. Always write zeros.
11:6	0x0	Tx_Clk_TAP_DELAY: Delays the clock going out to the external device with these tap values. Useful only in Master Mode.
5:0	0x0	Rx_Clk_TAP_DELAY: Delays the clock coming in from the external device with these tap values. Useful only in Master Mode.

37.3.3 SPI_TIMING_REG1_0

SPI CS Timing1 Register

Offset: 0x8 | Read/Write: R/W | Reset: 0x00000000 (0b00000000000000000000000000000000)

Bit	Reset	Description
31:28	0x0	CS_SETUP_TIME#3: Specifies the setup time of the chip select to the data being transmitted or received on CS#3 in numbers of cycles (16 cycles maximum). The default is 0. 1 = 2 clock cycle delay 2 = 3 clock cycle delay, etc.
27:24	0x0	CS_HOLD_ TIME#3: Specifies the hold time of the chip select to the data being transmitted or received on CS#3 in numbers of cycles (16 cycles maximum). The default is 0. 1 = 2 clock cycle delay 2 = 3 clock cycle delay, etc.
23:20	0x0	CS_SETUP_ TIME#2: Specifies the setup time of the chip select to the data being transmitted or received on CS#2 in numbers of cycles (16 cycles maximum). The default is 0. 1 = 2 clock cycle delay 2 = 3 clock cycle delay, etc.
19:16	0x0	CS_HOLD_ TIME#2: Specifies the hold time of the chip select to the data being transmitted or received on CS#2 in numbers of cycles (16 cycles maximum). The default is 0. 1 = 2 clock cycle delay 2 = 3 clock cycle delay, etc.

Bit	Reset	Description
15:12	0x0	CS_SETUP_ TIME#1: Specifies the setup time of the chip select to the data being transmitted or received on CS#1 in numbers of cycles (16 cycles maximum). The default is 0. 1 = 2 clock cycle delay 2 = 3 clock cycle delay, etc.
11:8	0x0	CS_HOLD_ TIME#1: Specifies the hold time of the chip select to the data being transmitted or received on CS#1 in numbers of cycles (16 cycles maximum). The default is 0. 1 = 2 clock cycle delay 2 = 3 clock cycle delay, etc.
7:4	0x0	CS_SETUP_ TIME#0: Specifies the setup time of the chip select to the data being transmitted or received on CS#0 in numbers of cycles (16 cycles maximum). The default is 0. 1 = 2 clock cycle delay 2 = 3 clock cycle delay, etc.
3:0	0x0	CS_HOLD_ TIME#0: Specifies the hold time of the chip select to the data being transmitted or received on CS#0 in numbers of cycles (16 cycles maximum). The default is 0. 1 = 2 clock cycle delay 2 = 3 clock cycle delay, etc.

37.3.4 SPI_TIMING_REG2_0

SPI CS Timing2 Register

Offset: 0xc │ Read/Write: R/W │ Reset: 0x20202020 (0bxx100000xx100000xx100000xx100000)

Bit	Reset	Description
31:30	N/A	Reserved for future use. Always write zeros.
29	0x1	CS_ACTIVE_BETWEEN_PACKETS#3: Specifies if CS stays active between two packets on CS#3 1 = CS active between two packets (default) 0 = CS inactive between two packets
28:24	0x0	CYCLES_BETWEEN_PACKETS#3: Specifies the number of cycles between two packets in the PIO/DMA Mode for communication on CS#3. The default is 0. 1 = 2 clock cycle delay 2 = 3 clock cycle delay, etc.
23:22	N/A	Reserved for future use. Always write zeros.
21	0x1	CS_ACTIVE_BETWEEN_PACKETS#2: Specifies if CS stays active between two packets on CS#2 1 = CS active between two packets (default) 0 = CS inactive between two packets
20:16	0x0	CYCLES_BETWEEN_PACKETS#2: Specifies the number of cycles between two packets in the PIO/DMA Mode for communication on CS#2. The default is 0. 1 = 2 clock cycle delay 2 = 3 clock cycle delay, etc.
15:14	N/A	Reserved for future use. Always write zeros.
13	0x1	CS_ACTIVE_BETWEEN_PACKETS#1: Specifies if CS stays active between two packets on CS#1 1 = CS active between two packets (default) 0 = CS inactive between two packets
12:8	0x0	CYCLES_BETWEEN_PACKETS#1: Specifies the number of cycles between two packets in the PIO/DMA Mode for communication on CS#1. The default is 0. 1 = 2 clock cycle delay 2 = 3 clock cycle delay, etc.
7:6	N/A	Reserved for future use. Always write zeros.
5	0x1	CS_ACTIVE_BETWEEN_PACKETS#0: Specifies if CS stays active between two packets on CS#0 1 = CS active between two packets (default) 0 = CS inactive between two packets

Bit	Reset	Description
4:0	0x0	CYCLES_BETWEEN_PACKETS#0: Specifies the number of cycles between two packets in the PIO/DMA Mode for communication on CS#0. The default is 0. 1 = 2 clock cycle delay 2 = 3 clock cycle delay, etc.

37.3.5 SPI_TRANSFER_STATUS_0

SPI TRANSFER Status Register

Read this register for the status of the transfer.

Offset: 0x10 | Read/Write: R/W | Reset: 0x00ff0000 (0bx0xxxxx11111111xxxxxxxxxxxxxxx)

Bit	R/W	Reset	Description
31	N/A		Reserved for future use. Always write zeros.
30	RW	0x0	RDY: Ready bit. This bit is set to 1 at the end of every transfer, and an interrupt is also generated if the corresponding interrupt enable is set in PIO/DMA Mode. Software writes a 1 to clear it. The interrupt is also cleared when this bit is cleared. 0 = NOT_READY (default) 1 = READY
29:24	N/A		Reserved for future use. Always write zeros.
23:16	RW	0xff	SLV_IDLE_COUNT: Slave Continuous Mode. If Sclk is not received for this number of cycles, then Slave Continuous mode is terminated, and the status bit FRAME_END is set. The default is 255 (8'hff).
15:0	RO	X	BLOCK_COUNT: Counts the number of packets in a transaction (Tx or Rx) in DMA/PIO Mode. In DMA Continuous Mode, this field gives the number of packets only if the number of packet is less than 2^{16}.

37.3.6 SPI_FIFO_STATUS_0

SPI Control/Status FIFO Status Register

SPI STATUS register: Read this register to know the status of the transfer. Error bit is set whenever errors such as Underflow/ Overflow are encountered.

Offset: 0x14 | Read/Write: R/W | Reset: 0x00400005 (0b00xxxxxxxxxxxxxx00xxxxx00000xxxx)

Bit	R/W	Reset	Description
31	RW	0x0	CS_INACTIVE: When the SPI is in Slave Mode, if CS is deasserted, this bit is set and the received number of bits is written in the Rx FIFO. An interrupt is generated if IE.Tx or IE.Rx is set. The default is 0.
30	RW	0x0	FRAME_END: When the SPI is in Slave Continuous mode, if Sclk is not received for the number of clocks specified in the SLV_IDLE_COUNT field, the continuous mode is terminated and this status bit is set. The default is 0.
29:23	RO	X	RX_FIFO_FULL_COUNT: Indicates the number of slots in the receive FIFO remaining before the FIFO is empty. This field is used by software for debugging purposes.
22:16	RO	X	TX_FIFO_EMPTY_COUNT: Indicates the number of slots in the transmit FIFO remaining before the FIFO is full. This field is used by software for debugging purposes.
15	RW	0x0	RX_FIFO_FLUSH: Software writes a 1 to this bit to flush the Rx FIFO. This bit reads as 1 when the flush operation is in progress and returns to 0 when it is finished. 0 = NOP (default) 1 = FLUSH
14	RW	0x0	TX_FIFO_FLUSH: Software writes a 1 to this bit to flush the Tx FIFO. This bit reads as 1 when the flush operation is in progress and returns to 0 when it is finished. 0 = NOP (default) 1 = FLUSH
13:9	N/A		Reserved for future use. Always write zeros.
8	RW	0x0	ERR: Will be set to 1 by hardware when errors such as underflow/overflow occur. Software writes a 1 to clear the flag. 0 = OK (default) 1 = ERROR

Bit	R/W	Reset	Description
7	RW	0x0	TX_FIFO_OVF: TX FIFO Overflow. This bit is set to 1 whenever the SPI controller or software tries to write to a full Tx FIFO. An interrupt is generated if the interrupt enable is set for transmit operations (IE.TX in the SPI_DMA_CTL register). Software writes a 1 to clear this bit. 0 = OK (default) 1 = ERROR
6	RW	0x0	TX_FIFO_UNR: TX FIFO Underrun. This bit is set to 1 whenever the SPI controller or software tries to read from an empty Tx FIFO. An interrupt is generated if the interrupt enable is set for transmit operations (IE.TXC in the SPI_DMA_CTL register). Software writes a 1 to clear this bit. 0 = OK (default) 1 = ERROR
5	RW	0x0	RX_FIFO_OVF: RX FIFO Overflow. This bit is set to 1 whenever the SPI controller or software tries to write into a full Rx FIFO. An interrupt is generated if the interrupt enable is set for receive operations (IE.RXC in the SPI_DMA_CTL register). Software writes a 1 to clear this bit. 0 = OK (default) 1 = ERROR
4	RW	0x0	RX_FIFO_UNR: RX FIFO Underrun. This bit is set to1 whenever the SPI controller or software tries to read from an empty Rx FIFO. An interrupt is generated if the interrupt enable is set for receive operations (IE.RXC in the SPI_DMA_CTL register). Software writes a 1 to clear this bit. 0 = OK (default) 1 = ERROR
3	RO	X	TX_FIFO_FULL: TX FIFO Full Status. Hardware sets this bit to 1 if the Tx FIFO is full; otherwise this bit is 0. The Tx FIFO is empty at power on reset (POR). 0 = NOT_FULL (default) 1 = FULL
2	RO	X	TX_FIFO_EMPTY: TX FIFO Empty Status. Hardware sets this bit to 1 if the Tx FIFO is empty; otherwise this bit is 0. The Tx FIFO is empty at POR. 0 = NOT_EMPTY 1 = EMPTY (default)
1	RO	X	RX_FIFO_FULL: RX FIFO Full Status. Hardware sets this bit to 1 if the Rx FIFO is full; otherwise this bit is 0. The Rx FIFO is empty at POR. 0 = NOT_FULL (default) 1 = FULL
0	RO	X	RX_FIFO_EMPTY: RX FIFO Empty Status. Hardware sets this bit to 1 if the Rx FIFO is empty; otherwise this bit is 0. The Rx FIFO is empty at POR. 0 = NOT_EMPTY 1 = EMPTY (default)

37.3.7 SPI_TX_DATA_0

SPI Transmit Data Register

Offset: 0x18 | Read/Write: RO | Reset: 0x00000000 (0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx)

Bit	Reset	Description
31:0	X	SPI_Tx_DATA. Transmit Data. This register holds the last data that was transmitted by the SPI controller.

37.3.8 SPI_RX_DATA_0

SPI Receive Data Register

Offset: 0x1c | Read/Write: RO | Reset: 0x00000000 (0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx)

Bit	Reset	Description
31:0	X	SPI_Rx_DATA. Receive Data. This register holds the last data that was received by the SPI controller.

37.3.9 SPI_DMA_CTL_0

SPI DMA Control Register

SPI DMA Control Register: Used in the DMA transfers. We can set trigger levels in this register

Offset: 0x20 | Read/Write: R/W | Reset: 0x00000000 (0b00xxxxxxxxx00xx00xxxxxxxxxxxxxxx)

Bit	Reset	Description
31	0x0	DMA: Enable DMA Mode transfer. Software writes a 1 to this bit to start a transfer in the DMA mode. All fields in the SPI_COMMAND1 and SPI_DMA_CTL register must be set before writing a 1 to this bit. This bit is cleared by the SPI controller after all packets have been transferred as indicated by the DMA_BLOCK_SIZE field. Clearing this bit by software will stop the shifter and latch the partial data into buffer. 0 = DMA Mode is disabled (default) 1 = DMA Mode is enabled
30	0x0	CONT: Enable Continuous Mode transfer. 0 = Continuous Mode is disabled (default) 1 = Continuous Mode is enabled
27:21	N/A	Reserved for future use. Always write zeros.
20:19	0x0	RX_TRIG: Receive FIFO trigger level. 00: 1 word. DMA trigger is asserted whenever there is at least 1 packet in the RX FIFO. (default) 01: 4 words. DMA trigger is asserted when there are at least 4 packets in the RX FIFO. 10: 8 words. DMA trigger is asserted when there are at least 8 packets in the RX FIFO. 11: 16 words. DMA trigger is asserted when there are at least 16 packets in the RX FIFO. (Presently, the APB DMA does not support this trigger level.)
18:17	N/A	Reserved for future use. Always write zeros.
16:15	0x0	TX_TRIG: Transmit FIFO trigger level. 00: 1 word. DMA trigger is asserted whenever there is space for at least 1 packet in the TX FIFO. (default) 01: 4 words. DMA trigger is asserted when there is space for at least 4 packets in the TX FIFO. 10: 8 words. DMA trigger is asserted when there is space for at least 8 packets in the TX FIFO. 11: 16 words. DMA trigger is asserted when there is space for at least 16 packets in the TX FIFO. (Presently, the APB DMA does not support this trigger level.)

37.3.10 SPI_DMA_BLK_SIZE_0

SPI DMA Block Size Register

Offset: 0x24 | Read/Write: R/W | Reset: 0x00000000 (0bxxxxxxxxxxxxxxxx0000000000000000)

Bit	Reset	Description
15:0	0x0	BLOCK_SIZE: Size of data block to be transferred in PIO/DMA Mode. The default is 0. In DMA Mode, the maximum number of 32-bit packets that can be transferred is 2^{16} = 65536. In PIO Mode, the maximum number of 32-bit packets that can be transferred is 64 (FIFO depth). The Block Size has to be programmed 1 packet lower than intended; for example, a value of 3 indicates 4 packets are to be transferred.

37.3.11 SPI_TX_FIFO_0

SPI TX FIFO Buffer Register

Offset: 0x108 | Read/Write: R/W | Reset: 0x00000000 (0b00000000000000000000000000000000)

Bit	Reset	Description
31:0	0x0	SPI Tx_FIFO. Tx FIFO.

37.3.12 SPI_RX_FIFO_0

SPI RX FIFO Buffer Register

Offset: 0x188 | Read/Write: R/W | Reset: 0x00000000 (0b00000000000000000000000000000000)

Bit	Reset	Description
31:0	0x0	SPI Rx_FIFO. Rx FIFO.

37.3.13 SPI_INTR_MASK_0

SPI Interrupt Mask Register

Offset: 0x18c | Read/Write: R/W | Reset: 0x00000000 (0b0000000xxxxxxxxxxxxxxxxxxxxxxxx)

Bit	Reset	Description
31	0x0	CS_INTR_MASK: Interrupt enable mask bit for CS deassertion in Slave Mode. 0 = Enable interrupt generation if CS is deasserted in the middle of a transaction in Slave mode. 1 = Disable interrupt generation if CS is deasserted in the middle of a transaction in Slave mode. 0 = DISABLE 1 = ENABLE
30	0x0	FRAME_END_INTR_MASK: Interrupt enable mask bit for Frame End in Slave Mode. 0 = Enable interrupt generation if Frame End is set in the middle of a transaction in Slave mode. 1 = Disable interrupt generation if Frame End is set in the middle of a transaction in Slave mode. 0 = DISABLE 1 = ENABLE
29	0x0	RDY_INTR_MASK: Interrupt enable mask bit for RDY. 0 = Enable interrupt generation when RDY bit is asserted. 1 = Disable interrupt generation when RDY bit is asserted. 0 = DISABLE 1 = ENABLE
28	0x0	TX_FIFO_OVF_INTR_MASK: Interrupt enable mask bit for TX_FIFO_OVF. 0 = Enable interrupt generation when TX_FIFO_OVF is asserted. 1 = Disable interrupt generation when TX_FIFO_OVF is asserted. 0 = DISABLE 1 = ENABLE
27	0x0	TX_FIFO_UNF_INTR_MASK: Interrupt enable mask bit for TX_FIFO_UNF. 0 = Enable interrupt generation when TX_FIFO_UNF is asserted. 1 = Disable interrupt generation when TX_FIFO_UNF is asserted. 0 = DISABLE 1 = ENABLE
26	0x0	RX_FIFO_OVF_INTR_MASK: Interrupt enable mask bit for RX_FIFO_OVF. 0 = Enable interrupt generation when RX_FIFO_OVF is asserted. 1 = Disable interrupt generation when RX_FIFO_OVF is asserted. 0 = DISABLE 1 = ENABLE
25	0x0	RX_FIFO_UNF_INTR_MASK: Interrupt enable mask bit for RX_FIFO_UNF. 0 = Enable interrupt generation when RX_FIFO_UNF is asserted. 1 = Disable interrupt generation when RX_FIFO_UNF is asserted. 0 = DISABLE 1 = ENABLE

37.3.14 SPI_SPARE_CTLR

SPI Spare Control Register

Offset: 0x190 | Read/Write: R/W | Reset: 0x0fff0000 (0b00001111111111111000000000000000)

Bit	Reset	Description
31:11	00001111111111100000b	Reserved for future use.
10:8	000b	SPI_SPARE_CONTROL_REGISTER_BYTE2. Program bits 8, 9, and 10 along with Rx_Clk_TAP_DELAY in the COMMAND2 register to adjust the clock delay on internal registers. Useful in Master Mode only.

Bit	Reset	Description
7:0	0x00	Reserved for future use.

CHAPTER 38: QUAD SERIAL PERIPHERAL INTERFACE (QSPI) CONTROLLER

The Quad Serial Peripheral Interface (Quad SPI) controller is a multi-bit serial communications link between the processor and on-chip/off-chip Serial Flash controllers. The QSPI controller works on the Serial Protocol – Serial Peripheral Interface (SPI). It has configurable features such as:

- Master
- Clock Polarity and Phase (Mode 0)
- DDR or SDR mode
- Dual or Quad mode

In this section:

- *Word* refers to 32-bit data in the TX or RX FIFO
- *Packet* refers to variable length data that is transmitted or received
  - In Packed Mode, packet size can be 8, 16, or 32 bits

38.1 Functionality

The Tegra® X1 QSPI Controller works only as a Master on the QSPI bus. It has independent transmit and receive FIFOs of 64 x 32 bits each. Software can program the controller to generate transactions of a required packet length on the QSPI bus, where a transaction is a sequence of packets in either direction.

The QSPI controller uses APB DMA to read and write from the FIFOs as required. At the end of each transaction, an interrupt can be generated, if enabled. Software uses transmit and receive operations in combination with chip select (CS) control to generate commands on the QSPI bus.

The QSPI controller is a sync client of APB. QSPI registers are in APB clk (pclk) domain. Internal data FIFOs are async FIFOs.

The interface consists of four signals:

- Chip Select (QSPI_CS_N)
- Serial Clock (QSPI_SCK)
- Master Data Out and Slave Data In (MOSI) / QSPI_IO0 for Dual or Quad commands
- Master Data In and Slave Data Out (MISO) / QSPI_IO1 for Dual or Quad commands

Features

- Master and Slave functionality
  - Master: Only Mode 0 is supported for both transmit and receive operations
  - Slave: Not supported
- Independent Rx and Tx FIFOs
- FIFO depth of 64 x 32 bits
- Byte-aligned bit-length in packed and unpacked mode. (BIT_LEN =7/15/31)
- PIO or DMA Mode depending on packet size

  Options include Packed/Unpacked (bit lengths of 7, 15, 31 are supported), Dual mode (x2 Mode), Quad mode (x4 mode), DDR mode (Double Data Rate), Bidirectional (in SDR mode only), Least Significant Bit, Least Significant Byte First (Endian-ness), software or hardware chip-select polarity selection

- Programmable clock phase and polarity
- Packed mode support for bit lengths of 7 (8-bit packet size), 15 (16-bit packet size), and 31 (32-bit packet size)
- In packed mode, it is expected that a minimum of 1 word will be transferred. Software can achieve less than 1 word transfer using unpacked mode.
- Only 1-chip support with programmable CS polarity for chip select
- DMA support
- Simultaneous receive and transmit operations supported
- The maximum frequency of the device clock is 166 MHz (SDR) and 83 MHz (DDR)

38.1.1 Transmission Format

Using the Mode field in the QSPI Command1 Register, software sets one of the two modes in which the QSPI controller works. The two bits of the Mode field specify the idle (inactive) state of SCLK before the chip select is asserted and the data transmitting/receiving edges of SCLK. Mode [1] determines the SCLK polarity. If the polarity is 0, then the SCLK signal is 0 when idle and transitions to 1 when a data transfer starts. If the clock polarity is 1, then the SCLK signal is 1 when idle and transitions to 0 when data transfer starts. Mode [0] is the SCLK phase control bit. If the clock phase is 0, then the receiver latches the data on the first transition of SCLK from the idle state. If the clock phase is 1, then the receiver latches the data on the second transition of SCLK.

Modes supported by the QSPI controller are:

- Master: Mode 0 is supported both for transmitting and receiving
- Slave: Not supported

The following table defines the mode for the QSPI protocol.

Table 238: QSPI Mode with Clock Polarity and Phase

QSPI Mode	Clock Polarity	Clock Phase	SCLK Inactive State	Data Latch IN	Data Latch OUT
0	0	0	Low	Latched IN on the positive edge of clock	Latched OUT on the negative edge of clock

38.1.2 Modes of Operation

38.1.2.1 Master Mode

The QSPI controller operates as a Master only. Only the QSPI master can initiate a transaction.

In Master x1 mode, data from the Tx FIFO is transmitted on the MOSI/IO0 pin. The data from the slave is received on the MISO/IO1 pin and sent to the Rx FIFO.

Similarly in x2 TX mode, the master transmits data on the IO0 and IO1 lines from the TX FIFO and in x2 RX mode, the same IO0 and IO1 lines are used to receive data and push into RX FIFO.

For x4 mode, the IO0 to IO3 lines are used to transmit and receive the data.

Table 239: QSPI Master Mode Port Configuration

Name	Direction	Description
MOSI / IO0	Bidirectional	Output in Tx Mode Input in Rx Mode
MISO / IO1	Bidirectional	Output in Tx Mode Input in Rx Mode
IO2	Bidirectional	Output in Tx Mode Input in Rx Mode

Table 239: QSPI Master Mode Port Configuration

Name	Direction	Description
IO3	Bidirectional	Output in Tx Mode Input in Rx Mode
SCLK	Output	Synchronization clock to slave
CS0#	Output	Slave select signal

38.1.2.2 DMA and PIO Modes

PIO and DMA are the two main operational modes for the QSPI controller. PIO mode is used when the number of packets to the transmitter or receiver is less than or equal to 64. DMA mode is used when the number of packets to the transmitter or receiver is greater than 64. In PIO or DMA mode, the QSPI controller sends an interrupt to the processor at the end of each transfer. In this mode software configures the number of packets and number of bits in each packet to be transmitted/received. The limitation of PIO Mode is that it can be used only if the maximum number of words that can be transferred is less than or equal to 64 words (the FIFO depth is 64). If software wants to transmit/receive more than 64 words in PIO Mode, it has to reconfigure the QSPI controller every 64 words.

To send/receive more than 64 words, the QSPI Controller can be configured in DMA mode (enabled by writing 1 to the DMA_EN bit in the QSPI DMA Control Register). The QSPI controller transmits or receives the number of packets as indicated by the BLOCK_SIZE field in the QSPI Block Size Register. BLOCK_SIZE is a 16-bit field, so 2^{16} packets (amounting to a maximum 256 KB if pkt_size = 32 bits) can be transmitted/received in a single software configuration.

CS Usage Guideline

If a hardware-based CS is used, the CS goes to the inactive state after the transfer of packets as programmed in the BLOCK_SIZE register field is completed. If CS has to stay active in multiple consecutive transactions (for example, the first transaction – Tx: 64 Packets; the second transaction – Rx: 128 Packets), then the software based CS has to be used (in hardware-based CS, CS goes to the inactive state after the completion of the first transaction).

> ***Note:*** *Hardware-based CS operates only on Flash devices that support it; otherwise data mismatches may occur. Please refer to the definition of CS in your Flash device's specification.*

38.1.2.3 Packed and Unpacked Modes

SPI communication can be carried out in Packed or Unpacked Mode. These are both present in DMA and PIO Modes.

- Packed Mode: In Packed Mode, data can be transmitted/received with each packet size equal to 8, 16, or 32 bits. The PACKED field and BIT_LEN field in the DMA Command1 Register determine if the mode is Packed or Unpacked and the length of each packet. If the BIT_LEN field is set to 07h, each packet is 8 bits long and each word in the Tx/Rx FIFO contains 8 such packets. If BIT_LEN is 0Fh, the packet length is 16. If BIT_LEN is 1Fh, the packet length is 32. In Packed Mode, if BIT_LEN is set to 07h and if the number of packets is set to a non-multiple of 4 (for example, 5), the last word in FIFO contains only the fifth packet with 8 valid bits; 24 extra invalid bits will be ignored by the controller for transmits and will contain invalid data for receives. In packed mode, a minimum transfer will be 1 word. For less than 1 word transfers, software can use Unpacked mode.

> ***Notes:***
>
> - *When the QSPI controller is programmed with BIT_LEN =7/15 in Packed mode and BLK_SIZE is 0xffff, software should use the RDY interrupt to indicate when the transfer is done instead of using the count in the BLK_CNT field in QSPI_TRANSFER_STATUS register.*
> - *The QSPI controller does not push data into the Rx FIFO in Packed mode with block size = 0xFFFF for x2 and x4 and bit length = 32.*

- Unpacked Mode: The main difference between Packed and Unpacked Mode is that in Packed Mode if BIT_LENGTH is set to 07h then each word in the Tx/Rx FIFO has 8 packets with 8 bits each, whereas in Unpacked Mode each word in Tx/Rx FIFO has (BIT_LEN + 1) bits with the remaining bits word being ignored.

38.1.2.4 Bidirectional Mode

Bidirectional mode is selected when the BIDIR bit is set in the QSPI Command1 Register. Bidirectional mode is possible only in x1 mode. In this mode, the IO0 line is used for both transmit and receive operations. When the BIDIR bit is set with the TX_EN bit, the IO0 line is in output mode to transmit data to external flash. And when BIDIR bit is set with RX_EN, the IO0 line is in input mode to receive data from external flash. Bidirectional mode is supported only in SDR mode.

Table 240: Bidirectional Mode Port Configuration (M/S Bit Set

Name	Direction	Description
MOSI (IO0)	Bidirectional	Data Output and Input to Slave(s)
MISO (IO1)	--	--
SCLK	Output	Synchronization clock to all Slaves
CS	Output	Slave select signal

38.1.2.5 En_LE_Bit and En_LE_Byte Modes

Note: *En_LE_Bit is Enable Little Endian Bit, and En_LE_Byte is Enable Little Endian Byte.*

These two bits allow a data packet to be transmitted or received in Little Endian or Big Endian format. Once a data packet is read from the Tx FIFO, it undergoes a two-step pre-processing based on En_LE_Byte and En_LE_Bit.

Step 1. In this step, En_LE_Byte configures whether a packet has to be arranged internally according to the Little Endian byte format or Big Endian byte format. For example, if a 2-byte packet is written into the FIFO by software as Byte 1,Byte 0, setting En_LE_Byte = 0 makes the QSPI controller arrange the packet internally as Byte 0,Byte 1(Big Endian format). If En_LE_Byte = 1, the QSPI controller internally arranges the packet as Byte 1,Byte 0 (Little Endian format) before the packet is transmitted.

Step 2. In this step, the output of Step 1 is taken, and data is put on the MOSI/MISO line according to En_LE_Bit. If En_LE_Bit is set to 0, the most significant bit of the output of Step 1 is put on the MOSI/MISO line first. If En_LE_Bit is set to 1, the least significant bit of Step 1 output is put on the MOSI/MISO line.

These steps are illustrated in the following table.

Step 1	FIFO Packet (MSB - LSB)	En_LE_Byte	Output of Step 1
	Byte 1, Byte 0	0	Byte 0, Byte 1
		1	Byte 1, Byte 0
Step 2	**Output of Step 1**	**En_LE_Bit**	**Data Transmitted on MOSI (Right-most Bit Sent First)**
	Byte 0, Byte 1	0	Byte 1 (0), Byte 1 (1), …, Byte 0 (6), Byte 0 (7)
	Byte 0, Byte 1	1	Byte 0 (7), Byte 0 (6), …, Byte 1 (1), Byte 1 (0)
	Byte 1, Byte 0	0	Byte 0 (0), Byte 0 (1), …, Byte 1 (6), Byte 1 (7)
	Byte 1, Byte 0	1	Byte 1 (7), Byte 1 (6), …, Byte 0 (1), Byte 0 (0)

Similarly for Receive operations, the first packet received will be internally rearranged first based on En_LE_Bit, then the output of the previous step will be rearranged based on En_LE_Byte before writing the final packet into the Rx FIFO.

The following examples explain the effect of these two bits:

- Unpacked Mode
  - Tx: The following example shows how a 20-bit length packet from the FIFO is transmitted. The right-most bit in Column D in the table below is transmitted first. B.7-B.0 indicates that bit 0 is transmitted first followed by bit 1 until bit 7, which is transmitted last.

A	B	C	D
FIFO WORD: 20 (MSB) – 0 (LSB)	En_LE_Bit	En_LE_Byte	Data Transmitted on MOSI/MISO Line
	0	0	16, 17,18, 19, 20, B.8-B.15, B.0-B.7
	0	1	B.0-B.7, B.8-B.15, 16, 17, 18, 19, 20
	1	0	B.7-B.0, B.15-B.8, 20, 19, 18, 17, 16
	1	1	B.20-B.0

- Rx: The following example shows how a 20-bit length packet from the FIFO is received. The right-most bit in Column D in the table below is received last on the MOSI/MISO lines. B.7-B.0 indicates that bit 7 is received first followed by bit 6 until bit 0, which is received last. B.20 – B.0 are always written into the FIFO after the En_LE_Byte and En_LE_Bit transformations.

A	B	C	D
FIFO WORD: 20 (MSB) – 0 (LSB)	En_LE_Bit	En_LE_Byte	Data Received on MOSI/MISO Line
	0	0	B.7-B.0, B.15-B.8, 20, 19, 18, 17, 16
	0	1	20, 19, 18,17, 16, B.15-B.8, B.7-B.0
	1	0	16, 17, 18, 19, 20, B.8-B.15, B.0-B.7
	1	1	B.0-B.20

- Packed Mode
  - Tx: The following example shows how three 16-bit packets are transmitted. Column B indicates the valid packets to be transmitted. Because FIFO Word2 is not transmitted entirely, valid packets are only from B.15-B.0. In Column D, P1(0 -15) indicates Packet1 of Column B is transmitted, B.15 is transmitted first, and B.0 is transmitted last.

A	B: Valid Packets	B	C	D
FIFO WORD1: 31 (MSB) – 0 (LSB)	P1(15-0), P0(15-0)	En_LE_Bit	En_LE_Byte	Data Transmitted on MOSI/MISO Line
FIFO WORD2: 31 (MSB) – 0 (LSB)	P2(15-0)	0	0	P2(8-15), P2(0-7), P1(8-15), P1(0-7), P0(8-15), P0(0-7)
		0	1	P2(0-7), P2(8-15), P1(0-7), P1(8-15), P0(0-7), P0(8-15)
		1	0	P2(7-0), P2(15-8), P1(7-0), P1(15-8), P0(7-0), P0(15-8)
		1	1	P2(15-8), P2(7-0), P1(15-8), P1(7-0), P0(15-8), P0(7-0)

  - Rx: The following example shows how three 16-bit packets are received. Column B indicates the valid received packets in the Rx FIFO. In column D, P1(0 -15) indicates Packet1 of Column B is received, B.0 is received first, and B.15 is received last.

A	B: Valid Packets	B	C	D
FIFO WORD1: 31 (MSB) – 0 (LSB)	P1(15-0), P0(15-0)	En_LE_Bit	En_LE_Byte	Data Received on MOSI/MISO Line
FIFO WORD2: 31 (MSB) – 0 (LSB)	P2(15-0)	0	0	P0(7-0), P0(15-8), P1(7-0), P1(15-8), P2(7-0), P2(15-8)
		0	1	P0(15-8), P0(7-0), P1(15-8), P1(7-0), P2(15-8), P2(7-0)
		1	0	P0(8-15), P0(0-7), P1(8-15), P1(0-7), P2(8-15), P2(0-7)
		1	1	P0(15-8), P0(7-0), P1(15-8), P1(7-0), P2(15-8), P2(7-0)

38.2 QSPI Programming Model

There are two basic modes of operation: DMA and PIO modes. It is required that software sets up all parameters in the QSPI Command1 and Command2 registers, QSPI CS Timing 1 and 2 registers, QSPI FIFO Control/Status register, QSPI DMA Control register, and QSPI Block Size register before enabling the PIO bit in any of these modes.

38.2.1 DMA Mode

This mode is enabled by writing 1 to the DMA bit in the QSPI DMA Control register. In this mode, the QSPI controller transmits or receives the number of packets as indicated by the BLOCK_SIZE field in the QSPI Block Size register.

Choose the INTERFACE_WIDTH to select among x1, x2, and x4 modes. Select SDR_DDR_SEL based on the external QSPI slave device.

If the PACKED bit is set and BIT_LEN is set to 7, then all FIFO words contain 8 packets to transfer (transmit or receive). Packets will be transferred as per the En_LE_Bit and En_LE_Byte bit configurations (see the En_LE_Bit and En_LE_Byte Modes section), with packet 0 in byte 0 of the FIFO and packet 3 in byte 3 of the FIFO.

In Unpacked Mode, if BIT_LEN is set to N, each packet will consist of (N + 1) bits. These bits will be transmitted/received in the Tx_FIFO/Rx_FIFO as per the En_LE_Bit and En_LE_Byte bit configurations (see the En_LE_Bit and En_LE_Byte Modes section). Any remaining bits in the FIFO will be ignored by the hardware. The maximum packet length is 32, which can be selected by setting BIT_LEN to 31. In this case, all data bits in the FIFO contain valid packet data.

A DMA request will be generated to APB_DMA in this mode depending on the setting of Tx_TRIG and Rx_TRIG. If transmits are enabled, setting Tx_TRIG to 00 will generate a Tx DMA request whenever the Tx FIFO has one word of space available (if not full). Setting Tx_TRIG to 01 will generate a Tx DMA request whenever the Tx FIFO has 4 words of space available. If receives are enabled, setting Rx_TRIG to 00 will generate an Rx DMA request whenever the Rx FIFO has one word of data available (is not empty). Setting Rx_TRIG to 01 will generate an Rx DMA request whenever the Rx FIFO has 4 words of data available.

Note: *In DMA mode, the APB DMA and QSPI controllers must be programmed for the same amount of data for correct operation. Otherwise the QSPI controller could fetch too much data.*

38.2.2 PIO Mode

This mode is enabled by writing 1 to the PIO bit in the QSPI Command1 register.

PIO Mode has the same features as DMA Mode. The difference between PIO Mode and DMA Mode is that in PIO Mode, the maximum number of packets that can be transmitted or received is less than or equal to 64.

The QSPI controller is expected to have all the data in FIFOs before software enables the PIO bit.

38.2.3 Interrupt Generation

The QSPI controller generates an interrupt to the processor at the end of a transfer in PIO Mode or when an error is detected (both in PIO and DMA Modes) if the IE.TX or IE.RX bit in the QSPI DMA Control register is enabled for transmit and receive modes of operation, respectively.

If IE.TX is enabled during transmits, an interrupt is generated whenever RDY or one of the FIFO status bits in the QSPI FIFO Control/Status Register is set by the hardware. During transmits, when the QSPI controller is configured as a Slave, if software/APB DMA cannot fill the transmit FIFO fast enough, hardware will set the Tx_FIFO_UNR bit and an underrun condition is generated. If software tries to write to a full Tx FIFO, hardware sets the Tx_FIFO_OVF bit as an indication that software attempted to overflow the Tx FIFO. Hardware makes sure that the overflowing data is never written to the Tx FIFO.

If IE.RX is enabled during receives, an interrupt is generated whenever RDY or one of the status bits in the QSPI FIFO Control/Status Register is set by the hardware. During receives, when the QSPI controller is configured as a Slave, if software/APB DMA cannot read the receive FIFO fast enough, hardware will set the Rx_FIFO_OVF bit and an overflow condition is

generated. However, if software tries to read from an empty Rx FIFO, hardware sets the RXF_UNR bit as an indication that software attempted to underrun the Rx FIFO.

The interrupt can be cleared by writing a 1 to the source of the interrupt. If the interrupt is generated by assertion of RDY, then writing a 1 to the RDY bit clears the interrupt. If the interrupt is generated by assertion of Tx_FIFO_OVF, then writing a 1 to the TXF_OVF bit clears the interrupt. If the interrupt is generated by assertion of Rx_FIFO_UNR, then writing a 1 to RXF_UNR bit clears the interrupt.

38.2.4 Clock Initialization and Control

Refer to Chapter 5: Clock and Reset Controller for details on clock initialization.

38.2.5 Programming Guidelines

This section provides guidelines for programming the QSPI controller:

- Program all the required register fields. Software needs to follow the sequence listed below. Please read this subsection completely to understand the considerations and exceptions):
  a. Clock Mode (Mode 0)
  b. Packed/Unpacked Mode
  c. INTERFACE_WIDTH and SDR_DDR_SEL
  d. Set the bit length (BIT_LEN) and block size (BLOCK_SIZE) values
  e. En_LE_Bit/En_LE_Byte
  f. CS_SW_HW (software based or hardware based)
  - If CS_SW_HW is set, the value on CS_SW_VAL will be driven out.
  - When CS HW is used, program the Setup and Hold Values in the CS Timing Register.
  g. Program the DMA Trig values appropriately, if DMA Mode is used
  h. Enable interrupts
  i. Trimmer settings need to be programmed based on frequency in SDR/DDR modes
  j. Tx_En/Rx_En
  k. Software needs to program num_of_dummy_cycles (required for fast read operation) while setting up a TX transfer (for CMD and ADDR). Note that dummy_cycles are valid only when sw_cs is selected.
  l. For PIO, the QSPI Controller is expected to have all the data in FIFOs before software enables the PIO bit.
  m. PIO or DMA must be programmed last to indicate the start of transfer.

Considerations and Exceptions

PIO or DMA has to be programmed last. These bits indicate the start of transfer. QSPI has sync APB plugin. Because the QSPI registers are in the pclk domain, it takes a couple of additional clock cycles to sync to the qspi_clk domain. In some cases, software might have to add a few clock cycle delay before programming PIO and DMA to make sure that PIO and DMA are programmed last.

For successful operation at various frequency combinations, a minimum 4-5 spi_clk cycle delay might be required before enabling the PIO or DMA bit. This is needed to overcome the MCP between the core and pad macro. The worst case delay calculation can be done considering the slowest qspi_clk as 1 MHz. based on that 1 µs delay should be enough before enabling PIO or DMA.

Once software enables PIO/DMA, no bits are changed until the end of transfer except for PIO/DMA bit. Clearing the PIO/DMA bit will end the transaction. In case the QSPI controller is configured to Receive Mode and software clears the PIO/DMA bit, then the partial data which the controller received until then will be written into the FIFO.

Do not enable conflicting features simultaneously. For example, bidirectional (BIDIR) mode works only with x1 mode.

If any error conditions occur, hardware will set the corresponding status bits in the QSPI FIFO Control/Status register and stop the transfer. If IE is enabled, an interrupt is generated. Software has to clear the source of the interrupt by writing a 1 to it, after the completion of ISR.

DDR output commands are sent to the device in SDR mode, whereas address and data are transferred in DDR mode. So software needs to program the necessary bits along with trimmer settings explicitly.

DDR TX mode uses 2x_clk. The QSPI controller has a clk_en for this clock based on DDR mode selection. When the DDR bit is selected then only the CAR will issue clk_2x to the controller. The CAR block has synchronizer to sync this clk_en. So software might have to wait for a few cycles after selecting DDR mode and before enabling DMA or PIO.

Note that the controller does not generate any interrupts to indicate dummy_cycle done. Software has to wait for some time (based on number of clocks) before setting up the next transfer.

- Set up a TX transfer for CMD and ADDR, configure num_of_dummy_cycles with that
- When the TX transfer is done, wait for some time (based on number of clocks) so that the controller is done with dummy_cycles on the QSPI interface
- Set up an RX transfer to read actual data.

Software needs to make sure that while programming the block_size field, the tx_en and rx_en bits must be zero. This is needed to avoid any internal glitches while loading the block_size value to counters and other comparators. The tx_en and rx_en bits should be programmed separately in the last in COMMAND register.

38.2.5.1 Error Conditions

When the QSPI controller is configured as a Master, the following error scenarios can happen:

- Tx_FIFO overflow

  Tx_FIFO overflow happens when the CPU/APB_DMA writes into the Tx FIFO when it is full. In this case, the QSPI controller will end the transaction by setting the PIO/DMA_EN bit to 0, and flag the error bit along with the Tx_FIFO_OVF bit in the QSPI FIFO Control/Status register. The QSPI controller will generate an interrupt if interrupts are enabled. Software has to clear the error bit and the Tx_FIFO_OVF bit. To start a new transaction, software has to flush the FIFOs by writing to the TX_FIFO_FLUSH/RX_FIFO_FLUSH bits in the QSPI FIFO Control/Status register.

- Rx_FIFO overflow

  Rx_FIFO overflow happens when the CPU/APB_DMA writes into the Rx FIFO when it is full in BOTH_EN Mode. In this case, the QSPI controller will end the transaction by setting the PIO/DMA_EN bit to 0, and flag the error bit along with Rx_FIFO_OVF bit in the QSPI FIFO Control/Status register. The QSPI controller will generate an interrupt if interrupts are enabled. Software has to clear the error bit and the Rx_FIFO_OVF bit. To start a new transaction, software has to flush the FIFOs by writing to the TX_FIFO_FLUSH/RX_FIFO_FLUSH bits in the QSPI FIFO Control/Status register.

- Tx_FIFO underrun

  Tx_FIFO underrun happens when the CPU/APB_DMA reads from the Tx FIFO when it is empty. In this case, the QSPI controller will end the transaction by setting the PIO/DMA_EN bit to 0, and flag the error bit along with the Tx_FIFO_UNR bit in the QSPI FIFO Control/Status register. The QSPI controller will generate an interrupt if interrupts are enabled. Software has to clear the error bit and the Tx_FIFO_UNR bit. To start a new transaction, software has to flush the FIFOs by writing to the TX_FIFO_FLUSH/RX_FIFO_FLUSH bits in the QSPI FIFO Control/Status register.

- Rx_FIFO underrun

  Rx_FIFO underrun happens when the CPU/APB_DMA reads from the Rx FIFO in BOTH_EN Mode. In this case, the QSPI controller will end the transaction by setting the PIO/DMA_EN bit to 0, and flag the error bit along with the Rx_FIFO_UNR bit in the QSPI FIFO Control/Status register. The QSPI controller will generate an interrupt if interrupts are enabled. Software has to clear the error bit and the Rx_FIFO_UNR bit, along with the Interrupt bit. To start a new transaction, software has to flush the FIFOs by writing to the TX_FIFO_FLUSH/RX_FIFO_FLUSH bits in the QSPI FIFO Control/Status register.

Note: *In Master Mode, all the errors above can happen only when the CPU/APB_DMA reads/writes an empty/full FIFO. The QSPI controller will never write/read a full/empty FIFO. Instead the*

controller will pause (stops sending clocks to the slave with chip select being in an active state) whenever the FIFOs are full/empty.

38.2.5.2 Programming Trimmers

The 2 programmable trimmers in the QSPI controller are used only in Master Mode:

- QSPI-Tx trimmer

  This trimmer is used in Master Tx mode to adjust/center the outgoing data with respect to the outgoing clock.

- QSPI-Rx trimmer

  This trimmer is used in Master Rx mode to delay the loopback clock to center align the RX data to meet setup/hold and data valid requirements.

In addition, there are 32 tap trimmers on incoming DATA lines as well. These are trimmers can be programmed in the QSPI_TIMING3 register.

38.2.5.3 Tuning Sequence

Tuning is about finding the right sampling point for incoming data. It is required to achieve the trimmer settings which might vary across the platforms. Software needs to follow the tuning procedure below before starting data transfers at higher speeds.

The QSPI controller does not implement auto-tuning. Tuning is completely software-based. Software is supposed to read the tuning pattern and change the trimmer setting accordingly.

However, Spansion flash supports data loss prevention (DLP) where the flash outputs data pattern during dummy cycle phase. Because the controller generated dummy cycles during TX phase, it will not be able to sample DLP data during dummy_cycle phase.

However, software can achieve the DLP scenario by following the steps below.

1. When tuning is not required OR software does not want to read DLP (as in SDR or DDR x1/x2 mode):
   a. Program num_of_dummy_cycle with TX transfer as mentioned above
   b. Set up a normal RX transfer to read main data
2. When tuning is required OR software wants to read/peel DLP:
   a. Programming dummy_cycle is not really required. software can set up a normal RX transfer (length of transfer can be num_of_dummy_cycle + some_extra_bytes), and then peel the DLP data out of it accordingly.
   b. Once tuning is done, software can disable the DLP by writing 0x00 in the VDLP register (using the WVDLR 4Ah command).
   c. Set up the normal RX transfer.

38.2.5.4 Pad Calibration

Software controls the “Reg_on” signal to enable the high-speed interface. This signal is controlled by the QSPI_COMP_PAD_REG_ON bit in the APB_MISC_GP_QSPI_COMP_CONTROL_0 register (see the APB chapter).

This bit has to be set to 0 during cold boot in the boot ROM phase.

In the boot loader phase, this bit should be set to 1. This turns on the regulator inside the comp pad and enables the interface for high-speed operation. Software needs to wait for 1 µs after that. This will turn on the regulator in the pad and the speed can be ramped up to 166 MHz without calibration.

38.3 QSPI Controller Registers

Refer to Section 1.4: Reading Register Tables in the Introduction chapter for the register table protocol as well as recommendations for accessing registers.

There is one set of the QSPI controller registers. The register descriptions below give the offset of each register within the QSPI controller's address range. See Chapter 2: Address Map for the starting address of the QSPI controller.

38.3.1 QSPI_COMMAND_0

QSPI Command1 Register

This register is used to set the bit length and to select the transfer mode.

Chip Select can also be selected to be in hardware mode as software mode with both active high and active low polarities to support devices with varying CS polarities.

Offset: 0x0 | Read/Write: R/W | Reset: 0x4050001f (0b010000xxx10100000xx00x000x011111)

Bit	Reset	Description
31	0x0	PIO: Program 1 after all the other bits in the QSPI_COMMAND2 and QSPI_COMMAND1 registers are programmed to start the transfer. Hardware clears this bit automatically after the transfer is done. Clearing of this bit by software will stop the shifter and latch the partial data into the buffer (in Receive Mode). 0 = STOP (default) 1 = GO
30	0x1	M/S: Master/Slave mode select. 0 = Reserved 1 = Master Mode (internal clock) (default)
29:28	0x0	MODE: The QSPI interface clock mode has to be programmed according to the device with which it is communicating. Only Master Mode 0 is supported. 0 = Mode 0 (default) 1 = RSVD 2 = RSVD 3 = RSVD Master: Only Mode 0 is supported both for Tx and Rx. Slave: Not supported.
27:26	0x0	CS_SEL: Only one chip select is supported to select one slave device. 0 = Selects CS0 (default) 1 = RSVD1 2 = RSVD2 3 = RSVD3
22	0x1	CS_POL_INACTIVE#0: In Master Mode, the inactive value of the external device's CS value, which is connected to CS0, needs to be programmed. 0 = CS0 Inactive value of External device is low 1 = CS0 Inactive value of External device is high 0 = LOW 1 = HIGH (default)
21	0x0	CS_SW_HW: Software control of the QSPI_CS signal in Master Mode. In Slave Mode, this bit need not be programmed. 0 = QSPI _CS# (CS_SEL) is driven to the active state during packet transfers by the hardware (default) 1 = QSPI _CS# (CS_SEL) is driven with the value in the CS_SW_VAL bit 0 = HARDWARE 1 = SOFTWARE
20	0x1	CS_SW_VAL: CS signal value in Master Mode. If CS_SW_HW is 1, then the value in CS_SW_VAL is driven out on CS. If CS_SW_HW is 0, then this bit has no effect. 0 = CS is LOW 1 = CS is HIGH (default)
19:18	0x0	IDLE.SDA: Inactive data signal format. Controls the output enable of the SDA line when the controller is inactive and not doing data transfers. 0 = Drive low. (Master Mode) (default) 1 = Drive high. (Master Mode) 2 = External Pull Down. (Slave Mode) 3 = External Pull high. (Slave Mode)
17	0x0	BIDIR: Bidirectional Transfer Control Bit: This bit enables the bidirectional mode of the transfer. Valid only for SDR mode. 0 = Normal Mode (default) 1 = Bidirectional Mode

Bit	Reset	Description
16	0x0	En_LE_Bit: 1 = Enable Little Endian Bit. 0 = Disable Little Endian Bit 0 = LAST 1 = FIRST
15	0x0	En_LE_Byte: 1 = Enable Little Endian Byte. 0 = Disable Little Endian Byte 0 = LAST 1 = FIRST
12	0x0	Rx_EN: Receive enable. Setting this bit to 1 enables the controller to receive the data. 0 = DISABLE (default) 1 = ENABLE
11	0x0	Tx_EN: Transmit enable. Setting this bit to 1 enables the controller to transmit the data. 0 = DISABLE (default) 1 = ENABLE
9	0x0	SDR_DDR_SEL: Selects between SDR (Single Data Rate) and DDR (Double Data Rate) mode. 0: SDR; Data is transmitted on falling edge of SCLK and received on rising edge of SCLK. 1: DDR; Data is transmitted and received on both the edges of SCLK 0 = SDR 1 = DDR
8:7	0x0	INTERFACE_WIDTH: This field is used to define the QSPI interface width 00 = Single bit mode (x1 mode) 01 = Dual mode (x2 mode) 10 = Quad mode (x4 mode) 11 = RSVD 0 = SINGLE 1 = DUAL 2 = QUAD
5	0x0	PACKED: Packed mode enable bit. 0 = Unpacked Mode (default) 1 = Packed Mode. This is only valid if the BIT_LEN field is set to 7 (8-bit transfer), 15 (16-bit transfer), or 31 (32-bit transfer). When enabled, all 32 bits of data in the FIFO contains valid data packets of either 8-bit, 16-bit, or 32-bit length. Packed mode should be selected when the minimum transfer is 1 word. For bit_len=31, this bit need not be set.
4:0	0x1f	BIT_LEN: This field represents the number of bits in a packet to transmit/receive. The minimum bit_length supported is 1 byte (BIT_LEN=7). Only byte aligned bit lengths are supported (BIT_LEN=7, 15, 31). N = N+1-bit transfer 31 = 32-bit transfer

38.3.2 QSPI_COMMAND2_0

QSPI Command2 Register

Offset: 0x4 | Read/Write: R/W | Reset: 0x00000000 (0bxxxxxxxxxxxxxxxxxx00000xx00000000)

Bit	Reset	Description
14:10	0x0	Tx_Clk_TAP_DELAY: Delays the clock going out to the external device with these tap values. Useful only in Master Mode.
7:0	0x0	Rx_Clk_TAP_DELAY: Delays the clock coming in from the external device with these tap values. Useful only in Master Mode.

38.3.3 QSPI_TIMING_REG1_0

QSPI CS Timing1 Register

Offset: 0x8 | Read/Write: R/W | Reset: 0x00000000 (0bxxxxxxxxxxxxxxxxxxxxxxxxx00000000)

Bit	Reset	Description
7:4	0x0	CS_SETUP_ 0: Specifies the setup time of the chip select to the data being transmitted or received on CS#0 in numbers of cycles (16 cycles maximum). The default is 0. 1 = 2 clock cycle delay 2 = 3 clock cycle delay, etc.

Bit	Reset	Description
3:0	0x0	CS_HOLD_0: Specifies the hold time of the chip select to the data being transmitted or received on CS#0 in numbers of cycles (16 cycles maximum). The default is 0. 1 = 2 clock cycle delay 2 = 3 clock cycle delay, etc.

38.3.4 QSPI_TIMING_REG2_0

QSPI CS Timing2 Register

Offset: 0xc │ Read/Write: R/W │ Reset: 0x00000020 (0bxxxxxxxxxxxxxxxxxxxxxxxxxxx100000)

Bit	Reset	Description
5	0x1	CS_ACTIVE_BETWEEN_PACKETS_0: Specifies if CS stays active between two packets on CS#0 1 = CS active between two packets (default) 0 = CS inactive between two packets Note: Hardware-based CS operates only on Flash devices that support it. Please refer to the definition of CS in your Flash device's specification.
4:0	0x0	CYCLES_BETWEEN_PACKETS_0: Specifies the number of cycles between packets in the PIO/DMA Mode for communication on CS#0. The default is 0. 1 = 2 clock cycle delay 2 = 3 clock cycle delay, etc.

38.3.5 QSPI_TRANSFER_STATUS_0

QSPI TRANSFER Status Register

Read this register for the status of the transfer.

Offset: 0x10 │ Read/Write: R/W │ Reset: 0x0000XXXX (0bx0xxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx)

Bit	R/W	Reset	Description
30	RW	0x0	RDY: Ready bit. This bit is set to 1 at the end of every transfer, and an interrupt is also generated if the corresponding interrupt enable is set in PIO/DMA Mode. Software writes a 1 to clear it. The interrupt is also cleared when this bit is cleared. 0 = NOT_READY (default) 1 = READY
15:0	RO	X	BLK_COUNT: Counts the number of packets in a transaction (Tx or Rx) in DMA/PIO Mode. When blk_cnt=0xffff is programmed, this field will show 0x0 at the end of a transfer.

38.3.6 QSPI_FIFO_STATUS_0

QSPI Control/Status FIFO Status Register

QSPI STATUS register: Read this register to know the status of the transfer. Error bit is set whenever errors such as Underflow/ Overflow are encountered.

Offset: 0x14 │ Read/Write: R/W │ Reset: 0x00400005 (0bxxxxxxxxxxxxxxxx00xxxxx00000xxxx)

Bit	R/W	Reset	Description
29:23	RO	X	RX_FIFO_FULL_COUNT: Indicates the number of slots in the receive FIFO remaining before the FIFO is empty. This field is used by software for debugging purposes.
22:16	RO	X	TX_FIFO_EMPTY_COUNT: Indicates the number of slots in the transmit FIFO remaining before the FIFO is full. This field is used by software for debugging purposes.
15	RW	0x0	RX_FIFO_FLUSH: Software writes a 1 to this bit to flush the Rx FIFO. This bit reads as 1 when the flush operation is in progress and returns to 0 when it is finished. 0 = NOP (default) 1 = FLUSH
14	RW	0x0	TX_FIFO_FLUSH: Software writes a 1 to this bit to flush the Tx FIFO. This bit reads as 1 when the flush operation is in progress and returns to 0 when it is finished. 0 = NOP (default) 1 = FLUSH

Bit	R/W	Reset	Description
13:9	N/A		Reserved for future use. Always write zeros.
8	RW	0x0	ERR: Will be set to 1 by hardware when errors such as underflow/overflow occur. Software writes a 1 to clear the flag. 0 = OK (default) 1 = ERROR
7	RW	0x0	TX_FIFO_OVF: TX FIFO Overflow. This bit is set to 1 whenever the QSPI controller or software tries to write to a full Tx FIFO. An interrupt is generated if the interrupt enable is set for transmit operations (IE.TX in the QSPI_DMA_CTL register). Software writes a 1 to clear this bit. 0 = OK (default) 1 = ERROR
6	RW	0x0	TX_FIFO_UNR: TX FIFO Underrun. This bit is set to 1 whenever the QSPI controller or software tries to read from an empty Tx FIFO. An interrupt is generated if the interrupt enable is set for transmit operations (IE.TXC in the QSPI_DMA_CTL register). Software writes a 1 to clear this bit. 0 = OK (default) 1 = ERROR
5	RW	0x0	RX_FIFO_OVF: RX FIFO Overflow. This bit is set to 1 whenever the QSPI controller or software tries to write into a full Rx FIFO. An interrupt is generated if the interrupt enable is set for receive operations (IE.RXC in the QSPI_DMA_CTL register). Software writes a 1 to clear this bit. 0 = OK (default) 1 = ERROR
4	RW	0x0	RX_FIFO_UNR: RX FIFO Underrun. This bit is set to1 whenever the QSPI controller or software tries to read from an empty Rx FIFO. An interrupt is generated if the interrupt enable is set for receive operations (IE.RXC in the QSPI_DMA_CTL register). Software writes a 1 to clear this bit. 0 = OK (default) 1 = ERROR
3	RO	X	TX_FIFO_FULL: TX FIFO Full Status. Hardware sets this bit to 1 if the Tx FIFO is full; otherwise this bit is 0. The Tx FIFO is empty at power on reset (POR). 0 = NOT_FULL (default) 1 = FULL
2	RO	X	TX_FIFO_EMPTY: TX FIFO Empty Status. Hardware sets this bit to 1 if the Tx FIFO is empty; otherwise this bit is 0. The Tx FIFO is empty at POR. 0 = NOT_EMPTY 1 = EMPTY (default)
1	RO	X	RX_FIFO_FULL: RX FIFO Full Status. Hardware sets this bit to 1 if the Rx FIFO is full; otherwise this bit is 0. The Rx FIFO is empty at POR. 0 = NOT_FULL (default) 1 = FULL
0	RO	X	RX_FIFO_EMPTY: RX FIFO Empty Status. Hardware sets this bit to 1 if the Rx FIFO is empty; otherwise this bit is 0. The Rx FIFO is empty at POR. 0 = NOT_EMPTY 1 = EMPTY (default)

38.3.7 QSPI_TX_DATA_0

QSPI Transmit Data Register

Offset: 0x18 │ Read/Write: RO │ Reset: 0x00000000 (0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx)

Bit	Reset	Description
31:0	X	QSPI_Tx_DATA. Transmit Data. This register holds the last data that was transmitted by the QSPI controller.

38.3.8 QSPI_RX_DATA_0

QSPI Receive Data Register

Offset: 0x1c | Read/Write: RO | Reset: 0x00000000 (0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx)

Bit	Reset	Description
31:0	X	QSPI_Rx_DATA. Receive Data. This register holds the last data that was received by the QSPI controller.

38.3.9 QSPI_DMA_CTL_0

QSPI DMA Control Register

QSPI DMA Control Register: Used in the DMA transfers. We can set trigger levels in this register

Offset: 0x20 | Read/Write: R/W | Reset: 0x00000000 (0b0xxxxxxxxxx00xx00xxxxxxxxxxxxxxx)

Bit	Reset	Description
31	0x0	DMA_EN: Enable DMA Mode transfer. Software writes a 1 to this bit to start a transfer in the DMA mode. All fields in the QSPI_COMMAND1 and QSPI_DMA_CTL register must be set before writing a 1 to this bit. This bit is cleared by the QSPI controller after all packets have been transferred as indicated by the DMA_BLOCK_SIZE field. Clearing this bit by software will stop the shifter and latch the partial data into buffer. 0 = DMA Mode is disabled (default) 1 = DMA Mode is enabled
20:19	0x0	RX_TRIG: Receive FIFO trigger level. 00: 1 word. DMA trigger is asserted whenever there is at least 1 packet in the RX FIFO. (default) 01: 4 words. DMA trigger is asserted when there are at least 4 packets in the RX FIFO. 10: 8 words. DMA trigger is asserted when there are at least 8 packets in the RX FIFO. 11: 16 words. DMA trigger is asserted when there are at least 16 packets in the RX FIFO. (Presently, the APB DMA does not support this trigger level.)
16:15	0x0	TX_TRIG: Transmit FIFO trigger level. 00: 1 word. DMA trigger is asserted whenever there is space for at least 1 packet in the TX FIFO. (default) 01: 4 words. DMA trigger is asserted when there is space for at least 4 packets in the TX FIFO. 10: 8 words. DMA trigger is asserted when there is space for at least 8 packets in the TX FIFO. 11: 16 words. DMA trigger is asserted when there is space for at least 16 packets in the TX FIFO. (Presently, the APB DMA does not support this trigger level.)

38.3.10 QSPI_DMA_BLK_SIZE_0

QSPI DMA Block Size Register

Offset: 0x24 | Read/Write: R/W | Reset: 0x00000000 (0bxxxxxxxxxxxxxxxx0000000000000000)

Bit	Reset	Description
15:0	0x0	DMA_BLOCK_SIZE: Size of data block to be transferred in PIO/DMA Mode. The default is 0. In DMA Mode, the maximum number of 32-bit packets that can be transferred is 2^{16} = 65536. In PIO Mode, the maximum number of 32-bit packets that can be transferred is 64 (FIFO depth). The Block Size has to be programmed 1 packet less than intended; for example, a value of 3 indicates 4 packets are to be transferred.

38.3.11 QSPI_TX_FIFO_0

QSPI TX FIFO Buffer Register

Offset: 0x108 | Read/Write: R/W | Reset: 0x00000000 (0b00000000000000000000000000000000)

Bit	Reset	Description
31:0	0x0	QSPI Tx_FIFO_REGISTER. Tx FIFO.

38.3.12 QSPI_RX_FIFO_0

QSPI RX FIFO Buffer Register

Offset: 0x188 | Read/Write: R/W | Reset: 0x00000000 (0b00000000000000000000000000000000)

Bit	Reset	Description
31:0	0x0	QSPI Rx_FIFO_REGISTER. Rx FIFO.

38.3.13 QSPI_INTR_MASK_0

QSPI Interrupt Mask Register

Offset: 0x18c | Read/Write: R/W | Reset: 0x00000000 (0bxx00000xxxxxxxxxxxxxxxxxxxxxxxx)

Bit	Reset	Description
29	0x0	RDY_INTR_MASK: Interrupt enable mask bit for RDY. 0 = Enable interrupt generation when RDY bit is asserted. 1 = Disable interrupt generation when RDY bit is asserted. 0 = DISABLE 1 = ENABLE
28	0x0	TX_FIFO_OVF_INTR_MASK: Interrupt enable mask bit for TX_FIFO_OVF. 0 = Enable interrupt generation when TX_FIFO_OVF is asserted. 1 = Disable interrupt generation when TX_FIFO_OVF is asserted. 0 = DISABLE 1 = ENABLE
27	0x0	TX_FIFO_UNF_INTR_MASK: Interrupt enable mask bit for TX_FIFO_UNF. 0 = Enable interrupt generation when TX_FIFO_UNF is asserted. 1 = Disable interrupt generation when TX_FIFO_UNF is asserted. 0 = DISABLE 1 = ENABLE
26	0x0	RX_FIFO_OVF_INTR_MASK: Interrupt enable mask bit for RX_FIFO_OVF. 0 = Enable interrupt generation when RX_FIFO_OVF is asserted. 1 = Disable interrupt generation when RX_FIFO_OVF is asserted. 0 = DISABLE 1 = ENABLE
25	0x0	RX_FIFO_UNF_INTR_MASK: Interrupt enable mask bit for RX_FIFO_UNF. 0 = Enable interrupt generation when RX_FIFO_UNF is asserted. 1 = Disable interrupt generation when RX_FIFO_UNF is asserted. 0 = DISABLE 1 = ENABLE

38.3.14 QSPI_SPARE_CTLR

QSPI Spare Control Register

Offset: 0x190 | Read/Write: R/W | Reset: 0x0fff0000 (0b00001111111111111000000000000000)

Bit	Reset	Description
31:11	00001111111111100000b	Reserved for future use.
10:8	000b	QSPI_SPARE_CONTROL_REGISTER_BYTE2. Program bits 8, 9, and 10 along with Rx_Clk_TAP_DELAY in the COMMAND2 register to adjust the clock delay on internal registers. Useful in Master Mode only.

Bit	Reset	Description
7:0	0x00	Reserved for future use.

38.3.15 QSPI_MISC_0

QSPI Miscellaneous Register

Offset: 0x194 | Read/Write: R/W | Reset: 0x00000000 (0bxxxxxxxxxxxxxxxxxxxxxxxxx00000000)

Bit	Reset	Description
7:0	0x0	NUM_OF_DUMMY_CLK_CYCLES: Number of dummy cycles required in case of Fast read commands. this is useful only in case of read from flash.

38.3.16 QSPI_TIMING3_0

QSPI Timing3 Register

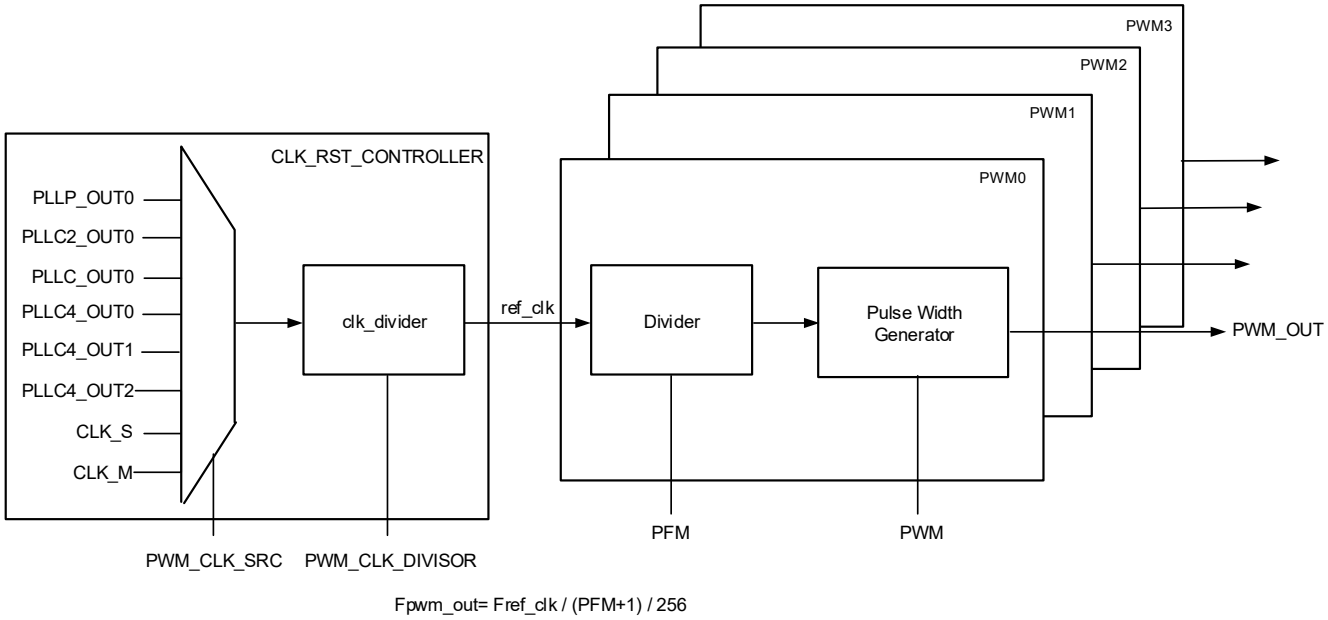
Offset: 0x198 | Read/Write: R/W | Reset: 0x00000000 (0bxxx00000xxx00000xxx00000xxx00000)

Bit	Reset	Description
28:24	0x0	DATA3_LINE_TAP_DELAY: Delays the Data3 coming in from the external device with these tap values.
20:16	0x0	DATA2_LINE_TAP_DELAY: Delays the Data2 coming in from the external device with these tap values.
12:8	0x0	DATA1_LINE_TAP_DELAY: Delays the Data1 coming in from the external device with these tap values.
4:0	0x0	DATA0_LINE_TAP_DELAY: Delays the Data0 coming in from the external device with these tap values.

CHAPTER 39: PWM CONTROLLER

The Pulse Width Modulator (PWM) controller is a four channel frequency divider whose pulse width varies. Each channel has a programmable frequency divider and a programmable pulse width generator.

Figure 166: PWM Controller Block Diagram



Note: *To derive PFM given the Fref_clk and desired Fpwm_out:*
PFM = max(min(round((Fref_clk / 256)/Fpwm_out)-1, 0x1fff), 0x0)
Where round() rounds result to nearest integer and min/max clamp the PFM to the valid 13-bit range.
Also, PWM computation: Given desired pulse with as a percentage (0..100 %):
*PWM = max(min(round(percent/100 * 256), 256), 0)*

Frequency division is a 13-bit programmable value, and pulse division is an 8-bit value.

The PWM controller runs off a device clock, which is programmed in the Clock and Reset controller, and can be any frequency up to the device clock maximum speed of 48 MHz.

The device clock frequency is always subject to a minimum divide by 256 to generate the PWM output frequency, and may also be subdivided to slow it down further based on the programmable value locally.

There is an APB interface that interfaces the register logic to the APB bus.

The PWM controller contains four independently programmable pulse width modulators. Each generated pulse has an n/256 duty cycle. PWM signals are useful for LCD contrast and brightness control, VCO-generated clocks and other analog voltage references where high precision is not required.

39.1 Functionality

There are four PWM controllers on four individual pins on the chip. The pinmux corresponding to these are SDC primary pin groups. For the four PWM controllers, there are four corresponding registers:

- PWM_CSR0
- PWM_CSR1

- PWM_CSR2
- PWM_CSR3

Each PWM controller must be enabled (bit 31) to be operational. Pulse Width [24:16] determines the output pulse width and must be programmed appropriately. Pulse Width [30:25] is not used and must be 0. Frequency Divider [12:0] determines the divided clock.

39.2 PWM Registers

Refer to Section 1.4: Reading Register Tables in the Introduction chapter for the register table protocol as well as recommendations for accessing registers.

39.2.1 PWM_CONTROLLER_PWM_CSR_<x>_0

There are four PWM CSR registers, where <x> is a value from 0 through 3.

PWM Output <x> Configuration Control Register

Offset: 0x0 + (<x> * 0x10) | Read/Write: R/W | Reset: 0x00000000 (0b00000000000000000xxx0000000000000)

Bit	Reset	Description
31	0x0	ENB: Enable Pulse width modulator 0 = DISABLE 1 = ENABLE
30:16	0x0	PWM_0: pulse width that needs to be programmed. 0=Always low. 1=1/256 Pulse high. 2=2/256 Pulse high. N=N/256 Pulse high Note: To achieve 100% duty cycle (constant high output), program register PWM_CONTROLLER_PWM_CSR_0 Bit 24 to 1.
12:0	0x0	PFM_<x>: Frequency divider that needs to be programmed. See the note on programming the PFM value at the start of this chapter.

CHAPTER 40: THERMAL SENSOR AND THERMAL THROTTLING CONTROLLER

40.1 Thermal Throttling Controller (SOC_THERM)

The functions of the thermal throttling controller (SOC_THERM) include:

- Thermal Sensor Management: Handles access, capture and processing of data from thermal sensors which are located in multiple locations around the SOC.
- Thermal Event Detection: Provides multiple software configurable thermal thresholds per sensor. Thermal threshold crossings can be configured to raise interrupts or trigger a hardware throttling response.
- Over-Current Detection:
  - Externally Signaled Event Detection: Configurable “over-current” (OC) input pins which can be used to trigger throttle responses. These pins might be wired to signals from the PMIC or battery monitors.
- Throttle Management and Prioritization: For each of the events that can trigger a throttle response, provides configuration of that throttling response. For example, a CPU temperature exceeding 90ºC could trigger a 50% throttling of the CPU clock. Also, this block provides for prioritizing the throttling responses when multiple thermal or over-current events are happening simultaneously.

The intention of this section is not to provide a full programmer’s guide, but solely to document the register interface to allow better understanding of NVIDIA provided drivers.

40.2 Thermal Sensor

Thermal sensors are used to constantly monitor the temperature on the chip. Sensors are placed across the die to gauge the temperature of the whole chip. The TSensor module can:

- Generate an interrupt to software to lower temperature via DVFS, on reaching a certain thermal threshold
- Generate a signal to the CAR block to reduce CPU frequency by half, on reaching a certain thermal threshold
- Generate a signal to the PMC when temperature reaches very high levels to reset the chip, and set a flag in the PMC

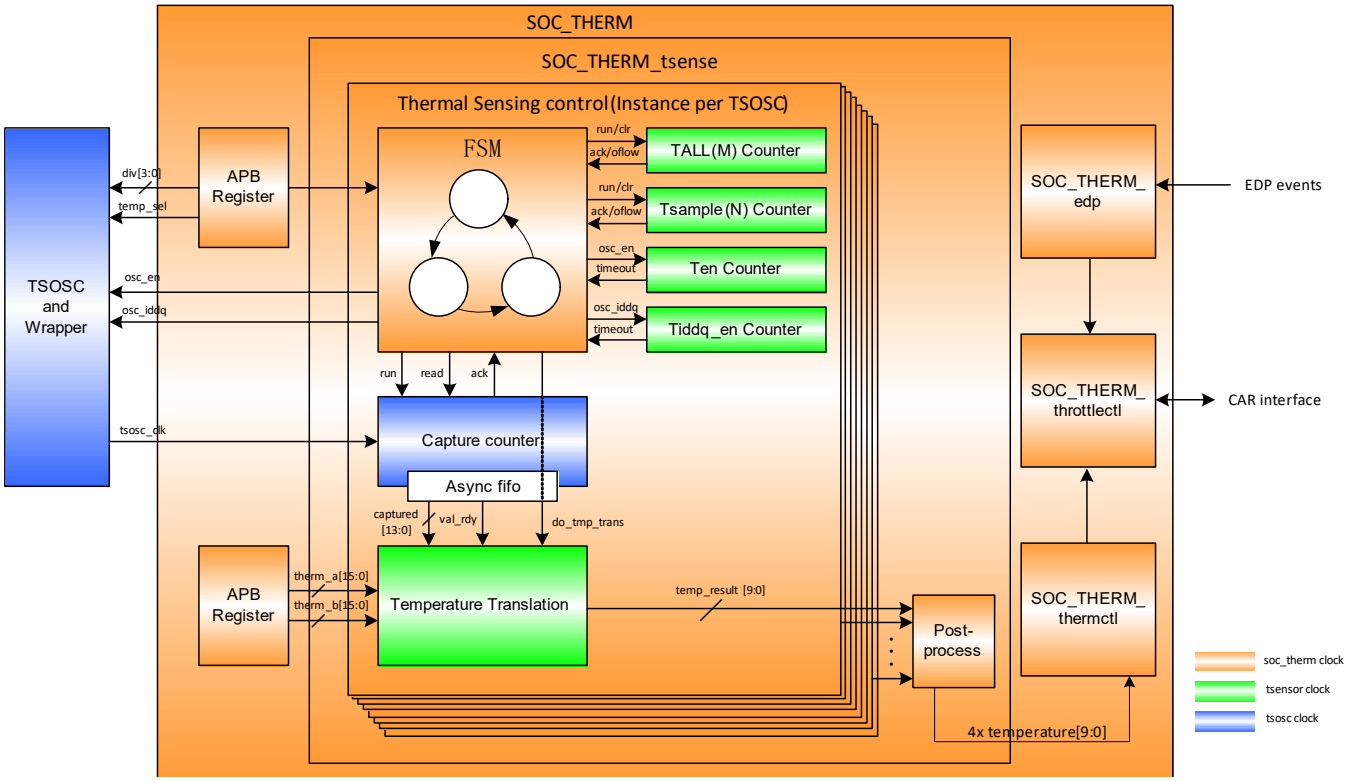
40.3 Thermal Sensing (SOC_THERM_tsense)

SOC_THERM_tsense centralizes management of eight on-chip thermal sensors: one per CPU core, one within the GPU, two near the memory I/O, and one near PLLX. Each sensor is an instance of the TSOSC_C cell -- a ring oscillator whose output frequency is proportional to temperature.

SOC_THERM_tsense includes

- capture logic for manipulating the TSOSC’s and measuring their output
- arithmetic logic for translating sensor readings to degrees Celsius (with 0.5ºC precision)
- post-processing logic (e.g., for handling “invalid” sensor data) and
- JTAG interface logic to support per-sensor calibration on ATE.

Figure 167: SOC_THERM_tsense in context



The output of SOC_THERM_tsense is a stream of four temperature measurements – CPU temperature, GPU temperature, memory I/O temperature, and PLLX temperature. SOC_THERM_tsense feeds these measurements directly to SOC_THERM_thermalctl but also exposes them to software via registers.

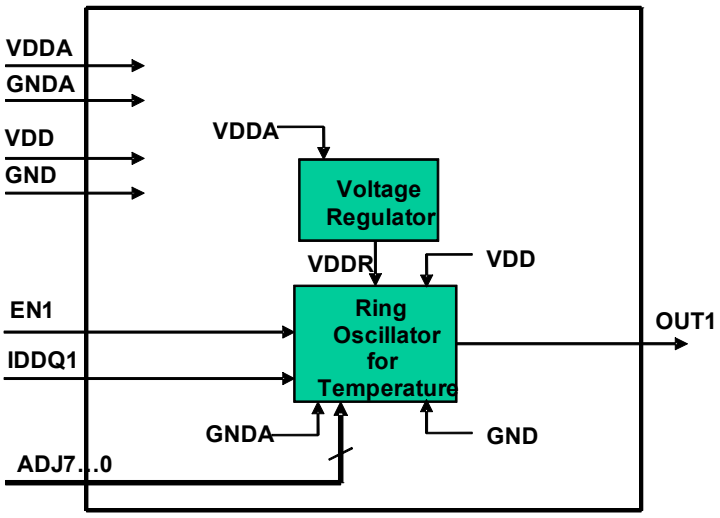
Temperature translation depends on per-sensor calibration data. This calibration data is collected on ATE (during chip manufacture) and stored in on-chip fuses. Prior to enabling thermal sensing, software must unpack the calibration data and pass it to SOC_THERM_tsense's translation logic via registers.

The real TSOSC Vmin will be higher than real standard logic Vmin. There is a software scheme to disable VDD TSOSCs when voltage goes too low and hardware scheme to redirect readings to I/O TSOSC with hot spot displacement. It is possible to overheat at Vmin.

40.3.1 TSOSC Thermal Sensor Cells

The figure below shows the basic TSOSC structure.

Figure 168: TSOSC Structure



The output frequency of any CMOS ring oscillator depends on manufactured characteristics (i.e., process), supply voltage, and temperature. When enabled at steady state, TSOSC acts as a temperature sensor because:

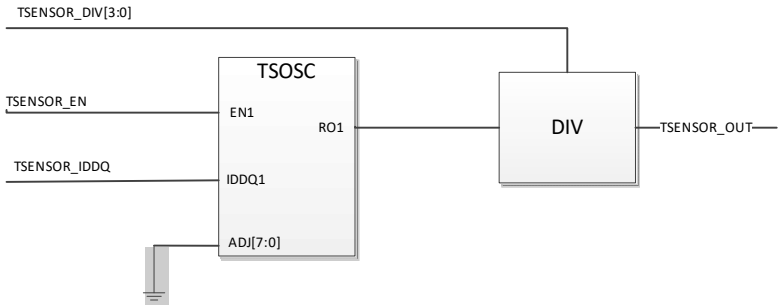
- the voltage regulator compensates for variation in supply voltage (VDDA/GNDA) and
- calibrate every TSOSC we manufactured is calibrated to compensate for manufacturing variation

Logic within SOC_THERM_tsense translates TSOSC output frequency to temperature. The TSOSC datasheet includes a table estimating TSOSC output frequency relative to temperature and silicon process. The content of that table is critical for validating the precision required in the SOC_THERM_tsense arithmetic.

40.3.1.1 Wrapper Logic

In order to decrease number of wires running across the chip and reduce RO frequency to the value safe to pass for a long distances each TSOSC is placed within a simple wrapper.

Figure 169: TSOSC Wrapper



SOC_THERM_tsense is on VDD_CORE. Therefore, signals between SOC_THERM_tsense and the CPU and GPU thermal sensors pass through level shifters and clamps.

To facilitate temperature processing in the capture unit Power Valid signals for each CPU and for the GPU should be generated. They should be deasserted when corresponding units are power gated and for CPUs – all 4 signals should be deasserted when VDD_CPU is rail gated.

When Tegra comes out of reset IDDQ signals will be asserted to all thermal sensors to minimize the leakage current.

TSENSOR_OUT must be <= ~50 MHz to facilitate its routing to the capture logic within SOC_THERM_tsense.

40.3.1.2 Placing and Powering TSOSCs (and Wrappers)

Tegra X1 has 9 TSOSCs powered as follows:

Table 241: Thermal Sensors in Tegra X1

Sensor Name	Sensor Type	VDD Connection	VDDA Connection	Comment
TS_AO	TSOSC_HV	VDD_RTC	VDDIO_SYS (1.8V)	Co-locate with TDIODE in pad-ring This TSOSC is controlled via PMC, not SOC_THERM. See the PMC chapter.
TS_PLLX	TSOSC_C	VDD_CORE	AVDD_PLLX	Placed adjacent to PLLX to shorten power trace from AVDD_PLLX and use its ESD protection
TS_GPU	TSOSC_C	VDD_GPU	VDD_GPU	Locate equidistance from the 2 SMs and as close as possible.
TS_MEM0	TSOSC_C	VDD_CORE	VDD_CORE	Placed between data bricks of pad blocks of memory channels 0 and 1 accordingly.
TS_MEM1	TSOSC_C	VDD_CORE	VDD_CORE	
TS_CPU0	TSOSC_C	VDD_CPU	VDD_CPU	Ideally, it is centrally located in the CPU. However, practical issues forced final location is on the outer edge.
TS_CPU1	TSOSC_C	VDD_CPU	VDD_CPU	
TS_CPU2	TSOSC_C	VDD_CPU	VDD_CPU	
TS_CPU3	TSOSC_C	VDD_CPU	VDD_CPU	

TSOSC requires two voltages digital (VDD) and analog (VDDA). VDDA can be connected either to I/O power through direct drill attachment or to core power. It doesn't have built-in ESD devices, so if connected to I/O power through direct drill it should be placed as near as possible to device having ESD protection.

40.3.1.3 TSOSC Vmin Limitations

Because TSOSCs include a built in LDO, they can provide accurate temperature values over a wide range of voltages. However, they do have a minimum operation voltage, below which sensor accuracy drops precipitously. Because of the LDO, this minimum operating voltage is consistently higher than the logic Vmin.

Managing TSOSC Minimum Voltage Requirements

SOC_THERM anticipated this problem and has a built in mitigation strategy to fall back to the PLLX-TSOSC when voltage is too low for the core-voltage TSOSCs to function. PLLX-TSOSC is powered on the AVDD_PLLX rail and does not suffer from Vmin concerns, but is further from the hotspot than the sensors it replaces.

There are a number of conditions that cause TSOSC voltage to be too low for the TSOSCs to function. Fallback to PLLX-TSOSC happens when hardware or software indicates a TSOSC is invalid. Ultimately, **software is responsible** for disabling a given thermal sensor before its VDDA drops too low. The following table lists the scenarios where TSOSC enable/disable awareness is required and which software agents are responsible.

Table 242: Agents Responsible for TSOSC Vmin Management

TSOSC Scenario	Agent Responsible	Using Which Register
CPU{0..3}, on-rail gating change	BPMP-L	TSENSOR_VALID
CPUn, on power-gating	Unnecessary	Unnecessary
CPU{0..3}, on voltage change	Kernel DVFS	SENSOR_STOP
CPU{0..3}, CC3	PMC	PMC2SOC_THERM_CRAIL_VOLTAGE_VALID
MEM{0,1}, on VDD_CPU voltage change	Kernel DVFS	SENSOR_STOP
GPU0, on voltage change	Kernel DVFS	SENSOR_STOP
GPU0, on rail-gating change		

PLLX_TSOSC Fall-Back Procedure

The PLLX_TSOSC is further away from the hotspot than the core TSOSCs. So the thermal sensing hardware adds a programmable offset to sensed temperatures to compensate for this.

To prevent temperature underestimation, this offset should be programmed to the difference between the hotspot deltas of PLLX_TSOSC and CPU_TSOSC (or other sensor group TSOSCs). However, programming in this way can cause

discontinuities in sensed temperature when the actual hotspot-delta is less than the worst-case delta. These discontinuities can cause immediate hardware shutdown or abrupt thermal governing transients.

To avoid this, the procedures below program the offset to be the actual measured difference between PLLX_TSOSC and CPU_TSOSC, immediately before switching to PLLX_TSOSC. Doing so makes temperatures smooth around the transition to PLLX_TSOSC, but at the risk of temperature underestimate if temperature gradient increases. This is an acceptable risk because gradients are expected to go DOWN when at Vmin. There is still a discontinuity on switch BACK to CPU TSOSC, but the expectation is that this will be tolerably small.

TSOSCs on VDD_CPU

If decreasing CPU frequency to below a predetermined threshold (Fmax@Vmin_tsosc):

1. Read PLLX and CPU_TSOSC temperature values.
2. Adjust CPU_HOTSPOT_OFF by MAX(CPU_TSOSCs) – PLLX.
3. Disable CPU_TSOSCs using SENSOR_STOP field in associated TSENSOR_SENSOR(N)_CONFIG registers.
4. Program VDD_CPU voltage target.

If increasing CPU frequency to the same predetermined threshold, or greater:

1. Program VDD_CPU voltage target.
2. Wait till voltage change is known to have happened. (SOC_THERM driver does not know when voltage change request completes. One solution is to use a timer set to a high-confidence maximum I2C delay.)
3. Enable CPU_TSOSCs using SENSOR_STOP.
4. Restore CPU_HOTSPOT_OFF to its default value.

The same procedure applies to sensors on VDD_GPU or VDD_CORE.

40.4 Temperature Translation Logic

SOC_THERM_tsense contains one instance of “temperature translation” logic per TSOSC. This logic takes a 16-bit count from the capture logic and performs a linear scaling (that is, Ax+B) to convert to temperature in degrees C.

```
wire signed [SOC_THERM_TSENSOR_CPU0_CONFIG2_0_THERM_A_SIZE-1:0] therm_a;
wire signed [SOC_THERM_TSENSOR_CPU0_CONFIG2_0_THERM_B_SIZE-1:0] therm_b;
reg  signed [29:0] temp_product;
reg  signed [17:0] temp_sum;
&Vector 14 captured;
&Vector 10 temperature_translated;

// therm_a * captured + therm_b
temp_product = therm_a * $signed({1'b0, captured});
// truncate lower 13 bits before adding with therm_b
temp_sum = $signed(temp_product[29:13]) + therm_b;
// overflow/underflow if all sign bits are not equal
overflow_underflow = !(&temp_sum[17:9]) && (|temp_sum[17:9]);
temperature_translated <0= temp_sum[9:0];
```

The resulting temperature is 10-bit signed and goes to throttling logic as a 10-bit signed. Coefficients will be programmed to get 1/2ºC units. To make reading back temperatures easier for humans – sign and bit 0 are split into separate readback bytes, so the high byte will just read absolute value in ºC. Lower byte will keep LSB in bit 7 and sign in bit 0. Bit assignment of 16-bit readback register will be:

- 15:8 – temperature absolute value high bits (with 1/2ºC programming – it will be the temperature in ºC

- 7 – LSB. 1/2ºC bit.
- 0 – sign bit. Negative temperatures will not be very readable, but likely, not many will be measured.

40.5 Post-Processing Logic

The capture and translation logic does its best to produce a temperature reading for each TSOSC. However, sensor readings may not be available due to a stopped (e.g., powered-down) sensor or due to overflow. The post-processing logic takes all available measurements, all error indications, and synthesizes four final temperature values – one each for CPU, GPU, MEM I/O and PLLX. The post-processing logic forwards these final temperature values to SOC_THERM_thermctl.

40.5.1 Calibration Fusing and ATE

The TSOSCs (and capture and translation logic) are only useful as thermal sensors if they are properly calibrated to compensate for process variation. So, as part of chip manufacture and test (ATE), a calibration process is executed. The TSOSC output frequency is measured at two temperatures and the result is fused into the chip. Then, at runtime, software reads those fused values and programs the temperature translation logic accordingly.

Tsosc hardware fuse map is mapped to the functional fields as follows:

Table 243: TSOSC Related Fuses in Tegra X1

Fuse Name	Logical Bits	Physical Fuses	Offset	Purpose	Functional fields
tsensor_common	32	64	0x280	CP1 and CP2 temperature and offset	temp_shift_cp[5:0], temp_shift_ft[4:0], base_calib_cp[9:0], base_calib_ft[10:0]
tsensor0_calib	26	52	0x198	CPU0-TSOSC at CP1 and CP2	tsensor0_calib_cp1[12:0], tsensor0_calib_cp2[12:0]
tsensor1_calib	26	52	0x184	CPU1-TSOSC at CP1 and CP2	tsensor1_calib_cp1[12:0], tsensor1_calib_cp2[12:0]
tsensor2_calib	26	52	0x188	CPU2-TSOSC at CP1 and CP2	tsensor2_calib_cp1[12:0], tsensor2_calib_cp2[12:0]
tsensor3_calib	26	52	0x22C	CPU3-TSOSC at CP1 and CP2	tsensor3_calib_cp1[12:0], tsensor3_calib_cp2[12:0]
tsensor4_calib	26	52	0x254	MEM0-TSOSC at CP1 and CP2	tsensor4_calib_cp1[12:0], tsensor4_calib_cp2[12:0]
tsensor5_calib	26	52	0x258	MEM1-TSOSC at CP and CP2	tsensor5_calib_cp1[12:0], tsensor5_calib_cp2[12:0]
tsensor6_calib	26	52	0x25C	GPU-TSOSC at CP1 and CP2	tsensor6_calib_cp1[12:0], tsensor6_calib_cp2[12:0]
tsensor7_calib	26	52	0x260	PLLX-TSOSC at CP1 and CP2	tsensor7_calib_cp1[12:0], tsensor7_calib_cp2[12:0]
tsensor9_calib	26	52	0x2D4	AOTAG TSOSC at CP1 and CP2	tsensor9_calib_cp1[12:0], tsensor9_calib_cp2[12:0]
tsensor10_calib	26	52	0x31C	Two TSOSCs TBD, at EXT	Tsensor10a_calib_ext[12:0], Tsensor10b_calib_ext[12:0]
tsensor10_calib_aux	16	32	0x320	EXT*(extended char)* temperature and offset	temp_shift_ext[5:0], base_calib_ext[9:0],

TSOSC calibration is done at two temperatures, called CP1 and CP2 (also known as FT). Target temperatures are CP1=25°C and CP2=100°C respectively, but real temperature may be +/-12°C for CP and +/-5ºC for CP2. So real temperature (from TjADT) is burned into the fuses. To save the bits the temperature shift is burned (in ½ ºC units) relative to target 25°C and 100°C temperatures. The real temperatures (in 1/2ºC units) at the time of measurement are reconstructed from fuse values as follows:

```
int32 capture_temp_cp1_2X = 25<<1 + ((int32)(temp_shift_cp<<(32-6)))>>(32-6);
int32 capture_temp_cp2_2X = 100<<1 + ((int32)(temp_shift_ft<<(32-5)))>>(32-5);
```

TSOSC frequency is measured as the number of oscillator periods counted during some fixed period of time. Calibration measurements are compressed in a (common) average plus per-TSOSC displacement to save on the number of fuse bits. The counts captured at CP1 (tsensorN_capture_cp1[15:0]) and at CP2 (tsensorN_capture_cp2) are reconstructed from fuse values as follows:

```
int32 tsensorN_capture_cp1 = base_calib_cp<<6 + ((int32)(tsensorN_calib_cp1<<(32-13)))>>(32-13);
int32 tsensorN_capture_cp2 = base_calib_ft<<5 + ((int32)(tsensorN_calib_cp1<<(32-13)))>>(32-13);
```

40.5.2 Calculating Therm_A and Therm_B from Fuse Values

The formulae to calculate THERM_A and THERM_B are:

$$\text{Therm\_A} = \frac{\text{CP2\_fuse\_temp\_in\_1/2\_C} - \text{CP1\_fuse\_temp\_in\_1/2\_C}}{\text{CP2\_fuse\_capture} - \text{CP1\_fuse\_capture}} \cdot 2^{13} \cdot \frac{\text{PDIV}}{\text{PDIV}_{\text{ATE}}} \cdot \frac{F_{\text{tsensor}}}{F_{\text{tsensor,ATE}}} \cdot \frac{\text{TSAMPLE}_{\text{ATE}}}{\text{TSAMPLE}}$$

$$\frac{\text{CP2\_fuse\_capture} \cdot \text{CP1\_fuse\_temp\_in\_1/2\_C} - \text{CP1\_fuse\_capture} \cdot \text{CP2\_fuse\_temp\_in\_1/2\_C}}{\text{CP2\_fuse\_capture} - \text{CP1\_fuse\_capture}}$$

The extra ratios in the THERM_A equation are to adjust for difference in capture settings between ATE calibration using JTAG and actual operation using soc_therm. ATE settings and suggested SOC_THERM settings are given in the table below. Note that programmed TSAMPLE values should be one less than value given in the table.

Table 244: Coefficients for ThermA/B Calculations in Tegra X1

	All-TSOSCs except AOTAG	AOTAG
PDIV	8	8
PDIV_{ATE}	8	8
F_{tensor}	400 kHz	
$F_{\text{tensor,ATE}}$	400 kHz	
TSAMPLE	120	
$\text{TSAMPLE}_{\text{ATE}}$	479	

40.5.3 Software Override of SOC_THERM_tsense Output

For testing SOC_THERM and related software drivers, it can be useful for software to be able to spoof the output of SOC_THERM_tsense. The _TEMP_SW_OVERRIDE fields and the _TEMP fields provide a mechanism for doing just that.

This override technique has limitations. When software override mode is used, it is expected that software periodically updates temperature registers, similar to the hardware sensor updates. When threshold levels are changed, it is important to follow this up with a temperature update from software so that internal threshold checks behave correctly.

40.6 Thermal Event Detection (SOC_THERM_thermctl)

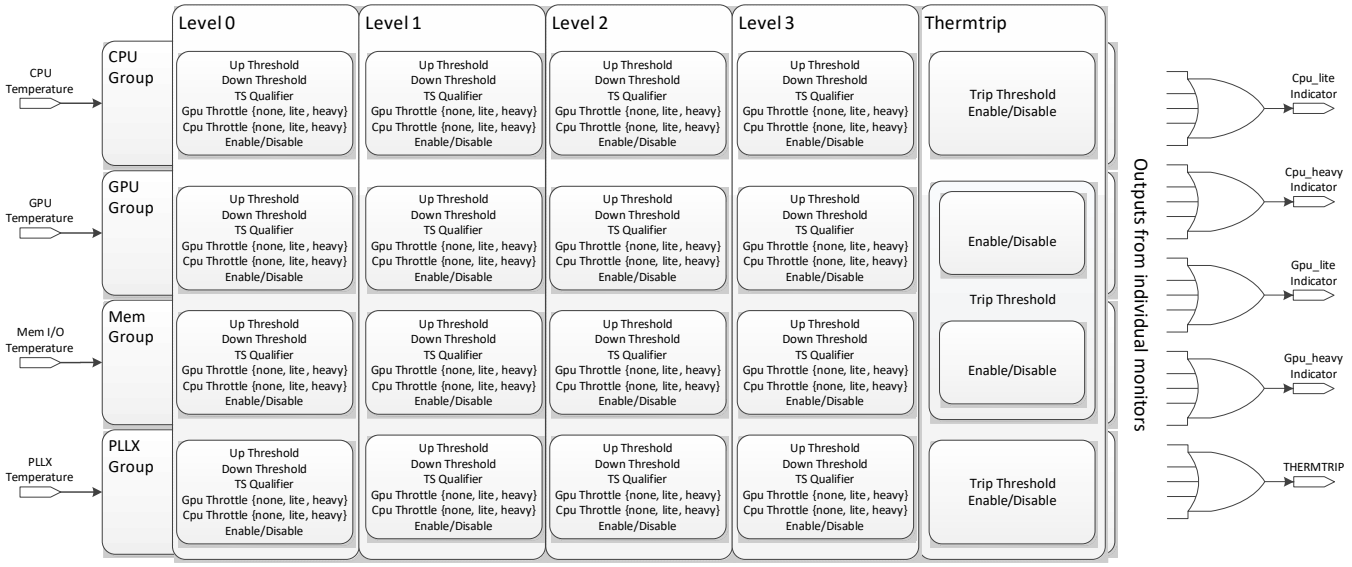
SOC_THERM_thermctl monitors temperatures coming from SOC_THERM_tsense and takes software-configured actions at software-configured temperature thresholds. The available actions are:

- generating an interrupt
- asserting one or more “throttle indicators” to SOC_THERM_throttlectl [1]or
- invoking “thermtrip” to shut down the system.

1. Depending on configuration of throttlectl, an asserted throttle indicator may lead to throttling of the GPU or CPU clock.

SOC_THERM_thermctl is organized as a two dimensional array – groups (horizontally) and levels (vertically). There are four groups – one each for CPU temperature, GPU temperature, memory I/O temperature, and PLLX temperature. There are 4 generic levels and one thermtrip level. Each intersection of a group and level has a “monitor”. Each monitor includes its own thermal threshold and its own programming of actions.

Figure 170: SOC_THERM_thermalctl Block Diagram



Each level is independent from the others. The groups are largely independent of one another with a few notable exceptions:

- Thermtrip for GPU temperature and memory I/O temperature share a trip threshold
- The behavior of any monitor with its “TS qualifier” bit set depends on the state of the PLLX temperature monitor within the same level.

Each monitor outputs a few “throttle request” signals – one each for “gpu_lite”, “gpu_heavy”, “cpu_lite” and “cpu_heavy”. SOC_THERM_thermctl combines these signals from the many monitors to produce a single set of “gpu_lite, “gpu_heavy”, “cpu_lite”, and “cpu_heavy” throttle indicators which it forwards to SOC_THERM_throttlectl.

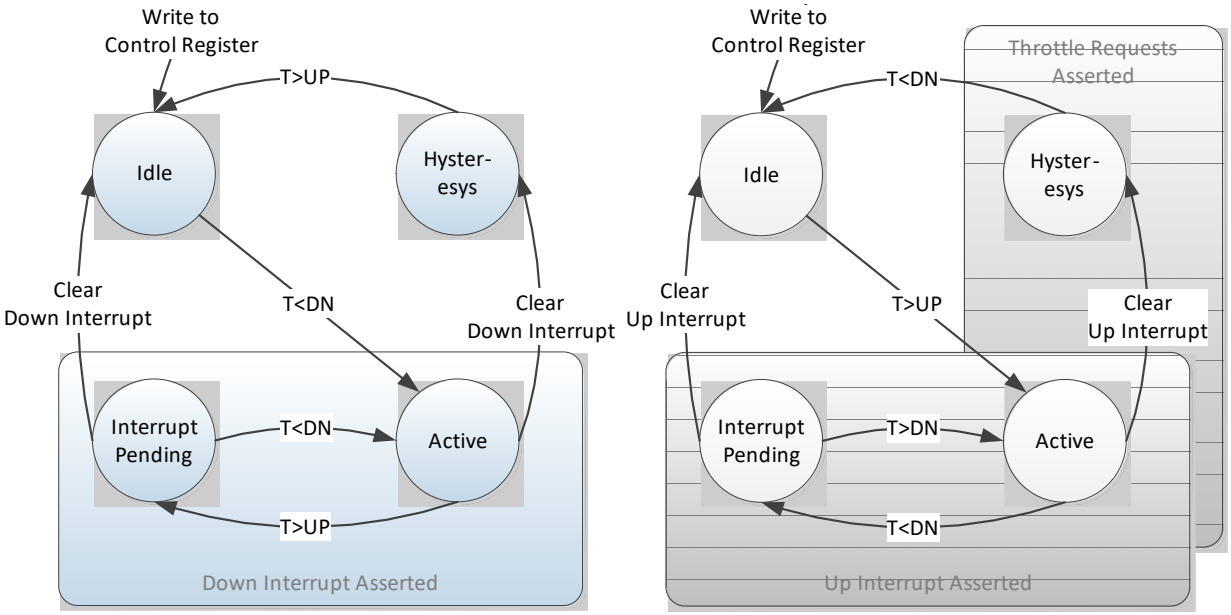
40.6.1 Monitors for Levels 0-3

Levels 0 – 3 are completely identical and interchangeable. Within a given level, there is one monitor per sensor group. The purpose of a monitor is to detect particular thermal conditions and take software-configured actions. Each monitor has several configuration options:

- EN – should the monitor operate or not?
- UP – A temperature threshold. Temperature rising beyond this threshold causes the monitor to assert its throttle requests
- DN – A temperature threshold. Temperature falling below this threshold causes the monitor to deassert its throttle requests.
- GPU – what GPU throttle request to issue. Can be “none”, “lite”, or “heavy”
- CPU – what CPU throttle request to issue. Can be “none”, “lite”, or “heavy”
- INTR_UP – should the monitor raise an interrupt when temperature rises above UP?
- INTR_DN -- should the monitor raise an interrupt when temperature falls below DN?
- TS – should the monitor operate on its own or should its behavior depend on the PLLX monitor at the same level?

A monitor includes two separate FSM's for generating the up and down interrupts. The state machines implement hysteresis. So, for example, once a "down interrupt" has been asserted and cleared it won't be re-asserted until after temperature has risen above UP. Similarly, once an "up interrupt" has been asserted and cleared it won't be re-asserted until after temperature has fallen below DN. Software can force a transition back to the idle by writing to the monitor's control register (SOC_THERM_THERMCTL_LEVEL<N>_GROUP_<S>).

Figure 171: Monitor State Machines (Ignoring TS)



Conceptually, a monitor asserts its throttle requests based on the state of the FSM which generates the up interrupt. As a consequence, the monitor cannot request "cold throttling" (i.e., throttle below a particular temperature). If "cold throttling" is required it must be implemented in software.

40.6.1.1 TS Qualifier Bit

Each monitor has a TS qualifier bit in its control register. When the bit is clear, the monitor operates as described above. When the bit is set, the monitor state machine transitions depend on the PLLX monitor at the same level. For example, suppose the following conditions are set:

- CPU_UP_THRESHOLD for level = 1 is set to 75ºC
- TS = 1 for SOC_THERM_THERMCTL_LEVEL1_GROUP_CPU
- TSENSE_UP_THRESHOLD for level = 1 is set to 70ºC

When the CPU_UPTHRESHOLD is breached (i.e., CPU sensor reports temperature > 75ºC), INTR_UP for CPU group is raised only if TSENSE reports temperature > 70ºC (i.e., the TSENSE_UP_THRESHOLD for Level=1 is also breached). The assumption is that TSENSE is more accurate than other sensors and this qualification can help reduce the frequency at which CPU, GPU, MEM is throttled based on their own tsense readouts. The same holds for breaching down thresholds.

40.6.1.2 Power Valid

Power-Good Signal from PMC

PMIC provides a power-good signal which is multiplexed with the PMIC over-current alarm. This is routed to the PMC which asserts a level signal to SOC_THERM when (and as long as) VDD_CPU power is good. Throttling actions for the CCPLEX are disabled when CPU pwrgood signal is de-asserted. The throttle control is applied in the SOC_THERM_throttlectl block.

40.6.1.3 Spurious Interrupts

At Startup

At start-up, spurious DN interrupts may be generated if DN thresholds are not programmed correctly. Software can prevent this by either:

1. Disabling the DN interrupt until the first UP threshold is breached.
2. Program the Level0 DN interrupt to a very small value (e.g., -50ºC), so that Level0 DN interrupt is effectively disabled. When temperature breaches the first Level0 UP threshold, software can program the DN threshold to an appropriate value to define a thermal zone.

Note: *No special hardware support is required that establishes any dependency between UP and DN thresholds/interrupts for a particular level. Creation of thermal zones is software's responsibility – hardware only provides indication of temperature moving outside the current zone.*

At Reprogramming

As mentioned previously, software is expected to define thermal zones by re-programming the UP and DN thresholds as part of the thermal interrupt response. Software should build in some hysteresis when updating thresholds to prevent spurious interrupts. For instance, continuing the previous example of thermal zones: 40ºC-60ºC, 60ºC-80ºC, etc. When software responds to temperature > 60ºC and it sets the new thresholds to be UP=80, DN=60, software will immediately get a spurious DN interrupt if temperature dips below 60ºC. This can be prevented by re-programming UP=80, DN=55 instead which adds some hysteresis for the DN interrupt. **Note: no special hardware support is required for this case.**

40.6.2 Monitors for Thermtrip

For each sensor group, SOC_THERM_thermctl provides a "thermtrip" capability. If enabled, this capability initiates an immediate shutdown when the group's temperature crosses a software-configured threshold. SOC_THERM implements the thresholding but relies on PMC and the boot ROM to implement the shutdown.

Thermtrip is the ultimate backstop for excessively high temperatures. It should only happen in truly exceptional circumstances (when normal thermal management fails to control temperatures). A thermtrip shutdown is NOT graceful.

1. It may cause storage media corruption
2. It provides no mechanism for alerting the user prior to the shutdown

The probability of corrupting storage on a thermtrip may be low, but it is non-zero. The only way to mitigate #1 is to avoid a thermtrip shutdown in the first place. Similarly, the mitigation for #2 is to avoid a thermtrip shutdown. Software can and should configure SOC_THERM (using one of the generic levels) to raise an interrupt at a temperature below the thermtrip threshold. When that interrupts occurs, software should initiate a controlled shutdown.

There is no THERMTRIP functionality for cold throttling (i.e., chip does not shutdown if it's "too cold"). This is a purely software-based thermal throttling solution.

40.6.3 Register Specification

SOC_THERM_thermctl registers are located with all other SOC_THERM registers. Threshold configuration/status registers are defined for each level and each set of temperature sensors. This is denoted below by the N and S in the name, where N=0~3 and S=CPU/GPU/M/TSENSE. Level activation for digital monitor groups may be preconditioned on TSENSE group being active (TS configuration bit).

40.7 Throttling Controller (SOC_THERM_throttlectl)

40.7.1 Introduction

Clock slowdown is the primary method for thermal management. This block serves the following functions:

- Arbitrating between different throttle indicators from other blocks to come up with the correct throttling level.
- Interfacing with the CAR block to perform clock slowdown in a di/dt safe manner.
- Communicating relevant throttling information to software so that clock frequency changes are coordinated.

Throttling is implemented by a combination of SOC_THERM_throttlectl and CAR. A summary of throttling controller function is as follows:

1. SOC_THERM_throttlectl receives all the thermal, EDP and overcurrent alert events from the other detection blocks.
2. Each indicator is associated with a “throttle vector” which contains programmable set of throttle settings for each indicator (thermal, EDP, ac_mode) and for each target (CPU, GPU). In case of multiple indicators firing, arbitration is performed to select final throttle settings.
3. To ensure that the relevant clocks are throttled in a di/dt safe manner, throttling is done gradually. This is done by a “Throttle Sequencer” which sequences through gradually increasing throttle settings to reach the target frequency specified by the throttle vector. The throttle sequencer provides the relevant information to CAR which actually effects the throttling.
4. To guard against di/dt issues, several throttling mechanisms are available. Only pulse skipping (skip M out of every N clock pulses) should be used. Controls for Dynamic Ramping PLL (PLLx) are present in the register space, but should not be used.

40.7.2 Specifying Throttle Settings: Throttle Vectors

Every throttling indicator and throttling target (CPU, GPU) is associated with what is called a “throttle vector”. There are two styles of “throttle vector”, CPU style and GPU style. The CPU style vector is a combination of PLLx and pulse skipper settings to be used when the associated throttle indicator is asserted. The GPU style vector is a 9-bit field (only lowest 3 bits are used, the other 6 bits reserved) to be used to drive the interface to the GPU when the associated throttling indicator is asserted. The throttle vector is configured by software.

As multiple throttling indicators can be active at any time, an arbiter is needed to identify the final throttle settings to be applied. CPU and GPU have separate arbiters. The CPU arbiter will output the PLL and the pulse skippers setting to CPU sequencer and the CPU sequencer will talk to the CAR to throttle the CPU accordingly. The GPU arbiter will directly drive the thermal event interface to the GK20A.

The CPU throttling vector contains settings to achieve a target frequency for a particular throttling indicator. It does not specify the actual clock slowdown factors. These are generated by the CPU throttle sequencer which is described in the next subsection.

There is a throttling vector per target M (= [CPU]) and indicator N, where N can be one of:

- Lite Thermal throttle
- Heavy throttle
- OC1 – OC5
- CPU BA EDP (do not use)
- CPU BA DIDT (do not use)

In addition, there is an additional register for software to configure the pulse skipper settings.

The registers are organized as top-level (used for fields that are common for all throttle vectors), GPU throttle vector register, CPU pulse skipper registers and CPU PLL registers.

GPU throttling is implemented in the GPU’s NV_THERM. SOC_THERM will just drive the thermal event interface to the GPU to trigger the throttling and no longer need to talk to CAR for GPU throttling, so most GPU Pskipper/PLL fields are obsolete.

40.7.2.1 Throttling Vector Arbitration

Since each indicator has its own throttle settings and multiple indicators can be asserted at the same time, an arbiter is needed to select the final throttle settings to be applied to the clocks. It is the software's responsibility to set priorities for the various indicators. Typically, vectors with lower target frequency (i.e., more aggressive throttling) would have higher priority.

SOC_THERM_throttlectl needs a simple max function to pick the throttle vector with the highest priority. Note that in addition to setting the pulse skipper throttle, the final throttle vector also sets other behavior such as HW_RESTORE_EN and LONG_LATENCY_THROTTLE bits.

Software requirements when setting priorities

- Software needs to ensure that critical thermal/OC alarms are given higher priority.
- Software needs to ensure that there is no race if priority of two vectors is set to the same value; i.e., if priority is the same, then the throttle settings should be the same, otherwise it cannot be guaranteed which vector is picked.

Note that the priority is per-indicator-only (not per target). When the arbiter selects a particular priority, it automatically selects everything about the throttle vector:

- All configuration/control registers which define how PLL and pulse skipper are throttled
- All behavior fields such as HW_RESTORE_EN and LONG_LATENCY_THROTTLE
- Priority
- Throttle hysteresis

Even though priority is per-indicator, there is a separate arbiter per throttling target (GPU or CPU). If a throttling indicator does not enable a throttling target (ENB=0), the indicator does not participate in the arbitration for that target.

40.7.3 Pulse Skipper Throttling

40.7.3.1 Software Programming of Pulse Skipper

There are two paths for software to control pulse skippers:

1. **Using the throttle sequencer:** An important difference is that software is now able to control the skippers through the throttle sequencer so that skippers can be correctly sequenced to avoid di/dt issues. Software can program the target M/N values directly to SOC_THERM_THROTTLECTL_SW_CPU_PSKIP_CTRL and SOC_THERM will sequence the skippers to these targets without needing software control. The skipper ramp rate is controlled by fields in SOC_THERM_THROTTLECTL_SW_CPU_PSKIP_RAMP_RATE.
2. **Direct control (similar to control through CAR):** Software still has the option to directly set pulse skipper config by setting the SEQ_BYPASS_MODE bit in SOC_THERM_THROTTLECTL_SW_CPU_PSKIP_RAMP_RATE[31]) which is used to bypass the throttle sequencer.

The software pulse skipper configuration is also used as the reference to restore the skippers to their un-throttled state.

40.7.3.2 Pulse Skipper Restore Mechanism

Since pulse skippers are primarily meant to be controlled by hardware, SOC_THERM provides a mechanism to automatically restore these to their un-throttled state when there are no active throttle indicators. Note that restoring also needs to happen in a di/dt safe manner to avoid an instantaneous change in frequency.

Pulse skippers are restored regardless of the HW_RESTORE_EN behavior of the final throttle vector if PSKIP_RESTORE_CTL=='0'. In this case, SOC_THERM ramps the skippers to the config programmed in SOC_THERM_THROTTLECTL_SW_CPU_PSKIP_CTRL.

40.7.3.3 Changing N-Value (Divisor)

SOC_THERM pulse skipper divisor value should be fixed at 256 (default).

40.7.4 Recovering from Throttled State

Once a throttling event has passed, the system needs to recover from the throttled state. The recovery mechanism is based on the type of throttle event.

40.7.4.1 Recovery from Thermal Throttling Events

In case of thermal events, software will be responsible for recovering from the throttled state. Both, Lite and Heavy, thermal throttling events result in an interrupt which software can use to initiate recovery. In the case of heavy hardware throttling, software cannot explicitly clear the interrupt – it is cleared when the temperature falls below the heavy hardware throttling threshold. Software can disable Lite hardware throttling. In either case, software has the knowledge of every thermal throttling event and can recover from the throttled state.

During recovery, software may want to know the throttled frequency. It can get this information by looking at one of the SOC_THERM_throttlectl status registers.

It is possible that another thermal throttling event occurs while software is trying to recover the system. In such cases, it is possible that the system ping-pongs between throttled and non-throttled states. This can be addressed somewhat by allowing throttling to continue for a longer duration to make sure that the temperature is lowered sufficiently so that software can recover the system successfully.

40.7.4.2 Recovery from EDP and Over-current Events

Recovery from Brief Throttling Mode

In brief throttling mode, hardware detects an EDP or over-current event and throttles the system for a certain time interval. In this mode, hardware is responsible for restoring the system to its pre-throttled state. This is done by rolling back the steps that the hardware took to throttle the system:

Recovery from Sticky Throttling Mode

In sticky throttling mode, hardware continues to throttle the system until software chooses to disable throttling. In this case, it is software's responsibility to recover the system to a non-throttled state.

40.8 Programming Guidance

40.8.1 Thermal Management

Software has a broad role in thermal management, both setting up and managing the thermal sensing/throttling hardware and implementing software-only thermal management policies. This section provides guidance only on setting up and using SOC_THERM hardware features.

40.8.2 Requirements Summary

To utilize SOC_THERM for thermal management, software must implement the following support functions:

1. Initialize the SOC_THERM Controller
    a. Program clocks (soc_therm_clk and tsensor_clk) and do basic controller initialization
    b. Initialize thermal sensors based on per-chip calibration values located in fuses. This is essential to get accurate temperature readings.
    c. Set appropriate thermal shutdown threshold and enable thermal shutdown function in SOC_THERM and PMC.
    d. Set appropriate temperature thresholds for interrupts to software. These thresholds are based on thermal policy, but must be margined as appropriate for sensor error and hotspot offset.
    e. Set appropriate temperature thresholds and throttling amounts for hardware thermal throttling. Hardware thermal throttling is a useful, but optional, addition to high-temperature thermal management policy. If used it must be configured.

2. Respond to SOC_THERM temperature interrupts as appropriate, potentially reprogramming interrupt thresholds to implement thermal management policies.
3. Manage limitations related to TSOSC Vmin and/or CPU/GPU rails being powered-off, using fallback mechanisms to use PLLX_TSOSC when necessary.

40.8.3 Clocks Configuration

Tegra X1 clock and reset unit (CAR) provides a clock source mux and a clock divider for configuring tsensor_clk. See the CLK_RST_CONTROLLER_CLK_SOURCE_TSENSOR_0 register in the Clock and Reset Controller chapter. The CAR allows tsensor_clock to be sourced from PLLP, PLLC, CLK_M, or CLK_S. Software should use CLK_M, which runs at 38.4 MHz in most cases, but 12 MHz is also an option. The tsensor_clk frequency must run at 400 kHz. The frequency can be reached from either a 12MHz XTAL (CLK_M_DIVISOR=1, TSENSOR_CLK_DIVISOR=30) or a 38.4 MHz XTAL (one of CLK_M_DIVISOR={1,2,3}, TSENSOR_CLK_DIVISOR={96,48,32}).

40.8.4 Thermal Sensor Initialization

This is covered in earlier sections, but to summarize:

For each TSOSC:

1. Read and decode fuses
2. Calculate and program ThermA/B coefficients

For each sensing group

1. Program offsets for fallback to PLLX_TSOSC
2. Program sensor thresholds, including margins for accuracy and hotspot offset
3. Arm thermal shutdown as appropriate
4. Enable thermal sensing

40.9 TSensor Registers

Refer to Section 1.4: Reading Register Tables in the Introduction chapter for the register table protocol as well as recommendations for accessing registers.

All SOC_THERM registers are in the APB address space. Refer to Chapter 2: Address Map for the base addresses.

40.9.1 SOC_THERM_THERMCTL_LEVEL0_GROUP_CPU_0

CHAPTER 41: BOOT AND POWER MANAGEMENT PROCESSOR-LITE

41.1 Overview

The Tegra® X1 Boot and Power Management Processor is referred to as “Boot and Power Management Processor – Lite”, or BPMP-Lite, as it represents a first architectural step towards a dedicated boot and power management processor. Future Tegra devices will add further features, and more dedicated processing power, and will likely drop the “Lite” nomenclature when describing this processor.

The Boot and Power Management Processor – Lite, or BPMP-Lite, is an ARM7™ based microcontroller used for power management and boot purposes. It is similar to, and based on, the processor referred to as AVP or COP in prior Tegra devices, but no longer has any responsibility for audio or video decoding in Tegra.

Outside of boot, the BPMP-Lite runs the “BPMP Firmware” (BPMP-FW). This firmware provides various services related to runtime power management. To implement these services, the BPMP-FW “owns” particular hardware resources within the Tegra X1 processor. The CPU is never allowed to access such hardware directly. The BPMP-FW provides proxy services to give the CPU indirect access to such hardware where appropriate.

In cold boot, the BPMP-Lite processor runs the boot ROM code as well as a portion of the Boot Loader. As part of cold boot, the BPMP-FW is loaded into DRAM and the CPU triggers the BPMP-Lite processor to begin executing that firmware.

The BPMP-Lite processor handles low-level power management sequences and assists in various power state transitions.

41.1.1 Deep Sleep Support

The BPMP-Lite stays active after CPU complex power domain has been power gated or the VDD_CPU rail has been switched off. BPMP-Lite is the last standing processor on a system when it progressively transitions into lower power SOC Idle states. The system supports a mechanism of entering deep sleep (SC7 state) which is decoupled from the last standing CPU core executing a WFI instruction.

The BPMP-Lite processor plays the following roles in deep sleep state transitions:

- Manages system deep-sleep entry by correlating the CPU idle residency times (CC7 latency tolerance) to the energy cost of deep-sleep transitions and monitoring wake events and interrupts when the CPU complex is powered off.
- Performs deep-sleep entry housekeeping tasks on SOC resources
- Triggers deep-sleep entry without requiring the main CPU complex to be kept powered on.
- Performs warm boot steps on deep-sleep exit.

As reset is released, the BPMP-Lite wakes up and secures the system. The BPMP-Lite, which is not a TrustZone® master, then defers TrustZone configuration to the CPU. Upon wake-up by the BPMP-Lite, the CPU (which has defaulted to a secure state) configures the TZ-DRAM aperture registers in the Memory Controller in order to secure the TrustZone Execution Environment (TEE). Once TEE has been locked down by the CPU, the BPMP-Lite can initiate untrusted BPMP-Lite firmware.

Deep-sleep entry through the CC7 state is supported from any of the CPU cores in the cluster. Any of the four cores can be the last standing core in the cluster prior to CC7 or SC7 entry. CC7 to SC7 entry is mainly supported through the BPMP-Lite processor. See Chapter 16: CPU Complex in this TRM for more information on the CPU Power states.

41.2 Address Map

Refer to Chapter 2: Address Map of this document for the address map details.

41.3 Interrupts

Interrupts are controlled for the BPMP-Lite by the system interrupt controller. Refer to Chapter 3: Interrupt Controller of this document. All system interrupts are available to be routed to the BPMP-Lite.

41.4 IRAM and Crossbar Bus

IRAM is a block of 256 KB of on-chip ‘internal’ RAM assigned to the BPMP-Lite for code and data.

IRAM is configured as four contiguous banks of 64 Kilobytes of RAM. Each of these banks is accessible over a crossbar bus architecture, so that simultaneous access is possible to each bank from the crossbar masters.

The masters on the crossbar bus are:

- The ARM7 core
- The CPU complex over the AXI to ARM7 bridge
- The AHB bus interface

41.5 Chip-Level Features Involving BPMP

The BPMP-Lite participates in various chip level features. The following table shows the features where involvement of the BPMP is:

Table 245: BPMP Chip Features List

	Feature
CPU Power States Policies/Flows	
CPU Power States Policies/Flows	Retention/CC-state support
CPU Power States Policies/Flows	Fmin @ Vmin = HVC ? no role
CPU Power States Policies/Flows	Idle Aware EDP Management Mode
Intermediate Wake States	
Intermediate Wake States	SOC idle states
Frequency Management	
Frequency Management	DFS for BPMP-Lite
Clock Hardware Management	
Clock Hardware Management	MC/EMC PLL control

41.5.1 Cold Boot

The BPMP-Lite processor participates in the cold boot flow by running the boot ROM code and running (a portion of) a boot loader. As part of cold boot, the BPMP-FW is loaded into DRAM and the CPU triggers the BPMP-Lite processor to begin executing that firmware.

There are at least two relevant flavors of cold boot: boot from storage media and boot via “USB Recovery Mode”. Both involve the loading and execution of BPMP-FW. See Chapter 13: Boot Process for the cold boot flow.

41.5.2 CC-State Transitions

The various CC states (CPU Complex Power States) and the related state transitions are described in Chapter 18: Flow Controller. The BPMP-FW assists in the transitions to/from CC4, CC6, CC7, and the Cluster Switch.

41.5.3 SC-State Transitions

On Tegra X1, the SOC idle states have been enhanced. More low power states have been inserted between the ACTIVE state “SC0” and the Deep Sleep state “SC7” where the SOC rail is off.

The various SC-states (System on Chip Power States) are described below. The BPMP-FW takes a leading role in most of the SC-state transitions.

Various preconditions must be met before dropping down to any particular SC-state. For example, Tegra cannot drop to SC2 unless the CCPLEX is in CC4-retention or deeper and DMA-capable peripherals are configured such that they won't access DRAM. Similarly, Tegra cannot drop to SC7 unless the CCPLEX is in CC7 and other conditions are met.

The BPMP-FW is responsible for determining when all preconditions for entering an SC-state are met. When the preconditions are met, BPMP executes a sequence to transition into that state.

41.5.4 SC7 (also known as LP0)

SC7 is a particularly special SC state. The BPMP-FW is central to SC7 entry (also known as LP0 entry). However, it is all but absent during SC7->SC0 transitions (also known as LP0 exit or LP0 wake).

The BPMP-FW implements the final decision of whether to transition Tegra X1 to SC7 (LP0). As software on the last running CPU prepares for entry to CC6/CC7, it optionally configures itself to tolerate a further transition to LP0. It advertises that tolerance to the BPMP-lite. Once the CCPLEX is in CC7, the BPMP-FW waits for all other preconditions to CC7 entry to be met. If a wake event comes to the CPU prior to SC7-preconditions being met, the BPMP allows the CPU complex to wake. If preconditions are met prior to a wake event, the BPMP-FW executes the SC7 entry sequence.

The BPMP-Lite processor plays a central role to wake from SC7. Both the boot ROM and the SC7 resume vector run on the BPMP-Lite processor. The BPMP-FW does not resume execution until very late in the SC7 wake sequence.

41.5.5 BPMP-Lite Clock Frequency Management

BPMP-Lite might be the only processor alive for a long time and it needs to manage its own DFS and idle time.

There is no separate clock controls for BPMP-Lite. BPMP-Lite shares its clock with the SCLK, HCLK, and PCLK. The clock trunks are all over the chip. Thus, the S/H/PCLK frequency will be managed properly.

1. BPMP-Lite can change the S/H/PCLK clock frequency as long as it is within the floor & ceiling frequencies set by the CPU.
2. BPMP-Lite has ownership of the I2C5 when CCPLEX is in CC4-Ret or deeper idle state. During this time, it can manage the S/H/PCLK DVFS.

41.5.5.1 ACTMON

ACTMON has a monitor for BPMP-Lite (previously AVP) that counts the clock cycles when BPMP-Lite is in halt state.

41.5.6 Idle Aware EDP Management Mode

As a CPU core enters into C7 state, BPMP-Lite boosts the CPU clock. As a core in C7 state gets a wake interrupt, BPMP-Lite drops the CPU clock and then BPMP-Lite wakes up the CPU core.

41.5.7 Out of Scope Features

BPMP-Lite is not responsible for all power management. There are many power-management related features in which BPMP-Lite has no role.

41.6 BPMP-Lite Services

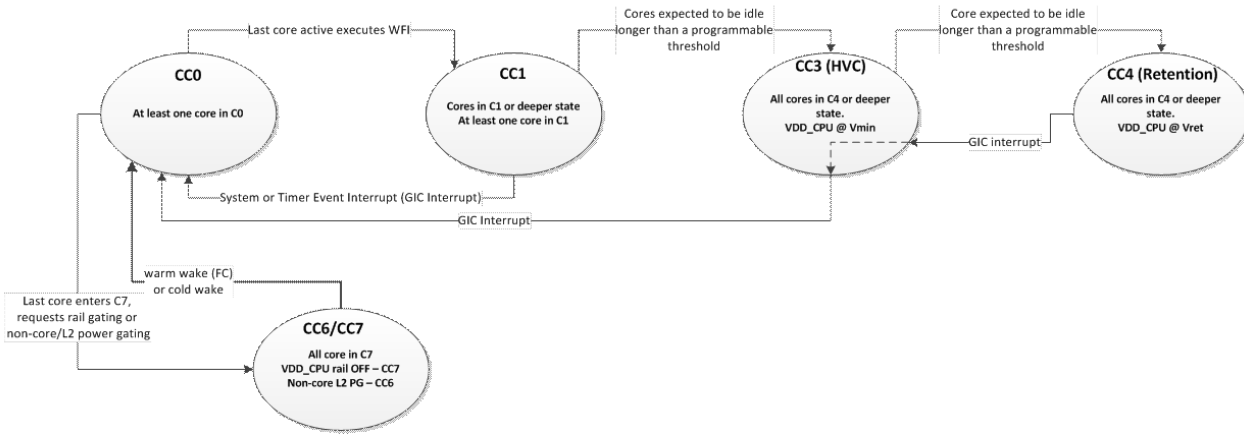
41.6.1 CC States Support

Here is the top level of the CC states transition diagram:

Figure 172: CC States Transition



41.6.1.1 CC4-Retention Sequencing

When the CCPLEX is in CC3-HVC and BPMP-Lite gets an interrupt from flow controller, BPMP-Lite makes the decision either to enter into CC4-retention or stay in CC3-HVC. It also coordinates the sequencing to enter and exit from CC4-retention state with the flow controller.

41.6.1.2 CC7 Entry

During CC7 entry, BPMP-Lite plays a role in coordinating with the flow controller to make sure there is no race condition and all cores are power gated. See details in a later section.

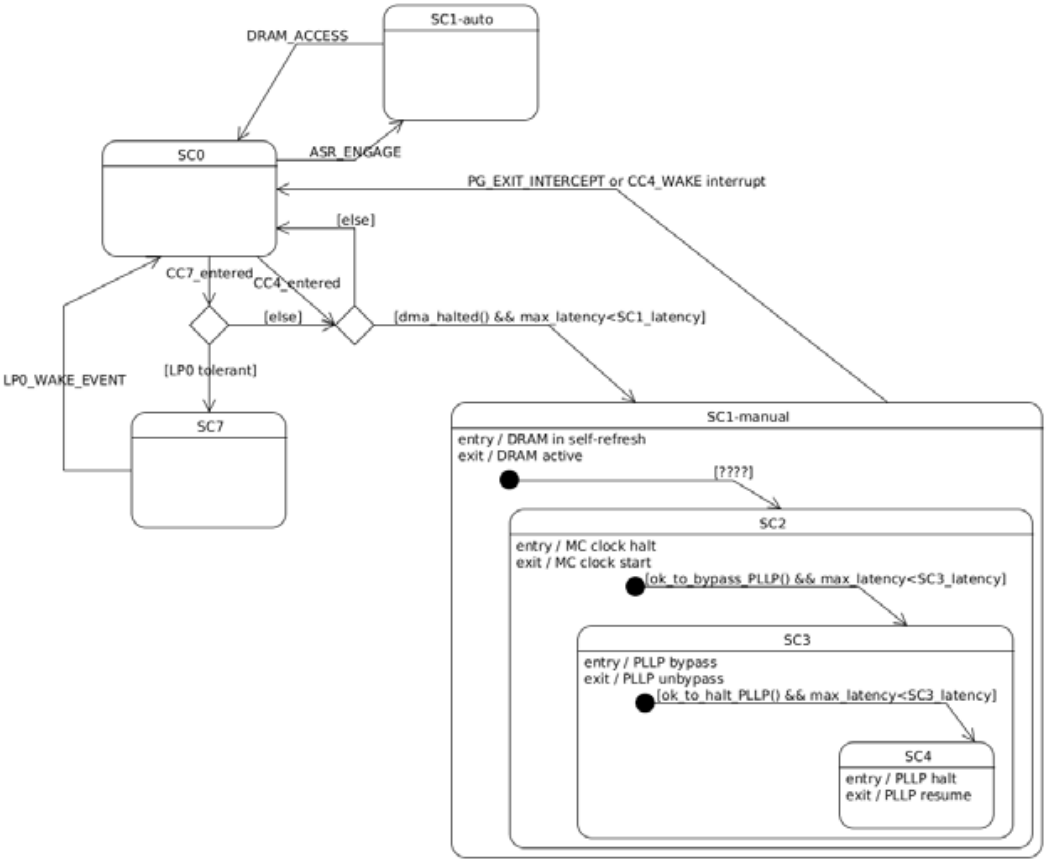
41.6.1.3 CC7 Exit

Upon SC7 exit, BPMP-Lite executes out of the Boot ROM, executes the (secure) SC7 exit vector, wakes the main CPU and then starts executing BPMP-Lite FW out of DRAM.

41.6.1.4 SC States Support

Refer to Section 41.9.3: SOC Idle States Support.

Figure 173: SC State Transition Diagram



41.6.1.5 SC7 Support

BPMP-Lite stays active after CPU complex power domain has been power gated or the VDD_CPU rail has been switched off. BPMP-Lite is the last standing processor on a system when it progressively transitions into lower power SOC Idle states. The system supports a mechanism of entering SC7 which is decoupled from the last standing CPU core executing a WFI instruction. Tegra X1 relies on BPMP-Lite in both ARM® based CPU complex and NVIDIA® Denver-based CPU complex.

The BPMP-Lite plays the following roles in SC7 state transitions:

1. Manages system SC7 entry by correlating the CPU idle residency times (CC7 latency tolerance) to the energy cost of SC7 transitions and monitoring wake events and interrupts when the CPU complex is powered off.
2. Performs SC7 entry house-keeping tasks on SOC resources
3. Triggers SC7 entry without requiring the main CPU complex to be kept powered on.
4. Performs warm boot steps on SC7 exit similar to previous generations of Tegra.

The BPMP is not capable of fully securing the Trust zone Execution Environment (TEE). In particular, the TZ-DRAM aperture registers in MC cannot be configured by the BPMP post SC7 exit. Therefore BPMP-FW is not run until the TEE is secured against any compromise by that code.

SC7 entry through CC7 state is supported from any of the CPU cores in the cluster. Any of the cores can be the last standing core in the cluster prior to CC7 or SC7 entry. On Tegra X1, CC7 to SC7 entry is mainly supported through BPMP-Lite.

The system extends the debug mode of SC7 entry using the PMC_DPD_ENABLE bit on previous generations to enable the BPMP-Lite to control SC7 entry. BPMP-Lite waits for CC7 entry to complete and then performs SC7 entry steps for the system resources including putting the DRAM in self refresh. Prior to triggering SC7 entry, BPMP-Lite ensures that there are no outstanding transactions in the system. It must disable its own interrupts. The flow controller must be prevented from triggering a CC7 exit to avoid race conditions. The last step performed by BPMP-Lite is to write to the PMC_DPD_ENABLE register and execute a halt. Following this, PMC hardware puts the system in SC7 state.

41.6.2 WatchDog for Main CPU Service

The software watchdog timer service for the main CPU implemented on BPMP-Lite allows for a graceful system shutdown after saving the state. Then it can reset and restart the system after which the state can be restored.

WatchDog Timer WDT4 can be dedicated to BPMP-Lite which can run slower than the main CPUs watchdog timers. If WDT4 expires, it is a sign of a hard CPU hang. When that happens, BPMP-Lite can log to CSITE or drive it on a UART. BPMP-Lite can also flush MC clients and put the DRAM into self-refresh.

41.7 BPMP-FW

The power management firmware (BPMP-FW) mainly resides in DRAM. It executes on the BPMP with run-time code being present either on DRAM or IRAM.

41.8 Hardware Resources

The hardware resources are split into five categories:

- Hardware resources owned by BPMP-FW
- Hardware resources accessible to BPMP-FW when main CPU is powered down
- Shared resources which are intrinsically safe
- Shared resources which require Locking
- Hardware resources not accessible by BPMP-FW

41.8.1 Hardware Resources Owned by BPMP-FW

This section lists the various hardware resources owned by the BPMP-FW. Code running on the CPU should never access these resources directly. The BPMP-FW provides proxy services for indirect access where appropriate.

- ARM7 CPU
- ARM7 cache
- IRAM[1]
  - BPMP-FW can choose to allocate particular addresses within IRAM for communication with CPU
- A DRAM carveout for BPMP-FW
- Some FC registers
  - FLOW_CTLR_FC_SEQUENCE_INTERCEPT_0
  - FLOW_CTLR_BPMP_CLUSTER_CONTROL_0
- CAR registers:
  - CLK_RST_CONTROLLER_SCLK_BURST_POLICY_0

1. There is an exception here for the Windows “crashdump” feature. When code on the CPU detects that the system is irretrievably hung, it can halt BPMP, write arbitrary data to IRAM, and trigger a full-system reset.

  - CLK_RST_CONTROLLER_SUPER_SCLK_DIVIDER_0
  - CLK_RST_CONTROLLER_CLK_SYSTEM_RATE_0
  - CLK_RST_CONTROLLER_COP_CLK_SKIP_POLICY_0
  - CLK_RST_CONTROLLER_CLK_SOURCE_SYS_0
  - CLK_RST_CONTROLLER_PLLMB_MISC1_0
- Some PMC registers
  - APBDEV_PMC_PWRGOOD_TIMER_0
  - APBDEV_PMC_CPUPWRGOOD_TIMER_0
  - APBDEV_PMC_CPUPWROFF_TIMER_0
  - APBDEV_PMC_WAKE_DELAY_0
- Some LIC registers
  - GIC_FWD_EN_BLOCK_BLOCK_CCPLEX_GIC_INTR_0
- Some interrupts
  - All interrupts are configurable to be routed to the main CPU or BPMP-Lite with the following exceptions:
    - WDT4-FIQ: is dedicated to the BPMP-Lite
    - Timer and software initiated interrupts inside the GIC are not routed to BPMP-Lite.
- SOC timers:
  - TMR2 (Tegra Timer 2)
- WatchDog timers:
  - WDT4

41.8.2 Hardware Resources Accessible to BPMP-FW When Main CPU is Powered Down

The following resources are time shared between main CPU and BPMP-Lite. BPMP-Lite accesses these resources only when the main CPU is in a power down state; otherwise these resources are owned by the main CPU when the main CPU cluster is in CC3-HVC state and above:

- I2C5 Control and Status Registers
- VDD_CORE voltage control
- Flow Controller
  - FLOW_CTLR_FC_SEQUENCE_INTERCEPT_0
  - FLOW_CTLR_CC4_FC_STATUS_0
  - FLOW_CTLR_CPU_PWR_CSR_0
- PMC
  - APBDEV_PMC_CNTRL2_0
  - APBDEV_PMC_WAKE_MASK_0
  - APBDEV_PMC_WAKE_LVL_0.
  - APBDEV_PMC_DPD_PADS_ORIDE_0
  - APBDEV_PMC_DPD_ENABLE_0
  - APBDEV_PMC_PLLP_WB0_OVERRIDE_0

41.8.3 Shared Resources Which are Intrinsically Safe

Resources in this section are shared by CPU and BPMP-FW at runtime. Access to the resources is intrinsically safe due to the design of the resource. For example, set/clear registers with certain bits owned by each processor are intrinsically safe.

- All LIC IER registers that have set and clear controls.

41.8.4 Shared Resources Which Require Locking

Resources in this section are shared by CPU and BPMP-FW at runtime and require some form of locking or mutual exclusion for the processors to make that sharing “safe”.

None exist in this class.

41.8.5 Hardware Resources Not Accessible by BPMP-FW

Resources not explicitly listed in the previous sections as allocated to, shared by, or time-shared by the BPMP-FW are forbidden to the BPMP-FW.

This list includes the following registers but not limited to:

- Flow Controller Reg: FLOW_CTLR_CC4_HVC_CONTROL_0
- Flow Controller Reg: FLOW_CTLR_CC4_RETENTION_CONTROL_0
- Flow Controller Reg: FLOW_CTLR_CC4_COREx_CTRL_0
- Flow Controller Reg: FLOW_CTLR_CC4_HVC_RETRY_0

41.9 Low Level Sequences

The following is a table of which sequence belong to which service that BPMP-Lite performs.

Table 247: Services and Sequences Mapping

	Services performed by BPMP-Lite								
Sequences	**Discovery**	**Trace on**	**SC4/7 Entry**	**CC4 Retention**	**SCLK Proxy**	**Calculate Deepest SC state**	**Return to SC0**	**CC7 Entry**	**CC7 Exit**
CC4-Ret				X					
CC7 Entry from any								X	
CC7 Entry from last								X	
CC7 Exit									X
SC7 Entry			X						
SC4 Entry			X						
SC4 exit							X		
Cluster Switch									

41.9.1 CC-States Assist

41.9.1.1 CC3–HVC□CC4-Retention and CC7 State

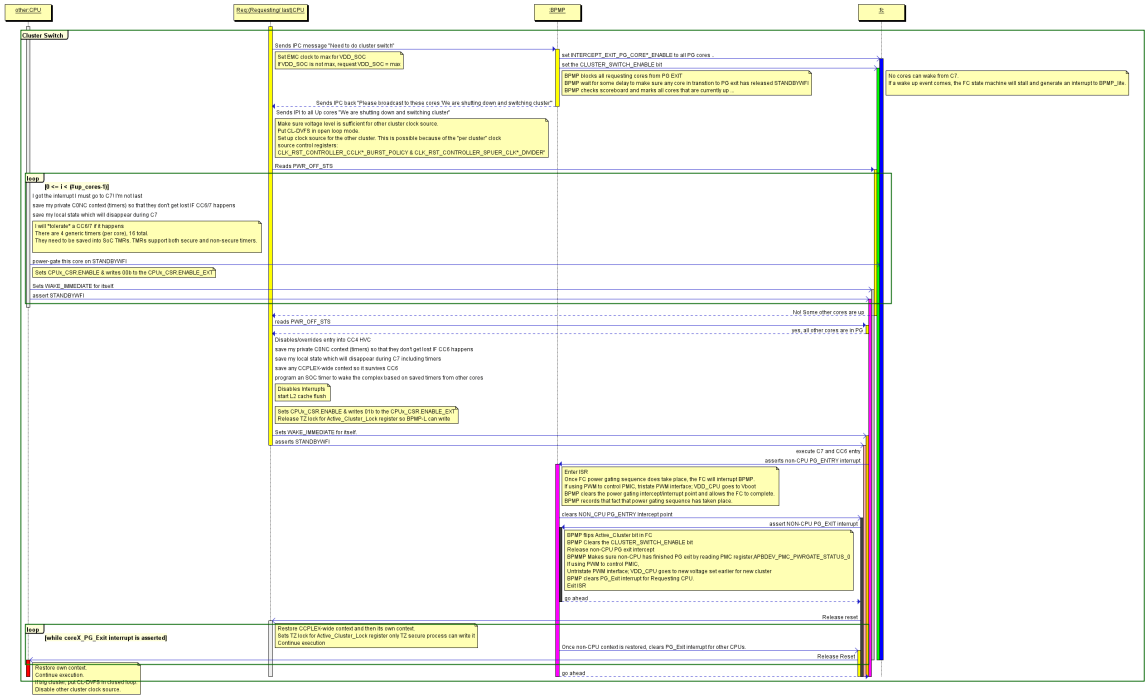
Refer to Chapter 18: Flow Controller for a description of these and their management.

41.9.2 Cluster Switch

The detailed Cluster Switch sequence is captured in the figure below.

BA is not supported for the slow cluster. To prevent spurious toggling, software must disable the BA_EDP logic and enable SLCG for the EDP logic before switching to the slow cluster. The reverse must be done before returning to the fast cluster.

Figure 174: Cluster Switch Sequence



41.9.3 SOC Idle States Support

41.9.3.1 SC2 Entry

SC2, SC3, and SC4 Entries are managed by the BPMP-FW. The main CPU sends a mailbox message to BPMP-Lite with information regarding tolerance for deeper idle SOC states based on runtime_PM (runtime power management) status.

The prerequisite for entering the SC2 state is that all DMA engines are turned off since the memory clock is turned off in this state.

41.9.3.2 SC3 and SC4 Entry

The prerequisite for entering the SC3 and SC4 states is the use of external thermal sensors. Since both SC3 and SC4 turn off the PLLP clock tree, SOC-Therm cannot run. Another prerequisite is that UART or any other modules need to use a non-PLLP originated clock.

In addition, the mailbox message from the main CPU to BPMP-Lite indicates tolerance to entering SC3 or SC4 based on the runtime_PM statuses that the main CPU checks before sending the message to BPMP-Lite.

41.9.3.3 SC2 SC3 and SC4 Exit

For SC2, SC3, and SC4 exits, no secure code is required to run since all states were saved prior to going into the deeper states.

41.9.3.4 SC7 Entry and Exit

Entry Procedure

The software processes involved in SC7 entry are complex. The Linux implementation of LP0 on Tegra SOCs involves the kernel, CPU Idle governor, PSCI interface and the EL3 Secure Monitor besides the BPMP-Lite FW that executes the chip-specific sequence for LP0 entry. The Android Linux kernel running on each individual CPU core signals the BPMP-Lite directly to indicate the deepest CPU cluster power state and SoC power states that the core can tolerate. The kernel does trigger CPU idle state entry via PSCI, but the core receives prior approval to enter certain CPU cluster and SoC idle states via BPMP interaction before entering the PSCI CPU_SUSPEND call. The EL3 secure monitor firmware does not communicate directly with the BPMP-Lite.

Exit Procedure

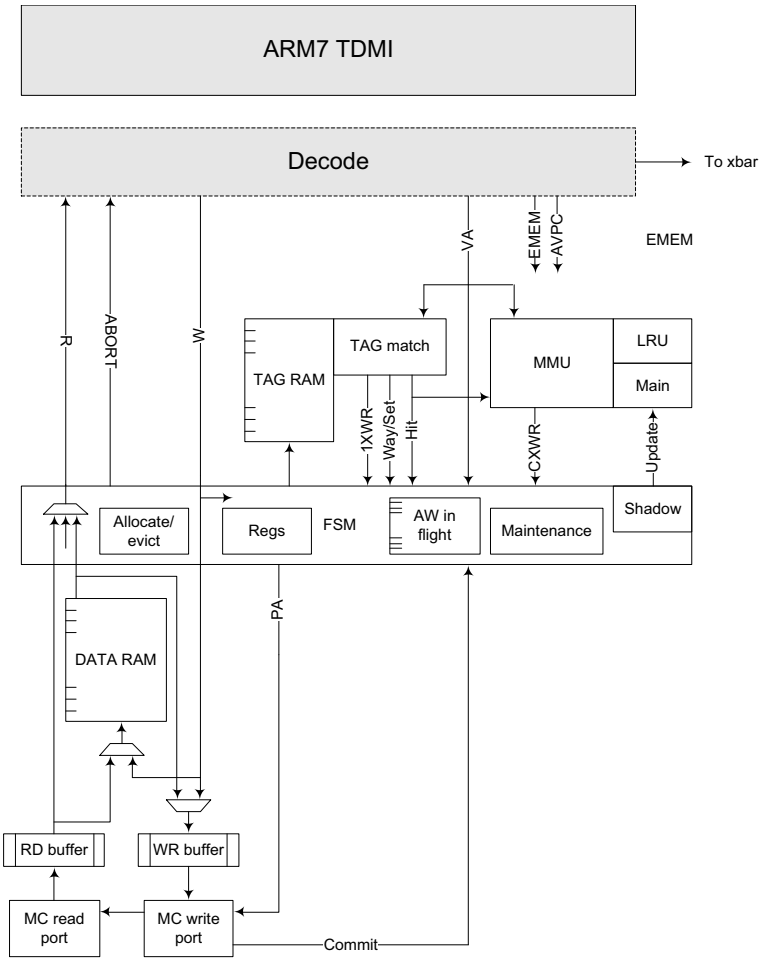
For SC7 exit, the BPMP-Lite SC7 resume code runs before the CCPLEX SC7 resume code runs. The BPMP-Lite SC7 resume code is responsible for booting the CCPLEX. The BPMP-Lite SC7 resume code runs from IRAM, after being copied over from DRAM to IRAM by Boot ROM and authenticated by Boot ROM. The BPMP-Lite SC7 resume code sequence is a separate entity from the BPMP-Lite firmware. The BPMP-Lite firmware is loaded by the CCPLEX late in SC7 exit.

41.10 Hardware Components

41.10.1 ARM7 and Cache

The following figure shows the block diagram of BPMP-Lite complex along with the cache.

Figure 175: BPMP-Lite Complex Block Diagram Showing the BPMP-Lite Cache



41.10.1.1 ARM7

ARM7 is a 32-bit RISC core based on the ARM v4 architecture that is designed for low power and small area applications. It is a three stage pipeline and it executes 32-bit ARM instruction set as well as 16-bit Thumb instruction set. The TDMI stands for:

- *T= Thumb instructions capable
- *D= Debug port
- *M = Fast multiply
- *I = ICE, in-chip emulator

41.10.1.2 BPMP-Lite (AVP) Cache

The BPMP-Lite cache is 32 Kbytes, 4-way set associative, unified (instruction & data). It is shown in Figure 175 above.

The BPMP-Lite does not have a full-fledged SMMU. It only adds attributes. So VA == PA.

41.10.2 IPC with CPU

The hardware synchronization primitives are used for inter-processor synchronization between the main CPU complex and the BPMP-Lite. Four types of mechanisms are provided for the synchronization.

- The shared semaphore provides a way to sync between the producer and consumer.
- Arbitrator semaphore is an arbitrator to decide if various resources are available for CPU or BPMP.
- Mailbox is like a single element FIFO between CPU and BPMP.
- Atomic: parallel to the existing Semaphores block, it is intended to extend that block's functionality with new capabilities. The advantage is to allow some specific algorithms that access shared resources to be performed lock free, for better performance.

The mailboxes and the Atomic resources can also be used as pointers to larger messages in iRAM and DRAM.

The shared mailboxes have the ability to generate interrupts in either direction on Full/Empty flags

Current mailboxes with the main CPU are implemented in hardware and they are only one deep in each direction.

The current hardware on Tegra X1 implements the mailbox in registers on the PPSB bus. Access to the hardware mailbox from BPMP is relatively fast (2-3 cycles). Reads to the hardware mailbox from main CPU are similar to reads from DRAM on the order of ~100 CPU cycles.

In addition, the software can implement software mailboxes between BPMP and main CPU in IRAM or DRAM by using circular buffers or linked lists. Circular buffers would require simpler software pointers than linked lists.

Table 248: IPC Registers

Group	Register	Description
Arres_sema	RES_SEMA (R)	Semaphore status
	SHRD_SMP_SET (W)	Set semaphore
	SHRD_SMP_CLR (W)	Clear semaphore
Mailbox	SHRD_INBOX (RW) (COP2CPU)	
	SHRD_OUTBOX (RW) (CPU2COP)	
Arb sem	SMP_GNT_ST (R)	Sem status
	SMP_GET (w)	Req sem
	SMP_PUT (w)	Clear sem
	SMP_REQ_ST (r)	Pending status
Atomics	AP0_TRIGGER	
	AP0_SETUP_V[] (rw)	
	AP0_SETUP_C[] (rw)	

Table 248: IPC Registers

Group	Register	Description
	AP0_RESULT[] (r)	

41.10.3 Semaphores and Mailboxes

Refer to Chapter 4: Semaphores of this document for more details.

41.11 BPMP-Lite Registers

Refer Section 1.4: Reading Register Tables in the Introduction chapter for the register table protocol as well as recommendations for accessing registers.

Arbitration for the various resources on the crossbar bus can be configured via the Arbitration Priority registers. Each crossbar master can be assigned a priority for each crossbar resource so that the resource controller can evaluate the latency needs for each master and complete the requests in the most efficient manner.

It is important that each master is assigned a different priority for each resource. If any two priorities are the same the hardware will override the settings with "safe" values, which may not be what the programmer has intended. So when updating the priorities, you should program all of the priority registers at the same time (one for each master).

41.11.1 ARB_PRIO_CPU_PRIORITY_0

Shared Resource Priority for CPU Register

CHAPTER 42: DESIGN FOR DEBUGGING (DFD)

The Tegra® X1 series processors leverage the enhancements in the design for debugging (DFD) feature. DFD enables the development and use of debugging tools that allow developers of Tegra-based implementations to place the Tegra X1 processor into known states and trace its behavior while running. Benefits of this enhanced DFD implementation include:

- Reduced power leakage
- Enhanced security
- Availability of standard interfaces

This chapter describes the Tegra X1 debuggable blocks and their debugging strategies. Use this information to help determine why something is not working in the software you have developed using NVIDIA® Tegra Board Support Package (BSP).

42.1 Related Documentation

Information in the following documentation is important to understand how to develop a debugging implementation using DFD. Some of these manuals are available from the public section of the ARM Infocenter website; others you may have to order from ARM.

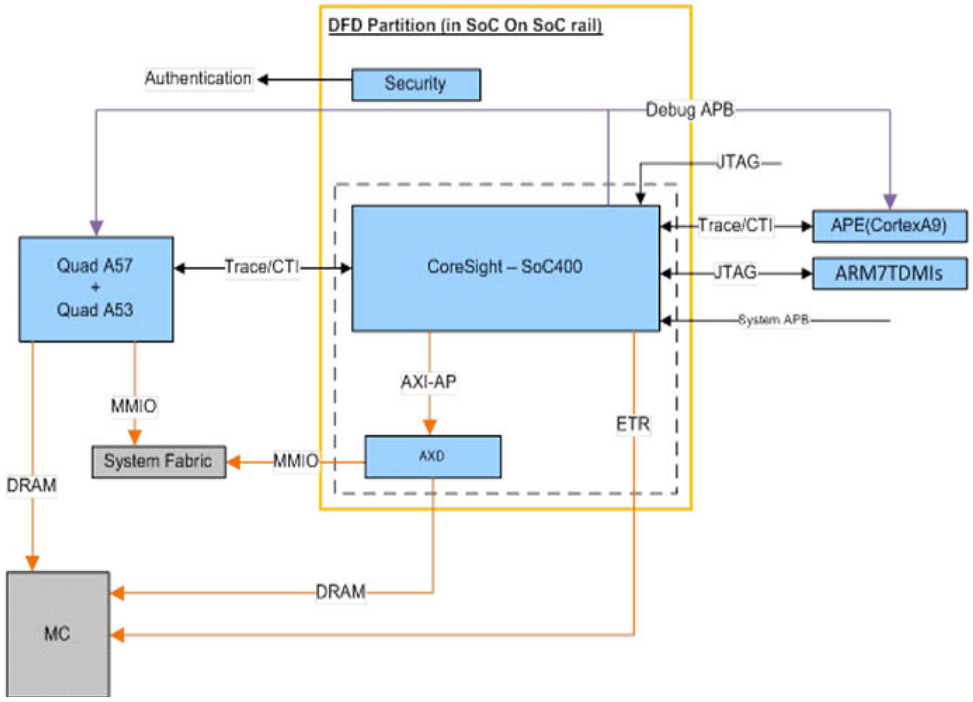
42.1.1 Tegra X1 DFD Components

Tegra X1 DFD components are contained in the CoreSight SOC-400 block. The location of this block, and interactions between it and other blocks, are described in this document.

42.1.2 Tegra X1 DFD Operation Overview

The following figure illustrates the general operation of the DFD components in Tegra X1.

Figure 176: DFD Components



Tegra X1 houses the DFD units in a separate power gateable partition shown in the yellow border in the diagram.

At the center of the block diagram is the CoreSight-SOC400 block. This block integrates with additional necessary IPs, such as the AXI address decoder (AXD), to interface with the SoC to yield the CoreSight Subsystem, indicated by the dotted border within the yellow border. Off chip access is realized via the standard Joint Test Action Group (JTAG) interface as in previous Tegra devices (IEEE 1149.1).

The CoreSight subsystem interfaces with the Cortex-A57/Cortex-A53 CCPLEX and provides the required CoreSight interfaces – Trace, Cross Trigger Matrix (CTM), Authentication, and the Debug Advanced Peripheral Bus (APB) – to provide all the architected debug support for the ARM v8 Cortex-A57/Cortex-A53 subsystem.

The CoreSight subsystem provides a similar debug ecosystem for the v7A based Cortex-A9 CPU called Audio DSP, within the Audio Processing Engine (APE).

For the v4 ARM7TDMI's Boot and Power Management Processor (BPMP), CoreSight provides only the JTAG interface as the ARMv4 architecture is older and not compatible to CoreSight.

CoreSight has complete access to the SoC registers (MMIO space). This, together with the Debug APB that can access the CPU registers, gives CoreSight complete access rights as the main Cortex-A57/Cortex-A53 CPUs. This is a major improvement in Tegra X1 over previous Tegra devices where CoreSight was an AHB master and limited to accessing SoC registers below the AHB fabric only.

CoreSight connects to the Memory Controller (MC) for both the Advanced eXtensible Interface Access Port (AXI-AP) and Embedded Trace Router (ETR) using NVIDIA specific IPs.

In addition, a security block has been added on the ungated SoC rail for driving authentication signals. Taken together, these new features provide Tegra X1 DFD unified CPU trace and SoC debug.

42.1.2.1 Managing CPU Power Down During Debug

Normal power management can interfere with the ability to debug CPUs. To allow debug, CPU power-down can be placed into an emulation mode so that the normal controls do not actually power down the CPUs. Refer to the section titled 'DBGNOPWRDWN' in the Flow Controller chapter of this TRM.

42.2 Tegra X1 DFD Improvements

The following table identifies DFD improvements in Tegra X1.

Table 249: Tegra X1 DFD Improvements

Hardware DFD Feature	Tegra K1 32 Bit	Tegra X1	Improvements
Connection to CPU (JTAG)	Debug Communication Channel	Debug Communication Channel with Memory Access Mode in v8	Faster code download/upload via the debugger.
Connection to AXI-AP (JTAG)	AHB-AP, 32 bit address. Can only access AHB peripherals	AXI-AP 34 bit address, Can access complete MMIO and DRAM without requiring SMMU	Complete system access when CPUs are powered down, dead, under reset, clock disabled, or unable break in.
Connection to ARM7(JTAG)	JTAG TAP	JTAG TAP	No change.
Connection to APE (JTAG)	N/A	CoreSight	All regular debug functionality is available to the APE that is available to the main CPU.
Trace Storage	ETB: 8KB circular buffer	ETF: 16KB circular buffer	Larger buffer for longer duration trace. Preserved through WDT resets.
Trace Streaming to DRAM	Not available	ETR: descriptor based throughput matched DMA to stream ETF to DRAM	Allows to get data output on WDT boot via USB or WiFi. Dramatically increases trace storage (1 MB with provision to increase as desired).
Trace Pipeline	32 bit	128 bit	No data drops when tracing at full CPU frequency.
SW Instrumentation (UART, USB)	CCPLEX UART	CCPLEX UART, APE UART, STM	STM can combine printfs from various threads and stream to DRAM and out over USB for closed system logging.
Debug APB Deadcodes	CCPLEX only	CCPLEX, APE	Provides information on accessing power gated, clock gated, reset CPU, and results in timeouts for other cases.
Power gateable DFD partition	DFD logic was all over the SoC	Separate Power-gateable partition	Continuous power savings on production systems where debug functionality is not required.
DFD security	BCT, Boot ROM, boot loader, NV legacy	BCT and Boot ROM only	Simplified and standardized
DFD Reset	Multiple standard resets which gets asserted on WDT.	Single Debug reset that does not assert on WDT reset	CoreSight ETF pointers preserved on WDT reset.
Cache Flush on WDT FIQ	Not supported	Supported	Debug of Soft-Lockups that require latest contents in DRAM
Scan Dump (JTAG)	Scan Dump GUI with web based utility to parse scanned dumps	Scan Dump GUI with web based utility to parse scanned dumps	No change.

42.2.1 CoreSight Major and Minor Blocks

The CoreSight SoC-400 module is divided into CoreSight Major and CoreSight Minor blocks.

The CoreSight Major block contains:

- The main Advanced Peripheral Bus (APB) Interconnect
- Funnel

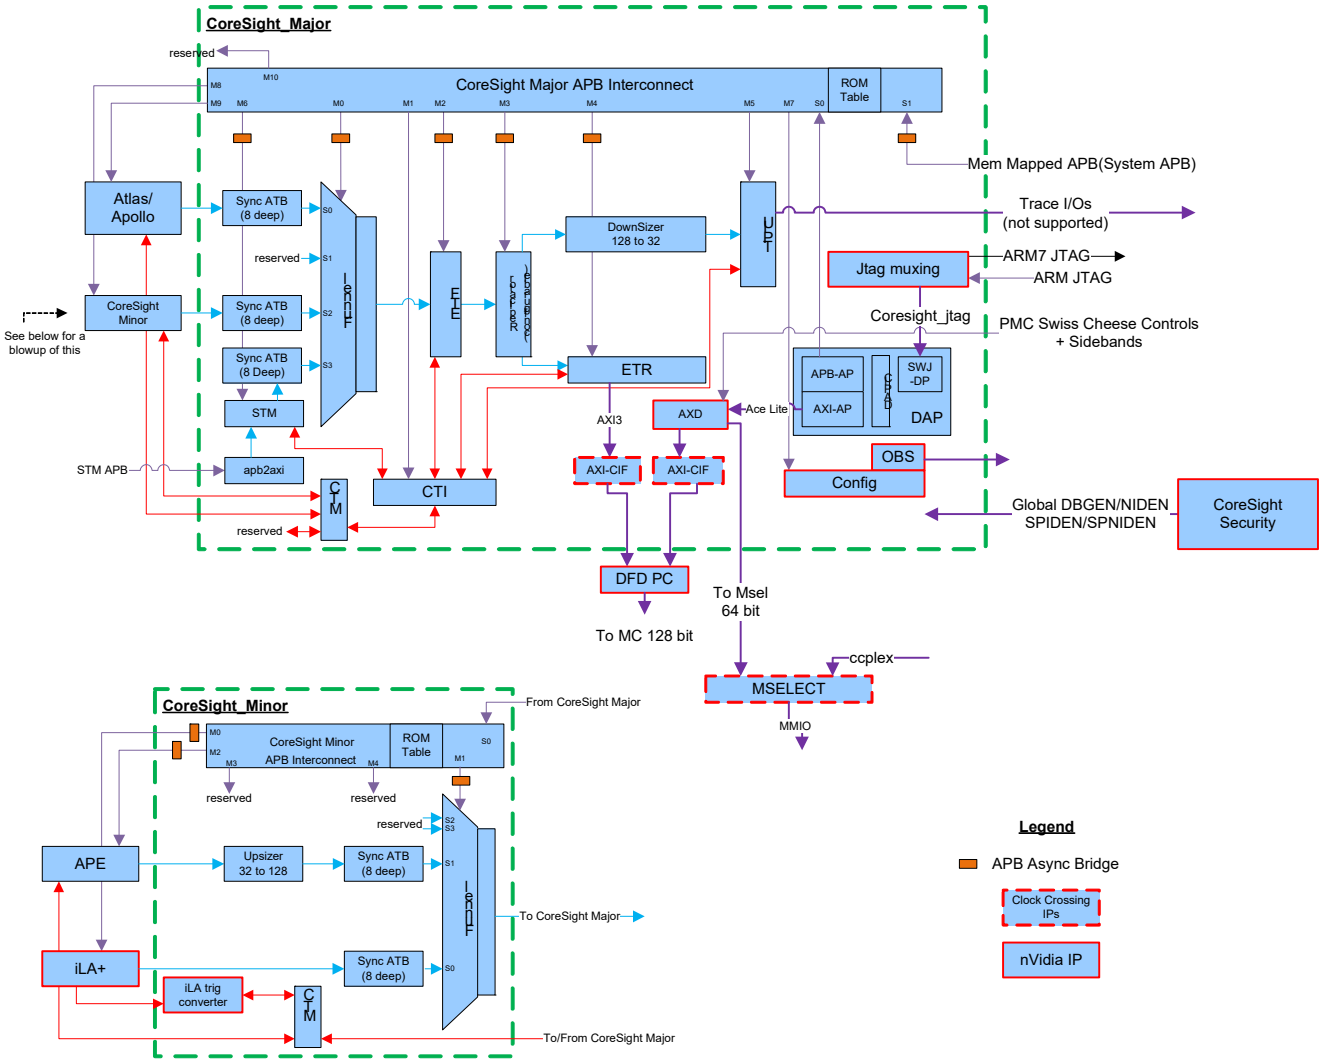
- Embedded Trace FIFO (ETF)
- Replicator
- Embedded Trace Router (ETR)
- Cross-Trigger Interface (CTI)
- Cross-Trigger Matrix (CTM)
- System Trace Macrocell (STM)
- Trace Port Interface Unit (TPIU)
- Bridges (for holding data while the funnel arbitrates across trace sources)
- APB Async Bridges (AB) to decouple Debug APB clock from the ATB clock

The CoreSight Minor block contains:

- A staggered APBIC (slave to the CoreSight_Major APBIC)
- Funnel (slave of the CoreSight_Minor APBIC)
- Sync ATB bridges
- CTM

The following figure illustrates the CoreSight microarchitecture.

Figure 177: CoreSight Major and Minor Block Diagram



42.2.2 Tegra X1 DFD CoreSight Components

The following table shows the CoreSight components that implement Tegra X1 DFD. A synopsis of the DFD functionality provided for each component.

Table 250: CoreSight Components with DFD

Component	Acronym	Synopsis
APB Interconnect	APBIC	Connects to APB-AP and System APB on the slave ports and provides master APB ports for all DFD components in the CoreSight subsystem, in various CPUs, and an NVIDIA specific configuration aperture. Occupies 32 MB on the system AMAP.
Funnel	N/A	Arbitrates traces from multiple sources and provides a single Trace bus.
Embedded Trace FIFO	ETF	16-kilobyte (KB) embedded buffer organized as 256 x 512 (<width> x <depth>) to store trace data.
Embedded Trace Router	ETR	Streams ETF contents to off-chip DRAM via an AXI master interface. Capable of streaming to secure DRAM apertures. Not capable of reading VPR region.
Upsizer (32 to 128)	N/A	Upsizes the trace bus by sampling across 4 clock cycles and transmitting every fourth cycle for matching throughput requirements.
Downsizer (128 to 32)	N/A	Downsizes the 128-bit trace interface into 32 bits to connect to TPIU.
Replicator	N/A	Replicates a single trace interface into 2 trace interfaces.
Trace Port Interface Unit	TPIU	Streams trace data to off-chip interface.Trace IOs are not brought out on Tegra X1. This module is not used but added for future use.

Table 250: CoreSight Components with DFD

Component	Acronym	Synopsis
Debug Access Port	DAP	Contains the AXI-AP, APBAP, SWJDP and DAPIC.
AXI-Access Port	AXI-AP	Converts JTAG into a master AXI interface to connect to system fabric. Capable of making secure accesses into the system. Not capable of reading VPR region.
APB Access Port	APBAP	Converts JTAG into debug APB master interface. Provides master interface to connect.
DAP Interconnect	DAPIC	Interconnect within the DAP to extend the JTAG interface to the APB AP and AXI-AP.
Serial Wire JTAG Debug Port	SWJDP	Interfaces with the external JTAG port and connects to the DAPIC. Serial Wire (reduced pin) not supported in Tegra X1. Only JTAG is supported.
Cross Trigger Matrix	CTM	Transmits events across trace sources.
Cross Trigger Interface	CTI	Connects to various trigger interfaces.
System Trace Macrocell	STM	Collects SW instrumentation (printfs) from system and coverts that data into ATB.
Timestamp Interpolator	TS INTP	Takes a slow timestamp and increases timestamp granularity.
APB Sync Bridge	N/A	APB pipe macro to close timing on the Debug APB interface.
APB Async Bridge	N/A	APB bridge for clock crossing.
ATB Sync Bridge	N/A	ATB pipe macro to close timing on ATB interface.
ATB Async Bridge	N/A	ATB bridge for clock crossing.

42.2.3 CoreSight System Interfaces

The following table shows the CoreSight system interfaces for Tegra X1 DFD, the components accessed for each interface and the address and data width for each interface.

Table 251: CoreSight System Interfaces for DFD

Interface	Accesses	Address Width	Data Width
Debug APB	CPU Components: (Cortex-A57 and Cortex-A9): PTM, CTI, PMU, and debug registers. CoreSight Components: APBIC, Funnel, ETF, Replicator, ETR, STM, TPIU, CTI This bus can have two masters: 1. JTAG from debugger for external debugging. 2. System APB for self-hosted debugging (debug code running on CPU). **Note**: ATB and APB sync/async bridges, Interpolator, Upsizer/ Downsizer, and CTM do not have any configurable registers and hence do not interface with Debug APB.	Variable, depends on the APB slave. But always less than 25.	32
System APB	CCPLEX and ARM7TDMIs can master the Debug APB using the System APB bus. This path is useful for self-hosted debugs. Also used for interfacing to the STM via the apb2axi bridge (32-bit data)	25	32
AXD AXI to System Fabric Registers (AXD + AXIAP)	Use this bus when it is not possible to halt or connect to the CPU due to a CPU hang/powerdown. Also use this bus for real-time debug (without disturbing the CPU). The actual physical address is set up by the debugger in the AXI-AP Control Status Word register to emanate an access into the possible AMAP of the SoC. This interface supports secure and non-Secure accesses. This interface is originally Ace-Lite from AXI-AP but reduced to AXI3 to connect to AXD.	34	64
MC interface (AXD + ETR)	The DRAM arm from AXD (34-bit address and 64-bit data) is combined with the AXI ETR traffic (34-bit address and 128-bit data) and sent to MC. This interface allows you to query/modify any DRAM location via the AXI-AP and stream trace contents via the ETR.	34	128
Trace Interface	One-trace Interface from the CCPLEX, One-trace Interface from the APE. The trace Interface does not have an address bus.	N/A	128 (CCPLEX) 32(APE)
Trigger Interface	One event and acknowledgment CTM interface from the CCPLEX, One event and acknowledgment CTM interface from the APE.	N/A	16

Table 251: CoreSight System Interfaces for DFD

Interface	Accesses	Address Width	Data Width
Authentication	Sidebands from the CoreSight configuration block consisting of global dbgen, niden, spniden, and spiden, for use by the Cortex-A9 and the Cortex-A57/Cortex-A53 processors and the internal CoreSight modules.	N/A	7
JTAG	This interface is used to connect to the external debugging equipment and is an implementation of the standard IEEE1149.1 specification. The TRST pin is not connected from the debugger, it is connected to the same power on reset. TRST is repurposed by NVIDIA to select signals to send JTAG chip, I/Os to DFT controller (TRST=1, NV_JTAG), or CoreSight (TRST=0, ARM_JTAG) The JTAG interface in Tegra X1 is daisy-chained across the ARM7TDMIs TAP and DAP TAP and is called Serial Mode: JTAG TDI --> ARM7TDMIs TDI. ARM7TDMIs TDO --> CoreSight TDI. CoreSight TDO --> JTAG TDO.	N/A	1 bit (TDI or TDO)

42.2.4 CoreSight Logic in CCPLEX

Earlier Tegra devices exported a 32-bit ATB interface for each CPU to CoreSight. This approach is not scalable as the number of CPUs change or as the number of CPU clusters change. Also, a 32-bit interface cannot handle the ATB throughput. Consequently, the CCPLEX adds another staggered interconnect with a funnel to combine the quad CPU trace with adequate buffering for the funnel switching times.

42.3 Implementing Tegra X1 DFD Components

The following sections provide information for implementing DFD on specific Tegra X1 components.

42.3.1 Audio Processor Engine (APE)

The Tegra X1 APE uses the ARM Cortex-A9 processor. The Cortex-A9 includes a discrete Program Trace Macrocell (PTM) instanced in the CPU power domain by the APE. The APE interfaces to the CoreSight Minor block for the APBIC, Funnel, and CTM. The trace bus from APE is 32-bits wide and upsized in the CoreSight Minor block.

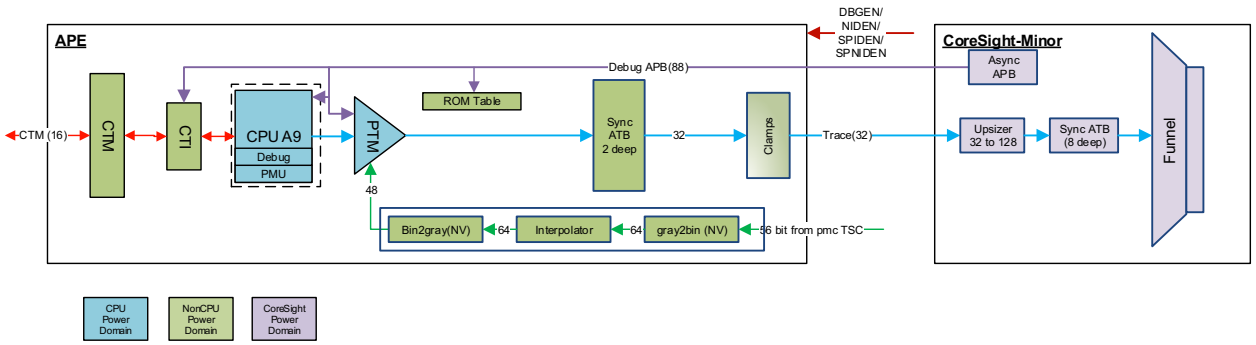
42.3.2 CoreSight Connections to the Audio Processor Engine

Tegra X1 has an Audio Processor Engine (APE) that uses a Cortex-A9 processor. The Cortex-A9 processor has a discrete PTM that is instanced in the CPU power domain by the APE.

The APE interfaces to CoreSight Minor for the APBIC, Funnel, and CTM. The trace bus from the APE is 32 bits wide and upsized in the CoreSight Minor block.

The following figure illustrates the APE CoreSight connectivity.

Figure 178: APE to CoreSight Connectivity



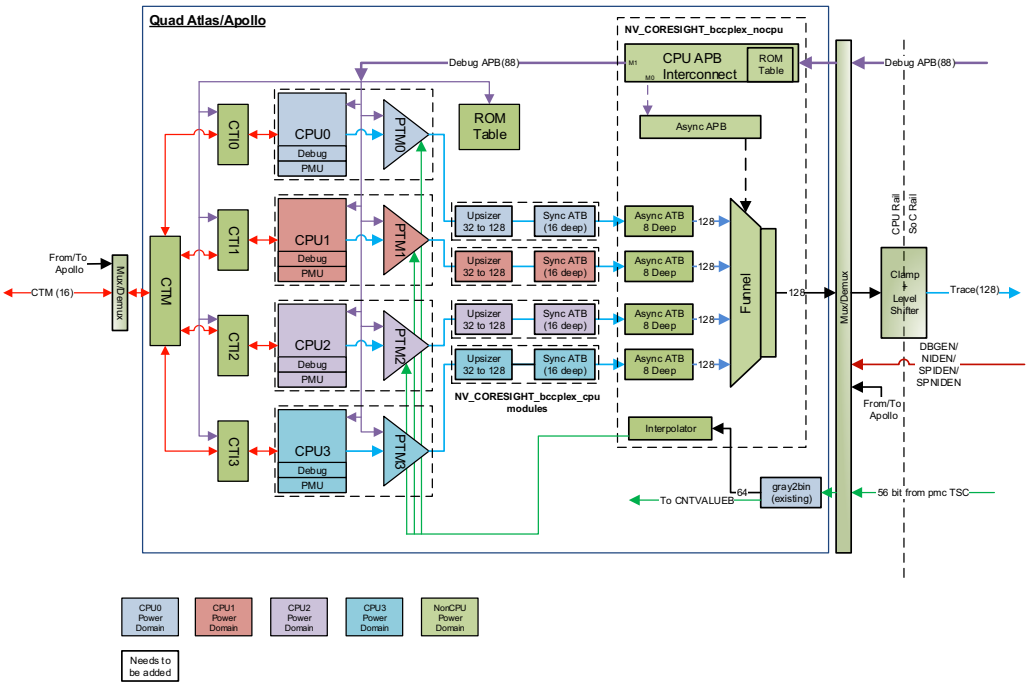
42.3.3 Cortex-A57/Cortex-A53 4+4 Switched Cluster Implementation

Tegra X1 is a quad Cortex-A57 and a quad Cortex-A53 implementation. Both Cortex-A57 and Cortex-A53 are implementations of the ARMv8 architecture and support identical debug feature list. Either the Cortex-A57 or Cortex-A53 can be active at a given time based on a register bit setting in the Flow Controller. The interfaces from CoreSight do not change at all with this switched cluster implementation. The CCPLEX accepts the interfaces from CoreSight and guarantees that these are correctly routed to the currently active cluster. The cluster switch happens only in CC6 state where both the clusters are off. The same set of registers from CAR is used to control the resets and clock enables for both the clusters. Therefore, CoreSight RTL implementation assumes that there is only one cluster. This also allows the debugger to identify a single set of ROM tables, either for the Cortex-A53 or for Cortex-A57.

42.3.4 Quad Cortex-A57/Cortex-A53 CoreSight Connectivity

The following figure illustrates the connections between the quad CPUs and CoreSight.

Figure 179: Quad CPUs and CoreSight Connectivity



42.4 CoreSight ROM Tables

Each APBIC implements a ROM table which tabulates the configurable components hanging off the APBIC. The ROM tables are housed at offset 0 of the defined aperture and are automatically read off by debuggers to determine the debug architecture of the SoC. There are:

- Three ROM tables were added by Tegra X1 DFD: one each in CoreSight Major and CoreSight Minor, and a third in the CoreSight non-CPU block
- One ROM table each in the CCPLEX complex
- One ROM table in the APE for a total of five ROM tables.

The CoreSight_Major ROM table points to:

- CoreSight Major Components
- CoreSight Minor ROM table (first level nested ROM)

- CoreSight Big Interconnect ROM table (first level nested ROM)

The CoreSight Minor ROM table points to the APE ROM table (second-level nested ROM).

The CoreSight Big Interconnect ROM table points to:

- CCPLEX ROM table (second level nested ROM)
- CCPLEX Funnel

The CCPLEX ROM table points to:

- Four PTMs
- Four CTIs
- Four PMUs
- Four DBGs (for either Cortex-A57 or Cortex-A53)

The APE ROM table points to:

- One PTM
- One CTI
- One PMU
- One DBG

Note: *The ROM in the ROM tables does not indicate a physical read-only memory. The ROM table is static data based on defines in the APBIC.*

42.5 CoreSight System Trace Macrocell

For software instrumentation, CoreSight implements a System Trace Macrocell. This is the ARM replacement for the older, narrower, slower Instrumentation Trace Macrocell. STM has a 32-bit address and 32-bit data AXI slave port to receive software instrumentation. The AMAP stipulated by STM is 16 MB.

42.6 CoreSight Address Map

The following table shows the CoreSight address map for Tegra X1 DFD. The table shows the base, start, and end addresses for each component, and the APBIC master port if available

Table 252: CoreSight Address Map

CoreSight Major

42.7 ETM/PTM Overview

Each ARM processor in Tegra X1 integrates either the Embedded Trace Macrocell (in the ARM Cortex-A57 and ARM Cortex-A53 processors) or the Program Trace Macrocell (in the ARM Cortex A9 processor) – referred to as the Trace Module. As the CPU executes instructions, it also outputs waypoint information (change in PC value) to the Trace Module. The Trace Module forwards these waypoints, post-packetization and compression, according to the supported trace protocol (ETMv4 for the Cortex-A57 and Cortex-A53 processors, or PFT1.0 for the Cortex-A9 processors), to CoreSight ETF along with a Trace ID, using the AMBA Trace Bus protocol (ATB). A formatter in ETF injects the Trace IDs along with the data packets and stores them in a circular 16KB buffer.

This 16 KB buffer is read out and the data is segregated based on IDs. Subsequently the segregated data is decompressed and depacketized for a parser to determine the exact waypoints. The parser also has a copy of the source code and is able to map the exact sequence of instructions that a CPU executed.

Getting the exact sequence of instructions executed is very beneficial in the case of a hard lockup. Other uses for the trace include code optimization for easy determination if some portion of code is causing additional latency.

42.8 CoreSight ATB Interface Throughput Calculations

One CPU generates three bits of instruction trace (non-cycle accurate) for 99.5 percent trace, and six bits for the cycle accurate case. CoreSight ATB sizing is done based on the non-cycle accurate tracing. The following table identifies the traces generated per CPU.

Table 253: Bits per Cycle per CPU

CPUs	Bits Per Cycle
1 Cortex-A57 CPU	3 bits per cycle
Quad Cortex-A57 CPUs	3 x 4 bits per cycle
Quad Cortex-A57 CPUs	3 x 4 x1.25 bits per cycle (v8 scaling factor is 1.25, as provided by ARM)
1 Cortex-A57 CPU	3 bits per cycle

The number of bits generated in one second is equal to 3 x 4 x 1.25 x <CPU_frequency>.

For CoreSight running at maximum CPU/4 frequency, the ATB interface width *N*, with protocol efficiency of 80% throughput handled is:

$$N \times \frac{CPU\_Frequency}{4} \times 0.8$$

This must be able to handle the CPU trace output running at CPU frequency, i.e.,

$$3 \times 4 \times 1.25 \times CPU_{Frequency} = N \times \frac{CPU_{Frequency}}{4} \times 0.8$$

$$N = 75 \text{ bits}$$

Since ATB supports a width of 128 bits as the next highest after 64 bits, the ATB interface is 128-bit for Tegra X1 devices.

The increased data width protects from additional trace from APE in rare cases where trace must be collected simultaneously with the CPUs. This also provides trace for the cycle accurate case with reduced frequency from the quad Cortex-A57 CPUs at:

$$128 \times CoreSight_{Frequency} \times 0.8 = 6 \times 4 \times 1.25 \times CPU_{Frequency}$$

Where:

$$CPU_{Frequency} : CoreSight_{Frequency} = 3.4 : 1$$

The ATB interface width cannot be further increased because all CoreSight components peak at 128 bits.

42.9 CoreSight Trace Sinks ETF and ETR

The following table shows the CoreSight trace sink characteristics for Tegra X1 DFD, the corresponding Embedded Trace FIFO (ETF), ETR, and USB limits.

Table 254: CoreSight Trace Sink Characteristics

Characteristic	ETF (16 KB)	DDR via ETR DMA	USB
Throughput	52 Gbps @ 408 MHz and 128 bit (contact NVIDIA for higher frequency requirements.)	52Gbps	Real-time processor tracing requires reduction of CPU frequency.
Intrusive	No	Yes	Yes
Available on Commercial Devices	Yes	Yes	Yes

Table 254: CoreSight Trace Sink Characteristics

Characteristic	ETF (16 KB)	DDR via ETR DMA	USB
Use Cases	Collect trace for watchdog reset, and code optimization for the CCPLEX.	Collects trace information for watchdog reset, and code optimization for the CCPLEX (note the high bandwidth requirement at DDR = 25%).	Use for single CPU trace at low frequency, or APE only trace to avoid saturation of DRAM bandwidth Tracing limited to USB speeds. Use for single CPU trace at low frequency, or APE only trace to avoid saturation of DRAM bandwidth.

42.10 CoreSight AMBA Trace ID (ATID) Mapping

The following table shows the mapping for CoreSight AMBA Trace ID (ATID). When collecting trace from multiple sources, the trace sinks (ETF and ETR) use ATIDs to segregate trace data.

Table 255: CoreSight ATID Mapping

BCCPLEX (also called Fast Cluster or Big Cluster) using Cortex-A57 processors		
ATID	**Processor**	**Protocol**
0x40	CPU0	ETMv4
0x41	CPU1	ETMv4
0x42	CPU2	ETMv4
0x43	CPU3	ETMv4
LCCPLEX (also called Slow Cluster or Little Cluster) using Cortex-A53 processors		
ATID	**Processor**	**Protocol**
0x30	CPU0	ETMv4
0x31	CPU1	ETMv4
0x32	CPU2	ETMv4
0x33	CPU3	ETMv4
APE Cortex-A9		
ATID	**Processor**	**Protocol**
0x20	CPU0	PFT1.0
STM		
ATID	**Processor**	**Protocol**
0x10	NA	MIPI STP

42.10.1 CoreSight Clocks

The following table shows the CoreSight clocks, the maximum frequency for each clock, and where they are used.

Table 256: CoreSight Clock Information

Clock	Maximum Frequency	Used By
CoreSight ATB Clock	624 MHz. Recommend to run at PLLP of 408 MHz fixed clock across voltage corners	CCPLEX and APE traces
CoreSight Debug APB Clock	136 MHz	All debug APB logic
JTAG TCK	Adaptive – uses RTCK	CoreSight and ARM7TDMIsTDMIs TAP

42.11 CoreSight Resets

For debugging Watchdog Timer (WDT) reset scenarios, CoreSight survives the WDT reset that occurs on 4th expiration of WDT. This allows ETF pointers to be read after a WDT reset and recover the trace (survived due to no power cycle).

CoreSight comes out of reset by default without any software intervention.

42.12 CoreSight CTI Connections

The Cross Trigger Interface collects triggers from the ETF, ETR and STM.

This CTI is distinct from the CTI for each CPU that exists together with the PTM for each CPU. The CPU CTIs implement triggers for entering Debug, triggers for PTMs, and other triggers.

The CTIs across CoreSight, CCPLEX and APE communicate via the Cross Trigger Matrix (CTM). The CTM receives the CTI triggers and converts them into channel events.

The following table shows the CoreSight connections with CTI input and output triggers.

Table 257: CoreSight CTI Connections

Input Trigger	Name	Driving Module
CTITRIGIN0	Full	ETF
CTITRIGIN1	ACQCOMP	ETF
CTITRIGIN2	Full	ETR
CTITRIGIN3	ACQCOMP	ETR
CTITRIGIN4	ASYNCOUT	STM
CTITRIGIN5	SPTE	STM
CTITRIGIN6	SW	STM
CTITRIGIN7	Tied off	NA
Output Trigger	**Name**	**Driving Module**
CTITRIGOUT0	TRIGIN	ETF
CTITRIGOUT1	FLUSHIN	ETF
CTITRIGOUT2	TRIGIN	ETR
CTITRIGOUT3	FLUSHIN	ETR
CTITRIGOUT4	TRIGIN	TPIU
CTITRIGOUT5	FLUSHIN	TPIU
CTITRIGOUT6	Not Connected	NA
CTITRIGOUT7	Not Connected	NA

For similar trigger connectivity for CTIs of the CPUs, refer to the respective CPU TRMs. For connectivity of CPU CTIs, refer to the respective CPU/PTM TRMs.

42.13 Timestamp Halt on Debug

The debug acknowledgments from the CCPLEX and ARM7TDMIs are used to halt the timers. This helps to debug the timer software for these modules and disable unwarranted WDT timeouts.

> ***Note:*** *APE DBGACK does not participate in this halt-on debug mechanism.*

42.14 CoreSight Debug APB Timeout and Access Block Deadcodes

In order to not hang the debugger while making accesses on the Debug APB, CoreSight adds a new internal NVIDIA module to perform the following functions:

- Time-limit the Debug APB accesses for the CCPLEX and the APE
- Block the accesses which are guaranteed to result in timeout due to a non-responsive CCPLEX or APE.

Either of these could be non-responsive due to power down, clock gating or reset.

In the event of either a timeout or access block, the access from CoreSight APB-AP completes by asserting respective master pready of the APBIC as 1. In addition, deadcodes are returned on the prdata bus to immediately identify what caused a

particular access to timeout or block. On receiving the deadcode, the debugger can query the respective CORESIGHT_CFG_<module>_ALIVE_STATUS register for the cause of timeout/blocking.

> **Note:** *In the event a CPU gclk register access operation results in a timeout, subsequent CPU pclkdbg register access operations also result in timeouts. The debugger must first fix the issue indicated by the ALIVE status register and then make subsequent access operations for the other registers.*

42.15 Lauterbach Debugger Configuration Parameters

CoreSight is a design kit with configurable components. CoreSight architecture must be indicated to external debuggers. ARM debuggers like DS5/DSTREAM boxes can detect this configuration by reading the registers within each core, already knowing the Instruction Register Lengths for various ARM CPUs.

Lauterbach, which caters to other processors outside the ARM ecosystem, requires Access Port (AP) configurations and Instruction Register Length for the additional TAP ports.

42.15.1 DAP

The CoreSight DAP has two access ports and each has a unique Identification Register (IDR). The Lauterbach debugger settings for the above DAP are listed in the following table.

Access Port	Identification Register (IDR)
APB-AP at port 0	0x44770002
AXI-AP at port 1	0x24770002

The DAP access port Lauterbach debugger settings are listed in the following table.

Access Port	Identification Register (IDR)
0x0	0x44770002 (MEM-AP APB) --> SYStem.CONFIG DEBUGACCESSPORT 0
0x1	0x44770001 (MEM-AP AHB) --> SYStem.CONFIG MEMORYACCESSPORT 1

42.15.2 TAP Position

The DAP is not the only Test Access Port (TAP) in the JTAG scan chain of Tegra X1 devices. You must set up the position of the ARM7TDMIsTDMIs TAP the JTAG scan chain:

```
TDI -> ARM7TDMIs -> DAP -> TDO
```

resulting in:

```
TAP1 = ARM7TDMIs, Instruction Register (IR) Length = 4
TAP2 = DAP
Data Register (DR) length is 1 bit for each TAP (IR = BYPASS)
SYStem.CONFIG.DAPIRPRE 0x0 ; IR for TAP after DAP - there is none.
SYStem.CONFIG.DAPIRPOST 0x4 ; IR TAP1
SYStem.CONFIG.DAPDRPRE 0x0 ; DR for the TAP after DAP - there is non
SYStem.CONFIG.DAPDRPOST 0x1 ; DR TAP1
```

42.15.3 Base Addresses

Refer to Section 42.6: CoreSight Address Map for any additional base address required. Define or otherwise code the offsets as the OR of the base of the module offset and 0x8000_0000, that is, with bit 31 set:

<Module_Offset> | 0x8000_0000 = <Final_Address>

For example, for the APE Debug Register, the offset is:

```
0xA10000 | 0x8000_0000 = 0x80A1_0000
```

42.16 DFD Partition

Tegra X1 devices group all debug units into a separate DFD partition that can be power gated.

The Tegra X1 DFD is a separately power-gateable partition of the device. Power to the DFD partition can be optionally applied during device boot, controlled by the boot loader. This allows production Tegra X1 devices to consume less power than previous NVIDIA devices because the boot loader can be built to not apply power to the DFD partition when debugging features are not needed.

To enable this power-saving feature, use the POWERGATE_DEBUG condition in the boot loader code to apply power to the DFD partition only for a debugging version of the software.

42.16.1 Possible CoreSight Accesses During Low Power States

When the CPU rail is powered down, the CoreSight AXI-AP port is used for debugging access. This requires that the DFD partition itself is not powered down in Suspend (LP1) and Deep Sleep (LP0) Debug states. The low power state access rights are listed in the following table.

Table 258: Access Rights in Low Power

Low Power State	Definition of the Low Power State	Access Rights
Deep Sleep (LP0)	DRAM is put in self-refresh, system state is saved in PMC + DRAM, VDD_SOC and VDD_CPU rails are powered off, and PMC is configured to monitor Deep Sleep (LP0) wake events which trigger Deep Sleep (LP0) exit.	No accesses can emanate from CoreSight as CoreSight which resides on the VDD_SOC rail is also powered down.
Suspend (LP1)	DRAM is put in self-refresh, VDD_CPU rail is powered off, devices are power-gated, SoC clock domains are put into min frequency (32Khz) and the flow-controller is configured to monitor Suspend (LP1) wake events which would trigger Suspend (LP1) exit.	CoreSight is clock enabled by default. It has osc clock as source and lives in the non-PG partition (AHB). Debugger remains connected via the AO JTAG pads. Daisy chain with ARM7TDMIs work as sclk is running. With DRAM is in self refresh, memory cannot be accessed. Registers of powered-up and clock-enabled modules can be accessed via the CoreSight AXI-AP port.

42.17 DFD Security

Debugging in ODM production Tegra devices can be disabled by:

- Blowing debug fuses. Recommended if debug never needs to be re-enabled on ODM-Production device. Each Debug Authentication signals has a corresponding fuse. Blowing fuse disables (zeroes out) the corresponding Debug Signal and the functionality governed by it.

Fuse Name	Debug Signal
FUSE_ODM_INFO[12]	DBGEN
FUSE_ODM_INFO[11]	NIDEN
FUSE_ODM_INFO[10]	SPIDEN
FUSE_ODM_INFO[9]	SPNIDEN
FUSE_ODM_INFO[8]	DEVICEEN
FUSE_ARM_JTAG_DIS	JTAG_ENABLE

- Not blowing the debug fuses and instead using a per-chip secure signed BCT. Recommended if there is a need to re-enable debug on ODM-Production devices.

  Debug for this mode is re-enabled by updating the value of the SecureDebugControl entry in the Boot ROM BCT.

Note: *For devices that are re-enabled for debug, it is strongly recommended that the JTAG interface pins: TMS, TCK, TDI, TDO, TRST, and RTCK are available as contact points on the main board. This allows partially opening the device and attaching a JTAG header.*

42.17.1 Re-enabling Debugging Using Per Chip Secure Signed BCT

To re-enable debugging, a unique Boot Configuration Table (BCT) is required per device. A BCT for one device does not enable debugging on another device. The per chip device unique ID allows you to apply control per chip BCT.

Prerequisites:

- NvBootECID: Specifies the Unique ID / ECID of the chip that the BCT is specifically generated for. This field is required if any debugging features are enabled through SecureDebugControl. Otherwise, this field is not required. This design prevents a signed BCT, with the debugging features enabled, from leaking into the field that would enable various debugging features for all devices signed with the same RSA private key or AES key.
- SecureDebugControl: Specifies which debugging features are enabled or disabled. This setting maps directly to APBDEV_PMC_DEBUG_AUTHENTICATION_0. It must specify the ECID of the chip in UniqueChipID on production systems.

Table 259: DFD Security BCT Entries Mappings

Name	Definition	Common Use Case(s)
DBGEN SecureDebugControl[5]	NonSecure Invasive Debug Enable	Must be 1 for CPUs to halt, AXI-AP to make system accesses, and for ETR to stream trace to DRAM.
NIDEN SecureDebugControl[4]	NonSecure NonInvasive Debug Enable	Must be 1 for PTM trace from CPUs.
SPIDEN SecureDebugControl[3]	Secure Invasive Debug Enable	Must be 1 for AXI-AP to make secure accesses into the system, ETR to write to Secure DRAM.
SPNIDEN SecureDebugControl[2]	Secure NonInvasive Debug Enable	Must be 1 for accessing secure registers in PMU and CPUs over the Debug APB.
DEVICEEN SecureDebugControl[1]	Device Enable	Must be 1 for accessing any registers on mapped over the Debug APB.
JTAG_ENABLE SecureDebugControl[0]	Enables JTAG TAP	Must be 1 to enable the JTAG interface to CoreSight-SoC400.

Boot ROM securely writes SecureDebugControl to APBDEV_PMC_DEBUG_AUTHENTICATION_0 as per table below.

Table 260: DFD Security Modes

Mode	APBDEV_PMC_DEBUG_AUTHENTICATION Handling	
	Tegra K1 32 Bit	Tegra X1
NvProduction and Secure Provisioning disabled	JTAG always enabled at exit	JTAG always enabled at exit
NvProduction and Secure Provisioning enabled	N/A	Depends on BCT*
ODM Production Mode	Depends on BCT†*	Depends on BCT†*
Notes		
* Check if the ECID specified in the BCT matches the ECID in the chip. The ECID check is an additional step for debug controls enablement purposes only. This is to ensure that a signed debug controls-enabled build can only work on one system. † For Tegra X1, the SecureDebugControl field in the BCT maps directly to DBGEN/NIDEN/ SPIDEN/SPNIDEN/DEVICEEN/ JTAG_ENABLE bits in APBDEV_PMC_DEBUG_AUTHENTICATION_0. For Tegra K1 32 Bit, the SecureJtagControl field controls this functionality.		

42.17.1.1 To Obtain a Target ECID of the Device

1. Place the device in recovery mode.

2. On the Linux host machine, open a terminal window to check if the device is listed by entering the lsusb command.

   The system returns a listing similar to the following:

```
Bus 001 Device 001: ID 1d6b:0002 Linux Foundation 2.0 root hub
Bus 002 Device 001: ID 1d6b:0002 Linux Foundation 2.0 root hub
Bus 003 Device 001: ID 1d6b:0001 Linux Foundation 1.1 root hub
Bus 004 Device 001: ID 1d6b:0001 Linux Foundation 1.1 root hub
Bus 005 Device 001: ID 1d6b:0001 Linux Foundation 1.1 root hub
Bus 006 Device 001: ID 1d6b:0001 Linux Foundation 1.1 root hub
Bus 007 Device 001: ID 1d6b:0001 Linux Foundation 1.1 root hub
Bus 008 Device 001: ID 1d6b:0001 Linux Foundation 1.1 root hub
Bus 001 Device 002: ID 0409:005a NEC Corp. HighSpeed Hub
Bus 008 Device 002: ID 046d:c05a Logitech, Inc. Optical Mouse M90
Bus 001 Device 003: ID 0403:6011 Future Technology Devices International, Ltd FT4232H Quad HS USB-UART/FIFO IC
Bus 001 Device 021: ID 0955:7021 NVidia Corp.
```

3. Execute the following command to obtain the UID of the device.

```
sudo $TOP/out/host/linux-x86/bin/tegrarcm –uid
```

   The system returns a 128-bit UID which must be interpreted as follows to obtain a 100-bit ECID:

```
BR_CID: 0x621010015c1971862000000002058300
MSB: 0x6 -> indicates the operating mode.0x6 stands for odm secure PKC mode.
rcm version : 0x2101 -> this indicates rcm version (0x21 -chipid  0x01 -minor revision)
ECID_0 = 0x02058300; // first 4bytes from LSB
ECID_1 = 0x20000000; // next 4bytes after ECID_0
ECID_2 = 0x5c197186; // next 4bytes after ECID_1
ECID_3 = 0x00000001; // ((next 4 bytes after ECID_2) & 0xF)
```

42.17.2 Generating the BCT with UID and SecureDebugControl

To generate the BCT with the UID, you must append the BCT configuration file with the parameters that were returned from the tegrarcm command in the previous topic. For example:

```
ECID_0=0x02058300;
ECID_1=0x20000000;
ECID_2=0x5c197186;
ECID_3=0x00000001;
SecureDebugControl=0x3f; // Value as per requirement
```

42.17.3 Signing the New BCT

Signing the BCT is performed as part of the process of generating the signed binaries for the secure device. You must obtain a private key for generating signed images.

42.18 CoreSight Registers

42.18.1 CORESIGHT_ETF_HUGO_CXTMC_REGS_LAR_0

This is used to enable write access to device registers.

Offset: 0x30fb0 I Read/Write: WO I Reset: 0xc5acce55 (0b11000101101011001100111001010101)

Bit	Reset	Description
31:0	-978530731	ACCESS_W:A write of 0xC5ACCE55 enables further write access to this device. A write of any value other than 0xC5ACCE55 will have the effect of removing write access. 3316436565 = Unlock

42.18.2 CORESIGHT_ETR_HUGO_CXTMC_REGS_LAR_0

This is used to enable write access to device registers.

Offset: 0x50fb0 I Read/Write: WO I Reset: 0xc5acce55 (0b11000101101011001100111001010101)

Bit	Reset	Description
31:0	978530731	ACCESS_W:A write of 0xC5ACCE55 enables further write access to this device. A write of any value other than 0xC5ACCE55 will have the effect of removing write access. 3316436565 = Unlock

42.18.3 CORESIGHT_ETF_HUGO_CXTMC_REGS_FFCR_0

This register allows user control of the stop, trigger, and flush events.

Offset: 0x30304 I Read/Write: R/W I Reset: 0x00000000 (0bxxxxxxxxxxxxxxxxxx000x000x000xx00)

Bit	R/W	Reset	Description
14	WO	0x0	DrainBuffer: This bit is used to enable draining of the trace data through the ATB Master interface after the formatter has stopped. This is useful in Circular buffer mode to capture trace data into trace memory and then drain the captured trace through the ATB Master interface. Writing a 1 to this bit when TMCReady=1 and TraceCaptEn=1 starts the drain of the contents of the trace buffer through the ATB Master interface. This bit always reads as zero. The TMCReady bit (STS register, 0x00C) goes low while the drain is in progress.This bit is functional only when the TMC is in Circular Buffer mode and formatting is enabled (EnFt bit in FFCR register is set). Setting this bit when the TMC is in any other mode or when formatting is disabled will result in Unpredictable behavior.Setting this bit other than when the TMCReady bit (STS Register, 0x00C) is set and TraceCaptEn=1 will result in Unpredictable behavior. Once trace capture is complete in Circular Buffer mode, all of the captured trace must be retrieved from the trace memory through the same mechanism - either read all trace data out through RRD reads or drain all trace data by setting the DrainBuffer bit. Setting the DrainBuffer bit after some of the captured trace has been read out through RRD will result in Unpredictable behavior. 1 = HIGH 0 = LOW
13	RW	0x0	StopOnTrigEvt: If this bit is set, the formatter is stopped when a Trigger Event has been observed. A Trigger Event is said to have occurred when the Formatter has written the set number of datawords (as programmed in the TRG register, 0x01C) into the trace memory after the occurrence of either a rising edge on the TRIGIN input or a trigger packet on the incoming trace stream (ATID = 7h7D). This bit is cleared on reset (disabled). Enabling the TMC in Software-read-FIFO mode or Hardware-read-FIFO mode with this bit set will result in Unpredictable behavior because in FIFO modes, the TMC is a trace link rather than a trace sink and trigger events are related to trace sink functionality. 1 = HIGH 0 = LOW
12	RW	0x0	StopOnFl: If this bit is set, the formatter is stopped on completion of a flush operation. The initiation of a flush operation is controlled by programming the register bits FlushMan, FOnTrigEvt and FOnFlIn in the FFCR register, 0x304. When a flush-initiation condition occurs, AFVALIDS is pulled HIGH. Once AFREADYS is sampled HIGH, trace capture is stopped. Any remaining data in the formatter is appended with a post-amble and written to trace memory. The flush operation is then said to have completed. This bit is cleared on reset (disabled).In the FIFO modes, if a flush is initiated due to any condition other than a manual flush request, its completion does not lead to a formatter stop regardless of the value programmed in this bit. When the TMC is configured as an ETF, if a flush is initiated by the ATB Master interface, its completion does not lead to a formatter stop regardless of the value programmed in this bit. 1 = HIGH 0 = LOW

Bit	R/W	Reset	Description
10	RW	0x0	TrigOnFI: = 0), then trigger indication on the trace stream is blocked regardless of the value programmed in this bit.When the TMC is configured as an ETF, if a flush is initiated by the ATB Master interface, its completion does not lead to a trigger indication on the trace stream regardless of the value programmed in this bit. 1 = HIGH 0 = LOW
9	RW	0x0	TrigOnTrigEvt: = 0), then trigger indication on the trace stream is blocked regardless of the value programmed in this bit. This bit is not supported in Software-read-FIFO mode or Hardware-read-FIFO mode because in FIFO modes, the TMC is a trace link rather than a trace sink and trigger events are related to trace sink functionality. 1 = HIGH 0 = LOW
8	RW	0x0	TrigOnTrigIn: = 0), then trigger indication on the trace stream is blocked regardless of the value programmed in this bit. 1 = HIGH 0 = LOW
6	WO	0x0	FlushMan_W: Manually generate a flush of the system. Setting this bit causes a flush to be generated. If TraceCaptEn bit in CTL register is 0, then writes to this bit are ignored. In Circular buffer mode and Hardware-FIFO mode, this bit is cleared automatically when AFREADYS is sampled HIGH. In Software-FIFO mode, this bit is cleared when the flush data is written to trace memory. This bit is clear on reset. 1 = HIGH 0 = LOW
6	RO	X	FlushMan_R: Manually generate a flush of the system. Setting this bit causes a flush to be generated. If TraceCaptEn bit in CTL register is 0, then writes to this bit are ignored. In Circular buffer mode and Hardware-FIFO mode, this bit is cleared automatically when AFREADYS is sampled HIGH. In Software-FIFO mode, this bit is cleared when the flush data is written to trace memory. This bit is clear on reset. 1 = HIGH 0 = LOW
5	RW	0x0	FOnTrigEvt: Setting this bit generates a flush when a Trigger event occurs. A trigger event is said to have occurred when the Formatter has written the set number of datawords (as programmed in the TRG register) into the trace memory after the occurrence of either a rising edge on the TRIGIN input or a trigger packet in the incoming trace stream (ATID = 7h7D). This bit is clear on reset. This bit is not supported in Software-read-FIFO mode or Hardware-read-FIFO mode because in FIFO mode, the TMC is a trace link rather than a trace sink and trigger events are related to trace sink functionality. 1 = HIGH 0 = LOW
4	RW	0x0	FOnFIIn: Setting this bit enables the detection of transitions on the FLUSHIN input by the TMC. If this bit is set and the Formatter has not already stopped, a rising edge on FLUSHIN initiates a flush request. This bit is clear on reset. 1 = HIGH 0 = LOW
1	RW	0x0	EnTI: Setting this bit enables the insertion of triggers in the formatted trace stream. A trigger is indicated by inserting one byte of data 8h00 with ATID 7h7D in the trace stream. Trigger indication on the trace stream is additionally controlled by the register bits TrigOnFI, TrigOnTrigEvt and TrigOnTrigIn in the FFCR register, 0x304. This bit can only be changed when TMCReady=1 and TraceCaptEn=0. This bit takes effect only when the EnFt register bit in this register is set. If EnTI bit is set to 1 when EnFt is 0, it results in formatting being enabled. This bit is clear on reset. 1 = Trigger_insertion_enabled 0 = Trigger_insertion_disabled
0	RW	0x0	EnFt: ace data. Disabling of formatting is deprecated and is supported in the TMC for backwards-compatibility with earlier versions of the ETB. Hence, disabling of formatting is supported only in Circular Buffer mode. Features in the TMC such as the FIFO modes and the DrainBuffer bit that are not part of the earlier versions of the ETB do not support disabling of formatting. If EnTI bit is set to 1 when EnFt is 0, it results in formatting being enabled. If the TMC is enabled in a mode other than Circular Buffer mode with EnFt 0, it will result in formatting being enabled. Attempting to write to this bit when TMCReady=0 or TraceCaptEn=1 will result in Unpredictable behavior. 1 = HIGH 0 = LOW

42.18.4 CORESIGHT_ETF_HUGO_CXTMC_REGS_RSZ_0

Defines the size, in 32-bit words, of the local RAM buffer.

Offset: 0x30004 I Read/Write: RO I Reset: 0xXXXXXXXX (0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx)

Bit	Reset	Description
30:0	X	RSZ: Size of the RAM in 32-bit words e.g., for 1KB RAM, this register field returns 0x00000100 on reads; for 4GB RAM, this register field returns 0x40000000 on reads.

42.18.5 CORESIGHT_ETF_HUGO_CXTMC_REGS_STS_0

TMC Status register

Offset: 0x3000c I Read/Write: RO I Reset: 0x000000XX (0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx)

Bit	Reset	Description
4	X	Empty:-Buffer mode, it is possible that the Empty bit and the Full bit (STS register) are 1 at the same time due to the fact that the Full bit in this mode, once set, does not clear unless TraceCaptEn is set. 1 = HIGH 0 = LOW
3	X	FtEmpty: This bit is set when trace capture has stopped, and all internal pipelines and buffers have drained. Unlike TMCReady, it is not affected by buffer drains and AXI accesses. The ACQCOMP output reflects the value of this bit unless the TMC is in integration mode. 1 = HIGH 0 = LOW
2	X	TMCReady: This bit is set when all the following are true:Trace capture has stopped and all internal pipelines and buffers have drained. This is equivalent to being in the Stopped or Disabled state.The TMC is not training because of the DrainBuffer bit of the FFCR being set.In ETR configuration, the AXI interface is not busy. This case can be used to detect page table reads in scatter-gather mode when in Stopped state. 1 = HIGH 0 = LOW
1	X	Triggered: The Triggered bit is set when trace capture is in progress and the TMC has detected a trigger event. A trigger event is said to have occurred when the TMC has written the set number of datawords (as programmed in the TRG register) into the trace memory after the occurrence of either a rising edge on the TRIGIN input or a trigger packet (ATID = 7h7D) in the incoming trace stream. This bit is cleared when trace capture is enabled again after having stopped. This bit is operational only in the Circular-buffer mode. In all other modes, this bit is always 0.This bit does not indicate that a trigger has been embedded in the formatted output trace data from the TMC. Trigger indication on the output trace stream is determined by the programming of the Formatter and Flush Control Register, FFCR, 0x304. 1 = HIGH 0 = LOW
0	X	Full: This bit can be used to help determine how much of the trace buffer contains valid data.Circular-buffer mode : This flag is set when the RAM write pointer wraps around the top of the buffer, and remains set until the TraceCaptEn bit is cleared and set. Software-read-FIFO mode and Hardware-read-FIFO mode : This flag indicates that the current space in the trace memory is less than or equal to the value programmed in the BUFWM register (ie. Fill level >= MEM_SIZE - BUFWM). In the ETR configuration, if the TMC is programmed for Scatter-Gather operation, this bit indicates whether the Trace memory is currently full regardless of the value programmed in the BUFWM register. TMC Disabled (TraceCaptEn=0 and TMCReady=1): The Full bit retains its last value. If TraceCaptEn is 0 and a 1 is written to it, the Full bit is cleared.The FULL output from the TMC reflects the value of this register bit, except when the Integration Mode bit in the ITCTRL register, 0xF00, is set. 1 = HIGH 0 = LOW

42.18.6 CORESIGHT_ETF_HUGO_CXTMC_REGS_RWP_0

The value written to this register must be a byte-address aligned to the width of the trace memory data bus and to a frame boundary.

Offset: 0x30018 I Read/Write: R/W I Reset: 0x00000000 (0bxxxxxxxxxxxxxxxxxx00000000000000)

Bit	Reset	Description
13:0	0x0	RWP: This value represents the location in trace memory that will be accessed on a subsequent write to the trace memory.

42.18.7 CORESIGHT_ETF_HUGO_CXTMC_REGS_RRD_0

Reading this register enables data to be read from the trace memory.

Offset: 0x30010 I Read/Write: RO I Reset: 0xXXXXXXXX (0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx)

Bit	Reset	Description
31:0	X	RRD: Reads return data from Trace RAM

42.18.8 CORESIGHT_ETF_HUGO_CXTMC_REGS_CTL_0

This register controls trace stream capture.

Offset: 0x30020 I Read/Write: R/W I Reset: 0x00000000 (0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx0)

Bit	Reset	Description
0	0x0	TraceCaptEn: Setting this bit to 1 enables the TMC to capture trace data. 1 = HIGH 0 = LOW

42.18.9 CORESIGHT_ETR_HUGO_CXTMC_REGS_CTL_0

This register controls trace stream capture.

Offset: 0x50020 I Read/Write: R/W I Reset: 0x00000000 (0bxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx0)

Bit	Reset	Description
0	0x0	TraceCaptEn: Setting this bit to 1 enables the TMC to capture trace data. 1 = HIGH 0 = LOW

Notice

The information provided in this specification is believed to be accurate and reliable as of the date provided. However, NVIDIA Corporation ("NVIDIA") does not give any representations or warranties, expressed or implied, as to the accuracy or completeness of such information. NVIDIA shall have no liability for the consequences or use of such information or for any infringement of patents or other rights of third parties that may result from its use. This publication supersedes and replaces all other specifications for the product that may have been previously supplied.

NVIDIA reserves the right to make corrections, modifications, enhancements, improvements, and other changes to this specification, at any time and/or to discontinue any product or service without notice. Customer should obtain the latest relevant specification before placing orders and should verify that such information is current and complete.

NVIDIA products are sold subject to the NVIDIA standard terms and conditions of sale supplied at the time of order acknowledgement, unless otherwise agreed in an individual sales agreement signed by authorized representatives of NVIDIA and customer. NVIDIA hereby expressly objects to applying any customer general terms and conditions with regard to the purchase of the NVIDIA product referenced in this specification.

NVIDIA products are not designed, authorized or warranted to be suitable for use in medical, military, aircraft, space or life support equipment, nor in applications where failure or malfunction of the NVIDIA product can reasonably be expected to result in personal injury, death or property or environmental damage. NVIDIA accepts no liability for inclusion and/or use of NVIDIA products in such equipment or applications and therefore such inclusion and/or use is at customer's own risk.

NVIDIA makes no representation or warranty that products based on these specifications will be suitable for any specified use without further testing or modification. Testing of all parameters of each product is not necessarily performed by NVIDIA. It is customer's sole responsibility to ensure the product is suitable and fit for the application planned by customer and to do the necessary testing for the application in order to avoid a default of the application or the product. Weaknesses in customer's product designs may affect the quality and reliability of the NVIDIA product and may result in additional or different conditions and/or requirements beyond those contained in this specification. NVIDIA does not accept any liability related to any default, damage, costs or problem which may be based on or attributable to: (i) the use of the NVIDIA product in any manner that is contrary to this specification, or (ii) customer product designs.

No license, either express or implied, is granted under any NVIDIA patent right, copyright, or other NVIDIA intellectual property right under this specification. Information published by NVIDIA regarding third-party products or services does not constitute a license from NVIDIA to use such products or services or a warranty or endorsement thereof. Use of such information may require a license from a third party under the patents or other intellectual property rights of the third party, or a license from NVIDIA under the patents or other intellectual property rights of NVIDIA. Reproduction of information in this specification is permissible only if reproduction is approved by NVIDIA in writing, is reproduced without alteration, and is accompanied by all associated conditions, limitations, and notices.

ALL NVIDIA DESIGN SPECIFICATIONS, REFERENCE BOARDS, FILES, DRAWINGS, DIAGNOSTICS, LISTS, AND OTHER DOCUMENTS (TOGETHER AND SEPARATELY, "MATERIALS") ARE BEING PROVIDED "AS IS." NVIDIA MAKES NO WARRANTIES, EXPRESSED, IMPLIED, STATUTORY, OR OTHERWISE WITH RESPECT TO THE MATERIALS, AND EXPRESSLY DISCLAIMS ALL IMPLIED WARRANTIES OF NONINFRINGEMENT, MERCHANTABILITY, AND FITNESS FOR A PARTICULAR PURPOSE. Notwithstanding any damages that customer might incur for any reason whatsoever, NVIDIA's aggregate and cumulative liability towards customer for the products described herein shall be limited in accordance with the NVIDIA terms and conditions of sale for the product.
